## P R O C E E D I N G S

8:32 a.m.

CHAIRMAN STETKAR: The meeting will now come to order. This is the first day of the 626th Meeting of the Advisory of the Committee on Reactor Safeguards. During today's meeting, the Committee will consider the following: Digital Instrumentation and Control Probabilistic Risk analyses, assessment of the quality of selected research projects, Nine Mile Point Unit 2 Maximum Extended Load Line Limit Analysis plus -- I always like saying that -- license amendment, preparation of ACRS reports.

This meeting is being conducted in accordance with the provisions of the Federal Advisory Committee Act. Ms. Christina Antonescu is the Designated Federal Official for the initial portion of the meeting.

We have received no written comments or requests to make oral statements from members of the public regarding today's sessions. There will be a phone bridgeline. To preclude interruption of the meeting, the phone will be placed in a listen-in mode during the presentations and Committee discussion.

A transcript of portions of the meeting is being kept, and it is requested that speakers use one

1 of the microphones, identify themselves, and speak  
2 with sufficient clarity and volume so that they can be  
3 readily heard. And I'll ask everyone to check your  
4 little portable communications devices and please turn  
5 them off.

6 As a matter of interest, after seven years  
7 of service on the ACRS, six years on the Advisory  
8 Committee of Nuclear Waste and Materials, and as  
9 Chairman and final Chairman of the ACMW, I'd like to  
10 thank and congratulate Dr. Michael Ryan on his  
11 retirement for the ACRS. Mike, congratulations.

12 (Applause.)

13 And with that, we will proceed with the  
14 first item on our agenda, which is the Digital  
15 Instrumentation and Control PRA. I'll lead us through  
16 that session.

17 I went back and looked at our history on  
18 this topic, and it's a long history. As best as we  
19 could determine, the last full Committee briefing  
20 we've had on this topic was May 8th, 2008, which  
21 precedes a good fraction of the current membership of  
22 the Committee. Michael will remember it but few of  
23 the rest of us. You don't remember to turn your mic  
24 on, but that's okay.

25 We've actually -- in seriousness, we

1 followed the subject at the subcommittee level, and  
2 we've had pretty much a meeting once every year or so.  
3 We missed a meeting in 2012. We had a two-day meeting  
4 last November, which was, in my opinion, very, very  
5 productive. And at that meeting, the subcommittee  
6 decided that it was probably time for the full  
7 Committee to get briefed on the status of this. As we  
8 all know, digital instrument and control systems  
9 remain a thorny, if I can use that word, issue for new  
10 reactors and, to some extent, retrofits of existing  
11 reactors. The methods and data and approaches that  
12 people use to model and evaluate the reliability of  
13 those systems, especially considering the behavior of  
14 the software, in the context of probabilistic risk  
15 assessments are challenging, and we decided that the  
16 Committee should hear an update on both the staff's  
17 and the industry's progress to date.

18 And with that, I will turn it over to Kevin  
19 Coyne, I believe.

20 MR. COYNE: Okay. Thank you very much,  
21 Chairman Stetkar. I'm Kevin Coyne from the Office of  
22 Nuclear Regulatory Research in the Division of Risk  
23 Analysis. Thank you very much for the opportunity to  
24 brief the full Committee today.

25 The timing of the meeting is very

1 fortuitous for us. We're in the process of updating  
2 our five-year digital I&Committee research plan, so  
3 we're looking forward to feedback from the meeting to  
4 help us with that plan update.

5 As you had stated, we have had numerous  
6 subcommittee briefings on the topic of digital  
7 I&Committee over the past several years, and the  
8 Committee has expressed some concerns with the degree  
9 of alignment between the research activities being  
10 conducted by the Research Division of Engineering and  
11 the Division of Risk Analysis, essentially the  
12 deterministic and probabilistic research activities  
13 we're doing. And we've taken those comments to heart  
14 and have done a number of activities to further  
15 improve the alignment between our research efforts,  
16 including more frequent periodic meetings between the  
17 staff working in these areas, review of each other's  
18 products and particularly early reviews as products  
19 are being developed, and having joint meetings, such  
20 as this, which we hadn't routinely done in the past  
21 but we're trying to make an effort to brief the  
22 Committee together, rather than doing separate  
23 briefings. And I think all these things have helped  
24 us make sure that our research activities continue to  
25 be complimentary and well aligned and going in a

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 unified direction.

2           There are still some big challenges we're  
3 facing. One of the big ones is vocabulary. The words  
4 people use to describe various aspects of digital  
5 systems is still a challenge. There's a different set  
6 of vocabulary that an I&Committee engineer would use  
7 versus a PRA engineer, and the vocabulary depends on  
8 the level of detail you are analyzing the system at.

9           We continue to work in the area. We think  
10 that we have a pretty good understanding of the core  
11 concepts that we're investigating, and we're  
12 continuing to work on trying to smooth out the  
13 vocabulary so that we have good communication between  
14 the I&Committee engineering community and the PRA  
15 community to make sure that stays unified.

16           This morning, we'll discuss several  
17 significant research activities, including the failure  
18 mode characterization work being done by the Division  
19 of Engineering, an update on the digital systems  
20 statistical testing that we've done in the PRA area,  
21 and joint work on software reliability modeling we're  
22 doing with the Korea Atomic Energy Research Institute.  
23 In addition, we're very fortunate to have Roy Torok  
24 from the Electric Power Research Institute with us  
25 today to talk about their research activities in this

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 area.

2 With that, I'll turn it over to Mauricio  
3 Gutierrez to begin the presentation.

4 MR. GUTIERREZ: Good morning. Thank you  
5 for your time today. I'll just jump in right into the  
6 presentation here on NRC's failure mode-related  
7 research.

8 For the agenda here, I'll just provide a  
9 quick summary of the digital failure mode-related  
10 research efforts that we have. I'll also provide a  
11 summary of feedback that the ACRS I&Committee  
12 Subcommittee provided and NRC's response to that  
13 feedback at our meetings. And after I review that,  
14 I'll just provide a summary of staff follow-up  
15 actions. Some of that will include just a review of  
16 the differences of how our each respective divisions  
17 look at the problem, the PRA perspective and the  
18 deterministic assessment perspective. And then we'll  
19 conclude with a look at the failure modes that we have  
20 identified.

21 So as mentioned before, ACRS has a  
22 longstanding concern on the digital I&Committee  
23 systems. Digital I&Committee system failure modes are  
24 not well understood. The concern here is that there  
25 are misbehaviors or things that digital I&Committee

1 systems can do that are not performance -- I'm sorry,  
2 excuse me. There are misbehaviors that can occur that  
3 occur when there's non-performance of required  
4 functions.

5 ACRS brought these concerns to the  
6 Commission's attention in 2008, and that resulted in  
7 an SRM, which directed the staff to do two things: to  
8 report the progress made with respect to identifying  
9 and analyzing digital I&Committee failure modes and to  
10 discuss the feasibility of applying failure mode  
11 analysis to quantification of risks associated with  
12 digital I&Committee.

13 On this slide here --

14 CHAIRMAN STETKAR: Mauricio, if I could,  
15 from the previous subcommittees and I think our letter  
16 way back then, our concern was, with failure modes our  
17 concern was especially with people trying to model  
18 failure without really understanding the failure  
19 modes.

20 MR. GUTIERREZ: Right, yes. That's a good  
21 clarification. I went back and looked at the original  
22 or, I guess, many of the original transcripts, and it  
23 goes along the lines of what you were saying. There  
24 was a lot of, there were a lot of statements  
25 indicating that there was a concern that it wasn't

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 just the failure modes. Failure modes was, I guess,  
2 a secondary issue. The issue was understanding how  
3 digital I&Committee systems operate and how they  
4 potentially fail. And that's the issue that we've  
5 been working on, the broader higher-level issue.

6 CHAIRMAN STETKAR: I think failure modes  
7 are not a secondary issue. Failure modes are an  
8 important issue for framing the PRA models. I go back  
9 to the analogy that we've always used. Until we  
10 identify clear failure modes for a valve, failure to  
11 open, failure to close, spurious opening, spurious  
12 close, people were floundering trying to develop  
13 models for valves. They would have, somebody would  
14 say, well, leakage from a seal is a failure mode, so  
15 I should model that. Loose bolts is a failure mode,  
16 so I should model that. Until you develop that  
17 taxonomy of failure modes, people don't have the  
18 construct to create the models. They don't understand  
19 what it is that should be in their logic model, nor do  
20 they understand how they should compile information  
21 and, if it's available, experiential data to support  
22 those particular failure modes.

23 So failure modes isn't an ancillary  
24 function. It's the primary function for making the  
25 transition from a drawing of a system or a description

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 of software to a discrete model for that system or the  
2 software. And I think that's the sense of our  
3 letters.

4 MR. GUTIERREZ: Okay. Perhaps I chose a  
5 poor word there in describing what was done. But,  
6 yes, I mean, to go back, that was a concern is how do  
7 digital systems operate, how did they fail? And one  
8 approach to looking at that was to try to identify the  
9 failure modes that can occur in digital I&Committee  
10 systems. Is that fair? Yes. Thank you.

11 MR. SKILLMAN: Mauricio, I would like to  
12 add perhaps a different perspective or reinforced  
13 perspective. As you identify at the bottom of slide  
14 three, report of the progress made with respect to  
15 identifying and analyzing digital I&Committee failure  
16 modes, would you contrast the difference between the  
17 failure of the software versus the failure of the  
18 digital hardware? Those are different issues, and it  
19 seems that those two are combined in this discussion  
20 when, in reality, the failure modes of each may  
21 contribute to the total system failure, but they are  
22 not the same.

23 MR. GUTIERREZ: You're right. I mean, so,  
24 yes, there are different things that can go wrong in  
25 hardware systems and there are certain things that can

1 go wrong in software systems. In RIL1002 and perhaps  
2 in some of our other work, we've made a distinction as  
3 to what is a digital system failure mode, and we're  
4 using words here like software failure modes. We've  
5 chosen to use a different terminology for what can go  
6 wrong with software.

7 I think our senior technical advisor,  
8 Sushil Birla, has a comment here.

9 MR. BIRLA: Thank you. Thank you for that  
10 question. I'm Sushil Birla, senior technical advisor  
11 at the NRC in the Office of Nuclear Regulatory  
12 Research Division of Engineering. The work that we  
13 performed focused at the system level, the system  
14 function level, rather than at a component level,  
15 whether it's a hardware component or a software  
16 component, and, at the function level, how to abstract  
17 the behavior in a manner that we can relate to bad  
18 effects, like adverse effects on safety.

19 Your observation is accurate, and that  
20 could be the thrust of some of the later slides that  
21 when you have a system that is not the traditional  
22 hardware component-based system, there are new kinds  
23 of misbehavior that are arising for which we do not  
24 have an adequate, good enough understanding.

25 So the traditional hardware component-based

1 systems, we used to think that if a hardware component  
2 fails, primarily due to wear and tear, the function  
3 that the system is supposed to be performing will not  
4 be performed to its specification. And there is,  
5 unfortunately, the carryover that, when we have  
6 systems that have something more than hardware,  
7 complex logic, whether it's in the form of software or  
8 firmware or whatever, that same kind of  
9 characteristic, the wear and tear oriented and then  
10 the hardware failure, that carryover does not occur.  
11 And we are victims of what we have grown up with, what  
12 we are used to, whatever our thinking is, and that has  
13 interfered with the proper understanding of  
14 misbehaviors when you have complex logic in the  
15 system. And he'll get to it, and if you are still  
16 unsatisfied I can come back and add more.

17 MR. SKILLMAN: Thank you, thank you.

18 MR. GUTIERREZ: Okay. So move on to the  
19 next slide here, and this slide basically just  
20 presents research that has included the use of failure  
21 modes or has identified failure modes within NRC. For  
22 the DRA portion, Ming Li we'll be speaking about this  
23 work a little later in his presentation.

24 For DE's work, here are the products that  
25 we have been working on: RIL1001, which dealt with

1 software-related uncertainties; NUREG IA-0254 dealt  
2 with understanding faults attributable to complex  
3 logic; RIL1002 that dealt with the identification of  
4 digital I&Committee failure modes; RIL1003 is a  
5 current work-in-progress and it deals with the  
6 feasibility of applying failure mode analysis to  
7 quantification of risks associated with digital  
8 I&Committee systems. RIL1001, which was recently  
9 completed, concerns a broad view of hazard analysis to  
10 address misbehaviors attributable to engineering  
11 deficiencies in digital I&Committee systems.

12 So in 2013, the ACRS I&Committee  
13 Subcommittee was briefed on RIL1002 and provided some  
14 feedback. They appreciated the synthesized set of  
15 digital system failure modes that were identified. In  
16 the most recent version of RIL1002, the final version,  
17 this is set out, and some members requested  
18 harmonization of the failure modes that were  
19 identified with work that has been done by DE,  
20 Division of Engineering, by the DRA, and by EPRI.

21 So the staff response to that feedback was  
22 that we have been meeting and working more closely.  
23 DE staff and DRA staff have been meeting regularly  
24 monthly since that time, and DE has also been meeting  
25 with EPRI to discuss harmonization of the failure

1 modes that have been identified.

2 MR. BLEY: I just want to interrupt with a  
3 note for the record. You've said a couple of times  
4 the subcommittee told you to do things and you have  
5 action items from the subcommittee and we requested.  
6 In fact, the ACRS only speaks through our letters, so  
7 members gave you individual comments, but we can't  
8 request or give direction, actually, except in our  
9 letters.

10 MR. GUTIERREZ: Yes, that's good feedback  
11 and a good point for clarification. In all the work  
12 that we do, we regularly discuss and obtain multiple  
13 viewpoints of the work that we do. We have our work  
14 reviewed, and, in our discussions, we take all the  
15 technical feedback and then we go back and look at  
16 what was provided, and we try to make the best  
17 technical decision of which the ACRS members that  
18 provided their comments. That's how we took that.

19 So one of the things that we did to begin  
20 our discussions was to try to take a look at the  
21 viewpoints from which each of our respective  
22 perspectives comes from. For deterministic licensing,  
23 the area that DE is mostly focused on, we looked at  
24 our objectives, and our objective is safety assurance:  
25 making sure that a system is safe, that it's able to

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 perform its functions. It involves asking questions,  
2 like what can go wrong and what are the consequences?  
3 Perhaps Ming can speak a little bit to this if I don't  
4 speak clearly enough on this subject, but, for  
5 probabilistic risk assessment, they're looking to  
6 support quantification of system reliability. They're  
7 looking to estimate risk by computing real numbers.  
8 They ask questions like what can go wrong, how likely  
9 is it to go wrong, what are the consequences, and  
10 which systems and components contribute most to risk?  
11 We find that we have a lot more in common than  
12 differences when we look at our different  
13 perspectives.

14 And this slide here, slide number eight, it  
15 just has the failure modes that have been identified  
16 and that we have been using. Failure mode set L on  
17 the right is a set of nine failure modes. The middle  
18 set was done by a WG Risk Survey, which was, I guess,  
19 partly sponsored by NRC. DRA had input to these  
20 failure modes. And the last set of, I guess, of  
21 failure modes that we have here, they were identified  
22 by EPRI. EPRI called them guidewords. And it should  
23 be important to note that EPRI has identified several  
24 different sets of guidewords or keywords that they can  
25 use for different hazard analysis methods and tools

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 that can be used for considering digital system  
2 failure modes.

3 And what we've found, as we've been  
4 discussing what DE has identified, what DRA has  
5 identified, and what EPRI has identified, is that,  
6 although we may be using different ways of describing  
7 or characterizing what we're talking about, that there  
8 is a considerable amount of overlap in terms of what  
9 we have identified. So there is no, as far as we can  
10 tell, no technical disconnect in terms of what we were  
11 discussing in terms of what can go wrong with digital  
12 systems.

13 CHAIRMAN STETKAR: Mic.

14 MR. BROWN: Sorry about that. Thank you  
15 very much. If you look at, I just clicked on output  
16 intermittent. I'm just asking a question here.  
17 That's not consistent, in my mind, with no signal  
18 actuation when demanded. You have intermittent  
19 function, intermittent output, and then you've got  
20 something definitely doesn't happen. So on a  
21 equivalency basis, I just, you've made the comment  
22 that they're roughly similar in terms of the concepts  
23 you came up with. That one had a little bit of a  
24 disconnect for me. I understand intermittent, but  
25 intermittent means a lot more than, hey, I've demanded

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 something and something doesn't happen. That's a  
2 different, that's a whole different thought process.  
3 It seemed to me that would be, from past experience,  
4 whether it's software or hardware, intermittent  
5 operation even in software -- I mean, a set of  
6 software commands or a sample time or whatever it's  
7 going to run through and it to not work, but when it  
8 comes to the next time it works just fine because of  
9 some initialization that was done or some particular  
10 signal was there. Tracking that relative to even in  
11 analog systems, intermittent stuff drove us crazy.  
12 Sometimes it worked, sometimes it didn't. We never  
13 could, you can't pin it down.

14 So it's a little hard for me to grab how  
15 you have typed that piece. I'm just making this from  
16 the observation that, when I look at these, I see  
17 concepts or thoughts or functions, but I'm still  
18 trying to grapple, as I made the comment in the  
19 subcommittee meeting, with is there another topdown  
20 approach that the PRA can take relative to these  
21 systems, as opposed to a piece part, build it up from  
22 the bottom, in terms of failure modes or how they  
23 operate or their risk assessment in terms of their  
24 operation, the risk associated. I still haven't come  
25 to grips with how you do that, but I know I've made

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 that comment several times. And I'm still struggling  
2 with how we get there. This is a very difficult task,  
3 no matter how you slice it.

4 So, anyway, that's just an observation on  
5 thought processes.

6 MR. SCHULTZ: Mauricio, let me ask this  
7 differently. You seem to present this to suggest that  
8 there's commonality among the columns, going left to  
9 right, right to left. Hearing the comment earlier  
10 that was made by Kevin that we're dealing with  
11 certainly communication and language and definition  
12 here, it seems to me that there's a lot of difference  
13 between the line items across the page. And I would  
14 have thought that you would be trying to come to a  
15 better agreement or common, commonality in terms of  
16 the terminology so that all of the document, the  
17 survey, EPRI's guidewords could all merge in some  
18 sense so everyone knows what is being said and it can  
19 be used analytically sometime in the future.

20 MR. GUTIERREZ: Yes. So --

21 MR. TOROK: May I? This is Ray Torok from  
22 EPRI. I'd just like to add a little clarification.  
23 In regard to the EPRI guidewords, those are from one  
24 of six hazard analysis methods that are documented in  
25 the report we put together. This particular one is

1 functional failure modes that affects analysis.

2 And in some of the other hazard analysis  
3 methods use guidewords. Not all of them do. And I  
4 guess the point is that, with different sets of  
5 guidewords, you can still cover the waterfront in  
6 terms of potential failures and misbehavior.

7 So if I look at these and try to compare  
8 them, for example for the operative intermittent one  
9 versus intermittent function, what I'm asking myself  
10 is about the effect on the downstream equipment  
11 because by itself, it doesn't do anything directly,  
12 right? It controls some component that's part of a  
13 system, and you want the system to work.

14 And so what I ask myself is under what  
15 circumstances could the system not actuate, let's say,  
16 or could the component not do what it's supposed to  
17 do? And if there's intermittent function from the  
18 control system or if there's output intermittent from  
19 it or if there's no actuation signal when demanded,  
20 all of those can pick up that kind of failure. So the  
21 point is can we put together a set of guidewords that  
22 will cover the waterfront that you really care about?  
23 And that's why our conclusion was the guidewords don't  
24 always have to be the same because different sets of  
25 them can lead you to the thing you care about, and

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1       that's what we've found.

2                   I can go into a lot more detail on that but  
3       . . .

4                   MR. POWERS:  It's still kind of a mystery  
5       to me why you didn't do exactly what Steve said  
6       because you end up with things like degraded function.  
7       There's a term that refers in another set to a whole  
8       variety of different things.

9                   MR. TOROK:  That's right.

10                  MR. POWERS:  And it seems to me, if you're  
11       using that as a framework for modeling, you're going  
12       to be very confused.

13                  MR. TOROK:  Yes.  Well, for us, where this  
14       came into play was in the assumption that -- and for  
15       PRA, you care about what the system is doing and you  
16       care about what the components within the system are  
17       doing to make the system work.  The I&Committee is at  
18       a lower level than that.  The I&Committee can affect  
19       these components.  And if you talk about degraded  
20       function, yes, you're right, the function can be  
21       degraded in lots of different ways by lots of  
22       different types of misbehaviors or failure modes at  
23       the level of the I&Committee, which we would probably  
24       call failure mechanisms, not failure modes.  But it's  
25       the same idea.  And the understanding of those is

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 important in helping you figure out if the system, or  
2 the I&Committee in this case, has design measures that  
3 act to prevent or avoid certain failure modes by  
4 defeating the mechanisms that cause them, that sort of  
5 thing.

6 So if I talk about degraded function, the  
7 waterways that I&Committee can push you down that  
8 path, depending on the failure mechanism you care  
9 about. Did the processor lock up, is there an  
10 incorrect control algorithm built into the thing, that  
11 sort of thing. But in the end, what you care about is  
12 whether or not the component that's controlled can  
13 misbehave, and there are ways that the I&Committee can  
14 help that happen.

15 I don't know if I answered the question or  
16 not.

17 MR. POWERS: Well, I mean, what I'm  
18 detecting is that you're directing your work for a  
19 very short-term kind of goal, do I need to fix it or  
20 not, and we're looking at a more comprehensive thing  
21 I think. We want to understand in a more predictive  
22 fashion when these things are going to happen, and  
23 you're not giving us the framework to do that.

24 MR. TOROK: Are you thinking in terms of  
25 looking at failure data and using that to generate

1 failure probability?

2 MR. POWERS: Sure.

3 MR. TOROK: Yes. It turns out, in our  
4 case, that's very difficult for the digital equipment,  
5 especially in high-integrity systems, because there's  
6 not a lot of failure data to look at and there  
7 probably won't ever be. Although we did do some of  
8 that. I shouldn't say we didn't do that. But in a  
9 lot of ways, for practical purposes, it appeared to be  
10 more useful to try to understand the failure  
11 mechanisms of the digital I&Committee and then look to  
12 see if the design was set up in such a way that it  
13 could defeat those. And that was a better way to get  
14 a handle on whether you're looking at a robust system  
15 or a not very good system.

16 So, yes, if you're talking about gathering  
17 the data to support it, like you would for a  
18 traditional piece of hardware, that's problematic for  
19 digital I&Committee. Oh, and somebody mentioned there  
20 are hardware failures and software failures, and  
21 that's right. But what we see in a lot of the high-  
22 integrity digital systems is they'll have redundant  
23 hardware with the same software in each channel. And  
24 what that does, effectively, is it eliminates hardware  
25 failures from a practical standpoint as significant

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 contributors to the system failure or to the  
2 I&Committee failure, and then your focus is on the  
3 software and now you're into design measures that can  
4 help you, as opposed to failure data.

5 MR. COYNE: If I could build off of this --  
6 this is Kevin Coyne from the staff. If I could build  
7 off one of Ray's point is this slide with the digital  
8 failure mode mapping is an imperfect exercise, at  
9 best. And one of the dimensions that's really missing  
10 here is a level of detail we're looking at the  
11 systems. And Mauricio actually has a backup slide  
12 that I'm not sure that he'll cover or not, but it's  
13 hard to find a good analogy but we did an analogy back  
14 in the November meeting of a failure of a system to  
15 deliver adequate flow, and it drills down on a valve.  
16 And depending on the level of detail, there's a  
17 cascading effect between the failure mechanism mode  
18 and effect. And, you know, as you move up and down  
19 those levels, failure modes change, and so to come up  
20 with a strictly consistent, uniform mapping of failure  
21 modes at all levels of detail is really beyond what we  
22 can do, so it really is dependent on the level of  
23 detail you're looking at the system.

24 And I think with the WG Risk Survey, one of  
25 the issues is that's looking at PRA function. So,

1 again, as Ray had said, you know, it's the  
2 availability of core cooling is the ultimate function  
3 you're looking at, and so you're looking at the  
4 digital I&Committee system's effect on your ability to  
5 maintain adequate core cooling.

6 MR. TOROK: That's a really good point,  
7 Kevin, and I neglected to mention that the guidewords  
8 in our cases go with this method called functional  
9 FMEA, and they're intended to be useful at any level  
10 of abstraction, from the I&Committee up to the system  
11 in the plant, and they work that way. And that's one  
12 of the reasons that I think that maybe you could look  
13 at and was kind of vague in regard to I&Committee.

14 So I consider them sort of generic failure  
15 modes in the sense that they can be applied at any  
16 level of abstraction, which is the normal thing, by  
17 the way, for hazard analysis methods. They don't  
18 focus on I&Committee.

19 MR. BROWN: John, you were going to say  
20 something? I was going to say something but let you  
21 go first.

22 CHAIRMAN STETKAR: No, go on, Charlie.

23 MR. BROWN: You mentioned level of detail,  
24 and I guess that's one of my concerns and maybe I  
25 didn't express it very artfully the last time. But if

1 you look at a whole chain of an instrumentation  
2 system, you've got a detector, you've got an analog-  
3 to-digital converter, you've got some processing you  
4 go through, you generate and go through an algorithm  
5 of a trip that's got other signals from other  
6 detectors coming into it, then you trip, then you go  
7 to an actuation device or you set up a conditional set  
8 of things for multiple, you know, two out of three or  
9 whatever it is. Where do you start with that?

10 I mean, the bottom line is the last part,  
11 the setting up the conditional condition, two out of  
12 three. I've got a trip. One of the three or four I  
13 need to do something. How far back in the food chain  
14 do you try to pick it up? Do I say, okay, this  
15 analog-to-digital converter failed, I now no longer  
16 have a valid piece of information out of that, and  
17 it's one of three signals that's used to develop or go  
18 into an algorithm that produces this signal. You work  
19 on that, or do you assess, hold it, there's dozens of  
20 little things that could go, do I get the trip or do  
21 I not? Which is the most important part? It's not  
22 intermittent. It's not necessarily duration too  
23 short. It's do I have it or not? Do I care about the  
24 other circumstances, and am I complicating the effort  
25 here to try to look at this stuff by going down to

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1       that level of detail? That's what I've been  
2       struggling with at looking at how you do this in this  
3       mode or with these systems.

4               MR. LI: This is Ming Li. By level of  
5       detail, we mean something a little bit different. Mr.  
6       Brown, you mentioned that the information flow changed  
7       at our level of details. Level of detail, like an  
8       RPS. So we can model the RPS in a PRA sequence, like  
9       take that to RPS, add one black box. So the black box  
10      RPS function which generates trip when the trip  
11      condition occurs. So one failure mode should be it  
12      did not trip when it should. Another failure mode, it  
13      trips when it should not. So we call this the system  
14      level.

15              And if we have data to support that failure  
16      mode, then everybody is happy. Then we just model the  
17      RPS at that level because we have data support. It's  
18      unfortunate we don't have data support that's a black  
19      box. Then we had to divide fuller to one level below,  
20      like the input module, output module, data processing,  
21      and the communication possibly. And then we started  
22      at whether we have data to support that. What's the  
23      failure mode for the input module? That might be  
24      incorrect value and incorrect timing, you know,  
25      something similar.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1           And for the PRA, normally, it's rare we go  
2 down to the very bottom level, like the transistor  
3 failed. Do we need to kill the transistor for PRA?  
4 It might sometime if we really don't have data. So we  
5 might come from the parts level. So you use the parts  
6 count method, start from each part individually, and  
7 then come up with failure data.

8           But whenever they have the data support  
9 that card, the communication card, if I know the  
10 failure rate for that communication card, I don't need  
11 to go down to the parts level. But if you have the  
12 failure rate for that card, the model, you know we've  
13 got the card at the black box in our, you know,  
14 models.

15           Software might be something different. I'm  
16 going to cover software a little more in my talk. But  
17 by level of detail, we mean the functional level,  
18 instead of the information flow from the input to the  
19 output where something happens.

20           MR. BROWN: I understand. I wasn't trying  
21 to say take it to that level. I'm just using it as an  
22 example. But I would argue that your ability to find  
23 a significant failure rate for what you call an input  
24 module or an output module, whatever it is, one level  
25 down from did it trip or did it not trip

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 functionality, is there a great industry reporting  
2 system for all that?

3 CHAIRMAN STETKAR: Charlie, try not to  
4 force everything into data and numbers, okay? That  
5 was the problem 35 years ago when people --

6 MR. BROWN: I, I --

7 CHAIRMAN STETKAR: Charlie. Thirty-five  
8 years ago when people first started to do risk  
9 assessment, people were trying to collect data for  
10 loose screws. But until they reached the taxonomy of  
11 failure modes and didn't care about the minutia, it  
12 got easier to understand the experience base to dump  
13 into that intermediate level of detail. You didn't  
14 care about the data for loose screws. You didn't care  
15 about the data for resistor open circuits or --

16 MR. BROWN: I agree with you.

17 CHAIRMAN STETKAR: Okay.

18 MR. BROWN: I'm not arguing with you. I  
19 agree with that.

20 CHAIRMAN STETKAR: But then don't talk  
21 about where is the data available or where are the  
22 data available.

23 MR. BROWN: He said several times, he threw  
24 data in, he says if we had the data to do something.  
25 I was responding --

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 CHAIRMAN STETKAR: And that's --

2 MR. BROWN: So that's part of his response,  
3 okay? And that -- because I think, I agree that is  
4 not a very useful way of getting to where you want to  
5 go.

6 CHAIRMAN STETKAR: The point is that, once  
7 one identifies a set of, we'll call them failure modes  
8 then everyone understands conceptually, we'll call  
9 this L1 through L9 and we'll give it names. It's just  
10 L1 through L9 boxes, but everybody knows what an L3  
11 is. Once we understand what the L3 is, we can then  
12 look at experience and find out what's our evidence  
13 for that thing. Sometimes we might not have any.  
14 Sometimes we might need to rely on expert opinion,  
15 okay? But that's important. I think we're saying the  
16 same thing. It's just I want to keep us pulled away  
17 from this notion of where are the data and we don't  
18 have any data and data, data, data.

19 MR. BROWN: That's what I was trying to get  
20 to in responding because they started talking about we  
21 get failure information on these pieces, whether it's  
22 here, or do we want to worry about the -- we don't.  
23 And the point is how far functionality do you look at  
24 it? And that's why I'm concerned that, when you look  
25 at these particular things in here, you're down in the

1 bottom part. You're down in the midst of the thing  
2 and close to a higher level of that -- I'll stop right  
3 there and we'll get on with this.

4 MR. POWERS: It seems to me the other  
5 question that rises from your discussion, I think I  
6 understood, is that you spoke in terms of trip/not  
7 trip, but I see on this list of roadmapping things  
8 fall somewhere in between, maybe fluttering or  
9 intermittent function or things like that. Have we  
10 gotten to the point that we can, indeed, set up  
11 modeling that treats yes/no kinds of responses or do  
12 we have this intermediate it functions but it  
13 functions badly or poorly or functions for a while and  
14 then stops, things like that?

15 MR. LI: I believe your question -- again,  
16 this is Ming Li. I believe your question regarding,  
17 you know, in my examples I talk about the failure mode  
18 happened, not happened, trip, not trip, at the very  
19 high levels. And this chart, the main thing here,  
20 it's a mixture failure mode at different levels. And  
21 if we take a look at spurious actuations, I'm talking  
22 about the middle column of WG Survey. Say they're to  
23 activate the failure mode that I was talking about,  
24 which is not trip when it should, and the spurious  
25 actuation is another. So those two, the row number

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 two and number three, is actually the system level  
2 failure mode I talked about.

3 MR. POWERS: I mean, you're hitting it --  
4 the philosophical issue that I have here is that we've  
5 got this map that's just not very useful to us because  
6 you want to use just a higher level than this map was  
7 operating at, and I'm just not sure what I do with the  
8 map now. Do I just throw it away or ignore it or . .  
9 .

10 MR. GUTIERREZ: I mean, I think that the  
11 mapping has actually been very useful to us because  
12 when we have our discussions and we start talking  
13 about things that can go wrong with digital systems,  
14 we find out that we're covering much of the same  
15 ground, that we have common understanding of how the  
16 systems function and what can go wrong with them.  
17 That's the purpose of the mapping.

18 MR. TOROK: Well, and it comes in very  
19 handy, for example, if you're doing hazard analysis on  
20 a system and you end up asking yourself under what  
21 circumstances is it a bad thing if the system doesn't  
22 actuate when it's supposed to or if it does actuate  
23 when it's not supposed to. And if it is problematic,  
24 then the next question is what is built into the  
25 system to prevent that or to avoid that, that kind of

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 thing. So it does help a lot in terms of figuring out  
2 if the system is robust. It gives certain failure  
3 mechanisms and failure modes. So it's very helpful  
4 there.

5 MR. POWERS: I suspect we're operating in  
6 a different mind set because I'm blatantly worrying  
7 about modeling these things, and I don't think that's  
8 your focus here because I look at this and I say, gee,  
9 I've got yes, no, and maybe, and I don't know how to,  
10 I mean, in a PRA context, maybe is a problem for us  
11 because PRA is not well set up for handling maybe.

12 MR. TOROK: I don't know that we use these  
13 at the PRA level. We're using them a level below that  
14 because the PRA is the controlled component, what  
15 that's doing, and this is a level below that, at least  
16 in our work.

17 MR. POWERS: Then the trouble I have is  
18 then just making it difficult for two levels to  
19 communicate with each other, which I think is what we  
20 kind of hoped we would get to the point that we would  
21 have smooth communication by understanding as failure  
22 mode issue.

23 MR. GUTIERREZ: Well, I mean, I think the  
24 communications is improved. I think some of the  
25 things that you're bringing up are legitimate things

1       that we've discussed is how do you define the problem,  
2       how do you set the boundaries, and what we're using  
3       here called failure modes, what is useful for the  
4       perspective that each of us is applying to try to work  
5       on one piece of the puzzle.

6               MR. POWERS: I'm just not seeing how you do  
7       that right now. Maybe as you go through the  
8       presentation I'll understand how you're doing that.  
9       Right now, it seems to me that we're no better off  
10      than we were whenever Apostolakis came on to the ACRS  
11      because he's the one that pushed this failure mode.

12             MR. TOROK: I think it was 1950, wasn't it?

13             MR. POWERS: No, he came on after I did so  
14      . . .

15             CHAIRMAN STETKAR: Oh, you were 1950.

16             MR. POWERS: I think I was 47, wasn't I?

17             CHAIRMAN STETKAR: We had two and a half  
18      hours on this. We're on slide eight.

19             CHAIRMAN STETKAR: Green light.

20             MR. RICARDELLA: What do you mean by  
21      Byzantine behavior?

22             MR. GUTIERREZ: So Byzantine behavior, we  
23      define that in RIL1002 as such, in a distributed  
24      system, arbitrary behavior as response to a failure or  
25      fault. It's arbitrary behavior of an element that

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 results in disruption of the intended system behavior.  
2 So it's arbitrary behavior.

3 MR. RYAN: It's everything else that's not  
4 above.

5 MR. BLEY: Weird stuff. That's really what  
6 they're talking about.

7 CHAIRMAN STETKAR: But see, Pete, in some  
8 sense, that's L9. In my taxonomy, that's L9. As long  
9 as everyone understands what an L9 is and if you see  
10 one of those you have evidence of an L9, whether you  
11 call it Byzantine behavior or whether you call it  
12 really weird stuff or whether you call it some other  
13 taxonomy that a particular I&Committee engineer might  
14 want to use. It doesn't make any difference. As long  
15 as everybody understands what an L9 is and what the  
16 effects of an L9 are if that thing occurs, that's the  
17 important part, in my opinion anyway, of this mapping  
18 process.

19 So, yes, Byzantine behavior may not be a  
20 very clearly-defined term. But if everybody from the  
21 engineering part who uses completely different  
22 terminology to the risk assessment people, who may  
23 want a different set of terms, if everybody  
24 understands what an L9 is and when it happens, yes, I  
25 had an L9 and how I evaluate the effects of an L9 in

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 my PRA model, you've solved the problem.

2 MR. BLEY: But since it is weird stuff, if  
3 I might, what happens in practice, I think, is if they  
4 collect a large number of those, pretty soon you'll  
5 see categories within it and you generate some new  
6 categories here. But you don't expect to see a whole  
7 lot of these or at least patterns of them yet, but if  
8 you have that could be interesting.

9 MR. SKILLMAN: What's been going through my  
10 mind is kind of addressing Charlie's question, where  
11 do you start in the food chain, and what I'm really  
12 thinking is we've gone from Boolean in analog-type  
13 equipment or Boolean logic in analog equipment to  
14 digital. What gives me comfort, to answer Charlie's  
15 question, is where can you test with certainty? And  
16 my experience is you can test at the card level. And  
17 if you begin with a notion that you can identify your  
18 failure by knowing how your card failed, then that  
19 becomes the smallest element upon which you can be  
20 certain of function. I'm thinking of ESAS modules, of  
21 RPS modules, where prior to modifying the system or  
22 repairing the system, you actually do a module test.  
23 You then know that that card or that module is  
24 healthy, it's fit for duty. And at least my  
25 experience is, you find the failures in the software

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 are actually embedded in the firmware on those cards,  
2 and that's where you detect the failure, particularly  
3 if you've had a spurious trip or a spurious actuation.  
4 You pull that card and you find that you have an EPROM  
5 or some device that is not functioning the way you had  
6 believed it was going to behave.

7 So I guess I start with answering Charlie's  
8 question to myself. If I know that the individual  
9 components are functioning the way they're supposed to  
10 function, then at least I can see how this matrix  
11 answers a whole bunch of questions. But if I don't  
12 settle on some form of architecture that has devices  
13 connected to the architecture, then, quite candidly,  
14 I get lost. It's got to be brought back to a  
15 practical arrangement of devices that you can actually  
16 put your finger on and test, and if you can test it I  
17 think you can figure your way through this. If you  
18 can't test it, I think we're pumping against the tide.

19  
20 MR. GUTIERREZ: But I think that there  
21 might be a little more to that than just testing  
22 something or looking at something once it's already  
23 been built. In all of our work here, both at DE and  
24 EPRI, we're looking at a broader view of things by  
25 looking at different hazard analysis techniques that

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 can be used starting from requirements identification  
2 of what you're trying to design.

3 What we find with digital systems is that  
4 you can't wait until it's already built to try to  
5 consider what might go wrong. You have to start right  
6 at the beginning.

7 MR. TOROK: Well, and the other thing that  
8 comes into play --

9 MR. SKILLMAN: Excuse me. I agree with  
10 that, and what I said before doesn't suggest that I  
11 don't agree with that. It's got to be designed right  
12 in the first place.

13 MR. GUTIERREZ: Right. I understand. I'm  
14 just trying to say that there's this broader view in  
15 which that's included. That's a part of the picture,  
16 but there's that --

17 MR. SKILLMAN: I would just submit you  
18 can't get to the broader view until you've assembled  
19 the components that you know accomplish the functions  
20 that are required. And if you haven't done that, then  
21 this grander view basically dissolves.

22 MR. TOROK: You said something I think is  
23 very important. The way we look at it, the failure  
24 mode is the behavior from outside the thing, the box,  
25 whatever, the card. Typically, the number of failure

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 modes is pretty limited if you look at it at that  
2 level. Now, there may be 47 things inside that box  
3 that can cause a failure mode, but the failure modes  
4 themselves, there aren't many of typically and that  
5 makes a thing far more manageable.

6 MR. BROWN: I'd like to make one more  
7 observations, and I'd request that John and Dennis not  
8 leap on me when I say this, okay? Because it's  
9 somewhat heretical. This is another thought process  
10 I've been going through for the last couple of years  
11 is how we address this.

12 Fundamentally, when you talk about your  
13 assessing it, does it trip or does it not trip, and  
14 what do you do whether you have data, whatever the  
15 circumstances are, but that's what you model in your  
16 PRA thought process. So I come back and say why isn't  
17 that enough? Why is modeling digital I&Committee  
18 different from what we do with other systems, what I  
19 call the mechanical blacksmith technology type  
20 systems? Because the digital I&Committee has an  
21 advantage that all these other systems, the hardware-  
22 based systems, valves, pumps, you know, all the things  
23 that can fail, operators, what have you, that they  
24 don't have. You can continuously test these systems,  
25 self diagnostics, in realtime, okay? And you can test

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 it for all the inputs because you can have little test  
2 units, you know, like a test signal, like a resistor  
3 for an RTE, a precision resistor that allows you to  
4 calibrate, is this thing calibrated right now?

5 So you can test the entire chain of  
6 processing from beginning to end over some period of  
7 sample time while you're doing this realtime  
8 operation. You can't do that with the other ones. So  
9 is one of the thought processes that, since we can  
10 know with a fairly high degree -- I don't want to get  
11 into the percentages here -- of certainty that that  
12 channel is working because, if it doesn't pass its  
13 test, a light goes on and somebody is told when that  
14 happens.

15 So another way to look at this is how far  
16 do we want to go? Why isn't your approach on the  
17 output enough? Why do I have to worry about the  
18 failure modes down in the rest of the system when they  
19 contribute to that if I'm able to test each and every  
20 division from beginning to end for each input? That's  
21 what they're doing. That's the stuff, the self  
22 diagnostics. We started doing that in 1979 and '80  
23 with the stuff we did in the Naval Nuclear Program.

24 The only ratchet on that is what if you  
25 don't complete your processing? And that's where the

1 watchdog timers come in, you know, the lockup comment  
2 you made a few minutes ago.

3 Just two thoughts on the lockup issue. If  
4 you have processing systems that, if you reset them,  
5 which is what we did with the watchdog timer -- we  
6 didn't trip anything -- but when you can start up and  
7 have your outputs within 250 milliseconds or so, it's  
8 a blink of an eye. You don't care. You just let it  
9 reset, and, as long as it's working, you're okay. If  
10 it's five minutes or ten minutes, like it is with the  
11 Common Q platform, that makes a big difference. You  
12 don't have functions for quite a while. But, still,  
13 you've got the diagnostics that let you know that's  
14 happening.

15 And I'm not trying to denigrate anything.  
16 Don't think that. I'm just trying to apply a  
17 different level of thought process as to how you  
18 address this. I wanted to get that on the record from  
19 a thought process standpoint. I hope I've been clear  
20 with my trying to articulate what I'm thinking.

21 MR. LI: This is Ming Li. I totally agree  
22 with your comment, and I just feel that trip and not  
23 trip, that one is a simple example that demonstrates  
24 the level of detail. I didn't mean to say that PRA  
25 can only wish they had that level. I totally agree

1 with you. Although the online diagnostic for  
2 tolerance of those 16 measures should be included in  
3 the PRA analysis, and in my presentation I'm going to  
4 talk a little bit more detail on that.

5 MR. BROWN: All right. Well, thank you for  
6 letting me rambling on. Thanks, John and Dennis, for  
7 letting me ramble on.

8 MR. GUTIERREZ: Okay. For our final slide  
9 here, I'll present conclusions and our next steps.  
10 Based on our work, DE, DRA, and EPRI, we believe we  
11 have a shared understanding of the issues that lead to  
12 misbehavior, other than non-performance of required  
13 function in digital systems. DE and DRA agree that  
14 Failure Mode Set L could be useful for each of our  
15 respective divisions in our work.

16 NRC and EPRI will continue to share  
17 technical information from digital system failure  
18 mode-related research. We are continually working on  
19 vocabulary harmonization. It's a topic that's on the  
20 I&Committee research plan 2015 to 2019 candidate pool.  
21 And we are continuing our work on RIL1003, which will  
22 report on the feasibility of applying failure mode  
23 analysis to quantification of risk associated with  
24 digital I&Committee system.

25 MR. BROWN: Should they continue, John?

1 CHAIRMAN STETKAR: Yes. This is the ACRS.  
2 Always interpret five seconds of silence as proceed as  
3 rapidly as possible.

4 MR. GUTIERREZ: So now I'll hand it over to  
5 Ming Li.

6 MR. LI: Good morning, Mr. Chairman and the  
7 Committee. My name is Ming Li. Next, I'm going to  
8 brief the Committee the standards of the NRC research  
9 on digital I&Committee PRA.

10 NRC started this research program trying to  
11 address the regulatory needs associated with a shift  
12 of the nuclear power plants' instrumentation and  
13 control systems from analog to digital. Since the  
14 Commission encouraged using PRA technology in  
15 regulatory measures as much as possible, this shift to  
16 the digital I&Committee system should be included in  
17 the PRA.

18 Since there are no agreement on the method  
19 that could be used in PRAs, the National Research  
20 Council recommended that NRC should develop a method  
21 to address failures from the digital component,  
22 including the software. The case to include the  
23 digital I&Committee system into PRA is to develop a  
24 reliability model to quantify and then to model and to  
25 quantify the digital I&Committee systems.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1           Since the digital I&Committee system  
2 consists of the hardware, the software, and a lot of  
3 dependent interactions among them, so, ideally, such  
4 reliability modeling for digital I&Committee system  
5 should also include reliability, hardware reliability  
6 models and the software reliability models and a model  
7 that can account for all the dependent interactions.

8           We already touched the concept of the level  
9 of the details a little bit. I want to highlight here  
10 again that the PRA focused on the functional levels,  
11 so here's an example that it's very rare to see a PRA  
12 started from the transistor failures or start from  
13 software statement errors, error in the statement  
14 levels. It rather focused on the functional level, as  
15 I mentioned, trip/no trip or even lower, like the  
16 input module, the output errors and the output models,  
17 the actuation errors or the processing modules so the  
18 processing failures.

19           So as for the hardware reliability model,  
20 I will claim that it's well developed and well  
21 accepted in the industry, especially in the  
22 telecommunications and aerospace industry. Normally,  
23 they use the two methods they call the parts count or  
24 parts stress, and they use a lot of handbook data to  
25 start if there are no field data available. If

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 fortunate and there are field data available, then  
2 people use the field data because the handbook data  
3 sometimes is way too much conservative. Their example  
4 from NASA that a reliability prediction is like a two-  
5 year lifetime, but after 20 years the satellite is  
6 still operational in space.

7 So if there -- yes, go ahead.

8 MR. BROWN: I'll wait until you're done.

9 MR. LI: So if there are field data  
10 available, operating experience data available, so  
11 people tend to use that data instead of the handbook  
12 data. But if start from scratch, their new design,  
13 there are no field data available, then start from the  
14 handbook data.

15 MR. BROWN: I would just make one  
16 observation there. We went after the handbook data  
17 years ago. There was an Air Force manual or some  
18 other manual that had voluminous quantities and how  
19 you would consider it and how often, you know, the  
20 failure rate for various types of parts. And the  
21 fundamental point was the more parts you had in it,  
22 the more likely you were to have failures. I mean,  
23 I'm generalizing somewhat, but that was generally the  
24 approach. The more parts you have, the higher the  
25 probability of some failure to not perform that final

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 function. And quite frankly, when I went from analog  
2 to digital equipment, I probably quadrupled the number  
3 of parts in our modules in the cards and every place  
4 else, and our failure rate for cards went down.

5 So I guess came up with the conclusion the  
6 more parts I had, if they were the right kind of  
7 parts, and, fundamentally, it was driven by the fact  
8 that it was digital, as opposed to an analog, and the  
9 drift and other types of functionality that caused  
10 them, whether it be temperature, vibration, or what  
11 have you, had less of an effect on the modes of those,  
12 you know, the failures than it did in the analog  
13 systems. I'm not trying to say that as an absolute  
14 statement, but that was it.

15 I had my boss at one time, when I wanted to  
16 increase the operational functionality of the  
17 submarines, I wanted to install two more of a  
18 particular type of instrument that are having two and  
19 tripping on one out of two, I wanted to go to four and  
20 trip on two out of four. He threw me out of his  
21 office.

22 When I got a new boss, I proposed the same  
23 thing, put it in, and the problems we had with those  
24 systems went down and it was not allowing the ship to  
25 operate. I put in more parts, a lot more parts,

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 doubled the parts, but, yet, the operational  
2 performance of the submarines and the carriers  
3 improved markedly. We no longer had midnight phone  
4 calls because you had noise preventing your source  
5 range or intermediate range, you couldn't start up  
6 because the rules you said you couldn't start up if  
7 you didn't have a full complement of such and such.

8 So the parts count part, I really get stuck  
9 on this parts count and those types of rules, in terms  
10 of defining what the failure probabilities are. I  
11 just don't think those rules of thumb are as  
12 applicable to the digital systems. The digital  
13 systems are more tolerant of variations, as you look  
14 at how the analog to digital and then how it's  
15 triggered. The variations, once you're digital, are  
16 very, very small. So, anyway, that's --

17 MR. LI: Yes, I agree.

18 MR. BROWN: That's my experience. I'm not  
19 speaking --

20 MR. LI: Yes, I totally agree with you, but  
21 we need to consider this from a different perspective.  
22 First of all, the digital parts are more reliable than  
23 analog part if you take a look at the handbook. So if  
24 the same amount of the part, so digital design are  
25 normally more reliable than analog design.

1           Second of all, you mentioned a redundancy,  
2           and the data are there to implement redundancies. If  
3           you implement redundancy in the system, so you  
4           dramatically drop your failure probabilities, from  
5           that perspective --

6           MR. BROWN:           Functional failure  
7           probabilities.

8           MR. LI: Functional failure probabilities,  
9           yes, yes. And if you have the same design, the same  
10          functionality, there are no redundancies. One, you  
11          have 100 parts, another one you have a million.  
12          That's a more complicated part more likely to fail.  
13          That's what I mean by parts count.

14          MR. BROWN: Maybe. Okay. Go ahead. I'm  
15          sorry.

16          MR. LI: All right. Thanks. On the  
17          contrary, software reliability are more complicated.

18          MR. BLEY: I'm sorry. Charlie is looking  
19          at me. You just discovered something that the Germans  
20          figured out in about 1940. But it's true, it's true.  
21          System reliability is different than piece part  
22          reliability. And the way you put the piece parts  
23          together make a big difference on how --

24          MR. BROWN: And the nature of --

25          MR. BLEY: Counting doesn't do it.

1           MR. LI: All right. Let's get to the  
2 software reliability. Software reliability modeling  
3 is more complicated than hardware reliability  
4 modelings. So although there are over a hundred  
5 software reliability models in the literature, so none  
6 of them is acceptable to current NRC and PRA  
7 requirements.

8           And there are still a lot of arguments in  
9 these disciplines. For example, one big argument is  
10 that software does not fail, so software failures is  
11 not a valid concept. And in this sense, we define  
12 software failures in terms of a functional deviation,  
13 sorry, deviation from expected behaviors. So software  
14 does behave differently from the end user expected  
15 them to do. So from that perspective, software does  
16 fail.

17           And another big argument is that what do  
18 you mean by software reliability? Software failure  
19 mechanism is a deterministic process. Software either  
20 fails or it functions. It's not a random process what  
21 we mean by software reliability.

22           So it's true that a software failure  
23 mechanism is deterministic. If one can repeat the  
24 software execution environment, normally we call it  
25 operational profile. Then you can repeat the same

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 errors. But think about that, that operational  
2 profile. That operational profile is statistic in  
3 nature. So think about the combination of the  
4 statistical input and the deterministic failure  
5 mechanisms. So the overall failure behavior manifests  
6 as a statistic process.

7  
8 MR. BROWN: When you're done.

9 MR. LI: So by that, so software  
10 reliability is still probability. It's still  
11 probabilistic process, so software reliability is a  
12 legitimate concept.

13 MR. BROWN: Okay. Let me provide just  
14 another observation comment here. The more complex  
15 the software, in terms of how it's configured or how  
16 it's set up, can translate into the type of what I  
17 call more unknown-unknown. The more interrupts you  
18 have in a processing chain in anything, if you run an  
19 interrupt-driven system, you significantly increase  
20 the probability of having collisions or confusion  
21 arise in the computational process from beginning to  
22 end. That's why you want a short sample time. You  
23 want everything to be executed in one pass, everything  
24 every time. The main operating loop just regurgitates  
25 itself.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. LI: And you block all interrupts.

2 MR. BROWN: But if you have no interrupts  
3 -- you can never get rid of all interrupts. There are  
4 certain types on the beginning in terms of putting  
5 stuff into memory buffers and things like that. You  
6 have those, but those don't interfere with the main  
7 processing path, okay?

8 So the reality is if I look back and I get  
9 rid of interrupts, I won't say there's very few but  
10 there's a more limited set of things that can prevent  
11 that deterministic main operating loop from not going  
12 from start to finish. Much fewer items that can do  
13 that. And now you're down to where a particular set  
14 of logic shifts doesn't trip when it's on the leading  
15 edge or the trailing edge of whatever the clock signal  
16 is. So you don't get the signal and all of a sudden  
17 it doesn't know what to do.

18 So you're more hardware-oriented in many  
19 circumstances if you get that. The complexity, in my  
20 experience, was a failure to the software. Whenever  
21 we had started introducing interrupts, that's where we  
22 started having problems and it was difficult to test  
23 them out. So, you know, it was just an observation.

24 MR. LI: Yes, I totally agree.

25 MR. SKILLMAN: I'd like to ask a question

1 here, please. You've got a definition at the bottom  
2 of the page of what software failure is. It's defined  
3 triggering of a defect of these software, which  
4 results and contributes to the host system failing to  
5 accomplish its intended function.

6 And in our homework package, in the BNL  
7 document, the NUREG draft, software failure, at least  
8 for the study, is identified as the triggering of a  
9 fault of software introduced during its development  
10 life cycle. And what I would ask you to do is to  
11 explain whether or not this software failure at the  
12 bottom of your slide is a failure that comes from an  
13 incipient failure from the software development or  
14 whether this failure is a random event because the  
15 software forgot what it was doing.

16 MR. LI: You are talking about, actually,  
17 two things. One, the failure mechanism. So the  
18 software failed because of a defect in the software.  
19 Defect could be the errors the developer made during  
20 the development process or even from the end user from  
21 the very beginning, the user requirements.

22 So the defects, those types of defects,  
23 including the end user requirement defect, as I call  
24 it, and the errors made by the developer and  
25 introduced what we call defects during development

1 process, those defects exist in the software. So  
2 during the software executions, some conditions  
3 triggers those defects. Then the software behavior  
4 manifests as a failure behavior, which means that the  
5 software does not perform the expected function.

6 So you're talking about the same thing but  
7 from a different angle. One, the failure mechanism is  
8 deterministic. Every time -- deterministic means that  
9 every time the input conditions trigger that defect,  
10 software fail. So there's a zero or one condition.  
11 But the randomness from the operation, the condition,  
12 the condition itself is random. So that's two  
13 aspects. I hope I answered your question.

14 MR. SKILLMAN: No, I understand the  
15 distinction that you have made. What I'm thinking  
16 about, though, is how do you ensure that the as-  
17 designed package is error free?

18 CHAIRMAN STETKAR: First of all, it's not.  
19 It can't be.

20 MR. SKILLMAN: Okay. So starting there  
21 then, how do we resolve this riddle?

22 MR. BROWN: I'll tell you what they've  
23 done. They test and test and test, putting in input  
24 and data and data and data, and they run it and they  
25 keep correcting the problems until it asymptotically

1 comes down to a constant low-level amount and they say  
2 it's good and we have -- whatever defects are  
3 remaining, that's what you issue and that's what  
4 you've got in your smartphone.

5 MR. SKILLMAN: Again, let me just respond.  
6 So you're down to testing even the smallest piece  
7 until you know that that piece is functioning the way  
8 you want it to function?

9 MR. BROWN: Within some --

10 MR. SKILLMAN: Good enough.

11 MR. BROWN: Good enough.

12 MR. SKILLMAN: Good enough. Okay. Well,  
13 that's where I was an hour ago. I'm good.

14 CHAIRMAN STETKAR: Good enough. But there  
15 still can be conditions, even though it's functioning  
16 good enough, that challenge it to perform in ways that  
17 the designers didn't anticipate. And that's the crux.  
18 That's the search in the risk assessment is to  
19 understand how it's supposed to work.

20 MR. TOROK: Yes, you're exactly right. I  
21 would argue, I would agree that software is not going  
22 to be defect free. You shouldn't expect that. But  
23 the good news is you don't really need that. What you  
24 need is software that doesn't do bad stuff, and that's  
25 different. And that's where you get into things like

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1        what Charlie was talking about with this simple loop  
2        architecture.

3                CHAIRMAN STETKAR: In a risk assessment, it  
4        doesn't do bad stuff at a frequency at which it's  
5        challenged to do bad stuff to get you into trouble.  
6        You don't design against meteorite strikes, okay? We  
7        accept that. We accept the risk of meteorite strikes,  
8        even though our plants are not hardened against  
9        meteorites. The software doesn't need to be perfect.  
10       It has to be good enough to withstand the types of  
11       challenges that it's going to be introduced to. If  
12       those challenges occur frequently enough, such that it  
13       misbehaves in ways that perhaps the designers didn't  
14       anticipate, that's part of the process of doing the  
15       risk assessment. So, yes, it has errors in it.

16               MR. TOROK: And there are many things you  
17        can do in software design to hedge your bets on that.  
18        A good example is, if you're talking about the  
19        operating system in a digital gadget and the way it's  
20        used to control a real system, you want to make sure  
21        that the operating system is blind to plant  
22        transients. And what that means is that every time  
23        step their operating system does what it does,  
24        regardless of what's going on in the plant. And why  
25        that's important is that means, on every condition

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 coming from the plant, it can't trigger a defect in  
2 the operating system. The operating system is never  
3 going to get to its defect because it's doing the same  
4 thing every time, regardless of what's going on in the  
5 plant. That's an important design feature.

6 MR. SKILLMAN: Thank you.

7 MR. TOROK: Right.

8 MR. BROWN: But the testing to get there  
9 can be difficult. I mean, if you take one instrument,  
10 a temperature, pressure, whatever it is, and if you  
11 had the resolution down to ones or maybe 0.1, 0.2, 0.3  
12 resolution, now there's a set of ones and zeros in a  
13 field that represents every one of those states. Try  
14 testing that millions of states even with a highspeed  
15 computer and feeding that into the system and making  
16 sure every field produces the proper response. It's  
17 very time-consuming and costly. And that's why when  
18 it's good enough and you're putting multiple channels  
19 in and that kind of covers the waterfront. You're  
20 kind of betting the ranch that one discrepant set of  
21 ones and zeros is not going to hit you and disrupt you  
22 in all four of them at the same time because no  
23 instruments ever read the same all the time. They  
24 just never do. You're betting on hope.

25 So, anyway, do you want to go on?

1                   MR. LI:     All right.     This digital  
2     I&Committee PRA research, the NRC digital I&Committee  
3     research plans. And the objective of this research is  
4     to identify and develop methods and the tools and,  
5     ultimately, the regulatory guidance to include the  
6     digital system into current NPP PRAs.

7                   And we already developed a number of  
8     deliverable here. In 2009, NUREG CR report on the  
9     application of traditional PRA methods to digital  
10    feedwater control systems and also the BNL internal  
11    technical reports based on the expert panels on the  
12    software reliability studies. This was published in  
13    2009, also.

14                  And another BNL internal letter report  
15    reveals the surveys on the so-called quantitative  
16    software reliability method. This is a summary. And  
17    a recent NUREG CR report, 7044, summarized the results  
18    on the selection of quantitative software reliability  
19    methods and picked up two of them, which BBN, Bayesian  
20    Belief Network, and the statistical testing method for  
21    further study.

22                  Two NUREG CR reports published in 2016 and  
23    2017. One is the Bayesian Belief Network study and  
24    another one, statistical testing studies. And,  
25    ultimately, we expect regulatory guidance out from

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 this research.

2 CHAIRMAN STETKAR: That's the current  
3 schedule for those, Ming? '16 and '17?

4 MR. LI: Yes. '16 is for STM, or  
5 statistical testing method, and the '17 is for  
6 Bayesian Belief Network report.

7 CHAIRMAN STETKAR: Okay. Thank you.

8 MR. LI: This chart depicts this digital  
9 I&Committee PRA research programs. This was previous  
10 research, and the staff identified some open issues  
11 and they proposed the ongoing research on software  
12 reliability and proposed future research on digital  
13 I&Committee dependencies and common cause failures and  
14 also to include some 60 design features, such as fault  
15 tolerance, online surveillance functionalities. And  
16 out from the current ongoing research and future  
17 research, a revised PRA framework to include digital  
18 I&Committee component are expected. And after that,  
19 a pilot study will be conducted before it reaches  
20 regulatory guidance.

21 And this research, of course, is not a  
22 standalone. So we collaborate --

23 CHAIRMAN STETKAR: Ming?

24 MR. LI: Yes?

25 CHAIRMAN STETKAR: Before we get into the

1 piece parts here, you said that the dates for the  
2 NUREGs are --

3 MR. LI: It's here.

4 CHAIRMAN STETKAR: -- 2016 and 2017.

5 MR. LI: Yes, it's here, ongoing.

6 CHAIRMAN STETKAR: Right. When might one  
7 expect the final endpoint of this process, that  
8 regulatory guidance? I'm just trying to figure out  
9 whether I need to worry about it before I retire. No,  
10 trust me, as chairman, I don't need to worry about it.  
11 I'm thinking, you know -- well, honestly, in some  
12 sense, we did have this discussion during the  
13 subcommittee meeting in terms of both, functionally,  
14 how the piece parts fit together, which I know you're  
15 going to get into. But the endpoint being that  
16 regulatory guidance, the focal point of this whole  
17 effort, it's been going on now for, you know, seven,  
18 eight, nine years or more. When might we expect some  
19 sort of useful practical output from it? And that is  
20 an honest, you know, all facetiousness aside. Are we  
21 looking at 2018, 2019, 2025?

22 MR. SCHULTZ: Does it show up in the five-  
23 year research that we described earlier?

24 MR. COYNE: It's a good question, but I'll  
25 say we've trained Ming well because he did give a good

1 answer that it is too soon to tell. And we have been  
2 doing this for a while, but it is a very complex  
3 research area. But I'll say we're very pleased and  
4 optimistic with this statistical testing work. That  
5 project actually has gone quite well, and we moved  
6 that up in advance of the BBN work, which we actually  
7 had the priorities of those research projects flipped.  
8 And then when we saw how well the statistical testing  
9 work was coming together, we decided to put a higher  
10 priority on that.

11 CHAIRMAN STETKAR: Yes, I think that's the  
12 first that we heard. Back in November, I'm not sure  
13 where they were in the --

14 MR. COYNE: Right. So you've seen the  
15 draft report on that, and Ming is going to talk about  
16 some of the redo of the testing that we did to further  
17 improve the approach we used. So that work is gelling  
18 together. Ming said '16 to publish it. You know, the  
19 report is going to be ready this year. It just takes  
20 a while to get through the publication process.

21 CHAIRMAN STETKAR: Okay.

22 MR. COYNE: The BBN work, which he'll also  
23 brief you on, is going quite well. It's been a very  
24 fruitful collaboration with KAERI and KAIST, who has  
25 a lot of experience in doing this kind of software

1 reliability work. We'd like to make that a joint  
2 report with our international colleagues, and that  
3 might take a little more time to get through the  
4 publication process.

5 So, honestly, the FY 16 for the publication  
6 is probably accurate, but we expect to get that report  
7 pulled together within the next 12 months to a pretty  
8 good state. And then --

9 MR. BLEY: Are we talking that that might  
10 be an CSNI report, as well as NRC, or something else?

11 MR. COYNE: It would be, it would be  
12 similar to what we've done with some of the fire work  
13 that it's a joint NRC/EPRI, except it would be --  
14 we'll have to decide if it's a NUREG IA or some other  
15 designator. But we want, we're moving forward with  
16 getting that report finalized.

17 Then the big question we've always had is  
18 is this practical and useful? Do we get good insights  
19 from the work? Is it practical to do? Is the  
20 information available? And, honestly, that's been a  
21 big challenge for us. The level of information we  
22 need on these systems and dealing with the proprietary  
23 nature of what's in the system and the software  
24 development cycle and that type of information that we  
25 actually need to implement the method has been very

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 challenging. We were very fortunate to have Idaho  
2 National Lab come forward and volunteer the advanced  
3 test reactor loop operating control system. Honestly,  
4 we were at kind of a dead end until that came through,  
5 so that's been very fruitful for us to have that  
6 available to us.

7 When Ming mentions that pilot study, that's  
8 going to be a big challenge for us to figure out how  
9 we're going to do that pilot study on a real realistic  
10 system. So we do have a target. We have the pieces  
11 really starting to come together. I can actually  
12 begin to see the light at the end of the tunnel on  
13 this. It's just I'm not sure, we have to come to the  
14 conclusion whether it's practical and useful with  
15 these methods and then how we're going to put the rest  
16 of the pieces together for things like a pilot study,  
17 which I really think would need to be done to have  
18 good confidence that whatever regulatory guidance we  
19 propose is appropriate.

20 CHAIRMAN STETKAR: I think, you know, we've  
21 learned a lot about the need to do realistic pilot  
22 studies in any proposed methodology. I'll mention  
23 NUREG CR 6850 and the fire analyses as one example.  
24 The experience has been, I think and I would hope  
25 going forward, is that if, indeed, the outcome of this

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 process seems to be a practical methodology that is  
2 endorsed both by the staff and, if not endorsed,  
3 accepted by the industry, there may very well then be  
4 a licensee who steps up to use their plant as a pilot,  
5 which is then obvious the need for the staff to obtain  
6 directly the proprietary information in a real system  
7 at a real plant. And, of course, there aren't going  
8 to be any volunteers for that, unless there's some  
9 evidence that, indeed, the methods are practical.

10 So getting to that center part there, the  
11 revised PRA framework, is certainly a necessary goal.  
12 And I was mostly trying to challenge what the timing  
13 on that is. Okay, thank you. Sorry to interrupt. I  
14 know you want to talk about the piece parts but . . .

15 MR. LI: Let me quickly finish this chart.  
16 As I mentioned, this work got a lot of collaboration  
17 under MOUs with EPRI and with NASA and the  
18 international collaboration and the bilateral with  
19 South Korea and also with NRC. And we got a lot of  
20 support from the Division of Engineering on the  
21 failure mode, on the operating experience analysis  
22 data collection, and also on the digital system  
23 inventory and the classification studies.

24 I want to quickly summarize our research in  
25 the past. For the hardware on the system-level

1 reliability modeling, Ohio State University worked  
2 together with ASCA and the University of Virginia,  
3 applied some dynamic reliability modeling method, such  
4 as the Marco Chen methods, to digital feedwater  
5 control systems and they published a number of NUREG  
6 reports in the 2006 to 2009 time frame. And the BNL  
7 also applies to some traditional reliability modeling  
8 methods, such as FMEA, they call it revised FMEA  
9 method, to the same systems and they published their  
10 results in a NUREG report in 2008 and another one in  
11 2009.

12 And if we go back further in the history,  
13 Ohio State University developed the so-called metrics-  
14 based studies for software reliability modeling. So,  
15 basically, this started, like, 40 software metrics and  
16 expert panel ranked those 40 metrics with respect to  
17 their capabilities of estimating software  
18 reliabilities and then developed 12 software  
19 reliability methods from those 40 metrics to verify  
20 the ranking. And there are some results from that,  
21 and they published the results in the GR report and  
22 two NUREG CR reports.

23 And the ongoing study conducted by the BNL,  
24 the national lab, and the NUREG CR 7044 that's already  
25 published summarized the expert panel results and the

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 philosophy, the foundation of the software reliability  
2 work and also identified two candidate methods which  
3 I mentioned, the Bayesian Belief Network and  
4 statistical testing, and applied that with a  
5 collaboration with Idaho National Labs to apply those  
6 two methods to estimate software reliability so that  
7 ATR, advanced testing reactors loop operating control  
8 systems. I'm going to talk a little more in detail  
9 later.

10 This research also got a lot of support  
11 from the international partners, including the South  
12 Korea, the KAERI and the KAIST colleagues. They  
13 provided a lot of valuable support on the STM method,  
14 which they practiced in the past. And also they're  
15 actively involved in the Bayesian Belief Network  
16 research. They provide the algorithm and they provide  
17 the models and the execution of that to support BNL's  
18 study on this.

19 And, furthermore, the PECD also worked on  
20 digital I&Committee PRA areas. So there are two  
21 reports published: one on the failure mode taxonomy  
22 published last year and there's another recommendation  
23 on digital I&Committee PRA published in the year 2009.  
24 And there's an effort called a COMPSIS, computer-based  
25 system important to safety project, spanned from 2005

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 and 2011. There's not much output from it because  
2 only the U.S. contributed to the data, so it's a pity.

3 Next, I'm going to talk about the ongoing  
4 research on software reliability, which is the focus  
5 of today's presentations. The first one I'm going to  
6 talk about is the statistical testing method. We  
7 already talked about software testing here a lot, but  
8 this statistical testing method is different from the  
9 functional software testing. In short, this  
10 statistical testing method tried to estimate the  
11 failure probability of the software instead of trying  
12 to prove the correctness of the software.

13 So in order to do that, I mentioned that  
14 software failures probability could be zero or one,  
15 depending on the input. So if you select a failure of  
16 an input, you can prove the software, you know, never  
17 failed. So as I mentioned, software reliability is a  
18 function of the defects and a function of operational  
19 profile.

20 So in order to test software in the PRA  
21 context, it's important that, I call it the testing  
22 conditions, and, fortunately, the PRA can provide the  
23 information, the software and the test, the  
24 conditions, and we call that, again we call that  
25 operational profiles. And, also, the PRA insight can

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 help to determine how many test cases is good enough.  
2 Think about --

3 MR. BLEY: Can I interrupt you at that  
4 point just a second? You use the PRA to define these  
5 conditions. However, there are lots and lots of cut  
6 sets evaluated by the PRA, so you're using some kind  
7 of a screen to find them. My concern would be that  
8 the kind of failures we might see here could elevate  
9 otherwise very unlikely cut sets up to be more likely  
10 through some kind of common effects. How did you try  
11 to look for that kind of problem and make sure you've  
12 got the cut sets that might be most important?

13 MR. LI: Okay. First of all, what the BNL  
14 did was to rank the cut sets, according to their  
15 likelihood.

16 MR. BLEY: So based on some assumption of  
17 failure rates?

18 MR. LI: Yes.

19 MR. BLEY: Okay.

20 MR. LI: And they picked up about 10,000  
21 cut sets.

22 MR. BLEY: Okay.

23 MR. LI: And then they used those 10,000  
24 cut sets, defined 10,000, RELAP5 starting conditions.  
25 Then they execute the random simulations because the

1 simulation generates all the plant conditions. Those  
2 are the inputs to the software and their tests. I  
3 hope this answered your question.

4 MR. BLEY: Well, a little. Doing it that  
5 way, depending on how they modeled or you modeled  
6 common cause among these things, through the common  
7 cause you might have elevated higher-level cut sets so  
8 that we make sure we see them. And if you don't do  
9 that, you're seeing primarily the higher order, the  
10 fewer element cut sets. And if you do it that way,  
11 then at least one ought to look and see if, when you  
12 go through this testing, you see some of the highest  
13 order among the set that you actually use showing up  
14 in important results, which might lead you to have to  
15 dig further. Did you take either of those two  
16 approaches?

17 MR. LI: Well, I'm not sure I'm the right  
18 one to answer your question. Definitely, I can pass  
19 this question to BNL. As far as I know, well, of  
20 course, the quality of this statistical testing work  
21 depends on the quality of the PRA. So what BNL did,  
22 they have the PRA from Idaho, they have the PRA from  
23 Idaho, so their cut sets are based on the Idaho PRAs.  
24 So I believe Idaho PRA, they addressed the common  
25 cause. They basically went to address all the common

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1       cause.

2                   MR. BLEY: I'd be real interested in being  
3       able to see some depth on that at some point to help  
4       increase confidence.

5                   MR. LI: Thank you. I just talked about  
6       the testing process. So, basically, BNL used PRA  
7       models from Idaho and generated the cut set, the  
8       10,000 cut set, and then it ran the RELAP simulations  
9       for those 10,000 conditions, then produced the test  
10      cases to the LOC system and then passed those test  
11      cases. So you can imagine, you know, for each  
12      condition, there might be 10,000 inputs, so 10,000,  
13      all those data points, pass all the information to  
14      Idaho. Then Idaho automatically have the actual LOC  
15      systems and then provide all the test results back to  
16      BNL.

17                   It's very interesting that the results, if  
18      we take a look at the testing results, before the  
19      November ACRS subcommittee meetings, BNL identified a  
20      large number of, they called it anomalies. It's  
21      either early or delayed trip. Early means that the  
22      trip occurs earlier than it should be, and a delay in  
23      the trip, of course, it's a couple millisecond or, you  
24      know, a half second after it should be tripped. And  
25      we examined those results, and then we figured out

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 that BNL introduced some artificial noise to that test  
2 data to mimic the actual operation, which means the  
3 noise from the sensors. Then that introduced an  
4 additional layer of uncertainties because, you know,  
5 for instance, the inputs to the software might be 4.01  
6 and that might lead to early trip. So after we  
7 realized that, then BNL regenerated, removed all the  
8 artificial noise.

9 CHAIRMAN STETKAR: Ming, you characterize  
10 this as artificial noise because you're trying to have  
11 a perfect laboratory setting here. In the real world,  
12 there really is noise. So by removing what you  
13 characterize as artificial noise, have you removed  
14 this one step from the real world?

15 MR. LI: Well, this is software testing.  
16 I completely understand your point, but this is  
17 software testing. So we have to know exactly what the  
18 input value is in order to decide whether the output  
19 is right or not. So you have to have that clear. You  
20 need to remove that uncertainty. For instance, if the  
21 input is 4 and the input becomes 4.01, then the  
22 software trips. So you never know is this a software  
23 error or error caused by the input noise.

24 And, in reality, yes, you're right. So the  
25 sensor introduced noise. But then that becomes part

1 of the plant. So within that threshold, the system  
2 need to trip. Even the plant condition, not there  
3 yet, but for the conservative consideration they trip  
4 that. But, in our case, we have to be able to tell  
5 exactly what the input is in order to decide whether  
6 this is a software error or --

7 CHAIRMAN STETKAR: What I'm trying to  
8 figure out here is are you trying to create a  
9 spherical chicken?

10 MR. LI: I'm sorry. I don't follow you,  
11 the last word.

12 CHAIRMAN STETKAR: It's an old joke. Look  
13 it up. You cannot predict how a chicken can fly  
14 unless you simplify it to the point where it's a  
15 perfectly spherical chicken. And that's, obviously,  
16 a useless piece of information.

17 What I'm trying to understand is you're  
18 saying, well, we had these artificial noise that  
19 Brookhaven introduced because they wanted to simulate  
20 the effect of differences that might be in the plant,  
21 and we didn't like that so we threw that away because  
22 we wanted to take a more purist approach to just the  
23 software. My question is what is the use of just  
24 having an artificial purist notion of the software  
25 under conditions that it probably never will really

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 see in the real world. We'll always see some sort of  
2 noise.

3 MR. LI: Well, they are two different  
4 things. We are talking about the input. Now you're  
5 talking about a pure system. So by input, I mean --  
6 well, let's talk about software testing.

7 So in order to test a software, you have to  
8 know for each input what the expected output is. If  
9 you don't have that information, you cannot tell  
10 whether your test is successful. So you have to be  
11 clear, there should be no uncertainty for input. If  
12 the input is four million, then it should be four  
13 million.

14 MR. BLEY: I agree with you, provided you  
15 keep careful note of this because, when we operate in  
16 the real world, the problems in software-driven  
17 systems might not be problems in the software. There  
18 might be problems in the input information that's  
19 outside of what we've tested and outside of what we  
20 expect. And that might be the main source of the  
21 risk. We don't know for sure yet. So step one in  
22 your testing makes sense to me, but don't forget the  
23 other --

24 CHAIRMAN STETKAR: In a sense, you're  
25 right. Step one in the testing is just to try to get

1 that pure notion. But step two of the testing would  
2 then be to introduce noise and find out how sensitive  
3 --

4 MR. LI: A statistical testing. We tested  
5 the LOC system. Now you're testing, it's a broader  
6 system --

7 CHAIRMAN STETKAR: No, no, no. Test your  
8 LOC system but with the noise and those input signals.

9 MR. COYNE: Kevin Coyne from the staff.  
10 There was a statement you made that I want to correct.  
11 We're not throwing away the initial data. In fact, we  
12 thought that was a more realistic portrayal of how the  
13 system behaved. But when 10 percent of the test cases  
14 fell out of the range we expected, we realized we had  
15 to do more work to understand why that was the case.  
16 And when we did the initial round of testing, INL  
17 calibrated the LOC system as they normally would  
18 calibrate the actual operating LOC system using their  
19 normal procedures and normal calibration tolerances.  
20 BNL introduced some additional noise on top of the  
21 RELAP output to represent what they expected real  
22 instrumentation would experience, and then we had this  
23 issue with 10 percent of the cases. We felt it was  
24 due to the input errors that were being sent into the  
25 software, but it's hard to prove that. So the idea

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 with the second round was we were going to calibrate  
2 everything as dead-on as we could get it, and INL  
3 actually could do a fairly good job at really getting  
4 the calibration of the analog-to-digital setup and the  
5 processing setup very well and removed the additional  
6 noise. And so now we're getting a much cleaner set of  
7 test cases with the second test.

8 So I think both sets of tests give you  
9 valuable information to how the system is performing.  
10 If you're focused solely on the software, a cleaner  
11 set is more representative of software, and the messy  
12 set is probably more representative of how the system  
13 would actually behave. So I think they both tell us  
14 something that's valuable, and it was a learning  
15 experience for us going through this process.

16 MR. BLEY: Okay. To me, that makes some  
17 sense. I'd also ask is the only function of the ATR  
18 LOCs to create a trip, or does it do other control  
19 functions?

20 MR. LI: Other --

21 MR. BLEY: Are you looking at those? Are  
22 they being affected? You're only looking at the one  
23 function?

24 MR. LI: We isolate the functions, yes.

25 MR. BROWN: Dennis, to the point, I

1 understand what you did trying to isolate the thing.  
2 But what we did, and just based on experience, we had  
3 the same circumstance. The fundamental problem of  
4 going from analog to digital, the digital was a nice  
5 crisp signal. But if you're a-to-D conversion had  
6 variability in it, then you had to design the system  
7 to account for that variability. So you didn't get  
8 the 10 percent unusual triggers.

9 So there's a way to use both sets of data  
10 or information in order to end up with a system that  
11 is reliable and functionally repeatable, which was the  
12 important, the key issue here.

13 MR. LI: I totally agree. But,  
14 unfortunately, in this case, our capability to study  
15 the system is limited because the proprietary system,  
16 we don't have document and we don't know how the  
17 system was designed, what's the part number, what's  
18 the, you know -- all the information we don't have.  
19 So even further LOCs is not safety system, per se.

20 MR. BROWN: No, another comment I was going  
21 to make is that there's a difference between the  
22 control systems, the feedback control system, and just  
23 a straight-through trip or don't trip type system.

24 MR. LI: Yes, I totally agree.

25 MR. BROWN: You just got to take that into

1 account. You've got to do things in a control system  
2 that you wouldn't necessarily do in a straight-through  
3 safety system, in terms of accomplishing your final  
4 function.

5 MR. LI: Sure. Thanks. Well, another very  
6 useful feature we added for the second round of  
7 testing, we introduced what we call synchronizing  
8 timing signals during the first testing. So there are  
9 trips there, but we didn't know this trip was caused  
10 by which input signals. So now we have the timing  
11 signal. There's a pulse there. So from the input,  
12 then we know the output, the pulse continues and then  
13 we can count where the input signals, which input  
14 signal triggered that, caused that trip signal.

15 There were still 45 delayed trips and the  
16 early trips. And the preliminary analysis on that,  
17 and Idaho agree with that, is that all the trips were  
18 caused the A-to-Digital I&C converter. It's still the  
19 revolution. Very small input errors caused early  
20 trips or delayed trips. It's like a 0.01 percent of  
21 the input range.

22 CHAIRMAN STETKAR: Ming, I'm assuming that,  
23 we discussed in November, mischaracterized it as an  
24 anomaly that you couldn't reproduce, one event where  
25 it actually never tripped. Delay was, like, infinite.

1 I'm assuming you haven't experienced that again?

2 MR. LI: No.

3 CHAIRMAN STETKAR: Okay.

4 MR. LI: That failure never repeated.

5 CHAIRMAN STETKAR: Never repeated.

6 MR. LI: Never repeated.

7 CHAIRMAN STETKAR: Okay.

8 MR. LI: Another ongoing research on  
9 software reliability, the Bayesian Belief Network. As  
10 I mentioned, that software failure defect there and  
11 the operational environment triggered those defects.  
12 So it would be useful to know how many defects in the  
13 software and then from the number of defects to the  
14 failure of probability by introducing the operational  
15 profiles. And this BBN approach, basically,  
16 established the causal relationship between what we  
17 call the software development or software product  
18 characteristics -- we call, each one is a node --  
19 that causal relationship between those nodes to the  
20 number of defects in the software.

21 And this research heavily relied on the  
22 expert opinion, unfortunately, because the lack of  
23 data. So we don't have any adequate data, so we used  
24 three rounds of expert opinions. Our first round  
25 established the set of attributes and then the column

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 network. Then the second round of expert opinion is  
2 used to quantify those causal relationships, what we  
3 call MPD tables. And the third round, we applied  
4 those networks to the ATR LOC systems, so we were  
5 utilizing the expert to provide input to each  
6 attribute because we are not developer of the system,  
7 so we are not very familiar with the systems.

8 And this chart is just a demo. This is not  
9 the actual network. This is just for demo purpose.

10 So the path forward, as I mentioned, we're  
11 going to publish the statistical testing method report  
12 next year.

13 MR. BLEY: Are you considering whether it  
14 might be a good idea to kind of put the two methods  
15 together, use statistical testing method to develop  
16 some estimates of parameters and then use the Bayesian  
17 Belief Network as the real model that you update with  
18 the results from the testing?

19 MR. LI: This is already under  
20 consideration. And, furthermore --

21 MR. BLEY: I kind of thought that's what  
22 you had said the last time, but I think it's really,  
23 it allows you to pick up things that maybe you didn't  
24 pick up in testing until we gathered much more  
25 experience.

1 MR. LI: That's a very good recommendation.  
2 Thanks. And, furthermore, normally, the BBN results  
3 served as prior information to Bayesian upgrades. So  
4 based on the BBN work, then we can estimate, a rough  
5 estimate, the failure probability. Then we can better  
6 do an STM, using STM, so it upgraded the STM results.  
7 So there are multiple ways that we can, you know, play  
8 on the numbers.

9 So we're going to publish the STM NUREG  
10 report in 2016 and the BBN report after that in 2017.  
11 And we're in the process of updating the digital  
12 I&Committee research plans to reflect the next stage  
13 of the digital I&Committee PRA work.

14 MR. BLEY: I lost track of what Kevin said.  
15 The BBN report, it's going to be an international  
16 report, or both of them?

17 MR. COYNE: It would be a NUREG  
18 publication, but we would cross-batch it, hopefully,  
19 with KAERI.

20 MR. BLEY: And that's the BBN?

21 MR. COYNE: That would be the BBN work.

22 MR. BLEY: Okay.

23 MR. LI: So the research plan is going to  
24 include the software failure data collection. We  
25 still need to continue collecting data on hardware

1 failures, and we continue working on the software  
2 reliability modeling work. And we're going to start  
3 the digital I&Committee dependency modeling. And we  
4 also need to model the safety design features, such as  
5 the floor tolerance, online surveillance, so forth and  
6 so on. And, ultimately, we're going to develop the  
7 reg guide.

8 And this concludes my talk. Any questions?

9  
10 CHAIRMAN STETKAR: Any further questions  
11 for the staff? If not, EPRI has prepared a  
12 presentation. Anything for the staff? Thank you  
13 very, very much. Ray, you're up.

14 MR. TOROK: Am I driving, or are you?

15 CHAIRMAN STETKAR: This is a low-budget  
16 operation. We can put you in the car and on the road,  
17 but you have to drive.

18 MR. TOROK: Okay.

19 MR. BLEY: Ray, before you even start, the  
20 work NRC just described to us, especially the testing  
21 and the BBN, you guys aren't directly cooperating, I  
22 don't think, but you're following?

23 MR. TOROK: Yes.

24 MR. BLEY: Any comments you have along the  
25 way would be helpful, and your paper is on the

1 microfilm.

2 MR. TOROK: Sorry about that. Yes, well,  
3 we periodically meet with NRC research under a  
4 memorandum of understanding where we share information  
5 on what each of us is doing. So in those meetings, we  
6 hear about it and we comment on it and maybe we'll  
7 raise questions as to things that ought to be  
8 addressed in what they're doing, those kinds of  
9 things. And then they do the same for us. So in that  
10 sense, yes, we know about it, but we're not involved  
11 in the research --

12 MR. BLEY: Okay.

13 MR. TOROK: -- at all. Okay. So moving  
14 right along now, as you know, we presented material to  
15 the I&Committee and PRA subcommittees back in  
16 November, and this is, today is an overview, a brief  
17 overview of the same topics we covered there. This  
18 list shows those same topics. So there's something on  
19 failure modes; modeling digital in PRA, what we've  
20 done; and ways to deal with potential failures in  
21 terms of prevention and mitigation; and hazard  
22 analysis. We talked about a demonstration project  
23 we're doing with Palo Verde and, you know, where they  
24 were and information from that. So I'm going to just  
25 briefly hit each of those things.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 Overall, the so what is that, you know, all  
2 this work we did started in a way with this notion  
3 that, with digital systems coming in, there's  
4 potential for new failure modes, including common-  
5 cause failure. That was raised as part of this SECY  
6 93087. And in a way, this concern about new failure  
7 modes and so on for digital pushed a lot of things.  
8 So we've been working on that for several years now.

9 And the same things we've been talking  
10 about, failure modes and how do you protect against  
11 the failure modes and, you know, what can you do about  
12 that. Our understanding now is much better than it  
13 was when the SECY was written and since the industry  
14 standards have come a long way. There's been multiple  
15 iterations of some of them. And this notion of what  
16 do you do with digital in PRA, we've been playing that  
17 game for several years now trying to understand what  
18 kind of insights we can get, what the limitations are,  
19 those kinds of things. And then this notion of hazard  
20 analysis, or failure analysis some people call it,  
21 because that turns out to be very useful in terms of  
22 identifying potential vulnerabilities and understand  
23 what you can or cannot do about them.

24 So from our position, it may be now that  
25 the SECY 93087 has seen its day and it's time to think

1 about applying the more recent knowledge and the work  
2 that's been done since then. It's been 20-something  
3 years. I mean, really, it started before 1993. And  
4 EPRI's role in this has been to develop methods and  
5 guidance and so on that can support the utilities.  
6 The utility engineers are our audience for the most  
7 part. And the idea is that if we can provide good  
8 technical guidance that's practical to use and so on,  
9 that's a good thing for them. Sometimes, it comes  
10 down to communicating the tech transfer issue,  
11 especially if it's something new. That can create  
12 problems by itself. So we do that, as opposed to  
13 discussing regulatory implications, let's say, and  
14 arguing about what's a good or defensible licensing  
15 position. That's somebody else's job.

16 But the main point is we know a lot more  
17 about this stuff now than we did, you know, 20 years  
18 ago. Any comment or --

19 Okay. So failure modes, just real brief  
20 because I think Mauricio already addressed the topic.  
21 But this issue of what's, you know, are the EPRI and  
22 NRC research treatments really compatible in a couple  
23 of areas. One is what are the words themselves? You  
24 know, do we understand each other? And is the  
25 coverage comparable? And I put the phrase in there

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 "level of interest." Some of you may remember our  
2 level of interest diagram from the last time we  
3 talked, but the idea is that, if you look at the  
4 plant, there are various levels of interest you can  
5 consider from the I&Committee and the software  
6 embedded in the I&Committee at the bottom all the way  
7 up to plant systems and the overall plant safety at  
8 the top. And you want to understand where you are in  
9 that hierarchy and what you care about, what you don't  
10 care about. That becomes important in terms of  
11 understanding what you can do and so on and how to  
12 deal with potential failure modes and so on.

13 Overall, it's important, I think, that  
14 we're communicating when we talk about failure modes,  
15 failure mechanisms and effects, and so on. And in the  
16 MOU discussions with NRC research where we get into  
17 that in some detail, our conclusion was we understand  
18 each other pretty well and we're pretty much on the  
19 same page throughout, you know, even when we're using  
20 different words. So that's okay.

21 Now, for us, the words are important and  
22 understanding the modes, mechanisms, and effects are  
23 important in all of this stuff, in hazard analysis for  
24 sure, in how you're modeling things in PRA because  
25 there are, as I said, multiple levels going on here.

1 We already mentioned these periodic meetings. Those  
2 are under the memorandum of understanding.

3 I wasn't going to go into anymore detail  
4 than that on this issue because I think it's already  
5 been presented and discussed.

6 CHAIRMAN STETKAR: But, again, presented  
7 and discussed to the subcommittee, so most of the rest  
8 of the folks haven't heard about this.

9 MR. TOROK: Well, the main issue was are we  
10 on the same page in terms of understanding, and I  
11 think Mauricio addressed that earlier, so I wasn't  
12 going to go anywhere with that.

13 Now, this is the next topic on that list,  
14 modeling digital in PRA. And this is something that  
15 we started working on in 2004, so it was quite a while  
16 ago. And there are a number of what I call hot-button  
17 issues tied to modeling digital in PRA. This notion  
18 of diversity and defense in depth, what can PRA help  
19 us with there?

20 And the reason that's driving this was  
21 because some guidance on the street was looking at the  
22 need for diverse backups for the I&Committee to deal  
23 with certain events, and I guess the leading one was  
24 a large-break LOCA where you're worried about low-  
25 pressure injection and you've got multiple trains of

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 low-pressure injection with the same software in each  
2 train and suppose there's a bug in the software that  
3 defeats all the trains. Wow, what am I going to do  
4 now? And you end up in a situation where you're  
5 talking about a diverse backup for the initiation of  
6 low-pressure injection. And some pressure rises,  
7 that's all well and fine. But what does the PRA tell  
8 us about that? Is that a good idea or not? And I'm  
9 not talking about a detailed understanding of failure  
10 probabilities. I'm talking about risk insights. And  
11 so you want to be in a regime where the risk insights  
12 are not sensitive to specific assumptions you've made  
13 in your analysis.

14 And so in this case, if I talk about large-  
15 break LOCA and diverse backups, I'm talking about a  
16 combination of a large-break LOCA, which is a  
17 relatively rare event, with a common-cause failure in  
18 the digital control system, which is a relatively rare  
19 event, and the PRA would say, wow, that's a really  
20 rare event. And, you know, so you end up in this  
21 discussion of whether it's beneficial to do that. So  
22 we got into that discussion.

23 The notion of estimating failure  
24 probabilities, we've been talking about that. We  
25 looked at a number of ways to do that based on design

1 measures built into the software and the digital  
2 system or attributes of the architecture that can help  
3 add some protection based on some data from French  
4 plants in terms of their experience with  
5 microprocessors and a lot of safety systems for a lot  
6 of years. We did some of that. This notion of  
7 modeling level of detail, we looked there again.

8 And this is where you get into the thing we  
9 talked about earlier today: failure mechanisms versus  
10 modes versus effects. Where are you in the software?  
11 What is it you really care about? And this notion  
12 that the software by itself doesn't do anything  
13 directly. It controls some component which is part of  
14 the system, and you care about the system  
15 functionality. And, typically, with the PRA, you're  
16 talking about what's the system doing and what are the  
17 key components in the system doing, not necessarily  
18 what the I&Committee is doing. Although I shouldn't  
19 be so glib about it. The I&Committee can certainly  
20 become a factor there. Anyway, so we have spent some  
21 time looking at that and the effects of the level of  
22 detail.

23 The latest EPRI publication on this is that  
24 -- the titles here, "Modeling Digital Instrumentation  
25 and Control in Nuclear Power Plant Probabilistic Risk

1 Assessments," and that was published in 2012. This  
2 figure on the right is a figure out of that report,  
3 and I don't want to encourage everybody to read all  
4 the fine print and we're not going to go through all  
5 those steps. The point is that it proposes a  
6 systematic nine-step process to model digital  
7 instrumentation and control in PRA, but what's more  
8 important is it pushes for a team effort between the  
9 I&Committee guys and the PRA guys. And so certain  
10 tasks, the I&Committee takes a lead. Others, it's  
11 PRA, and some may have to work together to do it. And  
12 this came out of a lot of discussions in our projects  
13 where it was really clear that, typically, the  
14 I&Committee guys in the plants and the PRA guys don't  
15 communicate very well. They're talking different  
16 languages. They don't necessarily want to be bothered  
17 with each other, that sort of thing. However, our  
18 position was that the PRA guys really had a lot to  
19 offer in terms of helping the I&Committee guys  
20 understand the risk significance of what they were up  
21 to and where they can get into trouble. And we wanted  
22 to make sure they were taking advantage of that.

23 You know, the I&Committee guy will say  
24 something like, wow, my I&Committee here is really  
25 important because this is a safety system. And the

1 PRA guy might look at that and say, well, yes, okay,  
2 but it's nowhere near as important as the feedwater  
3 system, right, because the PRA guy is seeing the whole  
4 plant and the I&Committee guy is focused on his  
5 I&Committee. So we were trying to get past that, so  
6 that's why there's this note here about the  
7 I&Committee in the context of the integrated plant  
8 design. The PRA guy can help them understand that,  
9 and I think that's important.

10 The next one, though, defensive measures  
11 for I&Committee, that's an I&Committee guy kind of  
12 thing. The I&Committee guy can help the PRA guy  
13 understand -- we're okay?

14 CHAIRMAN STETKAR: Just ignore it.

15 MR. TOROK: Okay.

16 CHAIRMAN STETKAR: If you can. It happens.  
17 It's our sophisticated system.

18 MR. TOROK: Okay.

19 CHAIRMAN STETKAR: But it's predictable  
20 Byzantine behavior. Go on, Ray.

21 MR. TOROK: Okay, okay. Wow, I forgot  
22 where I was. Defensive measures. Okay, yes. So the  
23 I&Committee guy can help the PRA guy understand what's  
24 going on in the software that affects the failure  
25 probability. Initially, when we started talking to

1 PRA guys, you know, they'd say, hey, just give us the  
2 data, we know what to do with the data. And  
3 I&Committee guy would say, oh, you don't understand,  
4 this software is not like that, it doesn't wear out.  
5 We have to look at it in a different way.

6 So we get into that whole thing. And  
7 somebody mentioned this earlier, this notion that  
8 software doesn't wear out and the failures, if we can  
9 call them failures -- a loaded word there -- it fails  
10 deterministically, but it fails in unanticipated  
11 conditions. When software is operating in anticipated  
12 tested conditions, it's pretty darn bulletproof. When  
13 it gets into trouble is when the going gets weird.  
14 And just about --

15 MR. POWERS: Apparently, any time it flies  
16 near Pluto.

17 MR. TOROK: All kinds of things. And there  
18 are a lot of stories about this, right? There's an  
19 air traffic control system that was used successfully  
20 in Denver for many years exported to the UK. It  
21 turned out it didn't work at all there because it  
22 didn't understand the difference between east and west  
23 longitudes, which doesn't matter in Denver, right?  
24 But it makes a big difference in London, right,  
25 because the Prime Meridian is right there. But,

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 again, the software designer knew he was building a  
2 system for Denver. He didn't care about east and west  
3 longitude.

4 Anyway, so that's just an example of  
5 anticipating conditions where you get stuck --

6 MR. BROWN: Before you push your finger  
7 down, you said it behaves deterministically. It  
8 doesn't behave deterministically unless you design it  
9 to behave deterministically. Let's say if you wanted  
10 to pull my chain a little bit, you certainly did.

11 MR. TOROK: Okay.

12 MR. BROWN: If I did not react, I would  
13 ruin the entire overview of the entire meeting.

14 MR. TOROK: I think I know what you mean,  
15 and what I was referring to was the notion that,  
16 whenever software sees the same set of conditions, it  
17 will react the same way. And when you get into this  
18 deterministic discussion is when you're talking about  
19 --

20 MR. BROWN: That's not the same. Bad word.

21 MR. TOROK: That's a different, that's a  
22 different application.

23 MR. BROWN: That's the wrong word.

24 MR. TOROK: I see what you mean. Next  
25 time, I guess I need to straighten that out so that

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1       you can't comment.

2                   MR. BROWN:  No, it's not a matter of me  
3       commenting.  It's a matter of people getting the wrong  
4       perception of what reality is.

5                   MR. TOROK:  I understand.  Yes, and that's  
6       an interesting comment because there are different  
7       uses of the word deterministic as it's applied to  
8       software.  Different people mean it different ways.  
9       And you're right, I created an unnecessary --

10                  MR. BROWN:  But you can go on now, please.

11                  MR. TOROK:  Thank you.  Okay.  So, again,  
12       in our world, it's not about the numbers and the  
13       failure probability and those kinds of things.  It's  
14       more about the insights you can get from this.

15                  And so, as I said, where you want to be is  
16       in a situation where I can vary the failure  
17       probability, the same failure probability to digital  
18       I&Committee by two or three orders of magnitude, and  
19       the risk insights remain the same.  And then I've  
20       learned something about what's important maybe and  
21       what's not.

22                  An example of that might be, just for  
23       comparison purposes, the one I was talking about  
24       earlier, large-break LOCA plus a common-cause failure  
25       in the I&Committee.  Pretty darn low probability and,

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 in fact, it doesn't really matter what you assume  
2 about the failure probability of the I&Committee.  
3 It's not going to be a large contributor to core  
4 damage frequency, okay?

5 However, if you do things like introduce  
6 the possibility of a common-cause failure that can  
7 affect multiple mitigating systems for an event or can  
8 affect both the initiator and the mitigating system,  
9 now you have a big impact on core damage frequency and  
10 you need to watch out for that and you need to be  
11 aware of that. Those are good insights, and you can  
12 find those without using numbers, so that's a good  
13 thing.

14 MR. SKILLMAN: Ray, let me ask you this.  
15 I understand the words that you just used, but I will  
16 tell you from experience if the I&Committee system  
17 misbehaves, while one might predict that the core  
18 damage frequency is low, what that I&Committee failure  
19 does is drives the operators into situations that they  
20 might not have been in before and the permutations and  
21 combinations of what those operators can do becomes an  
22 issue, and they may not do what they should because  
23 they've been thrown a curve ball by the behavior of  
24 this otherwise very reliable I&Committee system. And  
25 so one might say, based on the PRA, there's very

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 little core risk, core damage risk. If the operators  
2 are put in a situation where they are perhaps beyond  
3 their training, there is a different outcome for that  
4 event.

5 MR. TOROK: So in other words, you're  
6 saying that if it creates an unanticipated condition  
7 for the operators, that's a potential, that could be  
8 a real problem.

9 MR. SKILLMAN: That's what I'm saying.

10 MR. TOROK: Yes, okay. And I agree. In  
11 fact, one of the things that keeps coming up -- our  
12 PRA expert is Dave Blanchard. Many of you know him,  
13 I think. And he's been trying to teach me this stuff  
14 for several years now. But one of the things that he  
15 keeps harping in is that in a lot of events the  
16 operator really is the best backup for the systems.

17 So if you do something in updating I&C  
18 systems, that somehow creates an event and disables  
19 the indications that the operator needs, now you've  
20 got a real problem. So it's important to make sure  
21 you don't do things like that. In our technical work  
22 here, we're trying to make sure that we alert plant  
23 engineers to that kind of thing.

24 Another thing that we've seen here that's  
25 kind of interesting is you can look at, in the PRA you

1 can look at what kinds of reliability, what it has to  
2 be for the I&Committee to end up being a small  
3 contributor to risk compared to the hardware that's in  
4 the systems. And in some of our work, what it turns  
5 out is that lots of times the I&Committee reliability  
6 targets are pretty modest compared to what you should  
7 be able to get from digital equipment.

8 It's also very useful or can be very useful  
9 to look at the proposed I&Committee mods early in the  
10 design process before they're installed because PRA  
11 can identify potential vulnerabilities that you could  
12 get into based on the conceptual design and can help  
13 avoid those kinds of things early on. So we've seen  
14 cases like that.

15 It's also, another insight here is this  
16 notion that you can, if you did your job on the  
17 I&Committee, basically the PRA is going to be  
18 insensitive to what it's doing. And, typically, that  
19 means the I&Committee, the digital I&Committee should  
20 be at least as reliable as that of a comparable analog  
21 system. And, usually, the digital I&Committee is  
22 better than that for reasons like what Charlie was  
23 talking about earlier. And in many cases, what  
24 happens, especially in non-safety systems where one of  
25 the goals is the digital upgrade is to reduce the

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 incidence of failures coming from that system.

2 So what the engineers do is they look at  
3 all the failures that system has had and intentionally  
4 design the digital system so it can't have those  
5 failure modes. They design those failure modes out,  
6 and that has been very successful with things like  
7 feedwater systems and turbine control systems. So  
8 that's a good thing.

9 CHAIRMAN STETKAR: Ray, I think some of the  
10 feedback that we've been trying to give the staff and,  
11 to some extent, the industry is that you constantly  
12 present this in the sense of not doing what it's  
13 supposed to do. The problem is that we've seen is  
14 that when it does things that we don't expect it to  
15 do, those misbehaviors. We used that phrase. And  
16 that's the real challenge. It's not -- and everybody  
17 compares it to the old analog systems as if they were  
18 perfect. The analog systems, our experience is, until  
19 people started to look at fire analysis for example  
20 and think carefully about what combinations of  
21 spurious signals could set these systems off on  
22 trajectories that nobody even thought about in risk  
23 assessment. The designers hadn't thought about it  
24 because they weren't forced to think about those  
25 combinations of failure modes, and the risk assessment

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 people traditionally hadn't thought about them because  
2 they were only looking at not doing what it was  
3 supposed to do.

4 And one of the things we've learned from  
5 doing comprehensive fire analysis is, indeed, the  
6 analog systems misbehave also. It's just people  
7 hadn't thought about it before. And part of the  
8 message for going forward with digital systems is  
9 don't fall in that same trap. We've learned the  
10 message, the lesson that looking at only not doing  
11 what it's supposed to do may not very well be the  
12 source of the problem. It's doing things that it  
13 ought not to do.

14 MR. TOROK: Yes, yes, you're --

15 CHAIRMAN STETKAR: So I just, you know, I  
16 want to make that statement on the record because I  
17 think that's the real challenge.

18 MR. TOROK: I agree. And a common  
19 complaint about digital is an engineer, let's say, had  
20 to specify requirements for a new digital system  
21 that's going to replace an analog system, so he gets  
22 out the requirements for the old analog system, dusts  
23 them off, and gives them to his supplier who says got  
24 you covered, no sweat. What he gets is a system that  
25 does everything the analog system does and it does a

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 lot of other things that maybe you didn't want, right?

2 So I agree. That's --

3 CHAIRMAN STETKAR: And most of the time, it  
4 doesn't do those things, so you don't discover it  
5 until you get to a situation when it's not a good day.

6 MR. TOROK: That's right. And one of the  
7 things that we push for in terms of encouraging people  
8 to understand their system before they put it in the  
9 plant is look into that stuff. That's right.

10 Okay. Where am I? This is the new, a new  
11 topic here. Well, we've talked in this presentation  
12 the same thing we talked about last time, techniques  
13 for failure prevention and mitigation. And this is an  
14 ongoing project now, and it's about our understanding  
15 and managing, let's say, potential digital failure  
16 modes and misbehaviors and so on, including common-  
17 cause failure.

18 Now, I think you've heard about a project  
19 that I guess that NEI is pushing this. It has to do  
20 with the 50/59 rule and document in any IO 101. Does  
21 that ring a bell for anybody?

22 CHAIRMAN STETKAR: No.

23 MR. TOROK: Okay. Well, that's good.  
24 Maybe that simplifies things for me. The point is  
25 that there is some guidance out there. NEI is working

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 on updating it. This work is intended to be technical  
2 basis input for that, and so there is a relationship  
3 there. And I know Christina has been asking me about  
4 it so --

5 CHAIRMAN STETKAR: Given the answer is no,  
6 what is NEI's schedule for that, do you know?

7 MR. TOROK: What is NEI's schedule?

8 CHAIRMAN STETKAR: Yes.

9 MR. TOROK: I think they expect to have  
10 some draft guidance out late this year.

11 CHAIRMAN STETKAR: Late this year.

12 MR. TOROK: But don't hold me to that  
13 because I don't really know.

14 CHAIRMAN STETKAR: That's good enough.  
15 Thanks.

16 MR. TOROK: We're having periodic meetings  
17 with them to explain where we're headed and they  
18 explain to us where they're headed and so on. Anyway,  
19 so the point of this thing now is to produce guidance  
20 for addressing, as I said, the failure modes and  
21 misbehaviors and so on, which, of course, plays into  
22 licensing space at some point because you want to  
23 convince yourself that you do have adequate protection  
24 against those things.

25 We're using earlier EPRI reports, lessons

1 learned, where we've addressed bits and pieces of this  
2 thing. We wanted to or we are addressing both safety  
3 and non-safety applications in traditional licensing  
4 space. They worry more about the safety side. And  
5 our guideline is intended to be out late this year;  
6 and, hopefully, we'll hold to that.

7           The approach here is what I consider a  
8 little more holistic than some traditional approaches  
9 that are used in regulatory space. And what I mean by  
10 that is one way to look at potential failures in CCS  
11 is to assume they happen and be sure you can tolerant  
12 them. And that's all well and fine in one sense. The  
13 problem from the EPRI standpoint is if you just do  
14 that, you're not maybe paying enough attention to the  
15 good engineering that goes into the plants to make the  
16 failures unlikely or to defeat them because, from an  
17 engineering perspective, you're better off if it never  
18 happens. So you want to make sure you're taking the  
19 right steps to do what you can to make sure it doesn't  
20 happen. And that's what this notion of preventive  
21 measures is really about. What can you do with your  
22 system to make sure, not to make sure but to reduce  
23 the likelihood of failures, misbehaviors, CCS, and so  
24 on.

25           The coping analysis is a demonstration

1 that, should the failure occur, you have adequate  
2 mitigaiton. And, of course, if either you decide that  
3 your failure likelihood is too high or the coping  
4 analysis says you get results you don't like, you can  
5 go back and you should go back and redesign your  
6 system to reduce those things. Or another way of  
7 looking at it is to increase the overall protection  
8 against the failure.

9 In the end, it becomes somewhat  
10 qualitative. You look at the preventive measures you  
11 have. You look and see what the results are if the  
12 bad stuff happens and ask yourself have I got adequate  
13 protection? There's the notion of adequate protection  
14 in an engineering sense, and there's the notion of  
15 adequate protection in a licensing sense. They're not  
16 necessarily the same.

17 What you do want to do in our world is  
18 document what you've done in an assurance case where  
19 you're effectively making claims about why you think  
20 the system is okay and what evidence you have to back  
21 that up. That's what that's a reference to.

22 MR. BROWN: Before you leave that, you say  
23 it's a guideline. But I'm trying to figure out, you  
24 didn't say what type of information is going to be in  
25 this guideline. Is it just here's some good thoughts

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 and lessons learned, or is it going to be translated  
2 into design guidelines or dos and don'ts, or is there  
3 a framework? I mean, if you're going to publish it  
4 this year, that should mean there's a framework of  
5 what point you're trying to get across.

6 MR. TOROK: That's right. And it's really  
7 a step-by-step process where you assess the potential  
8 susceptibilities. You look at also how risk  
9 significant they can be, and you look at what kind of  
10 defensive measures you have in place to deal with the  
11 potential susceptibilities and whether there's a need  
12 for more. And if there is, you go back and reassess  
13 your conceptual design and start over, you know, and  
14 reiterate.

15 So it is intended to be a step-by-step  
16 process where there are various --

17 MR. BROWN: But is there an overriding  
18 message you're going to be trying to send, like make  
19 it simple?

20 CHAIRMAN STETKAR: Let's get away from  
21 I&Committee design and guidelines that might go into  
22 NEI guidance and keep focused on PRA because we've got  
23 about seven minutes left and PRA is the subject of the  
24 briefing.

25 MR. TOROK: We can talk more about it. The

1 concepts that go into this are considered here. The  
2 notion that you care about protection against the  
3 failures in the CCF, and that means some combination  
4 of prevention and mitigation. We want both.

5 I think we talked about this earlier, this  
6 notion that software failure needs a defect in the  
7 software, a fault, a bug, whatever you want to call  
8 it, and some trigger, which is typically unanticipated  
9 conditions that can activate the defect. And the  
10 reason that's important is because, in developing a  
11 system, you've got a chance to affect both of those  
12 quite a bit. In your good software development  
13 processes and so on, you can reduce the likelihood of  
14 the defect. You can also institute design measures  
15 that are there to avoid triggers. And we've talked  
16 about some of those things already today, you know,  
17 cyclic architecture, data validation, those kinds of  
18 things.

19 This notion that you can generate  
20 protection at various levels. One is to put in  
21 features in the software, like diagnostics and so on.  
22 Another is to do it at a higher level. If I'm talking  
23 about a fuel-handling crane for example and I'm  
24 worried about it running out of bounds, I can do  
25 things in the software to check the position against

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 where I want the thing to stay, but I can also put  
2 hard mechanical stops on the fuel crane so it can't  
3 overrun no matter what the software is telling it to  
4 do. Maybe I want both of those things. So you end up  
5 considering things like that.

6 Common-cause failure has a lot of different  
7 flavors. In 93087, in the olden days, it was about  
8 identical trains of safety equipment that all have the  
9 same software in them and you can defeat the whole  
10 system with a bug. But there's more to it than that,  
11 and that's what this cartoon is trying to show you.  
12 Here there are, on the upper right there, you use the  
13 same digital platform to update multiple non-safety  
14 systems. Each one is programmed a different way  
15 because it has a different application going on. They  
16 all communicate over a bus, and each of them is  
17 controlling multiple components. And that introduces  
18 all kinds of interesting possibilities in terms of  
19 common-cause failure. Suppose I do something to the  
20 network that affects all of the systems at one time.  
21 I can talk about spurious actuations coming from  
22 multiple systems at the same time. The point is  
23 there's a lot more to it than simply identical  
24 redundant trains in safety systems, and we're trying  
25 to make sure we cover those things, as well.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1           Ultimately, it ends up an integrated  
2           approach. What you would do for something that's  
3           highly safety significant might not be the same as for  
4           something that isn't. And what you really want is to  
5           make sure you've got adequate protection. There,  
6           again, you're getting subjective, you're applying  
7           engineering judgment, and so on.

8           Moving right along, as I said, the idea is  
9           to generate assurance of adequate protection, and  
10          there are a lot of things you look at in doing that.  
11          There's what you've done with the hardware, the  
12          software development practice, and so on, the design  
13          measures. And in my mind, the design measures are  
14          much more important than the process. Good process  
15          doesn't guarantee good design, so you want to make  
16          sure the design is okay. How good is your mitigation  
17          or your coping capability? How good is your test  
18          coverage? What's the operating history of the device  
19          saying? What are your risk insights telling you? So  
20          there, again, we see a role for the PRA guys in  
21          helping flavor this thing.

22          Simplicity. Somebody brought that up and,  
23          sure, that's a factor. Simple is better. And that's  
24          another interesting one, though, because there are a  
25          lot of different measures of simplicity or complexity

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 for digital. Again, it comes down to an engineering  
2 judgment and figuring out what matters in your  
3 application. So we can't get away from that notion of  
4 engineering judgment.

5 Oh, the last topic here, this goes back to  
6 this hazard analysis. There was a guideline we  
7 produced a couple of years ago now. The title is  
8 there. We looked at six methods, things like FMEA  
9 failure modes and effects. That's design FMEA,  
10 functional FMEA, fault tree, and so on.

11 In this demonstration, we wanted to work  
12 with the utility to apply this methodology to  
13 something real and looked for a couple of things. One  
14 is does it work, is it useful, is it helpful? And the  
15 other is how difficult is it to teach some of these  
16 new methods and get guidance to apply them? So from  
17 the EPRI standpoint, that's what we cared about.

18 And the idea here was that the plant  
19 actually does the hazard analysis. We coach them and  
20 try to make sure they understand what's in the  
21 guideline, those kinds of things. So that's what  
22 happened.

23 At Palo Verde, who stepped up to do this,  
24 they were looking at replacing their generator  
25 exciters on three units. It's non-safety, but they

1 really want to keep that plant running. They are  
2 putting in new exciter systems, one for each unit, and  
3 it's in a separate building. And, of course, Palo  
4 Verde is in a place that gets really hot in the  
5 summer. The air conditioning is pretty darn  
6 important. And at the time we talked with them, they  
7 were saying that if the HVAC goes down, they've got  
8 less than ten minutes before they have to trip the  
9 plant, although I heard more recently that they might  
10 reduce that number to something like two minutes.

11 Anyway, so they put in redundant HVAC  
12 units, and they wanted to use hazard analysis to look  
13 at that system to identify potential vulnerabilities  
14 and convince themselves that it was going to be robust  
15 enough for what they were doing. Their main focus  
16 wanted to be on this method called Systems Theoretic  
17 Process Analysis, or STPA, which is sort of a novel  
18 method developed by a team of researchers at MIT --

19 MR. BLEY: We had a presentation by them.

20 MR. TOROK: You did?

21 MR. BLEY: Yes, by one of her graduate  
22 students.

23 MR. TOROK: Okay. So you guys know all  
24 about that.

25 MR. BLEY: We had a presentation.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. TOROK: Okay. The really interesting  
2 thing about STPA, from our standpoint, is it's well  
3 suited to looking for not just failures of systems and  
4 components but also for what you call misbehaviors  
5 where every component works as designed but the  
6 overall plant does something wrong. And it's somewhat  
7 unique in that respect, compared to FMEA, which is a  
8 hard focus on failures.

9 Anyway, so that was what they wanted to  
10 look at. We also, sort of on the side, did a high-  
11 level PRA analysis on this system and gave them some  
12 additional insights that turned out to be pretty  
13 interesting, like do you really need three trains, you  
14 know, three redundant HVACs and why? And that's the  
15 kind of thing where risk insights from the PRA can be  
16 very helpful.

17 Okay. So this was their feedback or the  
18 results. The word "substantial gain with minimal  
19 cost" are in quotes because they're their words, not  
20 mine. They thought that it was really going to  
21 increase the odds of a successful project because they  
22 did discover some unanticipated failure modes, some  
23 vulnerabilities, that they were able to fix fairly  
24 well, able to address, let's say, fairly easily, even  
25 though they were at a pretty advanced stage of the

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 design at that point.

2 They also generated insights from the STPA  
3 that helped them look at a lot of other areas. For  
4 example, they identified behaviors under unanticipated  
5 conditions that could be really important to them. So  
6 they added those things to the testing matrix for the  
7 factory acceptance test and, you know, pre-  
8 installation testing and so on to make sure that the  
9 system really did behave the way the manufacturer was  
10 telling them it would, those kinds of things.

11 They also noted areas where they had to  
12 refine their procedures or training and so on. So  
13 they saw all that as advantageous. They were  
14 surprised that doing this helped them understand the  
15 system itself as much as it did, and the reason was it  
16 forced them to ask questions where they didn't know  
17 the answers. They had to go back to the supplier and  
18 find out what was going on, and it was important that  
19 they did understand what was going on.

20 Let's see. They liked the fact that doing  
21 this was really quick and identified vulnerabilities  
22 much faster and much easier than they could with FMEA,  
23 which had been their traditional approach. They also  
24 liked the fact that they ended up with a report that  
25 helped them explain to their management why it was

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 important to do some of these things. The report  
2 called attention to certain vulnerabilities where they  
3 knew they had to address them before the system went  
4 into operation, and they were able to make their case.

5 As a result of all of this, the guys who  
6 were involved in it are pushing to make it part of  
7 their standard procedure for mods and working to  
8 generate the right kind of management buy-in to make  
9 that happen.

10 Anyway, we're on schedule, right?

11 CHAIRMAN STETKAR: Close. I'm impressed.  
12 Ray, thanks a lot. Any further questions, comments  
13 for Ray, for EPRI? If not, first of all, I'd like to  
14 thank both the staff and EPRI. You covered a lot of  
15 ground this morning.

16 A couple of other administrative things  
17 that I need to do here. Is there any one in the room  
18 who would like to ask any questions, make any  
19 comments? If not, we'll get the bridgeline open, if  
20 there's anyone out there who'd like to make any  
21 comments.

22 Again, I know a lot of this stuff was  
23 pretty esoteric to a lot of the members, but both  
24 digital I&C and understanding of its performance in a  
25 risk perspective are important topics and they remain

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 important topics, both from a regulatory side of the  
2 fence and the industry side of the fence where these  
3 systems are being installed.

4 I'm told that the bridgeline is open. If  
5 someone is out there --

6 MR. LEWIS: Marvin Lewis, member of the  
7 public.

8 CHAIRMAN STETKAR: Thank you, Marvin. I  
9 appreciate it. And, again, just for the record,  
10 identify yourself because I was talking over you and  
11 make your comments, please.

12 MR. LEWIS: No, no, no, you have the right  
13 to talk. I interrupted.

14 CHAIRMAN STETKAR: No, that's -- go on.

15 MR. LEWIS: My name is Marvin, M-A-R-V-I-N,  
16 Lewis, L-E-W-I-S. And I'm very pleased today because  
17 from what I am hearing you're finally looking at the  
18 situation where a red light is being hidden behind a  
19 maintenance tag, like as in Three Mile Island number  
20 2 back in '79 and maybe a romantic triangle is going  
21 on winding up in a core meltdown, like at Chalk River,  
22 that there are things that go beyond I&Committee and  
23 analog. And I'm glad to hear you're finally bringing  
24 it into the record, and I'm very, very pleased to hear  
25 it because I've been listening since '79. Thank you.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 CHAIRMAN STETKAR: Thank you, Marvin. Is  
2 there any other member of the public on the bridgeline  
3 who'd like to make any comments? If not, again, I'd  
4 like to thank the presenters. They covered an awful  
5 lot of material this morning. And with that, we will  
6 recess and we'll go off the transcript until this  
7 afternoon. Let's return at 11:20, and we'll start the  
8 topic of our research report.

9 (Whereupon, the above-referred to matter  
10 went off the record at 11:05 a.m. and went  
11 back on the record at 1:01 p.m.)

12 AFTERNOON SESSION

13 1:01 p.m.

14 CHAIRMAN STETKAR: We are back in session.  
15 And the first topic for this afternoon is the Nine  
16 Mile Point Unit 2 MELLLA PLUS application. And Joy  
17 Rempe will lead us through that. Joy.

18 4. NMP2 MELLLA PLUS APPLICATION

19 MEMBER REMPE: Thank you, Mr. Chairman. On  
20 June 22nd, our Power Uprate Subcommittee reviewed the  
21 license amendment requests and the associated NRC  
22 draft safety evaluation to allow operation of Nine  
23 Mile Point Unit 2 and the expanded Maximum Extended  
24 Load Line Limit Analysis plus or MELLLA PLUS domain.  
25 At the end of our meeting, our Subcommittee

1 recommended that LAR be presented to the full  
2 committee.

3 This LAR for operation in the MELLLA PLUS  
4 domain is the third to be reviewed by the ACRS. The  
5 first was for the Monticello Nuclear Generating Plant  
6 and the second was for Grand Gulf Nuclear Station Unit  
7 1. And as you'll hear today, several features of the  
8 Nine Mile Point Unit 2 which differ from Monticello  
9 and Grand Gulf are of particular importance with  
10 respect to MELLLA PLUS operation.

11 Today we're going to hear presentations  
12 from the NRC staff, their consultant and  
13 representatives from licensee, Exelon Generation  
14 Company. Part of the presentations will be closed in  
15 order to discuss information that's proprietary to the  
16 licensee and its contractors. And I believe we'll be  
17 starting today by hearing from Travis Tate of NRR  
18 Management.

19 MR. TATE: Yes.

20 MS. REMPE: Thanks.

21 MR. TATE: Thank you. Good afternoon,  
22 everyone. I'm Travis Tate. I'm currently the Acting  
23 Deputy Director in the Division of Operator Reactor  
24 Licensing in NRR. And as was just previously  
25 communicated, the staff did meet with the Subcommittee

1 on June 22nd and is pleased to have the opportunity to  
2 discuss with the full Committee today our review of  
3 the MELLLA PLUS license amendment for Nine Mile Point  
4 Unit 2.

5 I also wanted to highlight in addition to  
6 the previous two that have gone before Nine Mile that  
7 we currently have a MELLLA PLUS application in house  
8 for Peach Bottom. Peach Bottom is currently under  
9 staff review and we will schedule in the near-term  
10 ACRS full Sub and full Committee reviews.

11 Those are basically my opening remarks.  
12 And I want to turn it over to Mike Dudek.

13 MR. DUDEK: Thanks, Travis. Good  
14 afternoon, everyone. Thank you for your time today in  
15 discussing this important issue. As Travis stated, my  
16 name is Michael Dudek. And I'm the Acting Chief of 11  
17 Projects Branch in NRR.

18 For efficiency today, in varying my opening  
19 remarks, instead of spelling out Nine Mile Point Unit  
20 2 every time, I'm going to say Nine Mile Point. And  
21 I'll be using licensee and Exelon interchangeably just  
22 for efficiency.

23 I'm going to use the next five minutes to  
24 discuss the specifics behind. As Ms. Rempe said, the  
25 maximum extended load line limited analysis or MELLLA

1 PLUS license amendment review that Exelon has  
2 submitted to the NRC for review. However, I would  
3 like to take the first couple of minutes and thank my  
4 NRR as well as in some instances my agency technical  
5 counterparts as well as my lead PM Bhalchandra Vaidya  
6 for the thorough review of the licensee's application  
7 and their excellent work in putting this SE together.  
8 I thought which I've read numerous times that it was  
9 comprehensive in addressing these complex technical  
10 issues as well as being easy to read for the layman  
11 such as myself.

12 With that being said, we are here today to  
13 discuss the specifics behind Exelon's license  
14 amendment request dated November 1, 2013 that proposed  
15 a revision to Nine Mile Point's technical  
16 specification to allow the operation of a currently  
17 licensed MELLLA domain to an expanded MELLLA PLUS  
18 domain established under the previously approved  
19 extended power uprate condition of 3,988 megawatts  
20 thermal rated core thermal power.

21 As a reference to those of you in the  
22 audience, an extended power uprate or EPU was approved  
23 for Nine Mile Point by License Amendment No. 140. And  
24 this was dated November 22nd. The extended power  
25 uprate increased power level to 3,988 megawatts

1 thermal from 3,467 megawatts thermal or approximately  
2 a 15 percent increase. In case you're taking notes,  
3 that's by ML113300041.

4 Specifically in the application, Exelon  
5 describes MELLLA PLUS as when Nine Mile Point would  
6 operate in a domain where its operating power is  
7 maintained constant, but the recirculation core flow  
8 is allowed to operate within a wider window than under  
9 the MELLLA conditions, i.e., a flow window between 85  
10 percent and 105 percent. The licensee in the  
11 application describes this operating window as  
12 providing flexibility that would reduce the need for  
13 frequent control rod motion.

14 The technical staff, thanks to Chris  
15 Jackson, performed a thorough review of Exelon's  
16 license amendment request application which as Travis  
17 and Ms. Rempe explained was the third such review  
18 request that we've conducted, the first two being  
19 Monticello and Grand Gulf and Peach Bottom which is  
20 currently under way. As a result of the staff's  
21 thorough review of Nine Mile Point, the staff's  
22 overall determination was that the licensee's proposed  
23 operation in the MELLLA PLUS demand provides  
24 additional operating flexibility while not  
25 compromising plant safety.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1           The staff initially presented as Travis  
2       stated these initial proposed findings to the ACRS  
3       Subcommittee during a meeting about two weeks ago.  
4       The ACRS provided some very good feedback on that  
5       meeting and presented the staff with a few takeaway  
6       issues which are open items to be closed and a couple  
7       of other items. From my perspective, the responses  
8       were provided to the Subcommittee expeditiously in  
9       which I hope through that initiative will help  
10      facilitate a useful dialogue between everyone in this  
11      room today.

12           CHAIRMAN STETKAR: Michael, just for the  
13      record, I have to interject this. The Subcommittee  
14      does not represent ACRS recommendations. The  
15      Subcommittee, anything you hear, individual comments  
16      from single members, we only communicate via Committee  
17      letters. I just always need to clarify that for the  
18      record.

19           MR. DUDEK: Understood. Apologies for  
20      that. At this point, that concludes my opening  
21      remarks. I'd like to turn the meeting over to my lead  
22      PM Balchandra Vaidya to give some additional  
23      information about the MELLLA PLUS license amendment  
24      for Nine Mile Point.

25           Thank you for your time and I look forward

1 to addressing any questions that you have as we move  
2 forward.

3 MR. VAIDYA: Thank you, Mike. I'm  
4 Balchandra Vaidya, Project Manager in NRR for Nine  
5 Mile Point MELLLA amendment request. I will coerce  
6 among the points that we have heard in previous  
7 Travis' and Mike's presentation.

8 One thing is the licensee submitted a  
9 revised application on June 13 that reflected the  
10 completion of their implementation of changes to  
11 Standby Liquid Control System. They implemented the  
12 improvements to Standby Liquid Control System in the  
13 spring 2014 outage. Amendment for that was approved  
14 just before the outage.

15 During the review of staff, multiple rounds  
16 of requests for additional information were issued to  
17 Licensee on various topics such as reactor systems,  
18 instrumentation, controls, human factors, etc.  
19 Licensee submitted their responses in the time period  
20 between March 10, 2014 and February 18, 2015.

21 NRC staff also performed an audit at the  
22 Nine Mile Point 2 plant site on November 20, 2014.

23 Multiple technical specifications changes  
24 as well as existing license condition support MELLLA  
25 PLUS application. Existing license condition seven

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 restricts feedwater Heater out of service by imposing  
2 a 20 degree Fahrenheit feedwater temperature band.

3 The proposed TS change for TS LCO 3.4.1  
4 prohibits single loop operation in MELLLA PLUS domain.  
5 Some other technical specification changes are  
6 revision of safety limit in TS 2.1.1.2 by increasing  
7 the SLMCPR for two recirculation loops in operation  
8 from greater than 1.07 to greater than 1.09. Another  
9 change is revision of the acceptance criteria in TS  
10 Surveillance Requirement 3.1.7.7 by increasing the  
11 discharge pressure from greater than 1,327 psig to  
12 greater than 1,335 psig.

13 These are just a few of the changes. There  
14 were some other changes also in the original  
15 application which are just too numerous to list all of  
16 them here.

17 Other than these, if you don't have any  
18 other questions, then I can ask colleagues to start  
19 their presentation.

20 MEMBER REMPE: I think that would be great.

21 MR. VAIDYA: Okay. Thank you.

22 MEMBER REMPE: Just so you're aware I think  
23 from our Subcommittee meeting you know you'll have to  
24 turn your own slides, right.

25 (Off record comments)

1                   MR. KHAN:    Good afternoon.    My name is  
2                   Mohamed Khan.   I'm the Senior Engineering Manager at  
3                   Nine Mile Point Nuclear Station.   I would like to  
4                   thank the ACRS Committee and the staff for the  
5                   opportunity to provide a brief overview of Exelon Nine  
6                   Mile Point Nuclear Station Unit 2 Operating License  
7                   Amendment Request to allow plant operation in a  
8                   Maximum Extended Load Line Limit Analysis Plus domain  
9                   or MELLLA PLUS.   That was previously approved under  
10                  the EPU conditions.

11                  The station greatly appreciates the staff's  
12                  completion of the safety evaluation final draft since  
13                  our last Subcommittee meeting on June 22.   This will  
14                  allow the station to complete and finalize our plans  
15                  to implement MELLLA PLUS during the week of September  
16                  13th.

17                  My technical and operations team are here  
18                  today along with representatives from Exelon Corporate  
19                  Fuels,       License       and       Regulatory       Assurance,  
20                  representatives from the Peach Bottom MELLLA PLUS team  
21                  and technical assistance from GE.       General  
22                  Electric/Hitachi are here today to support us in our  
23                  final overview to the Committee of the station's  
24                  project scope, the modifications that we've previously  
25                  implemented in the last Unit 2 spring 2014 outage, the

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 remaining implementation and testing activities,  
2 completed training and procedure changes and on our  
3 overall station readiness to implement in September.

4 The agenda for today includes a brief  
5 station overview followed by the MELLLA PLUS project  
6 overview provided by Dale Goodney, the Project  
7 Manager, to my left. And to his left will be George  
8 Inch, our Senior Staff Engineer, who will present the  
9 MELLLA PLUS design analysis and followed by current  
10 License Shift Manager, Dan Cifonelli who will present  
11 operator actions, validation and training.

12 A brief station overview, Nine Mile Point  
13 Unit 2 is a BWR-5 with a Mark II containment designed  
14 pressure of 45 pounds per square inch. The operating  
15 license was issued in 1987 with an original licensed  
16 thermal power of 3,323 megawatts thermal.

17 MEMBER SKILLMAN: Mohamed, excuse me. What  
18 was your design pressure please?

19 MR. KHAN: Forty-five pounds per square  
20 inch containment.

21 MEMBER SKILLMAN: Thank you.

22 MR. KHAN: In 2006, we renewed our  
23 operating license to allow operation until April of  
24 2046. But we will not enter that period of operation  
25 until 2026.

1           The station implemented EPU in July 2012  
2           with a current license power of 3,988 megawatts  
3           thermal. Unit 2 is currently in its second period of  
4           operating under EPU conditions. We are in a 24-month  
5           operating cycle.

6           MEMBER BANERJEE: Are you operating at 100  
7           percent?

8           MR. KHAN: Yes.

9           CHAIRMAN STETKAR: Green light.

10          MEMBER BANERJEE: I keep forgetting these  
11          new rules. So you're at 100 percent EPU.

12          MR. KHAN: Yes.

13          MEMBER BANERJEE: Are you able to get to  
14          105 percent flow?

15          MR. KHAN: George.

16          MR. INCH: Yes. As part of EPU, we  
17          installed clean mixer, jet pump mixers. So we're able  
18          to get to the design rated flow of 105 through the  
19          increase of flow regime. That's towards the end of  
20          cycle. At a rated EPU conditions, we can get to 104  
21          percent, the higher DPE conditions.

22          MEMBER BANERJEE: So you've operated in  
23          this range, 100.

24          MR. INCH: We operate typically between 100  
25          and 101 percent to 104 percent. I think in

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 Subcommittee we had some choice.

2 MEMBER BANERJEE: Yes, I missed the  
3 Subcommittee. All right. Thanks.

4 MR. KHAN: As part of the opening remarks  
5 by the staff for the MELLLA PLUS benefits, it has  
6 rolled out an extended operating domain to allow us to  
7 fuel reactivity manipulations. As mentioned  
8 previously, during the July 2014 outage, we did  
9 implement the detect and repress solution,  
10 confirmatory density algorithm for thermal hydraulic  
11 stability solution. And this will provide a more  
12 reliable and stable solution to detect any core  
13 instability.

14 We did also implement during the 2014  
15 spring refuel outage the enriched boron which provided  
16 us more margin for ATWS conditions. We did increase  
17 the boron enrichment from greater than 25 percent atom  
18 weight to 92 percent atom weight.

19 MEMBER REMPE: Mohamed, during our  
20 Subcommittee meeting, it was discussed that although  
21 this license amendment request is solely for GE14  
22 fuel, that there is subsequent information coming to  
23 the staff and the staff is reviewing it regarding your  
24 switching to GNF2 fuel. Correct?

25 MR. KHAN: That is correct.

1                   MEMBER REMPE: And the staff -- I didn't  
2 mention it earlier -- but that documentation has been  
3 submitted to the staff as I recall. Or it's in  
4 process.

5                   MR. INCH: Well, you said something I don't  
6 think is quite right.

7                   MEMBER REMPE: Maybe I'm confused. Correct  
8 me.

9                   MR. INCH: The process that's being used to  
10 introduce GNF2 is the G Start process. And that  
11 process will allow evaluation of the GNF2 fuel under  
12 50.59 provisions. And the 50.59 process will shake  
13 out whether or not any submittal of information is  
14 required. So there is currently -- The only thing  
15 that is required for the reload is the safety limit  
16 MCPR.

17                   And I think we can clarify that process.  
18 I believe Bob Close from our Fuels Department could  
19 speak to the process being used. Could you put up  
20 that backup slide that summarizes that process?

21                   (Off record comments)

22                   Bob, you can speak to this.

23                   MR. CLOSE: I'm just going to restate some  
24 of the points that Mr. Inch made. My name is Bob  
25 Close and I'm a senior engineer with our Nuclear Fuel

1 group. We will be performing evaluations and reload  
2 licensing analysis in accordance with the G Start 2  
3 requirements. And, of course, as part of those  
4 requirements, we'll also do those analyses necessary  
5 to meet limitations and conditions as well as the  
6 requirements of Develop PLUS LTR, DSS-CD LTR and the  
7 expanded operating domains LTR.

8 Our review to date has determined based on  
9 preliminary results that the safety limit MCPR change,  
10 an increase in that value, was expected with the  
11 transition to the GNF2 fuel bundle and consistent with  
12 what we've observed in the results for Peach Bottom  
13 and also Grand Gulf.

14 That will require a tech spec change. It  
15 will be greater than the value that was reviewed as  
16 part of this license application request. So there  
17 will be a submittal for that license amendment  
18 request. Our 50.59 review process will guide us in  
19 determining if there are any other changes requiring  
20 review by the NRC.

21 MEMBER REMPE: Thank you for clarifying  
22 that.

23 MEMBER BANERJEE: Can you just remind me  
24 please? GNF2, does it have CHF performance at low  
25 flow which is significantly different from G40?

1 MR. CLOSE: I would ask my vendor, GE/H to  
2 speak to that. But I'd also -- Is that potentially a  
3 response that should be done in closed session? Or  
4 can it be made in open session?

5 MEMBER BANERJEE: Yes, whatever you'd like.  
6 But I'd like to get some clarity on that.

7 MR. CLOSE: All right. So we'll jot that  
8 point down and we can respond to that question in the  
9 closed session. You guys understood the question?

10 (No verbal response)

11 Okay. We'll respond to that in closed  
12 session.

13 MEMBER BANERJEE: Okay. Thanks.

14 MR. JACKSON: Just to answer your question,  
15 that had not been submitted. That will be coming  
16 some time in the future, the safety limit for a tech  
17 spec change.

18 MEMBER REMPE: And the staff will follow  
19 whatever procedures are associated with the M PLUS  
20 generic LTR to deal with it.

21 MR. JACKSON: We will do a full 50.90,  
22 50.92 license amendment request safety evaluation and  
23 document our findings.

24 MEMBER REMPE: It's interesting to hear  
25 about the CPR performance. But I think it's outside

1 the scope of what we're talking to today. I just  
2 wanted to make sure that everybody on the Committee  
3 was aware of that.

4 MR. CLOSE: And just to clarify that  
5 submittal for the license amendment request safety  
6 limit MCPR change would be in approximately late  
7 August, very early September of this calendar year  
8 consistent with the NRC review period required to  
9 support loading GNF2 in spring of 2016.

10 MEMBER REMPE: Okay. Thank you.

11 MR. KHAN: This concludes the station  
12 overview at this time. I'm going to turn it over to  
13 our project manager, Dale Goodney.

14 MR. GOODNEY: Thank you, Mohamed. I'm Dale  
15 Goodney. I'm the MELLLA PLUS Project Manager at Nine  
16 Mile Point. And I'm going to provide a brief overview  
17 of the MELLLA PLUS benefits from what you've already  
18 discussed and also cover our MELLLA PLUS project  
19 implementation plan.

20 When Nine Mile 2 went to the extended power  
21 uprate in July of 2012, our available core flow window  
22 was reduced from 20 percent to six percent. And as was  
23 mentioned earlier, Operations maintains the core flow  
24 in a range from about 100 to 104 percent depending on  
25 where we are in the cycle.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 With MELLLA PLUS we'll be able to expand  
2 that core flow window back to 20 percent which is  
3 where we were prior to the extended power uprate.  
4 That will result in fewer control rod manipulations.  
5 We're projecting that the number of deep down powers  
6 that are required near the end of the operating cycle  
7 for control rod sequence exchanges to be reduced by  
8 about one-half.

9 MEMBER BANERJEE: So you're showing on your  
10 graph around 85 percent of rated flow as the full  
11 power lowest flow.

12 MR. GOODNEY: The lowest flow at --

13 MEMBER BANERJEE: You're not going down to  
14 85 percent.

15 MR. GOODNEY: We're not going down to 85  
16 percent. That's correct.

17 MEMBER BANERJEE: Just to 85.

18 MR. GOODNEY: That's correct.

19 MEMBER BANERJEE: All right.

20 MR. GOODNEY: Now we'll also with the  
21 expanded operating region --

22 MEMBER BANERJEE: Why are you just going  
23 down to 85 rather than 80?

24 MR. GOODNEY: That's a good question. The  
25 85 percent was the number that was selected very early

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 on in the project during the feasibility assessment  
2 for the MELLLA PLUS for Nine Mile Point. Mutually  
3 agreed to between General Electric and Nine Mile Point  
4 is a reasonable value that would essentially give us  
5 back the operating margin we had pre-EPU. And that  
6 was the basis that all the analysis was performed on  
7 from the beginning.

8 MEMBER BANERJEE: Not just to steer a  
9 little further away from the stability boundaries  
10 which was probably the --

11 MR. GOODNEY: No, that wasn't really a  
12 factor at that point.

13 MR. INCH: Clearly, we wanted to analyze  
14 where --

15 MEMBER BANERJEE: For a little bit more  
16 margin.

17 MR. INCH: Essentially, yes.

18 MR. GOODNEY: Yes.

19 MEMBER BANERJEE: And if you don't need if  
20 you need to get to 80 it's fine.

21 MR. GOODNEY: That's right.

22 MR. INCH: Yeah.

23 MR. GOODNEY: Okay. And also with this  
24 expanded core flow window, it will enable Operations  
25 to maintain two percent margin to the MELLLA PLUS line

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 compared to the one percent that they currently  
2 maintain to the MELLLA line. There are other benefits  
3 obviously for MELLLA PLUS, but the primary driver from  
4 a project standpoint was the improvement in reactivity  
5 management and the reduction in operator burn.

6 Also shown on the power to flow map is a  
7 point of reference or two key state points, the  
8 maximum power density which is point N and the maximum  
9 power to flow ratio of point M on the power to flow  
10 map. And those two values for Nine Mile Point fall in  
11 between the other two plants that have already been  
12 reviewed by ACRS for MELLLA PLUS.

13 The MELLLA PLUS project is comprised of  
14 several components that are shown on this slide.  
15 Those that are highlighted in green as was mentioned  
16 earlier have already been implemented. That was  
17 during the spring 2014 refueling outage including the  
18 enriched boron as well the DSS-CD. We have been  
19 operating with DSS-CD in service since May of 2012.  
20 I'm sorry. 2014 with the confirmation density  
21 algorithm trip bypass with jumpers pending a receipt  
22 of the MELLLA PLUS license amendment.

23 MEMBER BANERJEE: Was the plant previously  
24 an option three?

25 MR. GOODNEY: Yes. It was previously an

1 option three. Since 2000 we've been operating.

2 We expect to receive the license amendment  
3 in August. And based on that, we have scheduled the  
4 implementation for the remaining portions of the  
5 MELLLA PLUS project which will be implemented online  
6 in September of 2015.

7 We'll begin on September 8th with removal  
8 of the jumpers for enabling the DSS-CD as well as  
9 making the appropriate APRM/OPRM setting changes in  
10 accordance with the new tech specs. We'll also be  
11 implementing the MELLLA PLUS reload analysis including  
12 the MELLLA PLUS core operating limits report and  
13 updating the core monitoring computer with the new  
14 information for the MELLLA PLUS.

15 Once that's completed, we will implement  
16 the new tech spec and immediately after that begin  
17 MELLLA PLUS testing which is scheduled to start on  
18 September 12th. That will coincide with a planned  
19 downpower. It's scheduled for that same weekend for  
20 a control rod sequence exchange. We expect the test  
21 program to take approximately six days. And we will  
22 be completing all of the prescribed MELLLA testing  
23 prior to commencing normal operations in the MELLLA  
24 PLUS region.

25 Now there was a question raised at the

1 Subcommittee regarding the variability of the test  
2 results. In our next section the George will cover,  
3 we'd like to elaborate more on our response that we  
4 had discussed during the Subcommittee. Are there any  
5 questions from what we've covered so far?

6 (No verbal response)

7 All right. Given that, I'll now turn it  
8 over to George Inch to discuss the design analysis.

9 MR. INCH: Good afternoon. My name is  
10 George Inch. I'm the Senior Staff Engineer who is  
11 responsible for the MELLLA PLUS and extended power  
12 uprate design and analysis. I'd like to briefly cover  
13 a couple of key points with regards to the limitations  
14 and conditions.

15 We comply with all the applicable  
16 limitations and conditions. The 14 applicable from  
17 the methods, there are several that are not applicable  
18 mainly because the approach we've chosen with regard  
19 to the enriched boron. So some of the TRAC G analyses  
20 methods limitations are not applicable. And also we  
21 have a full core GE14. So some of the conditions  
22 associated with mixed cores don't apply.

23 For operability/flexibility limitations and  
24 conditions, I think Bhalchandra went through several  
25 of these. We have a tech spec for limiting single

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 loop operation for both MELLLA and MELLLA PLUS. The  
2 original licensing for single loop at Unit 2 was up to  
3 the MELLLA line and that has not changed with EPU. So  
4 it's now in tech specs. But it's always been part of  
5 the SAR.

6 We have an existing License Condition 7.  
7 We've had that since stretch uprate in mid '90s. It's  
8 a 20 degree design window about the rated feedwater  
9 temperature. And our assessment is that that  
10 limitation and condition satisfies the 12.5B. So  
11 we're not proposing a new one. That's sufficient to  
12 restrict feedwater heater out of service which is one  
13 of the restrictions in the MELLLA PLUS LTR.

14 And the COLR, there's another requirements  
15 for the power flow map to be part of the COLR. And  
16 those limitations will be part of that.

17 In Subcommittee, we discussed our power  
18 flow map and how that's integrated into our  
19 procedures. And it's under design control.

20 The key features of our license amendment  
21 request are that we've increased the enrichment to 92  
22 atom percent. And what that does is it meets the  
23 limitation and condition 12.18b. So we essentially  
24 keep the integrated heat loads of the containment as  
25 really unchanged from the original licensing bases at

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 75 percent flow which is the limitation and condition.

2 And it has a significant improvement to  
3 margin to the HCTL curve which is the curve under  
4 which Operations would need to emergency depressurize  
5 that reducing the impact on the suppression pool  
6 temperature. Dan Cifonelli will talk a little bit  
7 about how that's improved operator responses.

8 It also has a side benefit where we're able  
9 to meet the 10 CFR 50.62 rules with one pump, the  
10 equivalency equation. We haven't changed the tech  
11 spec LCO or any of those aspects. So you still have  
12 both pumps start and initiate in the RRCS system.

13 We also have at Nine Mile 2 the redundant  
14 reactivity control system. It has an automatic  
15 injection start of the pump and an automatic feedwater  
16 flow runback that was part of the original ATWS design  
17 and licensing basis for Unit 2. And we currently  
18 under EPU in the ATWS credit those automatic  
19 functions. And these for MELLLA PLUS significantly  
20 improves the ATWS instability operator time  
21 requirements.

22 The redundant activity control system I'd  
23 like to talk about a couple of key features. The  
24 standby liquid control system pump start is on high  
25 reactor pressure when the APRMs are not downscaled.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 So in any event where you lose the turbine, we have a  
2 25 percent bypass capability. You'll get the high  
3 pressure signal.

4 If you're APRMs are not downscale, you'll  
5 make up the logic. For the pump start, it's 98  
6 seconds. For analysis purposes, we use the 120 for  
7 the start. And for the feedwater runback, there is a  
8 delay of 25 seconds. The analysis uses 33.

9 The way the runback works is the redundant  
10 reactivity control system initiates a logic whereby  
11 the flow control valves on our feedwater pump, we have  
12 two motor-driven feedwater pumps under rated  
13 conditions. A third one's a spare. And it closes the  
14 flow control valve at max rate and opens them in flow  
15 valves simultaneously.

16 So within 21 seconds you're basically  
17 shutting the flow off to the reactor at which point  
18 the flow comes down quite rapidly.

19 CHAIRMAN STETKAR: You just have fixed  
20 speed motor-driven pumps. You don't have the  
21 variable.

22 MR. INCH: That's correct.

23 CHAIRMAN STETKAR: Thank you.

24 MR. INCH: For a dual recirc pump trip to  
25 trip the turbine, you don't have high pressure. And

1 for that condition, the analysis for the ATWS with  
2 instability for the dual pump trip assumes two manual  
3 actions. One is that the operators manually scram  
4 within 20 seconds and the other is to initiate runback  
5 within 70 seconds.

6 I think one of the questions from the  
7 Subcommittee was where did the 270 come from. That  
8 was a design input before that we came up with at Nine  
9 Mile based on observing operators. We came up with  
10 what they were doing in place with a little bit of  
11 margin. And that's what we gave to GE for further  
12 analysis. We ended up not needing to change it based  
13 on the results of the analysis for the dual pump trip.

14 Dan will go through some of the details on  
15 the qualifications for that.

16 MEMBER BANERJEE: Do you see some results  
17 from this?

18 MR. INCH: Yes.

19 MR. CIFONELLI: Yes, I'll be covering  
20 those.

21 MEMBER SCHULTZ: Will that include any  
22 sensitivities evaluations?

23 MR. INCH: Yes, we have that.

24 MEMBER SCHULTZ: Thank you.

25 MR. INCH: We have that in the closed

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 session. Thank you.

2 One of the things that's impacted by MELLLA  
3 PLUS Nine Mile 2 is the prediction that the moisture  
4 carryover will go up. We have one state point which  
5 gets to about 0.236 weight percent at the 85 percent  
6 core flow point.

7 Our design analyses for radiological impact  
8 was always based on 0.35 weight percent. We didn't  
9 need to change that. I shouldn't say always. It was  
10 based on it when we extended power uprate. So we  
11 didn't need to revise that.

12 When we did the detailed evaluation of flow  
13 accelerated corrosion and what limiting components  
14 would be there, we determined that the outboard MSIV  
15 we needed to keep it below. The main steam leaving  
16 the reactor needed to be below 0.25 to keep the  
17 outboard MSIV below 0.5. That was the limiting  
18 component. The other limiting component is the main  
19 turbine at one percent.

20 The conditions that create the moisture  
21 carryover are really governed by the performance of  
22 the steam separators. And it's not necessarily the  
23 core flow effect. But it's really the combination of  
24 the rod patterns and the cycle exposure as the wear  
25 and the quality coming out of the given region of the

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 core where you can get the quality not in that optimum  
2 band for the steam separator.

3 For Nine Mile at reduced core flow, we do  
4 see predictions of higher carryover that's not  
5 necessarily generically true. But that is true for  
6 us.

7 All of our evaluations of the moisture  
8 carryover have been done for 0.35 with the limitation  
9 of 0.25 going forward. That will be implemented in  
10 our implementation testing and then it will be  
11 embedded in our procedures.

12 Our experience with EPU core is really  
13 good. We've got the first cycle EPU data. We're  
14 below 0.2. The original predictions were about 0.08  
15 for EPU. So we believe that and as part of our  
16 application explained in some detail why we expect  
17 that moisture carryover to actually not get above 0.1.

18 In Subcommittee, we had a question on our  
19 test program and what was the variability of some of  
20 the testing. We thought about our answer and we put  
21 together a variability of each test. You know there's  
22 two dynamic tests that are done where we adjust the  
23 pressure set point and the other one is water level  
24 changes.

25 Those are normal operator maneuvering

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 actions. So you're on a higher rod line. There's  
2 higher void content. So there is the transience that  
3 you see and the control system stability could be  
4 impacted.

5 This is a confirmation test. We've looked  
6 at it. It's a low sensitivity to exposure in the  
7 cycle of the rod patterns. So we don't see much  
8 variability there. Similar the neutron flux noise  
9 remains bounded by the -- We confirm it remains  
10 bounded by set point counts and we don't see much  
11 sensitivity there.

12 The stability monitor is also a noise check  
13 on the OPRM set points. The two tests that do have  
14 variability are the moisture carryover, the TIP power  
15 distribution and core performance. So these  
16 particular tests are baseline tests that we do. And  
17 then they're proceduralized that they're monitored  
18 continuously throughout the cycle.

19 So moisture carryovers checked at least  
20 every month. And core power is proceduralized such  
21 there are lot of times reactor engineering has to  
22 govern those. Hopefully, that answers the question.

23 MEMBER BANERJEE: I've often wondered why  
24 this moisture carryover is such an importance  
25 consideration.

1 MR. INCH: It's primarily dose ALARA  
2 considerations. The radionuclides that are in the  
3 liquid phase get carried over and it does cause or can  
4 cause higher dose in the main turbine and also  
5 potential for damaging the main turbine. You get  
6 moisture carryover too high. You get impingement on  
7 the blades.

8 MEMBER BANERJEE: But this is not that  
9 high, right?

10 MR. INCH: It's not that high. So what  
11 we've determined is that as long as you stay below  
12 0.35 you'll be below the one percent. That's the  
13 important part. It's one of the things that we expect  
14 to change. We think we conservatively predicted it.

15 MEMBER SKILLMAN: George, when you say we  
16 expect a change, you expect a change from what to  
17 what?

18 MR. INCH: The predicted max value is 0.236  
19 and that occurred in the prediction that it occurred  
20 at before 2,000 megawatt days per short ton. And it  
21 was for one rod pattern. We estimated it was going to  
22 last for only a few weeks at that higher level. And  
23 then it came back down.

24 And we think it will follow actually very  
25 much the chart we put up there and would be much lower

1 than that value. But there's a potential that we  
2 could have a condition where you get higher moisture  
3 carryover.

4 MEMBER SKILLMAN: And if that were to  
5 occur, you would have temporary higher radiation  
6 levels and you would be considered at some level about  
7 your last stages of your low pressure turbine.

8 MR. INCH: As the moisture carryover --  
9 Right now, we're going to keep our limiting condition  
10 for increased monitoring at 0.07. We're running at  
11 0.02 right now. And we'll go into increased  
12 monitoring at 0.07.

13 There's an empirically -- It's both an  
14 analytical and empirical tool by which reactor  
15 engineering can predict the moisture carryover and  
16 also the core design as predicted to try and minimize  
17 the limiting rod patterns that are predicted to cause  
18 the carryover to develop higher.

19 MEMBER SKILLMAN: Thank you, George.

20 MEMBER CORRADINI: Since you brought it up,  
21 can we take a minute about the tool used? Can you  
22 tell us about that?

23 MR. INCH: The predictive tool?

24 MEMBER CORRADINI: Yes. I assume the  
25 measurement is dose-based.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 MR. INCH: No. The way we measure the  
2 carryover is they measure the sodium-24 in the  
3 condenser. And then they also take samples in  
4 reactor. And based on that they can figure how much  
5 get carried over from the reactor. That's a chemistry  
6 procedure that we --

7 MEMBER CORRADINI: That's the measurement.

8 MR. INCH: Yes, that's the measurement.

9 MEMBER CORRADINI: Okay. Thank you.

10 MR. INCH: And then that's used to improve  
11 the analytical tool with empirical data to allow it to  
12 get better and better with time.

13 MEMBER CORRADINI: Thank you.

14 MR. INCH: I'll cover the sensitivity  
15 studies in closed session. Dan.

16 MR. CIFONELLI: Thanks, George. Good  
17 afternoon. I'm Dan Cifonelli, Active SRO and Shift  
18 Manager for Nine Mile Point Unit 2 and assigned to the  
19 MELLLA PLUS project team. And today I'm going to talk  
20 about the operator critical actions, the validation of  
21 them and the results from that validation process and  
22 the training we've performed in preparation for MELLLA  
23 PLUS.

24 The design requires two new critical  
25 operator actions as George already mentioned, 20

1 seconds to insert a manual scram using the mode  
2 switch. That provides a redundant RPS scram signal  
3 and also bypasses our low pressure MSIV isolation.  
4 The second is the 270 seconds for the dual recirc pump  
5 trip scenario. And it's combated by contingency five  
6 standard ATWS strategy for terminating and preventing  
7 injection to the vessel.

8 These actions were validated in September  
9 of 2014 using the Exelon process for validating time  
10 critical operator actions. That Exelon program is  
11 based on industry standards including ANSI and ANI  
12 58.8 time response design criteria for nuclear safety-  
13 related operational activities.

14 These actions were validated using four  
15 normal operating crews. The purpose of the validation  
16 was to measure the actual time it takes for the  
17 operators to lower water level in the contingency 5  
18 ATWS strategy. There was no new training given to the  
19 operators or no procedure changes required for this  
20 action to occur within this time frame. So the  
21 validation process was rigorous, used the validation  
22 team and four crews.

23 We also as part of the process or  
24 requirements evaluated the sensitivity to staffing.  
25 A couple of the observations were made with the

1 operating crew at minimum staff. And what we found  
2 was the minimum staffing had no impact on either one  
3 of these actions and that's primarily because they're  
4 well trained. They're priority items in an ATWS.

5 All the controls are at the main control  
6 panel. The operator at the controls is continuously  
7 stationed at the controls area. And all the  
8 indications and controls are readily available to the  
9 operator at the front panels. And the actions are  
10 simple. Operator actions don't take many component  
11 manipulations for them to occur. So there is  
12 essentially no sensitivity to minimum staffing.

13 MEMBER SKILLMAN: Dan, would you comment as  
14 to whether or not your teams were preconditioned to  
15 know that they were going to see an ATWS-I event?

16 MR. CIFONELLI: Yes, the validation process  
17 includes the concept of them knowing what the criteria  
18 is. They are briefed on not doing anything any  
19 different than they normally do. The purpose of the  
20 exercise is to get a real valid result on what the  
21 time is. The crews are briefed on taking all the  
22 human performance actions, the procedures, as they  
23 normally do.

24 So the intent is to get real time. But  
25 they did know the criteria. That's part of the

1 process. In our subsequent NRC audit, it was also  
2 confirmed that these times were valid. So the results  
3 are really on the next slide.

4 CHAIRMAN STETKAR: Dan, just for clarity  
5 though, you told them that you were going to test them  
6 on ATWS. You told them what the criteria was and then  
7 you tested it. Is that correct?

8 MR. CIFONELLI: That's correct.

9 CHAIRMAN STETKAR: Okay. And why are those  
10 times representative of 3:00 a.m. on a Monday morning  
11 when nothing has ever happened in the plant in the  
12 last year and a half?

13 MR. CIFONELLI: Because the times are --  
14 Operators are trained. For a number of years they  
15 have been performing these actions since 1998.

16 CHAIRMAN STETKAR: So you've had several  
17 ATWS events at Nine Mile Point during 3:00 a.m. where  
18 these people have done this.

19 MR. CIFONELLI: We do out of the box  
20 examinations of operators for training.

21 CHAIRMAN STETKAR: I was an operator. I  
22 could find a steam generator tube rupture on a  
23 pressurized water reactor quicker than anybody else  
24 could in the simulator when I knew I was going to be  
25 tested on it. Not so much in the real plant.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1           So my question is you're characterizing  
2       these as representative times that I would expect 3:00  
3       a.m. on a Monday morning after a run of -- pick any  
4       particular run you want -- 275 days where nothing has  
5       happened.     They haven't even seen a glitch in  
6       feedwater flow.   And I'm questioning whether or not  
7       this testing that you've put the operators through  
8       under conditions where they know what to expect is  
9       actually representative.

10           MR. INCH:   It's not really testing though.  
11       What he's going through is a qualification for --

12           CHAIRMAN STETKAR:   Is your light on by the  
13       way?   I'm just making sure you're on.

14           MR. INCH:   Correct me if I'm wrong, Dan,  
15       but it's not a test we're giving them.   You're using  
16       an existing procedure for evaluating time critical  
17       actions.

18           MEMBER BLEY:   It sounds more like a time in  
19       motion study the way Dan described it rather than a --

20           MR. CIFONELLI:   That's correct.   It is.

21           MR. INCH:   That's what it is.

22           MR. CIFONELLI:   We want real times, how  
23       long it takes.

24           CHAIRMAN STETKAR:   But if I go to the  
25       grocery store and I know precisely where the can of

1       peas is located, exactly where it is on the shelf, and  
2       I make sure all of the aisles are clear and then I  
3       test whether or not I can retrieve that can of peas  
4       within 47 seconds, that's one thing.

5               If I send a person to the grocery store  
6       under average conditions on a Saturday when everybody  
7       is shopping and say, "Go get me a can of peas," that's  
8       a much different condition.

9               MR. CIFONELLI: There's no doubt in my mind  
10       that at 3:00 a.m. the operators are well within the  
11       270 second requirement. One of the observation  
12       criteria is that they're performing things that they  
13       normally would at 3:00 a.m., the use of diagnostic  
14       tools, three-way communications, time it takes to  
15       diagnose. And the margin that we're providing also is  
16       consistent with industry standards for examples of  
17       stress that you're talking about, Mr. Chairman, that  
18       would account for any variation under extreme  
19       circumstances.

20               MEMBER CORRADINI: But I guess I want to  
21       get back to the Subcommittee. But I think we went  
22       through this in the Subcommittee. What I remember was  
23       -- I'm not sure the human factors words with this, but  
24       this is some sense a rehearsal. But I thought NRC  
25       would go in with essentially an unknown and then do an

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1       audit check on this.

2                   I think we want to check this with staff.  
3       But I think we went through this in the Subcommittee  
4       and asked the same sort of questions. But you guys  
5       have got to remind me. But this is what I remember  
6       because we were questioning essentially what this was  
7       versus a test.

8                   MR. CIFONELLI: That's correct, Michael.  
9       And the audit results varied from 7.1 to 13.2 seconds  
10      for the scram and from 173 to 183 seconds for the 270  
11      seconds. These are real numbers.

12                   I watched the crews. I mean the guys are  
13      good. I'll tell you that. And this wasn't a race.  
14      We weren't trying to get them to achieve anything. We  
15      were trying to get a real number here.

16                   MEMBER REMPE: The one thing that -- Maybe  
17      I was confused from the Subcommittee meeting, but the  
18      one thing I remember initiate manual scram within 20  
19      seconds. That is something that is done for other  
20      reasons. And you just made it time critical for this  
21      particular application. So surely -- and maybe I'm  
22      inferring something incorrect -- you've had blind  
23      situations where the operators are having to do that  
24      in some of the others.

25                   MR. CIFONELLI: Absolutely yes.

1 MEMBER REMPE: I would think that that has  
2 been tested before.

3 MR. CIFONELLI: Also keep in mind --

4 MEMBER SCHULTZ: Dan, the change of these  
5 features to a time critical operator action, does that  
6 change the training program at all?

7 MR. CIFONELLI: No.

8 MEMBER SCHULTZ: Or any aspect of it? It's  
9 just something that you're going to monitor  
10 appropriately going forward.

11 MR. CIFONELLI: That's correct. Keep in  
12 mind George's presentation. The basis of the number  
13 was an input based on what operators did at the time  
14 at the beginning of the project. It's not a number  
15 that we have changed on our program or changed our  
16 trainer or change our procedures to achieve. This is  
17 a real number. This is what it takes.

18 We will maintain it going forward. There's  
19 a process. It's been recategorized as a time critical  
20 action now because it's part of our design basis. So  
21 there's a maintenance program for those times. We'll  
22 revalidate every five years. Any changes to  
23 procedures or any changes to design, we'll have to  
24 consider these time critical actions.

25 MEMBER SCHULTZ: But it doesn't change the

1 simulator program.

2 MR. CIFONELLI: No change in the simulator.

3 MEMBER SCHULTZ: The training program and  
4 so forth.

5 MR. CIFONELLI: Or the ATWS strategy.  
6 That's correct.

7 MEMBER SCHULTZ: Thank you.

8 MR. INCH: So the 270 second derivation was  
9 an observation of the normal training for ATWS events,  
10 dual pump trip. And they had no knowledge that we  
11 were timing them at that time. So when we came up  
12 with 270 we actually measured a value and then  
13 Engineering decided to add some margin on it.

14 When Dan came in with these numbers we're  
15 weren't surprised at all that they were able to do it  
16 faster. And I think the audit also included -- I  
17 think we talked about -- Diego as mentioned that there  
18 was a surprise event given to them.

19 MR. CIFONELLI: Just to states the results  
20 found, an average time of 8.5 seconds for shutting  
21 down the reactor and 193 seconds for terminating and  
22 preventing injection. These results demonstrate  
23 significant margin to the required times which account  
24 for uncertainties, stress, event recognition, action  
25 planning by the operators, team communications and

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 verification practices.

2 MEMBER BLEY: In which way do you justify  
3 that last claim? Do you go back to simulator  
4 exercises? I'm kind of bothered as John is. I don't  
5 suppose when you put the guys in the simulator for  
6 normal training you say "You're going in and you're  
7 going to see a small LOCA. Now let's go over the  
8 small LOCA procedures and make sure you know how these  
9 work." And then go in and run the drill. They don't  
10 know what's going to happen.

11 Now you're saying we've got time and covers  
12 all of these contingencies. And you had a list of  
13 about eight or six. Please go through the basis for  
14 why it covers all of those contingencies.

15 MR. CIFONELLI: The basis for why it  
16 covers all of those contingencies is built into the  
17 margin that we find values at. Like you said, we will  
18 be doing surprise examinations as we do for all our  
19 time critical actions.

20 Going forward, those examinations will  
21 confirm that the operators will be able to perform  
22 those actions within those times on a surprise  
23 examination basis. We do those on a Monday morning.  
24 We call them out of the box examinations. And if an  
25 operator were not to be able to achieve these actions

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 --

2 MEMBER BLEY: I would believe that more --  
3 I have a little trouble with the long list of things  
4 you gave me and said, "There's margin that covers all  
5 of these things" without showing me why it covers  
6 those things. What's your basis? How much time does  
7 it take for recognition? How much time does it take  
8 for getting out the procedures and going through them?  
9 It's just a blanket "Well, there's plenty of time for  
10 all of those things." Without a justification it  
11 leaves me wanting.

12 MR. CIFONELLI: The time it takes to get  
13 out the procedures and recognize the event are built  
14 into the range of 150 to 232 seconds. And the margin  
15 is what provides assurance of these other variables.

16 MEMBER CORRADINI: Can I clarify one thing  
17 because maybe I misunderstood? There are two times,  
18 one being the short time which occurs not just here  
19 but has to be -- I don't want to say practiced, but I  
20 can't come up with a better word -- practiced because  
21 of a number of other activities.

22 And the 270 is only if their automatic  
23 runback doesn't function. You don't need to do the  
24 manual runback. It's an automatic runback. This is  
25 a backup to the automatic runback.

1 MR. CIFONELLI: Well, that's not 100  
2 percent correct. The 270 seconds is for the event  
3 where the high pressure doesn't trigger the automatic  
4 runback.

5 MEMBER CORRADINI: Okay.

6 MR. CIFONELLI: And that's specific to the  
7 dual recirc pump trip scenario which is not a high  
8 pressure event. So that's a derivation of 270 seconds  
9 which is particular to the automatic runback. It  
10 would not be triggered.

11 MEMBER CORRADINI: Thank you.

12 MR. CIFONELLI: But it was true that the 20  
13 seconds is something we do very frequently.

14 MEMBER CORRADINI: Sure.

15 MR. CIFONELLI: That's the first thing the  
16 operator -- That's fundamental to initial operator  
17 training, how to shut down.

18 MEMBER BLEY: We weren't challenging that  
19 one.

20 MEMBER BANERJEE: So the runback, how  
21 reliable is that? Is it an automatic runback?

22 MR. INCH: The runback circuit within the  
23 reactivity control system has two divisions and has  
24 redundancy built in. And it's a digital system.

25 MEMBER BANERJEE: The 2RPT won't trigger

1 it.

2 MR. INCH: No. The high pressure in the  
3 reactor tends to be five pounds.

4 MEMBER BANERJEE: You'll have to --

5 MR. INCH: You have to have a high pressure  
6 to trigger it. You don't want to trip the turbine if  
7 you don't have to. So you can challenge containment.  
8 So you can get the reactor high pressure.

9 MEMBER BANERJEE: Okay. And if it doesn't  
10 trip with a turbine trip what happens then? Do you  
11 have some backup actions?

12 MR. INCH: Yes, we have some. We do have  
13 a presentation in the closed session to go through  
14 those details.

15 MEMBER BANERJEE: So we'll wait to the  
16 closed session.

17 MEMBER REMPE: During our Subcommittee  
18 meeting, we tried to anticipate some questions that  
19 other members might have. So that's why they're  
20 providing that in the closed session.

21 MEMBER CORRADINI: We knew you'd be here.  
22 So we're ready.

23 MR. CIFONELLI: So moving to the next slide  
24 we started our training early in the process, about a  
25 year ago, over a year ago in 2014. We introduced the

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 operators to the MELLLA PLUS concept, the purpose of  
2 benefits of MELLLA PLUS. We introduced the DSS-CD  
3 solution, the changes to the OPRMs and the changes to  
4 the technical specifications. I'll give an overview  
5 of the automatic backup scram protection circuitry and  
6 the manual backup scram protection scheme.

7 In August 2014, we started our initial  
8 simulator training. We provided the power to flow map  
9 to the operators and solicited their feedback as it  
10 was in draft format at that time. Also in August we  
11 provided a demonstration of how good the 92 percent  
12 enriched boron is for shutting down the reactor.  
13 Demonstrated that the hot shutdown boron injection  
14 time was reduced from 16.4 minutes to 5.1 minutes.

15 The operators understand the importance of  
16 early injection of the standby liquid portion for  
17 boron to slow down the overall ATWS. And it basically  
18 trains itself in the sense that they're positively  
19 rewarded by slowing down the whole transient once you  
20 have boron injection going.

21 We also performed five different ATWS  
22 scenarios in August of 2014 that were started at the  
23 85 percent flow, 100 percent power point.

24 In January of 2015, this year, we performed  
25 some additional classroom and simulator training. We

1 spent time with our off-normal procedures using the  
2 new power to flow maps that have different lines in  
3 them for exits in scram regions and how the operators  
4 have to drive around the different regions of the  
5 plant for rapid power reduction maneuvers or for a  
6 sudden reduction in core flow.

7 In May of this year due to a recent  
8 industry event we want to take the opportunity to  
9 reinforce some fundamentals with regard to  
10 instability. We reinforced the fundamentals of early  
11 water level reduction to reduce subcooling and reduce  
12 the potential or consequences of the instabilities.

13 We also reinforced the importance of early  
14 rod insertion on an unexpected reduction in core flow,  
15 for instance, for a recirc pump trip. And we also  
16 reinforced the fundamentals of how to recognize and  
17 respond to instabilities in the reactor.

18 In July of this year, we gave the operators  
19 some additional reinforcement training. The initial  
20 training is complete and we provided some more similar  
21 scenarios in the MELLLA PLUS region. The training we  
22 have planned is focused around just in time training  
23 which will be for the testing program. The emphasis  
24 there is going to be on reactivity maneuvers and risk  
25 management and the testing procedures.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1           MELLLA PLUS will eliminate the burden of  
2           frequent control rod manipulations to control and  
3           maintain power which will reduce the potential for  
4           control rod manipulation errors and therefore reduce  
5           the related potential for consequences of fuel  
6           failures. This will be an improvement in operational  
7           safety. MELLLA PLUS will allow operations to maintain  
8           additional margin to rod lines and eliminate the  
9           current requirement to operate near limitations. This  
10          will also improve operational safety.

11           Based on the completed training of  
12          procedures and display readiness, our operator  
13          critical action results in a detailed implementation  
14          plan. Operations is ready to implement MELLLA PLUS.

15           MEMBER REMPE: So if there aren't any  
16          additional questions from ACRS members, this is going  
17          to be the end of the open session. I believe this is  
18          a good time to ask if there are any members of the  
19          audience and to open the phone lines if there's anyone  
20          out there that wants to provide a comment. This is a  
21          good time to have such comments.

22           While Zanya is getting the phone lines open  
23          up, is there anyone in the audience who wants to  
24          provide a comment?

25           (No verbal response)

1                   We're just going to have to be patient here  
2                   for awhile.

3           5.       OPEN PUBLIC COMMENTS

4                   MR. THOMPSON: Hi, this is George Thompson  
5                   from GE/Hitachi.

6                   MEMBER REMPE: Okay.       So we know the  
7                   closed line is open. And you believe the open line is  
8                   open now, too.

9                   CHAIRMAN STETKAR: We got the closed line.  
10                  Thank you, George.

11                  MEMBER REMPE: We got that, George.

12                  MR. THOMPSON: Okay.

13                  (Off microphone comments)

14                  CHAIRMAN STETKAR: There we go.

15                  MEMBER REMPE: Now the public line is open.  
16                  If someone is out there, would you please just make a  
17                  noise and speak up so we can verify it is indeed open?

18                  (No verbal response)

19                  If anyone out there has a comment, would  
20                  you like to provide that comment at this time?

21                  (No verbal response)

22                  With that being said, we're going to close  
23                  the public line and verify it is indeed closed and  
24                  we'll start the closed session. I believe we'll still  
25                  have GE/H or Exelon up.

**NEAL R. GROSS**

COURT REPORTERS AND TRANSCRIBERS  
1323 RHODE ISLAND AVE., N.W.  
WASHINGTON, D.C. 20005-3701

1 CHAIRMAN STETKAR: Just procedurally, make  
2 sure that indeed everybody in the room is authorized  
3 to be here for the closed session.

4 MEMBER REMPE: And we're going to have to  
5 rely on --

6 CHAIRMAN STETKAR: Both staff and the  
7 licensee.

8 (Whereupon, the open session ended and the  
9 closed session begins.)

# NRC

## Failure Mode Related Research

Mauricio Gutierrez  
RES/DE/ICEEB

Ming Li  
RES/DRA/PRAB

July 08, 2015

# Agenda

- Background
  - Summary of NRC Digital System Failure Mode Related Research Efforts
  - Summary of Advisory Committee for Reactor Safeguards (ACRS) I&C Subcommittee Feedback and NRC Response
- Summary of Staff Follow-up Actions
  - PRA and Deterministic Assessment Perspectives
  - Digital System Failure Mode Terminology and Common Concepts in Selected Definitions
  - Digital System Failure Modes Mapping
- Conclusions and Next Steps

# Background

- ACRS has long standing concerns that based DI&C system failure modes are not well understood.
  - Misbehaviors other than non-performance of required function can occur.
- ACRS brought concerns to Commission attention in 2008.
- June 26, 2008 – Commission issued SRM-M080605B
  - Directed staff to
    - “report the progress made with respect to identifying and analyzing digital I&C failure modes ...”
    - and “discuss the feasibility of applying failure mode analysis to quantification of risk associated with DI&C...”

# Related NRC Research

- **DRA – PRA Methods for Digital Systems**
  - Brookhaven National Laboratory NUREG/CR reports
    - Traditional Probabilistic Risk Assessment Methods for Digital Systems (NUREG/CR 6962 and NUREG/CR 6997)
    - Quantitative Software Reliability Models for Digital Protection Systems (NUREG/CR 7044)
  - WGRisk
    - International effort to establish failure mode taxonomy for PRA related research.
  - Draft “Development of A Statistical Testing Approach for Quantifying Software Reliability and Its Application to an Example System” (NUREG/CR-xxxx, BNL-NUREG-yyy-20zz)
- **DE – Analytical Assessment of Digital I&C Systems**
  - RIL-1001 [ML111240017, 2011] and NUREG/IA-0254 [ML11201A179, 2011]
    - Software Related Uncertainties
    - Understanding faults attributable to complex logic (e.g., software)
  - RIL-1002 [ML14197A201, 2014]
    - DI&C safety system failure modes – what is known so far
  - RIL-1003 (scheduled for 2015 completion)
    - Feasibility of applying failure mode analysis to quantification of risk associated with DI&C systems.
  - RIL-1101 [ML14237A359, 2015]
    - Broader view of hazard analysis to address misbehaviors attributable to engineering deficiencies.

# ACRS I&C SC Feedback

September 19, 2013 – ACRS I&C Subcommittee Feedback on Research Information Letter 1002. Subcommittee Members:

- Appreciated the synthesized set of system failure modes identified (Set L).
- Requested harmonization of failure modes used by DE, DRA, and EPRI.

# Staff Response to I&C Subcommittee Feedback

- DE and DRA had technical discussions on harmonization.
- DE and EPRI also discussed harmonization.

# PRA and Deterministic Assessment Perspectives

	Technical Objectives	Involves asking:
Deterministic Licensing	Safety Assurance [RIL-1002].	1. What can go wrong? 2. What are the consequences? <a href="#">[NRC Website: Risk Assessment in Regulation]</a>
Probabilistic Risk Assessment	Support quantification of system reliability.  Estimate Risk by computing real numbers <a href="#">[NRC Public Website: How We Regulate]</a>	1. What can go wrong? 2. How likely is it to go wrong? 3. What are the consequences? 4. Which systems and components contribute the most to risk? [Apostolakis Presentation]

# Digital System Failure Mode Mapping

RIL-1002 Set L	WG Risk Survey	EPRI Guidewords
No output upon demand	Loss of function No actuation signal when demanded	No function Partial function
Output without demand	Spurious actuation	Over function Unintended function
Output value incorrect	Failure to actuate	No function Partial function Over function
Output at incorrect time	Failure to actuate in time	Unintended function
Output duration too short or too long.	Loss of communication	Partial function
Output intermittent	No actuation signal when demanded	Intermittent function
Output flutters	Spurious actuation	Degraded function
Interference	Adverse effects on other functions	Degraded function
Byzantine behavior	Other	Degraded function

# Conclusions/Next Steps

- DE, DRA, and EPRI have a shared understanding of the issues that lead to misbehavior other than the non-performance of a required function.
- DE and DRA staff agree that Failure Mode Set L could be useful for both DRA and DE.
- NRC and EPRI will continue sharing technical information from digital system failure mode related research.
- Vocabulary Harmonization topic is in the I&C Research Plan FY 2015-2019 candidate pool.
- RIL -1003 – will report on the feasibility of applying failure mode analysis to quantification of risk associated with DI&C systems.

# Overview of Digital I&C PRA Research Activities

ACRS Full Committee Meeting  
July 8<sup>th</sup> 2015

Ming Li  
Probabilistic Risk Assessment Branch  
Division of Risk Analysis  
Office of Nuclear Regulatory Research  
(301-415-2428, [ming.li@nrc.gov](mailto:ming.li@nrc.gov))

# Background – Regulatory Needs

- Nuclear Power Plant I&C systems shifting analog to digital
- Commission encouraged using PRA technology in all regulatory matters to the extent supported by the state-of-the-art in PRA methods and data – 1995 NRC PRA Policy Statement (60FR42622, August 16, 1995)
- National Research Council recommendation\*
  - The USNRC should require that the relative influence of software failure on system reliability be included in PRAs for systems that include digital components
  - The USNRC should strive to develop methods for estimating the failure probabilities of digital systems, including Commercial Off The Shelf (COTS), for use in PRA

\*National Research Council, "Digital Instrumentation and Control Systems in Nuclear Power Plants: Safety and Reliability Issues," National Academy Press, Washington, DC, 1997.

# Staff Positions for DI&C PRA Research

- DI&C PRA includes reliability modeling for hardware, software, and interactions among them
- Failure behaviors are examined (modeled and quantified) at functional levels of detail
- Hardware reliability modeling considers hardware random failures. Failure data sources include operation experience, and handbook data
- Software reliability modeling quantifies stochastic software failure behavior caused by logical errors in the design with deterministic failure mechanism
  - Software failure is defined as functional deviation from its expected behaviors

*software failure is defined as the triggering of a defect of the software, which results in, or contributes to, the host (digital) system failing to accomplish its intended function or initiating an unwanted action. - NUREG/CR7044*

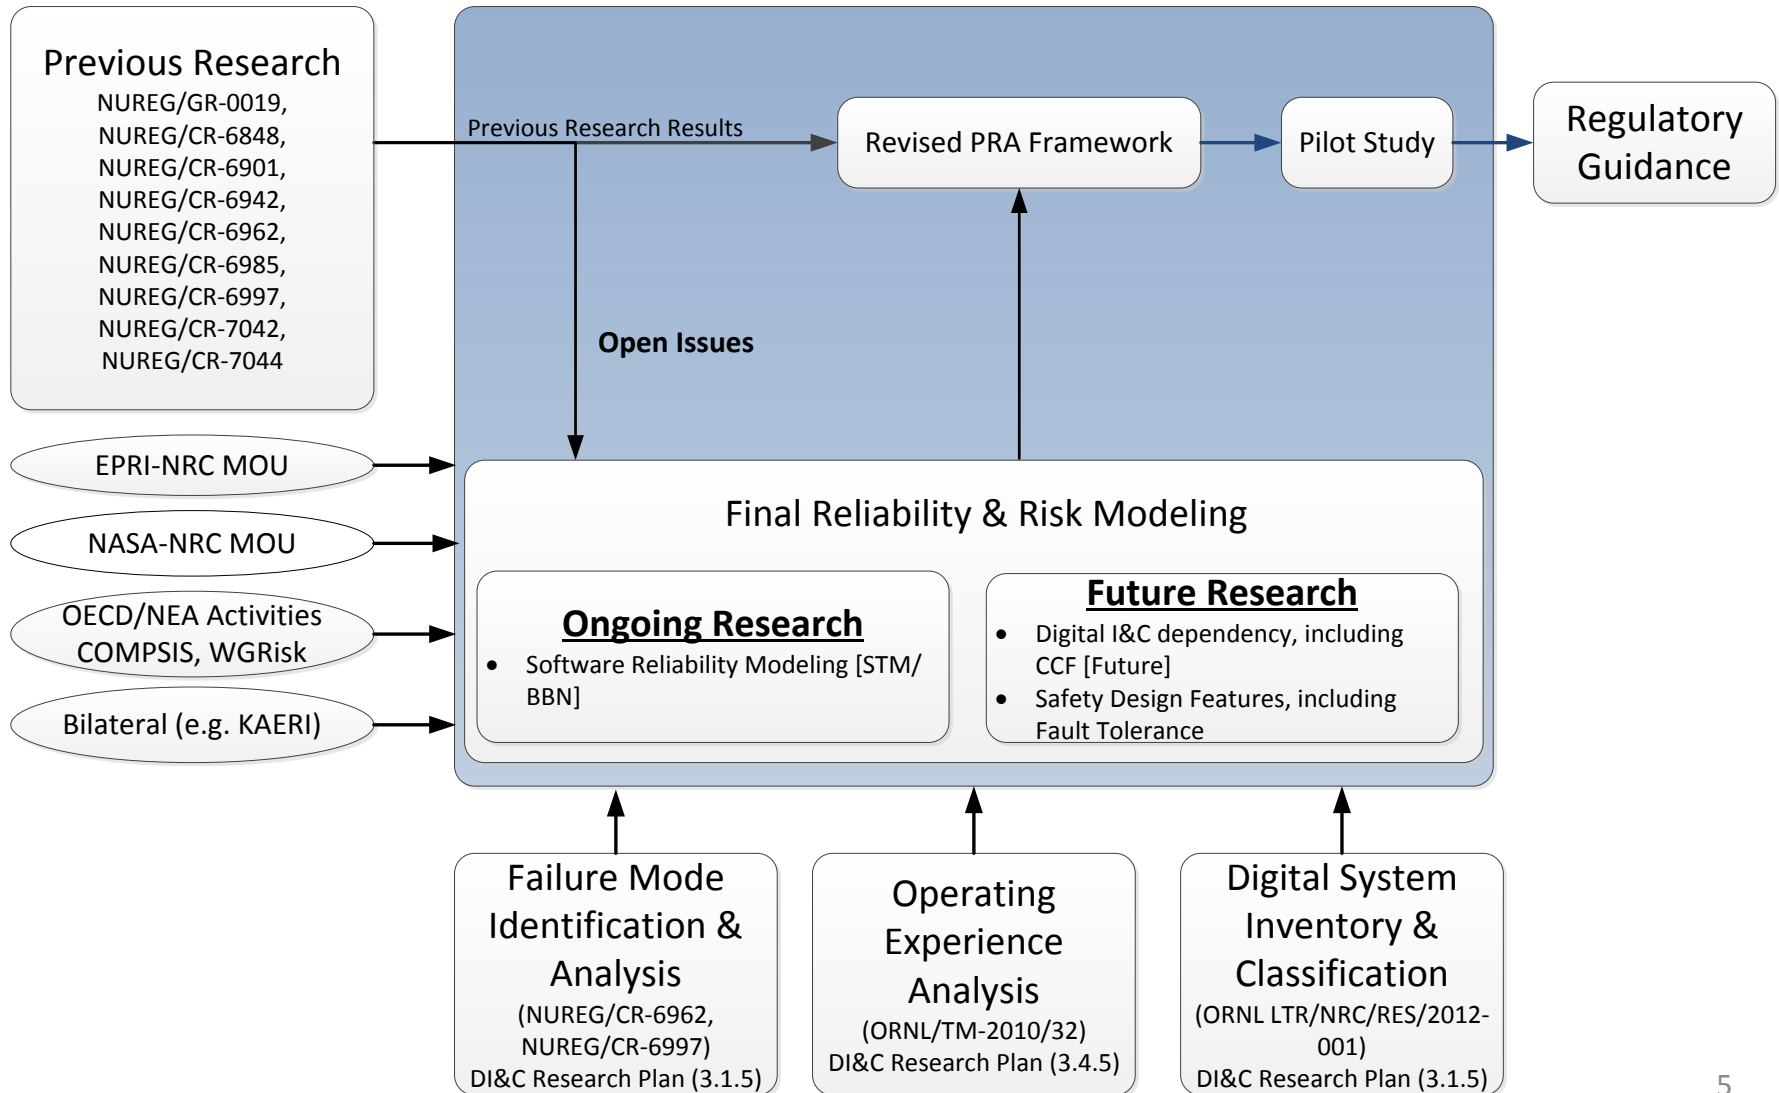

# NRC FY2009 – FY2014 Digital I&C PRA Research

- Objective: Identify and/or develop methods, analytical tools, and regulatory guidance for:
  - Including digital system models into nuclear power plant (NPP) PRAs
  - Incorporating digital systems into NRC's risk-informed licensing and oversight activities
- Deliverables
  1. NUREG/CR-6997: Applications of traditional PRA methods to a DFWCS (2009)
  2. BNL-90571-2009-IR: Philosophical Basis for Incorporating Software Failures into a Probabilistic Risk Assessment (2009)
  3. BNL-94047-2010: Review Of Quantitative Software Reliability Methods (2010)
  4. NUREG/CR7044: Selection of quantitative methods and how they will be applied to an example system (2013)
  5. Additional Reports:
    - NUREG/CRs on Application of selected QRSMs to candidate system (in progress)
    - Regulatory Guidance (future)

# NRC Digital I&C PRA Overview

## DI&C Research Plan (3.1.5, 3.1.6, 3.4.5)

# Previous Research on Hardware/System Reliability Modeling

- Ohio State University/ASCA/University of Virginia – Dynamic reliability modeling methods applied to a DFWCS (NUREG/CR-6901 [2006], NUREG/CR-6942 [2007], NUREG/CR-6985 [2009])
- BNL – Traditional reliability modeling methods applied to a DFWCS (NUREG/CR-6962 [2008], NUREG/CR-6997 [2009])

# Previous Research on Software Reliability Modeling

- UMD-OSU Metrics Based Studies (NUREG/GR-0019, NUREG/CR-6848, NUREG/CR-7042)
  - Ranked metrics with respect to estimating software reliability
  - From metrics to # of residual defects in the software
  - Estimate failure probability using finite state machine simulation and operational profile
- BNL Studies (NUREG/CR-7044 and ongoing)
  - Expert panel on software reliability
  - Ranked software reliability models and chose two for further study
    - Bayesian Belief Network (BBN)
    - Statistical Testing Method (STM)

# International Activities

- Bilateral
  - South Korea (KAERI/KAIST)
  - A NUREG/CR report on BBN study is expected in 2016
- OECD
  - Digital I&C – NEA/CSNI
    - NEA/CSNI/R(2014)16: Failure mode taxonomy
    - NEA/CSNI/R(2009)18: Recommendations on digital I&C PRA
  - COMPUter-based System Important to Safety project (COMPSIS) (2005-2011)

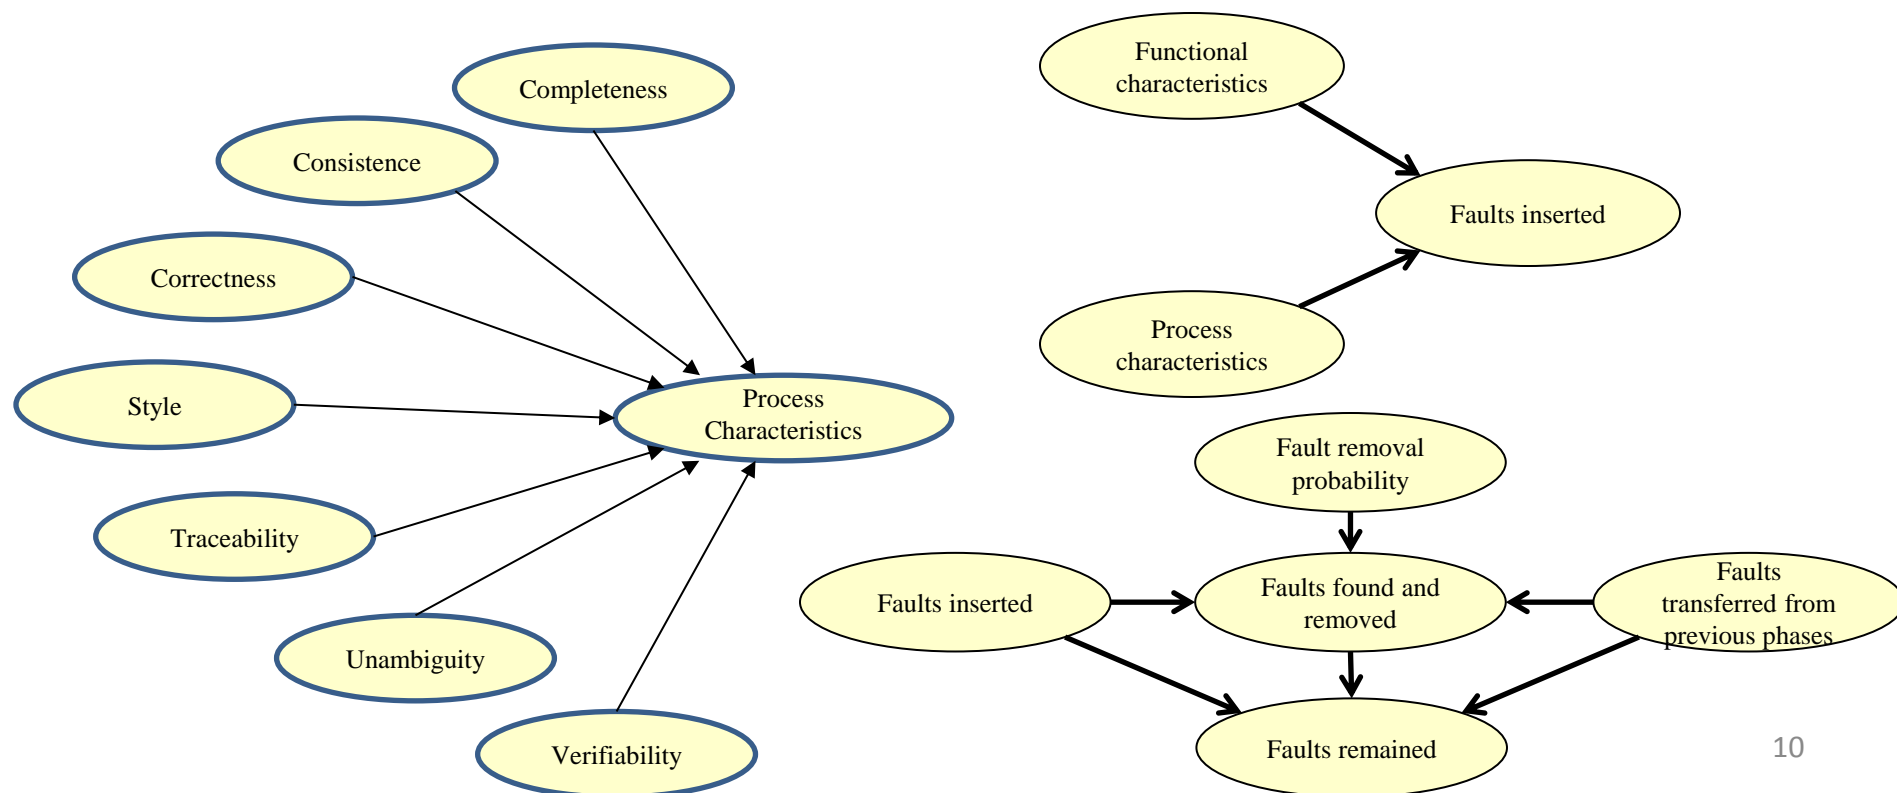

# Ongoing Research on Software Reliability

- Statistical Testing Method (STM)
  - Test software in a PRA context
    - Uses PRA to define conditions the software should be tested (operational profile)
    - Number of test cases required can be determined using PRA sequence frequency
    - Generates test cases via the operational profile based thermal hydraulic simulation
    - Integrated hardware/software testing environment
  - Applied to INL ATR LOCS (loop operating control system)
    - 10,000 conditions were identified and tested
    - A large number of early(27)/delayed(964) trip anomalies were observed
    - Test cases were regenerated by removing artificial noise added to inputs, adding synchronizing timing signals, and recalibrating input/output modules
    - 10,000 new test cases were rerun, 45 delayed and 16 early trip anomalies still exist:
      - Small errors in processing input signals caused an early or delayed trip
      - Hardware (IO modules) resolution limitation caused these anomalies, not the software

# Ongoing Research on Software Reliability

- BBN
  - Characterize software development and product attributes that can affect reliability
  - Establish a causal network that estimates the number of defects from software attributes, and then estimates software failure probability from the number of defects
  - Experts opinion elicitation is used to identify attributes, construct causal network, quantify the causal relationship and apply the model to the ATR LOCS system

# Path Forward

- Publish STM results in a NUREG/CR report
- Complete BBN research and publish results in a NUREG/CR report
- Update digital I&C research plan to reflect next phase of work
  - Hardware failure data collection
  - Software reliability modeling
  - Digital I&C dependency modeling
  - Safety design features (fault tolerant, online surveillance, etc) modeling
  - Development of regulatory guidance for modeling DI&C systems in NPP PRAs

## **Digital Instrumentation & Control Projects**

- **Digital System Failure Modes**
- **Modeling Digital I&C in PRA**
- **Techniques for Failure Prevention and Mitigation**
- **Hazard Analysis Demonstration Project**

**Ray Torok**  
EPRI

**Advisory Committee on Reactor Safeguards**  
July 8, 2015

# Update on EPRI Digital I&C Projects

## Key Points/Conclusions

- Problem statement: Potential digital failures, including common-cause failure, that result in loss of critical system functions (e.g. as expressed in SECY 93-087)
- Much progress in recent years:
  - Understanding of digital system failure modes and measures to prevent / mitigate them
  - Industry standards and guidance
  - Application of probabilistic risk assessment (PRA) to develop risk insights that help identify and address potential vulnerabilities
  - Advanced failure/hazard analysis techniques to identify and address potential vulnerabilities
- Time to apply updated knowledge and tools in plants
- Work ongoing by industry to update their guidance and plant procedures – EPRI supporting with technical guidance and tech transfer

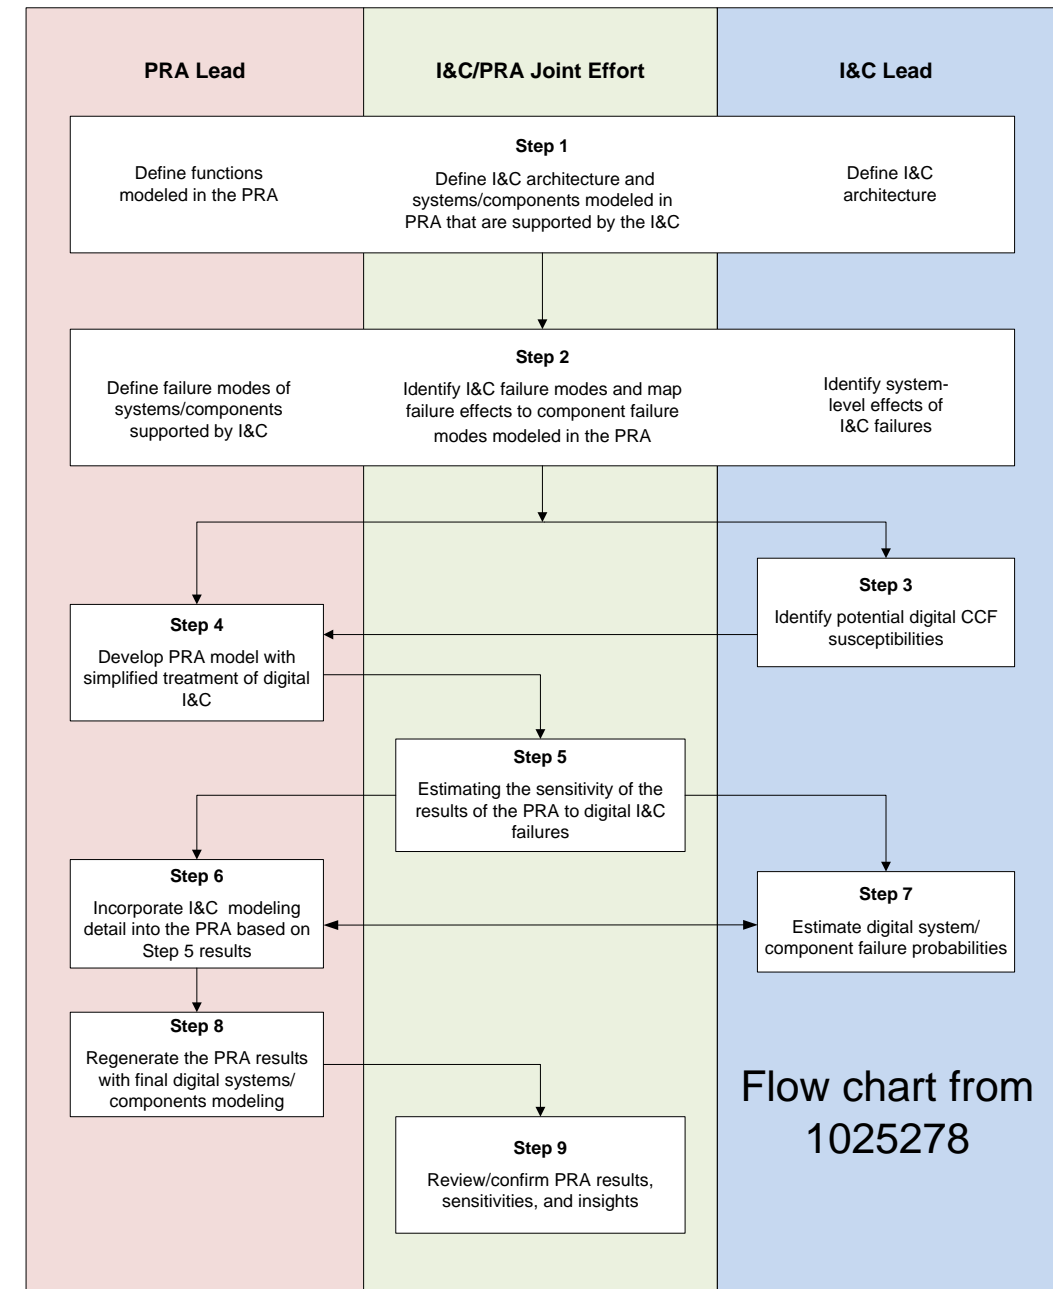

**Our ability to ensure high dependability of critical digital systems has improved significantly since the SRM to SECY 93-087**

# 1. Digital System Failure Modes

- Issue – Compatibility of EPRI and NRC Research treatments
  - Terms
  - Coverage / Level of interest
- Want consistent understanding of failure mechanisms, modes and effects for digital
- Important in PRA, hazard analysis, managing digital failure susceptibilities
- EPRI and NRC Research periodic meetings to share information
- For today's discussion - NRC Research addressed the details

## 2. Modeling Digital I&C in PRA

- EPRI projects started in 2004
  - Diversity and defense-in-depth
  - Estimating failure probabilities
  - Modeling level of detail
- Latest - *Modeling of Digital Instrumentation and Control in Nuclear Power Plant Probabilistic Risk Assessments*. 2012. (EPRI 1025278)
- Modeling is joint effort involving both I&C and PRA experts – considers:
  - I&C functions in context of the integrated plant design
  - Defensive measures in processes and designs that affect failure probability
  - Software is different – behaves **deterministically**, doesn't wear out, "fails" in unanticipated conditions

## 2. Modeling Digital I&C in PRA

### Insights

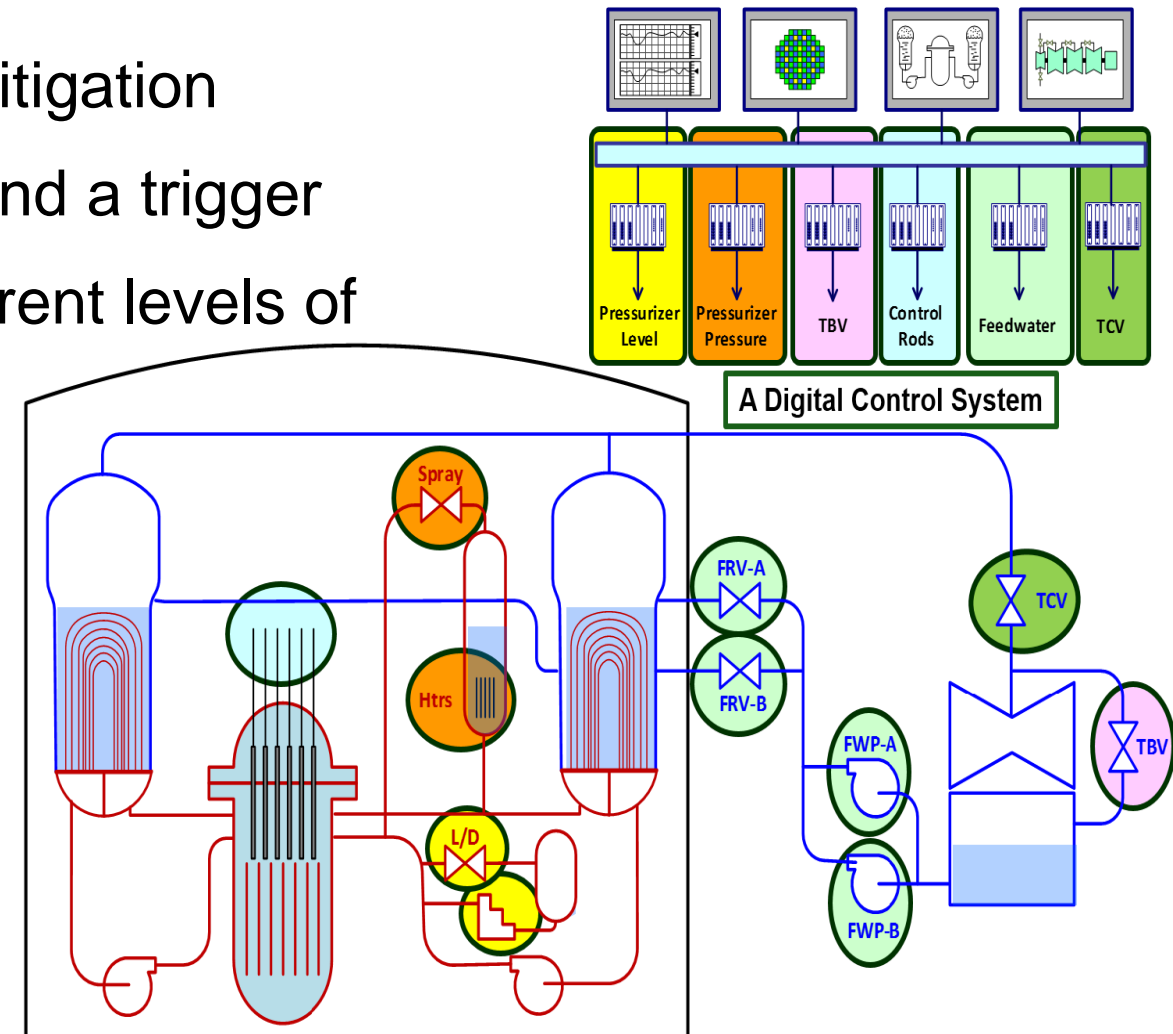

- Helpful to model digital systems in the PRA before they are installed:
  - Understand relative importance of I&C, full scope of the effects
  - Reliability target for I&C to be small contributor to risk
  - Influence the design
- The I&C can be designed such that the PRA is insensitive to its misbehaviors
  - To manage risk, the digital system reliability need only be similar to that of a comparable analog system
  - The defense-in-depth and diversity (D3) in the mechanical and electrical systems dictates the level of D3 that may be of value in the I&C

### 3. Techniques for Failure Prevention and Mitigation

- Ongoing project on assessing and managing digital failure/misbehavior susceptibilities, including common-cause failure (CCF)
  - Extend failure mode discussion to practical treatments and solutions
  - Apply results and lessons from earlier EPRI projects, industry standards, and industry guidance
  - Address safety and non-safety applications
  - Publish guideline late 2015
- More holistic approach
  - Assess susceptibility to failure/misbehavior of I&C and controlled components
  - Credit preventive measures (including diversity)
  - Apply risk insights
  - Use coping analysis where appropriate
  - Apply engineering judgment to assess overall protection
  - Document results in assurance case

# 3. Techniques for Failure Prevention and Mitigation

- Concepts / principles
  - Protection consists of prevention and mitigation
  - Software “failure” needs both a defect and a trigger
  - Protection can be accomplished at different levels of interest in plant architecture
  - Common-cause failure (CCF) has several contexts and initiators
  - Graded approach based on safety and operational significance
- The goal: assurance of adequate protection against effects of failures

### 3. Techniques for Failure Prevention and Mitigation

#### Assurance of Adequate Protection

Many potential contributors to assurance, e.g.,

- Traditional hardware practices - quality assurance, qualification testing, etc.
- Software development practices – e.g., standards, coding practices, etc.
- Defensive design measures in software, hardware, architecture, procedures, operation, etc.
- Mitigation and coping capability
- Extensive test coverage
- Performance records
- Risk and safety analysis insights
- Simplicity of digital platform and application

**Consider the evidence and apply engineering judgment to determine whether there is adequate protection**

## 4. Hazard Analysis Demonstration

### Project Objectives

- Trial application of EPRI guideline - *Hazard Analysis Methods for Digital Instrumentation and Control Systems* (EPRI 3002000509)
  - Looks at 6 methods – failure modes & effects, fault tree, etc.
- Capture lessons learned
  - Efficacy of methods
  - Learning / applying novel method

### Approach

- Plant takes lead in performing hazard analysis
- EPRI team provides training, coaching and reviews

## 4. Hazard Analysis Demonstration

### Palo Verde Exciter Replacement Project

- Replacing main generator exciters on three units (non-safety, but critical to generation):
  - Each exciter system (controller, rectifiers and peripherals) to be in its own new building, adjacent to turbine building, with dedicated HVAC
  - Building HVAC is critical to generation (i.e., less than 10 minutes before rectifiers overheat on loss of HVAC)
  - Each exciter system building is equipped with three redundant HVAC units, each sized for 100% heat load
- Hazard analysis methods applied to HVAC – primarily *Systems Theoretic Process Analysis* (STPA)

## 4. Hazard Analysis Demonstration Results

### **“Substantial Gain With Minimal cost”**

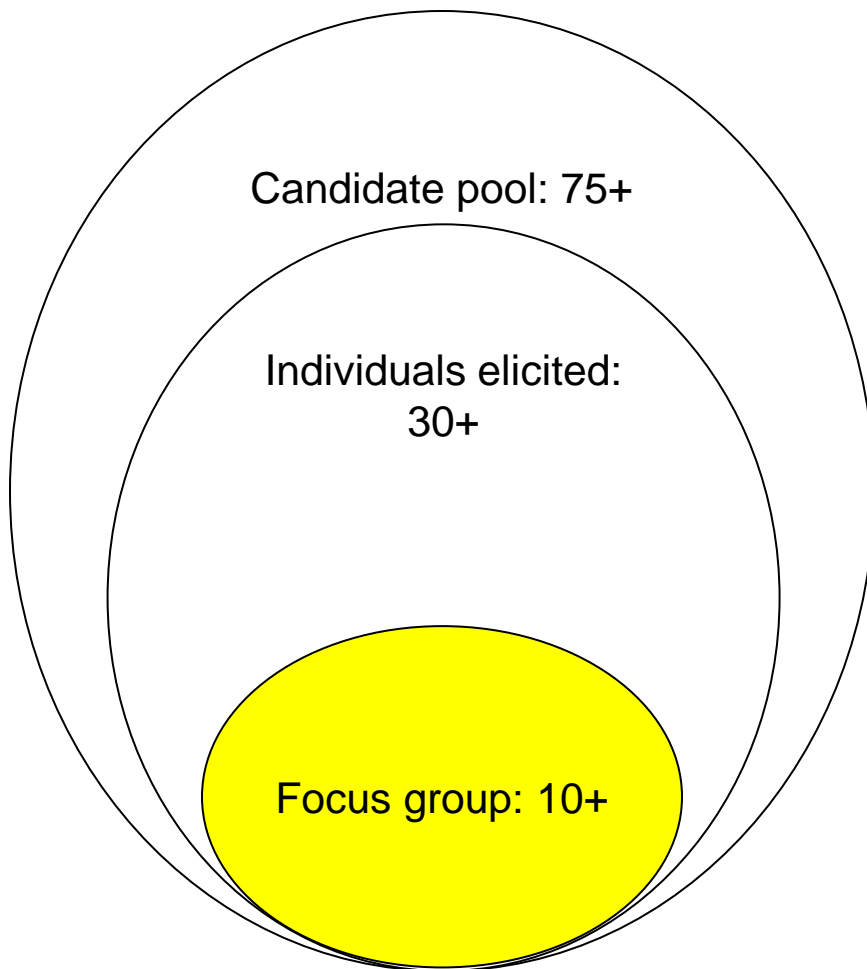

- Increase project success
  - Discovered unanticipated failure modes
  - Improved Design, Testing, Procedures, Training, Configuration Control, etc.
- Additional benefits
  - Increase staff knowledge
    - System training
    - Hazard analysis training
    - Facilitate handover to site personnel
  - Quick turnaround allows changes prior to implementation
  - Hazard analysis report helpful in design modification package
- Future plans
  - Investigating application to other projects

# Together...Shaping the Future of Electricity

# Backup Slides

# DE Expert Elicitation

- Significant technical knowledge and experience contributing to project objectives
  - Safety-/mission-critical DI&C systems
  - Elements of the NPP application domain
- Broad and integrative rather than narrowly specialized perspectives
- Ability to identify influencing factors and their inter-relationships
- Ability to identify failure modes, their causes, and their interrelationships
- No conflict of interest
- Availability

# Failure Mechanisms, Modes and Effects

- Failure mechanisms produce failure modes which in turn have failure effects on the system [NUREG-0492].
- As the level of analysis becomes more detailed:
  - Failure mechanisms become failure modes at the next level
  - Failure modes become failure effects at the next level

Level of Detail	Failure		
	Mechanism	Mode	Effect
Train	Valve Fails to Open	No Flow	
Component (Valve)	Stem Binding	Valve Fails to Open	No Flow
Subcomponent (Stem)	Corrosion of Stem	Stem Binding	Valve Fails to Open

# Digital System Failure Mode Terminology

Term	WGRisk/DRA	DE
Fault	Defect or abnormal condition that may cause a reduction in, or loss of, the capability of a functional unit to perform a required function ( <b>IEC 61508</b> ; “defect” added) [WGRisk].	The state of an item characterized by inability to perform a required function, excluding the inability during preventive maintenance or other planned actions, or due to lack of external resources ( <b>IEC 60050-191: IEC Vocabulary</b> ) [RIL-1002].
Failure	<p>Termination of the ability of a product to perform a required function or its inability to perform within previously specified limits (<b>ISO/IEC 25000:2005</b>) [WGRisk].</p> <p>Software Failure - The triggering of a defect of software, which results in, or contributes to, the host (digital) system failing to accomplish its intended function or initiating and unwanted event. [DRA Workshop]</p>	The termination of the ability of an item to perform a required function. (IEEE Standards Dictionary, <b>IEC 60050-191: IEC Vocabulary</b> ) [RIL-1002].
Failure Mode	The physical or functional manifestation of a failure ( <b>ISO/IEC/IEEE 24765:2010</b> ) [WGRisk].	<p>The effect by which a failure is observed to occur (modified from definition 1 in <b>IEEE Standards Dictionary</b>) [RIL-1002].</p> <p>The manner in which failure occurs. (modified from definition 4 in <b>IEEE Standards Dictionary</b>) [RIL-1002].</p>

# Common Concepts in Selected Terminology

Term	Common Concepts
Fault	<p>Unintentional impairment of desired or correct functioning.</p> <p>Faults are often revealed when triggered by a condition that was not considered or not thought possible to occur.</p> <p>Faults are systemic.</p>
Failure	<p>The termination of the ability of an item to perform a required function.</p>
Failure Mode	<p>The manner in which failure occurs.</p>

# RIL-1002 Cites DRA Research

- Set I and Set J in RIL-1002 were generated by DRA sponsored research projects.
- Set J: WGRisk Failure Mode Survey
  - Classify and organize digital I&C failure modes for the purposes of NPP PRAs or PSAs
  - No complete set of failure modes is developed
  - This taxonomy was demonstrated by an example study
    - Failure to actuate
    - Failure to actuate in time
    - Spurious actuation
    - Adverse effects on other functions
    - Loss of function
    - Loss of communication
    - No actuation signal when demanded

# RIL-1002 Cites EPRI Research

- Set K was added to RIL-1002 per ACRS comments.
  - No function
  - Partial function
  - Over function
  - Degraded function
  - Intermittent function
  - Unintended function
- Set K was found in EPRI report: Hazards Analysis Methods for Digital Instrumentation and Control Systems.

Nine Mile Point Nuclear Station*

**Exelon** Generation®

## Limitations and Conditions

---

- NMP2 Complies with all applicable Limitations and Conditions
  - 14 applicable section 9 Methods SER (NEDC-33173P-A rev 4)
  - 47 applicable section 12 MELLLA+ SER (NEDC-33006P-A rev 3)
  - 4 section 5 DSS-CD SER (NEDC-33075P-A rev 7)
- Operating Flexibility Limitation and Condition Compliance
  - 12.5.a: Technical specifications amended to prohibit operation in Single Loop Operation (SLO) in the MELLLA and MELLLA+ region
  - 12.5.b: The existing NMP2 License Condition 7 restricts operation with FW heating to within 20 degrees of the design FW temperature which satisfies M+ LTR SER Limitation and Condition
  - 12.5.c: The NMP2 MELLLA+ COLR includes the NMP2 plant specific power-flow map specifying the license domain

## Key Features of the NMP2 MELLLA+ LAR

---

- Design and Analysis credits Boron-10 92 atom % to maintain margin to HCTL (Heat Capacity Temperature Limit) as per MELLLA+ LTR L&C 12.18b.
  - Improves Margin to HCTL compared to EPU conditions by reducing impact on suppression pool temperature
  - Increases Standby Liquid system pump redundancy
- Design and Analysis credit NMP2 Redundant Reactivity Control System (RRCS) design attributes for automatic injection of Standby Liquid control System (SLS) and automatic feedwater flow runback
  - Improves operator action response time requirements to mitigate ATWS for MELLLA+

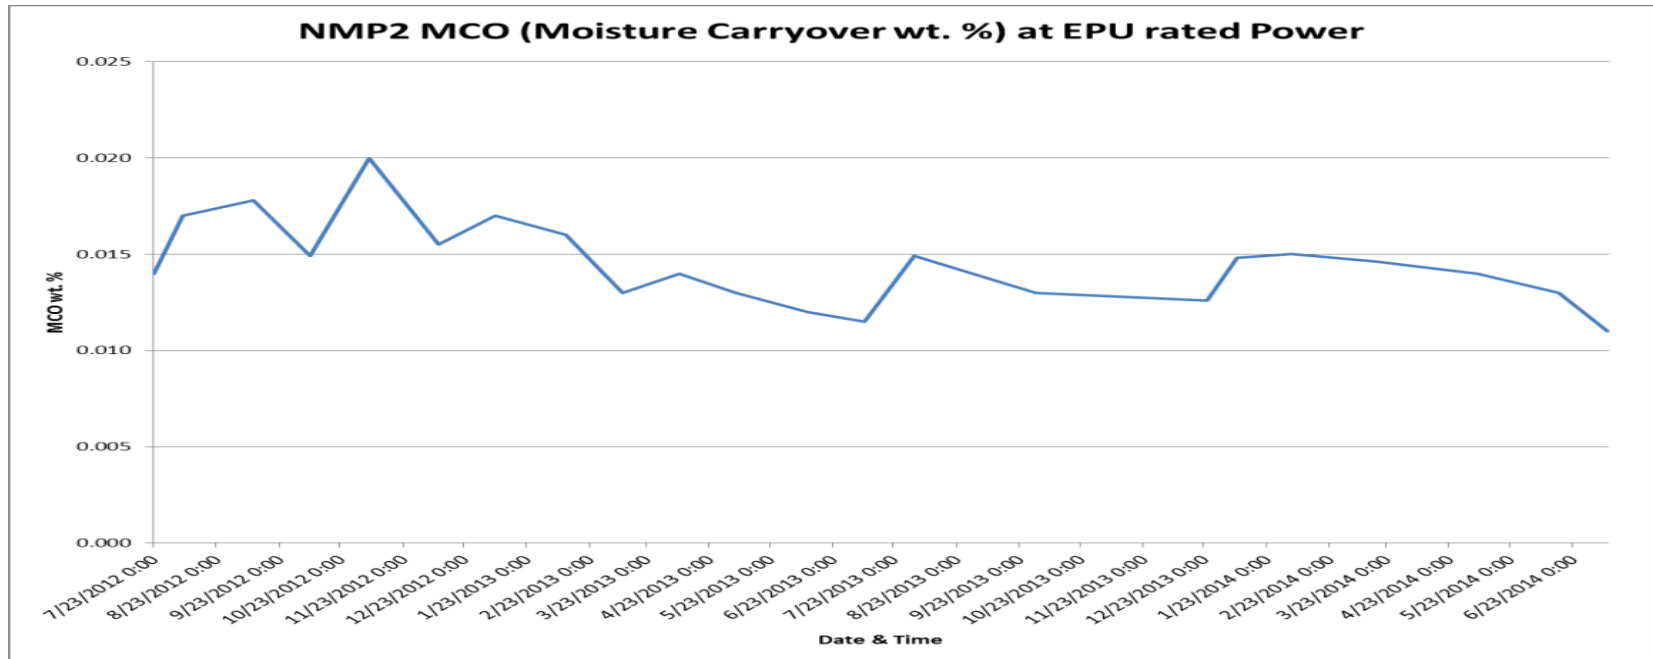

# NMP2 Redundant Reactivity Control System

---

- The NMP2 Redundant Reactivity Control System (RRCS) system includes two automatic features important for ATWS with Core Instability (ATWS-I) considerations:
  - Automatic SLS pump start on Hi reactor pressure, with APRMs not downscale
    - Nominal delay setting 98 seconds (RRCS has digital timers with minimal setpoint drift)
    - Analysis assumes 120 second initiation delay
  - Automatic feedwater runback on Hi reactor pressure, with APRMs not downscale
    - Nominal delay setting 25 seconds
    - Analysis assumes 33 second initiation delay
    - Runback from 100% to 0% in 21 seconds and automatically open FW pump minimum flow
- Operator actions required for Dual Recirculation pump trip where Hi reactor pressure is not reached:
  - Initiate manual scram within 20 seconds
  - Initiate manual FW runback within 270 seconds

# NMP2 MELLA+ Predicted MCO & EPU Operating Experience

- Maximum calculated MCO = 0.236 wt% for M+ conditions Point N (EPU rated / 85% core flow)
- Analyzed for MCO up to 0.35 wt%, Outboard MSIV is limiting component restricting MCO to below 0.25 wt%
- Actual EPU operating Main Steam Moisture Carryover (MCO) remained essentially unchanged from Pre-EPU power level measured MCO
- The EPU/MELLA+ transition core has similar characteristics

# NMP2 MELLA+ Testing

Tests	Basis	Variability
22- Pressure Regulator Setpoint Changes	Core responsiveness to pressure perturbation at the M+ rod line / higher void condition	Low - Sensitivity dominated by M+ rod line
23A- Water Level Setpoint changes	Core responsiveness to feedwater injection at the M+ rod line / higher void condition	Low - Sensitivity dominated by M+ rod line
99A- Neutron Flux Noise	Confirm APRM and LPRM noise remains bounded by setpoint calculation assumptions	Low - Sensitivity dominated by M+ rod line, possibility of increased bi-stable flow effects
99C- Stability Monitor Performance	Monitor OPRM data and confirm the plant noise level is within the expected range	Low - Sensitivity dominated by M+ rod line
1B-Steam Moisture	Test established MCO baseline at multiple points in M+ region	<ul style="list-style-type: none"> <li>- This is a baseline test, results are sensitive to cycle exposure rod patterns</li> <li>- Core design monitored through cycle by procedure</li> </ul>
99B -TIP Power Distribution 19 – Core Performance	Test results assessed against cycle specific predictions	<ul style="list-style-type: none"> <li>- This is a baseline test, results are sensitive to cycle exposure rod patterns</li> <li>- Core design monitored through cycle by procedure</li> </ul>

# MELLLA+ Operator Actions, Validation and Training

**Dan Cifonelli**

*NMP2 Shift Manager, Exelon  
Nine Mile Point Nuclear Station*

**Exelon** Generation®

# Time Critical Operator Actions & Validation

---

Two ATWS-I Mitigating Strategy Operator Actions have been re-classified as Time Critical Operator Actions.

1. 20 seconds insert a Manual Scram using the Mode Switch  
- Provides additional Scram signal and bypasses the low pressure MSIV Isolation
2. 270 seconds to Terminate and Prevent injection in a dual Recirc Pump Trip  
- Step L-9 in N2-EOP-C5, Mitigates power oscillations to a PCT of 912 °F

These actions times were validated in September 2014 per OP-AA-102-106, Operator Response Time Program.

1. A validation team including Engineers, Qualified Simulator and Operations Instructor, Shift Manager, and four active on-shift operating crews during a 5-week training cycle
2. The crews performed each action (Scram, Terminate and Prevent Injection into the Reactor Vessel (T/P)) while controlled by Qualified Instructor and Observed by Validation Team Members (time data captured by simulator computer and observers using watches)
3. Five scenarios were used for Scram data, one (Dual Recirc Pump Trip) used for T/P data gathering
4. Validation included minimum staffing review to test sensitivity of time to reduced staff. Reduced staffing had no measurable impact on times due to procedural priority, operator knowledge/proficiency, simplicity of tasks and action performance requires one operator.

# Time Critical Operator Actions & Validation Results

---

## Validation Results

1. Time Action 1: 5 to 16 seconds with an average of 8.5 seconds
  - Average Time is 43% of Required Time (20 seconds)
2. Time Action 2: 150 to 232 seconds with an average of 193 seconds
  - Average Time was 71.5% of Required Time (270 seconds)
3. Demonstrated times have significant margin to required times, which account for uncertainties, stress, event recognition, action planning, team communication and verification practices.
4. Required recognition instrumentation, controls manipulated and operator actions can be performed in front panels of the Control Room by a single operator.
5. Actions are controlled by formal procedures.
6. Validation reports were submitted to the NRC post Simulator Audit.

Actions are consistent with current Operator training, knowledge and proficiency. No procedure changes or training changes are needed to assure actions are met. The importance of timely reduction of reactor vessel water level to below the feedwater sparger to reduce subcooling and mitigate oscillations in an ATWS, has been and is reinforced during Licensed Operator training.

# Operator Training and Readiness

---

- June 2014 Initial Classroom Training
- August 2014 Initial Simulator Training
- January 2015 Classroom/Simulator Reinforcement
- May 2015 Reviewed Industry Instability OE
- July 2015 Simulator Continuing Training
- Just In Time Training for Implementation

Conclusion: Operations is ready for MELLLA+ implementation

# Review Timeline

- November 1, 2013 – MELLLA+ application submitted to NRC
- Acceptance Review completed with Supplemental Information from the Licensee on January 21, 2014. Additional Supplemental Information Received on February 25, 2014.
- Revised Application Dated June 13, 2014, to reflect the completion of Implementation of changes related to Standby Liquid Control System received.
- Multiple rounds of RAIs Issued to Licensee on the topics of Reactor Systems, Instrumentation & Controls, Human Factors, etc. Licensee responses received between March 10, 2014 to February 20, 2015.
- The NRC staff performed audit at NMP-2 on Nov 20, 2014

# **Licensing Actions Related to MELLLA+ Amendment**

The licensee's existing license condition and the proposed technical specification changes support the MELLLA+ Application

- Proposed technical Specification change for TS LCO 3.4.1 prohibits single loop operation in MELLLA+ domain
- Existing license Condition 7 restricts Feedwater Heater out of Service by imposing a 20°F FW temperature band

# Licensing Actions Related to MELLLA+ Amendment

The licensee's existing license condition and the proposed numerous technical specification (TS) changes support the MELLLA+ application

- Proposed TS change for TS LCO 3.4.1 prohibits single loop operation in MELLLA+ domain
- Existing License Condition 7 restricts feedwater heater out of service by imposing a 20°F FW temperature band
- Some of the TS changes are:
  - Revision of Safety Limit (SL) in TS 2.1.1.2 by increasing the SLMCPR for two recirculation loops in operation from  $\geq 1.07$  to  $\geq 1.09$ .
  - Revision of the acceptance criterion in TS Surveillance Requirement (SR) 3.1.7.7 by increasing the discharge pressure from  $\geq 1,327$  pounds per square inch gauge (psig) to  $\geq 1,335$  psig.
