NRC-009-R

Final Safety Evaluation Report for Combined Licenses for William States Lee III Nuclear Station Units 1 and 2

U. S. Nuclear Regulatory Commission
Office of New Reactors
Washington, DC 20555-0001

August 2016

ABSTRACT

This final safety evaluation report[1] (FSER) documents the U.S. Nuclear Regulatory Commission (NRC) staff's technical review of the combined license (COL) application submitted by the applicant for the William States Lee III Nuclear Station (WLS) Units 1 and 2. The applicant, Duke Energy Carolinas, LLC (DEC or the applicant), is a wholly owned subsidiary of Duke Energy Corporation.

By letter dated December 12, 2007, the applicant submitted its application to the NRC for COLs for two AP1000 advanced passive pressurized-water reactors pursuant to the requirements of Sections 103 and 185(b) of the Atomic Energy Act of 1954, as amended; Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, certifications and approvals for nuclear power plants," and the associated material licenses under 10 CFR Part 30, "Rules of general applicability to domestic licensing of byproduct material"; 10 CFR Part 40, "Domestic licensing of source material"; and 10 CFR Part 70, "Domestic licensing of special nuclear material." These reactors are identified as WLS Units 1 and 2, and would be located at a greenfield site in Cherokee County, South Carolina. The applicant submitted its final update to the COL application, Revision 11, on April 11, 2016.

The application incorporated by reference 10 CFR Part 52, Appendix D, "Design Certification Rule for the AP1000 Design," including the AP1000 Design Certification Document (DCD) Revision 19. The results of the NRC staff's evaluation of the AP1000 DCD are documented in NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," and its supplements.

This FSER presents the results of the staff's review of information submitted in conjunction with the COL application, except those matters resolved as part of the referenced design certification rule. Appendix A to this FSER identifies certain license conditions and inspections, tests, analyses and acceptance criteria (ITAAC) that the staff recommends the Commission impose, should COLs be issued to the applicant. In addition to the ITAAC in Appendix A, the ITAAC found in the AP1000 DCD Revision 19 Tier 1 material will also be incorporated into the COLs, should COLs be issued to the applicant.

[1] This FSER documents the NRC staff's position on all safety issues associated with the combined license application. The Advisory Committee on Reactor Safeguards (ACRS) independently reviewed those aspects of the application that concern safety, as well as the advanced safety evaluation report without open items (an earlier version of this document), and provided the results of its review to the Commission in reports dated December 14, 2015 and April 18, 2016. These reports are included as Appendix F to this FSER.

The staff's review[2] of the application, as documented in this FSER, supports the following conclusions with respect to the safety aspects of the COL application: 1) the applicable standards and requirements of the Atomic Energy Act and Commission regulations have been met; 2) required notifications to other agencies or bodies have been duly made; 3) there is reasonable assurance that the facility will be constructed and will operate in conformity with the license, the provisions of the Atomic Energy Act, and the Commission's regulations; 4) the applicant is technically and financially qualified to engage in the activities authorized; and 5) issuance of the license will not be inimical to the common defense and security or to the health and safety of the public.

[2] An environmental review was also performed of the COL application, and its evaluation and conclusions are documented in NUREG-2111, "Final Environmental Impact Statement for Combined Licenses for William States Lee III Nuclear Station Units 1 and 2," dated December 2013.

CONTENTS

The chapter and section layout of this FSER is consistent with the format of (1) NUREG-0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition)"; (2) Regulatory Guide (RG) 1.206, "Combined License Applications for Nuclear Power Plants"; and (3) the applicant's final safety analysis report (FSAR). Where applicable, references to other regulatory actions (e.g., design certifications) are included in the text of the safety evaluation report (SER).

APPENDICES

LIST OF FIGURES

LIST OF TABLES

EXECUTIVE SUMMARY

The U.S. Nuclear Regulatory Commission (NRC) regulations in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52 include requirements for licensing new nuclear power plants.[3] These regulations include the NRC's requirements for design certification and combined license (COL) applications. The COL process (10 CFR Part 52, Subpart C, "Combined Licenses") allows an applicant to seek authorization to construct and operate a new nuclear power plant.

This FSER describes the results of a review by the NRC staff of a COL application submitted for two new reactors to be located at the William States Lee III Nuclear Station (WLS) Units 1 and 2 site. The applicant is Duke Energy Carolinas, LLC (DEC). The staff's review was to determine the applicant's compliance with the requirements of Subpart C of 10 CFR Part 52, as well as the applicable requirements under 10 CFR Parts 30, 40, and 70 governing the possession and use of source, byproduct and special nuclear materials. This FSER identifies the staff's conclusions with respect to the COL safety review.

The NRC regulations in 10 CFR Part 51, "Environmental protection regulations for domestic licensing and related regulatory functions," also require an applicant to submit an environmental report. The NRC reviews the environmental report as part of the Agency's responsibilities under the National Environmental Policy Act of 1969, as amended. The NRC presents the results of that review in a final environmental impact statement (FEIS), which is a report separate from this FSER. The staff's FEIS, NUREG-2111, "Final Environmental Impact Statement for Combined Licenses (COLs) for William States Lee II Nuclear Station Units 1 and 2," was issued in December 2013, and can be accessed through the Agencywide Documents Access and Management System (ADAMS) at Accession Nos. ML13340A005, ML13340A006, and ML13340A007.[4]

---

[3] Applicants may also choose to seek a construction permit (CP) and operating license in accordance with 10 CFR Part 50, "Domestic licensing of production and utilization facilities," instead of using the 10 CFR Part 52 process.

[4] The Agencywide Documents Access and Management System (ADAMS) is the NRC's information system that provides access to all image and text documents that the NRC has made public since November 1, 1999, as well as bibliographic records (some with abstracts and full text) that the NRC made public before November 1999. Documents available to the public may be accessed via the Internet at http://www.nrc.gov/reading-rm/adams.html#web-based-adams. Documents may also be viewed by visiting the NRC's Public Document Room at One White Flint North, 11555 Rockville Pike, Rockville, Maryland. Telephone assistance for using web-based ADAMS is available at (800) 397-4209 between 8:30 a.m. and 4:15 p.m., Eastern Time, Monday through Friday, except Federal holidays. The staff is also making this FSER available on the NRC's new reactor licensing public web site at http://www.nrc.gov/reactors/new-reactors/col/levy/documents.html.

By letter dated December 12, 2007, the applicant submitted its initial application to the NRC for COLs for two AP1000 advanced passive pressurized-water reactors (PWRs) (ADAMS Accession No. ML073510494) to be located at the WLS site. The application identified the two units as WLS Units 1 and 2. The WLS site is located in Cherokee County, South Carolina, approximately 35 miles southwest of Charlotte, North Carolina, approximately 25 miles northeast of Spartanburg, South Carolina, and approximately 7.5 miles southeast of Gaffney, South Carolina.

The application incorporated by reference 10 CFR Part 52, Appendix D, “Design Certification Rule for the AP1000 Design,” including the AP1000 Design Certification Document (DCD) Revision 19. The results of the NRC staff’s evaluation of the AP1000 DCD are documented in NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design,” and its supplements. The applicant submitted its final update to the COL application, Revision 11, on April 11, 2016.

Appendix A to this FSER identifies certain license conditions, and inspections, tests, analyses and acceptance criteria (ITAAC) that the staff recommends the Commission impose, should COLs be issued to the applicant. In addition to the ITAAC in Appendix A, the ITAAC found in the AP1000 DCD Revision 19 Tier 1 material will also be incorporated into the COLs should COLs be issued to the applicant.

Inspections and audits conducted by the NRC have verified, where appropriate, the conclusions in this FSER. The inspections focused on selected information in the COL application and its references. The FSER identifies applicable inspection reports as reference documents.

The NRC’s Advisory Committee on Reactor Safeguards (ACRS) also reviewed the bases for the conclusions in this report. The ACRS independently reviewed those aspects of the application that concern safety, as well as the advanced safety evaluation report without open items (an earlier version of this document), and provided the results of its review to the Commission in a report dated December 14, 2015. Appendix F includes a copy of this report by the ACRS on the COL application, as required by 10 CFR 52.87, “Referral to the Advisory Committee on Reactor Safeguards (ACRS).”

1 INTRODUCTION AND INTERFACES

This chapter of the final safety evaluation report (FSER) is organized as follows:

- Section 1.1 provides an overview of the entire combined license (COL) application
- Section 1.2 provides the regulatory basis for the COL licensing process
- Section 1.3 provides an overview of the COL application principal review matters and where the staff's review of the 10 parts of the COL application is documented
- Section 1.4 documents the staff's review of Chapter 1 of the final safety analysis report (FSAR)
- Section 1.5 documents regulatory findings that are in addition to those directly related to the staff's review of the FSAR

1.1 Summary of Application

In a December 12, 2007, letter as supplemented by several additional letters, Duke Energy Carolinas, LLC (DEC or the applicant), a wholly owned subsidiary of Duke Energy Corporation, submitted an application to the U.S. Nuclear Regulatory Commission (NRC or the Commission) for a combined license (COL) for two Westinghouse AP1000 advanced passive pressurized water reactors (PWRs) pursuant to the requirements of Sections 103 and 185(b) of the *Atomic Energy Act*, and Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications and Approvals for Nuclear Power Plants." These reactors will be identified as William States Lee III Nuclear Station (WLS), Units 1 and 2, and will be located in the eastern portion of Cherokee County in north central South Carolina, approximately 35 miles southwest of Charlotte, North Carolina; approximately 25 miles northeast of Spartanburg, South Carolina; and approximately 7.5 miles southeast of Gaffney, South Carolina. DEC will be the licensed owner and operator of WLS Units 1 and 2.

According to the COL application, Duke Energy Carolinas, LLC, is a limited liability company duly organized and existing under the laws of the State of North Carolina. It is engaged in the business of generating, transmitting, distributing and selling electric power and energy. It is a "public utility" under the laws of North Carolina and subject to the jurisdiction of the North Carolina Utilities Commission (NCUC) with respect to its operations in that State. The company also transacts business and is an "electrical utility" under the laws of the State of South Carolina; accordingly, its operations in that State are subject to the jurisdiction of the Public Service Commission of South Carolina (PSCSC). DEC owns and operates regulated electrical facilities, including seven (7) nuclear units licensed by the NRC, as well as electrical distribution and transmission facilities.

The COL application incorporates the Design Control Document (DCD) for a simplified passive advanced light water reactor plant provided by Westinghouse Electric Corporation, the entity originally sponsoring and obtaining the AP1000 design certification documented in 10 CFR Part 52, Appendix D, Design Certification Rule for the AP1000 Design.

In addition, as discussed in Section 1.5.5 of this report, the applicant submitted a request for the associated material licenses under 10 CFR Part 30, “Rules of General Applicability to Domestic Licensing of Byproduct Material”; 10 CFR Part 40, “Domestic Licensing of Source Material”; and 10 CFR Part 70, “Domestic Licensing of Special Nuclear Material.”

Unless otherwise noted, this FSER (also referred to as the safety evaluation report (SER) or advanced safety evaluation (ASE) in later sections of this document) is based on Revision 11 of the WLS COL application, which was submitted in April 11, 2016.

As indicated in the applicant’s April 11, 2016 submission, the applicant incorporated by reference 10 CFR Part 52, Appendix D, “Design Certification Rule for the AP1000 Design,” and the Westinghouse Electric Corporation’s (Westinghouse’s) application for amendment to portions of the Design Control Document (DCD) Revision 19.

The AP1000 nuclear reactor design is a PWR with a power rating of 3400 megawatts thermal (MWt) and an electrical output of at least 1000 megawatts electric (MWe). The AP1000 design uses safety systems that rely on passive means, such as gravity, natural circulation, condensation and evaporation, and stored energy, for accident prevention and mitigation.

In developing the FSER for WLS Units 1 and 2, the staff reviewed the AP1000 DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to a particular review topic.

The WLS COL application is organized as follows:

- **Part 1 General and Administrative Information**

Part 1 provides an introduction to the application and includes certain corporate information regarding DEC pursuant to 10 CFR 50.33(a) – (d).

- **Part 2 Final Safety Analysis Report**

Part 2 includes information pursuant to the requirements of 10 CFR 52.79, “Contents of applications; technical information in final safety analysis report” and, in general, adheres to the content and format guidance provided in Regulatory Guide (RG) 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition).”

- **Part 3 Environmental Report**

Part 3 includes environmental information pursuant to the requirements of 10 CFR 52.80, “Contents of applications; additional technical information” and 10 CFR 51.50(c).

- **Part 4 Technical Specifications**

Part 4 addresses how the AP1000 Generic Technical Specifications (GTS) and Bases are incorporated by reference into the WLS Plant-Specific Technical Specifications (PTS) and Bases. Specifically, Section A addresses completion of bracketed information. Section B provides a complete copy of the WLS PTS and Bases.

- **Part 5 Emergency Plan**

Part 5 includes the WLS COL Emergency Plan, supporting information (e.g., evacuation time estimates (ETEs)), and applicable offsite State and local emergency plans.

- **Part 6 [Not Used - reserved for Limited Work Authorization/site redress information]**

- **Part 7 Departures Report**

Part 7 includes information regarding “departures” and “exemptions.” “Departures” refers to departures from the AP1000 DCD, Revision 19, incorporated by reference into the COL application. For each departure, Part 7 of the COL application identifies the portions of the AP1000 DCD and FSAR affected and includes a description, a justification, an evaluation against criteria in 10 CFR 52.63(b), and a concluding statement about whether the departure requires NRC approval pursuant to 10 CFR Part 52, Appendix D, Section VIII.B.5.

“Exemptions” refers to requests for exemptions from NRC regulations. For each exemption request, Part 7 identifies the regulation and specific wording from which an exemption is being requested and provides a discussion supporting the request.

- **Part 8 Security Plan**

Part 8 addresses the WLS Safeguards/Security Plan, which consists of the Physical Security Plan, the Training and Qualification Plan, the Safeguards Contingency Plan, and the Special Nuclear Material (SNM) Physical Protection Program Description. These security plans are submitted to the NRC as a separate licensing document in order to fulfill the requirements of 10 CFR 52.79(a)(35) and 10 CFR 52.79(a)(36). The Safeguards/Security Plan is categorized as Security Safeguards Information and is withheld from public disclosure pursuant to 10 CFR 73.21, “Protection of safeguards information: performance requirements.” The staff’s evaluation of the Safeguards and Security Plans is documented separately from this SER and is withheld from the public in accordance with 10 CFR 73.21. A non-sensitive summary of the staff’s evaluation of those plans is provided in Section 13.6 of this SER.

- **Part 9 Withheld Information**

Part 9 identifies sensitive information that is withheld from public disclosure under 10 CFR 2.390, “Public inspections, exemptions, requests for withholding.” The information in this part includes sensitive unclassified non-safeguards information (SUNSI), proprietary financial information, and figures from Part 2 of the application that meet the SUNSI guidance for withholding from the public. In addition, this part of the application includes the following information:

- The withheld portion of the Mitigative Strategies Description and Plans for loss of large areas of the plant due to explosions or fire, as required by 10 CFR 52.80(d)
- WLS Units 1 and 2 Cyber Security Plan, as required by 10 CFR 73.54, “Protection of Digital Computer and Communication Systems and Networks”
- The withheld portions of the COL application Part 2 – FSAR
- The withheld portions of the COL application Part 5 – Emergency Plan

- Administrative and Financial Information

- The staff's evaluation of the Safeguards and Security Plans is documented separately from this SER and is withheld from the public in accordance with 10 CFR 73.21. A non-sensitive summary of the staff's evaluation of those plans is provided in Section 13.6 of this SER.

- **Part 10 Proposed Combined License Conditions (Including ITAAC)**

Part 10 includes WLS proposed license conditions including inspections, tests, analyses, and acceptance criteria (ITAAC) information in accordance with 10 CFR 52.80. A table of the proposed license conditions is provided in Appendix A of this report.

The contents of the environmental protection plan (and associated license conditions) are not evaluated in this report. Part 10 of the application incorporates by reference the AP1000 DCD Tier 1 information including ITAAC. In addition, the application includes site-specific ITAAC (e.g., emergency planning, physical security, electrical, and piping).

- **Part 11 Enclosures**

Part 11 provides information submitted by the applicant in support of the WLS Units 1 and 2 application. Specifically, these sections include:

- Part 11A describes the DEC new nuclear deployment Quality Assurance Program Description (QAPD). The QAPD is the top-level policy document that establishes the quality assurance (QA) policy and assigns major functional responsibilities for COL/construction/preoperation and operation activities conducted by or for DEC.

- Part 11B includes mitigative strategies description and plans for loss of large areas of the plant due to explosions or fire, as required by 10 CFR 52.80(d).

- Part 11C of the application includes the cyber security plan. The SUNSI version of the cyber security plan is provided in Part 9 of the application.

- Part 11D of the application includes WLS Special Nuclear Material Control and Accounting Program Description.

- Part 11E of the application includes the new fuel shipping plan.

- Part 11F of the application contains supplemental information in support of the 10 CFR Part 70, "Domestic licensing of special nuclear material," special nuclear material license application.

1.2 Regulatory Basis

1.2.1 Applicable Regulations

10 CFR Part 52, Subpart C, "Combined Licenses," sets out the requirements and procedures applicable to Commission issuance of a COL for nuclear power facilities. The following are of particular significance:

- 10 CFR 52.79, “Contents of applications; technical information in final safety analysis report,” identifies the technical information for the FSAR
- 10 CFR 52.79(d) provides additional requirements for a COL referencing a standard certified design
- 10 CFR 52.80, “Contents of applications; additional technical information,” provides additional technical information outside of the FSAR (ITAAC and the environmental report)
- 10 CFR 52.81, “Standards for review of applications,” provides standards for reviewing the application
- 10 CFR 52.83, “Finality of referenced NRC approvals; partial initial decision on site suitability,” provides for the finality of referenced NRC approvals (i.e., standard design certification)
- 10 CFR 52.85, “Administrative review of applications; hearings,” provides requirements for administrative reviews and hearing
- 10 CFR 52.87, “Referral to the Advisory Committee on Reactor Safeguards (ACRS),” provides for referral to the ACRS

The staff reviewed this application according to the standards set out in:

- 10 CFR Part 20, “Standards for Protection Against Radiation”
- 10 CFR Part 30, “Rules of general applicability to domestic licensing of byproduct material”
- 10 CFR Part 40, “Domestic licensing of source material”
- 10 CFR Part 50, “Domestic licensing of production and utilization facilities”
- 10 CFR Part 51, “Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions”
- 10 CFR Part 52, “Licenses, Certifications, and Approvals for Nuclear Power Plants”
- 10 CFR Part 55, “Operators’ Licenses”
- 10 CFR Part 70, “Domestic Licensing of Special Nuclear Material”
- 10 CFR Part 73, “Physical Protection of Plants and Materials”
- 10 CFR Part 74, “Material Control and Accounting of Special Nuclear Material”
- 10 CFR Part 100, “Reactor Site Criteria”
- 10 CFR Part 140, “Financial Protection Requirements and Indemnity Agreements”

The staff evaluated the application against the acceptance criteria provided in the following:

- NUREG-0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition”
- NUREG-1555: “Standard Review Plans for Environmental Reviews for Nuclear Power Plants”
- NUREG-1577, “Standard Review Plan on Power Reactor Licensee Financial Qualifications and Decommissioning Funding Assurance”
- NUREG-0800, “Standard Review Plan on Foreign Ownership, Control, or Domination”

In addition, the staff considered the format and content guidance in RG 1.206[1] for the COL application.

1.2.2 Finality of Referenced NRC Approvals

In accordance with 10 CFR 52.83, “Finality of referenced NRC approvals; partial initial decision on site suitability,” if the application for a COL references a design certification rule (DCR), the scope and nature of matters resolved in the design certification (DC) for the application and any COL issued are governed by the relevant provisions. For the AP1000 DCR, finality is based on 10 CFR 52.63, “Finality of standard design certifications.”

Based on the finality afforded to referenced certified designs, the scope of this COL application review, as it relates to the referenced certified design, is limited to items that fall outside the scope of the certified design (e.g., COL information items, design information replacing conceptual design information (CDI), and programmatic elements that are the responsibility of the COL, and departures from the certified design).

The contents of the application are specified in 10 CFR 52.79(a), which requires the information submitted in the FSAR to describe the facility; identify the design bases and the limits on its operation; and present a safety analysis of the structures, systems, and components (SSCs) of the facility as a whole. For a COL application that references a DC, Section 10 CFR 52.79(d) requires the AP1000 DCD to be included in the FSAR or incorporated by reference into the FSAR. Addition, a COL application the references a design certification (DC) must also contain the information and analysis required to be submitted within the scope of the COL application but is outside the scope of the AP1000 DCD. This combined information addresses plant- and site-specific information and includes all COL action or information items; design information the replaces CDI; and programmatic information that was not review and approved in connection with the DC rulemaking.

During its evaluation of the COL application, the staff confirmed that the complete set of information required to be addressed in the COL application was addressed in the DC, the DC

---

[1] 10 CFR Part 52, Appendix D, Section IV.A.2.a requires the COL application to include a plant-specific DCD that describes the same type of information and uses the same organization and numbering as the generic DCD. The generic DCD used RG 1.70, “Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants (LWR Edition),” Revision 3 as a guide for the format and content. RG 1.206 was issued after the initial certification of the AP1000; thus, there are anticipated differences between the WLS Units 1 and 2 COL application and the guidance of RG 1.206.

as supplemented by the COL application or completely included in the COL application. Following this confirmation, the staff's review of the COL application is limited to the COL review items.

1.2.3 Overview of the Design-Centered Review Approach

The design-centered review approach (DCRA) is described in Regulatory Issue Summary (RIS) 2006-06, "New Reactor Standardization Needed to Support the Design-Centered Licensing Review Approach." The DCRA is endorsed by the Commission's Staff Requirements Memorandum (SRM) SECY-06-0187, "Semiannual Update of the Status of New Reactor Licensing Activities and Future Planning for New Reactors," November 16, 2006. The DCRA, which is the Commission's policy intended to promote standardization of COL applications, is beyond the scope of information included in the DC. This policy directs the staff to perform one technical review for each standard issue outside the scope of the DC, and use this decision to support decisions on multiple COL applications. In this context, "standard" refers to essentially identical information. In some cases the staff has expanded the use of this standard approach to other areas with essentially identical information for regulatory purposes. For example, the QA plan for the AP1000 COL applicants is essentially identical with the exception of title names being different. Other areas where this approach was used include cyber security, technical specifications, and loss of large area fire reviews and may include information provided by the applicant(s) to resolve plant-specific issues.

The first COL application submitted for staff review is designated in a design center as the reference COL (RCOL) application, and the subsequent applications in the design center are designated as subsequent COL (SCOL) applications. The WLS Units 1 and 2 COL application has been designated as an SCOL application in the AP1000 design center[2].

DEC, as an SCOL applicant in the AP1000 design center, organized and annotated its FSAR, Part 2 of the COL application, to clearly identify: (a) sections that incorporate by reference the AP1000 DCD; (b) sections that are standard for COL applicants in the AP1000 design center; and (c) sections that are site-specific and thus only apply to WLS Units 1 and 2. The following notations have been used by the applicant for the departures from and/or supplements to the referenced DCD included in this COL application:

- STD – standard (STD) information that is identical in each COL referencing the AP1000
- WLS – plant-specific information that is specific to this application
- DEP – represents a departure (DEP) from the AP1000 DCD
- COL – represents a COL information item identified in the AP1000 DCD

---

[2] In an April 28, 2009, letter, the NuStart Energy Development, LLC, consortium informed the NRC that it had changed the RCOL designation for the AP1000 design center from Bellefonte Nuclear Plant (BLN) Units 3 and 4 to the Vogtle Electric Generating Plant (VEGP) Units 3 and 4. The transition of the RCOL from BLN Units 3 and 4 to VEGP Units 3 and 4 occurred after the issuance of the BLN Units 3 and 4 SER with open items. As part of the transition, the staff concluded that the BLN evaluation material identified as Standard (STD COL, STD SUP, STD DEP and Interfaces for Standard Design) in the BLN SER was directly applicable to the VEGP review. As a result, standard content material from the SER for the RCOL (VEGP) application and referenced in the WLS SER includes evaluation material from the SER for the BLN COL application.

- SUP – represents information that supplements (SUP) information in the AP1000 DCD

- CDI – represents design information replacing conceptual design information (CDI) included in the AP1000 DCD but not addressed within the scope of the AP1000 DCD review

The following text is added to the Technical Evaluation sections in this report whenever the staff uses standard content evaluation material to resolve departures and/or supplements to the referenced DCD:

> Section 1.2.3 of this SER provides a discussion of the strategy used by the NRC to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (Vogtle Electric Generating Plant [VEGP] Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:
>
> - The staff compared the VEGP COL FSAR, Revision 5 to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from requests for additional information (RAIs).
>
> - The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.
>
> - The staff verified that the site-specific differences were not relevant.
>
> The staff has completed its review and found the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) includes evaluation material from the SER for the BLN Units 3 and 4 COL application.

To support the text added to the Technical Evaluation sections as described above, the staff evaluated any differences between the information provided by the WLS applicant and that provided by the VEGP applicant, regarding details in the application for the standard content material, to determine whether the standard content material of the VEGP SER is still applicable to the WLS application. These evaluations are in the SER sections that reference the standard content.

The staff compared the VEGP COL FSAR Revision 2 to the WLS COL FSAR at the time of the development of the ASE. The ASE included confirmatory items. Subsequent to the issuance of the ASE, DEC updated the standard portions of its application to be consistent with the VEGP COL application to close the standard content confirmatory items. A complete comparison between the subsequent VEGP COL FSAR revisions to the WLS COL FSAR revisions was not performed. However, the staff confirmed that responses to standard content confirmatory items were endorsed by DEC and that the changes discussed in the standard confirmatory items were made in the WLS COL FSAR.

The staff applied the design-centered review approach described above in Chapter 21 “Design Changes Proposed In Accordance With ISG-11” of this SER in conducting its evaluation of the five requests by the applicant to depart from the AP1000 certified design. These five departure requests were identical to departure requests in the Levy Nuclear Plant (LNP) COL review. Therefore, consistent with the NRC’s DCRA, , the staff referenced evaluations that were completed for the first time in the LNP review. The referenced evaluations in Chapter 21 of this SER are captured by use of italicized, double-indented formatting.

1.3 Principal Review Matters

The staff’s evaluations related to the COL application review are addressed as follows:

- **Part 1 General and Administrative Information**

The staff’s evaluation of the corporate information regarding DEC pursuant to 10 CFR 50.33 is provided in Section 1.5.1 of this report.

- **Part 2 Final Safety Analysis Report**

The staff’s evaluation of information in the WLS COL FSAR is provided in the corresponding sections of this report.

There are two SER chapters that have been issued that do not have a corresponding chapter in the FSAR.

Chapter 20 describes the staff’s evaluations and conclusions relating to the Fukushima Near-Term Task Force (NTTF) recommendations that are applicable to the WLS Units 1 and 2 COL application. The applicable recommendations address four topics: a reevaluation of the seismic hazard (related to Recommendation 2.1), mitigation strategies for beyond-design-basis external events (related to Recommendation 4.2), spent fuel pool instrumentation (related to Recommendation 7.1), and emergency preparedness staffing and communications (related to Recommendation 9.3).

Chapter 21 describes the staff’s evaluations and conclusions for departures from the certified design identified by the applicant in accordance with Interim Staff Guidance DC/COL ISG-011, "Finalizing Licensing-Basis Information."

- **Part 3 Environmental Report**

The applicant submitted an Environmental Report pursuant to the requirements of 10 CFR 51.50(c). The staff’s evaluation of this information is provided in the Environmental Impact Statement.

- **Part 4 Technical Specifications**

Chapter 16 of this report includes the staff’s evaluation of the WLS Units 1 and 2 PTS and Bases (specifically completion of bracketed text).

- **Part 5 Emergency Plan**

Chapter 13 of this report includes the staff's evaluation of the WLS Emergency Plan, including related ITAAC, supporting information such as ETEs, and the applicable offsite State and local emergency plans.

- **Part 6 Limited Work Authorization**

Part 6 of the application is not used and, therefore, has no corresponding staff review.

- **Part 7 Departures Report**

The staff's evaluation of the departures and exemptions in Part 7 is provided in the applicable chapters of this SER. The Table 1-1, below, lists the departures identified in the application and identifies where the evaluation appears in this SER. Several of the departures, as marked, correspond to exemptions requested by the applicant.

Table 1-1. Departures Identified in Part 7 of the COL Application

Description of Departure	Location of Evaluation in this Report
STD DEP 1.1-1. Departure for organization and numbering for the FSAR sections	1.5.4
WLS DEP 1.8-1. Departure correcting an inconsistency in regulatory citation in an interface description	1.4.4
WLS DEP 2.0-1 Lee Site Foundation Response Spectra	3.7
WLS DEP 3.2-1. Departure adding downspouts and downspout screens to the condensate return portion of the Passive Core Cooling System	21.1
WLS DEP 3.8-1. Lee Passive Earth Pressures	3.8
WLS DEP 3.11-1. Departure revising the "Envir. Zone" numbers for Spent Fuel Pool Level instruments	3.11
WLS DEP 6.2-1. Departure revising the ITAAC Acceptance Criteria for the in-containment PXS compartment vents to reflect the current plant configuration.[3]	21.4
WLS DEP 6.3-1. Departure to quantify the term "indefinitely" as used in the AP1000 DCD for maintenance of safe shutdown conditions using the PRHR HX during non-LOCA accidents.	21.1

Description of Departure	Location of Evaluation in this Report
WLS DEP 6.4-1. Departure revising estimated maximum doses to control room operators to meet 10 CFR Part 50, Appendix A, General Design Criterion 19, "Control Room".[3]	21.2
WLS DEP 6.4-2. Departure revising the heat generated in the control room during accident conditions and the conditions for actuating the normal ventilation system supplemental filtration and the emergency ventilation system.[3]	21.3
WLS DEP 7.3-1. Departure modifying the engineered safety features to provide an operating bypass for the boron dilution block to meet the requirements of IEEE 603-1991 in accordance with 10 CFR 50.55a(h), "Protection and safety systems."[3]	21.5
WLS DEP 8.3-1. Departure for Class 1E voltage regulating transformer current limiting features	8.3.2
WLS DEP 18.8-1. Emergency Response Facility Locations	13.3

Part 7 of the COL application, Part B, requests seven exemptions, as listed in Table 1-2.

Table 1-2. Exemption Requests Identified in Part 7 of the COL Application

Description of Exemption	Location of Evaluation in this Report
Exemption from 10 CFR Part 52, Appendix D, Section IV.A.2.a related to COL application organization and numbering	1.5.4
Exemption from the requirements of 10 CFR 70.22(b), 10 CFR 70.32(c), 10 CFR 74.31, 10 CFR 74.41 and 10 CFR 74.51, for SNM Material Control and Accounting Program Description	1.5.4
Exemption from AP1000 DCD Tier 1 Tables 2.2.3-1 and 2.2.3-2 and TS Surveillance Requirement (SR) 3.5.4.7 related to Containment Cooling Changes in regard to Passive Core Cooling System Condensate Return	21.1

[3] These departures include revisions to either AP1000 Tier 1 information or generic Technical Specification (TS) and correspond to exemptions requested by the applicant.

Description of Exemption	Location of Evaluation in this Report
Exemption from AP1000 DCD Tier 1 Subsection 2.7.1 and Tables 2.2.5-1 and 2.2.5-5 and TS Limiting Condition for Operation 3.7.4 and TS SR 3.7.4.1 related to Main Control Room Dose	21.2
Exemption from AP1000 DCD Tier 1 Tables 2.2.5-1, 2.2.5-4, 2.5.2-3 and 2.5.2-4, and TS 3.3.2 and 3.7.6 related to Main Control Room Heatup	21.3
Exemption from AP1000 Tier 1 Table 2.3.9-3 related to Combustible Gas Control in Containment	21.4
Exemption from AP1000 TS Table 3.3.2-1 related to Source Range Neutron Flux Doubling Block Permissive	21.5
Exemption from 10 CFR 52.93(a)(1)[4]	1.5.4

- **Part 8 Security Plan**

The staff's evaluation of the Physical Security Plan, the Training and Qualification Plan, and the Safeguards Contingency Plan is documented separately from this report and is withheld from the public in accordance with 10 CFR 73.21. A non-sensitive summary of the staff's evaluation of those plans is provided in Section 13.6 of this SER.

- **Part 9 Withheld Information**

The staff's evaluation of the withheld information occurs in the context of the specific subject being reviewed and is documented accordingly. A summary of the staff's evaluation of the Mitigative Strategies Description and Plans for loss of large areas of the plant due to explosions is provided in Appendix 19A of this report. The staff's complete evaluation is documented separately from this SER and is withheld from the public in accordance with 10 CFR 2.390.

The staff's evaluation of the WLS Units 1 and 2 Cyber Security Plan is provided in Section 13.8 of this SER.

- **Part 10 Proposed Combined License Conditions (Including ITAAC)**

The staff's evaluation of the proposed COL conditions and ITAAC is provided in the applicable SER chapters. Appendix A identifies the proposed license conditions and ITAAC and the location of the evaluations. Each license condition is sequentially numbered in individual

[4] Part 7 of the WLS COL application does not include an exemption request related to the requirements found in 10 CFR 52.93(a)(1). As discussed in Section 1.5.4 of this report, the staff determined that an exemption from this regulation is necessary.

chapters of this SER. The license conditions and ITAAC are based on the provisions of 10 CFR 52.97, "Issuance of combined license."

- **Part 11 Enclosures**

Part 11 includes enclosures submitted by the applicant in support of the WLS Unis 1 and 2 COL application. Specifically, these enclosures include:

- Part 11A of the WLS COL application regarding the QAPD is documented in Chapter 17 of this SER.
- Part 11B of the WLS COL application regarding mitigative strategies description and plans for loss of large areas of the plant due to explosions is provided in Appendix 19A of the SER. The staff's complete evaluation is documented separately from this SER and is withheld as non-public in accordance with 10 CFR 2.390.
- Part 11C of the application regarding the cyber security plan is in Section 13.8 of this SER.
- Part 11D of the application regarding the SNM, material control and accounting (MC&A) program description is in Section 1.5.5 of this SER.
- Part 11E of the application regarding the new fuel shipping plan is in Section 1.5.5 of this SER.
- Part 11F of the application regarding supplemental information in support of the 10 CFR Part 70 license is in Section 1.5.5 of this SER.

<u>Organization of this SER</u>

The staff's SER is structured as follows:

- The SER adheres to the "finality" afforded to COL applications that incorporate by reference a standard certified design. As such, this report does not repeat any technical evaluation of material incorporated by reference; rather, it points to the corresponding review findings of NUREG-1793 and its supplements. However, the referenced DCD and the WLS COL FSAR are considered in the staff's SER to the extent necessary to ensure that the expected scope of information to be included in a COL application is addressed adequately in either the AP1000 DCD or COL FSAR or in both.
- For sections that were completely incorporated by reference without any supplements or departures, the SER simply points to the AP1000 DCD and related NUREG-1793 and its supplements and confirms that all the relevant review items were addressed in the AP1000 DCD and the staff's evaluation was documented in NUREG-1793 and its supplements.
- For subject matter within the scope of the COL application that supplements or departs from the AP1000 DCD, this SER generally follows a six-section organization as follows:
    - "Introduction" section provides a brief overview of the specific subject matter.
    - "Summary of Application" section identifies whether portions of the review have

received finality and clearly identifies the scope of review for the COL.

- "Regulatory Basis" section identifies the regulatory criteria for the information addressed by the COL application.
- "Technical Evaluation" section focuses on the information addressed by the COL application.
- "Post Combined License Activities" section identifies the proposed license conditions, ITAAC or FSAR information commitments that are post-COL activities.
- "Conclusion" section summarizes how the technical evaluation resulted in a reasonable assurance determination by the staff that the relevant acceptance criteria have been met.

1.4 Staff Review of WLS COL FSAR Chapter 1

1.4.1 Introduction

There are two types of information provided in WLS COL FSAR Chapter 1:

1. General information that enables the reviewer or reader to obtain a basic understanding of the overall facility without having to refer to the subsequent chapters. A review of the remainder of the application can then be completed with a better perspective and recognition of the relative safety significance of each individual item in the overall plant description.
2. Specific information relating to qualifications of the applicant, construction impacts and regulatory considerations that applies throughout the balance of the application (e.g., conformance to the acceptance criteria in NUREG-0800).

This section of the report will identify the information incorporated by reference, summarize all of the new information provided, and document the staff's evaluation of the sections addressing regulatory considerations.

1.4.2 Summary of Application

The information related to COL/SUP items included in WLS COL FSAR, Revision 11, Chapter 1 encompasses the statements of fact or information recommended by RG 1.206. No staff technical evaluation was necessary where the statements were strictly background information. However, where technical evaluation of these COL/SUPs was necessary, the evaluation is not in this section of the report, but in subsequent sections as referenced below.

WLS COL FSAR Section 1.1 Introduction

WLS COL FSAR Section 1.1, incorporates by reference AP1000 DCD Section 1.1, "Introduction," with the following supplements.

- STD SUP 1.1-1

The applicant specified the incorporation of Revision 19 of the Westinghouse AP1000 DCD in all sections of the WLS COL FSAR. Additionally, the applicant incorporated by reference Nuclear Energy Institute (NEI) technical reports as identified in WLS COL FSAR Table 1.6-201.

- WLS SUP 1.1-2

The applicant clarified that the WLS COL FSAR was submitted to NRC by DEC under Section 103 of the *Atomic Energy Act* to construct and operate two nuclear power plants under the provisions of 10 CFR Part 52, Subpart C, "Combined Licenses."

- WLS COL 2.1-1

The applicant provided additional information in WLS COL FSAR Section 2.1-1 to address COL Information Item 2.1-1 (COL Action Item 2.1.1-1). Specifically, WLS Units 1 and 2 are to be located in the eastern portion of Cherokee County in north central South Carolina (SC); approximately 35 miles southwest of Charlotte, North Carolina (NC); approximately 25 miles northeast of Spartanburg, SC; and approximately 7.5 miles southeast of Gaffney, SC. This is a brief introductory summary of the plant location. An expanded discussion of WLS COL 2.1-1 is included in WLS COL FSAR Section 2.1.

- WLS COL 1.1-1

The applicant provided the anticipated schedule for site preparation and construction of two AP1000 reactors at WLS Units 1 and 2 in WLS COL FSAR Table 1.1-203. The applicant committed to provide a site-specific construction plan and startup schedule after issuance of the COL and after a positive decision had been made to construct the plant.

- STD SUP 1.1-6

The applicant identified that, while the WLS COL FSAR generally follows the AP1000 DCD organization and numbering, there were some organization and numbering differences that were adopted, where necessary, to include additional material, such as additional content identified in RG 1.206.

Related to this is STD DEP 1.1-1, "Administrative departure for organization and numbering of the FSAR sections," in WLS COL FSAR Section 1.8 and Part 7 of the WLS COL application. The staff's evaluation of this departure is included in Section 1.5.4 of this SER.

- STD SUP 1.1-3

The applicant provided additional information to describe annotations used in the left hand column of the WLS COL FSAR to identify departures, supplementary information, COL items, and CDI.

- STD SUP 1.1-4

The applicant provided additional information to indicate how proprietary, personal or sensitive information withheld from public disclosure pursuant to 10 CFR 2.390 and RIS 2005-026, "Control of Sensitive Unclassified Nonsafeguards Information Related to Nuclear Power Reactors," is identified in the WLS COL FSAR. Proprietary and sensitive material was provided in Part 9 of the COL application.

- WLS SUP 1.1-5

The applicant provided additional information to identify acronyms and system designations used in the WLS COL FSAR that are in addition to those identified in the AP1000 DCD.

WLS COL FSAR Section 1.2 General Plant Description

WLS COL FSAR Section 1.2, incorporates by reference Section 1.2, "General Plant Description," of the AP1000 DCD, Revision 19 with the following departures and supplements:

- WLS DEP 18.8-1

The applicant provided WLS COL FSAR Figure 1.2-201 to replace AP1000 DCD Figure 1.2-18 to reflect the proposed relocation of the Technical Support Center (TSC) and the Operations Support Center (OSC). The staff's evaluation of the locations of the TSC and OSC is discussed in Section 13.3 of this SER.

- WLS COL 2.1-1; WLS COL 3.3-1; and WLS COL 3.5-1

The applicant provided additional information on the site plan for WLS Units 1 and 2 summarizing the principal structures and facilities, parking areas, roads, and transmission lines. The location and orientation of the power block complex are also described. These COL information items are expanded in other sections of the WLS COL FSAR.[5]

WLS COL FSAR Section 1.3 Comparisons with Similar Facility Designs

WLS COL FSAR Section 1.3 incorporates by reference AP1000 DCD Section 1.3, "Comparisons with Similar Facility Designs" with no departures or supplements.

Section 1.4 Identification of Agents and Contractors

WLS COL FSAR Section 1.4 incorporates by reference AP1000 DCD, Revision 19, Section 1.4, "Identification of Agents and Contractors" with the following supplements:

- WLS SUP 1.4-1

The applicant provided additional information to identify Duke Energy Carolinas LLC (a subsidiary of Duke Energy Corporation) as the agent acting on behalf of itself for WLS Units 1 and 2. Additionally, the applicant identified Duke Energy Carolinas, LLC will own and operate WLS Units 1 and 2.

[5] WLS COL FSAR Table 1.8-202 provides a COL information item index of occurrences in the WLS COL FSAR.

Duke Energy Carolinas LLC is the principal subsidiary of Duke Energy Corporation. Duke Energy Corporation, one of the largest electric power companies in the United States, supplies and delivers energy to approximately 7.2 million U.S. customers. The company has nearly 50,000 megawatts of electric generating capacity in the Midwest, Florida, and the Carolinas.

- WLS SUP 1.4-2

The applicant addressed the contractors participating in the preparation of the COL application in WLS COL FSAR Section 1.4.2.8.

Further, the applicant addressed the specialized consulting firms that will assist with the design, construction, and operation of WLS Units 1 and 2 in proposed license condition 7, included in WLS COL application Part 10.

- WLS SUP 1.4-3

The applicant provided additional information related to specialized consulting firms that assisted in preparing the COL application for WLS.

WLS COL FSAR Section 1.5 Requirements for Further Technical Information

WLS COL FSAR Section 1.5, incorporates by reference AP1000 DCD, Revision 19, Section 1.5, “Requirements for Further Technical Information,” with no departures or supplements. This section of the AP1000 DCD provides information related to testing conducted during the AP600 conceptual design program to provide input into the plant design and to demonstrate the feasibility of unique design features. The AP1000 DCD also describes the analyses performed to show that the AP600 and AP1000 exhibit a similar range of conditions such that the AP600 tests are sufficient to support the AP1000 safety analysis.

WLS COL FSAR Section 1.6 Material Referenced

WLS COL FSAR Section 1.6, incorporates by reference AP1000 DCD, Revision 19, Section 1.6, “Material Referenced,” with the following supplements:

- STD SUP 1.6-1

The applicant provided additional information to identify the technical documents incorporated by reference in the WLS COL FSAR in addition to those technical documents incorporated by reference in the AP1000 DCD.

Section 1.7 Drawings and Other Detailed Information

WLS COL FSAR Section 1.7 incorporates by reference AP1000 DCD, Revision 19, Section 1.7, “Drawings and Other Detailed Information,” with the following supplements:

- WLS SUP 1.7-1

The applicant identified the site-specific system drawings. These are the circulating water system, raw water system, and transmission switchyard and offsite power system diagram.

Section 1.8 Interfaces for Standard Design

WLS COL FSAR Section 1.8, incorporates by reference AP1000 DCD, Revision 19, Section 1.8, “Interfaces for Standard Design,” with the following departures and supplements:

- WLS SUP 1.8-1

The applicant identified departures in WLS COL FSAR Table 1.8-201, “Summary of FSAR Departures from the AP1000 DCD.” The departures are:

- STD DEP 1.1-1 related to numbering and organization of the WLS COL FSAR sections to be consistent with RG 1.206 and NUREG-0800

- WLS DEP 1.8-1 related to the correcting the regulatory citation error in AP1000 DCD.

- WLS DEP 1.8-1 – This departure addresses an error in DCD Table 1.8-1, Item 13.1, that incorrectly references Appendix O of 10 CFR Part 50. This departure is evaluated in Section 1.4.4 of this document.

- WLS DEP 3.2-1 – The condensate return portion of the Passive Core Cooling System has been upgraded to add downspouts and plug fabrication holes in the Polar Crane Girder in order to maximize the return of condensate to the In-Containment Refueling Water Storage Tank and ensure long-term operation of the Passive Residual Heat Removal Heat Exchanger to meet design requirements. This departure is evaluated in Section 21.1 of this document.

- WLS DEP 3.11-1 – DCD Table 3.11-1 “Envir. Zone” numbers for Spent Fuel Pool Level Instruments SFS-JE-LT019A, SFS-JE-LT019B, and SFS-JE-LT019C are revised to be consistent with the location of the instruments. This departure is evaluated in Section 3.11 of this document.

- WLS SUP 1.8-2

The applicant provided a list of the COL information items in the AP1000 DCD. In WLS COL FSAR Table 1.8-202, DEC provides the sections of the application addressing these issues. The table further identifies the AP1000 COL items as an “applicant” item, a “holder” item or both. An applicant item is completely addressed in the application. DEC’s definition of a COL holder item is an item that cannot be resolved prior to issuance of the COL. These items are regulatory commitments of the COL holder and will be completed as specified in the appropriate section of the referenced DCD and their completion is the subject of a COL license condition presented in Part 10 of this COL application.

- WLS SUP 1.8-3

The applicant provided in WLS COL FSAR Table 1.8-203 a list of interface items from the AP1000 DCD and the corresponding WLS COL FSAR section(s) that address those interface items.

- WLS DEP 1.8-1

The applicant provided a departure to address an error in AP1000 DCD Table 1.8-1 listing of plant interfaces where Item 13.1 incorrectly references 10 CFR Part 50, Appendix O. This departure is evaluated in Section 1.4.4 of this report,

Section 1.9 Compliance With Regulatory Criteria

WLS COL FSAR Section 1.9, incorporates by reference AP1000 DCD, Revision 19, Section 1.9, "Compliance with Regulatory Criteria," with the following supplements:

- STD COL 1.9-1 and WLS COL 1.9-1

The applicant provided additional information in STD COL 1.9-1 (corresponding to COL Information Item 1.9-1) and WLS COL 1.9-1 related to regulatory guides cited in the WLS COL FSAR. WLS COL FSAR Table 1.9-201 identifies the regulatory guide revision and provides the WLS COL FSAR cross-references. In addition, WLS COL FSAR Appendix 1AA, "Conformance with Regulatory Guides," was developed by the applicant to supplement the detailed discussion presented in the referenced AP1000 DCD Appendix 1A, "Conformance with Regulatory Guides." Specifically, WLS COL FSAR Appendix 1AA delineates conformance to design aspects as stated in the AP1000 DCD and conformance to programmatic and/or operational issues as presented in the WLS COL FSAR. In certain regulatory guides, design aspects were beyond the scope of the AP1000 DCD and are also presented in the WLS COL FSAR.

- STD COL 1.9-2 and WLS COL 1.9-2

The applicant provided additional information in STD COL 1.9-2 and WLS COL 1.9-2 (corresponding to the first un-numbered COL information item identified at the end of AP1000 DCD Table 1.8-2) related to operational experience. WLS COL FSAR Table 1.9-204 provides a list of Bulletins and Generic Letters (GLs), the appropriate WLS COL FSAR cross-references and whether the subject matter was addressed in the AP1000 DCD.

- STD COL 1.9-3

The applicant provided additional information in STD COL 1.9-3 (related to the second un-numbered COL information item identified at the end of AP1000 DCD Table 1.8-2) related to review of unresolved safety issues and generic safety issues (GSIs). Specifically, WLS COL FSAR Table 1.9-203 lists Three Mile Island (TMI) Action Plan items, Task Action Plan items, New Generic Issues, Human Factors issues, and Chernobyl Issues and states how they were considered in the AP1000 DCD and COL application. In addition, the applicant provided discussion on four new generic issues: Issue 186 related to heavy load drops; Issue 189 related to susceptibility of certain containments to early failure from hydrogen combustion; Issue 191 related to PWR sump performance; and Issue 196 related to the use of Boral in long-term dry storage casks for spent reactor fuel.

- STD SUP 1.9-1

The applicant provided additional information related to conformance with NUREG-0800. Specifically WLS COL FSAR Table 1.9-202 delineates conformance with NUREG-0800 for design aspects as stated in the AP1000 DCD and conformance for subjects beyond the scope of the AP1000 DCD as presented in the WLS COL FSAR.

- STD SUP 1.9-2

The applicant clarified that the severe accident mitigation design alternatives evaluation for the AP1000 DCD Appendix 1B is not incorporated into the WLS COL FSAR; but is addressed in the COL application Environmental Report.

- STD SUP 1.9-3 and WLS SUP 1.9-4

The applicant provided information related to station blackout (SBO) procedures and training for operators to include actions necessary to restore offsite power after 72 hours by addressing alternating current (ac) power restoration and severe weather guidance in accordance with NUMARC-87-00, "Guidelines and Technical Bases for NUMARC Initiatives Addressing Station Blackout at Light Water Reactors."

WLS COL FSAR Section 1.10 Nuclear Power Plants to Be Operated On Multi-Unit Sites

The applicant provided an assessment of the potential impacts of construction of one unit on SSCs important to safety for an operating unit, in accordance with 10 CFR 52.79(a)(31). This section of the WLS COL FSAR provides an assessment of potential construction activity hazards, SSCs important to safety for the operating unit and related limiting conditions for operation (LCOs) for the operating unit, potentially impacted SSCs and LCOs and applicable managerial and administrative controls to be used to provide assurance that the LCOs for operating units are not exceeded as a result of construction activities at the multi-unit sites.

- STD SUP 1.10-1

The applicant identified this as a new section in the WLS COL application that was not part of the referenced AP1000 DCD.

- WLS SUP 1.10-1

The applicant identified that the power blocks for WLS Units 1 and 2 have a minimum separation of at least 800 feet between plant centerlines. In the standard portion of the application there is a discussion that the primary consideration in setting this separation distance is the space needed to support plant construction via the use of a heavy-lift crane.

License Conditions

- The applicant proposed that the ITAAC identified in the tables in WLS COL application, Part 10, Appendix B be incorporated into the COL.

1.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the introductory information in WLS COL FSAR Chapter 1 are given in NUREG-0800, Section 1.0.

The applicable regulatory requirements for the introductory information are as follows:

- 10 CFR 50.43(e), as it relates to requirements for approval of applications for a DC, COL, manufacturing license, or operating license that propose nuclear reactor designs that differ significantly from light-water reactor (LWR) designs that were licensed before 1997, or use simplified, inherent, passive, or other innovative means to accomplish their safety functions.

- 10 CFR 52.77, “Contents of applications; general information,” and 10 CFR 52.79, as they relate to general introductory matters.

- 10 CFR 52.79(a)(17), as it relates to compliance with technically relevant positions of the TMI requirements.

- 10 CFR 52.79(a)(20), as it relates to proposed technical resolutions of those unresolved safety issues and medium- and high priority GSIs that are identified in the version of NUREG-0933, “Resolution of Generic Safety Issues (Formerly entitled ‘A Prioritization of Generic Safety Issues’),” current on the date up to 6 months before the docket date of the application and that are technically relevant to the design.

- 10 CFR 52.79(a)(31) regarding nuclear power plants to be operated on multi-unit sites, as it relates to an evaluation of the potential hazards to the SSCs important to safety of operating units resulting from construction activities, as well as a description of the managerial and administrative controls to be used to provide assurance that the LCOs are not exceeded as a result of construction activities at the multi-unit sites.

- 10 CFR 52.79(a)(37), as it relates to the information necessary to demonstrate how operating experience insights have been incorporated into the plant design.

- 10 CFR 52.79(a)(41), as it relates to an evaluation of the application against the applicable NRC review guidance in effect 6 months before the docket date of the application.

- 10 CFR 52.79(d)(2) requires that for a COL referencing a standard DC, the FSAR demonstrate that the interface requirements established for the design under 10 CFR 52.47, “Contents of applications; technical information,” have been met.

- 10 CFR 52.97(a)(1)(iv) regarding technical and financial qualifications.

The related acceptance criteria from NUREG-0800, Chapter 1 are as follows:

- For regulatory considerations, acceptance is based on addressing the regulatory requirements as discussed in FSAR Chapter 1 or in the referenced FSAR section. The NUREG-0800 acceptance criteria associated with the referenced section will be reviewed in the context of that review.

- For performance of new safety features, the information is sufficient to provide reasonable assurance that: (1) these new safety features will perform as predicted in WLS COL FSAR; (2) the effects of system interactions are acceptable; and (3) the applicant provides sufficient data to validate analytical codes. The design qualification testing requirements may be met with either separate effects or integral system tests; prototype tests; or a combination of tests, analyses, and operating experience.

For conformance to regulatory criteria, RG 1.206 states an applicant should perform a similar evaluation for conformance with RGs that were in effect six months prior to the submittal of the COL application.

1.4.4 Technical Evaluation

The staff reviewed WLS COL Section 1 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[6] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to this introduction. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5 to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff completed its review and concluded that the evaluation performed for the standard content directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) includes evaluation material from the SER for the Bellefonte Nuclear Station (BLN) Units 3 and 4 COL application. Any confirmatory items in the standard content material retain the numbers assigned in the VEGP SER. Confirmatory items that are first identified in this report section have a WLS designation (e.g., WLS Confirmatory Item 1.4-1).

The staff reviewed the information in the WLS COL FSAR:

<u>WLS COL FSAR Sections 1.1, 1.2, 1.3, 1.6, and 1.7</u>

There are no specific NUREG-0800 acceptance criteria related to the general information presented in Sections 1.1, 1.2, 1.3, 1.6, and 1.7, and no specific regulatory findings. The information provides the reader with a basic overview of the nuclear power plant and the construct of the WLS COL FSAR, itself.

---

[6] See Section 1.2.2, "Finality of Referenced NRC Approvals" of this report for a discussion of the staff's review related to verification of the scope of information to be included within a COL application that references a DC.

In WLS COL FSAR Section 1.1, WLS COL 1.1-1 the applicant provided an overall anticipated schedule for site preparation and construction of two AP1000 reactors at the Lee Nuclear Site and is shown in WLS COL FSAR Table 1.1-203 and is based on various considerations.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.4.4:

> *In a letter dated November 11, 2010, the applicant added a discussion of incorporation of the proprietary information and safeguards information referenced in the AP1000 DCD. This information is included to meet the requirements of 10 CFR Part 52, Appendix D, Section IV.A.3, which indicates the applicant must "include, in the plant specific DCD, the proprietary information and safeguards information referenced in the AP1000 DCD" and, therefore, is acceptable. The incorporation of the above information into a future revision of the VEGP COL FSAR is* ***Confirmatory Item 1.4-1.***
>
> *Resolution of Standard Content Confirmatory Item 1.4-1*
>
> *Confirmatory Item 1.4-1 is an applicant commitment to revise FSAR Section 1.1 to include a discussion of incorporation of the proprietary information and safeguards information referenced in the AP1000 DCD. The staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 1.4-1 is now closed.*

WLS COL FSAR Section 1.4

- WLS SUP 1.4-1 and WLS SUP 1.4-3

This evaluation is limited to DEC's technical qualification to hold a 10 CFR Part 52 license in accordance with 10 CFR 52.97(a)(1)(iv). The financial qualifications that are also a requirement of 10 CFR 52.97(a)(1)(iv) are evaluated in Section 1.5.1 of this report.

In WLS COL FSAR Section 1.4, DEC provided justification for why it believes it is qualified to hold a 10 CFR Part 52 license. The WLS COL FSAR states that it has over 45 years of experience in the design, construction and operation of nuclear power stations, and currently has seven nuclear operating units that generates over 7000 megawatts of electricity. DEC operates Catawba Units 1 and 2, McGuire Units 1 and 2, and Oconee Units 1, 2, and 3. Since DEC holds 10 CFR Part 50 licenses for nuclear power plants and has demonstrated its ability to build and operate these plants, the staff finds that DEC is qualified to hold a 10 CFR Part 52 license. The staff notes that WLS COL FSAR Section 17.5, discusses the QA program to be implemented at the receipt of the WLS COL. The staff's evaluation of WLS COL FSAR Section 17.5 is discussed in Section 17.5 of this report. Based on DEC's experience with building and operating nuclear power plants and the staff's evaluation of DEC's QA program, the staff finds that DEC is technically qualified to hold a 10 CFR Part 52 license in accordance with 10 CFR 52.97(a)(1)(iv).

- WLS SUP 1.4-2

In WLS SUP 1.4-2 the applicant provided the names of contractors and description of the specialized services provided in the preparation of the COL application.

DEC received support from the following contractors in preparing the COL:

- AMEC Environment & Infrastructure (MACTEC Engineering and Consulting, Inc.)
- Furgo Consultants Inc. (formerly William Lettis & Associates, Inc.)
- Enercon Services, Inc.
- Burns & Roe Enterprises, Inc.
- Chicago Bridge and Iron (Stone & Webster)
- Atkins
- HDR/DTA

The staff finds this acceptable because the applicant identified contractors beyond those identified in the DCD and provided a description of the specialized consulting services rendered in preparation of the COL application.

WLS COL FSAR Section 1.5

10 CFR 50.43(e) requires additional testing or analysis for applications for a DC or COL that propose nuclear reactor designs that differ significantly from LWR designs that were licensed before 1997, or use simplified, inherent, passive, or other innovative means to accomplish their safety functions. This requirement was addressed in the AP1000 DCD and evaluated by the staff in NUREG-1793, Chapter 21, “Testing and Computer Code Evaluation.” The COL application does not include any additional design features that require additional testing.

WLS COL FSAR Section 1.6

There are no specific NUREG-0800 acceptance criteria related to the information presented in Section 1.6 and no specific regulatory findings.

WLS COL FSAR Section 1.7

There are no specific NUREG-0800 acceptance criteria related to the information presented in Section 1.7 and no specific regulatory findings.

WLS COL FSAR Section 1.8

- WLS SUP 1.8-1

As discussed in WLS COL FSAR Section 1.4.2, the applicant identified two departures in WLS COL FSAR Table 1.8-201 from the referenced AP1000 DCD (STD DEP 1.1-1 and WLS DEP 1.8-1). Section 1.3 of this report provides a cross-reference to where these departures are discussed in this report.

- WLS SUP 1.8-2

WLS SUP 1.8-2 includes the same type of information as VEGP SUP 1.8-2. Therefore, the following portion of this technical evaluation section is reproduced from VEGP SER Section 1.4.4:

In Sections 1.3 and 1.4.4 of the BLN SER, the staff identified a standard content ***Open Item 1-2*** *related to the decision regarding which of the BLN COL FSAR commitments, if any, should become a license condition. On January 21, 2010, the NRC issued ISG-15, "Final Interim Staff Guidance on the Post-Combined License Commitments," ESP/DC/COL-ISG-15. This guidance discusses options regarding completion of COL items that cannot be completed until after issuance of the COL. The VEGP applicant identified that certain COL information items cannot be resolved prior to the issuance of a COL. The applicant has identified proposed License Condition 2 in Part 10 of the COL application to ensure these COL items will be completed by the identified implementation milestones through completion of the action identified. The determination that these COL information items cannot be resolved prior to issuance of a COL is discussed in the relevant SER section related to the topic. In addition, using the guidance of ISG-15, the staff has identified certain FSAR commitments in individual sections of this SER and these FSAR commitments are listed in Appendix A.3 of this SER. The staff considers* ***Open Item 1-2*** *is resolved.*

- WLS SUP 1.8-3

AP1000 DCD Table 1.8-1 presents interface items for the AP1000. This section of the AP1000 DCD identifies certain interfaces with the standard design that have to be addressed in accordance with 10 CFR 52.47(a)(1)(vii).[7] As required by 10 CFR 52.79(d)(2), the COL application must demonstrate how these interface items have been met. In the WLS COL FSAR, the applicant provided WLS COL FSAR Table 1.8-203, which explicitly identifies the FSAR location of information addressing the interface items identified in AP1000 DCD Section 1.8. The staff's review of the identified FSAR locations confirmed that interface items are adequately addressed in the WLS COL FSAR. The technical discussions related to specific interface requirements are addressed in related sections of this report (e.g., Sections 8.2.2 and 11.3).

- WLS DEP 1.8-1

This Tier 2 departure, appearing in the WLS COL FSAR Table 1.8-203 listing of AP1000 plant interfaces, corrects an error in AP1000 DCD Table 1.8-1, Item 13.1. This interface addresses the design features that affect plans for coping with emergencies in the operation of the reactor facility or a major portion thereof. The departure changes the incorrect regulatory reference from 10 CFR Part 50, Appendix O, to 10 CFR 52.137(a)(11). In issuing the final rule for 10 CFR Part 52 in the *Federal Register* (FR) (see 72 FR 49352), the requirement relating to providing this interface information was moved from f 10 CFR Part 50, Appendix O to a new location in 10 CFR 52.137 (see 72 FR 49391). Therefore, the staff finds it reasonable that this departure does not require prior NRC approval because it made a technical correction only and did not make a substantive change to the interface item.

[7] Following the update to 10 CFR Part 52 (72 FR 49517), this provision has changed to 10 CFR 52.47(a)(25).

WLS COL FSAR Section 1.9

In this section of the application, the applicant demonstrates conformance to regulatory guides and NUREG-0800 and addresses unresolved safety issues, GSIs, TMI action items, and operating experience.

STD COL 1.9-1 and WLS COL 1.9-1

In comparing VEGP COL FSAR Table 1.9-201 and Appendix 1AA to the respective tables in the WLS COL FSAR, the staff notes that there are several differences. These differences are associated with site-specific information and are reflected in the WLS COL FSAR by a "WLS COL 1.9-1" designation. The staff reviewed the site-specific differences in the respective tables and appendices and determined that the WLS COL 1.9-1 information in these tables was updated consistent with the update provided for the standard information; therefore, the staff considers the standard content open item as it relates to issues associated with the site-specific information resolved.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.4.4[8]:

AP1000 COL Information Item

- *STD COL 1.9-1*

Regarding RGs, the applicant provides in BLN COL FSAR Table 1.9-201 a cross-reference between the RG and where it is discussed in the application, and Appendix 1AA, "Conformance with Regulatory Guides," to supplement the detailed discussion presented in Appendix 1A, "Conformance with Regulatory Guides," of the referenced DCD. The technical discussions related to this appendix are addressed in the related technical sections of the BLN COL FSAR. In addition, BLN COL FSAR Table 1.9-201 provides a listing of all RGs, the specific revision, and provides BLN COL FSAR and DCD cross-references.

The staff issued three RAIs associated with how the RG information in Table 1.9-201 and Appendix 1AA of the BLN COL FSAR is presented. In addition, there were two specific RAIs associated with how an individual RG is discussed in Table 1.9-201 and Appendix 1AA. A description of the RAIs and their responses follows.

RAI 1-5

In RAI 1-5, the staff noted that BLN COL FSAR Appendix 1AA lists the later version of the RG when compared with DCD Table 1.9-1 but in some cases does not discuss compliance with the later version. In other cases, exceptions to the RG were identified but not justified.

[8] The text reproduced from VEGP SER Section 1.4.4 is unaltered, but is presented in sequential order of the COL and SUP items.

<u>RAI 1-7</u>

In RAI 1-7, the staff noted that not all RGs listed in Appendix 1AA provided a cross-reference to where they were discussed in accordance with the guidance in Section 1 of NUREG-0800.

<u>RAI 1-11</u>

In RAI 1-11, the staff noted that the information that TVA provided in response to RAIs 1-5 and 1-7 conflicted with information that TVA provided in response to another RAI. TVA was requested to reconcile these differences.

<u>RAIs 1-1 and 1-10</u>

These RAIs are associated with specific RGs and RAI 1-1 and RAI 1-10 are evaluated in Chapters 13 and 12, of this SER, respectively.

In TVA's response to RAIs 1-5 and 1-7, TVA committed to make changes to BLN COL FSAR Table 1.9-201 and Appendix 1AA to:

- *Add an additional statement to Appendix 1AA that specifically addresses the later version of the RG.*
- *Revise BLN COL FSAR Sections 1.9.1.1, 1.9.1.2, 1.9.1.3, and 1.9.1.4, to reflect that one method of identifying and justifying an alternative to an RG is the use of previous revisions of the RG for design aspects as stated in the DCD in order to preserve the finality of the certified design.*
- *Revise BLN COL FSAR Table 1.9-201 to address the RG listed in Appendix 1AA, thereby providing a more complete cross reference of where each RG is discussed in the COL application.*

In response to RAI 1-11, TVA committed to revising BLN COL FSAR Table 1.9-201 and Appendix 1AA to ensure that they are consistent with commitments made in other RAI responses.

The staff's evaluation of the RGs is addressed in Chapters 2 through 19 of this SER as needed. At a minimum the NRC staff's FSER sections will discuss any RG that involves an exception.

The staff finds TVA's responses to RAIs 1-5 and 1-7 acceptable. However, the staff notes that BLN COL FSAR Table 1.9-201 and Appendix 1AA will most likely need additional changes based on the staff's evaluation of the RGs in this SER and TVA's response to RAI 1-11. The NRC staff is still evaluating TVA's response to RAI 1-11 and has not yet made a determination of whether the response is acceptable. This is Open Item 1.4-2. The updating of BLN COL FSAR Table 1.9-201 to reflect changes committed to by TVA in response to RAI 1-11 and the updating of this information to reflect TVA's commitments in other RAI responses is Confirmatory Item 1.4-2.

Resolution of Standard Content Confirmatory Item 1.4-2

The NRC staff verified that VEGP COL FSAR Table 1.9-201 was updated to provide an acceptable cross reference of where each RG is discussed in the COL application. As a result, Confirmatory Item 1.4-2 is resolved for VEGP.

Resolution of Standard Content Open Item 1.4-2

In a letter dated September 21, 2009, the VEGP applicant provided clarification to a previously submitted response dated January 27, 2009 from the BLN applicant. Specifically, the applicant proposed to revise the discussion in the "General comment" portion related to preserving the finality of the certified design in VEGP COL FSAR Sections 1.9.1.1, 1.9.1.2, 1.9.1.3, 1.9.1.4 and Appendix 1AA Note (b); to clarify in VEGP COL FSAR Section 17.5 the "DCD scope" and the "remaining scope" discussion for QA-related RGs (including RG 1.28; RG 1.30, "Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment (Safety Guide 30)"; RG 1.33, "Quality Assurance Program Requirements (Operation)," Revision 2; RG 1.38, "Quality Assurance Requirements for Packaging, Shipping, Receiving, Storage, and Handling of Items for Water-Cooled Nuclear Power Plants," Revision 2; RG 1.39, "Housekeeping Requirements for Water-Cooled Nuclear Power Plants," Revision 2; RG 1.94, "Quality Assurance Requirements for Installation, Inspection, and Testing of Structural Concrete and Structural Steel During the Construction Phase of Nuclear Power Plants," Revision 1; and RG 1.116, "Quality Assurance Requirements for Installation, Inspection, and Testing of Mechanical Equipment and Systems"). In addition, the applicant proposed to revise the VEGP COL FSAR, Appendix 1AA Note (c) to clarify the purpose of a "General" entry under the column labeled "Section Criteria" discussion. It is stated that a "Criteria Section" entry of "General" indicates a scope for the conformance statement of "all regulatory guide positions related to programmatic and/or operational aspects." Thus an associated conformance statement of "Conforms" indicates that the applicant "complies with all regulatory guide positions related to programmatic and or/or operational aspects." The proposed clarifications clearly provide the scope of conformance to the RGs and, therefore, they are acceptable. The staff verified that the VEGP COL FSAR was updated to reflect the above. The staff considers Open Item 1.4-2 resolved for VEGP.

<u>STD COL 1.9-2, WLS COL 1.9-2, STD SUP 1.9-3, and STD SUP 1.9-1</u>

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.4.4:

- *STD COL 1.9-2 (related to the first un-numbered COL information item identified at the end of DCD Table 1.8-2)*

Regarding demonstration of operating experience from Bulletins and GLs, as required by 10 CFR 52.79(a)(37), BLN COL FSAR Table 1.9-204 provides a list of Bulletins and GLs, the appropriate BLN COL FSAR cross-references, and whether the subject matter was addressed in the DCD. The technical discussions related to the specific safety issues are addressed in the related *sections of the BLN COL FSAR and are addressed in Chapters 2 through 19 of this SER as needed.*

The evaluation of GSI 163, "Multiple Steam Generator Tube Leakage," is described below because otherwise its evaluation would be spread across several SER chapters.

GSI 163 identified a safety concern associated with the potential multiple steam generator (SG) tube leaks triggered by a main steam line break outside containment that cannot be isolated. The issue was evaluated as part of the AP1000 DCD review and was resolved for the AP1000 design. The evaluation was documented in NUREG-1793, Chapter 20. The evaluation states in part the following:

> *The staff agrees that the issue should be closed for the AP1000 design. Issue 163 concerns the possibility that a multiple steam generator tube rupture (SGTR), resulting from a main steam line break and degraded SG tubes, could result in core damage due to depletion of the reactor coolant and safety injection fluid in the refueling water storage tank. For the AP1000 design, an SGTR is mitigated using the passive core cooling system, initially through the passive residual heat removal heat exchanger, and the core makeup tanks (CMTs). After the CMTs drain to the low level to actuate the automatic depressurization system, the reactor coolant depressurization would result in gravity injection from the in containment refueling water storage tank (IRWST), and eventually from the containment recirculation. The scenario that the safety injection from the refueling water storage tank, which is outside the containment in the existing plants, will be depleted to result in core damage is not likely for the AP1000 design because the IRWST and containment recirculation will continue to provide core cooling.*

Since the resolution of Issue 163 is an ongoing NRC effort, any future requirements for the resolution of this issue will be required of the COL applicant, if applicable to the AP1000 design.

Subsequent to the original issuance of NUREG-1793, GSI 163 was closed via a July 16, 2009, memorandum. In the safety evaluation accompanying the closure of the issue, the following is stated.

> *the staff concludes that the technical specification requirements relating to SG tube integrity provide reasonable assurance that all tubes will exhibit acceptable structural margins against burst or rupture during normal operation and DBAs (including MSLB [main steam line break]), and that leakage from one or multiple tubes under DBAs will be limited to very small amounts, consistent with the applicable regulations for offsite and control room dose.*

Therefore, in addition to the unique design features of the AP1000 cited in NUREG-1793 and its supplements as a basis for closure of the issue, the staff *notes that for PWR designs in general the issue is resolved based on the technical specification requirements. The staff discusses these technical specification requirements in Section 5.4, "Component and Subsystem Design," of this SER. Based on the evaluation in NUREG-1793 and its supplements, and based on the staff's evaluation of the SG tube surveillance program in Section 5.4 of this SER, the staff considers GSI 163 resolved for VEGP*.

- *STD COL 1.9-3*

Regarding consideration of new and generic safety issues as required by 10 CFR 52.79(a)(17) and 10 CFR 52.79(a)(20), BLN COL FSAR Table 1.9-203, provides a listing of the TMI Action Plan items, Task Action Plan items, New Generic Issues, Human Factors issues, and Chernobyl Issues and states how they were considered in the DCD and COL application. The technical discussions related to the specific safety issues are addressed in the related sections of the BLN COL FSAR.

In addition, the applicant provided discussion of four new generic issues: Issue 186 related to heavy load drops; Issue 189 related to susceptibility of certain containments to early failure from hydrogen combustion; Issue 191 related to PWR sump performance; and Issue 196 related to the use of Boral in long-term dry storage casks for spent reactor fuel.

The applicant identified that neither Issue 189 nor Issue 196 is applicable to the design or application and that therefore neither is addressed in the BLN COL FSAR. Issue 186 states that there are not any planned heavy load lifts outside those described in the DCD; nonetheless, special procedures to address heavy loads are discussed in Subsection 9.1.5.3. Related to Issue 191, the applicant provided a reference to the protective coatings program and containment cleanliness program in Subsections 6.1.2.1.6 and 6.3.8.1 of the BLN COL FSAR, respectively.

Issue 186 and Issue 196 are evaluated in Chapter 9 of this SER. Issues 189 and 191 are evaluated in Chapter 6 of this SER.

- *STD SUP 1.9-1*

Regarding conformance with regulatory review criteria as required by 10 CFR 52.79(a)(41), BLN COL FSAR Table 1.9-202 provides the applicant's review of conformance with the acceptance criteria of NUREG-0800. The technical discussions related to the specific acceptance criteria of NUREG-0800 are addressed in the related sections of the BLN COL FSAR and addressed in Chapters 2 through 19 of this SER as needed.

<u>STD SUP 1.9-2</u>

The applicant clarified that the severe accident mitigation design alternatives evaluation for the AP1000 in Appendix 1B to the AP1000 DCD is not incorporated into the WLS COL FSAR; but is addressed in the WLS COL Environmental Report. The staff reviewed this information as part of its development of the Final Environmental Impact Statement. Therefore, no further evaluation is needed for STD SUP 1.9-2.

STD SUP 1.9-3 and WLS SUP 1.9-4

The following portion of this technical evaluation section is reproduced from of VEGP SER Section 1.4.4:

- *STD SUP 1.9-3*

This COL supplemental item is addressed as VEGP SUP 8.1-2 [WLS SUP 8.1-2] *in SER Section 8.1*.

WLS COL FSAR Section 1.10

In this section of the application, the applicant provided an assessment of the potential hazards due to construction of one unit on SSCs important to safety for an operating unit, in accordance with 10 CFR 52.79(a)(31).

STD SUP 1.10-1

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.4.4:

- *STD SUP 1.10-1*

The NRC staff reviewed the information in BLN COL FSAR Table 1.10-201, identifying the potential hazards from construction activities, BLN COL FSAR Table 1.10-202 that cross-references the construction hazard with the impacted SSCs, and BLN COL FSAR Table 1.10-203, identifying the specific managerial and administrative controls to preclude or mitigate the construction hazard. There is the potential that review of other areas of the application could impact the hazards and management programs identified in the Bellefonte application. For example, site runoff from construction of Unit 4, if not properly controlled, could impact the operation of Unit 3. Site runoff is evaluated in Section 2.4 of this report. The staff has not yet completed its review of this application against the requirements of 10 CFR 52.79(a)(31). This is part of Open Item 1.4-3.

In the application, TVA stated that controls within Section 1.10 of the FSAR are not required unless there is an operating unit on the site. To clarify this FSAR commitment, the staff requests TVA to revise the application to positively state these programs will be in place when there is an operating unit on the site. This is Open Item 1.4-4.

Resolution of Standard Content Open Item 1.4-4

In a letter dated July 29, 2009, the applicant proposed to revise VEGP COL FSAR Section 1.10.3 to positively state that these programs will be in place when there is an operating unit on the site. The staff verified that the VEGP COL FSAR was appropriately updated to include the above. As a result, Open Item 1.4-4 is resolved.

WLS SUP 1.10-1

The supplemental information states that the power blocks for WLS Units 1 and 2 have a minimum separation of at least 800 feet between plant centerlines and notes that new units SSCs important to safety are described in WLS COL FSAR Chapter 3 and the LCOs for WLS Units 1 and 2 are identified in Part 4 of the WLS COL application. In the standard portion of WLS COL FSAR Section 1.10, there is a discussion that the primary consideration in setting the 800-ft separation distance is the space needed to support plant construction via the use of a heavy-lift crane.

The site-specific supplemental information is provided to supplement the standard information above and provides with specificity the location of the SSCs and LCOs required by 10 CFR 52.79(a)(31). The staff's review of this SUP item is included in the resolution of Open Item 1.4-3.

STD SUP 1.10-1

The following portion of this technical evaluation section is reproduced from of VEGP SER Section 1.4.4:

> *Resolution of Standard Content Open Item 1.4-3*
>
> *A new draft ISG-22 has been issued to assist the staff with the evaluation of COL applicants' compliance with the requirements of 10 CFR 52.79(a)(31). The above draft ISG document was made available to the public including the The regulation at 10 CFR 52.79(a)(31) requires, in part, that applicants for a COL intending to construct and operate new nuclear power plants on multi-unit sites provide an evaluation of the potential hazards to the SSCs important to safety for operating units resulting from construction activities on the new units. The requirement in 10 CFR 52.79(a)(31) can be viewed as having two subparts: applicant and was discussed at a public meeting on August 26, 2010.*
>
> 1. *The COL applicant must evaluate the potential hazards from constructing new plants on SSCs important to safety for existing operating plants that are located at the site.*
>
> 2. *The COL applicant must evaluate the potential hazards from constructing new plants on SSCs important to safety for newly constructed plants that begin operation at the site*
>
> *The interim guidance recommends that the applicant provide a construction impact evaluation plan that includes:*
>
> - *A discussion of the construction activity identification process and the impact evaluation criteria used to identify and evaluate the construction activities that may pose potential hazards to the SSCs important to safety for operating unit(s).*
>
> - *A table of those construction activities and the potential hazards that are identified using that construction impact evaluation plan, the SSCs important to safety for the operating unit potentially impacted by the construction activity, and expected mitigation method.*

- *Identification of the managerial and administrative controls, such as proposed license conditions that may involve construction schedule constraints or other restrictions on construction activities, that are credited to preclude and/or mitigate the impacts of potential construction hazards to the SSCs important to safety for the operating unit(s).*

- *A discussion of the process for communications and interactions planned and credited between the construction organization and the operations organization to ensure appropriate coordination and authorization of construction activities and implementation of the prevention or mitigation activities as necessary.*

- *A memorandum of understanding or agreement (MOU or MOA) between the COL applicant and the operating unit(s) licensee as a mechanism for communications, interactions, and coordination to manage the impact of the construction activities.*

- *An implementation schedule corresponding to construction tasks or milestones to ensure the plan is reviewed on a recurring basis and maintained current as construction progresses.*

The staff reviewed the VEGP COL FSAR Section 1.10, which provides information to address compliance with 10 CFR 52.79(a)(31). In order to complete the staff's review, in RAI 1.5-2, the staff requested that the applicant provide a construction impact evaluation plan that includes:

- *A discussion of the process for communications and interactions planned and credited between the construction organization and the operations organization to ensure appropriate coordination and authorization of construction activities and implementation of the prevention or mitigation activities as necessary.*

- *A memorandum of understanding or agreement (MOU or MOA) between the COL applicant and the operating unit(s) licensee as a mechanism for communications, interactions, and coordination to manage the impact of the construction activities.*

- *An implementation schedule corresponding to construction tasks or milestones to ensure the plan is reviewed on a recurring basis and maintained current as construction progresses.*

In addition, the applicant was requested to identify the managerial and administrative controls (VEGP COL FSAR Table 1.10-203) that are credited to preclude and/or mitigate the impacts of potential construction hazards to the SSCs important to safety for the operating units (VEGP Units 1 and 2).

In a letter dated November 2, 2010, the applicant stated:

- *VEGP COL FSAR Sections 1.10.2 and 13AA will be revised to include the discussion of the process for communications and interactions planned* *and credited between the construction organization and the operations organization.*

- *The COL applicant and the operating unit(s) licensee are the same entity, thus, no MOU or MOA is considered necessary.*

- *VEGP COL FSAR Sections 1.10.3 and 13AA will be revised to include the discussion of the implementation schedule corresponding to construction tasks or milestones.*

- *VEGP COL FSAR will be revised to indicate that managerial and administrative controls are developed and implemented as work progresses on site. These controls are intended to preclude and/or mitigate the impacts of potential construction hazards to the SSCs important to safety for the operating units.*

The proposed changes to the VEGP COL FSAR meet the draft guidance of ISG-22 and, therefore, meet the requirements of 10 CFR 50.79(a)(31). The incorporation of the above proposed changes into a future revision of the VEGP COL FSAR is ***Confirmatory Item 1.4-2****.*

Resolution of Standard Content Confirmatory Item 1.4-2

Confirmatory Item 1.4-2 is an applicant commitment to revise FSAR Sections 1.10.2 and 1.10.3 and Appendix 13A to address guidance included in ISG-22. The staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 1.4-2 is now closed.

License Conditions

- *Part 10, License Condition 1, ITAAC*

The applicant proposed that the ITAAC identified in the tables in Appendix B of Part 10 of the VEGP COL application be incorporated into the COL. The proposed license condition also states that after the Commission has made the finding required by 10 CFR 52.103(g), "Operation under a combined license," the ITAAC do not constitute regulatory requirements; except for specific ITAAC, which are subject to a hearing under 10 CFR 52.103(a), their expiration will occur upon final Commission action in such proceeding.

The ITAAC identified in tables in Appendix B of Part 10 of the VEGP COL application are evaluated throughout this SER. The remaining text of the proposed license condition is already covered by regulatory requirements of 10 CFR 52.103(h). Therefore, there is no need for a license condition.

1.4.5 Post Combined License Activities

There are no post-COL activities related to this section.

1.4.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to principal review matters, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

1.5 Additional Regulatory Considerations

1.5.1 10 CFR 52.97(a)(1)(iv) Applicant Financial Qualifications and Evaluation of Financial Qualification in accordance with 10 CFR 50.33

BACKGROUND:

Duke Energy Carolinas, LLC

According to the COL application, Duke Energy Corporation, the holding company of Duke Energy Carolinas LLC (Duke), is one of the largest electric holding companies in the United States. Through its regulated electric and gas utility operating companies, Duke Energy Corporation operates more than 36,000 MW of electric generation; over 75 percent of which is subject to cost of service ratemaking.

Duke is a wholly owned subsidiary of Duke Energy Corporation and is a limited liability company duly organized and existing under the laws of the State of North Carolina. Duke is engaged in the business of generating, transmitting, distributing and selling electric power and energy.

Duke owns and operates regulated electrical facilities, including seven (7) nuclear units licensed by the NRC, as well as electrical distribution and transmission facilities. Lee Units 1 and 2 (Lee 1 and 2) will be used to produce electricity for sale.

REGULATORY EVALUATION:

The applicant's request for the NRC to issue two combined licenses under Section 103 of the Atomic Energy Act of 1954, as amended, for construction and operation is subject to, among other things, the requirements of the Atomic Energy Act of 1954, as amended; Subpart C to 10 CFR Part 52, 10 CFR Part 50 and 10 CFR Part 140.

In its review, the NRC staff used guidance in NUREG-1577, "Standard Review Plan on Power Reactor Licensee Financial Qualifications and Decommissioning Funding Assurance," Revision 1, issued February 1999, to evaluate the financial qualifications of the applicant to construct, operate, and decommission the proposed facility.

In addressing foreign ownership, control, or domination (FOCD), the NRC staff used guidance in the Standard Review Plan (SRP), "Foreign Ownership, Control, and Domination of applicants for Reactor Licenses, "dated June 1999 (SRP on FOCD) to determine whether the applicant is owned, controlled or dominated by an alien, a foreign corporation, or a foreign government. The

NRC published the SRP on FOCD in the *Federal Register* on September 28, 1999 (64 FR 52357-52359).

The staff also used guidance in NUREG-1307, Revision 15, "Report on Waste Burial Charges: Changes in Decommissioning Waste Disposal Costs at Low-Level Waste Burial Facilities," to independently validate the licensee's calculation of the minimum funding needed for decommissioning.

The safety evaluation documents the staff's review and analysis of financial qualifications, decommissioning funding assurance, FOCD, and nuclear insurance and indemnity. In addition, this safety evaluation contains proprietary information that is withheld from public disclosure per 10 CFR 2.390 as commercially sensitive.

FINANCIAL QUALIFICATIONS:

Pursuant to 10 CFR 52.77, the application must include all of the information required by 10 CFR 50.33.

Construction:

Pursuant to 10 CFR 50.33(f)(1):

> [T]he applicant[s] shall submit information that demonstrates that the applicant[s] possess or [have] reasonable assurance of obtaining the funds necessary to cover estimated construction costs and related fuel cycle costs. The applicant[s] shall submit estimates of the total construction costs of the facility and related fuel cycle costs, and shall indicate the source(s) of funds to cover these costs.

Under 10 CFR Part 50, Appendix C, "A guide for the Financial Data and Related Information Required To Establish Financial Qualifications for Construction Permits and Combined Licenses," Section I.A.1:

> [E]ach applicant's estimate of the total cost of the proposed facility should be broken down as follows and be accompanied by a statement describing the bases from which the estimate is derived:
>
> (a) Total nuclear production plant costs; [and]
>
> (b) Transmission, distribution, and general plant costs; [and]
>
> (c) Nuclear fuel inventory cost for first core.
>
> If the fuel is to be acquired by lease or other arrangement than purchase, the application should so state. The items to be included in these categories should be the same as those defined in the applicable electric plant and nuclear fuel inventory accounts prescribed by the Federal Energy Regulatory Commission [FERC] or an explanation given as to any departure from therefrom.

In accordance with 10 CFR 50.33(f) and 10 CFR Part 50, Appendix C, the projected overnight costs for the construction of two AP1000 nuclear units at the Lee site are outlined below.

PROJECTED PROJECT COST
WILLIAM STATES LEE III NUCLEAR STATION, UNITS 1 & 2
(Combined, in millions 2015 $)[9]

	Unit 1 and Unit 2	Common	Total
Total Nuclear Production Plant Costs......	[[		]]
Transmission, Distribution...... & General Plant Costs	[[		]]
Nuclear Fuel Inventory & Cost for First Core.........	[[		]]
TOTAL (OVERNIGHT COST)	[[		]]

The construction cost estimate is expressed in terms of "overnight cost," which is a term commonly used in describing the cost of large capital projects[10]. The applicant calculated combined Unit 1 and Unit 2 cost estimates for plant construction. According to the COL application, the assumed construction period for Unit 1 is from 2019 to 2024 and for Unit 2, 2020 to 2025. Lee Units 1 and 2 is expected to operate at an estimated combined gross electrical power output of approximately 2234 MWe. Therefore, the total overnight cost, including fuel costs as described above, is [[ ]] million. This is approximately [[ ]]/kWe installed. As stated in the application, in part, estimated plant costs are informed by project pricing from the Westinghouse Electric Corporation and Chicago Bridge and Iron (WEC/CB&I) consortium (escalated to 2015 dollars); evaluation of owner's costs including costs for transmission system ties and upgrades; and contingency costs for construction. In consideration of the information provided in the application and as summarized above, the NRC staff finds the applicant's AP1000 overnight construction cost estimate to be a reasonable projection based on a number of studies[11] that have been conducted by governmental agencies, universities and other entities, and is consistent with the publicly available cost estimates of other U.S. AP1000 projects. In particular, the U.S. Energy Information Administration's (EIA) June 2012 report, "Annual Energy Outlook 2012 with Projections to 2035," (DOE/EIA-0383(2012)), states that "…the overnight capital costs associated with building a nuclear power plant planned in 2012 are assumed to be $5,335 per kilowatt of capacity…" The staff applied a conservative annual adjustment factor ranging from 3% to 10% to the EIA overnight capital cost estimate to account for inflation beyond 2012, and determined that the EIA projected 2015 overnight cost would range from $5,830 to $7,101/kWe installed. The construction cost estimate is expressed in terms of "overnight cost," which is a term commonly used in describing

[9] Commercially sensitive data. The data in brackets cannot be released to the public.

[10] Overnight cost is the cost of a construction project if no interest was incurred during construction, as if the project was completed "overnight." An alternate definition is: the present value cost that would have to be paid as a lump sum up front to completely pay for a construction project. The overnight cost is frequently used when describing power plants.

[11] See, e.g., the 2003 the Massachusetts Institute of Technology (MIT) interdisciplinary study entitled The Future of Nuclear Power; the U.S. Department of Energy's Energy Information Agency (EIA) 2012 Annual Energy Outlook (AEO); the Nuclear Energy Agency (NEA) of the Organization for Economic Cooperation and Development 2005 update on Projected Costs of Generating Electricity; and the Keystone Center 2007 report entitled Nuclear Power Joint Fact-Finding.

the cost of large capital projects[12]. The applicant's overnight cost estimate of [[ ]]/kWe installed is slightly less than, but in line with, the most recent EIA 2012 range of overnight costs as adjusted for inflation. Accordingly, the NRC staff finds Duke's overnight cost estimate to be reasonable as presented in its COL application.

Sources of Construction Funds:

Pursuant to 10 CFR, Part 50, Appendix C, I.A.2:

> [t]he application should include a brief statement of the applicant's general financial plan for financing the cost of the facility, identifying the source or sources upon which the applicant relies for the necessary construction funds, e.g., internal sources such as undistributed earnings and depreciation accruals, or external sources such as borrowings.

Duke's Source of Construction Funds

According to the COL application, Duke intends to construct Lee as a regulated asset eligible for cost recovery under North Carolina Statute, G.S. 62-110.1, 62-110.7, 62-133(b) and South Carolina Title 58, Chapter 33, Sections 58-33-220, 58-33-225, 58-33-270, 58-33-280 outlining the recovery for reasonable and prudently incurred costs for a nuclear generation construction project

Duke expects to finance this project through a mixture of internally generated cash and external funding. The three primary sources are cash from operations, debt issued by Duke Energy Carolinas, LLC, and retained earnings and equity infused by its parent, Duke Energy Corporation, as needed, to balance the utility's regulated capital structure to a targeted level. Further, the applicant stated that it may borrow from Duke Energy Corporation to fund a portion of its capital requirements until such time as it is opportune to issue long-term debt securities (bonds or debentures). The staff concludes that Duke Energy Carolinas, LLC and Duke Energy Corporation have sufficient financing capacity to fund this project from the following sources: internally generated operating cash flows, commercial paper and bank facilities, and long-term and equity capital markets.

<u>Financial Statements</u>

Pursuant to 10 CFR, Part 50, Appendix C, I.A.3:

> [t]he application should also include the applicant's latest published annual financial report, together with any current interim financial statements that are pertinent. If an annual financial report is not published, the balance sheet and operating statement covering the latest complete accounting year together with all pertinent notes thereto and certification by a public accountant should be furnished.

<u>Duke Energy Corporation Financial Statements</u>

Duke Energy Corporation files financial statements with the U.S. Securities and Exchange Commission (SEC) at the time the COL application was submitted. Duke submitted, pursuant to

Appendix C.I.A 3, to 10 CFR Part 50, annual financial statements. The NRC staff did not identify anything in Duke's financial statements that warranted further inquiry.

Operating License

Pursuant to 10 CFR 50.33(f)(3),

> If the application is for a combined license under Subpart C of 10 CFR Part 52 of this chapter, the applicant shall submit the information described in paragraphs (f)(1) and (f)(2) of this section.

10 CFR 50.33(f) provides that each application shall state:

> [e]xcept for an electric utility applicant for a license to operate a utilization facility of the type described in 10 CFR 50.21(b) or 50.22, information sufficient to demonstrate to the Commission the financial qualification[s] of the applicant to carry out, in accordance with the regulations in this chapter, the activities for which the permit or license is sought.

10 CFR 50.2, "Definitions" states, in part, that an electric utility is:

> [a]ny entity that generates or distributes electricity and which recovers the cost of this electricity, either directly or indirectly, through rates established by the entity itself or by a separate regulatory authority.

The applicant is an electric utility as defined in 10 CFR 50.2. The applicant generates and distributes electricity and recovers the cost of this electricity through cost-of-service based rates established by the North Carolina Public Utility Commission, South Carolina Public Service Commission, and FERC.

Based on the foregoing, the staff finds that Duke is an electric utility and not subject to a financial qualifications review pursuant to 10 CFR 50.33(f)(2).

DECOMMISSIONING FUNDING ASSURANCE:

Regulatory Requirements:

Pursuant to 10 CFR 50.33(k)(1):

> [A]n application for [a …] combined license for a production or utilization facility, information in the form of a report, as described in 10 CFR 50.75, indicating how reasonable assurance will be available to decommission the facility.

Under 10 CFR 50.75, "Reporting and recordkeeping for decommissioning planning," the report must include a certification that the applicant will provide financial assurance for decommissioning using one or more of the methods allowed under the regulation at 10 CFR 50.75(e) no later than 30 days after the Commission publishes notice in the *Federal Register* under 10 CFR 52.103(a). In addition, the amount of the financial assurance may be more, but not less, than the amount stated in the table in 10 CFR 50.75(c)(1), as adjusted under 10 CFR 50.75(c)(2). Under 10 CFR 50.75(b)(4), a COL applicant need not obtain a financial instrument appropriate to the method to be used or submit a copy of the instrument to the

Commission. (Once the COL is granted, the holder of a COL must submit an instrument as provided in 10 CFR 50.75(e)(3)).

Additionally, the staff used the guidance in NUREG-1577, Rev. 1, in its review of the Lee 1 and 2 COL application.

Decommissioning Funding Estimate

The proposed plant is a simplified passive advanced light water reactor plant that is being licensed in accordance with the Westinghouse AP1000 certified design, as documented in the referenced DCD and its supplements**.** This design has a per unit thermal power rating of 3400 MWt. In its April 11, 2016 submittal, the applicant stated that it will provide decommissioning funding assurance in an amount of $517 million (2015 dollars) per unit. This value was derived using the methodology delineated in 10 CFR 50.75(c), and guidance in NUREG-1307, Revision 15. The NRC staff independently calculated the minimum funding needed for Lee Units 1 and 2 using the regulations and guidance described above, and obtained results similar to Duke's. Accordingly, the staff finds that the amount provided by Duke is acceptable.

Decommissioning Funding Mechanism

Pursuant to 10 CFR 50.75(b), a reactor licensee is required to provide decommissioning funding assurance by one or more of the methods described in 10 CFR 50.75(e), as determined to be acceptable to the NRC. According to the COL application, Duke has chosen to provide decommissioning funding assurance for Lee 1 and 2 using an external sinking fund. Duke's external sinking fund will be in the form of a trust; will be established in writing and maintained at all times in the United States with an entity that is an appropriate State or Federal government agency, or an entity whose operations are regulated and examined by a State or Federal agency; and will include the provisions required by 10 CFR 50.75(h)(2). The staff finds that Duke's use of an external sinking fund is acceptable since it will recover, either directly or indirectly, the estimated total cost of decommissioning through rates established by "cost of service" or similar ratemaking regulation. Therefore, the staff finds this method to be acceptable since it meets the requirements in 10 CFR 50.75(e)(1)(ii).

Certification Updates, Financial Instruments, and Annual Adjustment

According to the application, two years and one year before the scheduled date for initial loading of fuel, Duke will submit a report updating this certification in accordance with 10 CFR 50.75(e)(3) and providing copies of the financial instruments to be used. In addition, no later than 30 days after the NRC publishes the notice in the Federal Register under 10 CFR 52.103(a), Duke will submit a report containing a certification that the financial assurance for decommissioning is being provided in an amount specified in the most recent updated certification and will include a copy of the executed financial agreements obtained to satisfy the requirements of 10 CFR 50.75(e). Thereafter, the decommissioning funding amount will be adjusted annually using a rate at least equal to that stated in 10 CFR 50.75(c)(2). The staff finds Duke's proposed plan as described above and in the application to be reasonable.

ANTITRUST REVIEW:

The Energy Policy Act of 2005 (EPAct) removed the antitrust review authority contained in section 105.c of the Atomic Energy Act of 1954, as amended (AEA), regarding license applications for production or utilization facilities submitted under sections 103 or 104b of the AEA after the date of enactment of the EPAct. Accordingly, the NRC is not authorized to conduct an antitrust review in connection with this combined license application.

FOREIGN OWNERSHIP, CONTROL, or DOMINATION:

Section 103 of the AEA, in relevant part, prohibits the Commission from issuing a license for a nuclear power plant to:

> an alien or any corporation or other entity if the Commission knows or has reason to believe it is owned, controlled, or dominated by an alien, a foreign corporation or a foreign government.

10 CFR Part 50.38 "Ineligibility of certain applicants," is the regulatory provision that implements this statutory prohibition.

The NRC staff reviewed the application pursuant the guidance provided in the SRP on FOCD to determine whether the applicant is owned controlled, or dominated by an alien, a foreign corporation, or a foreign government.

Duke Foreign Ownership, Control, or Domination

According to the application, Duke is not owned, controlled or dominated by any alien, foreign corporation or foreign government. Duke is a limited liability company organized under the laws of the State of North Carolina and whose principal place of business is Charlotte, North Carolina. Duke is wholly owned by Duke Energy Corporation, a Delaware corporation whose principal place of business is Charlotte, North Carolina. The shares of common stock of Duke Energy Corporation are publicly traded and widely held. The application also contains the names and addresses of the directors and officers of Duke Energy Corporation and Duke and indicates that all are United States citizens.

The NRC Staff performed an independent analysis, including open-source research and verification of the information provided in the application related to the ownership of Duke, and found no evidence FOCD.

Based on this review, the staff does not know or have reason to believe that Duke is owned, controlled, or dominated by a foreign interest. Therefore, Duke conforms to the guidance provided in the SRP for FOCD and meets the requirements of 10 CFR 50.38.

NUCLEAR INSURANCE and INDEMNITY:

This section of the SER addresses the applicant's offsite and onsite insurance requirements found in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 140, "Financial protection requirements and indemnity agreements," and 10 CFR 50.54(w), respectively.

The provisions of the Price-Anderson Act (Section 170 of the Atomic Energy Act of 1954, as amended) and the Commission's regulations in 10 CFR Part 140, "Financial Protection Requirements and Indemnity Agreements," require, in part, that each holder of a license issued pursuant to 10 CFR Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants," have and maintain financial protection. Further, 10 CFR 50.54(w) establishes requirements for each power reactor licensee to obtain insurance or provide an equivalent amount of protection for the onsite costs of an accident. Under these regulations, Duke is required to provide satisfactory documentation that it has obtained the amount of financial protection required by (1) 10 CFR 140.13, “Amount of financial protection required of certain holders of construction permits and combined licenses under 10 CFR part 52,” (2) 10 CFR 140.11(a)(4), and (3) 10 CFR 50.54(w). In addition, each licensee required to have and maintain financial protection under 10 CFR 140.11(a)(4) shall provide evidence that it maintains a guarantee of payment of deferred premiums pursuant to 10 CFR 140.21, “Licensee guarantees of payment of deferred premiums.” Finally, as required by 10 CFR 140.20, “Indemnity agreements and liens,” the NRC staff will amend Duke’s current indemnity agreement to include the addition of Lee Units 1 and 2.

The regulation in 10 CFR 140.13 provides the amount of financial protection required by a Part 52 license holder, who also holds a license under 10 CFR Part 70, “Domestic Licensing of Special Nuclear Material,” during the period before the Commission makes the finding under 10 CFR 52.103(g) (i.e., a finding that the acceptance criteria in the license are met, which allows the licensee to initially load fuel and operate). Because the 10 CFR Part 70 license will be issued with the COL, Duke must have and maintain $1,000,000 in financial protection from issuance of the COL until the 10 CFR 52.103(g) finding is made. In addition, as required by 10 CFR 140.11(a)(4), after the 10 CFR 52.103(g) finding is made, each licensee must have and maintain financial protection in an amount equal to the sum of primary financial protection ($375,000,000) and the amount available as secondary financial protection.

By letter dated February 19, 2016, (ADAMS Accession No. ML16056A014), Duke’s insurance broker, Marsh USA, Inc., provided proof of insurance coverage from American Nuclear Insurers in the amount of $1,000,000. Duke’s $1,000,000 insurance policy will remain in effect until the 10 CFR 52.103(g) finding. Therefore, the staff concludes that the proof of financial protection provided by DEC will satisfy the requirements in 10 CFR 140.13.

The staff notes that although licensees of large operating reactors under 10 CFR Parts 50 and 10 CFR Part 52 must have and maintain financial protection under 10 CFR 140.11 (a) (4) upon NRC action authorizing operation, the timing provisions for reporting under 10 CFR Part 140.21 do not explicitly address the 10 CFR Part 52 process. Under the requirements in 10 CFR 140.11(a)(4), 10 CFR 140.21, the coverage for secondary financial protection and the guarantee of payment of deferred premiums, are only required for reactors authorized to load fuel and operate. Under 10 CFR Part 52 COL process, the license authorizes operation only upon a Commission finding pursuant to 10 CFR 52.103(g). Therefore, these requirements apply as of the date the Commission makes such a finding. While 10 CFR 50.54(w) by its terms applies upon a Commission finding under 10 CFR 52.103(g), Duke also included a reporting requirement for 10 CFR 50.54(w) in its proposed condition.

Duke proposed the following license condition to address the reporting of 10 CFR Section 140.11(a)(4) requirements for secondary financial protection, and the reporting of 50.54(w) requirements for onsite financial protection. The staff agreed with the proposed license condition but made some modifications. The staff’s recommended license condition is stated below:

- License Condition (1-1) – Before the scheduled date for initial fuel load, and within ninety (90) days after the NRC publishes the notice of intended operation in the Federal Register, Duke shall provide satisfactory documentary evidence to the Director of the Office of Nuclear Reactor Regulation, or designee, that it has obtained the appropriate amount of primary and secondary financial protection required of licensees pursuant to 10 CFR 140.11(a)(4) and the appropriate amount of financial protection per 10 CFR 50.54(w).

With the license condition as described above, the staff concludes that Duke will satisfy the requirements of 10 CFR 140.11(a)(4) with respect to obtaining an appropriate amount of secondary financial protection and 10 CFR 50.54(w) with respect to obtaining the appropriate amount of financial protection. The staff notes that it will conform any license condition to the correct format if the Commission determines to issue the license. For example, the staff may change “the Director of the Office of Nuclear Reactor Regulation” to “the Director of the Office of New Reactors” and the like.

Duke also proposed the following license condition to address the reporting of 10 CFR 140.21 for guarantee of payment of deferred premiums. The staff agreed with the proposed license condition but made some modifications. The staff’s recommended license condition is stated below:

- License Condition (1-2) – Before the scheduled date of initial fuel load, and within ninety (90) days after the NRC publishes the notice of intended operation in the *Federal Register,* Duke shall provide evidence to the NRC that it would have the ability to pay into the nuclear industry retrospective rating plan in the event of a nuclear incident and in the amount specified in 10 CFR Part 140.11(a)(4) [sic] for one calendar year using one of the following methods:

  (a) Surety bond,

  (b) Letter of credit,

  (c) Revolving credit/term loan arrangement,

  (d) Maintenance of escrow deposits of government securities, or

  (e) Annual certified financial statement showing either that a cash flow (i.e., cash available to a company after all operating expenses, taxes, interest charges, and dividends have been paid) can be generated and would be available for payment of retrospective premiums within three (3) months after submission of the statement, or a cash reserve or a combination of cash flow and cash reserve.

  Thereafter, Duke shall provide evidence of the guarantees of payment of deferred premiums in accordance with the provisions specified in 10 CFR 140.21.

With the license condition as described above, the staff concludes that Duke will satisfy the requirement in 10 CFR 140.21.

In consideration of the staff’s evaluation and license conditions as described above, the staff concludes that DEC will satisfy the provisions of the Price-Anderson Act (Section 170 of the Atomic Energy Act of 1954, as amended) and the Commission’s applicable regulations in 10 CFR Part 140, 10 CFR Part 52, and 10 CFR Part 50 for insurance and indemnity.

CONCLUSION:

Based on the foregoing evaluation above, in consideration of the proposed license conditions, the NRC staff finds reasonable assurance that Duke is financially qualified to engage in the proposed activities regarding William States Lee III, Units 1 and 2 and that Duke satisfies the NRC requirements relating to financial qualification, decommissioning funding assurance, FOCD, and nuclear insurance and indemnity. The staff finds this acceptable since it conforms to the guidance in NUREG-1577, the SRP on FOCD, NUREG-1307, and meets the applicable regulations in 10 CFR Part 52, 10 CFR Part 50, and 10 CFR Part 140 as described above.

1.5.2 Nuclear Waste Policy Act

Nuclear Waste Policy Act of 1982, as amended, Section 302(b), “The Commission, as it deems necessary or appropriate, may require as a precondition to the issuance or renewal of a license under Section 103 or 104 of the Atomic Energy Act of 1954 [42 U.S.C. 2133, 2134] that the applicant for such license shall have entered into an agreement with the Secretary for the disposal of high-level radioactive waste and spent nuclear fuel that may result from the use of such license.”

On November 4, 2008, DEC entered into a contract with the United States Department of Energy (DOE) establishing the terms and conditions associated with the DOE’s responsibility for disposal of spent nuclear fuel and high-level radioactive waste generated at the proposed WLS Units 1 and 2 (ADAMS Accession No. ML083510882). The COE contract numbers applicable to WLS Units 1 and 2 are DE-CR01-09RW09003 and DE-CR01-09RW09004 respectively.

Since DEC has entered into contracts with the DOE for the disposal of high-level radioactive waste and spent nuclear fuel for WLS Units 1 and 2, the staff considers the applicable requirements of Nuclear Waste Policy Act of 1982, Section 302(b) to be met.

1.5.3 Consultation with Department of Homeland Security and Notifications

1.5.3.1 *Consultation with Department of Homeland Security*

In accordance with *Energy Policy Act of 2005,* Section 657, the staff consulted with the Department of Homeland Security (DHS). By letter, dated July 16, 2008, DHS provided their New Reactor Consultation Report on the William S. Lee Nuclear Station proposed to be built in Gaffney, South Carolina. The New Reactor Consultation Report satisfies the requirements of Section 657 of the Energy Policy Act of 2005.

1.5.3.2 *Notifications*

As required by Section 182c of the Atomic Energy Policy Act of 1954, as amended, and 10CFR 50.43(a), on December 15, 2011, the NRC notified the Public Service Commission of South Carolina and the North Carolina Utilities Commission of the WLS COL Application (ADAMS Accession Nos. ML112450014 and ML112450028).

In accordance with Section 182c of the Atomic Energy Policy Act of 1954, as amended, the staff also published a notice of application in the *Federal Register* on November 18, November 25, December 2, and December 9, 2011, 76 (FR 71608, 72725, 75566, and 77021).

Based on the staff's complete of notifications to regulatory agencies and the public notices described above, the staff concludes that, for the purposes of issuing COLs for WLS Units 1 and 2, any required notifications to other agencies or bodies have been duly made.

1.5.4 Evaluation of Departures and Exemption Associated with Application Organization and Numbering (10 CFR Part 52, Appendix D) and Exemption Associated with Special Nuclear Material Material Control and Accounting Program Description (10 CFR Part 70, Subpart D and 10 CFR Part 74 Subparts C, D, and E)

Evaluation of Departures and Exemption Associated with Organization and Numbering in the Application

In STD DEP 1.1-1 the applicant renumbered WLS COL FSAR Sections 2.1.1, 2.1.4, 2.2.1, 2.2.4, 2.4.1, 2.4.15, 2.5, 2.5.6, 9.2.11, 9.2.12, 9.2.13, 9.5.1.8, 9.5.1.9, 13.1, 13.1.4, 13.5, 13.5.3, 13.7, 17.5, 17.6, 17.7, and 17.8 to include content consistent with RG 1.206 and NUREG-0800. The departure and the exemption associated with the numbering scheme of the WLS COL FSAR are closely related.

Pursuant to 10 CFR 52.7, "Specific Exemptions," and 10 CFR 52.93, "Exemptions and Variances," the applicant requested an exemption from 10 CFR Part 52, Appendix D, Section IV.A.2.a, to include "a plant-specific DCD containing the same type of information and using the same organization and numbering as the generic DCD for the AP1000 design…." In WLS COL application Part 7, "Departures and Exemptions," the applicant stated that the exemption will not result in any significant departures from the expected organization and numbering of a typical FSAR, and the information is readily identifiable to facilitate an NRC review. The applicant states that the subject deviations are considered to be purely administrative to support a logical construction of the document. Further, the revised organization and numbering generally follows the guidance provided in RG 1.206 and NUREG-0800.

Pursuant to 10 CFR 52.7, the Commission may, upon application by any interested person or upon its own initiative, grant exemptions from the requirements of 10 CFR Part 52. 10 CFR 52.7 further states that the Commission's consideration will be governed by 10 CFR 50.12, "Specific exemptions," which states that an exemption may be granted when: (1) the exemptions are authorized by law, will not present an undue risk to public health or safety, and are consistent with the common defense and security; and (2) special circumstances are present. Special circumstances are present whenever, according to 10 CFR 50.12(a)(2)(ii), "Application of the regulation in the particular circumstances would not serve the underlying purpose of the rule or is not necessary to achieve the underlying purpose of the rule."

Before considering whether this numbering exemption should be granted, the staff needed to address a threshold question regarding the review standard applicable to the request. Under 10 CFR 52.93(a)(1), if a request for an exemption is from any part of a design certification rule, then the Commission may grant the exemption if the exemption complies with the appropriate change provision in the referenced design certification rule, or if there is no applicable change provision, if the exemption complies with 10 CFR 52.63. Here, there is no applicable change provision in the referenced design certification rule, so according to 10 CFR 52.93(a)(1), the exemption must meet 10 CFR 52.63. However, the standards of the appropriate provision of 10 CFR 52.63 applicable to requests for exemptions from a design certification rule in 10 CFR 52.63(b)(1), by their terms, also do not apply to this change. Specifically, 10 CFR 52.63(b)(1) applies to changes to "certification information," and not administrative or procedural design certification rule provisions such as this one under consideration. In the Statements of Consideration for 10 CFR 52.63, the Commission stated that it used the "phrase 'certification information' in order to distinguish the rule language in the DCRs from the design certification information (e.g., Tier 1 and Tier 2) that is incorporated by reference in the DCRs." (See 72 FR 49444). The exemption requested from the AP1000 DCD numbering scheme is an exemption from rule language, not Tier 1 or Tier 2 information; therefore, 10 CFR 52.63 should not be used to analyze this exemption.

Since there is not an applicable change provision in the referenced design certification, and because 10 CFR 52.63(b)(1) does not apply to this exemption, the exemption cannot comply with the plain language of 10 CFR 52.93(a)(1). In this situation, the language of 10 CFR 52.93(a)(1) does not appear to serve the underlying purpose of the regulation as described by the Commission in the Statements of Consideration to the rule, in which the Commission stated that only changes to certification information must meet 10 CFR 52.63. Instead, this exemption should have fallen under 10 CFR 52.93(a)(2), and, thus, be analyzed under the requirements in 10 CFR 52.7. Therefore, the staff finds that, pursuant to 10 CFR 52.7, an exemption to 10 CFR 52.93(a)(1) should be granted. This exemption is warranted because it meets the requirements in 10 CFR 50.12. First, because this is an administrative change regarding what exemption regulation applies, the exemption to 10 CFR 52.93(a)(1) is authorized by law, will not present an undue risk to public health or safety, and is consistent with the common defense and security. Additionally, application of the regulation in this case is not necessary to achieve the underlying purpose of the rule. The underlying purpose of the rule is to maintain the safety benefits of standardization by requiring any exemption from certification information to meet the requirements in 10 CFR 52.63(b)(1). This underlying purpose does not apply to this exemption, because the form and organization of the application does not affect the safety benefits of standardization of the certification information. Therefore, for the purpose of determining the standards applicable to the exemption related to STD DEP 1.1-1, the staff finds an exemption to 10 CFR 52.93(a)(1) acceptable for the review of the exemption related to STD DEP 1.1-1.

Pursuant to the exemption described above, the staff reviewed the exemption related to STD DEP 1.1-1 to determine whether the requirements in 10 CFR 52.7 are met. This exemption would allow the applicant to provide an FSAR with numbering and topics more closely related to NUREG-0800 and RG 1.206. The staff finds that this administrative change of minor renumbering will not present an undue risk to the public health and safety and is consistent with the common defense and security. In addition, this exemption is consistent with the Atomic Energy Act of 1954, as amended, and is authorized by law. Further, the application of the regulation in these particular circumstances is not necessary to achieve the underlying purpose of the rule. Therefore, the staff finds that the exemption to 10 CFR Part 52, Appendix D, Section IV.A.2.a is justified. Finally, for the same reasons the staff is granting the exemption request, the staff also finds the departure from the numbering scheme in the WLS COL FSAR acceptable.

Exemption Associated with Special Nuclear Material Material Control and Accounting Program

The applicant requested an exemption from the requirements of 10 CFR 70.22(b), 10 CFR 70.32(c) and, in turn, 10 CFR 74.31, 10 CFR 74.41, and 10 CFR 74.51. The provision of 10 CFR 70.22(b) requires an application for a license for SNM to include a full description of the applicant's program for MC&A of SNM under 10 CFR 74.31; 10 CFR 74.33, "Nuclear

material control and accounting for uranium enrichment facilities authorized to produce special nuclear material of low strategic significance"; 10 CFR 74.41; and 10 CFR 74.51[13].
10 CFR 70.32(c) requires a license authorizing the use of SNM to include and be subjected to a condition requiring the licensee to maintain and follow an SNM MC&A program. However, 10 CFR 70.22(b), 10 CFR 70.32(c), 10 CFR 74.31, 10 CFR 74.41, and 10 CFR 74.51 include exceptions for nuclear reactors licensed under 10 CFR Part 50. The regulations applicable to the MC&A of SNM for nuclear reactors licensed under 10 CFR Part 50 are provided in 10 CFR Part 74, Subpart B, 10 CFR 74.11 through 10 CFR 74.19, excluding 10 CFR 74.17. The purpose of this exemption request is to seek a similar exception for this COL under 10 CFR Part 52, such that the same regulations will be applied to the SNM MC&A program as nuclear reactors licensed under 10 CFR Part 50. In addition, the exemption request is evaluated under 10 CFR 52.7, which incorporates the requirements of 10 CFR 50.12. As stated previously, that section allows the Commission to grant an exemption if: 1) the exemption is authorized by law; will not present an undue risk to the public health and safety; and is consistent with the common defense and security; and 2) special circumstances are present as specified in 10 CFR 50.12(a)(2). The criteria in 10 CFR 50.12 encompass the criteria for an exemption in 10 CFR 70.17(a) and 10 CFR 74.7, the specific exemption requirements for 10 CFR Part 70 and 10 CFR Part 74, respectively. Therefore, by demonstrating that the exemption criteria in 10 CFR 50.12 are satisfied, the staff concludes that this request would also demonstrate that the exemption criteria in 10 CFR 52.7, 10 CFR 70.17(a), and 10 CFR 74.7 are satisfied.

The subject exemption would allow nuclear reactors licensed under 10 CFR Part 52 to be explicitly exempted from the requirements of 10 CFR 70.22(b), 10 CFR 70.32(c), 10 CFR 74.31, 10 CFR 74.41, and 10 CFR 74.51. There is no technical or regulatory basis to treat nuclear reactors licensed under 10 CFR Part 52 differently than reactors licensed under 10 CFR Part 50 with respect to the MC&A provisions in 10 CFR Part 74. As indicated in the Statement of Considerations for 10 CFR 52.0(b) (72 FR 49352, 49372, 49436 (August 28, 2007)), applicants and licensees under 10 CFR Part 52 are subject to all of the applicable requirements in 10 CFR Chapter I, whether or not those provisions explicitly mention a COL under 10 CFR Part 52. This regulation clearly indicates that plants licensed under 10 CFR Part 52 are to be treated no differently than plants licensed under 10 CFR Part 50 with respect to the substantive provisions in 10 CFR Chapter I (which includes 10 CFR Part 70 and 10 CFR Part 74). In particular, the exception for nuclear reactors licensed under 10 CFR Part 50, as in 10 CFR 70.22(b), 10 CFR 74.31, 10 CFR 74.41, or 10 CFR 74.51, should also be applied to reactors licensed under 10 CFR Part 52.

The staff agrees with the applicant's justification that nuclear reactors licensed under 10 CFR Part 52 should be treated the same as the reactors licensed under 10 CFR Part 50 regarding the MC&A for SNM.

Pursuant to 10 CFR 70.17(a), the Commission may, upon application of any interested person or upon its own initiative, grant such exemptions from the requirements of the regulations in this part as it determines are authorized by law and will not endanger life or property or the common defense and security and are otherwise in the public interest.

[13] While not including an explicit exception for 10 CFR Part 50 reactors, 10 CFR 74.33 applies only to uranium enrichment facilities and thus is not directly implicated in this exemption request.

In addition, pursuant to 10 CFR 74.7, "Specific exemptions," the Commission may, upon application of any interested person or upon its own initiative, grant such exemptions from the requirements of the regulations in this part as it determines are authorized by law and will not endanger life or property or the common defense and security, and are otherwise in the public interest.

Pursuant to 10 CFR 52.7, the Commission may, upon application by any interested person or upon its own initiative, grant exemptions from the requirements of 10 CFR Part 52. 10 CFR 52.7 further states that the Commission's consideration will be governed by 10 CFR 50.12, "Specific exemptions," which states that an exemption may be granted when: (1) the exemptions are authorized by law, will not present an undue risk to public health or safety, and are consistent with the common defense and security; and (2) when special circumstances are present. Special circumstances are present whenever, according to 10 CFR 50.12(a)(2)(ii), "Application of the regulation in the particular circumstances would not serve the underlying purpose of the rule or is not necessary to achieve the underlying purpose of the rule."

The staff reviewed the subject exemption, which will allow the applicant to have a similar exception for the COL under 10 CFR Part 52, such that the same regulations will be applied to the SNM MC&A program as nuclear reactors licensed under 10 CFR Part 50, and determined that this requested exemption will not present an undue risk to the public health and safety and is otherwise in the public interest. In addition, this exemption is consistent with the Atomic Energy Act of 1954, as amended, and is authorized by law. Therefore, granting this exemption will not adversely affect the common defense and security. Further, the application of the regulation in these particular circumstances is not necessary to achieve the underlying purpose of the rule. Since the exemption criteria in 10 CFR 50.12 are satisfied, the staff considers that this request also demonstrates that the exemption criteria in 10 CFR 52.7, 10 CFR 70.17(a), and 10 CFR 74.7 are satisfied. Therefore, the staff finds that the exemption from 10 CFR 70.22(b), 10 CFR 70.32(c) and, in turn, 10 CFR 74.31, 10 CFR 74.41, and 10 CFR 74.51, is justified.

1.5.5 Receipt, Possession, Use, and Transport of Source, Byproduct and Special Nuclear Material Authorized by 10 CFR Part 52 Combined Licenses

In DEC's Revision 4 of the COL application, dated August 9, 2011, including Part 1, "General and Financial Information," DEC requested material licenses for receipt, possession and use of source, byproduct and SNM in accordance with Commission regulations in 10 CFR Parts 30, 40, and 70. The reviews conducted for compliance with the requirements of 10 CFR Part 52 to support the issuance of the COLs encompass those necessary to support granting 10 CFR Parts 30, 40, and 70 licenses. In this respect, the 10 CFR Part 52 COLs for WLS will be consistent with the approach to 10 CFR Parts 30, 40, and 70 licensing followed for operating licenses for nuclear power plants licensed in accordance with 10 CFR Part 50. The staff considered the following proposed standard license provisions for the WLS COL as would relate to authorization pursuant to the regulations in 10 CFR Parts 30, 40, and 70[14].

[14] These proposed standard license conditions that the staff considered are based on similar license conditions found in other combined licenses.

Subject to the conditions and requirements incorporated herein, the Commission hereby licenses WLS:

(1) (a) pursuant to the Act and 10 CFR Part 70, to receive and possess at any time, special nuclear material as reactor fuel, in accordance with the limitations for storage and in amounts necessary for reactor operation, described in the FSAR, as supplemented and amended;

(b) pursuant to the Act and 10 CFR Part 70, to use special nuclear material as reactor fuel, after a Commission finding under 10 CFR 52.103(g) has been made, in accordance with the limitations for storage and amounts necessary for reactor operation, described in the FSAR, as supplemented and amended;

(2) (a) pursuant to the Act and 10 CFR Parts 30 and 70, to receive, possess, and use, at any time before a Commission finding under 10 CFR 52.103(g), such byproduct and special nuclear material (but not uranium hexafluoride) as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts not exceeding those specified in 10 CFR 30.35(d) and 10 CFR 70.25(d) for establishing decommissioning financial assurance, and not exceeding those specified in 10 CFR 30.72 and 10 CFR 70.22(i)(1);

(b) pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use, after a Commission finding under 10 CFR 52.103(g), any byproduct, source, and special nuclear material as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts as necessary;

(3) (a) pursuant to the Act and 10 CFR Parts 30 and 70, to receive, possess, and use, before a Commission finding under 10 CFR 52.103(g), any byproduct or special nuclear material (but not uranium hexafluoride) that is (1) in unsealed form; (2) on foils or plated surfaces, or (3) sealed in glass, for sample analysis or instrument calibration or other activity associated with radioactive apparatus or components, in amounts not exceeding those specified in 10 CFR 30.35(d) and 10 CFR 70.25(d) for establishing decommissioning financial assurance, and not exceeding those specified in 10 CFR 30.72 and 10 CFR 70.22(i)(1);

(b) pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use, after a Commission finding under 10 CFR 52.103(g), in amounts as necessary, any byproduct, source, or special nuclear material (but not uranium hexafluoride) without restriction as to chemical or physical form, for sample analysis or instrument calibration or other activity associated with radioactive apparatus or components; and

(4) pursuant to the Act and 10 CFR Parts 30 and 70, to possess, but not separate, such byproduct and special nuclear materials as may be produced by the operation of the facility.

The staff notes that WLS COL FSAR Table 13.4-201 “Operational Programs Required by NRC Regulations,” provides milestones for the implementation of various operational programs. Important milestone dates for various operational programs that support issuance of the license and requirements relative to 10 CFR Parts 30, 40, and 70 include the following:

- Radiation Protection Program (including as low as is reasonably achievable [ALARA] principles) – prior to initial receipt of byproduct, source, or special nuclear materials (excluding exempt quantities as described in 10 CFR 30.18, “Exempt quantities”)

- Fire Protection Program – prior to initial receipt of byproduct, source, or special nuclear materials (excluding exempt quantities as described in 10 CFR 30.18, “Exempt quantities”)

- Security Program including physical security, safeguards contingency programs, training and qualification program – prior to receipt of fuel onsite (protected area)

- Security Program including physical security, safeguards contingency, and transportation programs – prior to transport or receipt of special nuclear material of low strategic significance

- Non-licensed plant staff training program associated with receipt of the radioactive material – prior to initial receipt of byproduct, source, or special nuclear materials (excluding exempt quantities as described in 10 CFR 30.18, “Exempt quantities”)

In WLS COL FSAR, Table 13.4-201, the applicant includes the appropriate milestones and requirements related to the SNM MC&A program. In addition, as documented in the following table WLS endorsed VEGP standard content letters related to this subject.

VEGP Letter Date	**VEGP Letters ADAMS Accession Nos.**	**WLS Endorsement Letter Date**	**WLS Letters ADAMS Accession Nos.**
July 29, 2009	ML092120064	December 18, 2009	ML093570280
July 9, 2010	ML101940025	January 6, 2011	ML110110399
October 15, 2010	ML102920120	April 25, 2011	ML11116A162
November 23, 2010	ML103300034	April 25, 2011	ML11116A162

VEGP Letter Date	VEGP Letters ADAMS Accession Nos.	WLS Endorsement Letter Date	WLS Letters ADAMS Accession Nos.
March 3, 2011	ML110660153	April 25, 2011	ML11116A162
March 16, 2011[15]	ML110770137	April 25, 2011	ML11116A162
May 6, 2011	ML11129A155	May 18, 2011	ML11139A409
June 22, 2011	ML11175A169	July 28, 2011	ML11214A028

These letters identified the portions of the WLS COL application that demonstrate compliance with the requirements of 10 CFR Parts 30, 40, 70, and 74. The exemption request from the requirements of 10 CFR 70.22(b), 10 CFR 70.32(c) and, in turn, 10 CFR 74.31, 10 CFR 74.41, and 10 CFR 74.51 is addressed in Section 1.5.4 of this report.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff confirmed that the SNM Material and Control Accounting Program Description in Part 11 Enclosure D of the WLS COL application Revision 4 is identical to the November 23, 2010, VEGP submittal transmitting its SNM Material Control and Accounting Program Description. The only exceptions are that the title of the units are different and the identification that DEC and not Southern Nuclear Operating Company is responsible for implementation of the program is different.

- In an August 18, 2011, letter, the applicant concurred with the standard content of the VEGP SNMPPP description submitted in a March 16, 2011, letter. The staff confirmed that WLS SNMPPP description is identical with the only exception being the organization titles. However, there have been additional updates to the WLS SNMPPP in an October 16, 2014, letter from WLS. A specific review of the most recent WLS SNMPPP is discussed in Section 1.5.5 of this report.

[15] The March 16, 2011, letter from VEGP and the October 16, 2014, letter from WLS submitted the Special Nuclear Material Physical Protection Program (SNMPPP) Description for VEGP and WLS, respectively. Although the cover letters are publicly available, the SNMPP is considered safeguards information and is withheld from public disclosure.

- The staff confirmed that the VEGP new fuel shipping plan and the supplemental information in support of 10 CFR Part 70 special nuclear material found in Part 11 Enclosures E and F, respectively, of the VEGP COL application are identical to the material found in the WLS COL application Revision 8.

- The staff verified that the site-specific differences were not relevant and where the staff identified relevant differences, the staff performed additional review to determine the acceptability of the differences.

The staff completed its review and concluded that the evaluation performed for the standard content directly applicable to the WLS COL application, with the site-specific exceptions noted. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) includes evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.5.5:

> *In addition to the evaluation of the implementation milestones noted above, the staff's evaluation of the radiation protection program that supports the issuance of the 10 CFR Parts 30, 40, and 70 licenses is addressed in Chapter 12 of this SER. Additional staff evaluations that support the issuance of the 10 CFR Part 70 license are addressed in Chapter 9 of this SER (i.e., new fuel storage, spent fuel storage, and fire protection programs) and in the staff's evaluation of TVA's security program. The staff finds that the information in the Bellefonte COL application to support granting of the 10 CFR Part 70 license mentioned as part of the license above is sufficient, pending resolution of the open items in this report related to new and spent fuel, fire protection program, security program, and the implementation of the fire protection and security programs. However, TVA needs to provide a discussion of which parts of its COL application other than the reference to the radiation protection program provide sufficient information to support compliance with the applicable portions of 10 CFR Part 30 and 40, prior to the 10 CFR 52.103(g) finding. This is Open Item 1.5-1.*
>
> *<u>Resolution of Standard Content Open Item 1.5-1</u>*
>
> *In letters dated July 29, 2009, July 9, 2010, and October 15, 2010, the applicant provided additional information related to source, byproduct and SNM and its purposes, radiation safety personnel, personnel training, facilities and equipment, waste management, and the radiation safety program in general.*
>
> *Subsequent to the issuance of the SER with open items for the BLN application, the staff performed an additional review associated with granting the 10 CFR Parts 30, 40 and 70 licenses. For the 10 CFR Part 70 license, the staff considered SNM associated with the fuel (including security requirements) and SNM associated with non-fuel material (i.e., fission chambers). The staff also considered emergency plan requirements associated with SNM (fuel and non-fuel material). Based on these reviews, standard content Open Item 1.5-1 is resolved. These reviews are described below.*

Review of Parts 30 and 40 Materials

In a letter dated March 3, 2011, the applicant provided information regarding specific types of sources and byproduct material, the chemical or physical form, and the maximum amount at any time for the requested material licenses under 10 CFR Parts 30 and 40. The applicant also stated that SNM shall be in the form of reactor fuel, in accordance with the limitations for storage and amounts required for reactor operation, as described in the VEGP COL FSAR. Byproduct material and source material shall be in the form of sealed neutron sources for reactor startup and sealed sources for reactor instrumentation, radiation monitoring equipment, calibration, and fission detectors in amounts as required. The applicant also committed that no 10 CFR Part 40 specifically licensed source material, including natural uranium, depleted uranium and uranium hexafluoride will be received, possessed, or used during the period between issuance of the COL and the Commission's 10 CFR 52.103(g) finding for each of the VEGP Units 3 and 4. The applicant also stated that the quantity of any byproduct material with atomic numbers 1 through 93 would not exceed 100 millicuries for a single source and 5 Curies total. The maximum quantity for Americium 241 would not exceed 300 millicuries for single source and 500 millicuries total. Following the 10 CFR 52.103(g) finding for each of the VEGP Units 3 and 4, byproduct material, source material, and SNM in amounts as required, without restriction to chemical forms or physical form, would be used for the following:

- *Sample analysis,*
- *Instrument and equipment calibration, and*
- *Associated with radioactive apparatus or components.*

With respect to the requirements of 10 CFR Parts 30, 40, and 70 that are related to radiation protection (including administrative controls), the applicant provided information (in letters dated July 9, and November 23, 2010) on the purpose, storage and security of sources in VEGP COL FSAR Sections 12.2 and 12.5. Information related to the radiation protection program itself, including procedures for the use of these sources, is also described in VEGP COL FSAR Chapter 12. In addition, VEGP COL FSAR Section 13.4 states that the radiation protection program will be implemented according to the milestones listed in VEGP COL FSAR Table 13.4-201, Item 10. These milestones ensure that those portions of the program necessary to comply with the requirements of 10 CFR Parts 20, 30, 40, and 70, are implemented prior to the receipt of byproduct, source, SNM, or fuel, onsite.

The staff finds that the information provided by the applicant that describes the radiation protection measures (Chapter 12 of the VEGP COL FSAR) that will be implemented prior to receipt of byproduct, source or SNM, conforms to the applicable guidance in NUREG-1556, "Consolidated Guidance about Materials Licenses," and is, therefore, acceptable. The radiation protection program milestones included in the VEGP COL FSAR Table 13.4-201 are evaluated in Section 12.5 of this SER.

In a letter dated July 9, 2010, the applicant provided supplemental information relative to Item 14, Emergency Planning, in VEGP COL FSAR Table 13.4-201. In addition, the applicant proposed to revise the term 'portions applicable to SNM' to 'portions applicable to radioactive materials' for Item 14; Item 8, Fire Protection Program; Item 11, Non-Licensed Plant Staff Training Program; and Item 15, Physical Security Program. In addition, the applicant proposed to correct the references to regulatory citations of 10 CFR 30.32, "Application for specific licenses"; 10 CFR 40.31, "Application for specific licenses"; and 10 CFR 70.22, "Contents of applications." It also proposed to revise the "Requirements" column for Item 14 of the VEGP COL FSAR Table 13.4-201 to reference 10 CFR 30.32(i)(1), 10 CFR 40.31(j)(1), and 10 CFR 70.22(i)(1). It also proposed to revise Part 10 of the VEGP COL application, Proposed License Condition 3, "Operational Program Implementation," Section C, "Receipt of Materials," to include implementation of the portions of the emergency planning program applicable to SNM. In addition to the evaluation of the implementation milestones noted above, the staff's evaluation that supports the issuance of the 10 CFR Parts 30, and 40 licenses is addressed in Chapter 9 (the fire protection program).

The operational programs are specific programs that are required by regulations. VEGP COL FSAR Table 13.4-201 lists each operational program, the regulatory source for the program, the section of the FSAR in which the operational program is described, and the associated implementation milestone(s). The applicant proposed a license condition in Part 10, License Condition 3, Item C.3 of the VEGP COL application, which provides the milestones for implementing the portions of the non-licensed plant staff training program applicable to receipt of the radioactive material. However, Table 13.4-201 specifies implementation requirements (10 CFR 30.32(a), 10 CFR 40.31(a), and 10 CFR 70.22(a)) for the non-licensed plant staff training program associated with receipt of the radioactive material. Therefore, the staff determined that Item C.3 of proposed License Condition 3 is not needed because the implementation milestones for the non-licensed plant staff training program associated with receipt of radioactive material are governed by the applicable regulations.

The applicant proposed a license condition in Part 10 of the VEGP COL application to provide a schedule to support the NRC's inspection of operational programs, including the non-licensed plant staff training program applicable to receipt of the radioactive material. The proposed license condition is consistent with the policy established in SECY-05-0197, "Review of Operational Programs in a Combined License Application and Generic Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria," for operational programs and is acceptable.

In response to RAI 1.5-1, the applicant stated, in a letter dated October 15, 2010, that no byproduct material will be received, possessed, or used at AP1000 units of a physical form that is in unsealed form, on foils or plated sources, or sealed in glass, that exceeds the quantities in Schedule C of 10 CFR 30.72. Since the quantities do not exceed Schedule C, an emergency plan that meets the requirements of 10 CFR 30.32(i)(3) is not required. As such, the implementation of the emergency plan prior to the receipt of byproduct material will be removed from VEGP COL FSAR Table 13.4-201 and from Part 10 proposed License

Condition 3, Item C.4. The request for a 10 CFR Part 40 license does not involve authorization to receive, possess, or use uranium hexafluoride in excess of 50 kilograms in a single container or 1000 kilograms total. However, in a letter dated March 3, 2011, the applicant revised the request for a 10 CFR Part 40 license to state that no 10 CFR Part 40 specifically-licensed source material, including natural uranium, depleted uranium and uranium hexafluoride (UF_6), will be received, possessed, and used during the period between issuance of the COL and the Commission's 10 CFR 52.103(g) finding for each of the VEGP Units 3 and 4. Since the above quantities are not exceeded, an emergency plan for responding to the radiological hazards of an accidental release of source material and to any associated chemical hazards related to the material is not required. As such, the implementation of the emergency plan prior to the receipt of source material will be removed from VEGP COL FSAR Table 13.4-201. This applicant's proposal meets the requirements of 10 CFR 30.32 and 10 CFR 40.31 and is, therefore, acceptable. The incorporation of changes into a future revision of the VEGP COL FSAR is ***Confirmatory Item 1.5-1.***

Resolution of Standard Content Confirmatory Item 1.5-1

Confirmatory Item 1.5-1 is an applicant commitment to revise FSAR Table 13.4-201. The staff verified that the VEGP COL FSAR Table 13.4-201 was appropriately revised. As a result, Confirmatory Item 1.5- 1 is now closed.

The applicant also proposed an FSAR commitment to address the limitations during the period prior to the implementation of the emergency plan. In a letter dated March 16, 2011, the applicant stated that it has no plans to process UF_6 at the plant site at any time following the Commission's 10 CFR 52.103(g) finding, and consequently does not expect the requested 10 CFR Part 40 license to include receipt, storage, or use of UF_6 at the plant site. However, using the guidance of DC/COL-ISG-15, "Post-Combined License Commitments", the staff has determined that the commitment is not sufficient and instead the staff is proposing to add a restriction in the license condition related to 10 CFR Parts 30 and 40 (See License Condition 1-1.c(ii).

Review of Part 70 Materials

The staff reviewed information related to nuclear fuel as SNM included in the VEGP COL application including the AP1000 DCD against 10 CFR Part 70 requirements. Specifically, the staff's review included:

- *General information—financial qualification, site description, hydrology, geology, meteorology, the nearby population, and potential effects of natural phenomena (Part 1 of the application, FSAR Section 1.1 and Chapter 2, Section 4.1 and Table 4.1-1 of the AP1000 DCD against the requirements of 10 CFR 70.22(a)(1) through (a)(4));*

- *Organization and Administration—the responsibilities and associated resources for the receipt, possession, inspection, and storage of the SNM in the form of fresh fuel assemblies (Part 1 of the application, Quality Assurance Program included in Part 11 (Enclosure 11A) of the* *application, VEGP COL FSAR Section 13.1 for organization against the requirements of 10 CFR 70.22(a)(6) and (a)(8));*

- *Radiation Protection—Radiation protection program implementation, organization and personnel qualification, written procedures, ALARA, radiation survey and monitoring (AP1000 DCD Section 9.1 and Chapter 12 of VEGP COL FSAR against the requirements of 10 CFR 70.22(a)(6) through (a)(8));*

- *Nuclear Criticality Safety—use of area radiation monitors in lieu of criticality accident alarms (AP1000 DCD Sections 9.1.1.3 and 11.5.6 against the requirements of 10 CFR 70.22(a)(6) through (a)(8) and 10 CFR 50.68(b));*

- *Fire safety—fire protection program (VEGP COL FSAR Section 9.5.1 and Table 13.4-201 against the requirements of 10 CFR 70.22(a)(6) through (a)(8));*

- *Emergency Preparedness—emergency preparedness program for the VEGP site (VEGP COL FSAR Section 13.3 and Table 13.4-201 and the Emergency Plan against the requirements of 10 CFR 70.22(i));*

- *Environmental Protection—organization, procedures and controls that ensures that the environment is protected during the conduct of activities (i.e., receipt, possession, inspection, and storage of SNM) (VEGP COL FSAR Section 11.5 and AP1000 DCD Sections 9.1.1 and 11.5 against the requirements of 10 CFR 70.22(a)(7) and (a)(8)); and*

- *MC&A Program and Security (MC&A program included in the application against requirements of 10 CFR 70.22(b) and 10 CFR Part 74, and the Physical Security Plan (PSP) against the requirements of 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance").*

As indicated above, the applicant's compliance with several applicable 10 CFR Part 70 requirements regarding radiation protection, nuclear criticality safety, and environmental protection is already encompassed by the design information incorporated by reference from the AP1000 DCD and evaluated by the staff as part of the design certification proceeding. As explained further below, with respect to other applicable 10 CFR Part 70 requirements to be addressed by the COL applicant, the staff finds that the information provided regarding general information, organization and administration, radiation protection, nuclear criticality safety, fire safety, emergency preparedness, and environmental protection to support receipt, storage, and possession of SNM, conforms to the applicable guidance in NUREG-1520 and NUREG-0800 and, therefore, is acceptable. First, however, the staff's review of information regarding the MC&A program (10 CFR 70.22(b) and 10 CFR Part 74) and the PSP (10 CFR 73.67) is provided below.

MC&A Program for SNM (Fuel)

In RAI 1.5-3, the staff requested the applicant to review the requirements of 10 CFR 70.22(b) for the program addressing the control and accounting of SNM and provide descriptions of how the applicable requirements for material accounting and controls under 10 CFR Part 74 will be met for the possession and storage of SNM during construction and prior to the operation of the nuclear power plant. In addition, the staff requested the applicant to provide a proposed license condition to clearly establish full implementation of the MC&A program meeting the applicable requirements of 10 CFR Part 74 prior to receipt of SNM, consistent and concurrent with the proposed license condition for implementing the applicable security (i.e., physical protection) requirements of 10 CFR Part 73.

In response to RAI 1.5-3, the applicant, in a letter dated November 23, 2010, stated that all non-irradiated SNM for the AP1000 units is identified as Category III, SNM of low strategic significance, as defined in 10 CFR 74.4, "Definitions." No SNM at an AP1000 nuclear facility will exceed an uranium-235 isotope enrichment of 10 percent. The quantity of SNM will be documented, controlled, and communicated to the NRC as required in 10 CFR 74.13, "Material status reports"; 10 CFR 74.15, "Nuclear material transaction reports"; and 10 CFR 74.19, "Recordkeeping."

Subsequent to the applicant's endorsement of the standard content response to RAI 01.05-3 stating that no SNM onsite will exceed a 10-percent uranium-235 isotope enrichment level in an August 18, 2011, letter, the applicant updated its COL application to include Part 11F, "Supplemental Information of 10 CFR Part 70 Special Nuclear Material License Application" acknowledging that WLS would possess uranium sources containing uranium enriched to 93 percent uranium-235 in a quantity meeting the criteria of SNM of low strategic significance.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.5.5:

In its response to RAI 1.5-3, the applicant also described the SNM MC&A program and stated that this program will be provided as an enclosure in the VEGP COL application, Part 11. The SNM MC&A program will be developed for control and accounting of SNM in accordance with the applicable requirements of 10 CFR Part 74, Subparts A and B. This program will be consistent with guidance of American National Standards Institute (ANSI) 15.8-2009, "Material Control Systems – Special Nuclear Material Control and Accounting Systems for Nuclear Power Plants." The SNM MC&A program will be implemented prior to receipt of SNM at the plant site and will remain in effect until the SNM is shipped from the plant site. The procedures constituting the SNM MC&A program will delineate the requirements, responsibilities, and methods of SNM control necessary to address the following programmatic elements:

1. *Establish, maintain, and follow written MC&A procedures to account for SNM.*

2. *Maintain adequate records of the initial receipt or current inventory of SNM, including records of isotopic content, material received, material*

shipped, and material lost (material balance reports and physical inventory listing reports).

3. *Develop adequate inventory procedures and maintain adequate perpetual inventory records.*

4. *Inventory SNM within the 12-month prescribed frequency.*

5. *Report SNM inventories on the applicable forms.*

6. *Establish an individual responsible for the control and accountability of SNM.*

7. *Report the loss of or inability to find SNM items in a timely manner.*

8. *Control access to SNM.*

9. *Control the shipping and transfer of SNM.*

The applicant proposed to add a new FSAR Section 13.5.2.2.9, which will summarize the use of plant procedures to address MC&A of SNM. The applicant also stated that VEGP COL FSAR Table 13.4-201 will be revised to provide information related to implementation of the SNM MC&A program.

In order to address the applicable 10 CFR Part 74 MC&A requirements prior to power operation, the applicant proposed a license condition that will require implementation of a MC&A program prior to receipt of SNM on site. Implementation of the SNM MC&A program prior to SNM receipt will also address the SNM possession and storage requirements during construction and prior to operation of the nuclear power plant.

The applicant's MC&A program for SNM is consistent with ANSI 15.8 and meets reporting and recordkeeping requirements of 10 CFR 74.11, "Reports of loss or theft or attempted theft or unauthorized production of special nuclear material"; 10 CFR 74.13; 10 CFR 74.15; and 10 CFR 74.19. The documentation, submitted by the applicant, for a program addressing the control and accounting of SNM provided descriptions of how the applicable requirements for material accounting and controls under 10 CFR Part 74 are met and, therefore, is acceptable, subject to the proposed revision to the VEGP COL application and the VEGP COL FSAR (this has been tracked as ***Confirmatory Item 1.5-2****). In addition, the proposed license condition includes a provision to provide a schedule to support the NRC's inspection of the MC&A program for the SNM. This is consistent with the policy established in SECY-05-0197 and is thus acceptable.*

Resolution of Standard Content Confirmatory Item 1.5-2

Confirmatory Item 1.5-2 is an applicant commitment to revise its FSAR Sections 13.4, 13.5 and Parts 7 and 11 (Enclosure 11D) of its application to address the SNM MC&A program. The staff verified that the VEGP COL FSAR and Parts 7 and 11 (Enclosure D) of its application were appropriately revised. As a result, Confirmatory Item 1.5-2 is now closed.

<u>*Security Review for 10 CFR Part 70 Materials*</u>

In accordance with 10 CFR 73.55(a)(4), current applicants for an operating license under 10 CFR Part 50, or a COL under 10 CFR Part 52 who have submitted their applications to the Commission prior to the effective date of this rule must amend their applications to include security plans consistent with this section.

The Commission worded 10 CFR 73.55(a)(4) to require implementation of 10 CFR 73.55, "Requirements for physical protection of licensed activities in nuclear power reactors against radiological sabotage," "before fuel is allowed onsite (protected area)." The Commission explained this provision as follows:

> *This paragraph establishes when an applicant's physical protection program must be implemented. The receipt of special nuclear material (SNM) in the form of fuel assemblies onsite, (i.e., within the licensee's protected area) is the event that subjects a licensee or applicant to the requirements of this rule, and it is the responsibility of the applicant or licensee to complete the preliminary and preparatory actions required to implement an effective physical protection program at the time SNM is received onsite (within the protected area). 74 FR 13926, 13960 (Mar. 27, 2009).*

Further guidance is provided in the form of RGs to support implementation of this Rule. The following guidance is provided in RG 5.76, "Physical Protection Programs at Nuclear Power Reactors":

> *Except for mixed-oxide (MOX) fuel assemblies, the Commission requirements of 10 CFR 73.67, "Licensee Fixed Site and In-Transit Requirements for the Physical Protection of Special Nuclear Material of Moderate and Low Strategic Significance," apply and must be met until fuel assemblies are received inside an operational protected area. Consistent with 10 CFR 73.55(a)(4), applicants for an operating license under the provisions of 10 CFR Part 50, or holders of a COL under the provisions of 10 CFR Part 52, shall implement the requirements of 10 CFR 73.55 before special nuclear material (SNM) in the form of fuel assemblies are allowed on site (in the protected area).*

In a letter dated March 15, 2011, the NRC staff asked the applicant to provide its plan regarding the protection of new fuel as SNM at the VEGP Units 3 and 4 plant site prior to declaration of an operational protected area (PA) and implementation of the requirements of 10 CFR 73.55, as described in the SNM MC&A Program description. In addition, the staff also requested that the applicant consider the applicability of the substantive provisions of interim compensatory orders (ICMO) that were issued to Category III Fuel Cycle Facilities to ensure adequate protection when SNM is on site prior to the activation of the PA. In response to the staff's questions, in a letter dated March 16, 2011, the applicant provided a physical protection plan in accordance with 10 CFR 73.67(f) and (g). This plan was included as an annex to the PSP.

This plan includes transportation security provisions. The applicant also stated that once the PA is declared operational in accordance with 10 CFR 73.55(a)(4), the annex would no longer be required and could be removed in accordance with 10 CFR 50.54(p). Then, no separate transportation security provisions would be necessary for future new fuel shipments. The staff raised a question regarding the licensee's ability to receive new fuel and return new fuel rods/assemblies to the fuel manufacturer. In a letter dated May 6, 2011, the applicant proposed to revise its FSAR Section 13.5.2.2.8 to include the New Fuel Shipping Plan that addresses the applicable 10 CFR 73.67 requirements in the event that unirradiated new fuel assemblies or components are returned to the supplying fuel manufacturer(s) facility. The New Fuel Shipping Plan summarizes the procedures and the written agreement that the applicant will have in place prior to shipment of new fuel back to the fuel manufacturer and this plan will be included in Part 11, Enclosures of its application. The staff finds this New Fuel Shipping Plan acceptable because it meets the applicable requirements of 10 CFR 73.67(g). The staff verified that the VEGP FSAR Section 13.5 and Part 11 (Enclosure 11E) are appropriately updated.

In the RAI response dated March 16, 2011, the applicant addressed the Order imposing fingerprinting and criminal history records check requirements for unescorted access to radioactive material or other property dated April 30, 2007. In accordance with Section 5.4 of the PSP annex, the applicant committed to utilizing the access authorization program as outlined in Section 14.1 of the PSP. The access authorization program in Section 14.1 is in accordance with 10 CFR 73.56, "Personnel Access Authorization Requirements for Nuclear Power Plants," based on implementing guidance as provided by RG 5.66, "Access Authorization Program for Nuclear Power Plants," Revision 1 and Section 652 of the Energy Policy Act of 2005 (EP Act).

The applicant conducted a critical target area analysis (CTA), and determined that a CTA would not exist. Because there is no CTA at the facility, there is no need to address security issues related to CTAs. In addition, the applicant has adequately addressed security issues related to; security response procedures, coordination with local law enforcement for response support, storage of hazardous materials on-site, review of emergency shutdown/cool down procedures, supplementing of the Emergency Actions Levels, site accountability and evacuation strategies, emergency communications, evaluation of computer and communications networks for vulnerabilities, capabilities to provide fire suppression, evaluation of the need for offsite medical support, emergency support, and access to Federal support, and limiting public access to sensitive plant information. However, the staff has determined that the commitment included in the RAI responses is not sufficient and instead the staff is proposing to add a license condition to ensure adequate protection prior to implementation of the requirements of 10 CFR 73.55. This license condition (1-5) will preclude changes to the security plan provisions related to these issues without prior NRC approval until such matters fall under the new reactor security requirements of 10 CFR 73.55.

The staff's review of the applicant's PSP for the protection of SNM of low strategic significance (LSS) [Note: WLS refers to this plan as the SNMPPP] *includes information that has been marked as "Safeguards Information" by the* *applicant, pursuant to ~~10 CFR 2.390~~*[10 CFR 73.21 and 73.22]*. The NRC staff reviewed the applicant's PSP for fixed site physical protection of SNM- LSS and chemicals of concern. The methods and procedures outlined in the PSP satisfy the performance objectives, systems capabilities, and reporting requirements specified in 10 CFR 73.67. The PSP for the facility is acceptable and provides reasonable assurance that the requirements for the physical protection of SNM-LSS and chemicals of concern will be met. The staff also verified that the PSP is appropriately updated.*

Non-Fuel SNM

In a letter dated, June 22, 2011, the applicant provided information regarding the name, amount, and specifications (including the chemical and physical form and, where applicable, isotopic content) of the non-fuel SNM (Fission Chambers) the applicant proposes to use (10 CFR 70.22(a)(4)). The letter also provided information to confirm that the applicable design and programmatic elements provided in the licensing basis will satisfy the requirements in 10 CFR 70.22(a)(6) through (8) prior to receipt of non-fuel SNM.

10 CFR Part 70 Requirements - Other than MC&A (10 CFR 70.22(b) and 10 CFR Part 74) and Security (10 CFR 73.67) - for Fuel and Non-Fuel Material

As noted above, in addition to MC&A and security, the staff also examined the applicant's compliance with 10 CFR Part 70 requirements regarding general information, organization and administration, radiation protection, nuclear criticality safety, fire safety, emergency preparedness, and environmental protection to support receipt, storage, and possession of SNM.

The staff's analysis follows with respect to those other requirements not already resolved via the applicant's incorporation of the AP1000 DCD. For the reasons described in Section 1.4.4 of this FSER the staff agrees that the applicant is technically qualified to engage in the proposed activities associated with this license, based on the applicant's ongoing experience in the safe operation of nuclear power plants, as presented in Section 1.4.1 of the VEGP COL FSAR. Likewise, the applicant's financial qualifications and ownership structure meet the requirements of 10 CFR 70.22 for the same reasons described above in Section 1.5.1.

Note: WLS COL FSAR Section 1.4.1 has a similar discussion regarding DEC's operation of Catawba Units 1 and 2, McGuire Units 1 and 2, and Oconee Units 1, 2, and 3. The staff also concludes DEC is technically qualified to engage in the proposed activities associated with this license based on DEC's on-going experience with the safe operation of Catawba Units 1 and 2, McGuire Units 1 and 2, and Oconee Units 1, 2, and 3. In addition, Section 1.5.1 of this report finds that the financial qualifications and ownership structure for the WLS COL application acceptable.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 1.5.5:

Similarly, the applicant has explained the anticipated amounts, types, and uses of 10 CFR Part 70 materials at the site are consistent with the provisions of 10 CFR 70.22. The VEGP COL FSAR and Part 1 of the application provide *adequate description of the VEGP Units 3 and 4 facility and the proposed activities related to 10 CFR Parts 30, 40 and 70 material. In addition the VEGP COL FSAR provides information regarding regional hydrology, geology, meteorology, the nearby population, and potential effects of natural phenomena that could occur at the facility. The applicant has described the responsibilities and associated resources (see Part 1, "General and Administration Information," and Enclosure 11A, "Nuclear Development Quality Assurance Manual" of the application) for the receipt, possession, inspection, and storage of the 10 CFR Part 70 material (fuel and non-fuel). Therefore, it meets the requirements of 10 CFR 70.22(a)(1). Furthermore, as indicated in VEGP COL FSAR Table 13.4-201, applicable portions of the Radiation Protection Program will be implemented prior to initial receipt of byproduct, source, or SNMs. In accordance with VEGP COL FSAR Table 13.4-201, Item 10, Implementation Milestone #1, and the NRC-approved template, Nuclear Energy Institute (NEI) 07-03A, "Generic FSAR Template Guidance for Radiation Protection Program Description," which is incorporated by reference into VEGP COL FSAR Appendix 12AA (see SER Section 12.5), the appropriate radiation protection program elements associated with organization, facilities, instrumentation and equipment, procedures (e.g., procurement, receipt, inventory, labeling, leak testing, surveillance, control, transfer, disposal, storage, issuance, and use of radioactive sources), and training will be in place prior to initial receipt of byproduct, source, or special nuclear materials, thereby satisfying the requirements of 10 CFR 70.22(a)(4), (6), (7), and (8). VEGP COL FSAR Section 12.2 includes the requirements for written procedures that address leak-testing of radioactive sources. The leak-test will be consistent with 10 CFR 20.1501, "General," survey and monitoring requirements for evaluating the quantities of radioactive material and the potential radiological hazard of the radioactive source.*

The fission chambers will be disposed of consistent with the operating procedures that specify the processes to be followed to ship waste that complies with the waste acceptance criteria (WAC) of the disposal site, the waste classification and characteristics requirements of 10 CFR 61.55, "Waste classification," and 10 CFR 61.56, "Waste characteristics," and the requirements of third party waste processors as applicable. This process is identified in VEGP COL FSAR Section 11.4.6.1.

With respect to fire safety, prior to installation, the new fission chambers (along with the new fuel) will be stored in the Auxiliary Building fuel handling area, which is an area protected by the fire protection program and fire protection system, as discussed in the AP1000 DCD Section 9A.3.1.3.1.2. Temporary storage of these non-combustible sealed sources is not specifically addressed in the AP1000 fire protection analysis in DCD Appendix 9A; however, the approach to extinguishing fires and containing material releases associated with the fission chambers would be similar to, and bounded by, the approach considered for the fuel handling area in general. The fuel handling area has been evaluated and determined acceptable for the storage of SNM in a full core load of new fuel. The hazards imposed by the relatively small quantity of SNM associated with the fission chambers (less than 100 grams), is not expected to be a challenge to the existing fire protection analysis for the new fuel storage (see Section 9.5.1 of this SER). The VEGP COL FSAR Section 12.2 includes the requirements for written *procedures that address leak testing of radioactive sources (byproduct, source, and devices that contain SNM, as appropriate). Further, the fission chambers that contain the non-fuel SNM are sealed sources that are tested periodically to confirm their leak-tightness. Therefore, it is expected that the capabilities of the fire protection program and the fire protection equipment servicing this area are sufficient to meet the requirements of 10 CFR 70.22(a)(7) and 10 CFR 70.22(a)(8).*

Emergency Plan (SNM, Fuel and Non-Fuel)

The applicant will be storing the new fuel in the new fuel rack (stored dry) or in the spent fuel racks prior to loading into the reactor. The safety analysis included in AP1000 DCD Sections 9.1.1.3 and 9.1.2.3 provides safety analysis that indicates that: (1) the design of new fuel rack is such that K_{eff} remains less than or equal to 0.95 with full density unborated water and less than equal to 0.98 with optimum moderation and full reflection conditions; and (2) the design of spent fuel rack is such that K_{eff} remains less than or equal to 0.95 under design basis conditions. This criticality evaluation meets the requirements of 10 CFR 50.68(b). Therefore, a criticality accident alarm system to meet the requirements of 10 CFR 70.24, "Criticality accident requirements," is not required. As a result, an emergency plan (to receive and possess) pursuant to 10 CFR 70.22(i) is also not required. In addition, an emergency plan for the fission chambers (to receive and possess) pursuant to 10 CFR 70.22(i) is not required due to the small quantity of SNM (less than 100 grams) associated with the fission chambers.

1.5.5.1 *Physical Protection of Special Nuclear Material*

1.5.5.1.1 Introduction

This section addresses the physical protection of special nuclear material while possessed, used, and transported by the applicant, including during the period prior to implementation of the nuclear power reactor physical security plan (PSP). This review was performed by the Office of Nuclear Security and Incident Response (NSIR), Division of Security Policy (DSP), Fuel Cycle and Transportation Security Branch (FCTSB).

1.5.5.1.2 Summary of Application

The post September 11, 2001, security order for SNM of low strategic significance was sent to the applicant to be addressed in the form of a request for additional information. The letter conveying the order was sent on June 30, 2014 (ADAMS Accession No. ML14154A249) and the safeguards-information-containing order was sent under separate cover (Safeguards LAN Electronic Safe (SLES) Accession No. NS113121). In a letter dated October 16, 2014, the applicant provided a crosswalk that pointed out the text of the application that described the intent of meeting each element of the applicable portions of 10 CFR 73.67 (ADAMS Accession No. ML14290A523). In addition, the applicant submitted another letter dated October 16, 2014 that contained safeguards information and included a revised Special Nuclear Material Physical Protection Program Plan (SNMPPP) and a reviewer's aid matrix. The reviewer's aid matrix covered both the applicable 10 CFR 73.67 requirements and the applicable post September 11, 2001, security order.

1.5.5.1.3 Regulatory Basis

The regulatory requirements and guidance applicable to fixed site and in-transit physical protection are as follows:

- 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance"
- Post September 11, 2001, Security Order for SNM of Low Strategic Significance
- RG 5.59, "Standard Format and Content for a Licensee Physical Security Plan for the Protection of Special Nuclear Material of Moderate or Low Strategic Significance," Revision 1 (1983)"
- RG 5.66, "Access Authorization Program for Nuclear Power Plants"
- RIS 2005-22, "Requirements for the Physical Protection During Transportation of Special Nuclear Material of Moderate and Low Strategic Significance: 10 CFR Part 73 vs. RG 5.59 (1983)"

1.5.5.1.4 Technical Evaluation

A technical evaluation of the DEC, Lee Units I and 2, COL FSAR, against applicable 10 CFR 73.67 fixed site and in-transit general performance objectives, general requirements and physical protection requirements for SNM of low strategic significance, was performed.

In addition the post September 11, 2001, security order for SNM of low strategic significance was sent to the applicant to be addressed in the form of a request for additional information. The letter conveying the order was sent on June 30, 2014 (ADAMS Accession No. ML14154A249) and the safeguards-information-containing order was sent under separate cover (SLES Accession No. NS113121). A technical evaluation of how the order was addressed was also performed. In a letter dated October 16, 2014, the applicant provided a crosswalk that pointed out the text of the application that described the intent of meeting each element of the applicable portions of 10 CFR 73.67 (ADAMS Accession No. ML14290A523). In addition, in a letter dated October 16, 2014, the applicant provided a revised SNMPPP and a reviewer's aid matrix (SLES Accession No. NS112457). The reviewer's aid matrix covered both the applicable 10 CFR 73.67 requirements and the applicable post September 11, 2001, security order.

1.5.5.1.4.1 *Fixed Site General Performance Objectives*

The applicable physical protection requirements specified in 10 CFR 73.67 titled, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance," provide general performance objectives.

The physical protection requirements of 10 CFR 73.67(a)(1), states, "General performance objectives.

(1) Each licensee who possess, uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives:

(i) Minimize the possibilities for unauthorized removal of special nuclear material consistent with the potential consequences of such actions; and

(ii) Facilitate the location and recovery of missing special nuclear material.

(2) To achieve these objectives, the physical protection system shall provide:

(i) Early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material;

(ii) Early detection of removal of special nuclear material by an external adversary from a controlled access area;

(iii) Assure proper placement and transfer of custody of special nuclear material; and

(iv) Respond to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery.

Therefore, the fixed site physical protection requirements of 10 CFR 73.67(a)(1) are applicable because of the manner in which SNM of low strategic significance was described in the WLS Units 1 and 2 COL application.

Applicable Requirement: 10 CFR 73.67(a)(1), "General performance objectives. (1) Each licensee who possesses, uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives:…"

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." Establishment of the physical protection system is outlined in the SNMPPP, Revision 1, dated October 2014 (SLES Accession No. NS112457). Specifically, in Subsection 4.4.1, "Establishment of the Physical Protection System," there are six establishment elements described that pertain to: lighting, detection, alarm station status, communications, access control and physical barriers of the controlled access area. In addition, within Subsection 4.4.2, "Maintenance of the Physical Protection System," of the SNMPPP there is an explanation of the maintenance that will be applied to the physical protection system. The application as written stated that DEC will implement the applicable requirements of the physical protection program required by 10 CFR 73.67 before SNM is received on site.

DEC's application described that 10 CFR 73.67 will be fully implemented before SNM is on site. Also, the application outlined establishment and maintenance elements for the physical protection system. Therefore, the staff finds the requirement of 10 CFR 73.67(a)(1) to have a physical protection system established and maintained, would be met.

Applicable Requirement: 10 CFR 73.67(a)(1)(i), "General performance objectives. Each licensee who possesses, uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives: (i) Minimize the possibilities for unauthorized removal

of special nuclear material consistent with the potential consequences of such actions. . .”

The applicant stated in “Table 13.4-201,” (ADAMS Accession No. ML11229A602) under “Item 15,” titled “Implementation Milestone,” their commitment to meet the requirements of 10 CFR 73.67, “…prior to initial receipt of SNM.” In addition, the SNMPPP describes in Subsection 5.3.1, “Monitoring SNM (Non-Fuel SNM-HEU Neutron Sources),” how this general performance objective will be met for the highly enriched uranium (HEU) sources by detailing adversary scenarios and how the physical protection system will work to meet the requirement. In addition, the SNMPPP in Subsection 5.3.2, “Monitoring SNM (New Fuel Assemblies),” describes adversary scenarios applied to SNM reactor fuel and how the physical protection system is designed to meet this requirement.

DEC’s application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP describes how the possibilities for unauthorized removal are minimized consistent with the consequences of such actions. Therefore, the staff finds the requirement of 10 CFR 73.67(a)(1)(i) to have a physical protection system established and maintained that has the objective to minimize the possibilities for unauthorized removal of special nuclear material consistent with the potential consequences of such actions, would be met.

Applicable Requirement: 10 CFR 73.67(a)(1)(ii), “General performance objectives. Each licensee who possesses uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives: “…(ii) Facilitate the location and recovery of missing special nuclear material.”

The applicant stated in “Table 13.4-201,” (ADAMS Accession No. ML11229A602) under “Item 15,” titled “Implementation Milestone,” their commitment to meet the requirements of 10 CFR 73.67, “…prior to initial receipt of SNM.” In addition, their SNMPPP in Section 5.10, “Contingency Response,” describes the detection assessment and response strategies of the physical protection system that would facilitate the location and recovery of missing special nuclear material.

DEC’s application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP describes the detection, assessment and response attributes of the physical protection system that would facilitate the location and recovery of missing special nuclear material. Therefore, the staff finds the requirement, of 10 CFR 73.67(a)(1)(ii) to have a physical protection system established and maintained that has the objective to facilitate the location and recovery of missing special nuclear material, would be met.

Applicable Requirement: 10 CFR 73.67(a), “General performance objectives. (2) To achieve these objectives, the physical protection system shall provide: (i) Early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material. . .”

The applicant stated in “Table 13.4-201,” (ADAMS Accession No. ML11229A602) under “Item 15,” titled “Implementation Milestone,” their commitment to meet the requirements of 10 CFR 73.67, “…prior to initial receipt of SNM.” In addition, their SNMPPP in Subsections 5.3.1 and 5.3.2 describes how the physical protection system provides for early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material.

DEC's application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP adequately describes the early detection and assessment physical protection strategies to address unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material. Therefore, the staff finds the requirement, of 10 CFR 73.67(a)(2)(i) to have a physical protection system that provides early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material, would be met.

Applicable Requirement: 10 CFR 73.67(a)(2)(ii), "General performance objectives. To achieve these objectives, the physical protection system shall provide: (ii) Early detection of removal of special nuclear material by an external adversary from a controlled access area. . ."

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." In addition, their SNMPPP in Subsections 5.3.1 and 5.3.2 describes how the physical protection system provides for early detection of removal of special nuclear material by an external adversary from a controlled access area.

DEC's application describes that 10 CFR73.67 will be fully implemented before SNM is received. In addition, their SNMPPP describes the early detection and assessment physical protection strategies to address removal of special nuclear material by an external adversary from a controlled access area. Therefore, the staff finds the requirement, of 10 CFR 73.67(a)(2)(ii) to have a physical protection system that provides early detection of removal of special nuclear material by an external adversary from a controlled access area, would be met.

Applicable Requirement: 10 CFR 73.67(a)(2)(iii), "General performance objectives. To achieve these objectives, the physical protection system shall: …(iii) Assure proper placement and transfer of custody of special nuclear material; and…"

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 22," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 74, (i.e., Material Control and Accounting of Special Nuclear Material) "Prior to receipt of special nuclear material" as a "license condition." Also, the applicant stated in "FSAR Part 11D," "Special Nuclear Material (SNM) Material Control and Accounting Program Description," that the applicant will establish, a "…SNM control and accounting system,"…" including internal control, physical inventory and shipment of SNM."

In addition, the applicant stated in their SNMPPP in Section 5.1, "Receipt of SNM," within Subsection 5.1.1 (pertaining to non-fuel SNM), Subsection 5.1.2 (pertaining to fuel SNM), and in Section 5.8, "Internal Transfers," material control and accounting (MC&A) measures specific to the non-fuel and fuel SNM, respectively.

DEC's application describes that the appropriate provisions of 10 CFR 74 will be fully implemented before SNM is received. In addition, the applicant has described in the SNMPPP how specific MC&A measures apply to meet this general performance objective, therefore, the staff finds the requirement, of 10 CFR 73.67(a)2(iii), to assure proper placement and transfer of custody of special nuclear material, would be met.

Applicable Requirement: 10 CFR 73.67(a)(2)(iv), "General performance objectives. To achieve these objectives, the physical protection system shall: … (iv) Respond to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery."

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." In addition, their SNMPP in Section 5.10 describes the detection, assessment and response measures that would provide indications of missing or stolen SNM and subsequent recovery thereof. The appropriate response from offsite (i.e., the specifically coordinated with local law enforcement agency (LLEA), etc.) was pointed out in the SNMPPP by referencing Section 8 of the power reactor physical security plan (PSP) (Revision 3, dated April 10, 2013, (SLES Accession No. NS112930)), and Sections 5.6, 5.7 and 5.8 of the power reactor contingency plan (CP) (Revision 3, dated April 10, 2013, (SLES Accession No. NS112930)).

DEC's application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP adequately describes the early detection, assessment and response physical protection strategies that would facilitate recovery of missing or stolen SNM; therefore, the staff finds the requirement, of 10 CFR 73.67(a)(2)(iv) to have a physical protection system that shall respond to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery, would be met.

1.5.5.1.4.2 *Fixed Site General Requirements*

The applicable requirements specified in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance," include the following general requirements for fixed sites.

> "(c) Each licensee who possesses, uses, transports, or delivers to a carrier for transport special nuclear material of moderate strategic significance, or 10 kg or more of special nuclear material of low strategic significance shall:
>
> (1) Submit a security plan or an amended security plan describing how the licensee will comply with all the requirements of paragraphs (d), (e), (f), and (g) of this section, as appropriate, including schedules of implementation. The licensee shall retain a copy of the effective security plan as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the original plan was submitted. Copies of superseded material must be retained for 3 years after each change.
>
> (2) Within 30 days after the plan submitted pursuant to paragraph (c)(1) of this section is approved, or when specified by the NRC in writing, implement the approved security plan."

Applicable Requirement: 10 CFR 73.67(c)(1), "Submit a security plan…including schedules for implementation…shall retain a copy …for 3 years..." … "Copies of the superseded material must be retained for 3 years after each change."

The applicant stated in Section 5.7, “Audits and Records,” of their SNMPPP that the security plan (i.e., the SNMPPP) would be retained for 3 years and that copies of superseded material will be retained for 3 years after each change.

The application stated that DEC will not receive SNM of low strategic significance (both fuel and non-fuel) on site until implementation of the physical protection system required by 10 CFR 73.67 is accomplished.

In addition, DEC’s SNMPPP adequately describes the required retention parameters for the SNMPPP and changes to it.

Therefore, the staff finds the requirement, of 10 CFR 73.67(c)(1) to submit a security plan, retain the security plan for 3 years after the specific type of SNM has been removed from the site, and to retain superseded security plan change(s) for 3 years after each change, would be met.

Applicable Requirement: 10 CFR 73.67(c)(2), “Within 30 days after the plan submitted pursuant to paragraph (c)(1) of this section is approved, or when specified by the NRC in writing, implement the approved security plan.”

The applicant stated in their revised SNMPPP, in Section 1, “Scope,” thereof, that: “The NRC will be notified 180 days prior to the establishment of the CAA for SNM receipt.” However, this leaves the NRC staff without provisions specific for implementation of the complete SNMPPP and the required provisions of SNM of low strategic significance for transport, therefore a license condition will be configured to meet the requirement. This requirement would be met through a license condition that states, (or conveys the same meaning with different wording):

1. DEC will notify the NRC 120 days prior to shipment of special nuclear material of low strategic significance to, or receipt of special nuclear material of low strategic significance at, the Lee Nuclear Plant Unit 1 or Unit 2 owner controlled area, and

2. DEC will implement the Special Nuclear Material Physical Protection Plan that describes the physical protection strategies for special nuclear material of low strategic significance, 120 days prior to the shipment of special nuclear material of low strategic significance to, or receipt of special nuclear material of low strategic significance at, the Lee Nuclear Plant Unit 1 or Unit 2 owner controlled area.”

1.5.5.1.4.3 *Fixed Site Physical Protection Requirements*

The applicable requirements specified in 10 CFR 73.67 titled, “Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance,” provide fixed site physical protection requirements for SNM of low strategic significance.

The physical protection requirements of 10 CFR 73.67(f), state, “Fixed site requirements for special nuclear material of low strategic significance. Each licensee who possesses, stores, or uses special nuclear material of low strategic significance at a fixed site or contiguous sites, except those who are licensed to operate a nuclear power reactor pursuant to Part 50, shall:

(1) Store or use the material only within a controlled access area,

(2) Monitor with an intrusion alarm or other device or procedures the controlled access areas to detect unauthorized penetrations or activities,

(3) Assure that a watchman or offsite response force will respond to all unauthorized penetrations or activities, and

(4) Establish and maintain response procedures for dealing with threats of thefts or thefts of this material. The licensee shall retain a copy of the current response procedures as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the procedures were established. Copies of superseded material must be retained for 3 years after each change."

The fixed site physical protection requirements of 10 CFR 73.67(f) are applicable because of the manner in which SNM of low strategic significance was described in the WLS Units 1 and 2 COL application.

Applicable Requirement: 10 CFR 73.67(f)(1), "Fixed site requirements for special nuclear material of low strategic significance. Each licensee who possesses, stores, or uses special nuclear material of low strategic significance at a fixed site or contiguous sites, except those who are licensed to operate a nuclear power reactor pursuant to Part 50, shall: (1) Store or use the material only within a controlled access area…"

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." In addition, their SNMPPP in Sections: 5.2 "Storage," 5.8 and in Figures 1 through13, describe the physical characteristics of the controlled access area.

DEC's application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP adequately describes the characteristics of their planned-for controlled access area; therefore, the staff finds the requirement, of 10 CFR 73.67(f)(1) to store or use the material only within a controlled access area, would be met.

Applicable Requirement: 10 CFR 73.67(f)(2), "Fixed site requirements for special nuclear material of low strategic significance. Each licensee who possesses, stores, or uses special nuclear material of low strategic significance at a fixed site or contiguous sites, except those who are licensed to operate a nuclear power reactor pursuant to Part 50, shall: (2) Monitor with an intrusion alarm or other device or procedures the controlled access areas to detect unauthorized penetrations or activities. . ."

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." In addition, their SNMPPP in Subsections 5.3.1 and 5.3.2 describes the detection processes that would result in recognition of unauthorized penetrations or activities in the locations of SNM of low strategic significance and the controlled access area.

DEC's application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP describes the detection processes that would result in recognition of unauthorized penetrations or activities in the locations of SNM of low strategic significance and the controlled access area. Therefore, the staff finds the requirement, of 10 CFR 73.67(f)(2) to monitor with an intrusion alarm or other device or procedures the controlled access areas to detect unauthorized penetrations or activities, would be met.

Applicable Requirement: 10 CFR 73.67(f)(3), "Fixed site requirements for special nuclear material of low strategic significance. Each licensee who possesses, stores, or uses special nuclear material of low strategic significance at a fixed site or contiguous sites, except those who are licensed to operate a nuclear power reactor pursuant to part 50, shall: (3) Assure that a watchman or offsite response force will respond to all unauthorized penetrations or activities. . ."

The applicant stated in "Table 13.4-201," under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." In addition, their SNMPPP in Subsections: 5.3.1, 5.3.2, and in Section 5.10, describes the detection, assessment and response measures for the physical protection of the material. Furthermore, the appropriate response from offsite (i.e., the specifically coordinated with local law enforcement agency (LLEA), etc.) was pointed out by referencing Section 8 of the reactor physical security plan (PSP) (Revision 3, dated April 10, 2013, (SLES Accession No. NS112930)) and Sections 5.6, 5.7 and 5.8 of their reactor contingency plan (CP) (Revision 3, dated April 10, 2013, (SLES Accession No. NS112930)).

DEC's application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP and other information referenced in the SNMPPP describes the detection, assessment and response measures for the physical protection of the material; therefore, the staff finds the requirement, of 10 CFR 73.67(f)(3) to assure that a watchman or offsite response force will respond to all unauthorized penetrations or activities, would be met.

Applicable Requirement: 10 CFR 73.67(f)(4), "Fixed site requirements for special nuclear material of low strategic significance. Each licensee who possesses, stores, or uses special nuclear material of low strategic significance at a fixed site or contiguous sites, except those who are licensed to operate a nuclear power reactor pursuant to Part 50, shall: (4) Establish and maintain response procedures for dealing with threats of thefts or thefts of this material. The licensee shall retain a copy of the current response procedures as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the procedures were established. Copies of superseded material must be retained for 3 years after each change."

The applicant stated in "Table 13.4-201," (ADAMS Accession No. ML11229A602) under "Item 15," titled "Implementation Milestone," their commitment to meet the requirements of 10 CFR 73.67, "…prior to initial receipt of SNM." In addition, their SNMPPP in Section 4.1 "Procedures," Subsection 5.3.1, Subsection 5.3.2, Section 5.7, and in Section 5.10, describes the framework of and details to the development of response procedures. In addition, in Section 5.7 of the SNMPPP the retention of 3 years for response procedures and changes thereof, are noted.

DEC's application describes that 10 CFR 73.67 will be fully implemented before SNM is received. In addition, their SNMPPP describes the framework of the response procedures, details on the development of response procedures and retention actions of 3 years of the response procedures; therefore, the staff finds the requirement, of 10 CFR 73.67(f)(4), to establish and maintain response procedures, would be met.

1.5.5.1.4.4 *In-Transit General Performance Objectives*

The applicable requirements specified in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance," include general performance objectives.

The physical protection requirements of 10 CFR 73.67(a), state the following, "General performance objectives":

(1) Each licensee who possesses, uses, or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives:

   (i) Minimize the possibilities for unauthorized removal of special nuclear material consistent with the potential consequences of such actions; and

   (ii) Facilitate the location and recovery of missing special nuclear material.

(2) To achieve these objectives, the physical protection system shall provide:

   (i) Early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material;

   (ii) Early detection of removal of special nuclear material by an external adversary from a controlled access area;

   (iii) Assure proper placement and transfer of custody of special nuclear material; and

   (iv) Respond to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery.

The in-transit physical protection requirements of 10 CFR 73.67(a) are applicable because of the manner in which SNM of low strategic significance was described in the WLS Units 1 and 2 COL application.

Applicable Requirement: 10 CFR 73.67(a), "General performance objectives. (1) Each licensee who possesses, uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives:…"

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper; other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6, “Shipment,” of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has “…plans and procedures…” that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet each general performance objective, subsequently that SNM-qualified licensee will have the ability to meet the requirement to establish and maintain a physical protection system.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet each general performance objective; therefore, the staff finds the requirement, of 10 CFR 73.67(a)(1) to establish and maintain a physical protection system, would be met.

Applicable Requirement: 10 CFR 73.67(a)(1)(i), “General performance objectives. Each licensee who possesses, uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives: (i) Minimize the possibilities for unauthorized removal of special nuclear material consistent with the potential consequences of such actions. . .”

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has “…plans and procedures…” that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet each general performance objective, subsequently that SNM-qualified licensee will have the ability to meet the requirement to establish and maintain a physical protection system that has the capability to minimize the possibilities for unauthorized removal of special nuclear material consistent with the potential consequences of such actions.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet each general performance objective. Therefore, the staff finds the requirement, of 10 CFR 73.67(a)(1)(i) to minimize the possibilities for unauthorized removal of special nuclear material consistent with the potential consequences of such actions, would be met.

Applicable Requirement: 10 CFR 73.67(a)(1)(ii), “General performance objectives. Each licensee who possesses uses or transports special nuclear material of moderate or low strategic significance shall establish and maintain a physical protection system that will achieve the following objectives: “…(ii) Facilitate the location and recovery of missing special nuclear material.”

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet each general performance objective, subsequently that SNM-qualified licensee will have the ability to meet the requirement of establishing and maintaining a physical protection system that has the capability to facilitate the location and recovery of missing special nuclear material.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet each general performance objective. Therefore, the staff finds the requirement, of 10 CFR 73.67(a)(1)(ii) to "(i) Minimize …; and," (ii) Facilitate the location and recovery of missing special nuclear material," would be met.

Applicable Requirement: 10 CFR 73.67(a), "General performance objectives. (2) To achieve these objectives, the physical protection system shall provide: (i) Early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material. . ."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet each general performance objective-subsequently that SNM-qualified licensee will have the ability to meet the requirement of establishing and maintaining a physical protection system that has the capability to provide for early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet each general performance objective. Therefore, the staff finds the requirement, of 10 CFR 73.67(2)(i) to provide "Early detection and assessment of unauthorized access or activities by an external adversary within the controlled access area containing special nuclear material...," would be met.

Applicable Requirement: 10 CFR 73.67(a)(2)(ii), "General performance objectives. To achieve these objectives, the physical protection system shall provide: (ii) Early detection of removal of special nuclear material by an external adversary from a controlled access area. . ."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet each general performance objective-subsequently that SNM-qualified licensee will have the ability to meet the requirement of establishing and maintaining a physical protection system that has the capability to provide for early detection of removal of special nuclear material by an external adversary from a controlled access area.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet each general performance objective. Therefore, the staff finds the requirement, of 10 CFR 73.67(2)(ii) to provide "Early detection of removal of special nuclear material by an external adversary from a controlled access area...," would be met.

Applicable Requirement: 10 CFR 73.67(a)(2)(iii), "General performance objectives. To achieve these objectives, the physical protection system shall: (iii) Assure proper placement and transfer of custody of special nuclear material; and…"

The applicant included a description of how it intended to meet the in- transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Also, DEC, in their SNMPPP, describes in Section 5.1, "Receipt of SNM," within Subsections 5.1.1 (for non-fuel SNM) and 5.1.2 (for fuel SNM), the process for receiving and placing SNM. Furthermore, SNM to be transported from the site or received at the site will have an MC&A program applied to it as described in Part 11D of the application. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance, will confirm that such a licensee has the physical protection measures in place to meet each general performance objective, has procedures for receipt/placement of SNM and has an MC&A program that will apply to SNM; subsequently that SNM-qualified licensed shipper and DEC will have the ability to meet the requirement of establishing and maintaining a physical protection system that has the capability to assure proper placement and transfer of custody of special nuclear material.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed- shipper has physical protection measures in place to meet each general performance objective. In addition, DEC has a described process for receiving and placing SNM and will have a MC&A program applied to SNM to be shipped or received. Therefore, the staff finds the requirement, of 10 CFR 73.67(2)(iii) to assure proper placement and transfer of custody of special nuclear material, would be met.

Applicable Requirement: 10 CFR 73.67(a)(2)(iv), "General performance objectives. To achieve these objectives, the physical protection system shall: (iv) Respond to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that each general performance objective of 10 CFR 73.67 will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet each general performance objective, subsequently that SNM-qualified licensee will have the ability to meet the requirement of responding to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet each general performance objective. Therefore, the staff finds the requirement, of 10 CFR 73.67(a)(2)(iv) to respond to indications of an unauthorized removal of special nuclear material and then notify the appropriate response forces of its removal in order to facilitate its recovery, would be met.

1.5.5.1.4.5 *In-Transit General Requirements*

The applicable requirements specified in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance," include the following general requirements.

> (c) Each licensee who possesses, uses, transports, or delivers to a carrier for transport special nuclear material of moderate strategic significance, or 10 kg or more of special nuclear material of low strategic significance shall:
>
> (1) Submit a security plan or an amended security plan describing how the licensee will comply with all the requirements of paragraphs (d), (e), (f), and (g) of this section, as appropriate, including schedules of implementation. The licensee shall retain a copy of the effective security plan as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the original plan was submitted. Copies of superseded material must be retained for 3 years after each change.
>
> (2) Within 30 days after the plan submitted pursuant to paragraph (c)(1) of this section is approved, or when specified by the NRC in writing, implement the approved security plan."

Applicable Requirement: 10 CFR 73.67(c)(1), "Submit a security plan including schedules for implementation. . . shall retain a copy. . . for 3 years. . ." "Copies of the superseded material must be retained for 3 years after each change."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(c)(1) would be met.

DEC's application describes that 10CFR73.67 will be fully implemented before SNM is received. In addition, their SNMPPP describes the required retention parameters for the SNMPPP and changes to it; therefore, the requirement of 10 CFR 73.67(c)(1) to retain the security plan for 3 years after the specific type of SNM has been removed from the site, and superseded security plan change(s) shall be retained for 3 years after each change, would be met.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has provisions in place to meet 10 CFR 73.67(c)(1); therefore, the staff finds the requirement, of 10 CFR 73.67(c)(1), to "Submit a security plan or as amended security plan describing how the licensee will comply with all the requirements of paragraphs (d), (e), (f), and (g) of this section, as appropriate, including schedules of implementation. The licensee shall retain a copy of the effective security plan as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the original plan was submitted. Copies of superseded material must be retained for 3 years after each change…," would be met.

Applicable Requirement: 10 CFR 73.67(c)(2), "Within 30 days after the plan submitted pursuant to paragraph (c)(1) of this section is approved, or when specified by the NRC in writing, implement the approved security plan."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of its SNMPPP. The SNMPPP states that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, Section 6 of the SNMPPP states that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(c)(2), would be met.

1.5.5.1.4.6 *In-Transit Physical Protection Requirements*

The applicable requirements specified in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance," describes in-transit physical protection requirements.

The physical protection requirements of 10 CFR 73.67(g) state, "In-transit requirements for special nuclear material of low strategic significance.

(1) Each licensee who transports or who delivers to a carrier for transport special nuclear material of low strategic significance shall:

   (i) Provide advance notification to the receiver of any planned shipments specifying the mode of transport, estimated time of arrival, location of the nuclear material transfer point, name of carrier and transport identification,

(ii) Receive confirmation from the receiver prior to commencement of the planned shipment that the receiver will be ready to accept the shipment at the planned time and location and acknowledges the specified mode of transport,
(iii) Transport the material in a tamper indicating sealed container,
(iv) Check the integrity of the containers and seals prior to shipment, and
(v) Arrange for the in-transit physical protection of the material in accordance with the requirements of Section 73.67(g)(3) of this part, unless the receiver is a licensee and has agreed in writing to arrange for the in-transit physical protection.

(2) Each licensee who receives quantities and types of special nuclear material of low strategic significance shall:

(i) Check the integrity of the containers and seals upon receipt of the shipment,
(ii) Notify the shipper of receipt of the material as required in Section 74.15 of this chapter, and
(iii) Arrange for the in-transit physical protection of the material in accordance with the requirements of Section 73.67(g)(3) of this part, unless the shipper is a licensee and has agreed in writing to arrange for the in-transit physical protection.

(3) Each licensee, either shipper or receiver, who arranges for the physical protection of special nuclear material of low strategic significance while in transit or who takes delivery of such material free on board (f.o.b.) the point at which it is delivered to a carrier for transport shall:

(i) Establish and maintain response procedures for dealing with threats or thefts of this material. The licensee shall retain a copy of the current response procedures as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the procedures were established. Copies of superseded material must be retained for 3 years after each change.

(ii) Make arrangements to be notified immediately of the arrival of the shipment at its destination, or of any such shipment that is lost or unaccounted for after the estimated time of arrival at its destination, and

(iii) Conduct immediately a trace investigation of any shipment that is lost or unaccounted for after the estimated arrival time and notify the NRC Operations Center within one hour after the discovery of the loss of the shipment and within one hour after recovery of or accounting for such lost shipment in accordance with the provisions of Section 73.71 of this part."

The in-transit physical protection requirements of 10 CFR 73.67(g) are applicable because of the manner in which SNM of low strategic significance was described in the WLS Units I and 2 COL application.

Applicable Requirement: 10 CFR 73.67(g), "In-transit requirements for special nuclear material of low strategic significance. (1) Each licensee who transports or who delivers

to a carrier for transport special nuclear material of low strategic significance shall: (i) Provide advance notification to the receiver of any planned shipments specifying the mode of transport, estimated time of arrival, location of the nuclear material transfer point, name of carrier and transport identification. . .”

The applicant included a description of how it was intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has “…plans and procedures…” that are developed and implemented in such a manner that 10 CFR 73.67(g)1)(i) will be met. DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet 10 CFR 73.67(g)1)(i). Therefore, that SNM-qualified licensee will have the ability to meet the requirement of providing advance notification to the receiver of any planned shipments specifying the mode of transport, estimated time of arrival, location of the nuclear material transfer point, name of carrier and transport identification.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet 10 CFR 73.67(g)(1)(i). Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(1)(i) to provide advance notification to the receiver of any planned shipments specifying the mode of transport, estimated time of arrival, location of the nuclear material transfer point, name of carrier and transport identification, would be met.

Applicable Requirement: 10 CFR 73.67(g)(1)(ii), “In-transit requirements for special nuclear material of low strategic significance. (1) Each licensee who transports or who delivers to a carrier for transport special nuclear material of low strategic significance shall: (ii) Receive confirmation from the receiver prior to commencement of the planned shipment that the receiver will be ready to accept the shipment at the planned time and location and acknowledges the specified mode of transport. . .”

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used to transport SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has “…plans and procedures…” that are developed and implemented in such a manner that 10 CFR 73.67(g)(1)(ii) will be met. Because DEC will be using a SNM-qualified licensee to perform the shipment of SNM of low strategic significance and will confirm that such a licensee has the physical protection measures in place to meet 10 CFR 73.67(g)(1)(ii), subsequently that SNM-qualified licensee will have the ability to meet the requirement of receiving confirmation from the receiver prior to commencement of the planned shipment that the receiver will be ready to accept the shipment at the planned time and location and acknowledges the specified mode of transport.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet 10 CFR 73.67(g)(1)(ii). Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(1)(ii) to receive confirmation from the receiver prior to commencement of the planned shipment that the receiver will be ready to accept the shipment at the planned time and location and acknowledges the specified mode of transport, would be met.

Applicable Requirement: 10 CFR 73.67(g)(1)(iii), "In-transit requirements for special nuclear material of low strategic significance. (1) Each licensee who transports or who delivers to a carrier for transport special nuclear material of low strategic significance shall: (iii) Transport the material in a tamper indicating sealed container. . ."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(1)(iii) will be met.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has physical protection measures in place to meet 10 CFR 73.67(g)(1)(iii). Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(1)(iii) to transport the material in a tamper indicating sealed container, would be met.

Applicable Requirement: 10 CFR 73.67(g)(2)(i), "In-transit requirements for special nuclear material of low strategic significance. (2) Each licensee who receives quantities and types of special nuclear material of low strategic significance shall: (i) Check the integrity of the containers and seals upon receipt of the shipment,…"

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. Specifically, in Section 5.1, within Subsections 5.1.1.4 (for non-fuel SNM) and 5.1.2.4 (for fuel SNM), it is described that the integrity of both shipping containers and tamper-seals will be checked.

The DEC application described that shipment containers and tamper-seals applied to those containers would be checked upon receipt; therefore, the staff finds the requirement, of 10 CFR 73.67(g)(2)(i) to check the integrity of the containers and seals upon receipt of the shipment, would be met.

Applicable Requirement: 10 CFR 73.67(g)(2)(ii), "In-transit requirements for special nuclear material of low strategic significance. (2) Each licensee who receives quantities and types of special nuclear material of low strategic significance shall: (ii) Notify the shipper of receipt of the material as required in Section 74.15 of this chapter. . ."

In the DEC SNMPPP in Section 5.1, within Subsections 5.1.1.1 (for non-fuel SNM) and 5.1.2.1 (for fuel SNM), it is described that the shipper would be notified in accordance with 10 CFR 74.15. In addition, the development of procedures for "Receiving and shipping SNM" was described in the SNMPP within Section 4.1.

The DEC application described that the shipper would be notified in accordance with 10 CFR 74.15 for both non-fuel and fuel SNM; therefore, the staff finds the requirement, of 10 CFR 73.67(g)(2)(ii) to notify the shipper of receipt of SNM, as required per 10 CFR 74.15, would be met.

Applicable Requirement: 10 CFR 73.67(g)(2)(iii), "Arrange for the in-transit physical protection of the material in accordance with the requirements of Section 73.67(g)(3) of this part, unless the shipper is a licensee and has agreed in writing to arrange for the in-transit physical protection."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(2)(iii) will be met.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has provisions in place to meet10 CFR 73.67(g)(2)(iii). Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(2)(iii) to arrange for the in-transit physical protection of the material in accordance with the requirements of Section 73.67(g)(3) of this part, unless the shipper is a licensee and has agreed in writing to arrange for the in-transit physical protection, would be met.

Applicable Requirement: 10 CFR 73.67(g)(3), "Each licensee, either shipper or receiver, who arranges for the physical protection of special nuclear material of low strategic significance while in transit or who takes delivery of such material free on board (f.o.b.) the point at which it is delivered to a carrier for transport shall: (i) Establish and maintain response procedures for dealing with threats or thefts of this material. The licensee shall retain a copy of the current response procedures as a record for 3 years after the close of period for which the licensee possesses the special nuclear material under each license for which the procedures were established. Copies of superseded material must be retained for 3 years after each change."

The applicant included a description of how the how it was intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(3)(i) will be met.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has provisions in place to meet 10 CFR 73.67(g)(3)(i). Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(3)(i) to, "Establish and maintain response procedures …," would be met.

Applicable Requirement: 10 CFR 73.67(g)(3), "Each licensee, either shipper or receiver, who arranges for the physical protection of special nuclear material of low strategic significance while in transit or who takes delivery of such material free on board (f.o.b.) the point at which it is delivered to a carrier for transport shall: (ii) Make arrangements to be notified immediately of the arrival of the shipment at its destination point, or of any

shipment that is lost or unaccounted for after the estimated time of arrival at its destination."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(3)(ii) will be met. The SNMPP stated that DEC will use an SNM licensed shipper and that DEC will verify that the shipper will be able to meet the requirement.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has provisions in place to meet10 CFR 73.67(g)(3)(ii). Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(3)(ii) to, "make arrangements to be notified immediately of the arrival of the shipment at its destination point, or of any shipment that is lost or unaccounted for after the estimated time of arrival at its destination," would be met.

Applicable Requirement: 10 CFR 73.67(g)(3), "Each licensee, either shipper or receiver, who arranges for the physical protection of special nuclear material of low strategic significance while in transit or who takes delivery of such material free on board (f.o.b.) the point at which it is delivered to a carrier for transport shall: (iii) Conduct immediately a trace investigation of any shipment that is lost or unaccounted for after the estimated arrival time and notify the NRC Operations Center within one hour after the discovery of the loss of the shipment and within one hour after recovery of or accounting for such lost shipment in accordance with the provisions of Section 73.71 of this part."

The applicant included a description of how it intended to meet the in-transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(3)(iii) will be met. DEC has committed to meeting the requirement in their SNMPPP in Section 5.1, within Subsections 5.1.1.1 (for non-fuel SNM) and 5.1.2.1 (for fuel SNM). Furthermore, DEC noted that a procedure would be developed for notification process in Section 4.1 of the SNMPPP.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has provisions in place to meet 10 CFR 73.67(g)(3)(iii). In addition, DEC has committed to meeting the 10 CFR 73.67(g)(3)(iii) trace investigation/notification requirement. Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(3)(iii) to, "conduct immediately a trace investigation of any shipment that is lost or unaccounted for after the estimated arrival time and notify the NRC Operations Center within one hour after the discovery of the loss of the shipment and within one hour after recovery of or accounting for such lost shipment in accordance with the provisions of Section 73.71 of this part," would be met.

Applicable Requirement: 10 CFR 73.67(g)(4), "Each licensee who exports special nuclear material of low strategic significance shall comply with the appropriate requirements

specified in paragraphs (c) and (g) (1) and (3) of this section. The licensee shall retain each record required by these sections for 3 years after the close of period for which the licensee possesses the special nuclear material under each license that authorizes the licensee to export this material. Copies of superseded material must be retained for 3 years after each change."

How the requirements of 10 CFR 73.67(c) would be met by the applicant are described in Section 1.5.5.1.4.5, "In-Transit General Requirements," of this safety evaluation report. Also, the applicant included a description of how it intended to meet the in- transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(4) will be met.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed- shipper has provisions in place to meet 10 CFR 73.67(c) requirements, as specified in the SNMPPP Section 6.1. How the requirements of 10 CFR 73.67(g)(1) and (3) would be met are detailed in this safety evaluation report in Section 1.5.5.1.4.6, "In-Transit Physical Protection Requirements." Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(4), "Each licensee who exports special nuclear material of low strategic significance shall comply with the appropriate requirements specified in paragraphs (c) and (g) (1) and (3) of this section. The licensee shall retain each record required by these sections for 3 years after the close of period for which the licensee possesses the special nuclear material under each license that authorizes the licensee to export this material. Copies of superseded material must be retained for 3 years after each change…," would be met.

Applicable Requirement: 10 CFR 73.67(g)(5)(i), "Each licensee who imports special nuclear material of low strategic significance shall: (i) Comply with the requirements specified in paragraphs (c) and (g) (2) and (3) of this section and retain each record required by these paragraphs for 3 years after the close of period for which the licensee possesses the special nuclear material under each license that authorizes the licensee to import this material. Copies of superseded material must be retained for 3 years after each change."

The applicant included a description of how it intended to meet the in- transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. It is stated in the SNMPPP that a SNM-qualified licensed shipper, other than DEC, will be used for transport of SNM of low strategic significance both to and from the site. In addition, it is stated in Section 6 of the SNMPPP that DEC will confirm that the licensee used for transport of SNM has "…plans and procedures…" that are developed and implemented in such a manner that 10 CFR 73.67(g)(4) will be met.

The DEC application stated that arrangements with a SNM-qualified licensed shipper would be made for the transport of SNM of low strategic significance, and that DEC will confirm that the licensed shipper has provisions in place to meet 10 CFR 73.67(c) requirements, as specified in the SNMPPP Section 6.1. How the requirements of 10 CFR 73.67(c) would be met by the applicant are described in Section 1.5.5.1.4.5, "In-Transit General Requirements," of this safety evaluation report. In addition, how the requirements of 10 CFR 73.67(g)(2) and (3) would be met are detailed in this safety evaluation report in Section 1.5.5.1.4.6, "In-Transit Physical Protection Requirements." Therefore, the staff finds the requirement, of 10 CFR 73.67(g)(5), "Each licensee who exports special nuclear material of low strategic significance shall comply with the appropriate requirements specified in paragraphs (c) and (g) (2) and (3) of this section. The licensee shall retain each record required by these sections for 3 years after the close of period for which the licensee possesses the special nuclear material under each license that authorizes the licensee to export this material. Copies of superseded material must be retained for 3 years after each change," would be met.

Applicable Requirement: 10 CFR 73.67(g)(5)(ii), "Each licensee who imports special nuclear material of low strategic significance shall: (ii) Notify the person who delivered the material to a carrier for transport of the arrival of such material."

The applicant included a description of how it intended to meet the in- transit physical protection requirements of 10 CFR 73.67(g) in Section 6 of their SNMPPP. Specifically, in the DEC SNMPPP in Section 5.1, within Subsections 5.1.1.1 (for non-fuel SNM) and 5.1.2.1 (for fuel SNM), it is described that the shipper would be notified upon receipt of SNM. In addition, the development of procedures for "Receiving and shipping SNM" was described in Section 4.1 of the SNMPPP.

The staff finds that because DEC has described: 1) notification actions to be made upon the receipt of SNM in their SNMPPP, and 2) the development of procedures that would pertain to "Receiving and shipping SNM" the requirement, of 10 CFR 73.67(g)(5)(ii) to "notify the person who delivered the material to a carrier for transport of the arrival of such material," would be met.

1.5.5.1.4.7 *WLS COL FSAR Section 13.5.2.2.8*

The applicant included in WLS COL FSAR Section 13.5.2.2.8, in general terms, the correct manner in which the requirements of 10 CFR 73.67 must be applied to the non-fuel HEU sources that are SNM of low strategic significance, that the applicant proposes to possess, transport and use at the Lee site. Therefore, the staff finds the application of the correct physical protection measures, as stated in 10 CFR 73.67, to all types of SNM of low strategic significance, would be met.

1.5.5.1.4.8 *Post-September 11, 2001, Security Orders for SNM of Low Strategic Significance*

Applicable Requirement: "General Performance Objectives and Requirements" Analysis required per the order.

The applicant considered the order and assessed that only parts C and D of the order must be addressed. The discussion of the analysis that justified only part C and D of the order needed to be addressed was in the SNMPPP within Section 1. Therefore, the analysis requirement presented in the beginning of the order, would be met.

Part C of the Order "Response"

Applicable Requirement: Part C.1. of the order "Develop security response procedures…"

The applicant described the procedures that would be developed in Section 4.1 of the SNMPPP. Those procedures listed to be developed; included response procedures.

Because the applicant committed to develop response implementing procedures, the order requirement of C.1., would be met.

Applicable Requirement: Part C.2. of the order (Part C.2. contains safeguards information and is not described here).

The applicant addressed Part C.2. in Section 5.10 of the SNMPPP.

Because the applicant described the response attributes that aligned with Part C.2. of the order, the order requirement of C.2., would be met.

Part D of the Order "General"

Applicable Requirement: Part D.1. of the order "…hexafluoride…"

This part of the order was associated with uranium hexafluoride. The applicant addressed this order requirement in Section 1 of the SNMPPP.

Because the applicant described the conditions associated with uranium hexafluoride with the Lee site, Part D.1., of the order, would be met.

Applicable Requirement: Part D.2. of the order "…hazardous material…" This part of the order was associated with hazardous material.

The applicant addressed this order requirement in Section 5.9 "Chemicals and Hazardous Materials." In addition, a procedure to implement the strategy outlined in Section 5.9 of the SNMPPP was committed to be developed in Section 4.1 of the SNMPPP.

Because the applicant described a strategy to address Part D.2. of the order, and committed to the development of a procedure to implement that strategy, Part D.2. of the order would be met.

Applicable Requirement: Part D.3. of the order "Supplement the Emergency Action Levels…"

The applicant addressed Part D.3 of the order in section 5.11 "Emergency Response" of the SNMPPP.

Because the applicant described how the requirement of Part D.3. of the order would be addressed, Part D.3. of the order, would be met.

Applicable Requirement: Part D.4. of the order "Evaluate computer and communications…"

The applicant addressed Part D.4. of the order in Section 5.11 "Emergency Response" of the SNMPPP.

Because the applicant described how the requirement of Part D.4. of the order would be addressed, Part D.4. of the order, would be met.

Applicable Requirement: Part D.5. of the order "Evaluate capabilities…fire suppression…"

The applicant addressed Part D.5. of the order in Section 5.12 "Fire Response" of the SNMPPP.

Because the applicant described how the requirement of Part D.5, of the order would be addressed, Part D.5 of the order would be met.

Applicable Requirement: Part D.6. of the order "Evaluate…medical…"

The applicant addressed Part D.6. of the order in Section 5.13 "Medical Response" of the SNMPPP.

Because the applicant described how the requirement of Part D.6, of the order would be addressed, Part D.6 of the order would be met.

Applicable Requirement: Part D.7. of the order "Limit…access…"

The applicant discussed in Section 5.7 how the order requirement D.7 would be addressed.

Because the applicant described how the requirement of Part D.7, of the order would be addressed, Part D.7 of the order would be met.

Part 3 of the Order "Access Control and Badging"

The applicant stated in Section 5.4 "Access Control and Badging" of the SNMPPP that those persons afforded access to the controlled access area would be under the access authorization program as presented in Section 14.1 of their power reactor PSP. In Section 14.1 of the PSP, Rev. 3, dated April 10, 2013, (SLES No. NS112930), the RG 5.66 "Access Authorization Program for Nuclear Power Plants" was the applicable access authorization program. The access authorization program as described in RG 5.66 includes fingerprinting and an overall more-stringent access authorization program than that described in Part 3 of the order.

In addition, individuals not under the subject access authorization program would be escorted into, out of, and within the controlled access area in accordance with Section 14.4.6 of the PSP which describes escort methodologies developed for the Lee power reactors.

The applicant described that RG 5.66 would be applied to meet Part 3 of the order and it is recognized that in doing so a more stringent access authorization process would be utilized than that described in Part 3 of the order. Therefore, Part 3 of the order, which includes fingerprinting and other access authorization provisions, would be met.

Conclusion

The NRC staff reviewed DEC, WLS Units I and 2, Docket Nos. 52-018 and 52-019, application (ADAMS Accession No. ML073510494), and finds that the applicable requirements specified in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of SNM of moderate and low strategic significance" and the post September 11, 2001, security order for SNM of low strategic significance, would be met.

1.5.5.2 *Conclusion and Post Combined License Activities*

The NRC staff reviewed DEC, WLS Units I and 2, Docket Nos. 52-018 and 52-019, application (ADAMS Accession No. ML073510494), and finds that the applicable requirements specified in 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of SNM of moderate and low strategic significance" and the post September 11, 2001, security order for SNM of low strategic significance, would be met.

With respect to the applicable fixed site and in-transit physical protection requirements for SNM of low strategic significance specified in 10 CFR 73.67 and the post September 11, 2001, security order for the fixed site possession and use of SNM of low strategic significance, the NRC staff reviewed application and concludes that the relevant information in the application is acceptable because it meets the pertinent recommendations stated in RG 5.59.

The license condition language in this section has been modified, per a letter from the applicant dated March 22, 2016 (ADAMS Accession No. ML16084A099), confirming the acceptability of the following license conditions proposed by the staff. These changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license conditions acceptable:

- License Condition (1-3) – Subject to the conditions and requirements incorporated herein, the Commission hereby licenses DEC:

    (1) (a) pursuant to the Act and 10 CFR Part 70, to receive and possess at any time, special nuclear material as reactor fuel, in accordance with the limitations for storage and in amounts necessary for reactor operation, described in the FSAR, as supplemented and amended;

    (b) pursuant to the Act and 10 CFR Part 70, to use special nuclear material as reactor fuel, after a Commission finding under 10 CFR 52.103(g) has been made, in accordance with the limitations for storage and amounts necessary for reactor operation, described in the FSAR, as supplemented and amended;

    (2) (a) pursuant to the Act and 10 CFR Parts 30 and 70, to receive, possess, and use, at any time before a Commission finding under 10 CFR 52.103(g), such byproduct and special nuclear material (but not uranium hexafluoride) as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts not exceeding those specified in 10 CFR 30.35(d) and 10 CFR 70.25(d) for establishing decommissioning financial assurance, and not exceeding those specified in 10 CFR 30.72 and 10 CFR 70.22(i)(1);

    (b) pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use, after a Commission finding under 10 CFR 52.103(g), any byproduct, source, and special nuclear material as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts as necessary;

    (3) (a) pursuant to the Act and 10 CFR Parts 30 and 70, to receive, possess, and use, before a Commission finding under 10 CFR 52.103(g), any byproduct or special nuclear material (but not uranium hexafluoride) that is (1) in unsealed form; (2) on foils or plated surfaces, or (3) sealed in glass, for sample analysis or instrument calibration or other activity associated with radioactive apparatus or components, in amounts not exceeding those specified

in 10 CFR 30.35(d) and 10 CFR 70.25(d) for establishing decommissioning financial assurance, and not exceeding those specified in 10 CFR 30.72 and 10 CFR 70.22(i)(1);

(b) pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use, after a Commission finding under 10 CFR 52.103(g), in amounts as necessary, any byproduct, source, or special nuclear material (but not uranium hexafluoride) without restriction as to chemical or physical form, for sample analysis or instrument calibration or other activity associated with radioactive apparatus or components but not uranium hexafluoride; and

(4) pursuant to the Act and 10 CFR Parts 30 and 70, to possess, but not separate, such byproduct and special nuclear materials as may be produced by the operation of the facility.

- License Condition (1-4) - Prior to initial receipt of special nuclear materials onsite, the licensee shall implement the Special Nuclear Material Control and Accounting Program. No later than 12 months after issuance of the COL the licensee shall submit to the Director of the Office of New Reactors a schedule that supports planning for and conduct of NRC inspections of the Special Nuclear Material Control and Accounting Program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the Special Nuclear Material Control and Accounting Program has been fully implemented.

- License Condition (1-5) – No later than 12 months after issuance of the COL, the licensee shall submit to the Director of the Office of New Reactors a schedule that supports planning for and conduct of NRC inspection of the non-licensed plant staff training program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the non-licensed plant staff training program has been fully implemented.

- License Condition (1-6) – Prior to initial receipt of special nuclear material on site, the licensee shall implement the Special Nuclear Material Physical Protection Program. No later than 12 months after issuance of the COL, the licensee shall submit to the Director of the Office of New Reactors a schedule that supports planning for and conduct of NRC inspection of the Special Nuclear Material Physical Protection Program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the Special Nuclear Material Physical Protection Program has been fully implemented.

1.5.6 Physical Protection of Category 1 and Category 2 Quantities of Radioactive Material

On March 19, 2013, a new 10 CFR Part 37 rule was published in the FR in which the NRC amended its regulations to establish security requirements for the use and transport of Category 1 and Category 2 quantities of radioactive material. The NRC considers these quantities to be risk significant and, therefore, to warrant additional protection. Category 1 and Category 2 thresholds are based on the quantities established by the International Atomic Energy Agency (IAEA) in its Code of Conduct on the Safety and Security of Radioactive Sources, which the NRC endorses. The objective of the 10 CFR Part 37, “Physical Protection of Category 1 and Category 2 Quantities of Radioactive Material," regulation is to provide reasonable assurance of preventing the theft or diversion of Category 1 and Category 2 quantities of radioactive material. The regulations also include security requirements for the transportation of irradiated reactor fuel that weighs 100 grams or less in net weight of irradiated fuel.

2 SITE CHARACTERISTICS

Chapter 2, "Site Characteristics," of the William States Lee III Nuclear Station (WLS) Final Safety Analysis Report (FSAR) addresses the geological, seismological, hydrological, and meteorological characteristics of the site and vicinity, in conjunction with present and projected population distribution and land use, and site activities and controls.

2.0 Introduction

2.0.1 Introduction

The site characteristics are reviewed by the U.S. Nuclear Regulatory Commission (NRC) staff (the staff) to determine whether the applicant has accurately described the site characteristics and site parameters together with site-related design parameters and design characteristics in accordance with Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, certifications, and approvals for nuclear power plants." The review is focused on the site characteristics and site-related design characteristics needed to enable the staff to reach a conclusion on all safety matters related to siting of WLS Units 1 and 2. Since this combined license (COL) application references the AP1000 design certification (DC), this section focuses on the applicant's demonstration that the characteristics of the site fall within the site parameters specified in the DC rule or, if outside the site parameters, that the design satisfies the requirements imposed by the specific site characteristics and conforms to the design commitments and acceptance criteria described in the AP1000 Design Control Document (DCD).

2.0.2 Summary of Application

WLS COL FSAR, Revision 11, Section 2.0 incorporates by reference AP1000 DCD, Revision 19, Chapter 2, including Section 2.0. In this section, the applicant provided WLS COL FSAR Table 2.0-201, which provides a comparison of the AP1000 DCD site parameters against WLS site parameters. In addition, in WLS COL FSAR Section 2.0, the applicant provided the following:

Departures

- WLS DEP 2.0-1

The applicant departed from the AP1000 standard plant certified seismic design response spectra (CSDRS) that is addressed in AP1000 DCD, Section 3.7.1.1. The application deviated from the CSDRS due to a new seismic model for the local area described in NUREG-2115, "Central and Eastern United States Seismic Source Characterization for Nuclear Facilities." Considering this new seismic model and updated seismic hazards and site-specific foundation response spectra resulted in exceeding the AP1000 CSDRS and the need for a departure from the AP1000 DCD. The sections affected by this departure are WLS COL FSAR Table 2.0-201, Sections 3.7.1.1.1, 3.7.2.8.4, and 3.7.2.15, Appendix 3I, and Section 19.55.6.3. Sections in other chapters of the WLS COL FSAR will be discussed in the appropriate chapters of this report.

Supplemental Information

- WLS SUP 2.0-1

The applicant provided supplemental information in WLS COL FSAR Section 2.0, "Site Characteristics," which describes the characteristics and site-related design parameters of WLS.

Interface Items

These items are listed in the AP1000 DCD as plant interfaces.

- Interface Item 2.1

The WLS COL FSAR addresses the envelope of AP1000 plant site-related parameters in Tables 2.0-201 and 2.0-202.

- Interface Item 2.2

The WLS COL FSAR addresses external missiles from manmade hazards and accidents in Table 2.0-201, Sections 2.2.3.1.1 and 3.5.

- Interface Item 2.3

The WLS COL FSAR addresses maximum loads from manmade hazards and accidents in Section 2.2.3.

- Interface Item 2.4

The WLS COL FSAR addresses limiting meteorological parameters for accidents, releases, and extreme conditions, related to the design of systems and components exposed to the environment. This information is found in WLS COL FSAR Tables 2.0-201 and 2.0-202.

- Interface Item 2.5

The WLS COL FSAR addresses tornado and operating basis wind loadings in Table 2.0-201.

- Interface Item 2.6

The WLS COL FSAR addresses external missiles generated by natural phenomena in Table 2.0-201.

- Interface Item 2.7

The WLS COL FSAR addresses snow, ice, and rain loads in Table 2.0-201.

- Interface Item 2.8

The WLS COL FSAR addresses ambient air temperatures in Table 2.0-201.

- Interface Item 2.9

The WLS COL FSAR addresses onsite meteorological measurement program in Section 2.3.3.

- Interface Item 2.10

The WLS COL FSAR addresses Flood and groundwater elevations in Table 2.0-201.

- Interface Item 2.11

The WLS COL FSAR addresses Hydrostatic loads on systems, components, and structures in Table 2.0-201 and Section 2.4.12.5.

- Interface Item 2.12

The WLS COL FSAR addresses seismic parameters such as peak ground acceleration, response spectra, and shear wave velocity, in Table 2.0-201.

- Interface Item 2.13

The WLS COL FSAR addresses required bearing capacity of foundation materials in Table 2.0-201.

2.0.3 Regulatory Basis

The information in the WLS COL FSAR that is incorporated by reference, the regulatory basis is addressed in NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," and its supplements. The applicable regulatory requirements for site characteristics are as follows:

- 10 CFR 52.79(a)(1)(i) through (vi), as it relates to the requirements for the site-related contents of the application.

- 10 CFR 52.79(d)(1), as it relates to information sufficient to demonstrate that the characteristics of the site fall within the site parameters specified in the DC.

- 10 CFR Part 100, "Reactor site criteria," as it relates to the siting factors and criteria for determining an acceptable site.

The related acceptance criteria associated with these site characteristic requirements are given in NUREG 0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition)," Section 2.0. The related acceptance criteria are as follows:

- The acceptance criteria associated with specific site characteristics/parameters and site-related design characteristics/parameters are addressed in the related Chapter 2 or other referenced sections of NUREG-0800.

- Acceptance is based on the applicant's demonstration that the characteristics of the site fall within the site parameters of the certified design. If the actual site characteristics do not fall within the certified standard design site parameters, the COL applicant provides sufficient justification (e.g., by request for exemption or amendment from the DC) that the proposed facility is acceptable at the proposed site.

The regulatory requirements associated with the Tier 1 and 2 departures and the exemption request are as follows:

- 10 CFR 50.12(a), “Specific exemptions.”

  > (a) The Commission may, upon application by any interested person or upon its own initiative, grant exemptions from the requirements of the regulations of this part, which are authorized by law, will not present an undue risk to the public health and safety, and are consistent with the common defense and security. The Commission will not consider granting an exemption unless special circumstances are present.

- 10 CFR Part 52, “Licenses, certifications, and approvals for nuclear power plants,” Appendix D, “Design certification rule for the AP1000 design,” Section VIII, “Processes for changes and departures,” Item B.5.

- 10 CFR Part 52, Appendix D, Section IV.A.2.d.

  > An applicant for a combined license that wishes to reference this appendix shall…comply with the following requirements: Include, as part of its application…Information demonstrating compliance with the site parameters and interface requirements.

- 10 CFR 52, Appendix D, Section VIII.A.4. This section states that exemptions from Tier 1 material are governed by 10 CFR 52.63(b)(1). 10 CFR 52.63(b)(1) references 10 CFR 52.7, “Specific exemptions.”

- 10 CFR 52.7. This section states that the Commission may grant exemptions from the requirements of the regulations of this part as governed by 10 CFR 50.12, “Specific exemptions,” of this chapter.

2.0.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 2.0 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to site

[1] See Section 1.2.2 of the staff’s Safety Evaluation Report for a discussion of the staff’s review related to verification of the scope of information to be included in a COL application that references a DC.

characteristics. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the following information in the WLS COL FSAR:

Supplemental Information

- WLS SUP 2.0-1

The staff reviewed supplemental information WLS SUP 2.0-1 in WLS COL FSAR Section 2.0 describing the characteristics and site-related design parameters of WLS Units 1 and 2. In the WLS COL FSAR, the site parameters in AP1000 DCD Table 2-1 are compared to the site-specific site characteristics in WLS COL FSAR Table 2.0-201. In addition, control room atmospheric dispersion factors for accident dose analysis are presented in WLS COL FSAR Table 2.0-201.

The staff reviewed and compared the site-specific characteristics included in WLS COL FSAR Table 2.0-201 against AP1000 DCD Table 2-1. The staff's evaluation of the site characteristics associated with air temperature, precipitation, wind speed, atmospheric dispersion values, and control room atmospheric dispersion values is addressed in Section 2.3 of this report.
The staff's evaluation of site characteristics associated with flood level, ground water level, and plant grade elevation is addressed in Section 2.4 of this report. The staff's evaluation of seismic and soil site characteristics is addressed in Section 2.5 of this report. The staff's evaluation of site characteristics associated with missiles is addressed in Section 3.5 of this report.

2.0.5 Post Combined License Activities

There are no post COL activities related to this section.

2.0.6 Conclusion

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to site characteristics, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

As set forth above, the staff reviewed the application to ensure that sufficient information was presented in WLS SUP 2.0-1 to demonstrate that the characteristics of the site fall within the site parameters specified in the DC.

2.1 Geography and Demography

2.1.1 Site Location and Description

2.1.1.1 *Introduction*

The descriptions of the site area and reactor location are used to assess the acceptability of the reactor site. The review covers the following specific areas: (1) specification of reactor location with respect to latitude and longitude, political subdivisions; and prominent natural and manmade features of the area; (2) site area map to determine the distance from the reactor to the boundary lines of the exclusion area, including consideration of the location, distance, and orientation of plant structures with respect to highways, railroads, and waterways that traverse or lie adjacent to the exclusion area; and (3) any additional information requirements prescribed in the "Contents of application" sections of the applicable subparts to 10 CFR Part 52. The purpose of the review is to ascertain the accuracy of the applicant's description for use in independent evaluations of the exclusion area authority and control, the surrounding population, and nearby manmade hazards.

2.1.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.1, incorporates by reference AP1000 DC, Revision 19, Section 2.1. In addition, in WLS COL FSAR Section 2.1, the applicant provided the following:

Departures

- STD DEP 1.1-1

The applicant proposed the following Tier 2 standard departure from the AP1000 DCD. WLS COL FSAR Section 2.1.1, "Site Location and Description," identifies instances where the WLS COL FSAR sections are renumbered to include content consistent with Regulatory Guide (RG) 1.206, as well as NUREG-0800. WLS COL FSAR Section 2.1.4, "Combined License Information for Geography and Demography," references WLS COL 2.1-1 as discussed in WLS COL FSAR Sections 2.1.1, 2.1.2, and 2.1.3.

AP1000 COL Information Item

- WLS COL 2.1-1

The applicant provided additional information to resolve WLS COL 2.1-1, which addresses the provision of site-specific information related to site location and description, including the site exclusion area and its control, population, natural and manmade features, highways, railways, waterways, and other significant features of the area. WLS COL 2.1-1 is discussed in WLS COL FSAR Sections 2.1.1, 2.1.2, and 2.1.3.

2.1.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the site location and description are given in NUREG-0800, Section 2.1.1.

The applicable regulatory requirements for identifying site location and description are:

- 10 CFR 50.34(a)(1) and 10 CFR 52.79(a)(1),as they relate to the inclusion in the safety analysis report (SAR) of a detailed description and safety assessment of the site on which the facility is to be located, with appropriate attention to features affecting facility design.
- 10 CFR Part 100, as it relates to the following: (1) defining an exclusion area and setting forth requirements regarding activities in that area (10 CFR 100.3, "Definitions)); (2) addressing and evaluating factors that are used in determining the acceptability of the site as identified in 10 CFR 100.20(b); (3) determining an exclusion area such that certain dose limits would not be exceeded in the event of a postulated fission product release as identified in 10 CFR 50.34(a)(1), as it relates to site evaluation factors identified in 10 CFR Part 100; and (4) requiring that the site location and the engineered features included as safeguards against the hazardous consequences of an accident, should one occur, would ensure a low risk of public exposure.

The related acceptance criteria from NUREG-0800, Section 2.1.1 are as follows:

- Specification of Location: The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.34(a)(1) and 10 CFR 52.79(a)(1) if it describes highways, railroads, and waterways that traverse the exclusion area in sufficient detail to allow the reviewer to determine that the applicant has met the requirements in 10 CFR 100.3.
- Site Area Map: The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.34(a)(1) and 10 CFR 52.79(a)(1) if it describes the site location, including the exclusion area and the location of the plant within the area, in sufficient detail to enable the reviewer to evaluate the applicant's analysis of a postulated fission product release, thereby allowing the reviewer to determine (in Sections 2.1.2 and 2.1.3, and Chapter 15 of this report) that the applicant has met the requirements of 10 CFR 50.34(a)(1) and 10 CFR Part 100.

2.1.1.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.1 and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the site location and description. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the following information in the WLS COL FSAR:

Departures

- STD DEP 1.1-1

The applicant proposed the following Tier 2 standard departure from the AP1000 DCD. WLS COL FSAR Section 2.1.1, "Site Location and Description," identifies instances where the WLS COL FSAR sections are renumbered to include content consistent with RG 1.206, as well as NUREG-0800. This change is acceptable because it does not alter the information required to be provided.

AP1000 COL Information Item

- WLS COL 2.1-1

The staff reviewed WLS COL 2.1-1 related to site location and description, including political subdivisions, natural and manmade features, population, highways, railways, waterways, and other significant features of the area included in WLS COL FSAR Section 2.1.1. COL Information Item 2.1-1 in AP1000 DCD, Section 2.1.1 states:

> Combined License applicants referencing the AP1000 certified design will provide site-specific information related to site location and description, exclusion area authority and control, and population distribution. Site-specific information on the site and its location will include political subdivisions, natural and man-made features, population, highways, railways, waterways, and other significant features of the area.

Using publicly available maps, the staff independently verified the applicant-supplied latitude and longitude. The staff then converted this latitude and longitude to Universal Transverse Mercator (UTM) coordinates for the proposed WLS Units 1 and 2 and used the calculated values to verify the UTM coordinates provided in the WLS COL FSAR. The staff then verified the UTM coordinates of the WLS units.

The staff reviewed the site area map provided in the WLS COL FSAR for the proposed Units 1 and 2 to verify that the distance from the reactor to the boundary line of the exclusion area meets the guidance in NUREG-0800, Section 2.1.1. On the basis of the staff's review of the information in the WLS COL FSAR, and also the staff's confirmatory review of pertinent information, such as the location, site area map, effluent release limit boundaries, and prominent natural and manmade features of the area as described in publicly available documentation, as well as information collected during a site visit, the staff determined the information provided by the applicant with regard to the site location and description is considered adequate and acceptable.

2.1.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.1.1.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to site location and description, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

As set forth above, the applicant presented and substantiated information to establish the site location and description. The staff reviewed COL 2.1-1, and for the reasons given above, concludes that it is sufficient for the staff to evaluate compliance with the siting evaluation factors in 10 CFR 100.3, as well as with the radiological consequence evaluation factors in 10 CFR 52.79(a)(1). The staff further concludes that the applicant provided sufficient details about the site location and site description to allow the staff to evaluate, as documented in Sections 2.1.2, 2.1.3, and Chapter 11, Section 13.3, and Chapter 15 of this report, whether the applicant has met the relevant requirements of 10 CFR Part 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site.

2.1.2 Exclusion Area Authority and Control

2.1.2.1 *Introduction*

The descriptions of exclusion area authority and control are used to verify the applicant's legal authority to determine and control activities within the designated exclusion area, as provided in the application, are sufficient to enable the reviewer to assess the acceptability of the reactor site. The review covers the following specific areas: (1) establishment of the applicant's legal authority to determine all activities within the designated exclusion area; (2) the applicant's authority and control in excluding or removing personnel and property in the event of an emergency; (3) establish that proposed or permitted activities in the exclusion area unrelated to operation of the reactor do not result in a significant hazard to public health and safety; and (4) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.1.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.1, incorporates by reference AP1000 DCD, Revision 19, Section 2.1. In addition, in WLS COL FSAR Section 2.1.2, the applicant provided the following:

AP1000 COL Information Item

- WLS COL 2.1-1

The applicant provided additional information to resolve COL Information Item 2.1-1, which addresses the provision of site-specific information related to exclusion area authority and control, including size of the area, and activities that may be permitted within the designated exclusion area.

2.1.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the exclusion area authority and control are given in NUREG-0800, Section 2.1.2.

The applicable regulatory requirements for verifying exclusion area authority and control are:

- 10 CFR 50.34(a)(1), and 10 CFR 52.79(a)(1), as it relates to the inclusion in the FSAR of a detailed description and safety assessment of the site on which the facility is to be located, with appropriate attention to features affecting facility design (10 CFR 50.34(a)(1), and 10 CFR 52.79(a)(1)).

- 10 CFR Part 100, as it relates to the following: (1) defining an exclusion area and setting forth requirements regarding activities in that area (10 CFR 100.3); (2) addressing and evaluating factors that are used in determining the acceptability of the site as identified in 10 CFR 100.20(b); and (3) determining an exclusion area such that certain dose limits would not be exceeded in the event of a postulated fission product release as identified in 10 CFR 50.34(a)(1) as it relates to site evaluation factors identified in 10 CFR Part 100.

The related acceptance criteria from NUREG-0800, Section 2.1.2 are as follows:

- Establishment of Authority for the Exclusion or Removal of Personnel and Property: The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.33, “Contents of applications; general information”; 10 CFR 50.34(a)(1); 10 CFR 52.79, “Contents of applications; technical information in final safety analysis report”; and 10 CFR Part 100 if it provides sufficient detail to enable the staff to evaluate the applicant’s legal authority for the exclusion or removal of personnel or property from the exclusion area.

- Proposed and Permitted Activities: The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.33, 10 CFR 50.34(a)(1), 10 CFR 52.79, and 10 CFR Part 100 if it provides sufficient detail to enable the staff to evaluate the applicant’s legal authority over all activities within the designated exclusion area.

2.1.2.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.1.2 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to the exclusion area authority and control. The results of the staff’s evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the following information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 2.1-1

The staff reviewed WLS COL 2.1-1 related to the exclusion area authority and control, including the exclusion area boundary, and activities that may be permitted within the designated exclusion area included in WLS COL FSAR Section 2.1.2. COL Information Item in AP1000 DCD, Section 2.1.1 states:

> Combined License applicants referencing the AP1000 certified design will provide site-specific information related to site location and description, exclusion area authority and control, and population distribution. Site-specific information on the exclusion area will include the size of the area and the exclusion area authority and control. Activity that may be permitted within the exclusion area will be included in the discussion.

The applicant supplied the following information: There are no residences and only limited commercial and recreational activities within the Units 1 and 2 exclusion area. No public highways or active railroads traverse the exclusion area. There are four historical cemeteries within the site boundary area. Access of members of the public to these cemeteries will be controlled by site security personnel.

The staff also verified for consistency that the exclusion area boundary (EAB) is the same as that being considered by the applicant for the radiological consequences in WLS COL FSAR Section 13.3 and Chapter 15. The acceptance criteria of NUREG-0800, Section 2.1.2 states, “Absolute ownership of all lands within the exclusion area, including mineral rights, is considered to carry with it the required authority to determine all activities on this land and is acceptable.” Thus, the staff concludes that the applicant has the required authority to determine and control all activities within the designated exclusion area.

The staff reviewed the resolution to the site-specific items related to the exclusion area authority and control included under WLS COL FSAR Section 2.1. The staff verified the applicant’s description of the exclusion area as well as the authority under which all activities within the exclusion area can be controlled. The staff also verified for consistency that the EAB is the same as that being considered for the radiological consequences by the applicant in WLS COL FSAR Chapters 15 and 13.3. The staff used publicly available maps and satellite pictures, a site visit, and the area map provided in the Unit 1 and 2 WLS COL FSAR to verify that no publicly used transportation mode crosses the EAB; therefore, no arrangements for the control of traffic in the event of an emergency are required. The staff also verified that no public roads cross the exclusion area; therefore, neither relocation nor abandonment of roads is needed. The staff concludes that the applicant has acquired authority to control all activities within the designated exclusion area.

2.1.2.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.1.2.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the exclusion area authority and control, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

As set forth above, the applicant provided and substantiated information concerning its legal authority and control of all activities within the designated exclusion area. The staff reviewed WLS COL 2.1-1 and, for the reasons given above, concludes that the applicant's exclusion area is acceptable to meet the requirements of 10 CFR 50.34(a)(1), 10 CFR 52.79(a)(1), 10 CFR Part 100, and 10 CFR 100.3 with respect to determining the acceptability of the site. This conclusion is based on the applicant having appropriately described the plant exclusion area, the authority under which all activities within the exclusion area can be controlled, the need for relocation or abandonment of public roads, and the methods by which access and occupancy of the exclusion area can be controlled during normal operation and in the event of an emergency situation. In addition, the applicant has the required authority to control activities within the designated exclusion area, including the admission, exclusion, and removal of persons and property, and has established acceptable methods for control of the designated exclusion area. The staff finds that the application adequately addresses COL Information Item 2.1-1. The staff finds that the applicant has provided sufficient information to satisfy 10 CFR Part 52.79(a)(1) and 10 CFR Part 100 and, therefore, is acceptable.

2.1.3 Population Distribution

2.1.3.1 *Introduction*

The description of population distributions addresses the need for information about: (1) population in the site vicinity, including transient populations; (2) population in the exclusion area; (3) whether special protective measures should be taken on behalf of the populace in the specified low-population zone (LPZ) in the event of a serious accident; (4) whether the nearest boundary of the closest population center containing 25,000 or more residents is at least one and one-third times the distance from the reactor to the outer boundary of the LPZ; (5) whether the population density in the site vicinity is consistent with the guidelines given in RG 4.7, "General Site Suitability Criteria for Nuclear Power Stations;" Regulatory Position C.4 and (6) any additional information requirements prescribed in the "Contents of Application," sections of the applicable subparts to 10 CFR Part 52.

2.1.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.1, incorporates by reference AP1000 DCD, Revision 19, Section 2.1. In addition, in WLS COL FSAR Section 2.1.3, the applicant provided the following:

AP1000 COL Information Item

- WLS COL 2.1-1

The applicant provided additional information resolve COL Information Item 2.1-1, which addresses the provision of site-specific information related to the site environment, specifically, population centers and distribution up to 80 km (50 mi) from the WLS site.

2.1.3.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for population distribution are given in NUREG-0800, Section 2.1.3. The applicable regulatory requirements for identifying site location and description are:

- 10 CFR 50.34(a)(1), as it relates to consideration of the site evaluation factors identified in 10 CFR 100.3, 10 CFR Part 100 (including consideration of population density), and 10 CFR 52.79, as they relate to provision by the applicant in the SAR of the existing and projected future population profile of the area surrounding the site.

- 10 CFR 100.20 and 10 CFR 100.21, as they relate to determining the acceptability of a site for a power reactor. In 10 CFR 100.3, 10 CFR 100.20(a), and 10 CFR 100.21(b), the NRC provides definitions and other requirements for determining an exclusion area, LPZ, and population center distance.

The related acceptance criteria from Section 2.1.3 of NUREG-0800 are as follows:

- Population Data: The population data supplied by the applicant in the FSAR is acceptable under the following conditions: (1) the FSAR includes population data from the latest census and projected population at the year of plant approval and 5 years thereafter, in the geographical format given in RG 1.70, “Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants (LWR Edition),” Section 2.1.3, Revision 3, and in accordance with DG-1145, “Combined License Applications for Nuclear Power Plants (LWR Edition)”; (2) the FSAR describes the methodology and sources used to obtain the population data, including the projections; and (3) the FSAR includes information on transient populations in the site vicinity.

- Exclusion Area: The exclusion area should either not have any residents, or such residents should be subject to ready removal if necessary.

- Low-Population Zone: The specified LPZ is acceptable if it is determined that appropriate protective measures could be taken on behalf of the enclosed populace in the event of a serious accident.

- Nearest Population Center Boundary: The nearest boundary of the closest population center containing 25,000 or more residents is at least one and one-third times the distance from the reactor to the outer boundary of the LPZ.

- Population Density: If the population density exceeds the guidelines given in RG 4.7, Regulatory Position C.4, the applicant must give special attention to the consideration of alternative sites with lower population densities.

2.1.3.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.1.3 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to population distribution. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 2.1-1

The staff reviewed WLS COL 2.1-1 related to the population distribution around the site environs included in WLS COL FSAR Section 2.1.3. COL information item in AP1000 DCD, Section 2.1.1 states:

> Combined License applicants referencing the AP1000 certified design will provide site-specific information related to site location and description, exclusion area authority and control, and population distribution. Site-specific information will be included on population distribution.

The staff reviewed the data on the population in the site environment to determine whether the exclusion area, LPZ, and population center distance for the proposed WLS site comply with the requirements of 10 CFR Part 100. The staff also evaluated whether, consistent with RG 4.7, Regulatory Position C.4, the applicant should consider alternative sites with lower population densities. The staff also reviewed whether appropriate protective measures could be taken on behalf of the enclosed populace within the emergency planning zone (EPZ), which encompasses the LPZ, in the event of a serious accident. The staff compared and verified the applicant's population data against U.S. Census Bureau data available on the Internet. Transient population estimates were based on evaluations of seasonal transient business, hotels, motels, recreation, schools, hospitals, nursing homes, correctional facilities, festivals, and migrant workers populations. The staff reviewed the projected population data provided by the applicant, including the weighted transient population for 2016, 2021, 2026, 2036, 2046, and 2056. The staff reviewed the extensive transient population data provided by the applicant. Based on this information, the staff finds that the applicant's estimate of the population and the population projections are acceptable.

The staff verified the distances to the nearest population centers are well in excess of the minimum population center distance of 4.3 km (2.7 miles) (1 1/3 times the distance from center point to the outer boundary of the LPZ). The LPZ is defined as a two-mile radius from the site center point. The center point is defined as the midway point between Unit 1 and Unit 2. The nearest population center, as defined by 10 CFR 100.3, is Gastonia, NC. The distance to

Gastonia's urban boundary, as defined by US Census files, is 25 km (16 mi) northeast from the center point between the two reactors. Using the county's population projection ratios for both transient and permanent population, results in Gaffney, SC having a total population number greater than 25,000 people. Gaffney's closest boundary, defined by the US Census Bureau, is 10 km (6 mi) northwest from the center point between the two reactors. Both of these distances are greater than one and one-third times the distance from the reactor center point to the boundary of the low population zone as required by NUREG-0800 and comply with the guidance provided by RG 4.7, "General Site Suitability Criteria for Nuclear Power Stations." Therefore, the staff concludes that the proposed site meets the population center distance requirement as defined in 10 CFR Part 100, Subpart B.

The staff evaluated the site population density against the criterion in RG 4.7, Regulatory Position C.4, Revision 2, regarding whether it is necessary to consider alternative sites with lower population densities. The evaluation included the review and verification of whether the population densities at the time of initial site approval (assumed 2016) and 5 years thereafter, would not exceed the criteria of 500 persons per square mile averaged over a radial distance of 32 km (20 mi) (cumulative population at a distance divided by the area at that distance). The staff independently verified the applicant's calculated population density for the years 2016 and 2021 based on the staff's linear calculation projection estimate, and concludes that the population density for the WLS site is well below the criterion. Therefore, the staff finds that the WLS site conforms to RG 4.7, Regulatory Position C.4, Revision 2.

2.1.3.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.1.3.6 *Conclusion*

The applicant initially estimated the commercial operation of WLS to be 2016 and revised it to 2024. Due to this change, the applicant has reviewed the impact and determined it is not significant. As discussed in NUREG-1793 and its supplements, the applicant provided an acceptable description of current and projected population densities in and around the site. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to population distribution, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

The staff reviewed WLS COL 2.1-1 and, for the reasons given above, concludes that the population data meet the requirements of 10 CFR 50.34(a)(1), 10 CFR 52.79(a)(1), 10 CFR 100.20(a), 10 CFR 100.20(b), 10 CFR Part 100, and 10 CFR 100.3. This conclusion is based on the applicant having provided an acceptable description and safety assessment of the site, which includes present and projected population densities that are within the guidelines of RG 4.7, Regulatory Position C.4, and properly specified the LPZ and population center distance. In addition, the staff reviewed and confirmed, by comparison with independently obtained population data, the applicant's estimates of the present and projected populations surrounding the site, including transients. The applicant also calculated the radiological consequences of design-basis accidents (DBAs) at the outer boundary of the LPZ (NUREG-0800, Chapter 15) and has provided reasonable assurance that appropriate protective measures can be taken within the LPZ to protect the population in the event of a radiological emergency. The staff notes this addresses and resolves COL Information Item 2.1-1 regarding population distribution. The staff finds that the applicant has provided sufficient information to satisfy the requirements in 10 CFR Part 50, 10 CFR Part 52, and 10 CFR Part 100.

2.2 Nearby Industrial, Transportation, and Military Facilities

2.2.1 Locations and Routes

This section of the report discusses the application and the staff review of nearby industrial facilities, transportation routes, storage tanks, military and other facilities with potential to impact the safe operation of WLS.

2.2.1.1 *Introduction*

The description of locations and routes refers to potential external hazards or hazardous materials that are present or may reasonably be expected to be present during the projected lifetime of the proposed plant. The purpose is to evaluate the sufficiency of information concerning the presence and magnitude of potential external hazards so that the reviews and evaluations described in NUREG-0800, Sections 2.2.3, 3.5.1.5, and 3.5.1.6, can be performed. The review covers the following specific areas: (1) the locations of, and separation distances to, transportation facilities and routes including airports and airways, roadways, railways, pipelines, and navigable bodies of water; (2) the presence of military and industrial facilities, such as fixed manufacturing, processing, and storage facilities; and (3) any additional information relevant to meeting the requirements prescribed in the “Contents of Application,” sections of the applicable subparts to 10 CFR Part 52.

2.2.1.2 *Summary of Application*

WLS COL FSAR Revision 11, Section 2.2, incorporates by reference AP1000 DCD, Revision 19, Section 2.2. In addition, in WLS COL FSAR Section 2.2, the applicant provided the following:

Departures

- STD DEP 1.1-1

The applicant proposed the following AP1000 DCD Tier 2 standard departure. WLS COL FSAR Section 2.2.1, “Locations and Routes,” identifies instances where the WLS COL FSAR sections are renumbered to include content consistent with RG 1.206, as well as NUREG-0800. Here, AP1000 DCD, Section 2.2.1 is renumbered as Section 2.2.4.

In addition, this WLS COL FSAR section addresses the following COL-specific information identified in AP1000 DCD, Section 2.

AP1000 COL Information Item

This WLS COL FSAR section addresses the following COL-specific information identified in AP1000 DCD, Chapter 2.

- WLS COL 2.2-1

The applicant provided additional information in WLS COL 2.2-1 to resolve COL Information Item 2.2-1, which addresses information about industrial, military, and transportation facilities and routes to establish the presence and magnitude of potential external hazards.

Interface Items

- Interface Item 2.2

WLS COL FSAR Table 2.0-201, Sections 2.2.3.1.1 and 3.5 address Interface Item 2.2, “External missiles from manmade hazards and accidents.”

- Interface Item 2.3

WLS COL FSAR Section 2.2.3 addresses Interface Item 2.3, “Maximum loads from manmade hazards and accidents.”

2.2.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the nearby industrial, transportation, and military facilities are given in NUREG-0800, Sections 2.2.1-2.2.2. The applicable regulatory requirements for identifying locations and routes are as follows:

- 10 CFR 52.79(a)(1)(iv), as it relates to the evaluation of sites, which requires the location and description of industrial, military, or transportation facilities and routes, and of 10 CFR 52.79(a)(1)(vi) as it relates to the compliance with 10 CFR Part 100.

- 10 CFR 100.20(b), as it relates to the requirement that the nature and proximity of man related hazards (e.g., airports, dams, transportation routes, military and chemical facilities) be evaluated to establish site parameters for use in determining whether plant design can accommodate commonly occurring hazards, and whether the risk of other hazards is very low.

- In addition, in accordance with 10 CFR Part 52, Appendix D, Section VIII, the applicant identified a Tier 2 departure, which does not require prior NRC approval. This departure is subject to the requirements in Section VIII, which are similar to the requirements in 10 CFR 50.59, “Changes, tests and experiments.”

The related acceptance criteria from NUREG-0800, Section 2.2.1-2.2.2 are as follows:

- Data in the FSAR adequately describes the locations and distances from the plant for nearby industrial, military, and transportation facilities and that such data are in agreement with data obtained from other sources, when available.
- Descriptions of the nature and extent of activities conducted at the site and in its vicinity, including the products and materials likely to be processed, stored, used, or transported, are adequate to permit identification of the possible hazards cited in NUREG-0800, Sections 2.2.1-2.2, Section III.
- Sufficient statistical data with respect to hazardous materials are provided to establish a basis for evaluating the potential hazards to the plant or plants considered at the site.

2.2.1.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.2 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to nearby industrial, transportation, and military facilities. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

Departures

- STD DEP 1.1-1

The applicant's evaluation in accordance with 10 CFR Part 52, Appendix D, Section VIII, Item B.5 determined that this departure did not require prior NRC approval. The staff finds that it is reasonable that the departure does not require prior NRC approval because the numbering system proposed by the applicant does not alter the information required to be provided.

AP1000 COL Information Item

- WLS COL 2.2-1

The staff reviewed WLS COL 2.2-1 related to information about industrial, military, and transportation facilities and routes to establish the presence and magnitude of potential external hazards included in WLS COL FSAR Section 2.2. AP1000 DCD, Section 2.2.1, COL information item 2.2-1 states:

> Combined License applicants referencing the AP1000 certified design will provide site-specific information related to the identification of potential hazards within the site vicinity, including an evaluation of potential accidents and verify that the frequency of site-specific potential hazards is consistent with the criteria outlined in Section 2.2. The site-specific information will provide a review of

aircraft hazards, information on nearby transportation routes, and information on potential industrial and military hazards.

The staff reviewed the WLS COL FSAR using the review procedures described in NUREG-0800, Section 2.2.1-2.2.2. This section of the report evaluates the applicant's identification of industrial, transportation, mining, and military installations in the WLS area. The evaluation of potential effects on the safe operation of the nuclear facility is described in Section 2.2.3 of this report.

Locations and Routes

The applicant identified and provided information regarding potential external hazard facilities and operations within an 8 km (5 mi) radius of the WLS site. Within the 8 km (5 mi) radius of the site, there are four major industrial facilities, a railroad, and four State and one Federal highway.

Dams

The Ninety-Nine Islands hydroelectric dam is on the Broad River adjacent to the WLS site boundary, approximately 1.8 km (1.1 mi) south of the WLS center point.

Quarrying or Mining Facilities

The staff verified that there are three permitted quarrying or mining facilities are located within the 8 km (5 mi) radius of the WLS site. The closest permitted mine is 1.6 km (1 mi) north of the site operated by Thomas Sand Company, called Blacksburg Plant, is a sand mine. Cunningham Brick Company operates a mine 5 km (3.2 mi) north of the site to mine mica. The Kings Creek Mine, operated by Industrial Materials, Inc., is 7.9 km (4.9 mi) northeast of the site and also mines mica. No explosives are used in these mining operations.

Storage Tanks

The applicant provided information from a database of registered storage tanks in South Carolina. The database includes all underground storage tanks for regulated substances greater than 416 liter (L) (110 gallon (gal)) capacity. Within an 8 km (5 mi) radius there are, registered aboveground storage tanks. At the WLS site, liquid hydrogen will be stored according to the AP1000 design, as well as other compressed gasses, including compressed hydrogen, liquid nitrogen, and liquid carbon dioxide.

Oil and Gas Pipelines

Nine major pipelines are located within 8 km (5 mi) of the WLS site. The information about whether these pipelines could, in the future, carry different and potentially more hazardous products is considered to be sensitive information. In addition to local major pipelines, there are branch distribution lines to local residential, commercial, and industrial facilities ranging from 15 to 2.5 cm (6 to 1 in.) diameter.

Military Facilities

There are no military facilities within 8 km (5 mi) of the WLS site.

Description of Railroads

The staff verified that no active railroads are located within the 8 km (5 mi) radius of the WLS site. Two railroad lines, an abandoned track and an active line, are located within 16 km (10 mi) of the WLS site.

Manufacturing and Storage of Hazardous Materials

The staff verified that no manufacturing facilities that use or store hazardous products are located within the 8 km (5 mi) radius of the WLS site (WLS COL FSAR Figure 2.2.2-201).

Description of Waterways

The WLS site is approximately 1.5 km west and 0.7 km south (4800 ft west and 2400 ft south) of the Broad River and 1.8 km (1.1 mi) north of the Ninety-Nine Islands hydroelectric station.

Upstream of WLS, the Broad River is shallow and generally unnavigable and south of the Ninety-Nine Islands hydroelectric station to the Pacolet River is considered “navigable waters” under the laws of South Carolina. There are public access points on the nearby Broad River. The access points are the Ninety-Nine Islands boat landing operated by Duke Energy and the Cherokee Landing, located across the river from the Ninety-Nine Islands boat landing. The intake structure for the WLS site is also located on the Broad River.

Description of Highways

The staff verified that the major highway located near the WLS site is U.S. 29, passing 7.4 km (4.6 mi) northwest, at its closest point. In addition, segments of South Carolina Routes 5, 97, 105 and 329 are located within 8 km (5 mi) of WLS at their closest point. The application included estimate average daily traffic counts.

Description of Railways

The staff verified that two railroad lines are located within 16 km (10 mi) of the WLS site. The Norfolk Southern Railroad Company (NSRC) owns a spur line that passes 7.5 km (4.7 mi) from the site and averages two trains per day (one round-trip) with the speed limit of 40 km/hr (25 mi/hr) and 16 km/hr (10 mi/hr) on curves, carrying freight only. The NSRC owns a major rail line located 8.8 km (5.5 mi) from WLS. This line averages 22 trains per day at an average speed of 80 km/hr (50 mi/hr). Future activities include a proposed Southeast High-Speed Rail Corridor running in the current rail right-of-way expected to reach a maximum speed of 180 km/hr (110 mi/hr). In accordance with RG 1.206, further analysis of the NSRC rail line is not required because it is outside of the 8 km (5 mi) radius of the WLS site. A railroad spur is expected to be constructed that will join the WLS site to the NSRC line. It will be owned and maintained by the applicant. This spur will be generally limited to shipments, and supporting activities, for the WLS site only.

Description of Airports

There are two commercial airports within 80 km (50 mi) of the WLS site. Greenville-Spartanburg International Airport is 66 km (41.3 mi) west and Charlotte Douglas

International Airport is 55 km (34.4 mi) northeast of WLS. The approach and departure paths of these commercial airports do not align with the WLS site. These airports within 80 km (50 mi) of the WLS site do not meet or exceed the acceptance criteria of NUREG-0800, Section 3.5.1.6 and RG 1.206, Part I, Subsections C.I.2.2.2.7 and C.I.3.5.6. There are no airports located within 16 km (10 mi) of WLS. At 24 km (14.7 mi) east of the site is York Airport. This airport is used exclusively by single-engine private aircraft of which there are 12 based at the field. However there is one heliport, with one helipad, located approximately 10 km (6 mi) north of the site. The staff verified that no active military facilities are within 8 km (5 mi) of the WLS site. The staff verified that no airports are within the 8 km (5 mi) radius of the WLS.

WLS COL FSAR Tables 2.2-205 and 2.2-207 describes the historical air traffic for passenger-aircraft-associated airports within the region. The applicant stated that neither of these airports has approach or departure paths aligned with WLS.

<u>Airways</u>

The applicant addressed and evaluated potential aircraft hazards following the approach and methods outlined in NUREG-0800, Section 3.5.1.6, "Aircraft Hazards," and determined an aircraft crash into the effective plant areas of the safety-related structures on the site met the acceptance criteria. Due to the close proximity of airways to the proposed WLS site, the applicant provided additional evaluation of hazards from air traffic in WLS COL FSAR Section 3.5.1.6. There are two low-altitude (below 5.5 km (18,000 ft)) Federal air routes within 24 km (15 mi) of the site. One air route is 6.4 km (4 mi) north of the site and the other is 16 km (10 mi) southwest of the site and is used by general aviation aircraft. Two high altitude (5.5 - 13.8 km (18,000 - 45,000 ft)) Federal air routes are located within 24 km (15 mi) of the site. One is 15 km (9 mi) southeast and the other is 20 km (12.5 mi) northeast of WLS. These air routes are primarily used by commercial air carriers, military, and high performance general aviation aircraft.

<u>Projections of Industrial Growth</u>

There are no commercial industrial parks within 8 km (5 mi) of the WLS site. However, there are two industrial companies within 8 km (5 mi); the Broad River Energy Center and Herbie's Famous Fireworks. There is no planned industrial growth within an 8 km (5 mi) area.

2.2.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.2.1.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to nearby industrial, transportation, military facilities, and other places of interest, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

As set forth above, the applicant has presented and substantiated information to establish an identification of potential hazards in the site vicinity. The staff reviewed WLS COL 2.2-1, and for the reasons given above, concludes that the applicant has provided information with respect to identification of potential hazards in accordance with the requirements of 10 CFR 52.79(a)(1)(iv) and 10 CFR 52.79(a)(1)(vi). The nature and extent of activities involving potentially hazardous materials that are conducted at nearby industrial, military, and transportation facilities have been evaluated to identify any such activities that have the potential for adversely affecting plant safety-related structures. Based on an evaluation of information in the WLS COL FSAR, as well as information that the staff independently obtained, the staff concluded that all potentially hazardous activities on site and in the vicinity of the plant have been identified. The hazards associated with these activities have been reviewed and are discussed in Sections 2.2.3, 3.5.1.5, and 3.5.1.6 of this report.

2.2.2 Descriptions

The staff's review of WLS COL FSAR Section 2.2.2, "Descriptions," is addressed in Section 2.2.1, "Locations and Routes," of this report.

2.2.3 Evaluation of Potential Accidents

2.2.3.1 *Introduction*

The evaluation of potential accidents considers the applicant's probability analyses of potential accidents involving hazardous materials or activities on site and in the vicinity of the proposed site to confirm that appropriate data and analytical models have been used. The review covers the following specific areas: (1) hazards associated with nearby industrial activities, such as manufacturing, processing, or storage facilities; (2) hazards associated with nearby military activities, such as military bases, training areas, or aircraft flights; and (3) hazards associated with nearby transportation routes (aircraft routes, highways, railways, navigable waters, and pipelines). Each hazard review area includes consideration of the following principal types of hazards: (1) toxic vapors or gases and their potential for incapacitating nuclear plant control room operators; (2) overpressure resulting from explosions or detonations involving materials such as munitions, industrial explosives, or explosive vapor clouds resulting from the atmospheric release of gases (such as propane and natural gas or any other gas) with a potential for ignition and explosion; (3) missile effects attributable to mechanical impacts, such as aircraft impacts, explosion debris, and impacts from waterborne items such as barges; and (4) thermal effects attributable to fires.

2.2.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.2, incorporates by reference AP1000 DCD, Revision 19, Section 2.2. In addition, in WLS COL FSAR Section 2.2, the applicant provided the following:

<u>*AP1000 COL Information Item*</u>

- WLS COL 2.2-1

The applicant provided additional information in WLS COL 2.2-1 to resolve COL Information Item 2.2-1, which addresses the provision of information about industrial, military, and transportation facilities and routes to establish the presence and magnitude of potential external hazards, including the following accident categories: explosions, flammable vapor clouds (delayed ignition), toxic chemicals, fires, and airplane crashes.

2.2.3.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the evaluation of potential accidents are given in NUREG-0800, Section 2.2.3. The applicable regulatory requirements for evaluation of potential accidents are as follows:

- 10 CFR 52.79(a)(1)(iv), as it relates to the evaluation of sites, including the location and description of industrial, military, or transportation facilities and routes, and the requirements of 10 CFR 52.79(a)(1)(vi) as it relates to compliance with 10 CFR Part 100.

- 10 CFR 100.20(b), as it relates to the requirement that the nature and proximity of manmade related hazards (e.g., airports, dams, transportation routes, military and chemical facilities) be evaluated to establish site parameters for use in determining whether plant design can accommodate commonly occurring hazards, and whether the risk of other hazards is very low.

The related guidance and acceptance criteria from NUREG-0800, Section 2.2.3 are as follows:

- Event Probability: The identification of design-basis events (DBEs) resulting from the presence of hazardous materials or activities in the vicinity of the plant or plants of specified type is acceptable if all postulated types of accidents are included for which the expected rate of occurrence of potential exposures resulting in radiological dose in excess of the 10 CFR 50.34(a)(1) limits as it relates to the requirements of 10 CFR Part 100 is estimated to exceed the staff's objective of an order of magnitude of 10^{-7} per year.

- Design-Basis Events: The effects of DBEs have been adequately considered, in accordance with 10 CFR 100.20(b), if analyses of the effects of those accidents on the safety-related features of the plant or plants of specified type have been performed and measures have been taken (e.g., hardening, fire protection) to mitigate the consequences of such events.

In addition, the toxic gas evaluations should be consistent with appropriate sections from RG 1.78, "Evaluating the Habitability of a Nuclear Power Plant Control Room during a Postulated Hazardous Chemical Release," Revision 1.

2.2.3.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.2 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the evaluation of potential accidents. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 2.2-1

The staff reviewed WLS COL 2.2-1 related to information regarding industrial, military, and transportation facilities and routes to establish the presence and magnitude of potential external hazards, including the following accident categories: explosions, flammable vapor clouds (delayed ignition), toxic chemicals, fires, and airplane crashes included in WLS COL FSAR Section 2.2.3. COL information item in AP1000 DCD, Section 2.2 states:

> Combined License applicants referencing the AP1000 certified design will provide site-specific information related to the identification of potential hazards within the site vicinity, including an evaluation of potential accidents and verify that the frequency of site-specific potential hazards is consistent with the criteria outlined in Section 2.2. The site-specific information will provide a review of aircraft hazards information on nearby transportation routes, and information on potential industrial and military hazards.

Explosions

The applicant considered hazards involving potential explosions that could result in blast overpressure because of detonation of explosives, chemicals, liquid fuels, and gaseous fuels for facilities and activities either onsite or within the site vicinity of the proposed units. The applicant evaluated potential explosions from nearby highways, railways, or facilities using 0.07 bar (1 psi) overpressure as a criterion for adversely effecting plant operation or preventing safe shutdown of the plant. In accordance with RG 1.91, "Evaluation of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plants," peak positive incident overpressures below 0.07 bar (1 psi) are considered to cause no significant damage.

The applicant determined a minimum safe standoff distance of 0.8 km (0.52 mi) for truck transport using conservative assumptions and RG 1.91 methods. By comparison, the distance to the closest highway is 7 km (4.24 mi) from the nearest safety-related structure. The applicant also calculated the minimum safe standoff distance of 2.8 km (1.76 mi) for a railroad accident, using conservative assumptions and RG 1.91 methods. The staff performed independent calculations, which confirmed the applicant's results. Therefore, the staff concludes the applicant's assumptions and methods are adequate.

The nearest and largest nearby natural gas pipelines are owned by Colonial Pipeline and by Plantation Pipeline are located 5.2 km (3.24 mi) from the WLS site, at the closest point. The 1 m (40 in) diameter pipeline, buried 1-1.2 m, (3-4 ft) underground, was analyzed using conservative assumptions and RG 1.91 methods. The analysis concluded that the minimum safe standoff distance is 4.6 km (2.83 mi) and the distance to the closest point on the site boundary is 5.2 km (3.24 mi). In WLS COL FSAR Section 2.2.3.1.1.2, the applicant stated that unconfined vapor explosions of natural gas are not considered credible events. The applicant also stated that deflagration of a natural gas/air mixture is the limiting case, assuming that a mixture within the flammable limits is not present near the safety-related structures. In WLS COL FSAR Section 2.2.3.1.2, a delayed flammable cloud ignition is discounted on the basis of insufficient gas concentrations at the WLS site. In WLS COL FSAR Section 2.2.3.1.1.3, other nearby industrial facilities identified were reviewed for their minimum standoff distance from the site for explosive hazard with similar results to those discussed for pipelines. In WLS COL FSAR Section 2.2.3.1.1.4, the hazard from onsite chemicals was reviewed. Except as noted in the application, the hazardous chemicals listed by the WLS COL FSAR are bounded by the AP1000 design. The staff finds that this WLS COL FSAR discussion satisfies the requirement in Interface Item 2.2 to address external missiles from manmade hazards.

Toxic Chemicals

As previously noted, there is no major barge traffic within 8 km (5 mi) of the WLS site. The highway with heavy commercial traffic, nearest the WLS site, is U.S. Highway 29, passing about 7.2 km (4.5 mi) northwest of the site. South Carolina Highways 5, 97, 105, and 329 are located within 8 km (5 mi) of the site. Annual average traffic data for 2005 was used to estimate traffic volume for the hazards analysis. The result of the analysis was that the release frequencies are higher than the acceptance criteria of RG 1.78 (1E-6/yr for mobile sources). The additional analysis is discussed in WLS COL FSAR Section 2.2.3. After independently reviewing available information on the internet from local, State and Federal agencies, the staff concluded that the applicant's review is adequate.

Regarding the onsite storage of chemicals, the applicant stated that the chemicals stored on site are bounded by the standard chemicals identified in AP1000 DCD, Table 6.4-1. These chemicals were assessed by Westinghouse as part of the main control room habitability hazard analysis supporting the application. The Westinghouse analysis concluded that the chemicals listed in AP1000 DCD Table 6.4-1 did not present a hazard to the control room operators or to safety-related systems, structures, or components (SSCs). The applicant stated that the analysis was applicable because chemicals stored on site are bounded by the types, locations, and quantities of chemicals specified in the AP1000 DCD. Therefore, no further analysis is required. However, the staff independently reviewed the Westinghouse analysis and the site-specific analysis and concluded that the immediate danger to life and health (IDLH) is still exceeded outside the control room for carbon dioxide and hydrazine. The effect of these two gases on the habitability of the control room is evaluated in Section 6.4 of this report. The staff concurs with the applicant's conclusions on the other chemicals listed in AP1000 DCD, Table 6.4-201.

Fire, Smoke, and Heat Fluxes

The distances between any fires originating from facilities or transportation accidents and the WLS facility is at least 3.7 km (2.31 mi), and do not have the potential to affect the safe operation of WLS. The WLS main control room heating, ventilation, and air conditioning (HVAC) system is described in the application as follows: "continuously monitors the outside air using smoke monitors located at the outside air intake plenum and monitors the return air for smoke upstream of the supply air handling units (DCD Section 9.4.1.2.3.1). If a high concentration of smoke is detected in the outside air intake, an alarm is initiated in the main control room and the main control room/technical support center HVAC subsystem is manually realigned to the recirculation mode by closing the outside air and toilet exhaust duct isolation valves. Therefore, any potential heavy smoke problems at the main control room air intakes would not affect the WLS operators." The staff reviewed and verified the above information and concluded that the applicant's determination is adequate.

Collision with the Intake Structure

This section is not applicable, as the WLS intake structure is not located on a navigable portion of the Broad River waterway, collision with commercial traffic is not considered credible. Neither is collision with any of the site make-up ponds.

Liquid Spills

There is no safety-related equipment at the WLS intake structure. Liquid spill of petroleum or similar products or corrosive liquids would collect or disperse depending on its particular attributes. Spills that float on the river would not be drawn into the WLS water supply because of the location of the intake pipes. Spills that sink would be drawn into the intake structure and would be sent to Makeup Pond A and would likely be diluted in the process. Failure of the raw water system would not prevent essential functions of WLS safety-related systems. The staff reviewed and verified the information given above and concurs with the applicant's conclusion.

2.2.3.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.2.3.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to evaluation of potential accidents, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

As discussed above, the applicant presented and substantiated information to identify potential hazards in the site vicinity. The staff reviewed the information provided and, for the reasons given above, concludes that the applicant provided sufficient information with respect to identification of potential hazards in accordance with the requirements of 10 CFR 52.79(a)(1)(iv) and 10 CFR 52.79(a)(1)(vi). The nature and extent of activities involving potentially hazardous materials that are conducted at nearby industrial, military, and transportation facilities have been evaluated to identify any such activities that have the potential for adversely affecting plant safety-related structures. Based on an evaluation of information in the WLS COL FSAR as well as information that the staff independently evaluated, the staff concludes that potentially hazardous activities on site and in the vicinity of the plant have been identified. This addresses and resolves COL Information Item 2.2-1 and Interface Item 2.2. In addition, the staff finds that the applicant has provided sufficient information to satisfy the requirements of 10 CFR Part 50, 10 CFR Part 52, and 10 CFR Part 100.

2.3 Meteorology

To ensure that a nuclear power plant or plants can be designed, constructed, and operated on an applicant's proposed site in compliance with NRC regulations, the staff evaluated regional and local climatological information, including climate extremes and severe weather occurrences that may affect the design and siting of a nuclear plant. The staff reviewed information on the atmospheric dispersion characteristics of a nuclear power plant site to determine whether the radioactive effluents from postulated accidental releases, as well as routine operational releases, comply with NRC regulations. The staff prepared Sections 2.3.1 through 2.3.5 of this safety evaluation report (SER) in accordance with the review procedures described in NUREG-0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition)," using information presented in WLS COL FSAR Section 2.3 (which references the AP1000 DCD), responses to staff requests for additional information (RAIs), and generally available reference materials (as cited in applicable sections of NUREG-0800).

2.3.1 Regional Climatology

2.3.1.1 *Introduction*

WLS COL FSAR Section 2.3.1, "Regional Climatology," addresses averages and measured and probabilistic extremes of climatic conditions and regional meteorological phenomena that could affect the safe design and siting of the plant. This includes information describing the general climate of the region, seasonal and annual frequencies of severe weather phenomena, and other climatological conditions to be used for design and operating-basis considerations. This section of the report also addresses the supplemental information in WLS COL FSAR Section 2.3.6 related to regional climatology.

2.3.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.3, incorporates by reference AP1000 DCD, Revision 19, Section 2.3. In WLS COL FSAR Section 2.3.1, the applicant addressed the following:

<u>AP1000 COL Information Item</u>

- WLS COL 2.3-1

The applicant provided additional information in WLS COL 2.3-1 to address COL Information Item 2.3-1. WLS COL 2.3-1 addresses site-specific information related to regional climatology.

In addition, this WLS COL FSAR section addresses Interface Item 2.4 related to extreme meteorological conditions for the design of systems and components exposed to the environment, Interface Item 2.5 related to tornado and operating basis wind loadings, Interface

Item 2.7 related to snow, ice and rain loads, and Interface Item 2.8 related to ambient air temperatures.

2.3.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed NUREG-1793 and its supplements. The acceptance criteria and information needed to evaluate regional climatological and meteorological characteristics are based on meeting the relevant requirements of NRC regulations under 10 CFR Part 52 and 10 CFR Part 100. The staff considered the following regulatory requirements in reviewing the applicant's descriptions of the regional climatological and meteorological characteristics around the proposed WLS site.

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR Part 100, 10 CFR 100.20(c)(2), and 10 CFR 100.21(d) with respect to the consideration given to the regional meteorological characteristics of the site.

NUREG-0800, Section 2.3.1, recommends the following acceptance criteria be provided by a COL applicant:

- The description of the general climate of the region should be based on standard climatic summaries compiled by the National Oceanic and Atmospheric Administration (NOAA). In addition, consideration of the relationships between regional, synoptic scale atmospheric processes and local (site) meteorological conditions should be based on appropriate meteorological data.

- Data on severe weather phenomena should be based on standard meteorological records from nearby representative National Weather Service (NWS), military, or other stations recognized as standard installations that have long periods of data on record. The applicability of these data to represent site conditions during the expected period of reactor operation should be substantiated.

- Tornado parameters to be used in establishing pressure and tornado missile loadings on SSCs important to safety should be based on RG 1.76, "Design-Basis Tornado and Tornado Missiles for Nuclear Power Plants," Revision 1. Alternatively, an applicant may specify any tornado parameters that are appropriately justified, provided that a technical evaluation of site-specific data is conducted.

- The basic (straight-line) 100-year return period 3-second gust wind speed to be used in establishing wind loadings on plant structures should be based on appropriate standards, with suitable corrections for local conditions.

- The ultimate heat sink (UHS) meteorological data that would result in the maximum evaporation and drift loss of water and minimum water cooling should be based on long-period regional records that represent site conditions in accordance with RG 1.27, "Ultimate Heat Sink for Nuclear Power Plants," Revision 2. If applicable, the potential for water freezing in the UHS water storage facility should also be analyzed. (Note: Not applicable to a Passive Containment Cooling System design that does not use a cooling tower or cooling pond, such as the AP1000, where the UHS is the atmosphere.)

- The weight of the 100-year return period snowpack or snowfall and the weight of the 48-hour probable maximum winter precipitation (PMWP) are to be used in determining the weight of snow and ice on the roofs of safety-related structures. Consistent with the staff's branch position on winter precipitation loads, the winter precipitation loads to be included in the combination of normal live loads should be based on the weight of the 100-year snowpack or snowfall, whichever is greater, recorded at ground level. The weight of the 100-year return period snowpack or snowfall should be based on data recorded at nearby representative climatic stations or obtained from appropriate standards with suitable corrections for local conditions. The winter precipitation loads to be included in the combination of extreme live loads should be based on the weight of the 100-year snowpack or snowfall at ground level plus the weight of the 48-hour PMWP of which should be determined in accordance with reports published by NOAA's Hydrometeorological Design Studies Center.

- Ambient temperature and humidity statistics for use in establishing heat loads for the design of normal plant heat sink systems, post-accident containment heat removal systems, and plant heating, ventilating, and air conditioning systems should be derived from data recorded at nearby representative climatic stations or obtained from appropriate standards with suitable corrections for local conditions.

- High air pollution potential information should be based on U.S. Environmental Protection Agency (EPA) studies.

- All other meteorological and air quality conditions identified by the applicant as climate site characteristics or used as design and operating bases should be documented and substantiated.

Generally, the information should be presented and substantiated in accordance with acceptable practice and data as issued by NOAA, industry standards, and regulatory guides. The following regulatory guides and other related guidance documents were also taken into consideration in the staff's review of WLS COL FSAR Section 2.3.1 and Appendix 2CC (as applicable):

- RG 1.27, "Ultimate Heat Sink for Nuclear Power Plants," which provides criteria for selecting the UHS meteorological data that would result in the maximum evaporation and drift loss of water and minimum water cooling.

- RG 1.76, "Design-Basis Tornado and Tornado Missiles for Nuclear Power Plants," Revision 1, which includes criteria for selecting design-basis tornado parameters for locations within the contiguous United States (U.S.);

- RG 1.206, "Combined License Applications for Nuclear Power Plants," which summarizes the types of regional climatological and meteorological information, identified in NUREG-0800, Section 2.3.1, that an applicant should provide in FSAR Section 2.3.1 when describing the general climatic conditions of the site area and region, and characterizing the meteorological conditions against which the plant design and operating bases will be evaluated;

- RG 1.221, “Design-Basis Hurricane and Hurricane Missiles for Nuclear Power Plants,” which provides new guidance for selecting the design-basis hurricane wind speed and hurricane-generated missiles to be addressed in permit, license, and design certification applications for new nuclear reactors proposed to be located in the contiguous U.S., and, where applicable, for comparison against corresponding design-basis tornado wind speeds and tornado missiles to determine the controlling severe weather phenomenon;

- Interim Staff Guidance (ISG) document DC/COL-ISG-7, “Interim Staff Guidance on Assessment of Normal and Extreme Winter Precipitation Loads on the Roofs of Seismic Category I Structures,” which was issued subsequent to the publication of NUREG-0800, Section 2.3.1 to clarify the staff’s position on identifying winter precipitation events as site characteristics and site parameters for determining normal and extreme winter precipitation loads on the roofs of Seismic Category I structures.

2.3.1.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.3.1 and checked the applicable site parameters in AP1000 DCD Tier 1 (Table 5.0-1) and Tier 2 (Table 2-1) to ensure that the combination of the DCD and the information in the COL application represent the complete scope of information relating to this review topic. The staff’s review confirmed that the information contained in the application and incorporated by reference (as related to site parameters) addresses the required information relating to regional climatology. The staff reviewed AP1000 DCD, Section 2.3.1 under Docket Number 52-006. The staff’s technical evaluation of the applicable site parameters incorporated by reference related to regional climatology will be documented in the staff’s separate SER on the DC application for the AP1000 design. In addition, the staff reviewed the information in the WLS COL FSAR corresponding to the following:

AP1000 COL Information Item

- WLS COL 2.3-1

The staff reviewed information related to regional climatological conditions included by the applicant under WLS COL FSAR Section 2.3.1 in response to COL 2.3-1. The specific text of this COL Information Item in AP1000 DCD Tier 2, Section 2.3.6.1 states:

> Combined License applicants referencing the AP1000 certified design will address site-specific information related to regional climatology.

The staff relied upon the review procedures presented in NUREG-0800, Section 2.3.1, to independently assess the technical sufficiency of the information presented by the applicant.

2.3.1.4.1 General Climate

The applicant provided descriptions of the general climate of both South Carolina (including the Piedmont region in which the proposed WLS site is located) and for North Carolina. The discussion for South Carolina is primarily based on a climate summary available from the State Climatology Office[2]. The following discussion briefly summarizes the information provided by the applicant in WLS COL FSAR Section 2.3.1.1 and the staff's evaluation of this information.

The State's proximity to the Atlantic Ocean, the proximity to the Appalachian Mountains, and local elevation all influence the local climate. As indicated above, the proposed WLS site is located in the Piedmont region of South Carolina. In RAI 446, Question 02.03.01-1, the staff requested that the applicant identify the National Climatic Data Center's (NCDC) State climatic division for the proposed WLS site or an alternative. In an October 10, 2008, response to RAI 446, Question 02.03.01-1 and in accordance with NUREG-0800, the applicant updated Revision 0 of WLS COL FSAR Section 2.3.1.1 to indicate the State climatic division in which the proposed WLS site is located (i.e., South Carolina Climate Division 2, Northwest[3]).

The climate of South Carolina is humid, subtropical, and characterized by a short cold season and a relatively long warm season. During the summer, a maritime tropical air mass, known as the Bermuda High (where anticyclonic, or clockwise, motion brings additional moisture into the state) dominates South Carolina's weather. The State's annual average temperature varies around 12 °Centigrade (C)) (mid-50 (Fahrenheit (F)) in the mountains to the low-15 °C (60s F) along the coast.

Precipitation in South Carolina is ample and well distributed with two maxima and two minima throughout the year. The maxima occur around March and August, and the minima occur around April and November. Precipitation varies across the State, averaging from about 101 - 203 cm (40 to 80 inches (in.)) annually[1].

The staff notes the following with respect to this information:

- the proposed WLS site is located about 8 km (5 mi) west of York County, SC, one of several counties referred to as South Carolina Climate Division 3 (or North Central)

- average temperatures are similar between South Carolina Climate Divisions 2 and 3 (monthly and annual means are only about 0.55 ° C (1 to 1.5 °F) cooler in Climate Division 2)

- annual average total precipitation is about 10 percent higher (by about 11 to 13 cm) (4.5 to 5 in.) in Climate Division 2 than in Climate Division 3; being similar during the

[3] National Climatic Data Center, "US Climate Divisions," http://www.ncdc.noaa.gov/monitoring-references/maps/us-climate-divisions.php Accessed September 15, 2014

summer months and generally about 20 percent higher in Climate Division 2 from autumn through early spring[4]

Measurable snowfall may occur from one to three times a winter in all areas of the State, except in the Low Country. The greatest snowfall measured at the nearby Ninety-Nine Islands cooperative observing station, approximately one mile northeast of the site, was 33 cm (13 in.) on January 7, 1988. Overall, however, the greatest observed 24-hour snowfall total in the State (60 cm) (24 in.)) was recorded at Rimini, SC in February of 1973[5]. The staff notes that the Rimini cooperative observing station is located in the south-central part of the state in the Midlands region (i.e., between the Piedmont and Coastal Plain) about 177 km (110 mi) southeast of the proposed WLS site.

The occurrence of sleet and freezing rain varies across the state, averaging from 0.75 to 3.75 events per year. The highest monthly frequency occurs in January and ranges from approximately 0.25 to 1.5 events across the state[1].

Hail-producing storms are infrequent events that can occur at any time of the year but are generally associated with thunderstorm activity during the spring. The incidence of such events is higher in the Midlands, Piedmont, and Foothills regions (averaging about 1 to 2 days annually), decreasing to less than one day per year (on average) in the Low Country[1].

Average surface wind speeds across the state for all months range between 10 to 16 km (6 to 10 mi/hr). The Appalachian Mountains exert a strong influence on the surface wind direction. Prevailing winds tend to have a southwesterly orientation in the spring and summer and a northeasterly orientation in the autumn and winter. However, the staff notes that the undulating topography that characterizes the Piedmont region, which includes the site vicinity, also affects local airflow, especially under low wind speed conditions (such as that which occurs diurnally during the overnight and early morning hours, particularly during the autumn and summer seasons)[1].

The applicant characterized the relative potential for air pollution (rather, for prolonged periods of poor atmospheric dispersion) based on the frequency of air stagnation conditions in the site region. These conditions typically occur during an extended summer season from about May to October, with a minimum during the month of July. In South Carolina, air stagnation conditions generally occur about 10 to 20 days per year.

An air stagnation case is an episode of poor dispersion that persists for at least 4 days (as defined in the applicant's reference material). The applicant suggested that in the eastern U.S., "six cases" occur during the spring, "14 cases" in the summer, and "11 cases" in the fall, based

[5] South Carolina State Climatology Office, "South Carolina Maximum 24-Hour Snow, 1890-2007," http://www.dnr.sc.gov/climate/sco/ClimateData/cli_table_24hr_max_snow.php Accessed September 17, 2014

on a regionally averaged mean annual cycle. Figure 5 of Wang and Angell[6], as cited by the applicant, shows that all mean annual stagnation case frequencies are less than one for each of the months through the period of May through October, with the highest frequency being in September (0.75 case per month). Since this information is not a direct input to any of the analyses under WLS COL FSAR Section 2.3, the staff did not evaluate this discussion further.

The applicant briefly described some of the effects that tropical cyclones (which include hurricanes and tropical storms) have on the weather and climate of South Carolina, primarily focusing on the coast but also noting that these events have a significant influence over other areas inland by enhancing rainfall during the summer and fall months. The applicant also provided a graphic plot of tropical cyclone tracks based on a 156-year period of record (POR), whose paths at one point crossed within a 120 km (75 mi) radius of the Greenville/Spartanburg International Airport. While the center of this radial area lies about 64 km (40 mi) west of the proposed WLS site, the plot nevertheless shows that tropical cyclone storm intensities decrease as they move inland from the coast (Hurricane Hugo, despite its diminishing strength, retained its hurricane status as it traversed this area).

Finally, the applicant summarized tornado occurrences on a statewide basis indicating that such events were observed, on average, about 11 times per year based on a 40-year POR. Most of these storms occur between February and September, with May and August being the peak months. The peak in May is attributed primarily to the passage of squall lines and cold fronts; the August peak is said to often be associated with the passage of tropical cyclones.

Consistent with NUREG-0800, Section 2.3.1, except as noted above, the applicant provided an acceptable description of the general climate of South Carolina based on a recent summary prepared by the State Climatology Office.

2.3.1.4.2 Regional Meteorological Conditions for Design and Operating Bases

2.3.1.4.2.1 *Hurricanes*

In WLS COL FSAR Section 2.3.1.2.1, Revision 0, the applicant provided data on historical hurricane events that have affected North and/or South Carolina (i.e., having made landfall in either one or both states) using NOAA Technical Memorandum NWS SR-206.[7] The staff was unable to identify the same number of hurricane events as presented by the applicant. Therefore, in RAI 446, Question 02.03.01-2, the staff requested that the applicant explain their data sources.

In an October 10, 2008, response RAI 446, Question 02.03.01-2, the applicant revised the original hurricane statistics by creating a composite dataset, which was based on data provided by the NOAA Coastal Services Center (CSC)[7] and in NOAA Technical Memorandum NWS

---

[6] J. X. L. Wang and J. K. Angell, “Air Stagnation Climatology for the United States (1948-1998),” NOAA Air Resources Laboratory Atlas No. 1, Air Resources Laboratory, Environmental Research Laboratories, Office of Oceanic and Atmospheric Research, Silver Spring, MD, April 1999.
[7] NOAA Coastal Services Center, “Historical Hurricane Tracks,” http://coast.noaa.gov/hurricanes/# Accessed November 3, 2014.

SR-206.[8] The applicant stated that where there were inconsistencies noted between the two sources of information, the most conservative storm category was chosen. Table 2.3.1-1 of this report contains the applicant's (original and revised) event counts.

Table 2.3.1-1 Historical Hurricane Data for North and South Carolina

Storm Strength	Applicant	Composite Data
Category 5	0	0
Category 4	2	4
Category 3	12	11
Category 2	10	15
Category 1	20	20
Total	**44**	**50**

The staff considers the revised composite data counts to be a reasonable representation of overall hurricane frequency for the two states over the 107-year POR from 1899 through 2005, with slight differences in counts because of potential double-counting of storm entries made for the two adjacent states. Data reported by the applicant indicates that hurricanes have made landfall in these two states as early as July and as late as November; the greatest frequencies of these events occur during September and August. The most intense of these hurricanes (rated on the Saffir-Simpson scale as Category 4 storms (209 to 261 km/hr (130 to 156 mi/hr) sustained wind speed)) occurred during September and October.

WLS COL FSAR Section 2.3.1.2.1 correctly states that hurricanes lose strength as they move inland from the coast. The applicant's October 10, 2008, response to RAI 446, Question 02.03.01-2 also indicated that only two of these storms tracked within 65 statute miles of the proposed WLS site during the POR considered (i.e., Hurricane Able in 1952 and Hurricane Hugo in 1989). Current NOAA-CSC records checked by the staff show that the path of a third (unnamed) hurricane traversed within this radial distance during 1893. At their maximum intensity while in this area, Hurricane Able had diminished to a tropical storm, the unnamed storm noted above decreased to Category 1 level, and Hugo, although weakened, was still a Category 2 hurricane as it passed through and continued into western North Carolina.

Consistent with the intent of the recently issued RG 1.221 and in support of Section 3.3 of this report, the staff estimated the maximum hurricane wind speed in the site area based on observed data to help assess whether the proposed WLS site might reasonably be expected to

[8] NOAA Technical Memorandum NWS SR-206, "Atlantic Tropical Storms and Hurricanes Affecting the United States: 1899-1999," http://www.srh.noaa.gov/ssd/techmemo/sr206.htm Accessed November 3, 2014.

experience hurricane-related wind speeds in excess of design-basis tornado wind speeds. WLS COL FSAR Table 2.3-203 includes Saffir-Simpson wind speed ranges associated with each of the five storm categories. Based on the discussion above, the highest storm category experienced in the site area over at least a 113-year POR (i.e., going back to the unnamed 1893 hurricane identified by the staff – and likely closer to a 150-year POR given that NOAA-CSC records extend back to the 1850's) was designated as a Category 2 hurricane. Sustained winds from Category 2 storms, under the Saffir-Simpson scale, range from 155 to 177 km/hr (96 to 110 mi/hr).

Sustained wind speeds nominally represent the peak speed averaged over a one-minute period. Conversely, design-basis tornado wind speeds from RG 1.76 and hurricane-related wind speeds based on RG 1.221 are both expressed as 3-second gust speeds for evaluating structural wind pressure loadings and for the generation of wind-borne missiles. As such, these wind speeds are not directly comparable.

The American Society of Civil Engineers – Structural Engineering Institute (ASCE-SEI) Standard 7-10, "Minimum Design Loads for Buildings and Other Structures," Table C26.5-2 provides an approximate relationship between sustained and 3-second gust wind speeds. For Category 2 hurricanes, the corresponding 3-second gust wind speeds over land at 10 m (33 ft) above open ground range from 170 to 195 km/hr (106 to 121 mi/hr). In comparison, the information in RG 1.221 indicates a 258 km/hr (160 mi/hr) hurricane wind speed for the WLS site area, noting that this latter value corresponds to an exceedance probability of 1×10^{-7}. Section 2.3.1.4.2.2 of this report provides a comparison of these values with the maximum design-basis tornado wind speed.

2.3.1.4.2.2 *Tornadoes and Waterspouts*

The applicant used a 56-year period of tornado reports (1950 to 2005) from the NCDC[9] to determine the number of tornadoes recorded near the proposed WLS site. In WLS COL FSAR Section 2.3.1.2.2, the applicant stated that 118 tornadoes had been reported in the eight counties that contain and surround the site, including Cherokee, Spartanburg, Union, Chester, and York in South Carolina, and Cleveland, Gaston, and Mecklenburg in North Carolina. Using the same tornado database, the staff independently confirmed the tornado statistics, as presented in WLS COL FSAR Table 2.3-204.

Following the methods of H.C.S. Thom, as presented in WASH-1300[10], "Technical Basis for Interim Regional Tornado Criteria," and using data from the tornado reports referred to above, the applicant estimated the probability of a tornado striking any particular location in the eight-county area around the proposed WLS site, during any one year, as:

[9] National Climatic Data Center, "Storm Events Database," http://www.ncdc.noaa.gov/stormevents/ Accessed October 13, 2014.
[10] WASH-1300, "Technical Basis for Interim Regional Tornado Criteria," U.S. Atomic Energy Commission, Washington, DC, May 1974.

$$P = \frac{z_{avg} \bullet t_{avg}}{A}$$

where, for the area being considered:

P = mean probability of a tornado striking a point in any year

t_{avg} = mean number of tornadoes per year

z_{avg} = mean path area of a tornado (sq-mi)

A = total area being considered

or 2.00×10^{-4} per year. The equivalent recurrence interval based on this probability, calculated as (1 / P), was estimated to be once every 5,000 years.

Similarly, the applicant used the same methods to estimate the probability of a tornado striking any particular location within Cherokee County, SC (where the proposed WLS site is located), as 1.64×10^{-4} per year, or an equivalent recurrence interval of 6,108 years, slightly lower than for the larger area that includes the surrounding counties.

The staff attempted to verify the applicant's probabilistic estimate for the eight-county area using the same on-line tornado database from the NCDC (i.e., "Storm Events" for North Carolina and South Carolina, Tornado Event Summaries). However, the staff could not confirm the area considered, finding a smaller total land area using the current (i.e., 2010) version of the same U.S. Census Bureau database – that is, 11,190 sq-km (4,320 sq-mi) versus the 13,290 sq-km (5,131 sq-mi) area used by the applicant. The staff also noted that observations of tornado path length and path width (used to estimate the area of individual tornado events) were missing for nearly one-third of the 118 recorded events. Both of these inputs appear to have competing effects on the probability (recurrence interval) calculation.

In Revision 9 of the WLS COL FSAR, the applicant reconciled the area used in the probabilistic tornado strike estimate (i.e., 13,290 sq-km) (5,131 sq-mi)) with the counties from which tornado occurrences were selected. In resolving this issue, the applicant added tornado event observations reported for Polk and Rutherford Counties, in North Carolina, over the 56-year POR, one and six events, respectively. The additional land area for these two counties, based on 2010 U.S. Census Bureau data, accounts for the discrepancy noted by the staff in its initial evaluation of the area considered. In re-confirming the applicant's probabilistic estimate for the ten-county area around the proposed WLS site, the staff finds the applicant's estimated strike probability and recurrence interval conservative and reasonable.

The staff also considered the tornado strike probabilities and other characteristics calculated for the 1°, 2°, and 4° box areas of latitude and longitude (Latitude/Longitude (Lat/Lon)) in the continental U.S. as reported in NUREG/CR-4461, "Tornado Climatology of the Contiguous United States," Revision 2. Based on the Lat/Lon coordinates of the two units at the proposed WLS site (i.e., approximately 35.0° north / 81.5° west – see WLS COL FSAR Section 2.1.1) and the results for the 1° and 2° box areas in NUREG/CR-4461, Revision 2, that include the site, the staff concluded that the applicant included the correct tornado statistics in WLS COL FSAR

Section 2.3.1.2.2. Based on the statistical summaries for the 1° and 2° Lat/Lon box areas around the proposed WLS site, the staff notes that the site is located in an area of transition with decreasing tornado point strike probabilities and increasing recurrence intervals to the south and east. Using the 2° Lat/Lon box area, the staff considers the point strike probability of about 2.0×10^{-4} reasonable. The applicant followed the methods presented in NUREG/CR-4461 to determine the tornado strike probabilities. Therefore, the staff finds information presented by the applicant acceptable.

The applicant chose tornado site characteristics based on RG 1.76, Revision 1, which specifies design-basis tornado characteristics for three tornado intensity regions defined within the continental U.S. Each region's parameters represent a 10^{-7} per year probability of occurrence. The applicant stated, and the staff agrees, that the proposed WLS site is located in Tornado Intensity Region I. The applicant proposed the following tornado site characteristics, which are listed in WLS COL FSAR Table 2.0-201:

- Maximum Wind Speed 230 mi/hr (370 km/hr)
- Pressure Drop 1.2 pounds per square inch (psi) (8.2 kN/mm^2)

The maximum tornado wind speed above is comparable (conservatively so) to the 10^{-7} probability wind speeds presented in NUREG/CR-4461, Revision 2 for the adjacent 1° and 2° Lat/Lon box areas that include and that are located to the south of the proposed WLS site.

The AP1000 site parameter tornado wind speed value of 482 km/hr (300 mi/hr) conservatively bounds the applicant's site characteristic tornado wind speed of 370 km/hr (230 mi/hr). In addition, this maximum design-basis tornado wind speed is well above the derived 3-second gust for hurricane wind speed. The wind speeds could range from about 170 to 195 km/hr (106 to 121 mi/hr), based on both the highest intensity hurricane recorded in the WLS site area (i.e., a Category 2 storm) and the 258 km/hr (160 mi/hr) 3-second gust hurricane wind speed for the site area based on RG 1.221 (Section 2.3.1.4.2.1 of this report has a more detailed discussion). The staff finds that the applicant's tornado wind speed site characteristic value follows the guidance provided in RG 1.76, Revision 1, and is therefore acceptable.

Finally, the applicant stated that waterspouts can occur over seas, bays, and lakes, but that none are expected near the proposed WLS site because the only nearby body of water is the Broad River. The staff agrees that waterspouts are typically a coastal phenomenon and notes that such events, when they do occur, are typically less intense than tornadoes. Given that and the design-basis tornado characteristics for the site as indicated above, the staff does not consider this weather element (i.e., waterspouts) an issue at the proposed WLS site.

2.3.1.4.2.3 *Thunderstorms, Lightning, and Hail*

The applicant's discussions on thunderstorms, lightning frequency, and hail occurrences in WLS COL FSAR Subsections 2.3.1.2.3-2.3.1.2.5 are intended to provide a general understanding of the occurrence of these severe weather events in the site area but do not result in the generation of site characteristics for use as design or operating bases.

The applicant's initial characterization of thunderstorm activity that could potentially occur in the site area used information from the NCDC's online "Storm Events" database. However, the staff noted an inconsistency in thunderstorm reporting when using the "Storm Events" database, rather than Local Climatological Data (LCD)[11] station summaries, also available from the NCDC. Therefore in RAI 446, Question 02.03.01-4, the staff requested that the applicant clarify the data referenced.

In an October 10, 2008, response to RAI 446, Question 02.03.01-4, the applicant provided a revised thunderstorm frequency analysis based on the LCD summaries for the first-order NWS stations at Greenville/Spartanburg (Greer), SC (GSP) Airport and Charlotte, NC (CLT) covering the periods from 1963 through 2007 and 1948 through 2007, respectively. WLS COL FSAR Table 2.3-205 was updated by the applicant to report the monthly and annual average frequencies of thunderstorms for the two locations and the composite average for both stations. From this evaluation, the applicant stated that thunderstorms occur on average 41.6 days per year.

Consistent with NUREG-0800, Section 2.3.1, the applicant compiled information about thunderstorm frequencies in the site area based on readily available LCD summaries from the NCDC. The staff notes that these data represent average frequencies of thunderstorm days (i.e., days on which thunder is either heard or lightning is observed when environmental noise is high at a manned observation station, or, in more recent years, when lightning is detected by a sensor at an automated weather observing station). The staff also notes that the reported average frequencies appear to represent arithmetic rather than weighted averages despite the different periods of record between the GSP and CLT stations (i.e., 45 and 60 years, respectively). Nevertheless, the staff finds the applicant's updated information reasonable and acceptable.

The applicant indicated that about 14 - 26 lightning strikes to earth per year per square mile could be expected in the WLS site area and that this range likely represents upper bounds for the lighting strike density. The staff independently evaluated this estimated range and assessment based on:

- the average annual frequencies of thunderstorm days reported in the LCD summaries for Greenville/Spartanburg (Greer), SC airport and Charlotte, NC, and a method attributed to the Electric Power Research Institute (EPRI) (yielding an expected frequency of about 13 strokes to earth per square mile per year)

- a more recent 14-year flash density map from the National Lightning Detection Network (NLDN) operated by Vaisala, Inc. (indicating a range of about 9 to 12 strokes to earth per square mile per year)[12]

- a 1999 paper by G. Huffines and R.E. Orville, "Lightning Ground Flash Density and Thunderstorm Duration in the Continental United States": 1989-96 (indicating about

[11] National Climatic Data Center, "Local Climatological Data." http://www.ncdc.noaa.gov/IPS/lcd/lcd.html Accessed October 13, 2014.
[12] Vaisala's National Lightning Detection Network, "Cloud-to-Ground Lightning Incidence in the Continental US (1997-2007)," http://www.lightningsafety.noaa.gov/stats/08_Vaisala_NLDN_Poster.pdf Accessed November 3, 2014.

3 to 5 strokes to earth per square kilometer (8 to 13 strokes to earth per square mile) per year)[13]

The staff considers the applicant's estimate of the frequency of lightning strokes to earth in the site area acceptable and conservative.

In WLS COL FSAR Section 2.3.1.2.5, Revision 0, the applicant's initial analysis of the frequency of hail events utilized information from the NCDC's online "Storm Events" database. The staff noted, as it did above with respect to thunderstorm activity, that use of the "Storm Events" database reflected some inconsistencies; in this case, that the frequency of recorded hail events appeared to increase markedly and become more consistent after 1984. Therefore, in RAI 446, Question 02.03.01-5, the staff requested that the applicant clarify the using data reported over the POR from 1950 through 2005.

In an October 10, 2008, response to RAI 446, Question 02.03.01-5, the applicant indicated that because there is no NCDC Local Climatic Data to be used in lieu of the hail event data from the "Storm Events" database, a revised analysis would be limited to the years from 1995 through 2006. WLS COL FSAR Table 2.3-206, Revision 0 was updated based on the revised POR. The applicant indicated that 432 hailstorms occurred in an eight-county region around the site over the period from January 1, 1995, through May 31, 2006, with the largest hail size reported at 7 cm (2.75 in.) in diameter. Cherokee County received approximately 10 percent of the reported hailstorms on an annual basis, averaging about 3.5 events per year. The staff performed an independent verification using information from the NCDC's "Climate Atlas of the United States" and obtained similar results.

With regard to the annual percent frequencies of occurrence by county, as listed in WLS COL FSAR Table 2.3-206, the staff notes that hail events are point observations, where aerial distribution may be biased by the population distribution depending on the area being considered, as recognized by the NCDC. This appears to be the case in the WLS site region, which reflects higher percentages reported for Spartanburg County in South Carolina and Mecklenburg County in North Carolina. Among the eight considered, these two counties have the highest populations and population densities based on U.S. Census Bureau data for 2010.

Although the database was limited to a POR of about 11.5 years (based on the applicant's response to RAI 446, Question 02.03.01-5), the frequency of hailstorm events could still be examined using other means of available data (some being recorded as early as the mid to late 1950s). The staff queried the NWS' Storm Prediction Center's severe weather database (Online Severe Plot 3.0)[14] for the eight-county area and determined that several events had occurred in the site region with hailstones larger than the maximum reported by the applicant (i.e., 7 cm (2.75 in.)). The largest hailstone reported in the area was 11.5 cm (4.5 in.) in diameter (a large softball is 9.7 cm (3.8 in.) in diameter) in Gaston County, NC, on April 3, 1974.

[14] Storm Prediction Center, "SPC National Severe Weather Database Browser," http://www.spc.noaa.gov/climo/online/sp3/plot.php Accessed November 7, 2014.

Given that these characteristics are not used for design or operating bases of safety-related SSCs, the staff finds the applicant's analysis acceptable.

2.3.1.4.2.4 *Regional Air Quality*

The applicant's discussion on regional air quality in WLS COL FSAR Section 2.3.1.2.6 intends to provide a general understanding of the air quality conditions in the site region and area but does not result in the generation of site characteristics for use as a design basis.

Consistent with 40 CFR 81.106, "Greenville-Spartanburg Intrastate Air Quality Control Region," the applicant correctly indicated that Cherokee County, SC, where the proposed WLS site is located, is included in the Greenville-Spartanburg Intrastate Air Quality Control Region (AQCR). National Ambient Air Quality Standards (NAAQS) have been issued by the EPA under 40 CFR Part 50 for the six principal air pollutants: carbon monoxide, nitrogen dioxide, ozone, particulate matter less than 10 microns and less than 2.5 microns in aerodynamic diameter (or PM-10 and PM-2.5), sulfur dioxide, and lead. Under 40 CFR 81.341, Cherokee County is designated as being in attainment (i.e., currently meets) or as unclassifiable/attainment (i.e., meeting the standard or expected to be meeting the standard despite a lack of monitoring data) for all criteria pollutants. The same is true for all other counties in South Carolina, except as indicated below for ozone.

The discussion in WLS COL FSAR Section 2.3.1.2.6 refers to a "newly promulgated" 8-hour ozone standard of 0.08 parts per million (ppm) at "62 *Federal Register* 36," dated July 18, 1997 (the staff notes that the correct regulatory citation is 62 FR 38894). Shortly after the initial submittal of the application in December 2007, the EPA revised that standard on March 27, 2008 (i.e., at 73 FR 16511) under new section 40 CFR 50.15, to be 0.075 ppm expressed to three decimal places.

Further, the listing of non-attainment counties/areas in South Carolina for the 8-hour ozone standard has remained unchanged in WLS COL FSAR Section 2.3.1.2.6 since the original application submittal. However, the staff notes that only a portion of York County, SC, is currently designated as being in marginal non-attainment for the 8-hour ozone standard (2008) per EPA's "Green Book"[15] (as of July 2, 2014). The staff agrees with the stated attainment and non-attainment statuses described for the surrounding counties in North Carolina.

As one means of characterizing the potential for restrictive atmospheric dispersion conditions, the applicant estimated average ventilation rates for the WLS site region based on a 7-year dataset of upper air observations (1984 to 1987 and 1989 to 1991) taken at the NWS station at Greensboro-High Point, NC. The data were obtained from the EPA Support Center for Regulatory Atmospheric Modeling (SCRAM) archive.[16] That NWS observing station is located in north-central North Carolina about 185 km (115 mi) to the northeast of the proposed WLS

[15] US Environmental Protection Agency, "The Green Book Nonattainment Areas for Criteria Pollutants" http://www.epa.gov/oar/oaqps/greenbk/ As of July 2, 2014.
[16] http://www.epa.gov/scram001/* Technology Transfer Network Support Center for Regulatory Atmospheric Modeling" U.S. EPA.

site. The elevation of the observing station is about 274 m (900 ft) above mean sea level (MSL) compared to an elevation of about 180 m (590 ft) above MSL for the proposed WLS site.

The ventilation rate was determined by the applicant as the product of the mixing height and wind speed within the mixing layer. Higher ventilation rates typically correspond to greater atmospheric dispersion potential, and vice versa. The applicant presented mean morning, afternoon, and daily ventilation rates in WLS COL FSAR Table 2.3-207 and discussed time periods during which relatively more or less atmospheric dispersion is expected to occur. However, the discussion of ventilation rates, as it relates to higher and lower air pollution potential, is somewhat redundant and disjointed between WLS COL FSAR Sections 2.3.1.2.6 and 2.3.2.4.1. The composite information is evaluated below.

In WLS COL FSAR Section 2.3.1.2.6, the applicant indicated that the “highest daily air pollution potentials” (or more restrictive dispersion conditions) exist in the morning from June through October, owing to lower ventilation rates. Conversely, the "lowest daily air pollution potentials” (or less restrictive dispersion conditions) occur from December through March because of relatively higher morning ventilation rates. In addition, WLS COL FSAR Section 2.3.2.4.1 states that highest daily air pollution potentials exist during the afternoon from August through January when ventilation rates are lower and that lowest air pollution potentials occur in the spring because of relatively high mean ventilation rates.

The staff performed an independent analysis using data derived from the online Ventilation Climate Information System (VCIS), one of the Wildland Fire Air Quality Tools developed through the U.S. Forest Service as part of the Wildland Fire Decision Support System. Similar results were found in terms of when lower and higher mean morning ventilation rates might be expected to occur—that is, June through October, and January through April, respectively. Likewise, lower mean afternoon ventilation rates (i.e., more restrictive dispersion) based on VCIS are estimated to occur from about September to February, with higher mean afternoon ventilation rates (i.e., less restrictive dispersion) from about April to July.

The method used by the applicant to estimate ventilation rates is similar to that employed by Holzworth (Reference 24 in NUREG-0800, Section 2.3.1). In both cases, the wind speed component of the calculation accounts for winds throughout the entire mixing layer, which can extend a few thousand meters in the vertical. Comparatively, the VCIS methods uses surface-level wind speeds that are usually lower because wind speed generally increases with height. The staff considers surface-level winds to be more representative of the dispersion conditions that potential radiological releases from an AP1000 unit would experience (i.e., conditions at or near ground level). Consequently, the staff’s results suggest that the ventilation rates reported by the applicant could be consistently overstated throughout the year: in the morning by about a factor of two (for some months even more); in the afternoon; and similarly on a mean daily basis, about 1.5 to 2.5 times higher.

In addition, the VCIS method adjusts (models) its calculations for the location of interest and accounts for topographic conditions. More importantly, the VCIS database covers a longer, more climatologically representative, period of record—about 30 years—compared to the 7-year POR used by the applicant. All of these factors likely contribute to the slight differences observed between the two approaches in the months associated with relatively more or less restrictive atmospheric dispersion conditions. At the time of the initial WLS COL FSAR submittal, the VCIS database was available through the Bureau of Land Management. After contacting the Bureau of Land Management, the staff determined that this database appears to no longer be supported or available for use.

As another indicator of the potential for restrictive dispersion conditions at the WLS site, in WLS COL FSAR Section 2.3.1.2.6, the applicant described the frequency of air stagnation conditions in the site region. Based on a 51-year POR (1948 to 1998) as reported by Wang and Angell, the applicant stated that South Carolina averages four air stagnation cases per year, with a mean duration of 5 days for each case, and 20 air stagnation days per year. The staff finds this description reasonable and acceptable and slightly conservative with respect to frequency of occurrence.

The applicant also indicated that air stagnation days occur more frequently from July through October and less often from November through March. This monthly variation is generally in agreement with the applicant's analysis and the staff's evaluation of morning ventilation rates (above); less so with respect to the monthly variation of afternoon and mean daily ventilation rates. Given that no site characteristics relate to this information, nor is this information used as input for any of the applicant's atmospheric dispersion modeling, the staff considers the applicant's discussion of these conditions in the WLS site region reasonable and acceptable.

2.3.1.4.2.5 *Severe Winter Storm Events*

In WLS COL FSAR Section 2.3.1.2.7, the applicant addressed severe winter storms in the site region from two perspectives. First, the introduction describes the frequency and other characteristics of such storms to provide a general understanding of the phenomena in the site region. As a group, these events may include snow, sleet, or freezing rain (the latter term usually referred to as ice storms in climatological records). However, this information does not result in the generation of site characteristics for use as design-or-operating-basis conditions or for comparison to corresponding site parameter values.

Second, specific characteristics of certain events that are considered in evaluating the acceptability of structural (roof) loads expected for the proposed WLS site are addressed in WLS COL FSAR Sections 2.3.1.2.7.1 through 2.3.1.2.7.3. This information generates a site characteristic value that is compared against a corresponding Tier 1 and Tier 2 site parameter.

2.3.1.4.2.5.1 General Conditions

In WLS COL FSAR Section 2.3.1.2.7, the applicant summarized 283 ice storms (i.e., snow, sleet, and/or freezing rain), by date, which were reported in the NCDC's online "Storm Events" database between 1993 and 2005. These data were obtained for the eight counties that include and surround the proposed WLS site (i.e., Cherokee, Spartanburg, Union, Chester, and York in South Carolina, and Cleveland, Gaston, and Mecklenburg in North Carolina). Based on this information, which appears in WLS COL FSAR Table 2.3-208, the applicant estimated that 22 such events occur annually in this region. The staff notes that this value simply represents the average number of individual dates with an event reported at any location across all eight counties during this 13-year POR. The applicant also stated that Cherokee County averages 3.6 such events per year.

Using the same database from this eight-county region, the staff, through analysis of the events by county in total each year, determined that a winter storm event could last for one or more days (as some of the "Storm Data" entries indicate) and impact multiple counties included in the region of analysis during the same time period. The staff's independent evaluation shows that winter storms occur, on average, about 2 to 3 days per year, with Cherokee and Spartanburg Counties, in South Carolina, and Cleveland County, in North Carolina, at the upper end of that range. As many as eight events, and as few as none, have occurred during any given year over the selected 13-year POR when looking at a particular county included in the eight county region. On average, the data show that the region around the WLS site might experience winter storms about four times per year. The staff considers the frequency of winter storm events based on the average of regional individual or multi-day occurrences to be more representative of conditions that might possibly occur at the proposed WLS site.

In WLS COL FSAR Section 2.3.1.2.7, the applicant also stated that the equivalent ice thickness because of freezing rain with concurrent 3-second gust speeds for a 100-year mean recurrence interval is 1.9 cm (0.75 in.) for north-central South Carolina. The 3-second gust speed value(s) was not indicated. The applicant based this ice thickness value on information in the American Lifelines Alliance's report titled "Extreme Ice Thicknesses from Freezing Rain" (September 2004). In its review of the cited reference, the staff determined that a 1.9 cm (0.75 in.) ice thickness is also associated with a 45 km/hr (30 mi/hr) concurrent 3-second gust wind speed and a 50-year mean recurrence interval. The reference also provides a conversion factor of 1.25 for scaling 50-year return period values for radial ice thicknesses in the range of 1.3 cm (0.5 in.) and greater to a 100-year return period. Expecting the 100-year mean recurrence period value to generally be higher than the 50-year value, in RAI 446, Question 02.03.01-6, the staff requested that the applicant verify the accuracy of the 100-year value.

In an October 10, 2008, response to RAI 446, Question 02.03.01-6, the applicant verified that the equivalent radial ice thicknesses for both the 50-year and 100-year mean recurrence intervals were the same for the WLS site location (i.e., 1.9 cm (0.75 in.)) based on the respective data plots in the cited reference. The RAI response also confirmed that the concurrent 3-second gust wind speed associated with these values was 48 km/hr (30 mi/hr) but was silent with respect to the scaling factor. The applicant concluded that no conversion factor was necessary to estimate a 100-year mean recurrence interval equivalent ice thickness value from the 50-year value.

Based on review of reports in the NCDC on-line "Storm Events" database covering the period back to 1996, the staff accepts the conclusion provided by the applicant. These event summaries suggest that radial ice thickness values because of freezing rain in the range of 1.9 cm (0.75 in.), up to about 2.5 cm (1 in.), could possibly occur in the WLS site region.

As stated previously, this general information on severe winter storm events does not generate site characteristics used as design or operating-basis conditions nor was it made to be compared against a corresponding AP1000 site parameter value. Nevertheless, with the clarifications noted above from the staff's review, these descriptions are reasonable indicators of severe winter storm events in the WLS site region and their potential effects.

2.3.1.4.2.5.2 Design-Basis Conditions

As discussed in the preceding paragraphs, snow and ice events do occur in the WLS region of South Carolina. The staff issued DC/COL-ISG-007, which clarifies the staff's position for identifying winter precipitation events as site characteristics and site parameters for determining normal and extreme winter precipitation loads on the roofs of Seismic Category I structures. The ISG revises the previously issued staff guidance as discussed in NUREG-0800, Section 2.3.1.

The ISG states that normal and extreme winter precipitation events should be identified in NUREG-0800, Section 2.3.1, as COL site characteristics for use in NUREG-0800, Section 3.8.4, in determining the normal and extreme winter precipitation loads on the roofs of Seismic Category I structures. The normal winter precipitation roof load is a function of the normal winter precipitation event; whereas, the extreme winter precipitation roof loads are based on the weight of the antecedent snowpack resulting from the normal winter precipitation event plus the larger resultant weight from either: (1) the extreme frozen winter precipitation event; or (2) the extreme liquid winter precipitation event. The extreme frozen winter precipitation event is assumed to accumulate on the roof on top of the antecedent normal winter precipitation event; whereas, the extreme liquid winter precipitation event may or may not accumulate on the roof, depending on the geometry of the roof and the type of drainage provided. The ISG further states:

- The normal winter precipitation event should be the highest ground-level weight (in pounds per square foot (lb/ft^2)) among: (1) the 100-year return period snowpack; (2) the historical maximum snowpack; (3) the 100-year return period two-day snowfall event; or (4) the historical maximum two-day snowfall event in the site region.

- The extreme frozen winter precipitation event should be the higher ground-level weight (in lb/ft^2) between: (1) the 100-year return period two-day snowfall event; and (2) the historical maximum two-day snowfall event in the site region.

- The extreme liquid winter precipitation event is defined as the theoretically greatest depth of precipitation for a 48-hour period that is physically possible over a 25.9-sq-km (10-sq- mi)) area at a particular geographical location during those months with the historically highest snowpack.

During the review, the staff identified slightly higher extreme snowfall statistics at another nearby cooperative observing station, Gaffney 6E, also located in Cherokee County and within 16 km (10 mi) of the proposed WLS site. These values included a 100-year return period snowfall amount of 41 cm (16.3 in.), a maximum observed snowfall of 43 cm (17.0 in.), and a maximum observed snow depth of the same amount. Therefore, in RAI 446, Question 02.03.01-8, the staff requested that the applicant justify why the WLS COL FSAR did not consider the more conservative snowfall data source.

In an October 10, 2008, response to RAI 446, Question 02.03.01-8, the applicant reiterated a portion of DC/COL-ISG-7 by restating the four parameters to be considered in establishing what that guidance refers to as the "Normal Winter Precipitation Event." These parameters include the highest among: the 100-year return period snowpack, the historical maximum snowpack, the

100-year return period snowfall event, or the historical maximum snowfall event in the site region. The applicant also stated that the 100-year return period snowpack from Ninety-Nine Islands is the maximum of these values and that the more conservative Gaffney 6E data would "be used in the PMWP evaluation." For clarification, the staff notes that the information discussed above pertains to determining the normal winter precipitation event, not the PMWP (i.e., probable maximum winter precipitation). The 48-hour PMWP component, discussed under the heading that follows, in combination with the controlling normal winter precipitation event, is used to estimate the extreme winter precipitation event.

Beginning with WLS COL FSAR, Revision 1, Section 2.3.1.2.7.1, the applicant incorporated the normal winter precipitation event value based on the Gaffney 6E data (i.e., 43 cm (17.0 in.)) and estimated the corresponding ground-level weight as 17.7 lb/ft^2 for the proposed WLS site, using the conversion factors indicated above. Therefore, with the clarifications and corrections noted above from the staff's review, the staff finds the applicant's estimate acceptable and considers RAI 446, Question 02.03.01-8 resolved.

<u>48-hour Probable Maximum Winter Precipitation</u>

As indicated previously and in DC/COL-ISG-7, the 48-hour PMWP is the second of two components used to estimate the extreme winter precipitation event applicable to a given site, which, in turn, provides input for the determination of the extreme winter precipitation live roof load calculation.

The introductory discussion of severe winter storm events discussed in WLS COL FSAR Section 2.3.1.2.7, Revision 0, reported a 48-hour PMWP value of 8.99 cm (3.54 in.) for the proposed WLS site. This value was based on data from the Greenville/Spartanburg (Greer) NWS station over a 9-year POR from 1997 to 2005. The applicant did not discuss the methods for its determination. Generally, the staff does not consider a 9-year period of record to be climatologically representative of long-term conditions. Therefore, in RAI 446, Question 02.03.01-7, the staff requested that the applicant justify the reported 48-hour PMWP value of 8.99 cm (3.54 in.) in light of 24-hour winter precipitation totals recorded at the nearby Ninety-Nine Islands and Gaffney 6E cooperative observing stations (i.e., 8.56 and 9.55 cm (3.37 and 3.76 in.)) and at the Greenville/Spartanburg (Greer) NWS station (i.e., 9.65 cm (3.80 in.)). In addition, the staff requested that the applicant either clarify the terminology used in WLS COL FSAR Section 2.3.1.2.7 to describe this 8.99 cm (3.54 in.) estimate or to explain an 8.99 cm (3.54 in.) 48-hour PMWP value, also discussed in WLS COL FSAR Section 2.3.1.2.7.2 but attributed to the Ninety-Nine Islands cooperative observing station. The latter section also identified another 48-hour PMWP value of 77.5 cm (30.5 in.) for the site area based on NOAA HMR 53[17].

In an October 10, 2008, response to RAI 446, Question 02.03.01-7, the applicant stated that the data from the Ninety-Nine Islands station is most representative of site conditions because of its location on the Broad River and close proximity to the site. However, the applicant also stated that the data from this location (referring to the Ninety-Nine Islands observing station) does not

---

[17] NOAA Hydrometeorological Report No. 53 – Seasonal Variation of 10-Square Mile Probable Maximum Precipitation Estimates, United States East of the 105th Meridian, NUREG/CR-1486.

provide a bounding value for design conditions, while also acknowledging that the PMWP value is established by NOAA's HMR 53 report as 77.5 cm (30.5 in.) as stated in WLS COL FSAR Section 2.3.1.2.7.2. Subsequently, in WLS COL FSAR Revision 1, the applicant reconciled the conflicting text in WLS COL FSAR Sections 2.3.1.2.7 and 2.3.1.2.7.2 by:

- in WLS COL FSAR Section 2.3.1.2.7, deleting the maximum one-day rainfall total of 18.2 cm (7.16 in.) for the Ninety-Nine Islands cooperative observing station

- correcting the descriptor for the 48-hour rainfall total from the Greenville/Spartanburg NWS station in WLS COL FSAR Section 2.3.1.2.7, now referring to that measurement as a maximum recorded winter precipitation value rather than a 48-hour PMWP value

- in WLS COL FSAR Section 2.3.1.2.7.2, deleting the 8.99 cm (3.54 in.) 48-hour PMWP value that had been attributed to the Ninety-Nine Islands cooperative observing station

The staff agrees with the applicant's use of NOAA HMR No. 53, consistent with the guidance in DC/COL-ISG-7 and NUREG-0800, Section 2.3.1, for characterizing the 48-hour PMWP for the proposed WLS site. Furthermore, the staff's independent analysis indicates that the applicant's 48-hour PMWP estimate of 77.5 cm (30.5 in.) is conservatively higher than the staff's evaluation, which the staff finds acceptable. With the clarifications noted above, the staff considers RAI 446, Question 02.03.01-7 resolved.

Regarding the applicant's characterization of design-basis conditions associated with the 48-hour probable maximum winter precipitation, in RAI 446, Question 02.03.01-9, the staff requested that the applicant describe the additional weight contributed by the 48-hour PMWP if the central hole on the roof of the passive containment cooling system (PCS) tank is blocked by a pre-existing 100-year snowpack. The staff also requested that the applicant estimate the additional weight if at least part of the 48-hour PMWP falls as frozen precipitation.

In an October 10, 2008, response to RAI 446, Question 02.03.01-9, the applicant first reiterated a portion of the discussion from WLS COL FSAR Section 2.3.1.2.7.2 concluding that water and snowmelt build-up on the roofs of the Nuclear Island are negligible because the roofs have no lips (i.e., parapets) around their edges. Furthermore, the shield building roof is sloped with no lips around its edges that would allow water build-up. The PCS tank (set atop the Shield Building) is also flat with no lip; therefore, water would not build up. The PCS tank also includes a central hole that would allow water to drain down in between the shield wall and the steel containment vessel, further reducing accumulation of water on the PCS tank roof area.

The applicant also summarized a response to an AP1000 design certification-related RAI, which discussed design features, as well as physical conditions, during normal operation and accident scenarios to protect against ice blockage of the chimney area. Provisions include the use of non-safety-related electrical heaters for air inlet structures to keep these structures free of ice and snow build-up; heat transferred from the reactor containment would help keep the chimney gratings free of ice build-up because of the flow of heated air upward through the gratings. The staff accepts, as reasonable, the preceding explanations as justification that the central PCS tank hole would not be blocked by a pre-existing 100-year snowpack.

The applicant's response to RAI 446, Question 02.03.01-9 addresses an additional roof loading because of rain-on-snow based on ASCE Standard 7-05, "Minimum Design Loads for Buildings and Other Structures." ASCE/SEI 7-05 (and its successor, ASCE/SEI 7-10) indicates that if the ground snow load is less than 20 lb/ft^2, an additional rain-on-snow surcharge of 5 lb/ft^2 is to be applied to low-sloped roofs. The previously stated ground snow load associated with the normal winter precipitation event for the WLS site region (i.e., 17.7 lb/ft^2) meets this criterion. Therefore, the applicant indicated that the 5 lb/ft^2 rain-on-snow surcharge applied. Given the shedding characteristics for rain and snowmelt from the roofs of Seismic Category I structures in the AP1000 design, and the staff's guidance in DC/COL-ISG-7, this rain-on-snow surcharge value corresponds to the extreme liquid winter precipitation event.

The ISG recommends characterization of the extreme frozen winter precipitation event as the higher ground-level weight of either the 100-year return period snowfall event or the historical maximum snowfall event in the site region. As identified earlier, the ground-level weight of the historical maximum snowfall event is 17.7 lb/ft^2 for the WLS site and as such, represents the extreme frozen winter precipitation event (as well as the controlling normal winter precipitation event). This value is the greater of the extreme frozen and extreme liquid winter precipitation events (i.e., 17.7 lb/ft^2 versus 7.2 lb/ft^2) and, therefore, represents the controlling ground-level weight of the extreme winter precipitation event.

Based on the additional information provided by the applicant regarding roof design and the application of the ASCE guidance, the staff finds the applicant's evaluation of the estimated weight of the 48-hr PMWP acceptable.

<u>Weight of Snow and Ice on Safety-Related Structures</u>

As discussed above, the applicant's revised site characteristic value for the weight of winter precipitation on safety-related structures equals 17.7 lb/ft^2. WLS COL FSAR Table 2.0-201 presents a comparison between the AP1000 Tier 1 site parameter and corresponding WLS site characteristic values for snow load. The staff notes that, as discussed above, the applicant did not include an additional rain-on-snow surcharge of 5 lb/ft^2 called for in ASCE 7/05. The staff recognizes that because of the large difference between the site characteristic snowload and the AP1000 DCD site parameter, this surcharge would not change the conclusions reached in this report. The AP1000 DCD site parameter value conservatively bounds the applicant's site characteristic for snow load, and therefore, the staff finds this acceptable.

2.3.1.4.2.6 *100-Year Return Period Fastest Mile of Wind*

In WLS COL FSAR Section 2.3.1.2.8, the applicant provided a 100-year return period fastest-mile wind estimate for Cherokee County, SC, of 140 km/hr (88 mi/hr) based on NWS-recorded storm events and a Gumbel-Lieblein extreme value analysis. The dataset included a maximum reported value of 130 km/hr (80.6 mi/hr or 70 knots). Using the same data source, the staff independently confirmed the applicant's wind estimate to be numerically reasonable. Given the stated POR (i.e., 1950 to 2006), the dataset used by the applicant appears to be from the NCDC's online "Storm Events" database, where thunderstorm winds and high winds typically represent a wind gust (i.e., a 5-second average wind speed). The staff notes that the AP1000 DCD site parameter for the operating basis wind speed, while associated with a 100-year return period, represents a 3-second gust wind speed rather than a fastest-mile wind speed.

The applicant estimated the 100-year return period site characteristic 3-second gust wind speed for the proposed WLS site based on ASCE 7-95, “Minimum Design Loads for Buildings and Other Structures.” The applicant stated that the 50-year return period 3-second gust speed is 150 km/hr (90 mi/hr) and used a conversion factor of 1.07 (based on ASCE-95. Table C6-5) to determine a 100-year return period 3-second gust speed of 155 km/hr (96 mi/hr). Although the applicant refers to this value as the design basis wind velocity, this site parameter is more appropriately referred to as the operating basis wind speed consistent with NUREG-0800, Section 2.3.1, WLS COL FSAR Table 2.0-201, and AP1000 DCD, Tier 2, Table 2-1.

The staff compared the applicant’s 3-second gust wind speed against a more recent version of the industry standard, “Minimum Design Loads for Buildings and Other Structures” (i.e., ASCE/SEI 7-05, which is cited in NUREG-0800, Section 2.3.1). The staff noted the values were the same. Further, this site characteristic value was also compared by the staff to various reports of high wind events in the eight counties that include and surround the proposed WLS site (i.e., Cherokee, Spartanburg, Union, Chester, and York in South Carolina, and Cleveland, Gaston, and Mecklenburg in North Carolina) as recorded in the NCDC “Storm Events” database. Thunderstorm wind gusts of 150 km/hr (80 knots (about 92 mi/hr)) were reported in Spartanburg County, SC in 1991 and 1992, and Mecklenburg County, NC in 1962. Based on the staff’s independent review, the 100-year return period 3-second gust site characteristic value is considered to be reasonably representative of conditions that might be expected to occur in the WLS site area.

2.3.1.4.2.7 *Probable Maximum Annual Frequency and Duration of Dust Storms*

The following discussion on dust storms intends to provide a general understanding of the occurrence of this phenomenon in the site region but does not result in the generation of site characteristics for use as design or operating bases.

The applicant stated that there have been no reported dust storms in the WLS site area. Consistent with NUREG-0800, Section 2.3.1, the applicant compiled this information from the NCDC. The staff independently confirmed the information provided by the applicant and finds it reasonable because this area is not prone to dust storms.

2.3.1.4.2.8 *Climate Change*

RAI 446, Question 02.03.01-10 was asked by the staff to the applicant in light of 10 CFR 52.79(a)(1)(iii), which requires the applicant to identify the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated. In addition, NUREG-0800, Section 2.3.1, states that the applicant should substantiate the applicability of data on severe weather phenomena to represent site conditions during the expected period of reactor operation.

In an October 20, 2008, response to RAI 446, Question 02.03.01-10, the applicant identified that certified climatological data was used for the severe weather phenomena evaluations and that the data selected supports accurate severe weather phenomena projections for the area near the proposed WLS site. The site characteristic temperatures were developed considering both 100-year return period and zero percent exceedance temperatures. The applicant stated that the margin between the WLS site characteristics and the DCD site parameters accounts for any limitations to the accuracy, quantity, and period of time in which the historical data have been accumulated, and the applicant predicts the site parameters presented in the DCD to be bounding for the expected period of reactor operation.

In addition, the applicant stated that the WLS site characteristics were already based on an extensive record of readily available and well-documented climatological observations. The applicant also cited that general predictions of potential global or U.S. climate change, particularly on severe weather phenomena during the period of reactor operation, are uncertain and only possible on a macroclimatic scale. Maximum data spans were used in the severe weather analysis for the proposed WLS site, and projections were made based on best-available historic data.

The U.S. Global Change Research Program (USGCRP) released a report to the President and Members of Congress in June 2009,[18] and again in May 2014,[19] titled, "Global Climate Change Impacts in the United States," and, "Climate Change Impacts in the United States." These reports, produced by an advisory committee chartered under the Federal Advisory Committee Act, summarize the science of climate change and the impacts of climate change on the United States.

In the southeast region, which encompasses both North and South Carolina, both the 2009 and 2014 report noted that average annual air temperature did not increase significantly over the last century as a whole. However, the 2009 report indicated that average annual temperature has risen about 1.1 °C (2 °F) since 1970, with the most significant seasonal increase occurring during the winter months. The 2009 report also stated that average temperatures are projected to rise even more by the 2080s, by a potential range of 2.5 °C to 5.0 °C (4.5 °F to 9.0 °F) (with a possible 5.83 °C (10.5 °F increase in the summer), depending on the released emissions scenario. The 2014 report provides a slightly lower increased temperature range for the region of 2.2 °C to 4.4 °C (4 °F to 8 °F), but this range accounts for both higher and lower emission scenarios throughout this century.

The 2009 report mentioned that, despite the fact that autumn precipitation has increased by about 30 percent in the southeast region since the early 1900s, summer and winter precipitation have both decreased by about 10 percent. The 2009 report states that the percentage of the region in moderate to severe drought has risen by 12 percent and 14 percent, respectively, since the mid-1970s. The 2014 report also states, "Because the Southeast is located in the transition zone between projected wetter conditions to the north and drier conditions to the southwest, many of the model projections show only small changes relative to natural variations. However, many models do project drier conditions in the far southwest of the region

---

[18] U.S. Global Change Research Program, "Global Climate Change Impacts in the United States," A State of Knowledge Report, Federal Advisory Committees, June 2009.
[19] U.S. Global Change Research Program, "Climate Change Impacts in the United States," US National Climate Assessment, Federal Advisory Committees, May 2014.

and wetter conditions in the far northeast of the region, consistent with the larger continental-scale pattern of wetness and dryness." As far as future changes in total precipitation, climate models are not as consistent with predicting precipitation totals for the region as compared to predicting temperature changes, so there is no consensus on how seasonal amounts will change, except for possible indications that rainfall amounts from individual hurricanes will increase.

Both USGCRP reports also mention that the intensity and occurrences of hurricanes have increased in recent decades and are likely to increase even more into this century, correlating with an increase in sea surface temperatures. The 2014 report even goes on to state that the number of Category 4 and 5 hurricanes in the Atlantic basin has increased substantially since the early 1980s when compared to the historical record dating back to the mid-1880s; this can be attributed to both natural variability and climate change. However, there has been little change regarding the total number of landfalling hurricanes because a variety of features influence whether a hurricane can potentially make landfall. As mentioned previously, hurricane-related rainfall amounts, in addition to wind, are expected to increase.

Both reports mention that severe weather event reports, including tornado reports, have increased since the 1950s, but improvements in monitoring technologies, growth in population, and increased public awareness most likely account for this surge in reports. When these factors are taken into account, there is no clear trend in the frequency or strength of tornadoes since the 1950s in the United States.

The staff acknowledges that long-term climatic change resulting from human or natural causes may introduce changes into the most severe natural phenomena reported for the site. However, no conclusive evidence or consensus is available on the rapidity or nature of such changes. There is a level of uncertainty in projecting future conditions because the assumptions regarding the future level of emissions of heat trapping gases depend on projections of population, economic activity, and choice of energy technologies. If it becomes evident that long-term climatic change is influencing the most severe natural phenomena reported at the site, the COL holders have a continuing obligation to ensure that their plants stay within the licensing basis.

2.3.1.5 *Post Combined License Activities*

There are no post COL activities associated with this WLS COL FSAR section.

2.3.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to regional climatology, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

COL Information Item 2.3-1 states that a COL applicant shall address the site-specific regional climatology information. As set forth above, the applicant has presented and substantiated information to establish the regional meteorological characteristics. The staff reviewed the information provided and for the reasons given above, concludes that the applicant has established the meteorological characteristics at the site and in the surrounding area acceptable to meet the requirements of 10 CFR 100.20(c)(2) and 10 CFR 100.21(d) with respect to determining the acceptability of the site. The staff finds that the applicant has provided a sufficient description to adequately address COL Information Item 2.3-1.

The staff finds that the applicant has considered the most severe natural phenomena historically reported for the site and surrounding area in establishing the site characteristics. Specifically, the staff has accepted the methodologies used to analyze these natural phenomena and determine the severity of the weather phenomena reflected in these site characteristics. Since the applicant has correctly implemented these methodologies, as described above, the staff finds that the applicant has considered these historical phenomena with margin sufficient for the limited accuracy, quantity, and period of time in which the data have been accumulated in accordance with 10 CFR 52.79(a)(1)(iii).

2.3.2 Local Meteorology

2.3.2.1 *Introduction*

WLS COL FSAR Section 2.3.2, "Local Meteorology," addresses the local (site) meteorological parameters, assesses the potential influence of construction and operation of the proposed plant and its facilities (e.g., terrain modifications, buildings and other plant infrastructure, and sources of heat and moisture) on local meteorological conditions and the impact of those modifications on plant design and operation. WLS COL FSAR Section 2.3.2 also provides a topographical description of the site and its environs and the design basis dry and wet-bulb temperatures, in addition to the evaluation of the UHS. To follow the format of the WLS COL FSAR, the staff incorporated the design basis dry and wet-bulb temperatures and the evaluation of the UHS into Section 2.3.2 of this report.

This section of the report also addresses the supplemental information in WLS COL FSAR Section 2.3.6 related to local meteorology.

2.3.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.3, incorporates by reference AP1000 DCD, Revision 19, Section 2.3. In WLS COL FSAR Section 2.3.2, the applicant addressed the following:

AP1000 COL Information Item

- WLS COL 2.3-2

The applicant provided additional information in WLS COL 2.3-2 to address COL Information Item 2.3-2. WLS COL 2.3-2 addresses site-specific information related to local meteorology. In addition, the applicant chose to provide the design basis temperature and moisture-related site characteristics in WLS COL FSAR Section 2.3.2, rather than WLS COL FSAR Section 2.3.1, as suggested in RG 1.206, Subsection C.I.2.3.1.2, Part III, This portion of WLS COL 2.3-2 correlates with COL Information Item 2.3-1 from Tier 2, Table 1.8-2, of the AP1000

DCD. This additional design basis information addresses Interface Item 2.4 related to extreme meteorological conditions for the design of systems and components exposed to the environment and Interface Item 2.8 related to ambient air temperatures.

2.3.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria and information needed to evaluate local meteorological and climatological characteristics are based on meeting the relevant requirements of NRC regulations under 10 CFR Part 52 and 10 CFR Part 100. The staff considered the following regulatory requirements in reviewing the applicant’s descriptions of the local meteorological and climatological characteristics around the proposed WLS site:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c)(2) and 10 CFR 100.21(d), with respect to the consideration given to the local meteorological and air quality characteristics of the site.

NUREG-0800, Section 2.3.2, recommends the following acceptance criteria to be provided by a COL applicant:

- Summaries of local meteorological data based on onsite measurements made in accordance with RG 1.23, “Meteorological Monitoring Programs for Nuclear Power Plants,” Revision 1, and NWS station summaries or other standard installation summaries from appropriate nearby locations (e.g., within 80 km (50 mi)) should be presented as specified in RG 1.206, “Combined License Applications for Nuclear Power Plants,” Part I, Subsection C.I.2.3.2.1.

- A complete topographical description of the site and environs out to a distance of 80 km (50 mi) from the plant, as described in RG 1.206, Part I, Subsection C.I.2.3.2.2, should be provided.

- A discussion and evaluation of the influence of the plant and its facilities on the local meteorological and air quality conditions should be provided. Applicants should also identify potential changes in the normal and extreme values, as presented in the safety analysis report, resulting from plant construction and operation.

- The description of local site airflow should include wind roses and annual joint frequency distributions (JFDs) of wind speed and wind direction by atmospheric stability for all measurement levels using the criteria provided in RG 1.23.

The following regulatory guides were also taken into consideration in the staff’s review of WLS COL FSAR Section 2.3.2 and Appendices 2CC and 2DD (as applicable):

- RG 1.23, "Meteorological Monitoring Programs for Nuclear Power Plants," Revision 1, which provides criteria for establishing and operating an onsite meteorological measurements program for the collection of basic meteorological data needed to support plant licensing and operation.

- RG 1.206, "Combined License Applications for Nuclear Power Plants," which identifies the types of local meteorological and other climatological data summaries, topographic information, and any local meteorological and air quality conditions used for design and operating bases that an applicant should provide in FSAR Section 2.3.2 when describing these conditions at the site, and in the site vicinity and area.

2.3.2.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.3.2 and checked the applicable site parameters, including the design basis temperature and moisture related site parameters, in AP1000 DCD Tier 1 (Table 5.0-1) and AP1000 DCD Tier 2 (Table 2-1) to ensure that the combination of the AP1000 DCD and the COL application represents the complete scope of information relating to the review topic. The staff's review confirmed that the information contained in the application and incorporated by reference (as related to site parameters, where applicable) addresses the required information relating to local meteorology. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the information in the WLS COL FSAR corresponding to the following:

AP1000 COL Information Item

- WLS COL 2.3-2

WLS COL 2.3-2 addresses COL Information Item 2.3-2 in AP1000 DCD Tier 2, Table 1.8-2 regarding local meteorological conditions.

The staff reviewed WLS COL 2.3-2, related to local meteorological conditions included under WLS COL FSAR Section 2.3.2. COL Information Item 2.3-2 in AP1000 DCD, Section 2.3.6.2 states:

> Combined License applicants referencing the AP1000 certified design will address site-specific local meteorology information.

In this section, the staff reviewed information presented by the applicant concerning the local (site) meteorological parameters, including their normal and extreme values. Summaries of parameters should be based on long-term data from nearby reasonably representative locations (e.g., within 80 km (50 mi), and shorter-term onsite data, based on NRC guidance).

Representativeness of submitted data should be demonstrated by comparing the longer-term datasets to the shorter-term onsite data. The applicant should provide at least two consecutive annual cycles (and preferably three or more entire years) of onsite meteorological data for the evaluation. The applicant initially submitted the minimum amount (i.e., 1 year) of onsite meteorological data at the time of application and provided a complete 2-year dataset once it had been collected. Therefore, in RAI 447, Question 02.03.02-1, the staff requested that the applicant provide revisions related to discussions presented WLS COL FSAR Section 2.3.2 based on the completed 2-year dataset or justification for an alternate approach.

The applicant chose an alternative approach, which involved demonstrating that the first year of meteorological data was representative when compared to the 2-year dataset. The applicant stated that revision of the suggested sections would create an inconsistency in the WLS COL FSAR unless all sections that use the onsite data were revised. The applicant provided a new appendix (i.e., Appendix 2CC) to the WLS COL FSAR to demonstrate that analyses based on the first year of onsite monitoring data were consistent with the full, 2-year dataset.

Based on the information provided in the new appendix, the applicant concluded that the 2-year meteorological dataset is consistent with the first year dataset and the historic dataset from the nearby Greenville/Spartanburg (Greer) NWS station. No anomalous behavior was observed between the 2 years' comparison of the normal conditions observed at the nearby NWS station. The applicant concluded that WLS COL FSAR Section 2.3 needed no changes based on the second year of meteorological data collected.

The staff analysis results agree that the 2-year onsite meteorological dataset is consistent with the 1-year dataset. A comparison, between the 2 years, did not exhibit abnormal trends or behaviors. Therefore, this is acceptable to the staff. Sections 2.3.4 and 2.3.5 of this report evaluate further analysis of these data with respect to atmospheric dispersion modeling.

The staff relied upon the review procedure presented in NUREG-0800, Section 2.3.2, to independently assess the technical sufficiency of the information presented by the applicant.

2.3.2.4.1 Winds

2.3.2.4.1.1 *Offsite Wind Direction and Wind Speed Distributions*

In WLS COL FSAR Section 2.3.2.1.1, the applicant provided monthly and annual wind data summaries from data obtained at the first-order NWS station at Greenville/Spartanburg (Greer), SC for a POR from 1997 through 2005. This data is presented in WLS COL FSAR Tables 2.3-209 to 2.3-221. The applicant presented these data summaries in the form of joint frequency distributions of wind speed and wind direction and graphical wind roses. NUREG-0800, Section 2.3.2, recommends that the offsite wind summaries be based on data from nearby representative stations (e.g., within 80 km (50 mi). The Greenville/Spartanburg (Greer) NWS station is approximately 66 km (41 mi) west-southwest of the site; the staff does not consider wind data from this NWS station to be representative for characterizing site-specific wind speed and direction conditions. Therefore, in RAI 447, Question 02.03.02-2, the staff requested that the applicant support the statement that the net regional air movement can be deduced from the monthly wind joint frequency distributions for the Greenville/Spartanburg International Airport. The staff notes that the applicant revised WLS COL FSAR Section 2.3.2 by removing the statement. The staff finds that the WLS COL FSAR provides an acceptable description of the wind distribution for the proposed WLS site and considers RAI 447, Question 02.03.02-2 resolved.

2.3.2.4.1.2 *Lee Nuclear Wind Distribution*

For the WLS site, the applicant stated that the annual wind direction frequency is fairly uniform. The northwest wind direction represents the prevailing wind direction. Wind from the west occurs least frequently at 3 percent of the time. The applicant also stated that the mean annual wind speed was about 8 km/hr (5 mi/hr).

The staff acknowledges that the proposed WLS site is located in a river valley area having distinct wind characteristics unlike the Greenville/Spartanburg (Greer) and Charlotte wind distributions described in the previous section. The staff independently reviewed the wind speed and direction distributions for the proposed WLS site and finds the results consistent with the information provided by the applicant in the WLS COL FSAR.

2.3.2.4.1.3 *Wind Direction Persistence*

WLS COL FSAR Tables 2.3-242 through 2.3-244 summarize maximum persistence periods (in consecutive hours) by direction sector for each year of a 9-year POR from 1997 to 2005. These tables are based on hourly observations taken at the Greenville/Spartanburg (Greer) NWS station. Each sector also identifies the maximum and average persistence durations for the composite 9-year POR. The applicant indicated that the longest periods of wind direction persistence for a single sector and for three and five adjoining sectors were all associated with winds from the northeast (i.e., 23, 82, and 150 consecutive hours). The northeast sector also showed the highest average of all annual persistence maxima during the nine-year POR (i.e., 14.0, 57.8, and 91.0 hours).

WLS COL FSAR Table 2.3-245, “Comparison of Maximum Wind Persistence at Lee Nuclear Station Site and Greenville/Spartanburg, South Carolina,” lists wind direction persistence durations for a single sector and for three and five adjacent sectors based on wind measurements at the 10 m (33 ft) level from the proposed WLS site during the period of December 1, 2005, through November 30, 2006. WLS COL FSAR Figure 2CC-208, “Wind Direction Frequency (10 m (33 ft) level),” and Figure 2CC-209, “Wind Direction Frequency (60 m (197 ft) level),” compare the wind direction frequencies for the 1-year and 2-year periods of the onsite meteorological record. These two figures show that the datasets are very similar in regards to wind direction frequency. For comparison, WLS COL FSAR Table 2.3-245 also summarizes persistence based on hourly data from the Greenville/Spartanburg (Greer) NWS station, which corresponds to the same period of onsite data as well as the maximum persistence durations, again by sector, identified in WLS COL FSAR Tables 2.3-242 through 2.3-244.

For the onsite meteorological data, the applicant indicated that the longest periods of persistence for a single sector and for three adjoining sectors were associated with winds from the northwest and that the longest duration of persistence for five adjoining sectors was for the north-northeast direction. No comparative statement regarding persistence was provided between the concurrent onsite and offsite datasets or between the 1-year and 9-year offsite datasets. However, the staff notes that during the concurrent offsite data period, the longest durations of persistence were:

- 15 hours for a single-sector under north winds

- 50 hours for three adjacent sectors under north-northeast winds
- 88 hours for five adjacent sectors under southwest and west-southwest winds

The concurrent onsite/offsite datasets did not compare very well in terms of directional persistence. The same can be said when comparing the persistence statistics based on the one-year onsite dataset and the nine-year dataset from the Greenville/Spartanburg (Greer), SC, NWS station and an inter-comparison between the one and nine-year offsite datasets. The wind direction persistence data does not directly lead to any site characteristic values and therefore is accepted as general climatological information. Offsite wind information is discussed in more detail in Section 2.3.2.4.1.1 of this report.

2.3.2.4.2 Air Temperature

In WLS COL FSAR Section 2.3.2.2, the applicant stated that the average maximum temperatures at the site ranged from between 10 and 13 °C (50 and 55 °F) in January to between 29 and 32 °C (85 and 90 °F) in July. Comparatively, average minimum temperatures ranged from between -3.9 and -1.1 °C (25 and 30 °F) in January to between 18 and 21 °C (65 and 70 °F) in July. The applicant stated that the average maximum monthly temperature at the Ninety-Nine Islands cooperative observing station occurred in July with a temperature of 32 °C (89 °F). The average minimum monthly temperature was -2.94 °C (26.7 °F), which occurred in January at the Ninety-Nine Islands station. Using local climate data provided by NCDC and data provided by the South Carolina State Climatology Office, the staff independently reviewed the average temperatures and average temperature ranges and finds this information acceptable.

Unlike wind speed and direction, ambient air temperatures across the region are similar. FSAR Figure 2CC-201, "Dry Bulb Temperature Comparison," shows a comparison of ambient dry-bulb temperature statistics between measurements provided by the applicant and measurements provided by a first-order NWS station and a cooperative observing station. The staff considers the Greenville/Spartanburg airport off-site station representative of expected site conditions and accepts site-specific dry-bulb and wet-bulb temperature summaries based on data from this station.

NUREG-0800, Section 2.3.1, identifies the need for meteorological data in the design of the ultimate heat sink. The applicant provided an analysis using only 9 years (1997-2005) of meteorological data. Therefore, in RAI 447, Question 02.03.02-3, the staff requested that the applicant provide justification for not providing 30 years of meteorological data, a standard recommend by NUREG-0800 in Section 2.3.1.

In a November 25, 2008, response to RAI 447, Question 02.03.02-3, the applicant stated that, for a passive containment plant (e.g., AP1000), a site-specific UHS evaluation was not necessary. The applicant revised WLS COL FSAR Section 2.3.2.2 by removing the worst 1-day, 5-day and 30-day discussion and by deleting WLS COL FSAR Tables 2.3-247 through 2.3-252. The staff finds this acceptable because many plants use a cooling tower as a UHS to dissipate residual heat after an accident. Instead of using a cooling tower to release heat to the atmosphere, the AP1000 design uses a passive containment cooling system (PCS) to provide the safety-related UHS. The PCS is designed to withstand the maximum safety dry-bulb and coincident wet-bulb air temperature site parameters specified in AP1000 DCD Tier 1, Table 5.0-1 and Tier 2, Table 2-1. Therefore, the staff notes that the applicant need not identify meteorological characteristics for evaluating the design of a UHS cooling tower.

The applicant reported the maximum safety dry and wet-bulb temperature and the minimum safety dry-bulb temperature site characteristics in WLS COL FSAR Table 2.0-201 using the 0.4 percent exceedance values summarized by the American Society of Heating, Refrigerating and Air Conditioning Engineers (ASHRAE), as listed in WLS COL FSAR Table 2.3-293, "Lee Nuclear Station Design Temperatures." This was not consistent with the methodology of choosing the higher of the historic (zero percent exceedance) value(s) or the 100-year return period value(s) based on 10 CFR 52.79(a)(1)(iii). In RAI 447, Question 02.03.02-4, the staff requested that the applicant address this concern.

In a November 25, 2008, response to RAI 447, Question 02.03.02-4, the applicant provided a revision that provided the zero percent exceedance values rather than the higher 100-year return period values for the maximum and minimum safety dry- or wet-bulb temperature site characteristics. As summarized in WLS COL FSAR Table 2.0-201, the applicant used 100-year return period temperatures for comparison against the AP1000 maximum and minimum safety air temperature site parameters. The applicant also used the 0.4 percent annual exceedance temperatures for comparison against the AP1000 maximum and minimum normal air temperature site parameters. The staff reviewed the site characteristic temperature values presented in WLS COL FSAR Table 2.0-201 and finds them acceptable and considers RAI 447, Question 02.03.02-4 resolved.

2.3.2.4.3 Atmospheric Moisture

In WLS COL FSAR Section 2.3.2.3, the applicant addressed atmospheric moisture conditions in terms of relative humidity levels observed at the site and the nearby first-order NWS station located at the Greenville/Spartanburg airport. The applicant also discussed several other topics related to atmospheric moisture in WLS COL FSAR Section 2.3.2.3. These topics include precipitation, snowfall, and fog in WLS COL FSAR Sections 2.3.2.3.1 through 2.3.2.3.3. The staff's evaluation of this information follows a similar sequence.

In the analysis of atmospheric moisture, the applicant stated that the local site meteorological conditions reflect the synoptic-scale atmospheric processes consistent with the regional meteorology, except for the local effects of the Broad River. The applicant further stated that there was slightly higher humidity directly adjacent to the river, and that the site humidity data was more appropriate for site estimates than the Greenville/Spartanburg data. In RAI 447, Question 02.03.02-5, the staff requested that the applicant clarify why the wet-bulb temperature site characteristic, as presented in WLS COL FSAR Table 2.0-201 and based on data from the Greenville/Spartanburg NWS station, was more appropriate for site estimates.

In a November 25, 2008, response to RAI 447, Question 02.03.02-5, the applicant stated that the site data had been recorded for only a relatively short period and that no long-term wet-bulb or humidity measurements were recorded at a location near the site and in close proximity to a body of water. The applicant stated that the variability in humidity measurements because of a body of water diminishes dramatically within a short distance of the shoreline. Therefore, it was expected that any increase in humidity at the site location would be minimal. The applicant also stated that significant variability exists within a single year dataset when compared to a 30-year dataset (i.e., data from the Greenville/Spartanburg (Greer) NWS station). As a result, the applicant chose to use the longer-term NWS dataset to minimize variability and more accurately represent long-term averages. The staff notes that the revised WLS COL FSAR Section 2.3.2 clarifies the applicability of the Greenville/Spartanburg (Greer) data, which the staff finds acceptable and, therefore, considers RAI 447, Question 02.03.02-5 resolved.

2.3.2.4.3.1 *Precipitation*

The applicant indicated that precipitation averages 122.9 cm (48.37 in.) annually at the Ninety-Nine Islands cooperative observing station and is generally well distributed throughout the year, as shown in WLS COL FSAR Table 2.3-246, "Ninety-Nine Islands Monthly Climate Summary, NCDC 1971-2000 Monthly Normals," (as reported by the Southeast Regional Climate Center). A total rainfall of 100.9 cm (39.72 in.) was reported for the initial 1-year onsite dataset (December 2005, through November 2006) at the proposed WLS site. In WLS COL FSAR Appendix 2CC.2 of the "Precipitation Comparison" section, the applicant reported a total rainfall of 83.1 cm (32.7 in.) for the second year (December 2006 through November 2007), and cited drought conditions, in addition to geographical influences, as a possible factor for the decrease in precipitation between the two years. The staff independently confirmed the information provided by the applicant and finds it acceptable.

The staff was unable to verify the accuracy of the Greenville/Spartanburg (Greer) NWS data presented in WLS COL FSAR Section 2.3.2.3.1. Therefore, in RAI 447, Question 02.03.02-6, the staff requested that the applicant provide further justification of the data. In a November 25, 2008, response to RAI 447, Question 02.03.02-6, the applicant revised the applicable information regarding precipitation under WLS COL FSAR Sections 2.3.2.1, 2.3.7, and Table 2.3-256, "Precipitation Data (inches of rain) Greenville/Spartanburg, South Carolina," with data reported in the 2007 NCDC LCD summary for Greenville/Spartanburg (Greer), SC. The staff independently verified the new information and finds the response acceptable.

The staff also confirmed the average daily and monthly precipitation and extreme precipitation statistics provided by the applicant in WLS COL FSAR Figures 2.3-242 and 2.3-243 and independently confirmed the accuracy of WLS COL FSAR Tables 2.3-259, 2.3-260, and 2.3-261. The three tables summarized the monthly percent of total observations of precipitation and wind direction, the monthly rainfall frequency distribution, and various precipitation data, including the maximum 24-hour rainfall, at the proposed WLS site. These data showed that the highest rainfall frequency occurs during the months of October through January and the highest frequency directions are north through northeast. The staff finds the applicant's data acceptable.

2.3.2.4.3.2 *Snow*

The applicant stated that the average annual snowfall at the proposed WLS site is approximately 7.6 cm (3.0 in.). This estimate was based on snowfall data from the nearby Ninety-Nine Islands cooperative observing station. Based on the NCDC U.S. Snow Climatology Database for three nearby observation stations (Gaffney 6E, Gaston Shoals, and Ninety-Nine Islands) in Cherokee County, the staff independently confirmed the applicant's annual snowfall estimate to be reasonable.

The applicant also stated that the maximum monthly snowfall at Ninety-Nine Islands was 35 cm (14 in.) in February 1978-79. The staff concluded that the maximum 24-hour snowfall for Cherokee County was approximately 33 cm (13 in.). Therefore, the staff finds the applicant's discussion on particular maximum snowfall amounts acceptable.

2.3.2.4.3.3 *Fog*

The staff notes that onsite fog observations are not taken. The closest observation location that routinely records the occurrence of fog conditions is the NWS station at Greenville/Spartanburg (Greer), SC (approximately 66 km (41 mi) from the WLS site). The applicant stated that this station has averaged approximately 38 hours per year of fog, with November, December, and January having the greatest frequency of occurrence. The staff was unable to confirm these values. Therefore, in RAI 447, Question 02.03.02-7 for clarification on the information reported in the WLS COL FSAR.

In a November 25, 2008, response to RAI 447, Question 02.03.02-7, the applicant stated that its statistics on fog occurrence were based on 9 years (i.e., 1997-2005) of unedited data from the NCDC for Greenville/Spartanburg (Greer), SC, for any hourly observation described as "fog." The applicant also provided a second estimate of 29 hours per year of heavy fog conditions (visibility less than or equal to 0.4 km (0.25 mi) based on 44 years (1964-2007) of edited data from the NCDC LCD summary for the Greenville/Spartanburg (Greer) NWS station. The applicant's original dataset of approximately 38 hours per year of fog was more conservative when compared with the NCDC data, so the applicant retained this dataset.

The staff notes that based on the 2006 NCDC LCD summary for Greenville/Spartanburg airport for a period of 43 years, there are 29.3 days per year, on average, with heavy fog conditions (visibility less than or equal to 0.4 km (0.25 mi). November, December, and January have the highest average number of days with observed heavy fog conditions.

Since these data do not establish design-related site characteristics, the staff accepts the applicant's data as reasonable estimates. However, the staff also recognizes that the higher frequency of occurrence based on the 9-year dataset includes any observation-recorded fog as opposed to those conditions that qualify, more stringently, as "heavy fog." Nevertheless, a higher frequency of occurrence is a reasonably representative indicator for this weather element because of the site's location in the valley of the Broad River.

2.3.2.4.4 Atmospheric Stability

The information presented by the applicant regarding atmospheric stability in WLS COL FSAR Section 2.3.2.4 is not to be understood as having the same meaning as atmospheric stability determined from meteorological tower measurements in accordance with RG 1.23, "Meteorological Monitoring Programs for Nuclear Power Plants," Revision 1 (see WLS COL FSAR Table 2.3-281). In addition to this, the information is not used as input for the dispersion modeling analyses addressed in WLS COL FSAR Sections 2.3.4 and 2.3.5 (see WLS COL FSAR Section 2.3.4.2). Rather, WLS COL FSAR Section 2.3.2.4 discusses atmospheric stability in terms of the frequency and relative strength of temperature inversions based on regional-scale observations taken by balloon soundings.

The applicant evaluated the frequency and strength of inversion layers using 7 years of weather balloon data collected at the Greensboro radiosonde station. An inversion refers to a layer of air in which the dry-bulb temperature increases with height. In WLS COL FSAR Table 2.3-276, “Inversion Heights and Strengths, Greensboro, North Carolina,” the applicant presented annual averages of the number of mornings and afternoons containing temperature inversions, the average elevation of these inversion layers, and the average strength of the inversion, in terms of the change in degrees Celsius per meter in height. The staff compared delta-temperature measurements at the proposed WLS site from December 2005 - November 2006 to the inversion data presented by the applicant. The staff concluded that the average morning and afternoon inversion strength at the proposed WLS site is consistent with those values presented by the applicant. The staff finds the applicant’s discussion on atmospheric stability reasonable and acceptable.

Information on temperature inversions, like the discussions of ventilation rates and air stagnation in WLS COL FSAR Section 2.3.1.2.6, and on mixing heights and ventilation rates in WLS COL FSAR Section 2.3.2.4.1, provides a general indication of atmospheric dispersion potential in the larger region that includes the site. However, information on any of these conditions does not result in the generation of site characteristics used as design or operating bases. The staff finds the applicant’s discussion on atmospheric stability in WLS COL FSAR Section 2.3.2.4 reasonable.

2.3.2.4.4.1 *Mixing Heights*

As indicated previously in this report, the applicant obtained mixing height data based on measurements taken at the Greensboro-High Point, upper air observing station and archived in the EPA Support Center for Regulatory Atmospheric Modeling (SCRAM) database. Initially, the staff was unable to reproduce the mean afternoon mixing height values summarized by the applicant in WLS COL FSAR Table 2.3-277, “Mixing Heights at Greensboro, North Carolina.” Therefore, in RAI 447, Question 02.03.02-8, the staff requested that the applicant verify these values. In a November 25, 2008, response, the applicant stated that the monthly mixing height values were averaged directly from the referenced EPA SCRAM morning and afternoon mixing height data for a 6-year POR (1984-1987, 1990, and 1991). The staff reviewed the averages obtained from this data and finds them correct.

Using the online VCIS database (see Section 2.3.1.4.2.4 of this report), the staff determined average morning mixing heights for the WLS site area about 20 percent lower than mixing heights reported in WLS COL FSAR Table 2.3-277 but with similar month-to-month variation (i.e., lowest values occurring during autumn and highest values seen from about mid-winter to early spring). The VCIS database generated mean afternoon mixing heights within about 10 percent of the values reported in WLS COL FSAR Table 2.3-277. Month-to-month variation is essentially the same with the lowest mixing height values occurring from about mid-autumn to mid-winter and the highest values seen from about mid-spring to mid-summer. At the time of the initial WLS COL FSAR submittal, the VCIS database was available through the Bureau of Land Management. However, this database appears to be unsupported or unavailable for use. The staff notes that the mixing height data has not changed in the latest revision of the WLS COL FSAR and, therefore, the staff still finds this analysis correct and adequate.

The staff recognizes that there are no corresponding site characteristics related to mixing height, nor are these data input for any of the applicant's atmospheric dispersion modeling. Therefore, the staff considers the applicant's discussion of mixing height conditions in the WLS site region reasonable and acceptable.

2.3.2.4.5 Potential Influence of the Plant and Its Facilities on Local Meteorology

WLS COL FSAR Section 2.3.2.5 states that the potential for the operation of WLS Units 1 and 2 to influence (impact) local climatology (meteorological conditions) will be negligible. The applicant later addresses several aspects of plant operations that could have climate-related effects on the environment – particulate emissions (presumably linked to the increased occurrence of fog and haze) and the discharge of heat into the Broad River.

The applicant expects the likely sources of particulate emissions (i.e., infrequent diesel generator operations and a modest increase in vehicular traffic) to only result in a negligible net increase in particulates. Most of the plant heat will be ejected into the atmosphere by the cooling towers, resulting in a relatively small amount of heat input for the Broad River. The applicant then reiterates its earlier conclusion. Although not discussed in much detail, the staff agrees with the applicant's assessment that operational effects on meteorological conditions should be minimal.

In the context of potential construction-related impacts, in WLS COL FSAR Section 2.3.2.5, the applicant briefly describes some of the "climate-shaping" topographic features at and in the area of the proposed WLS site (e.g., the proximity of the proposed WLS site to the Ninety-Nine Islands Reservoir and the Broad River). These features potentially lead to increased humidity levels at the site and demonstrate a slight tendency for the river valley to channel lower-level winds. The applicant also identified several new types of construction activities that will take place at the site (e.g., some ground leveling, some tree removal, the building of plant structures and facilities). The applicant also indicated that no significant changes are predicted or proposed in terms of local hydrologic features and anticipate no changes to local roadways in support of the proposed new facility.

As discussed above, the applicant indicated that there is a slight tendency for the Broad River valley to channel lower-level winds along its length. The staff agrees with this observation but further notes that these conditions appear to be associated with night-time drainage flow as these conditions predominate during moderately and extremely stable atmospheric conditions (i.e., Stability Classes F and G) as indicated by the JFDs presented in WLS COL FSAR Tables 2.3-235 through 2.3-241. This characteristic is important to recognize because it is reflected in the locations of the maximum offsite, accident-related dispersion estimates addressed in WLS COL FSAR Section 2.3.4 and the maximum offsite, routine release-related dispersion estimates discussed in WLS COL FSAR Section 2.3.5.

2.3.2.4.5.1 *Cooling Tower Plumes*

In WLS COL FSAR Revision 9, the applicant's design included three circular mechanical draft cooling towers (CMDCTs). In WLS COL FSAR Revision 9, the design changed to reflect two CMDCTs per unit (4 total), still applicable to the current revision. Each unit will result in the emission of small water droplets entrained in the tower's exhaust airflow (i.e., drift). The droplets contain the dissolved solids found in the circulating water (e.g., salts) that may eventually deposit on the ground as well as on structures, equipment, and vegetation. The use of drift eliminators, which rely on inertial separation caused by exhaust flow directional changes, controls the drift droplet emissions. Drift eliminators installed in the CMDCTs are capable of reducing the emissions to approximately 0.0005 percent of the circulating water flow. Under relatively high wind speeds and humid conditions, the aerodynamic wake turbulence caused by air flowing around the tower housing may result in the visible plume touching down causing ground level fogging and, under freezing conditions, icing.

The applicant stated that an analysis of the potential environmental impacts caused by the operation of CMDCTs was conducted using the EPRI-sponsored Seasonal/Annual Cooling Tower Impact (SACTI) Program. The applicant further chose NWS Charlotte (CLT) wind distributions to represent site conditions. In RAI 447, Question 02.03.02-9, the staff requested that the applicant provide SACTI input files for conducting a confirmatory analysis and a justification for using CLT wind data.

In a November 25, 2008, response to RAI 447, Question 02.03.02-9, the applicant provided SACTI input files and a justification for using NWS data from CLT. The applicant chose CLT data because a 5-year dataset (2001-2005) was available from CLT, but less than 1 year of data was available from the proposed WLS site at the time of the analysis. CLT was judged to be spatially more representative than NWS station at Greenville/Spartanburg in terms of distance from the site and ground elevation. CLT's annual average wind speed and annual average humidity also appear to be closer to onsite data than to the Greenville/Spartanburg (Greer) data. The applicant further performed sensitivity tests to address the differences in the three datasets.

In WLS COL FSAR Table 2.3-278, "Visible Plume Frequency of Occurrence by Season (All Wind Directions)," the applicant provided the visible plume frequency of occurrence by season. The applicant stated that the majority (i.e., greater than 50 percent) of visible plumes did not reach 1000 m (0.6 mi) downwind and 300 m (0.2 mi) in height. The longest and largest visible plumes tend to occur in the winter, with smaller plumes occurring in the spring and especially in the summer. The cold air in winter tends to cause condensation of moist plumes more extensively when compared to warmer seasons because the dewpoint temperature and air temperature are normally closer together nearer the surface, which generally leads to complete saturation. Since both the dewpoint and air temperature are lower, the colder air has a much smaller capacity for holding water vapor. Further, the applicant stated that the largest visible plumes reach a downwind distance of 9900 m (6.2 mi) and a height of approximately 1600 m (1.0 mi) approximately one percent of the time.

In WLS COL FSAR Table 2.3-279, "Frequency of Plume Shadowing by Season (Average for All Wind Directions," the applicant provided the frequency of plume shadowing by season. The applicant stated that consistent with the visible plume frequency results, most plume shadowing occurs in the winter season, with lesser amounts in the spring and fall and the least amounts in the summer. The applicant stated further that plume shadowing effects reach 1200 m (0.75 mi) downwind 1 percent of the time, with the farthest impact reaching approximately 4000 m (2.5 mi) downwind 0.5 percent of the time on an annual basis.

Additionally, the applicant stated that the SACTI output showed that there were virtually no occurrences of ground level fogging, and more importantly, no occurrences of ground-level icing were predicted by SACTI.

In WLS COL FSAR Table 2.3-280, "Maximum Salt Drift Deposition Rate (KG/KM^2/MO), the applicant provided the maximum salt drift rate in kg/km^2 per month. The applicant stated that salt deposition was negligible, with a maximum rate of approximately 1.03 kg/km^2 (2.11E-07 lb/ft^2) per month occurring 200 m (656 ft) to the north of the towers in the summer, and that all other salt deposition amounts are below 1 kg/km^2 (2.05E-07 lb/ft^2) per month.

The staff focused on the salt deposition that would impact the switchyard southwest of Unit 1 and southeast of Unit 2 cooling towers at an approximate distance of 600 m (based on WLS COL FSAR Figure 2.1-201). The staff concluded from the results in WLS COL FSAR Table 2.3-280 that salt deposition to this switchyard would be well below 1 kg/km^2 (2.05E-07 lb/ft^2) per month (worst case 1.03 kg/km^2 (2.11E-07 lb/ft^2) per month).

The applicant stated that the maximum water deposition rate that occurs during the fall season is 740 kg/km^2 (1.52 lb/ft^2) per month at a downwind distance of 900 m (2,950 ft) southeast of the cooling towers. The applicant further stated that this rate was a trivial amount, equivalent to the rainfall equivalent of 0.8 microns (0.00003 in.) per month based on the density of water (i.e., 1000 kg/m^3 (62.43 lb/ft^3)). The staff confirmed the applicant's information based on FSAR Figure 2.3-278.

The applicant provided an electronic copy of the input and output files from the SACTI computer model. The staff reviewed the model input files to assure that the applicant made conservative assumptions. The SACTI results indicate that several months of salt accumulation would result in amounts far below the lower end of the "Light Contamination Level" range defined by the Institute of Electrical and Electronic Engineers (IEEE) standard. The staff independently verified the source cited by the applicant. The staff finds that the description of the total accumulation reaching amounts that require mitigation as highly unlikely because of local precipitation removing any salt deposits before it reaches a level of concern is acceptable and considers RAI 447, Question 02.03.02-9 resolved.

2.3.2.4.6 Topographical Description of the Surrounding Area

In WLS COL FSAR Section 2.3.2.6, the applicant provided a general understanding of the topographic features and characteristics within an 80-km (50-mi) radius of the proposed WLS site. The proposed WLS site is a greenfield site in that there are no operating nuclear units. The applicant indicated that the proposed site is located approximately 910 m (1000 yards) west of the Broad River. The staff notes, however, that at its closest approach the Broad River is only a few hundred yards from the northern boundary of the site based on WLS COL FSAR Figure 1.1-202. The applicant also stated that mountain ridges ranging in height from 300 to 760 m (1000 to 2500 ft) above MSL are located to the northwest, north, and northeast. Although not indicated in the description, the terrain elevation profiles in WLS COL FSAR Figure 2.3-246 show that the highest terrain is located at least 64 km (40 mi) from the proposed WLS site; elevations exceeding 0.3 km (1000 ft) above MSL are located as close as 16 km (10 mi) to the northeast.

Gently rolling hills characterize the terrain in the immediate vicinity of the proposed site. The applicant identified several elevated terrain features within about 8 km (5 mi) of the facility, the most notable being McKowns Mountain, located to the south--southwest with an elevation of approximately 240 m (800 ft) above MSL (or about 60 m (200 ft) above plant grade). Based on WLS COL FSAR Section 2.3.4.1, McKowns Mountain is within 1.6 km (1 mi) from the proposed site.

WLS COL FSAR Figure 2.3-245 displays topographic maps of the areas within 80 and 8 km (50 and 5 mi) of the proposed WLS site. While each sheet does state that the contour interval is 150 m (500 ft), there does not appear to be a reference contour for particular terrain elevations. The staff used WLS COL FSAR Figures 2.5.1-221 and 2.1-204 to provide additional information for the review of the near-field topographical description. Given the information provided in WLS COL FSAR Section 2.3.2.6 and other applicable locations in the application, the staff considers the general topographic description acceptable.

2.3.2.4.7 Current and Projected Site Air Quality Conditions

The applicant's discussion of current air quality conditions near the WLS site in WLS COL FSAR Section 2.3.2.7 presents some similarities with regard to the information pertaining to air quality initially presented in WLS COL FSAR Section 2.3.1.2.6, including similar discussions with respect to the following:

- the 8-hour NAAQS for ozone
- the regulatory citation documenting promulgation of that standard
- identification of the now current attainment status for that criteria air pollutant

Refer to Section 2.3.1.4.2.4 of this report for an explanation of the staff's clarifications and corrections pertaining to this information.

The applicant stated that these air quality characteristics are not expected to be a significant factor in the design and operating bases for proposed Units 1 and 2. The applicant also identified several sources of criteria pollutant emissions during facility operations (e.g., auxiliary boilers, emergency diesel generators, and station blackout generators) but indicated that this equipment should not develop into significant sources of such emissions because it would operate on an intermittent test or emergency basis. The staff agrees with this information and the applicant's assessment of the expected emissions, assuming that the equipment is operated and well maintained in accordance with good practice and any applicable permit requirements.

2.3.2.5 *Post Combined License Activities*

There are no post COL activities associated with this WLS COL FSAR section.

2.3.2.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to local meteorology, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

COL Information Item 2.3-2 states that a COL applicant will provide site-specific local meteorology information. As set forth above, the applicant has presented and substantiated information describing the local meteorological conditions and the air quality and topographic characteristics important to evaluating the adequacy of the design and siting of this plant. The staff reviewed the information provided in COL Information Item 2.3-2 and, for the reasons given above, concludes that the identification and consideration of the meteorological, air quality, and topographical characteristics of the site and the surrounding area are acceptable and meet the requirements of 10 CFR 100.20(c)(2) and 10 CFR 100.21(d). In addition, COL Information Item 2.3-2 includes COL Information Item 2.3-1 when reviewing the design basis dry and wet-bulb site characteristics pertaining to extreme meteorological conditions for the design of structures, systems, and components exposed to the environment and ambient air temperatures. The staff finds that the applicant has provided a sufficient description to adequately address COL Information Item 2.3-2 and, where applicable, COL Information Item 2.3-1.

The staff finds that the applicant has considered the appropriate site phenomena in establishing the site characteristics. Specifically, the staff has accepted the methodologies used to determine the meteorological, air quality, and topographic characteristics. Since the applicant has correctly implemented these methodologies, as described above, the staff finds that the site characteristics, including margins, are sufficient for the limited accuracy, quantity, and period of time in which the data have been accumulated in accordance with 10 CFR 52.79(a)(1)(iii).

2.3.3 Onsite Meteorological Measurements Program

2.3.3.1 *Introduction*

The WLS onsite meteorological measurements program addresses the need for onsite meteorological monitoring and the resulting data. The staff's review covers the following specific areas: (1) meteorological instrumentation, including siting of sensors, sensor type, and performance specifications, methods and equipment for recording sensor output; the quality assurance program for sensors and recorders, data acquisition and reduction procedures, and special considerations for complex terrain sites; and (2) the resulting onsite meteorological database, including consideration of the period of record and amenability of the data for use in characterizing atmospheric dispersion conditions.

The WLS COL FSAR describes a program, which, if successfully implemented, provides an appropriate onsite meteorological measurements program and that data from this program provides an acceptable basis for estimating atmospheric dispersion for DBAs and routine releases from an AP1000 design.

Supplemental information in WLS COL FSAR Section 2.3.6 related to the onsite meteorological measurements program is addressed in this report.

2.3.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.3, incorporates by reference AP1000 DCD, Revision 19, Section 2.3.

AP1000 COL Information Item

- WLS COL 2.3-3

The applicant provided additional information in WLS COL 2.3-3 to address COL Information Item 2.3-3. WLS COL 2.3-3 addresses the onsite meteorological measurements program. In addition, this WLS COL FSAR section addresses Interface Item 2.9 related to the onsite meteorological measurements program.

2.3.3.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria and information needed to evaluate an onsite meteorological measurements program are based on meeting the relevant requirements of NRC regulations under 10 CFR Part 20, 10 CFR Part 50, 10 CFR Part 52, and 10 CFR Part 100. The staff considered the following regulatory requirements in reviewing the applicant's descriptions of the pre-construction (pre-operational) and operational phases of the onsite meteorological measurements program:

- 10 CFR Part 20, Subpart D, as it relates to the meteorological data used to demonstrate compliance with dose limits for individual members of the public. 10 CFR Part 50, Paragraphs 50.47(b)(4), 10 CFR 50.47(b)(8), and 10 CFR 50.47(b)(9), as well as Appendix E, "Emergency planning and preparedness for production and utilization facilities," Section IV.E.2 as they relate to the onsite meteorological information available for determining the magnitude and continuously assessing the impact of releases of radioactive materials to the environment during a radiological emergency.

- 10 CFR Part 50, Appendix A, GDC 19, "Control room," as it relates to the meteorological considerations used to evaluate the personnel exposures inside the control room during radiological and airborne hazardous material accident conditions.

- 10 CFR Part 50, Appendix I, as it relates to meteorological data used in determining compliance with the numerical guides for design objectives and limiting conditions for operation to meet the requirement that radioactive material in effluents released to unrestricted areas be kept as low as is reasonably achievable (ALARA).

- 10 CFR 100.20(c)(2), as it relates to the meteorological characteristics of the site that are necessary for safety analysis or that may have an impact upon plant design in determining the acceptability of a site for a nuclear power plant.

- 10 CFR 100.21(c), as it relates to the meteorological data used to evaluate site atmospheric dispersion characteristics and establish dispersion parameters such that: (1) radiological effluent release limits associated with normal operation can be met for any individual located off site, and (2) radiological dose consequences of postulated accidents meet prescribed dose limits at the EAB and the outer boundary of the LPZ.

The following regulatory guide is applicable for this section:

- RG 1.23, "Meteorological Monitoring Programs for Nuclear Power Plants," Revision 1

NUREG-0800, Section 2.3.3, requires the following acceptance criteria to be provided by a COL applicant:

- The pre-operational and operational phase monitoring programs should be described, including: (1) a site map (drawn to scale) that shows meteorological tower location and True North with respect to manmade structures, topographic features, and other features that may influence site meteorological measurements; (2) distances to nearby obstructions to air flow in each downwind direction sector; (3) measurements made; (4) elevations of measurements; (5) exposure of instruments; (6) instrument descriptions; (7) instrument performance specifications; (8) calibration and maintenance procedures and frequencies; (9) data output and recording systems; and (10) data processing, analysis, and archiving procedures.

- Meteorological data should be presented in the form of JFDs of wind speed and wind direction by atmospheric stability class in the format described in RG 1.23, Revision 1. An hour-by-hour listing of the hourly-averaged parameters should be provided in the format described in RG 1.23, Revision 1. If possible, evidence of how well these data represent long-term conditions at the site should also be presented, possibly through comparison with offsite data.

- At least two consecutive annual cycles (and preferably 3 or more whole years), including the most recent 1-year period, should be provided with the application. If 2 years of onsite meteorological data are not available at the time the application is filed, the staff expects that the applicant will provide at least one annual cycle of meteorological data collected on site with the application. These data should be used by the applicant to calculate: (1) the short-term atmospheric dispersion estimates for accident releases discussed in NUREG-0800, Section 2.3.4; and (2) the long-term atmospheric dispersion estimates for routine releases discussed in NUREG-0800, Section 2.3.5. The applicant should continue to monitor the data and submit the complete 2-year dataset when it has collected all the data. This supplemental submittal should also include a reanalysis of the FSAR Section 2.3.4 and 2.3.5 atmospheric dispersion estimates based on the complete 2-year dataset.

- The applicant should identify and justify any deviations from the guidance provided in RG 1.23, Revision 1.

The following regulatory guides and other related guidance documents were also taken into consideration in the staff's review of WLS COL FSAR Section 2.3.3, as applicable.

- RG 1.206, "Combined License Applications for Nuclear Power Plants," which essentially reiterates the types of information, identified in NUREG-0800, Section 2.3.3, that an applicant should provide in FSAR Section 2.3.3 when describing the pre-operational and operational phase onsite meteorological monitoring programs.

- NUREG-0917 (July 1982), "Nuclear Regulatory Commission Staff Computer Programs for Use with Meteorological Data," which includes a series of computer programs used to examine the quality and validity of an applicant's hourly meteorological data. The staff subsequently adapted these routines to run on a desktop computer spreadsheet program.

2.3.3.4 *Technical Evaluation*

The staff relied upon the review guidance in NUREG-0800, Section 2.3.3 and the regulatory guidance referred to in the preceding subsection to independently assess the technical sufficiency of the information presented by the applicant.

The staff based their evaluation on information obtained during a pre-application readiness assessment held on May 9-10, 2007.[20] The purpose of the readiness assessment was to: (1) become familiar with the then-prospective applicant's site and site selection process, plans, schedules, and initiatives; (2) observe and review the pre-construction (pre--operational) phase onsite meteorological monitoring program; and (3) review the applicant's plans for the operational phase of its onsite monitoring program.

The staff reviewed WLS COL FSAR Section 2.3.3 (including WLS COL 2.3-3) to ensure that the discussion represents the necessary scope of information related to the onsite meteorological measurements programs. The topics related to the siting and instrumentation associated with the onsite meteorological monitoring programs, handling of the collected data (i.e., acquisition, processing, and validation), and the inspection and maintenance of its systems are, for the most part, organized in the same sequence as they were presented in WLS COL FSAR Section 2.3.3. However, section numbering is consistent with the organization of this report. Likewise, section titles are generally similar to those in WLS COL FSAR Section 2.3.3.

2.3.3.4.1 Pre-Operational Meteorological Measurements Program

In WLS COL FSAR Section 2.3.3.1, Revision 0, the applicant stated that there are two meteorological towers at the site. An older meteorological tower (referred to as Tower 1) was part of the original Cherokee Nuclear site. The applicant indicated that Tower 1 did not meet the structural requirements of RG 1.23, Revision 1, and consequently the applicant decided not to use any of that monitoring data to support preparation of the application for WLS Units 1 and 2. The applicant subsequently indicated, beginning in Revision 4 of the application, that Tower 1 was decommissioned in May 2011.

The second meteorological tower (referred to as the primary tower, or Tower 2) was installed for the pre-construction (i.e., pre-operational) measurement phase and began data collection in December 2005 to support the COL application. The second meteorological tower is a 60 m (200 ft) tower with an elevation at the base of about 186 m (611 ft) above MSL, or about 5.5 m

[20] William S. Lee Pre-Application Site Visit: Review of the Pre-Operational Onsite Meteorological Monitoring Program.

(18 ft) higher than the expected final plant grade of 181 m (593 ft) above MSL. The staff agrees with the applicant that Tower 2 is sufficiently removed from any existing structures or significant topographic features, based on the following criteria:

- the staff's pre-application site visit in May 2007
- information depicted in FSAR Figure 2.3-247 (an aerial photograph adapted to illustrate the general locations of current pre-application structures and Towers 1 and 2)
- the near-field topographic map in FSAR Figure 2.3-245 (Sheet 2 of 2)

Consistent with the guidance in RG 1.23, Revision 1, the staff agrees with the applicant that Tower 2 is sufficiently removed from any existing structures or significant topographic features.

The original application submittal in December 2007 included 1 year of onsite meteorological data from Tower 2 covering the period from December 1, 2005, through November 30, 2006. These data were used in WLS COL FSAR Section 2.3.2 to describe local meteorological conditions (i.e., winds, temperature, humidity, and rainfall) and in WLS COL FSAR Sections 2.3.4 and 2.3.5 for estimating short-term and long-term atmospheric dispersion characteristics. However, the guidance in NUREG-0800, Section 2.3.3, and RG 1.23 recommends a minimum of two consecutive annual cycles (i.e., a 24-month period) of onsite meteorological data to be provided at the time of application for a combined license. Therefore, in RAI 448, Question 02.03.03-3, the staff requested that the applicant address this issue.

In a December 17, 2008, response to RAI 448, Question 02.03.03-3, the applicant stated that the evaluation and submittal of the 2-year onsite meteorological dataset was provided in its November 25, 2008, response to RAI 447, Question 02.03.02-1, which included a then-new Appendix 2CC. This appendix presented comparisons of onsite temperature, moisture, atmospheric stability class, precipitation, and winds between the 1- and 2-year datasets and both onsite monitoring periods against longer-term temperature, moisture, and rainfall summaries for the Greenville / Spartanburg, SC, NWS station. Except for the data recovery, Section 2.3.2.4 of this report addresses the staff's evaluation of the response to RAI 447, Question 02.03.02-1.

The applicant's response to RAI 448, Question 02.03.03-3 further supplemented this new Appendix 2CC by comparing or revising estimated short- and long-term atmospheric dispersion factors based on both the 1- and 2-year datasets. The staff's evaluations of these comparisons are provided in Sections 2.3.4.4 and 2.3.5.4 of this report, respectively.

WLS COL FSAR Section 2.3.3.1 concludes by reporting meteorological data recovery statistics for the first year of onsite monitoring at Tower 2 (i.e., for December 2005 through November 2006). Based on the data evaluation, the applicant determined a rate of 96.5 percent for the joint recovery of wind direction, wind speed, and delta-temperature (change in temperature), using the data screening criteria in NUREG-0917, and a rate of 99.2 percent for the same period (presumably for the joint recovery of these parameters) prior to applying this additional screening.

As a follow-up to RAI 448, Question 02.03.03-3 and based on NUREG-0800, Section 2.3.3 and RG 1.23, Revision 1, Regulatory Position C.5, in RAI 6357, Question 02.03.03-5, the staff requested that the applicant provide information demonstrating that 90 percent data recovery was achieved during each annual cycle of the 2-year POR and, because a normalized 2-year dataset had been input into the dispersion modeling, for the composite 2-year period.

- for the joint recovery of all meteorological variables used to model atmospheric dispersion (i.e., the joint frequency of wind speed, wind direction, and atmospheric stability class)
- individually for all measured parameters

In a May 2, 2012, response to RAI 6357, Question 02.03.03-5, the applicant provided a table listing the data recoveries for individual meteorological parameters for the requested times without having applied the data screening criteria in NUREG-0917. While not summarized in the table, the applicant reiterated the 96.5 percent joint recovery rate for the dispersion model input data during the first year of onsite monitoring (December 2005 through November 2006). The applicant also stated the joint recovery rates for the second year of monitoring (December 2006 through November 2007) and the composite 2-year POR as 95.7 and 96.1 percent, respectively, noting also that the NUREG-0917 screening criteria had been applied to these parameters, including the recovery rate for the first yearly record. Data recoveries for the pre-operational onsite meteorological monitoring program meet or exceed the 90-percent objective in RG 1.23, Regulatory Position C. 5, Revision 1. Therefore, the staff considers these data acceptable for use in the summaries and analyses under WLS COL FSAR Sections 2.3.2, 2.3.4, and 2.3.5. Accordingly, the staff considers RAI 448, Question 02.03.03-3 and RAI 6357, Question 02.03.03-5 resolved.

After completion of the pre-construction (pre-operational) monitoring phase, the applicant plans to terminate the meteorological measurement program at Tower 2. Information regarding the monitoring program for the operational phase is discussed in Section 2.3.3.4.2 of this report.

2.3.3.4.1.1 *Tower Configuration, Instrument Descriptions, and Siting*

Tower 2 has two instrumented levels, 10 and 60 m (32 and 200 ft) above ground level, at which ambient dry-bulb temperature, wind speed, and wind direction are measured. The vertical temperature gradient (or delta-temperature), an indicator of atmospheric stability, is calculated based on the difference between the 60-m and 10-m (32 and 200 ft) level temperature measurements. Dewpoint temperature is also measured at the 10-m (32 ft) level. Located near Tower 2, station pressure and ambient temperature measurements are taken at 2 m (7 ft) above ground level; precipitation, incoming solar and outgoing longwave radiation are measured at a height of 1 m (3 ft). Delta-temperature was also determined between the 10 m and 2 m (32 ft and 7 ft) temperature measurement levels but not used in any calculations that rely on atmospheric stability.

The accuracy and (presumed) precision of each instrument was initially provided in WLS COL FSAR Table 2.3-281. In RAI 538, Question 07.05-1, the staff requested, in part, that the applicant define the monitored meteorological parameters in compliance with RG 1.97, Revision 3 as had been committed to in the application. In an October 1, 2009, response, the applicant stated that meteorological monitoring at the Lee Nuclear Station conformed to RG 1.97, Revision 4 per WLS COL FSAR Appendix 1AA and that the meteorological variables are defined consistent with RG 1.97, Revision 3. As part of its October 1, 2009, response to RAI 538, Question 07.05-1, the applicant updated WLS COL FSAR Table 2.3-281 by:

- identifying the measurement range of each instrument
- clarifying the accuracy specifications and measurement resolution (previously referred to as “precision”) of each instrument
- identifying the regulatory or technical basis for all specifications
- adding two other monitoring system variables (i.e., time and data sampling rate)

The applicant stated that all instrumentation and measurements associated with Tower 2 meet the guidance provided in RG 1.23, Revision 1. However, the staff noted that WLS COL FSAR Table 2.3-281 identifies station pressure, incoming solar radiation, and outgoing longwave radiation as optional measurement variables for which the accuracy guidance in ANS/ANSI 3.11-2005 has been adopted as the “state-of-the-art specification” in the absence of such criteria in RG 1.23. The staff finds the applicant’s instrument complement and corresponding specifications for the pre-operational phase acceptable and, therefore, considers RAI 538, Question 07.05-1 resolved.

RG 1.23 states that wind sensors should be located over level, open terrain at a distance of at least 10 times the height of any nearby obstruction, if the height of the obstruction exceeds one-half the height of the wind measurement. The applicant stated that trees and vegetation were cleared around Tower 2 to ensure an open exposure area to meet this criterion. Further, wind and temperature instruments were mounted on 2.4 m (8 ft) booms extending out from the northwest side of the tower, generally oriented perpendicular to the prevailing (predominant) winds. Temperature sensors were housed in aspirated radiation shields. The applicant stated that this configuration should avoid measurement interference that could be caused by the tower itself.

Consequently, based on the applicant’s description of the meteorological equipment installed on Tower 2 and under WLS COL FSAR Section 2.3.3.1, and considering the staff’s pre-application site visit, the staff finds the siting of meteorological Tower 2 and the deployment of its instrumentation acceptable.

2.3.3.4.1.2 *Data Acquisition*

WLS COL FSAR Section 2.3.3.2.1 summarizes the data flow as follows. Electronic signals from the instrument sensors located on or near the meteorological tower are sent to signal conditioning equipment in a co-located instrument shelter/building and from there to a data logger. The data logger then stores the measured data and performs some additional processing. The system also includes provisions for remote access. The data are downloaded from the data logger by a dedicated computer (“central PC”) at the Duke Energy Environmental Center for validation, reporting, and archiving. The onsite meteorological data are then recorded in digital form.

The data acquisition system was one of the topics discussed during the staff's pre-application site visit. The equipment and techniques employed by the applicant meet the recommendations provided in RG 1.23, Regulatory Position C.6, Revision 1.

2.3.3.4.1.3 *Data Processing*

WLS COL FSAR Section 2.3.3.2.2 summarizes the automated processing of the meteorological measurement data from Tower 2 as follows. The data logger, at a minimum of once per second, samples data channels; output from each sensor is scaled to the appropriate units of measure; then 1-minute and 1-hour averages or totals are calculated, recorded, and assigned a time stamp for each calculation. Among the measured parameters:

- wind speed and wind direction are determined as scalar values
- precipitation amounts represent total accumulation
- incoming solar radiation is the total incident shortwave radiation
- outgoing longwave terrestrial radiation represents total upwelling infrared radiation from the ground

The data logger also checks the quality of the data and assigns a quality flag as needed.

RG 1.23, Regulatory Position C.6, Revision 1 states that digital data should be: (1) compiled as 15-minute average values for real-time display in the appropriate emergency response facilities (e.g., the Control Room, Technical Support Center, and Emergency Operations Facility); and (2) compiled and archived as hourly values for use in historical climatic and dispersion analyses. While the first of these two items pertains specifically to the operational phase of the monitoring program, in RAI 448, Question 02.03.03-1, the staff requested that the applicant address these topics in WLS COL FSAR Section 2.3.3.2.2.

The applicant provided the requested information in Revision 1 of the COL application, but only with respect to the first item. In a May 2, 2013, response to RAI 448, Question 02.03.03-1, the applicant correctly pointed out that WLS COL FSAR Sections 2.3.3.2.2 and 2.3.3.2.3 already addressed the compilation and archival of hourly data values. The staff agrees with that portion of the applicant's response as well as the revisions made. Data processing was one of the topics discussed during the staff's pre-application site visit. The staff finds that the equipment and techniques employed meet the recommendations provided in RG 1.23, Regulatory Position C.6, Revision 1. Accordingly, the staff considers RAI 448, Question 02.03.03-1 resolved.

2.3.3.4.1.4 *Data Validation*

WLS COL FSAR Section 2.3.3.2.3 briefly summarizes the data review and validation process as follows:

- daily data are reviewed to detect system problems and to perform preliminary data verifications

- onsite system checks are conducted by field staff at least monthly to verify proper operation of the systems

- site technicians review all of the meteorological data collected for the previous month after completion of the system checks

In-house personnel, including a staff meteorologist, also review the data. Following these reviews, the database is edited, as necessary, on the central computer. Both raw (unedited) and quality assured (edited) data are archived, along with backup copies, on the central computer.

The data review process was among the topics discussed during the staff's pre-application site visit. The staff finds the applicant's general approach to data review and validation consistent with the intent of achieving a valid data recovery rate of at least 90 percent on an annual basis as stated in RG 1.23, Regulatory Position C.5, Revision 1.

2.3.3.4.1.5 *Inspection and Maintenance of Meteorological Instrumentation*

WLS COL FSAR Section 2.3.3.3 states that meteorological equipment (i.e., sensors, recorders, electronics, data logger, etc.) are inspected and serviced at a frequency designed to assure at least 90 percent data recovery, as specified in RG 1.23, Revision 1, and to minimize extended periods of instrument outage. This process includes the performance of field checks, field calibrations, or replacement by laboratory-calibrated components. Equipment is either calibrated or replaced after at least every 6 months of service. A reserve of spare parts and equipment is maintained to minimize periods of instrument outage. Administrative controls such as maintenance procedures are used to calibrate and maintain meteorological and station equipment. Records documenting the results of calibrations, major causes of instrument outages or drift from calibration, and corrective action taken are maintained. The meteorological instrumentation inspection, maintenance, and calibration processes summarized by the applicant meet the intent of RG 1.23, Regulatory Position C.5, Revision 1, for achieving acceptable data recovery and are, therefore, acceptable to the staff.

2.3.3.4.2 Operational Meteorological Measurement Program

The applicant's initial description of the onsite meteorological measurement program for the operational phase is somewhat limited. WLS COL FSAR Section 2.3.3 and Section 2.3.3.1 briefly indicated that the applicant plans to end the pre-operational monitoring program at Tower 2 and install a new permanent meteorological tower at a different location on the plant site to support operation of WLS Units 1 and 2. WLS COL FSAR Section 2.3.3.3 states that monitoring is continuous during the operational phase beginning with initial fuel loading and continuing through the life of the plant. The applicant further states that the meteorological program "has been developed to be consistent with the guidance given in RG 1.23, Revision 1." Its basic objective is "to maintain data collection performance to assure at least 90 percent joint recoverability and availability of data needed for assessing the relative concentrations and doses resulting from accidental or routine releases."

In RAI 448, Question 02.03.03-2, the staff requested that the applicant address the following aspects of the operational phase of the onsite meteorological measurement program:

- the siting of Tower 3, including tower elevation, and the representativeness of the location and resultant data
- a comparison of the meteorological data between Tower 2 and Tower 3 for data consistency
- proposed or existing nearby obstructions, including distance from the tower (such as the containment building, cooling towers, trees, nearby terrain, etc.), and the potential impact on the accuracy and representativeness of the measurements
- the instrument maintenance and servicing schedules and the planned data reduction and compilation procedures for the operational meteorological program (including data acquisition, processing, and validation)
- how data from the operational program will be used to support emergency preparedness procedures, compiled and archived for later use

In a December 17, 2008, response to RAI 448, Question 02.03.03-2, the applicant stated that the data collected from Tower 2 would continue to serve as the licensing basis for the application and that Tower 3 was not erected with the intent of providing data in support of the application. The applicant also stated in the response that monitoring at Tower 3 was not yet operational and that a full year of data would not be collected until the end of 2009. The applicant also indicated its expectation to transition from Tower 2 to Tower 3 as the recognized source of onsite meteorological data following receipt of a combined license and prior to receipt of fuel.

The applicant stated that Tower 3 will comply with the guidance in RG 1.23, Revision 1, and that it will use the same procedures and maintenance / servicing schedules as Tower 2 that are already described in WLS COL FSAR Section 2.3.3.3. The applicant also stated that the compilation and archiving of meteorological data are addressed in WLS COL FSAR Section 2.3.3.2 and that the use of meteorological data in emergency planning is described in Lee Nuclear Station Emergency Plan, Section II.H.8 and Appendix 2. This addresses to the fourth and fifth items of RAI 448, Question 02.03.03-2.

NUREG-0800, Section 2.3.3 provides guidance for the staff to make two findings through its evaluation of the onsite meteorological monitoring program. The first is how the program relates to determining the acceptability of the site (based on the data measured at the tower site and as input for required atmospheric dispersion modeling analyses), and the second is the monitoring program's adequacy to support facility operations. Regarding the latter, NUREG-0800, Section 2.3.3, Subsection IV states that the staff should verify that the applicant has provided sufficient information to conclude that the equipment that measures meteorological parameters during the course of accidents is sufficient to provide reasonable prediction of atmospheric dispersion of airborne materials in accordance with 10 CFR Part 50, Appendix E. The staff considers RAI 448, Question 02.03.03-2 resolved.

In follow-up RAI 6357, Question 02.03.03-4, the staff requested that the applicant provide information that would allow the staff to complete its evaluation of the adequacy and acceptability of the onsite meteorological measurement program for the operational phase pursuant to:

- 10 CFR 50.47(b)(8) and (b)(9) via 10 CFR 52.79(a)(21), as it relates to emergency planning
- RG 1.206, Section C.IV.4.2, as it relates to the treatment of operational programs in the applications
- 10 CFR 52.79(a)(41), as it relates to the staff's evaluation against relevant NUREG-0800 acceptance criteria

The staff requested that the applicant update WLS COL FSAR Section 2.3.3 by either completing the descriptions of the operational monitoring program or justifying why they did not need this information. Consistent with guidance in NUREG-0800, Section 2.3.3, Subsection II and RG 1.23, Revision 1, the staff requested that the applicant provide or specify the following:

- a site map (to scale) showing the location of Tower 3 relative to any existing and planned structures for the proposed facility and topographic and other features that may influence site meteorological measurements
- a corresponding list of distances from Tower 3 to nearby obstructions to air flow by direction sector
- an update to WLS COL FSAR Table 2.3-281 or a separate listing of the performance specifications for the meteorological instrumentation to be installed on Tower 3
- the elevation at the base of Tower 3 relative to finished grade elevations at existing (if applicable) and planned structures (e.g., cooling towers, buildings from which accident or routine radioactive releases to the atmosphere may occur, trees or other vegetation, topographic features)
- the orientation and length of the various instrument booms at all tower levels, the type of tower construction, and longest horizontal dimension (side) of the tower
- the characteristics of the surface underlying the meteorological tower

In a May 2, 2012, response to RAI 6357, Question 02.03.03-4, the applicant included changes to WLS COL FSAR Section 2.3.3.1 that designate Tower 3 as the permanent meteorological (MET) tower, identify the tower's relative location on the plant site, and state that it is sufficiently removed from the influence of permanent plant structures and topographical features (supported by an updated version of WLS COL FSAR Figure 1.1-202). The applicant also indicated the elevation of the tower at its base (i.e., 181.5 m (595.5 ft) above MSL), which is about 1.5 m (5 ft) above expected plant grade.

Further, these changes reiterate that the instrumentation associated with the Permanent MET Tower meets the guidance provided in RG 1.23, Revision 1, consolidate information about the sensors installed on all towers in an update to WLS COL FSAR Table 2.3-281, and indicate that nearby trees and vegetation were also cleared around Tower 3 to ensure an open exposure. The staff notes that updates to WLS COL FSAR Section 2.3.3.2.2 clarify the processing and storage of 1-minute and 1-hour data averages by the data logger.

Part of the applicant's May 2, 2012, response to RAI 6357, Question 02.03.03-4 included a separate listing of distances between potential obstructions to airflow and the Permanent MET Tower, along with two separate figures to illustrate, in more detail, their relative orientations to and distances from the tower. The staff finds that this information, although not incorporated into the WLS COL FSAR but retained as part of the response to RAI 6357, Question 02.03.03-4, demonstrates that the separation criterion from such obstructions in RG 1.23 is satisfied. WLS COL FSAR Figure 1.1-202, "Site Layout," provides a detailed representation of the location of Tower 3 in relation to other plant structures.

In addition, the applicant's response to RAI 6357, Question 02.03.03-4 indicated that the Permanent MET Tower is an open-lattice structure installed above a natural, grassy surface. The "tower" (instrument) booms are 2.4 m (8 ft) in length and oriented to 300 degrees relative to True North and that the sensor cross-arm assemblies are more than two tower widths away from the tower. This information demonstrates that potential influences of the tower and underlying ground surface should have negligible effects on wind and temperature measurements made at the 10-m and 60-m (32 and 197 ft) levels of the tower.

Given the applicant's statements that the onsite meteorological measurements program during the operational phase will be the same as the pre-construction (pre-operational) monitoring program (in terms of instrument complement and specifications; data acquisition, processing, and validation; and implementation of inspection and maintenance procedures) and given the applicant's responses to RAI 448, Question 02.03.03-2 and RAI 6357, Question 02.03.03-4, the staff expects the operational meteorological monitoring program to be established and operated in conformance to RG 1.23, Regulatory Positions C.2 through C.6, and C.8, Revision 1. Therefore, the staff considers this acceptable. Accordingly, the staff considers RAI 448, Question 02.03.03-2 and RAI 6357, Question 02.03.03-4 resolved.

2.3.3.5 *Post Combined License Activities*

Part 10 of the WLS COL application describes COL conditions, including inspections, tests, analyses, and acceptance criteria (ITAAC). Table 3.8-1 in Part 10 of the WLS COL application contains the emergency planning (EP) ITAAC. The following two EP ITAAC involve demonstrating that the operational onsite meteorological monitoring program appropriately supports the emergency plan for WLS Units 1 and 2:

- EP-ITAAC 6.3: The means exist to continuously assess the impact of the release of radioactive materials to the environment, accounting for the relationship between effluent monitor readings, and onsite and offsite exposures and contamination for various meteorological conditions. An analysis of emergency plan implementing procedures will be performed to demonstrate that the corresponding acceptance criterion has been—that is, that a methodology has been provided to establish the relationship between effluent monitor readings and onsite and offsite exposures and contamination for various radiological conditions.

- EP-ITAAC 6.4: The means exist to acquire and evaluate meteorological information. An inspection of the control room, Technical Support Center (TSC), and Emergency Operations Facility will be performed to demonstrate that the corresponding acceptance criterion has been met, that is, that the specified meteorological data (i.e., wind speed, wind direction, and air temperature at the 10-m and 60-m (32 ft and 197 ft) levels) were available at these facilities.

EP, including EP ITAAC is addressed in Section 13.3, "Emergency Planning" of this report.

2.3.3.6 *Conclusion*

The staff reviewed the application, including the information provided as WLS COL 2.3-3, evaluated the applicant's responses to several RAI questions issued as a result of that review, and checked the referenced AP1000 DCD. The staff's review confirmed that the applicant has addressed the required information relating to the onsite meteorological measurements programs for the pre-operational and operational phases. The staff notes there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section.

COL Information Item 2.3-3 states that a COL applicant shall address the site-specific onsite meteorological measurements program. As set forth above, the applicant has presented and substantiated information pertaining to the onsite meteorological measurements program and the resulting database. The staff reviewed the information provided in WLS COL 2.3-3. The staff concludes that the applicant has established consideration of the onsite meteorological measurements program, and the resulting databases are acceptable and meet the requirements of 10 CFR 100.20 with respect to determining the acceptability of the site. The staff also finds that the onsite data also provide an acceptable basis for making estimates of atmospheric dispersion for DBA and routine releases from the plant to meet the requirements of 10 CFR 100.21, GDC 19, 10 CFR Part 20, and 10 CFR Part 50, Appendix I. Finally, the equipment provided for measurement of meteorological parameters during the course of accidents is sufficient to provide reasonable prediction of atmospheric dispersion of airborne radioactive materials in accordance with 10 CFR Part 50, Appendix E. Part 5, "Emergency plan" of the WLS COL application identifies alternative offsite sources of meteorological data during an emergency. The staff finds that the applicant has provided a sufficient description to adequately address COL Information Item 2.3-3.

2.3.4 Short-Term Diffusion Estimates

2.3.4.1 *Introduction*

The short-term diffusion estimates are used to determine the amount of airborne radioactive materials expected to reach a specific location during an accident situation. The diffusion estimates address the requirement for conservative atmospheric dispersion (relative concentration) factor (χ/Q value) estimates at the EAB, the outer boundary of the LPZ, and at the control room for postulated design-basis accidental radioactive airborne releases. The review covers the following specific areas: (1) atmospheric dispersion models to calculate atmospheric dispersion factors for postulated accidental radioactive releases; (2) meteorological data and other assumptions used as input to atmospheric dispersion models; (3) derivation of diffusion parameters (e.g., σ_y and σ_z); (4) cumulative frequency distributions of χ/Q values; (5) determination of conservative χ/Q values used to assess the consequences of postulated design-basis atmospheric radioactive releases to the EAB, LPZ, and control room; and (6) any additional information requirements prescribed in the "Contents of application" sections of the applicable subparts to 10 CFR Part 52, "Licenses, certifications, and approvals for nuclear power plants." This section of the report also addresses the supplemental information in WLS COL FSAR Section 2.3.6 related to the short-term diffusion estimates.

2.3.4.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.3, incorporates by reference AP1000 DCD, Section 2.3.

In addition, in WLS COL FSAR Section 2.3, the applicant addressed the following:

Departures

- WLS DEP 18.8-1

The applicant provided additional information in WLS COL 2.3-4 to address COL Information Item 2.3-4. WLS COL 2.3-4 addresses the provision of site-specific short-term diffusion estimates for staff review to ensure that the bounding values (AP1000 DCD, Appendix 15A, Table 2-1) of relative concentrations are not exceeded. In addition, this WLS COL FSAR section addresses Interface Item 2.4 related to the limiting meteorological parameters (χ/Q) for DBAs.

AP1000 COL Information Item

- WLS COL 2.3-4

The applicant provided additional information in WLS COL 2.3-4 to address COL Information Item 2.3-4 (COL Action Item 2.3.4-1). WLS COL 2.3-4 addresses the provision of site-specific short-term diffusion estimates for NRC review to ensure that the bounding values (Table 2-1 and Appendix 15A from the AP1000 DCD) of relative concentrations are not exceeded.

In addition, this WLS COL FSAR section addresses Interface Item 2.4 related to the limiting meteorological parameters (χ/Q) for DBAs.

2.3.4.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The applicable regulatory requirements for the applicant's description of atmospheric diffusion estimates for accidental releases are as follows:

- 10 CFR Part 50, Appendix A, GDC 19, as it relates to the meteorological considerations used to evaluate the personnel exposures inside the control room during radiological and airborne hazardous material accident conditions.

- 10 CFR 52.79(a)(1)(vi), as it relates to a safety assessment of the site, including consideration of major SSCs of the facility and site meteorology, to evaluate the offsite radiological consequences at the EAB and LPZ.

- 10 CFR 100.21(c)(2), as it relates to the atmospheric dispersion characteristics used in the evaluation of the EAB and LPZ radiological dose consequences for postulated accidents.

NUREG-0800, Section 2.3.4 recommends the following acceptance criteria to be provided by a COL applicant:

- A description of the atmospheric dispersion models used to calculate χ/Q values for accidental releases of radioactive and hazardous materials to the atmosphere. The models should be documented in detail and substantiated within the limits of the model so that the staff can evaluate their appropriateness of use with regard to release characteristics, plant configuration, plume density, meteorological conditions, and site topography.

- Meteorological data used for the evaluation (as input to the dispersion models), which represent annual cycles of hourly values of wind direction, wind speed, and atmospheric stability for each mode of accidental release. Any dispersion estimates should be calculated from the most representative meteorological data available for the site.

- A discussion of atmospheric diffusion parameters, such as lateral and vertical plume spread (σ_y and σ_z) as a function of distance, topography, and atmospheric conditions should be related to measured meteorological data. The methodology for establishing these relationships should be appropriate for estimating the consequences of accidents within the range of distances which are of interest with respect to site characteristics and established regulatory criteria.

- Hourly cumulative frequency distributions of χ/Q values from the effluent release point(s) to the EAB and outer boundary of the LPZ should be constructed to describe the probabilities of these χ/Q values being exceeded. All cumulative frequency distributions of χ/Q values should be presented for appropriate distances (as indicated above) and time periods as specified in RG 1.206, Part I, Subsection C.I.2.3.4.2. The methods for generating these distributions should be adequately described.

- Atmospheric dispersion factors used for the assessment of consequences related to atmospheric radioactive release to the control room for design-basis, other accidents, and onsite and off-site releases of hazardous airborne materials should be provided.

- For control room habitability analysis, a site plan drawn to scale should be included showing true North and potential atmospheric accident release pathways, control room air intake(s), and unfiltered in-leakage pathways.

The following regulatory guides and other related guidance documents were also taken into consideration in the staff's review of WLS COL FSAR Section 2.3.4, as applicable:

- RG 1.23, “Meteorological Monitoring Programs for Nuclear Power Plants” Revision 1, which includes guidance on the measurement and processing of onsite meteorological data for use as input to atmospheric dispersion models in support of plant licensing.

- RG-1.145, “Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants”, Revision 1, which provides guidance on appropriate dispersion models for estimating offsite relative air concentrations (χ/Q values) as a function of downwind direction and distance (i.e., at the EAB and outer boundary of the LPZ) for various short-term time periods (up to 30 days) after an accident, provisions and guidance to account for ground-level and elevated releases, meteorological conditions, and modified plume dispersion due to building wake effects, plume meander under low wind speed conditions, non-straight plume trajectories, and fumigation conditions at coastal and inland site locations.

- RG-1.194, “Atmospheric Relative Concentrations for Control Room Radiological Habitability Assessments at Nuclear Power Plants”, which discusses acceptable approaches for estimating short-term (i.e., 2 hours to 30 days post-accident) average χ/Q values in the vicinity of buildings at control room ventilation air intakes and at other locations of significant air in-leakage to the control room envelope due to postulated design-basis accidental radiological airborne releases, provisions and guidance for determining release point characteristics, receptors, source-receptor distances and directions, and meteorological input data.

- RG 1.206, “Combined License Applications for Nuclear Power Plants”, which summarizes the types of information, identified in NUREG-0800, Section 2.3.4, that an applicant should provide in FSAR Section 2.3.4 for estimating dispersion factors (χ/Q values) used to assess the consequences of design-basis and other accidental atmospheric radiological releases on control room habitability.

- NUREG/CR-2858 (November 1982), “PAVAN: An Atmospheric Dispersion Program for Evaluating Design Basis Accidental Releases of Radioactive Materials from Nuclear Power Stations”, prepared by Pacific Northwest Laboratory (PNL-4413), the user’s manual for the NRC-sponsored PAVAN dispersion model.

- NUREG/CR-6331 (Revision 1, May 1997), “Atmospheric Relative Concentrations in Building Wakes”, prepared by Pacific Northwest National Laboratory (PNNL-10521), the user’s manual for the NRC-sponsored ARCON96 dispersion model.

2.3.4.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.3.4 and checked the applicable site parameters in AP1000 DCD Tier 2, Table 2-1, to ensure that the combination of the DCD and the information in the COL application represent the complete scope of information relating to this review topic. The staff’s review confirmed that the information contained in the application and incorporated by reference addresses the required information relating to the short-term dispersion estimates. AP1000 DCD, Section 2.3.4 was reviewed by the staff under Docket

Number 52-006. The results of the staff's evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

The staff reviewed the information contained in the WLS COL FSAR corresponding to the following:

AP1000 COL Information Item

- WLS COL 2.3-4

The staff reviewed information related to the short-term diffusion estimates of accidental releases to the atmosphere included by the applicant under WLS COL FSAR Section 2.3.4 in response to COL Information Item 2.3-4. The specific text of this COL Information Item in AP1000 DCD, Section 2.3.6.4 states:

> Combined License applicants referencing the AP1000 certified design will address the site-specific χ/Q values specified in subsection 2.3.4. For a site selected that exceeds the bounding χ/Q values, the Combined License applicant will address how the radiological consequences associated with the controlling design basis accident continue to meet the dose reference values given in 10 CFR Part 50.34 and control room operator dose limits given in General Design Criteria 19 using site-specific χ/Q values. The Combined License applicant should consider topographical characteristics in the vicinity of the site for restrictions of horizontal and/or vertical plume spread, channeling or other changes in airflow trajectories, and other unusual conditions affecting atmospheric transport and diffusion between the source and receptors.
> No further action is required for sites within the bounds of the site parameters for atmospheric dispersion.
>
> With regard to assessment of the postulated impact of an accident on the environment, the COL applicant will provide χ/Q values for each cumulative frequency distribution that exceeds the median value (50 percent of the time).

Regarding the latter portion of WLS COL 2.3-4, the staff notes that the postulated impact of an accident on the environment is addressed in the Environmental Report. The staff relied upon the review procedures presented in NUREG-0800, Section 2.3.4, to independently assess the technical sufficiency of the information presented by the applicant.

2.3.4.4.1 Atmospheric Dispersion Models

2.3.4.4.1.1 *Offsite Dispersion Estimates*

The applicant used the PAVAN computer code (NUREG/CR-2858, "PAVAN: An Atmospheric Dispersion Program for Evaluating Design-Basis Accidental Releases of Radioactive Materials from Nuclear Power Stations") to estimate ground-level χ/Q values at the EAB and at the outer boundary of the LPZ for potential accidental releases of radioactive material to the atmosphere. The PAVAN model implements the methods outlined in RG 1.145.

The PAVAN code estimates χ/Q values for various time-average periods ranging from 2 hours to 30 days. The meteorological input to PAVAN consists of a JFD of hourly values of wind speed and wind direction by atmospheric stability class. The χ/Q values calculated through PAVAN are based on the theoretical assumption that material released to the atmosphere will be normally distributed (Gaussian) about the plume centerline. A straight-line trajectory is assumed between the point of release and all downwind receptor distances for which χ/Q values are calculated.

For each of the 16 downwind direction sectors (true North, North-Northeast, Northeast, East-Northeast, etc.), PAVAN calculates χ/Q values for each combination of wind speed and atmospheric stability at the appropriate downwind distance (i.e., the EAB and the outer boundary of the LPZ). The χ/Q values calculated for each sector are then ordered from greatest to smallest and an associated cumulative frequency distribution is derived based on the frequency distribution of wind speed and stabilities for each sector. The smallest χ/Q value in a distribution will have a corresponding cumulative frequency equal to the wind direction frequency for that particular sector. PAVAN determines for each sector an upper envelope curve based on the derived data (plotted as χ/Q versus probability of being exceeded), such that no plotted point is above the curve. From this upper envelope, the χ/Q value, which is equaled or exceeded 0.5 percent of the total time, is obtained. The maximum 0.5 percent χ/Q value from the 16 sectors becomes the 0-2 hour “maximum sector χ/Q value.”

Using the same approach, PAVAN also combines all χ/Q values independent of wind direction into a cumulative frequency distribution for the entire site. An upper envelope curve is determined, and the program selects the χ/Q value which is equaled or exceeded 5.0 percent of the total time. This is known as the 0-2 hour “5-percent overall site χ/Q value.”

The larger of the two χ/Q values, either the 0.5-percent maximum sector value or the 5-percent overall site value, is selected to represent the χ/Q value for the 0-2 hour time interval (note that this resulting χ/Q value is based on 1-hour averaged data but is conservatively assumed to apply for 2 hours). An alternative method to determine the χ/Q value for the 0-2 hour time interval is to retain the maximum possible χ/Q value based on the distance, calm wind speeds, and G-stability.

To determine χ/Q values for longer time periods (i.e., 0-8 hour, 8-24 hour, 1-4 days, and 4-30 days), PAVAN performs a logarithmic interpolation between the 0-2 hour χ/Q value and the corresponding annual average (8760-hours) χ/Q value for each of the 16 sectors and overall site. For each time period, the highest among the 16 sectors and overall site χ/Q values are identified and are designated as the short-term site characteristic χ/Q value for that time period.

2.3.4.4.1.2 *Control Room Dispersion Estimates*

The applicant used the computer code ARCON96 (NUREG/CR-6331, “Atmospheric Relative Concentrations in Building Wakes”) to estimate χ/Q values at the control room for potential accidental releases of radioactive material. The ARCON96 model implements the methods outlined in RG 1.194, “Atmospheric Relative Concentrations for Control Room Radiological Habitability Assessments at Nuclear Power Plants.”

The ARCON96 code estimates χ/Q values for various time-averaged periods ranging from 2 hours to 30 days. The meteorological input to ARCON96 consists of hourly values of wind speed, wind direction, and atmospheric stability class. The χ/Q values calculated through ARCON96 are based on the theoretical assumption that material released to the atmosphere will be normally distributed (Gaussian) about the plume centerline. A straight-line trajectory is assumed between the release points and receptors. The diffusion coefficients account for enhanced dispersion under low wind speed conditions and in building wakes.

The hourly meteorological data are used to calculate hourly relative concentrations. The hourly relative concentrations are then combined to estimate concentrations ranging in duration from 2 hours to 30 days. Cumulative frequency distributions, prepared from the average relative concentrations and the relative concentrations that are exceeded no more than five percent of the time for each averaging period, are determined.

2.3.4.4.2 Meteorological Input Data

2.3.4.4.2.1 *Offsite Dispersion Estimates*

The meteorological data input to the PAVAN dispersion model is in the form of a JFD of wind speed and wind direction by atmospheric stability class. The structure of the JFD meets the intent of the guidance in RG 1.23, Regulatory Position C.6, Revision 1, and the resolution of lower wind speed classes as recommended in the review procedures under NUREG--0800, Section 2.3.3.

As indicated previously, the JFD was prepared based on hourly-averaged onsite measurements for a 2-year POR from December 1, 2005, through November 30, 2007. Wind data were obtained from the 10-m (32 ft) level of the onsite meteorological tower; stability data were derived from the vertical temperature difference between the 60 m and 10 m (197 and 32 m) measurement levels.

With regard to the 1-year of meteorological data, RG 1.23, Revision 1, states that the minimum amount of onsite meteorological data to be provided at the time of application for a combined license is a consecutive 24-month period of data that is defendable, representative, and complete but not older than 10 years from the date of the application. However, the guidance further states that three or more years of data are preferable and, if available, should be submitted with the application. To rectify this deviation from guidance, in RAI 448, Question 02.03.03-3, the staff requested that the applicant address the scope of the meteorological dataset.

In a December 17, 2008, response to RAI 448, Question 02.03.03-3, the applicant included a 2-year meteorological dataset for the period December 1, 2005, through November 30, 2007. Additionally, In WLS COL FSAR, Appendix 2CC, the applicant provided an evaluation of short-term offsite dispersion estimates based on the 2-year dataset with a comparison against the 1-year site characteristic χ/Q values and the corresponding site parameter χ/Q values in the AP1000 DCD. The applicant stated that the site characteristic χ/Q values were consistent for the two datasets.

The staff observed the consistency identified by the applicant but also observed that the 2-year short-term offsite dispersion estimates were generally higher, and therefore the use of the 1-year dataset appeared to be non-conservative when compared to the 2-year dataset. Therefore, in follow-up RAI 3726, Question 02.03.04-4, the staff requested that the applicant resolve the issue. In an April 6, 2010, response to RAI 3726, Question 02.03.04-4, the applicant included an analysis of the 2-year short-term offsite dispersion estimates and updated both text and tables relating to these estimates. The staff reviewed and confirmed the updated text and tables from the RAI and confirmed that these changes were incorporated into the WLS COL FSAR. Accordingly, the staff finds the response to RAI 3726, Question 02.03.04-4 acceptable and considers the RAI resolved. Subsequent revisions to the WLS COL FSAR removed the comparison of 1-year and 2-year of short-term offsite dispersion estimates from WLS COL FSAR Appendix 2CC.

The staff completed a detailed review related to the acceptability and representativeness of the hourly meteorological data as discussed in Sections 2.3.2 and 2.3.3 of this report. Based on this review, the staff considers the onsite meteorological database suitable for input to the PAVAN model.

2.3.4.4.2.2 *Control Room Dispersion Estimates*

The meteorological data input to the ARCON96 dispersion model consisted of hourly-averaged values of wind speed, wind direction, and atmospheric stability class covering a 2-year POR of onsite measurements from December 1, 2005, through November 30, 2007. The wind data were obtained from the 10 m and 60 m (32 and 197 ft) levels of the onsite meteorological tower (the 60 m (197 ft)) wind data were only used by the model when data from the 10 m (32 ft) level were unavailable). The stability data were derived from the vertical temperature difference between the 60 m and 10 m (32 and 197 ft) measurement levels.

The staff completed a detailed review related to the acceptability and representativeness of the hourly meteorological data as discussed in Sections 2.3.2 and 2.3.3 of this report. Based on this review, the staff considers the onsite meteorological database suitable for input to the ARCON96 model.

2.3.4.4.3 Diffusion Parameters

2.3.4.4.3.1 *Offsite Dispersion Estimates*

The applicant chose to implement the diffusion parameter assumptions outlined in RG 1.145, Revision 1, as a function of atmospheric stability and downwind distance from the source, for its PAVAN model runs. Significant local topography can influence short-term dispersion estimates. In RAI 449, Question 02.03.04-1, the staff requested that the applicant discuss the potential effects of the local topography on the atmospheric dispersion estimates. In an October 10, 2008, response to RAI 449, Question 02.03.04-1, the applicant included an update to WLS COL FSAR Section 2.3.4.1. In the response the applicant described the terrain in the immediate vicinity of the site as gently rolling hills and that McKowns Mountain was the only notable terrain feature. Further, the applicant stated that the mountain peak was approximately 61 m (200 ft) above plant grade at a distance of approximately 1.6 km (1 mi). Given the distance and minimal elevation rise, the applicant concluded that McKowns Mountain would have no significant effect on short term diffusion estimates. The staff agrees with the discussion provided in the applicant's response to RAI 449, Question 02.03.04-1 and confirmed that the proposed changes were incorporated into the WLS COL FSAR. Accordingly, the staff considers RAI 449, Question 02.03.04-1 resolved.

The staff evaluated the applicability of the PAVAN diffusion parameters and concluded that no unique topographic features (such as rough terrain, restricted flow conditions, coastal or desert areas) preclude the use of the PAVAN model for the proposed WLS site. Therefore, the staff finds that the applicant's use of diffusion parameter assumptions, as outlined in RG 1.145, Revision 1, acceptable.

2.3.4.4.3.2 *Control Room Dispersion Estimates*

The diffusion coefficients used in ARCON96 have three components. The first component is the diffusion coefficient used in other NRC models such as PAVAN. The other two components are corrections to account for enhanced dispersion under low wind speed conditions and in building wakes. These components are based on analysis of diffusion data collected in various building wake diffusion experiments under a range of meteorological conditions. Since the diffusion occurs at short distances within the plant's building complex, the ARCON96 diffusion parameters are not affected by nearby topographic features such as bodies of water or elevated terrain. Therefore, the staff finds the applicant's use of the ARCON96 diffusion parameter assumptions acceptable.

2.3.4.4.4 Relative Concentrations for Accident Consequences Analyses

2.3.4.4.4.1 *Conservative Short-Term Atmospheric Dispersion Estimates for the EAB and LPZ*

The applicant stated that it modeled one ground-level release point for each unit by assuming a 136 m (448 ft) radius circle, centered on each unit's containment, which encompasses all release points. Further, the applicant stated it conservatively estimated the area of the reactor building to be used for determining wake effects by calculating the above ground, cross-sectional area of the shield building. Shorter EAB and LPZ distances (assuming the 136 m (448 ft) radius circle) resulted in higher (more conservative) χ/Q values. The LPZ distances are defined by a 3.2 km (2 mi) radius circle centered on the midpoint between Units 1 and 2 containment buildings. A ground-level release with the stated assumptions is consistent with RG 1.145, Revision 1 and, therefore, is acceptable to the staff.

In accordance with AP1000 DCD, Section 2.3.6.4, WLS COL FSAR Section 2.3.4.2 compared the site characteristic EAB and LPZ χ/Q values to the corresponding site parameters provided in the DCD. This comparison, provided in WLS COL FSAR Table 2.0-201, showed that the

AP1000 DCD EAB and LPZ χ/Q values conservatively bound the site characteristic χ/Q values.[21]

Using the information provided by the applicant, including the 10 m (32 ft) level joint frequency distributions of wind speed, wind direction, and atmospheric stability discussed in Section 2.3.2 of this report, the staff confirmed the applicant's χ/Q values by running the PAVAN computer code and obtaining consistent results. Therefore, the staff accepts the short-term χ/Q values presented by the applicant.

2.3.4.4.4.2 *Short-Term Atmospheric Dispersion Estimates for the Control Room*

The applicant provided the following as the necessary input to the ARCON96 dispersion modeling analysis:

- Onsite Hourly Meteorological Data: December 1, 2005 - November 30, 2007
- AP1000 DCD Table 15A-7: Control Room Source / Receptor Data
- AP1000 DCD Figure 15A-1: Site Plan with Release and Intake Locations
- WLS COL FSAR Table 2.3-284: Lee Control Room χ/Q Input Data
- WLS COL FSAR Figure 2.1-202: Plant Layout on the Lee Site

In accordance with the AP1000 DCD, two receptor (i.e., air intake) points, the Control Room HVAC Intake and Annex Building Access (control room door), were modeled for the following eight release points:

- Plant Vent
- PCS Air Diffuser
- Fuel Building Blowout Panel
- Radwaste Building Truck Staging Area Door
- Steam Line Break Releases
- Power Operated Relief Valves (PORV) / Safety Valves
- Condenser Air Removal Stack

[21] Smaller χ/Q values are associated with greater dilution capability, resulting in lower radiological doses. When comparing a DCD site parameter χ/Q value and a site characteristic χ/Q value, the site is acceptable for the design if the site characteristic χ/Q value is smaller than the site parameter χ/Q value. Such a comparison shows that the site has better dispersion characteristics than that required by the reactor design.

- Containment Shell PCS Air Diffuser

WLS COL FSAR Table 2.3-285 lists the site-specific control room χ/Q values calculated by the applicant. WLS COL FSAR Table 2.0-202 compared the site-specific control room χ/Q values to the corresponding site parameters provided in the AP1000 DCD. This comparison showed that the AP1000 control room χ/Q values conservatively bounded the site-specific values.

The staff confirmed the applicant's atmospheric dispersion estimates by running the ARCON96 computer model and obtaining similar results. Both the staff and applicant used a ground-level release assumption for each of the release/receptor combinations as well as other conservative assumptions. Based on its confirmatory analysis, the staff finds the applicant's control room χ/Q values acceptable.

2.3.4.4.4.3 *Short-Term Atmospheric Dispersion Estimates for the Technical Support Center*

The applicant provided the following as the necessary input to the ARCON96 dispersion modeling analysis:

- Onsite Hourly Meteorological Data: December 1, 2005 - November 30, 2007
- WLS COL FSAR Table 2.3-294: Lee TSC HVAC Distances and Directions
- WLS COL FSAR Section 2.3.4.4: Control Room Source / Receptor Data

The Technical Support Center (TSC) HVAC Intake was modeled for the following two release points:

- Unit 1 Containment Shell
- Unit 2 Containment Shell

WLS COL FSAR Table 2.3-295 lists the site-specific TSC χ/Q values calculated by the applicant.

The staff confirmed the applicant's atmospheric dispersion estimates by running the ARCON96 computer model and obtaining similar results. Both the staff and applicant used a ground-level release assumption for each of the release/receptor combinations as well as other conservative assumptions. Based on its confirmatory analysis, the staff finds the applicant's TSC χ/Q values acceptable.

The applicant took a departure in WLS COL FSAR Chapter 18, "Human Factors Engineering," in that the WLS TSC is not located in the control building as identified in the AP1000 DCD (WLS DEP 18.8-1). Additional information regarding this departure can be found in the WLS COL application, Part 7 "Departures and Exemptions Requests."

2.3.4.4.5 Onsite and Offsite Hazardous Materials

A review of the applicant's identification of onsite and offsite hazardous materials that could threaten control room habitability is performed in Sections 2.2.1, 2.2.2, and 2.2.3 of this report. The accident scenarios, including release characteristics and atmospheric dispersion model descriptions, model inputs, and assumptions are also discussed in these sections.

2.3.4.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.3.4.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to short-term diffusion estimates, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

COL Information Item 2.3-4 states that a COL applicant shall address the site-specific χ/Q values as specified in AP1000 DCD, Section 2.3.4. The staff concludes that the applicant's atmospheric dispersion estimates are acceptable and meet the relevant requirements of 10 CFR 100.21(c)(2). This conclusion is based on the conservative assessments of post-accident atmospheric dispersion conditions that have been made by the applicant and the staff from the applicant's meteorological data and appropriate diffusion models. These atmospheric dispersion estimates are appropriate for the assessment of consequences from radioactive releases for DBAs in accordance with 10 CFR 52.79(a)(1)(vi), 10 CFR 100.21(c)(2), and GDC 19. The staff finds that the applicant has provided sufficient information to adequately address COL Information Item 2.3-4.

2.3.5 Long-Term Diffusion Estimates

2.3.5.1 *Introduction*

The long-term diffusion estimates are used to determine the amount of airborne radioactive materials expected to reach a specific location during normal operations. The diffusion estimates address the requirement concerning atmospheric dispersion and dry deposition estimates for routine releases of radiological effluents to the atmosphere. The review covers the following specific areas: (1) atmospheric dispersion and deposition models used to calculate concentrations in air and amount of material deposited as a result of routine releases of radioactive material to the atmosphere; (2) meteorological data and other assumptions used as input to the atmospheric dispersion models; (3) derivation of diffusion parameters (e.g., σ_z); (4) atmospheric dispersion (relative concentration) factors (χ/Q values) and deposition factors (D/Q values) used for assessment of consequences of routine airborne radioactive releases; (5) points of routine release of radioactive material to the atmosphere, the characteristics of each release mode, and the location of potential receptors for dose computations; and (6) any additional information requirements prescribed in the “Contents of Application” sections of the applicable subparts to 10 CFR Part 52. This section of the report also addresses the supplemental information in WLS COL FSAR Section 2.3.6 related to the long-term diffusion estimates.

2.3.5.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.3, incorporates by reference AP1000 DCD, Section 2.3. In WLS COL FSAR Section 2.3.5, the applicant addressed the following:

AP1000 COL Information Item

- WLS COL 2.3-5

The additional information provided in WLS COL 2.3-5 is responsive to AP1000 DCD Tier 2, Table 1.8-2, COL Information Item 2.3-5 by addressing long-term (atmospheric) diffusion estimates at and near the site boundary and out to a distance of 80 km (50 mi). In addition, this WLS COL FSAR section addresses Interface Item 2.4 related to the limiting meteorological parameters (χ/Q values) for routine airborne radiological releases.

2.3.5.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria for evaluating the analysis of long-term atmospheric dispersion and deposition conditions for routine releases of radiological effluents to the atmosphere during normal plant operation are based on meeting the relevant requirements of 10 CFR Part 20, 10 CFR Part 50, and 10 CFR Part 100. The staff considered the following regulatory requirements in reviewing the applicant’s estimates of atmospheric dispersion and deposition:

- 10 CFR Part 20, Subpart D, as it relates to establishing atmospheric dispersion-related site characteristics for demonstrating compliance with dose limits for individual members of the public;

- 10 CFR 50.34a, “Design objectives for equipment to control releases of radioactive material in effluents—nuclear power reactors,” and 10 CFR Part 50, Appendix I Sections II.B, II.C, and II.D, as they relate to the numerical guides for design objectives and limiting conditions for operation to meet the requirements that radioactive material in effluents released to unrestricted area be kept ALARA.

- 10 CFR 100.21(c)(1), as it relates to establishing atmospheric dispersion-related site characteristics such that radiological effluent release limits associated with normal operation can be met for any individual located offsite.

The related acceptance criteria from NUREG-0800, Section 2.3.5 are as follows:

- A detailed description of the atmospheric dispersion and deposition models used to calculate annual average concentrations in air and amount of material deposited as a result of routine releases of radioactive materials to the atmosphere.

- A discussion of atmospheric diffusion parameters, such as vertical plume spread (σ_z) as a function of distance, topography, and atmospheric conditions.

- Meteorological data summaries (onsite and regional) used as input to the dispersion and deposition models.

- Points of routine release of radioactive material to the atmosphere, including the characteristics (e.g., location, release mode) of each release point.

- The specific location of potential receptors of interest (e.g., nearest vegetable garden, nearest resident, nearest milk animal, and nearest meat cow in each 22.5 degree direction sector within an 8 km (5 mi) radius of the site).

- The χ/Q and D/Q values to be used for assessment of the consequences of routine airborne radiological releases as described in RG 1.206, Section C.I.2.3.5.2: (1) maximum annual average χ/Q values and D/Q values at or beyond the site boundary and at specific locations of potential receptors of interest using appropriate meteorological data for each routine venting location; and (2) estimates of annual average χ/Q values and D/Q values for 16 radial sectors to a distance of 80 km (50 mi) from the plant using appropriate meteorological data.

The following regulatory guides and other related guidance documents were also taken into consideration in the staff's review of WLS COL FSAR Section 2.3.5, as applicable:

- RG 1.23, "Meteorological Monitoring Programs for Nuclear Power Plants," Revision 1, which includes guidance on the measurement and processing of onsite meteorological data for use as input to atmospheric dispersion models in support of plant licensing and operation

- RG 1.109, "Calculation of Annual Doses to Man from Routine Releases of Reactor Effluents for the Purpose of Evaluating Compliance with 10 CFR Part 50, Appendix I," Revision 1, which includes guidance on identifying the location of potential receptors of interest

- RG 1.111, "Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors," Revision 1, which discusses different types of atmospheric transport and diffusion models and criteria for characterizing long-term (annual) average atmospheric dispersion and deposition conditions

- RG 1.112, "Calculation of Releases of Radioactive Materials in Gaseous and Liquid Effluents from Light-Water-Cooled Power Reactors," Revision 1, which includes guidance on identifying release point characteristics

- RG 1.206, “Combined License Applications for Nuclear Power Plants,” which summarizes the types of information, identified in NUREG-0800, Section 2.3.5, that an applicant should provide in FSAR Section 2.3.5 regarding the estimation of annual average χ/Q and D/Q values used for annual average release limit calculations and person-rem estimates

- NUREG/CR-2919, “XOQDOQ: Computer Program for the Meteorological Evaluation of Routine Effluent Releases at Nuclear Power Stations,” prepared by Pacific Northwest Laboratory (PNL-4380), the user’s manual for the NRC-sponsored XOQDOQ dispersion model

2.3.5.4 ***Technical Evaluation***

The staff reviewed WLS COLFSAR Section 2.3.5 and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic. The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to the long-term diffusion estimates. The results of the staff’s evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements. The staff reviewed the information contained in the WLS COL FSAR corresponding to the following:

AP1000 COL Information Item

- WLS COL 2.3-5

The staff reviewed information related to the long-term diffusion estimates of routine releases to the atmosphere included by the applicant in WLS COL FSAR Section 2.3.5 in response to WLS COL 2.3-5. The specific text of this COL information item in AP1000 DCD, Section 2.3.6.5 states:

> Combined License applicants referencing the AP1000 certified design will address long-term diffusion estimates and χ/Q values specified in subsection 2.3.5. The Combined License applicant should consider topographical characteristics in the vicinity of the site for restrictions of horizontal and/or vertical plume spread, channeling or other changes in airflow trajectories, and other unusual conditions affecting atmospheric transport and diffusion between the source and receptors. No further action is required for sites within the bounds of the site parameter for atmospheric dispersion.
>
> With regard to environmental assessment, the COL applicant will also provide estimates of annual average χ/Q values for 16 radial sectors to a distance of 50 mi from the plant.

The staff relied upon the review procedures presented in NUREG-0800, Section 2.3.5, to independently assess the technical sufficiency of the information presented by the applicant.

2.3.5.4.1 Atmospheric Dispersion Model

The applicant used the NRC-sponsored computer code XOQDOQ (described in NUREG/CR-2919, “XOQDOQ Computer Program for the Meteorological Evaluation of Routine Releases at Nuclear Power Stations”) to estimate ground-level χ/Q and D/Q values resulting from routine airborne releases. The XOQDOQ model implements the constant mean wind direction model methods outlined in RG 1.111, “Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors,” Revision 1.

The XOQDOQ model is a straight-line Gaussian plume model based on the theoretical assumption that material released to the atmosphere will be normally distributed (Gaussian) about the plume centerline. In predictions of χ/Q and D/Q values over long time periods (i.e., annual averages), the plume’s horizontal distribution is assumed to be distributed within the downwind direction sector (i.e., “sector averaging”). A straight-line trajectory is assumed between the release point and all downwind receptors.

2.3.5.4.2 Release Characteristics and Receptors

Routine operational releases of radioactive materials to the atmosphere typically occur through vents near the tops of buildings or from tall stacks. In its XOQDOQ dispersion modeling analysis, the applicant assumed that such releases occur at ground level although the exhaust point for the plant vent is 55.7 m (183 ft) above grade based on AP1000 DCD Tier 2, Table 15A-7. The applicant assumed that these releases occurred at ground level from a single point located mid-way between the Units 1 and 2 reactor buildings.

The applicant assumed a minimum building cross-sectional area of 2,843 m^2 (0.70 acres) and a building height of 69.8 m (229 ft), but did not provide a reference for this information. Therefore, in RAI 451, Question 02.03.05-1, the staff requested that the applicant provide a reference for these inputs to the XOQDOQ model. In a December 17, 2008, response to RAI 451, Question 02.03.05-1, the applicant provided the requested references from AP1000 DCD Tier 1 material and Westinghouse drawing APP-1000-P2-902, Revision 0, used to calculate the height and the building cross-sectional area of the Shield Building. The applicant provided a discussion in the response to RAI 451, Question 02.03.05-1 that a sensitivity study was performed to determine the effects of changes to the dimensions of the Shield Building. The applicant stated that the effects were negligible. The staff confirmed the information provided in the response to RAI 451, Question 02.03.05-1 through the documentation provided in the AP1000 DCD. Accordingly, the staff considers RAI 451, Question 02.03.05-1, resolved.

The applicant assumed a ground-level release in modeling routine releases. A ground-level release is a conservative assumption resulting in higher χ/Q and D/Q values when compared to a mixed-mode (i.e., part-time ground-level, part-time elevated) release or a 100 percent elevated release, as discussed in RG 1.111, Revision 1. A ground-level release assumption is therefore acceptable to the staff.

The distance to the receptors of interest (i.e., EAB, milk animal (cow/goat), garden, meat animal, and resident) were presented in WLS COL FSAR Section 2.3.5.2. The distances to each of these receptors has been calculated from a location defined as the mid-point of the two proposed units. This method provides representative results and is acceptable to the staff.

2.3.5.4.3 Meteorological Input Data

The meteorological data input to the XOQDOQ dispersion model consisted of a JFD of wind speed, wind direction, and atmospheric stability class based on hourly onsite data collected during a 2-year period from December 1, 2005, through November 30, 2007. The wind data were obtained from the 10 m (32 ft) level of the onsite meteorological tower, and the stability data were derived from the vertical temperature difference (delta-temperature) measurements taken between the 60 m and 10 m (197 and 32 ft) levels on the onsite meteorological tower.

Based on the applicant’s responses to all RAIs related to the acceptability of the hourly meteorological data as discussed in Section 2.3.3 of this report, the staff considers the December 1, 2005, through November 30, 2007, onsite meteorological database suitable for input to the XOQDOQ model.

2.3.5.4.4 Diffusion Parameters

The applicant chose to implement the diffusion parameter assumptions outlined in RG 1.111, Revision 1, as a function of atmospheric stability and downwind distance from the source, for its XOQDOQ model runs. The staff evaluated the applicability of the XOQDOQ diffusion parameters and concluded that no unique topographic features preclude the use of the XOQDOQ model for the proposed WLS site. This section of the WLS COL FSAR, however, lacked a discussion of nearby topographical features that would preclude the use of the XOQDOQ model on long-term dispersion estimates. Therefore, in RAI 451, Question 02.03.05-2, the staff requested that the applicant provide this information.

In a December 17, 2008, response to RAI 451, Question 02.03.05-2, the applicant provided a revision to WLS COL FSAR Section 2.3.5.1. The revision provided a description of the terrain in the vicinity of the proposed WLS site and further discussed that the terrain in the vicinity of the proposed site would not have a significant effect on atmospheric dispersion estimates. The staff finds the applicant’s use of diffusion parameter assumptions, as outlined in RG 1.111, Revision 1, acceptable. Accordingly, the staff considers RAI 451, Question 02.03.05-2 resolved.

2.3.5.4.5 Resulting Relative Concentration and Relative Deposition Factors

For the purpose of conducting confirmatory analyses of the applicant’s long-term, routine release dispersion estimates using the XOQDOQ computer code, in RAI 451, Question 02.03.05-3, the staff requested that the applicant provide the input files or output files for the 1-year meteorological data set and the 2-year meteorological data set (requested in RAI 3727, Question 02.03.05-4). Along with a December 17, 2008, letter, the applicant submitted the XOQDOQ input and output files for the 2-year meteorological dataset. The staff notes that input and output files were updated for the most recent version of the WLS COL FSAR in a letter dated September 30, 2013. The staff confirmed the receipt of these files and, therefore, considers RAI 3727, Question 02.03.05-4 resolved.

WLS COL FSAR Table 2.3-289, "χ/Q and D/Q Values for Normal Releases," lists the long-term atmospheric dispersion and deposition estimates for the EAB and special receptors of interest that the applicant derived from its XOQDOQ modeling results. WLS COL FSAR Table 2.3-287, "Annual Average χ/Q (sec/m^3) for Normal Releases No Decay, Undepleted," and Table 2.3-288, "Annual Average χ/Q (sec/m^3) for Normal Releases No Decay, Depleted," also contain the applicant's long-term atmospheric dispersion and deposition estimates for the 16 radial sectors from the site boundary to a distance of 80 km (50 mi) from the proposed WLS site.

The χ/Q values presented in WLS COL FSAR Tables 2.3-289 and 2.3-288 reflect several plume radioactive decay and depletion by deposition scenarios. RG 1.111, Regulatory Position C.3 states that radioactive decay and dry deposition should be considered in radiological impact evaluations of potential annual radiation doses to the public, resulting from routine releases of radioactive materials in gaseous effluents. RG 1.111, Revision 1, Regulatory Position C.3 states that an overall half-life of 2.26 days is acceptable for evaluating the radioactive decay of short-lived noble gases and an overall half-life of 8 days is acceptable for evaluating the radioactive decay for all Iodines released to the atmosphere. Definitions for the χ/Q categories listed in the headings of Table 2.3.5-1 of this report are as follows:

- Undepleted/No Decay χ/Q values are used to evaluate ground-level concentrations of long-lived noble gases, Tritium, and Carbon-14. The plume is assumed to travel downwind, without undergoing dry deposition or radioactive decay.

- Undepleted/2.26-Day Decay χ/Q values are used to evaluate ground-level concentrations of short-lived noble gases. The plume is assumed to travel downwind without undergoing dry deposition, but is decayed assuming a half-life of 2.26 days based on the half-life of Xenon-133m.

- Depleted/8.00-Day Decay χ/Q values are used to evaluate ground-level concentrations of radioiodine and particulates. The plume is assumed to travel downwind, with dry deposition, and is decayed, assuming a half-life of 8.00 days, based on the half-life of Iodine-131.

Using the information provided by the applicant, including the 10-m level JFDs of wind speed, wind direction, and atmospheric stability presented in WLS COL FSAR Tables 2.3-235 through 2.3-241, the staff confirmed the applicant's χ/Q and D/Q values by running the XOQDOQ computer code and obtaining consistent results. The JFDs used by the applicant for the long-term diffusion estimates consisted of 13 wind speed categories, compared to the 11 wind speed categories in RG 1.23, Revision 1. To provide a consistent confirmatory analysis of the applicant's methods, the staff also used 13 wind speed categories.

AP1000 DCD Tier 2, Section 2.3.6.5 also states that with regard to environmental assessment, estimates of annual average χ/Q values for 16 radial sectors to a distance of 80 km (50 mi) from the plant should be provided. The applicant provided these values in WLS COL FSAR Tables 2.3-287 through 2.3-292. Using staff-generated JFDs and the XOQDOQ computer code, these χ/Q values were confirmed by the staff and were found to be adequate and acceptable.

2.3.5.5 *Post Combined License Activities*

There are no post COL activities associated with this WLS COL FSAR section.

2.3.5.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to long-term diffusion estimates and there is no outstanding information expected to be addressed in the WLS COL FSAR relating to this section. The results of the staff's technical evaluation of the information incorporated by reference in the application are documented in NUREG-1793 and its supplements.

COL Information Item 2.3-5 states that a COL applicant shall address the site-specific diffusion estimates and χ/Q values as specified in AP1000 DCD, Section 2.3.5. Based on the meteorological data provided by the applicant and an atmospheric dispersion model that is appropriate for the characteristics of the site and release points, the staff concludes that representative atmospheric dispersion and deposition factors have been calculated for 16 radial sectors from the site boundary to a distance of 80 km (50 mi) as well as for specific locations of potential receptors of interest. The characterization of atmospheric dispersion and deposition conditions are acceptable to meet the criteria described in RG 1.111, Revision 1 and are appropriate for the evaluation to demonstrate compliance with the numerical guides for doses in 10 CFR Part 20 Subpart D and 10 CFR Part 50, Appendix I. The staff finds that the applicant has provided sufficient information to adequately address COL Information Item 2.3-5.

2.4 Hydrologic Engineering

To ensure that a nuclear power plant or plants can be designed, constructed, and safely operated on the combined license (COL) applicant's site and in accordance with the U.S. Nuclear Regulatory Commission (NRC) regulations, the staff evaluated the hydrologic characteristics of the site and surrounding vicinity that may affect the safety of the proposed nuclear power plant. These site characteristics included the maximum flood elevation of surface water from precipitation, riverine processes (runoff, dam breach discharge, channel blockage or diversion), and combined events (e.g., from coincident wind waves). In addition, the staff reviewed the maximum elevation of groundwater and the characteristic ability of the site to attenuate a postulated accidental release of radiological material into surface water and groundwater. The surface-water hydrologic site characteristics determine the design basis flood for the proposed nuclear power plant (William States Lee III Nuclear Station (WLS) Units 1 and 2) and provide the basis for determining whether flood protection will be required. The groundwater hydrologic site characteristics determine the design basis groundwater loadings and provide the basis for radiological dose analysis for a potential receptor from the postulated accidental release of radioactive liquid effluents in surface and ground waters.

The staff prepared Sections 2.4.1 through 2.4.14 of this safety evaluation report (SER) in accordance with the review procedures described in NUREG-0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition," Sections 2.4.1

through 2.4.14, using information presented in Section 2.4, "Hydrologic Engineering," of the WLS Units 1 and 2 Final Safety Analysis Report (FSAR) Revisions 0 through 11, AP1000 Design Control Document (DCD) Revision 19, the applicant's responses to the staff's requests for additional information (RAIs), and generally available reference materials (e.g., those cited in applicable sections of NUREG-0800).

In Part 7 of the application, the applicant described an administrative standard departure (STD DEP) (Standard Departure 1.1-1) that remaps WLS COL FSAR section numbers to the associated AP1000 DCD section numbers. This standard departure affected Sections 2.4.1 and 2.4.15 in WLS COL FSAR Section 2.4. The staff determined that this departure has no safety significance.

The nominal proposed site grade for the WLS Units 1 and 2 nuclear power block is 180.4 meters (m) (592 feet (ft)) above mean sea level (MSL) with the nuclear island finished floor elevation[22] at 180.7 m (593 ft) above MSL. The ultimate heat sink (UHS) of the advanced passive pressurized water reactor (AP1000) design is the atmosphere. Therefore, hydrologic characteristics associated with conditions that would result in a loss of external water supply (e.g., low water, channel diversions) are not relevant for this particular design. Also, seismic design considerations of water-supply structures are not relevant for this particular design. Therefore, Regulatory Guide (RG) 1.27, "Ultimate Heat Sink for Nuclear Power Plants," and RG 1.29, "Seismic Design Classification," were not part of the regulatory basis for this Section 2.4 review.

As stated above, the site grade near the WLS Units 1 and 2 nuclear power block is 180.4 m (592 ft) above MSL. The following flooding hazard mechanisms, including associated effects, were computed and reported in the WLS COL FSAR.

Table 2.4.1-1 Flooding Hazard Mechanisms

Calculated Flooding Hazards and Associated Effects as Evaluated in WLS COL **FSAR**	**Water-Surface Elevation**	
	ft[(a)]	**m[(a)]**
Local Intense Precipitation and Associated Drainage	592.6	180.6
Flooding from Streams and Rivers	592.3[(b) (c)]	180.5[(b) (c)]
Failure of Dams and Onsite Water-Control/Storage Structures	592.3[(b) (c)]	180.5[(b) (c)]
Flooding from Storm Surge with Wave Runup	583.9	178
Flooding from Seiche[(c)]	--	--
Flooding from Tsunami[(d)]	--	--

[22] The nuclear island finished floor elevation, 180.7 m (593 ft) above MSL, corresponds to the AP1000 DCD reference floor elevation.

Ice-Induced Flooding[(d)]	--	--
Flooding from Channel Migrations or Diversions[(d)]	--	--
(a) above MSL (b) stillwater-surface elevation (c) bounded by other flooding mechanisms (d) not plausible at the site		

2.4.1 Hydrologic Description

2.4.1.1 *Introduction*

WLS COL FSAR Section 2.4.1 describes the site and all safety-related elevations, structures, and systems from the standpoint of hydrologic considerations and provided a topographic map showing the proposed changes to grading and to natural drainage features.

Section 2.4.1 of this report provides a review of the following specific areas: (1) interface of the plant with the hydrosphere including descriptions of site location, major hydrologic features in the site vicinity, surface-water and groundwater characteristics, and the proposed water supply to the plant; (2) hydrologic causal mechanisms that may require special plant design bases or operating limitations with regard to floods and water-supply requirements; (3) current and likely future surface and groundwater uses by the plant and water users in the vicinity of the site that may affect the safety of the plant; (4) available spatial and temporal data relevant for the site review; (5) alternate conceptual models of the hydrology of the site that reasonably bound hydrologic conditions at the site; (6) potential effects of seismic and non-seismic data on the postulated design bases and how they relate to the hydrology in the vicinity of the site and the site region; and (7) any additional information requirements prescribed within the “Contents of Application,” sections of the applicable Subparts to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, “Licenses, Certifications, and Approvals for Nuclear Power Plants.”

As stated above in Section 2.4, hydrologic characteristics associated with conditions that would result in a loss of external water supply and seismic design considerations of water-supply structures are not relevant for the AP1000 design. Therefore, specific area (6), above, was not part of the staff’s review.

2.4.1.2 *Summary of Application*

This section of the WLS COL FSAR describes the site and all safety-related elevations, structures and systems from the standpoint of hydrologic considerations and provides a topographic map showing the proposed changes to grading and to natural drainage features.

The applicant addressed the COL information item identified in AP1000 DCD Tier 2, Section 2.4.1.1, Revision 19 related to hydrologic description as follows:

AP1000 COL Information Item

- WLS COL 2.4-1

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.1, Revision 19.

> Combined License applicants referencing the AP1000 certified design will describe major hydrologic features on or in the vicinity of the site including critical elevations of the nuclear island and access routes to the plant.

2.4.1.3 *Regulatory Basis*

NRC regulations for the hydrologic description, and the associated acceptance criteria, are specified in NUREG-0800, Section 2.4.1.

The applicable regulatory requirements for identifying site location and describing the site hydrosphere are set forth in the following:

- 10 CFR 52.79(a)(1)(iii), "Contents of Applications; Technical Information in Final Safety Analysis Report," as it relates to the hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrologic features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100,20(c).

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.1:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, "Flood Protection for Nuclear Power Plants," as it relates to providing assurance that structures, systems, and components (SSCs) important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.1.4 *Technical Evaluation*

2.4.1.4.1 Site and Facilities

Information Submitted by the Applicant

The applicant stated in WLS COL FSAR Section 2.4.1.1 that the WLS site is located in eastern Cherokee County, SC, southwest of the Ninety-Nine Islands Reservoir, a portion of the Broad River, approximately 1.6 km (1 mi) northwest of the Ninety-Nine Islands Dam. The applicant noted that in addition to the Broad River and several tributaries, the Ninety-Nine Islands Reservoir, Make-Up Pond A, Make-Up Pond B, Make-Up Pond C, and Hold-Up Pond A make up the majority of the surface-water features in the vicinity of the WLS site. An embankment within Make-Up Pond B creates the Upper Arm Pond, which is connected to Make-Up Pond B by a culvert. The applicant stated that Make-Up Pond C is an offsite facility, located on a tributary of the Broad River, west of the WLS site.

The applicant selected the AP1000 certified plant design for the WLS application with the designed finished floor elevation at 180.7 m (593 ft) above MSL with the nuclear island basemat at 168.7 m (553.5 ft) above MSL. The WLS site grade would be at 180.4 m (592 ft) above MSL. The applicant also described the plant water systems including the water-consumption and water-treatment system, the intake system, which provides all raw water requirements for the plant, and the discharge system, which disperses cooling-tower blowdown into the Broad River.

Construction activities related to the abandoned Cherokee Nuclear Station resulted in extensive alteration of the site, including clearing of vegetation, construction of roads, a railroad spur, warehouses, power unit buildings, and other support buildings, and extensive excavation, and grading. Currently, the site is a partially developed industrial land.

The partially built reactor containment building of the abandoned Cherokee Nuclear Station would be removed during construction activities for the proposed units. The basemat slab and some warehouses would be retained. A new intake structure for the normal cooling-water supply is planned to be installed on the Broad River and the blowdown discharge would be placed on the upstream side of the Ninety-Nine Islands Dam near the turbine intakes.

Two new AP1000 units are proposed to be built near the abandoned Cherokee Units 1 and 3, at the west and east sides of the existing excavation, respectively (Figure 2.4.1-1 of this report). Each of the two proposed AP1000 units would use two mechanical draft cooling towers for its circulating-water system (CWS) cooling with makeup water supplied from the Broad River via Make-Up Pond A during normal river discharge conditions. Water stored in Make-Up Ponds B and C would be used, in that order, to provide water to Make-Up Pond A for CWS cooling water during low-flow conditions in the Broad River. The UHS for the AP1000 units is the atmosphere.

The AP1000 design consists of five principal structures: the nuclear island, the turbine building, the annex building, the diesel generator building, and the radioactive waste building. Only the nuclear island is designed as a Seismic Category I structure and contains all safety-related equipment.

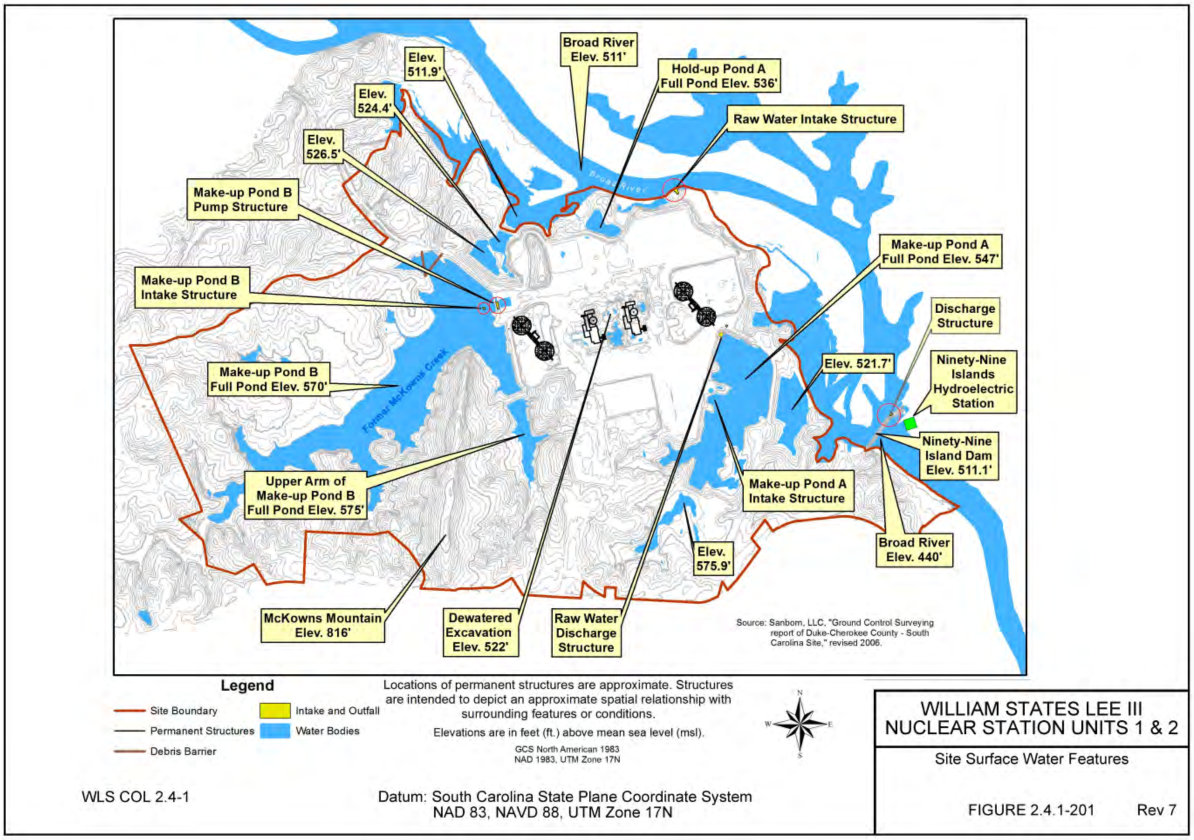

Figure 2.4.1-1 Map of the WLS site (adapted from WLS COL FSAR Revision 7, Figure 2.4.1-201)

The finished floor elevation of the nuclear island, or the AP1000 DCD reference floor elevation of 30.48 m (100 ft), would be placed at 180.7 m (593 ft) above MSL with the nuclear island basemat placed at 168.7 m (553.5 ft) above MSL. The plant grade elevation would be at 180.4 m (592 ft) above MSL.

The applicant stated that the intake system would provide all raw water required by the plant. Raw water would be pumped to Make-Up Pond A from the Broad River under the river's normal flow conditions. During low-flow conditions in the Broad River, water from Make-Up Pond B would be pumped to Make-Up Pond A to provide cooling water to the plant. When the storage in Make-Up Pond B is depleted and low-flow conditions in the Broad River persist, water from Make-Up Pond C would be pumped into Make-Up Pond B and subsequently into Make-Up Pond A to provide cooling water for the plant. Water from the Broad River can also be pumped directly into Make-Up Pond B from the river intake structure. After the Broad River flow returns to normal, Make-Up Pond B would be replenished from water withdrawn from the river. Normally, Make-Up Pond C would be refilled directly from the river intake structure, but an alternate path for refilling Make-Up Pond C would use water from the river intake structure pumped via Make-Up Ponds A and B, in that order.

The applicant stated that the discharge system would use a submerged pipe, perforated along its last portion that would be located near the hydroelectric generating station's intakes upstream of the Ninety-Nine Islands Dam. The discharge from WLS Units 1 and 2 would include non-radioactive and low-level radioactive wastes.

NRC Staff's Technical Evaluation

The staff reviewed the information related to COL Information Item 2.4-1 related to the provision of a description of all major hydrologic features on or in the vicinity of the site, including critical elevations of the nuclear island and access routes to the plant included under WLS COL FSAR Section 2.4.

In RAI 818, Question 02.04.01-1, the staff requested that the applicant clarify the process for determining the conceptual models of the interface of the plant with the hydrosphere and those of the hydrologic causal mechanisms and to ensure that the most conservative of plausible conceptual models has been identified. In a November 18, 2008, response, to RAI 818, Question 02.04.01-1, the applicant stated that the process followed to determine the conceptual models of the interface of the plant with the hydrosphere and those of the hydrologic causal mechanisms would be addressed in the responses to similar staff RAIs issued for the respective subsections of the WLS COL FSAR. The staff reviewed the applicant's responses to these individual RAIs issued for the respective subsections of the WLS COL FSAR and concluded that the applicant had responded to the individual RAIs and included sufficient information to address the staff's concerns. The staff's evaluations of these individual RAIs are presented in the respective sections of this report. Accordingly, the staff considers RAI 818, Question 02.04.01-1, resolved.

The staff conducted a hydrology site audit May 18 to 20, 2008. The site audit included a visit to the WLS site and a tour of the east end of the existing, dewatered excavation pit, the basemat of abandoned Cherokee Nuclear Station Unit 1 on the west end of the excavation pit, Make-Up Pond B, Hold-Up Pond A, the south end of the excavation pit, the dam impounding the south section of the east arm of Make-Up Pond B, the top of McKowns Mountain, the existing intake structure located on Make-Up Pond A, the proposed location of the new intake on the Broad River, and the Ninety-Nine Islands Dam. The applicant and the staff also reconnoitered the Broad River in the vicinity of the site during a boat tour. The staff reviewed the information regarding major hydrologic features in the vicinity of the site from publicly available sources of hydrologic data. The staff's review is described in the subsections below.

In RAI 818, Question 02.04.01-3, the staff requested that the applicant clarify an ambiguity related to the AP1000 DCD reference elevation and the WLS Units 1 and 2 finished floor elevation. In a November 18, 2008, response to RAI 818, Question 02.04.01-3, the applicant stated that the finished floor elevation refers to the AP1000 DCD reference floor elevation of 30.5 m (100 ft), as stated in AP1000 DCD Tier 2, Section 2.4. The applicant modified the WLS COL FSAR text to indicate that the AP1000 DCD reference floor elevation of 30.5 m (100 ft) corresponds to the site-specific nuclear island finished floor elevation. The staff concluded that the applicant provided sufficient information for staff to proceed with its review. Accordingly, the staff considers RAI 818, Question 02.04.01-3, resolved.

In RAI 818, Question 02.04.01-4, the staff requested that the applicant clarify Make-Up Ponds A and B relationship to safety. In a November 18, 2008, response to RAI 818, Question 02.04.01-4, the applicant confirmed that Make-Up Ponds A and B would not be used for any safety-related purpose. After responding to RAI 818, Question 02.04.01-4, the applicant decided to install Make-Up Pond C to address low-water conditions related to normal operations of the proposed units. The exchange of water among the three ponds is described in the "Information Submitted by the Applicant" section above. Since the water pumped from the Broad River to the three makeup ponds would only provide cooling during normal operations, the staff concluded that none of this water would be safety-related. The UHS for the AP1000 units is the atmosphere. The staff concluded that the applicant provided sufficient information related to the function of Make-Up Ponds A and B. Accordingly, the staff considers RAI 818, Question 02.04.01-4, resolved.

In a November 22, 2011, submittal, the applicant provided revisions to the CWS. The applicant stated that the revisions resulted from the change in the design of two cooling towers from the previous design that used three cooling towers per unit.

Based on a review of the material presented by the applicant in WLS COL FSAR Section 2.4.1 and the staff's observations made during the WLS site audit, and based on the reasons given above, the staff concluded that the applicant adequately considered the hydrologic characteristics of the WLS site as they relate to identifying and evaluating hydrologic features.

2.4.1.4.2 Hydrosphere

Information Submitted by the Applicant

The applicant provided a detailed description of the main hydrologic features in the vicinity of the WLS site including the Broad River and the Ninety-Nine Islands Reservoir. The applicant's description included a specific description of the site and all safety-related elevations, structures, exterior access, equipment, and systems from the standpoint of hydrology considerations. The applicant also described the current surface-water features on and off the site (Make-Up Ponds A, B, and C and Hold-Up Pond A) and the local groundwater conditions.

The WLS site is located within the Piedmont physiographic province, the non-mountainous portion of the older Appalachians. The main drainage in the region is the Broad River with tributaries that drain through deep and steep valleys. The Broad River Basin contains rolling hills and small floodplains.

The Broad River and most of its tributaries originate in the Blue Ridge Mountains of North Carolina. The WLS site is located in the Upper Broad River Basin (U.S. Geological Survey (USGS) Hydrologic Unit Code (HUC) 03050105), parts of which lie in both the states of North Carolina and South Carolina. The drainage basin above the Ninety-Nine Islands Dam, approximately 4,014 km^2 (1,550 mi^2) in size, contains tributaries to the Broad River, including the Green River, the First and Second Broad rivers, and Buffalo Creek. Elevations in the watershed upstream of the Ninety-Nine Islands Reservoir range from approximately 366 m (1,200 ft) above MSL at the headwaters of the First Broad River, to approximately 155.8 m (511 ft) above MSL above the Ninety-Nine Islands Dam, and approximately 134 m (440 ft) above MSL below the Ninety-Nine Islands Dam.

Discharge in the Broad River, recorded at USGS streamflow gauge 02153551, located just downstream of the Ninety-Nine Islands Dam, ranges from 3.9 cubic meters per second (m^3/s) (138 cubic feet per second (cfs) on September 14, 2002, to more than 1,699 m^3/s (60,000 cfs) in September 2004. The Gaffney USGS streamflow gauge 02133500, is located approximately 12.9 km (8 mi) upstream of the WLS site and has a contributing area of 155.4 km^2 (60 mi^2) less than that of the Broad River above the Ninety-Nine Islands Dam. The Gaffney USGS gauge recorded the highest discharge on record at 3,373 m^3/s (119,100 cfs) on August 14, 1940. Based on streamflow data at the USGS Gaffney gauge, the applicant estimated that the 100- and 500-year flood discharges in the Broad River are 2,722 to 3,956 m^3/s (97,900 to 127,000 cfs). The applicant also estimated the corresponding water-surface elevations based on the rating curve of the Ninety-Nine Islands Dam, assuming flashboard failure as being at 158.8 and 159.3 m (521 and 522.6 ft) above MSL, respectively.

The applicant filled in data gaps and extrapolated streamflow records from the Gaffney streamflow gauge to construct an 83-year record of streamflow discharge. The applicant estimated that the average annual flow in the Broad River is 70.8 m^3/s (2,500 cfs). The applicant also quantified the low-flow condition in the Broad River using the lowest consecutive 7-day streamflow likely to occur every 10 years, or 7Q10, as 12.4 m^3/s (439 cfs). The applicant stated that the monthly water temperature data from the USGS streamflow gauge 02156500, located near Carlisle, SC, for the period 1996 to 2006, ranged from 4.9ºC to 29.6ºC (40.8ºF to 85.3ºF).

Several small streams in the vicinity of the WLS site exist, including Cherokee Creek, Doolittle Creek, London Creek, McKowns Creek, and an intermittent stream that flows into Make-Up Pond A. McKowns Creek, which has a drainage area of approximately 661 hectares (ha) (1,633 acres (ac)), is impounded by a dam to create Make-Up Pond B on the WLS site. The intermittent stream that flows into Make-Up Pond A has a drainage area of approximately 156 ha (385 ac).

The dam impounding Make-Up Pond B, an earthen structure with its crest elevation at 179.8 m (590 ft) above MSL, was constructed during the 1970s for the abandoned Cherokee Nuclear Station. The spillway elevation is 173.7 m (570 ft) above MSL, which also indicates full pool elevation with a storage capacity of 4,933,927 m^3 (4000 ac-ft) at a surface area of 61 ha (150 ac). Make-Up Pond B is divided into two sections by a submerged dam with a crest elevation of approximately 164.6 m (540 ft) above MSL. Make-Up Pond B has an average depth of 9.6 m (31.4 ft) and a maximum depth of 18.1 m (59.3 ft).

The applicant stated that the outlet structure for Make-Up Pond B is adequately sized. Since the pond is not located on a large stream or river, the applicant expects minimal potential for significant blockage from debris collected at the outlet during flood events. The applicant reported that floating debris has not caused any problems in the past and the spillway has not been clogged. However, the applicant would create a shoreline management program along the banks of Make-Up Pond B. The program would consist of annual inspection of the shoreline and would remove trees that could potentially fall into the pond and trees that may be down on the ground. The applicant would also inspect the spillway for debris accumulation after rainfall events greater than 7.6 cm (3 in.) per hour. The applicant would also install a debris barrier system that rises and falls with the water level in the pond approximately 107 m (350 ft) from the spillway. The applicant stated that the debris barrier system is not considered a safety-related system.

An embankment within Make-Up Pond B creates the Upper Arm Pond, which is connected to Make-Up Pond B by a 137 centimeter (cm) (54 inch (in.)) culvert; the pond has a maximum depth of 9.8 m (32.2 ft), average depth of 9.6 m (31.4 ft), total storage capacity of 124,582 m^3 (101 acre-feet (ac-ft)), a normal pool elevation of 175.3 m (575 ft) above MSL, and a surface area of 3.7 ha (9.1 ac) at full pool. The embankment that impounds the Upper Arm Pond has a crest elevation of 179.8 m (590 ft) above MSL.

Make-Up Pond A was created in the 1970s during the construction of the abandoned Cherokee Nuclear Station by installing an earthen dam, which has a crest elevation varying from 169.9 to 169.2 m (557.5 to 555 ft) above MSL. The full pool elevation of Make-Up Pond A is 166.7 m (547 ft) above MSL; the pond has a surface area of about 25 ha (62 ac) and an estimated volume of 1,757,712 m^3 (1,425 ac-ft).

A small impoundment, named Hold-Up Pond A, is located north of the proposed reactor units and was also created in the 1970s by installing two dams with a crest elevation of 164.5 m (539.7 ft) above MSL. Hold-Up Pond A has a storage volume of about 69,568 m^3 (56.4 ac-ft) at a full pool elevation of 163.4 m (536 ft) above MSL and a surface area of 1.8 ha (4.4 ac).

Make-Up Pond C would be located approximately 2 mi west of the WLS site on London Creek, formed by an earthen dam impounding London Creek just upstream of its confluence with Little London Creek. The Make-Up Pond C Dam crest elevation would be at 201.2 m (660 ft) above MSL with a normal pool elevation of 198.1 m (650 ft) above MSL, a surface area of approximately 251 ha (620 ac), and a total storage capacity of 27,136,600 m^3 (22,000 ac-ft). The usable storage in Make-Up Pond C would be approximately 21,585,932 m^3 (17,500 ac-ft). The drainage area upstream of Make-Up Pond C would be 1,003 ha (2,479 ac).

There are about 132 dams upstream of the WLS site, six of which, Make-Up Pond C Dam, Whelchel Dam, Kings Mountain Reservoir or Moss Lake Dam, Lake Adger or Turner Shoals Dam, Lake Lure Dam, and Lake Summit Dam, impound about 88 percent of total storage in the Broad River Basin. Cherokee Falls Dam and Gaston Shoals Dam, both run-of-river structures, are located on the Broad River immediately upstream of the WLS site and are used for hydroelectric power generation but not for flood control. Cherokee Falls Dam was the first dam constructed in the Upper Broad River Basin in 1826. Two reservoirs located downstream of the WLS site are the Ninety-Nine Islands Reservoir and the Lockhart Reservoir. Dams impounding these two reservoirs are also run-of-river structures and not used for flood control.

The U.S. Army Corps of Engineers (USACE) and the Cleveland County Water (CCW) (previously Cleveland County Sanitary District [CCSD]) proposed to construct a dam on the First Broad River, a tributary of the Broad River upstream of the WLS site, approximately 1.6 km (1 mi) north of Lawndale, NC. The applicant reported that initial feasibility studies estimate that the dam may be approximately 25.3 m (83 ft) high with a 379.5-m (1,245 ft) bottom width and a 304.8 m (1,000 ft) wide spillway. The applicant stated that the surface area of the impoundment would be approximately 909 ha (2,245 ac), covering areas lower than 262.1 m (860 ft) above MSL.

The Piedmont aquifer system mainly consists of two sloped layers. The shallow unconfined layer, the water table aquifer, is composed of saprolite and residual soils. The deeper layer, the bedrock aquifer, is composed of weathered and unweathered crystalline igneous and metamorphic rocks. In the bedrock aquifer, water is stored and transmitted through fractures. The shallow aquifer is unconfined. The fracture system of the bedrock aquifer increases upward in prevalence of fractures as the crystalline rock transitions into saprolite. Due to the increased permeability of the transition zone, the saprolite and bedrock zones function as a single, interconnected aquifer system.

The applicant stated that although there is no single, widespread aquifer in the Piedmont region, local aquifer systems are hydraulically connected. The main source of recharge in the area is infiltration of local precipitation. Local groundwater flow directions can vary depending on topography, fracture characteristics and rock texture.

During the 1973 investigation for the abandoned Cherokee Nuclear Station, several springs and seeps were identified; they were located within valleys that directed surface runoff to the north and to the southeast. During site grading for construction of the abandoned Cherokee Nuclear Stations, these springs and seeps were cut and filled to level the site. Undisturbed topographic features on the WLS site are generally rounded hilltops and narrow valleys. Elevations on the site range from approximately 155.8 m (511 ft) above MSL at the Broad River to approximately 246.9 m (810 ft) above MSL on top of McKowns Mountain, located west of the nuclear power block area and between the two arms of Make-Up Pond B.

The applicant stated that the maximum water use from the Broad River during plant operation is estimated to be 1.8 m^3/s (63 cfs), which is approximately three percent of the average annual mean discharge in the river. The applicant also stated that groundwater would not be used as a primary source for any purpose and for any safety-related purposes for WLS and water for temporary fire protection, concrete batching, and other construction uses would be provided by the Draytonville Water District.

NRC Staff's Technical Evaluation

To review the hydrosphere description and to verify that the analyses in subsequent WLS COL FSAR sections are appropriate, in RAI 818, Question 02.04.01-2, the staff requested that the applicant provide spatially referenced data sets that were used to delineate subbasins and to derive surface and subsurface hydrologic and geologic properties.

In an October 10, 2008, response to RAI 818, Question 02.04.01-2, the applicant provided the geographic information system (GIS) layers for the Broad River watershed including sub-basins, major streams, stream gauge locations, and dam locations. The applicant also provided GIS layers for local site drainage including elevation contours and details of the plant layout. The staff used these data to review the applicant's method to determine flooding in the Broad River watershed, flooding in the drainage areas of Make-Up Ponds A, B, and C, and flooding during the local intense precipitation event. The staff's review is described in subsequent sections herein. The applicant also provided soils search results from the U.S. Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) Web Soil Survey website at and near the site. Based on its review of the data provided by the applicant, the staff concluded that the applicant provided sufficient information for staff to proceed with its review. Accordingly, the staff considers RAI 818, Question 02.04.01-2, resolved.

To review the appropriateness of COL applicant's methods, in RAI 818, Question 02.04.01-5, the staff requested that the applicant describe the method used to fill gaps in the 81-year streamflow record for the Broad River. In a November 18, 2008, response to RAI 818, Question 02.04.01-5, the applicant stated that it derived the 81-year daily average streamflow record for the Broad River near the WLS site from three USGS stream gauges: the Broad River gauge near Gaffney, SC, located just upstream of the site and with an associated drainage area of 1,490 mi^2; the Broad River gauge near Blacksburg, SC, located approximately 5.0 river km (3.1 river miles) upstream of the Gaffney gauge and with an associated drainage area of 3,341 km^2 (1,290 mi^2); and the Broad River gauge near Boiling Springs, NC, located approximately 26.1 river km (16.2 river miles) upstream of the Gaffney gauge and with an associated drainage area of 2,266 km^2 (875 mi^2). The applicant stated that streamflow data were available for the Gaffney gauge from 1938 to 1971 and from 1986 to 1990, for the Blacksburg gauge from 1997 to 2006, and for the Boiling Springs gauge from 1926 to 2006. The applicant stated that it estimated the 81-year streamflow record for the Gaffney gauge, from 1926 to 2006, by pro-rating the available streamflow data at other gauges by the respective drainage area ratios to fill data for absent years. The applicant estimated the streamflow data at the Gaffney gauge for absent years using the Blacksburg gauge first because that gauge is closer to the Gaffney gauge. The applicant used data from the Boiling Springs gauge for the years that did not have measurements at Gaffney and Blacksburg gauges.

The staff reviewed the applicant's method for estimating the 81-year streamflow record near the site and concluded that it is a commonly used method in hydrologic engineering and therefore, is acceptable. Accordingly, the staff considers RAI 818, Question 02.04.01-5, resolved.

To clarify the description of Make-Up Pond B and changes that may be made to it, the staff issued RAI 818, Question 02.04.01-6. In a November 18, 2008, response to RAI 818, Question 02.04.01-6, the applicant stated that the two sub-basins of the Make-Up Pond B refer to a bathymetric feature of the pond. During the construction of the pond in 1970s, a cofferdam was emplaced to facilitate construction of the Make-Up Pond B Dam. After the pond filled with water, the cofferdam was submerged, creating a division within the pond. The applicant stated that the cofferdam appears as two approximately parallel elevation contours at 164.6 m (540 ft) above MSL midway between the McKowns Mountain and the Make-Up Pond B Dam. The applicant also stated that this cofferdam would be removed during construction of WLS Units 1 and 2 to allow full communication between the two currently existing bathymetric divisions of Make-Up Pond B. The applicant stated that the Make-Up Pond B only provides water storage to support plant operations and has no safety-related function. The staff reviewed the applicant's response and concludes that the applicant provided sufficient information for staff to proceed with its review. Accordingly, the staff considers RAI 818, Question 02.04.01 6, resolved.

To gain a clear understanding of the significance of Hold-Up Pond A with respect to surface release pathways, the staff issued RAI 818, Question 02.04.01-7. In a November 18, 2008, response to RAI 818, Question 02.04.01-7, the applicant stated that the Hold-Up Pond A would be used as a settling pond for stormwater runoff during pre-construction and construction activities, as the discharge point for maintenance dewatering during plant construction, and as a stormwater detention basin during plant operations. The applicant reported that Hold-Up Pond A has a surface area of 1.7 ha (4.2 ac) with a watershed area of 0.08 km^2 (0.03 mi^2). In WLS COL FSAR Revision 2, the applicant reported that the surface area of Hold-Up Pond A is 1.8 ha (4.4 ac) with a storage volume of 69,568 m^3 (56.4 ac-ft) at a full pool elevation.

The applicant also stated that the underground piping constructed for the Cherokee project would be removed and backfilled during construction of WLS Units 1 and 2, which would eliminate man-made preferential groundwater pathways. The staff concluded that the applicant provided sufficient information for the staff to proceed with its review. Accordingly, the staff considers RAI 818, Question 02.04.01-7, resolved. The staff reviewed the technical validity of the applicant's response and its effects on groundwater pathways, and the staff's evaluation is presented in Section 2.4.12 of this report.

To facilitate direct comparison among several elevation values reported in the WLS COL FSAR, in RAI 818, Question 02.04.01-8, the staff requested that the applicant provide clarification regarding consistency of datums used throughout the WLS COL FSAR Section 2.4. In a November 18, 2009, response to RAI 818, Question 02.04.01-8, the applicant provided a list of datums used in WLS COL FSAR figures and has updated the WLS COL FSAR with this information. The staff concluded that the applicant provided sufficient information for staff to proceed with its review. Accordingly, the staff considers RAI 818, Question 02.04.01-8, resolved.

WLS COL FSAR Section 2.4.1.2.3 discusses the existing dams and reservoirs, and also refers to the proposed CCW Dam in WLS COL FSAR Section 2.4.1.2.3.3 "Water Management Changes." The staff subsequently requested additional information from the applicant, the USACE District Office in Wilmington, NC, and the CCW. The USACE provided some information about design details of the proposed reservoir.

In July 7, 2008, and July 11, 2008, emails to the staff, the USACE stated that the proposed CCW Dam would be an earth-fill structure approximately 25.3 m (83 ft) high and 379.5 m (1,245 ft) wide at the base with a 305 m (1,000 ft) wide emergency spillway. The dam would inundate areas below 262 m (860 ft) MSL upstream of it to create a reservoir with a surface area of approximately 526 ha (1,300 ac). The staff noted that the reservoir surface area value of 526 ha (1,300 ac), stated in the USACE email, differs from 909 ha (2,245 ac), the value stated in the *Federal Register* notice of intent pertaining to this proposed dam action. In WLS COL FSAR Section 2.4.4.1, the applicant stated that the estimated storage volume of the reservoir is approximately 58,590,386 m^3 (47,500 ac-ft). In a January 31, 2012, letter to the staff, McGill Associates provided currently available information regarding the proposed First Broad River Reservoir (impounded by the above-mentioned CCW Dam). The dam would be located approximately 5.6 river kilometers (3.5 river miles) upstream of North Carolina Highway 182 and 3.9 river kilometers (2.4 river miles) upstream of the confluence of Knob Creek with the First Broad River. The dam would be an earth-filled structure with the normal pool at 260.9 m (856 ft) above MSL; bottom of the dam at 242.3 m (795 ft) above MSL; crest of the dam, although not final yet, at approximately 266.7 m (875 ft) above MSL; spillway crest elevation at 261.5 m (858 ft) above MSL; and storage capacity at full pool elevation of 260.9 m (856 ft) above MSL of 26,153,778 m^3 (6,909,292,000 gal or 21,203 ac-ft). The spillway would be designed to safely pass 50 percent of the probable maximum precipitation (PMP) storm with a

0.9 m (3 ft) freeboard. The State of North Carolina may require the spillway to be designed to safely pass the PMP storm. The reservoir operation policy has not yet been determined.

On January 2, 2014, the staff received additional information regarding the CCW Dam and the First Broad River Reservoir from the USACE. The USACE informed the staff that the physical characteristics of the proposed dam and the First Broad River Reservoir have not changed. However, the USACE is still working to develop a plan for completing its review of the CCW proposal. The USACE also stated that its review of the CCW proposal may possibly find an alternative site that is more suitable in terms of environmental considerations. The staff's evaluation of the proposed CCW Dam and its potential effects on the safety of the WLS units is described in Section 2.4.4 of this report. As stated in Section 2.4.4.4.3 of this report, the staff concluded that a hypothetical failure of the proposed CCW Dam would not affect the safety of the WLS units.

Based on a review of the material presented by the applicant in WLS COL FSAR Section 2.4.1 and the staff's observations of the WLS site during the May 18 to 20, 2008, site audit, and based on the reasons given above, the staff concluded that the applicant has adequately considered the hydrosphere near the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified the hydrologic characteristics of the proposed site with appropriate consideration of the most severe natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.1.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has demonstrated that the characteristics of the site fall within the site parameters specified in the Design Certification (DC) rule, and that no outstanding information is expected to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.1 herein, that the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This section addressed the major hydrologic features, satisfying COL Information Item 2.4-1. The staff concluded that the applicant provided sufficient information to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.2 Floods

2.4.2.1 *Introduction*

WLS COL FSAR Section 2.4.2 describes historical flooding at the proposed site or in the region contiguous with the WLS site. The information summarizes and identifies the individual types of flood-producing phenomena, and combinations of flood-producing phenomena considered in establishing the flood design bases for safety-related plant features. The discussion also covers the potential effects of local intense precipitation.

Section 2.4.2 of this report provides a review of the following specific areas: (1) a description of the flood history; (2) flood design considerations; and (3) the effects of local intense precipitation.

2.4.2.2 *Summary of Application*

This section of the WLS COL FSAR describes information about site-specific flooding. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to floods as follows:

AP1000 COL Information Item

- WLS COL 2.4-2 Floods

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information about historical flooding and potential flooding factors, including the effects of local intense precipitation.
>
> - Probable Maximum Flood (PMF) on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.
> - Dam Failures – Site-specific information about potential dam failures.
> - Probable Maximum Surge and Seiche Flooding – Site-specific information about probable maximum surge and seiche flooding.
> - Probable Maximum Tsunami Loading – Site-specific information about probable maximum tsunami loading.
> - Flood Protection Requirements – Site-specific information about flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.2, the applicant addresses the effects of local intense precipitation including the local PMF at the site. Other causes of floods and their effects are discussed in subsequent WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.2.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification of floods and flood design considerations, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.2.

The applicable regulatory requirements for identifying floods are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to the hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.2:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," as supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, "Flood Protection for Nuclear Power Plants," as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.2.4 *Technical Evaluation*

The staff reviewed COL Information Item 2.4-2 related to the provision of site-specific information about historical flooding and potential flooding factors at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.3, 2.4.4, 2.4.5, 2.4.6, 2.4.7, and 2.4.10 of this report.

To ensure that the design basis flood is based on the most conservative of plausible conceptual models, in RAI 820, Question 02.04.02-1, the staff requested that the applicant describe the process followed to determine the conceptual models for floods from local intense precipitation, PMF in the drainage area upstream of the site, surges, seiche, tsunami, seismically induced dam failures, landslides, and ice effects. In an October 27, 2009, response to RAI 820, Question 02.04.02-1, the applicant stated that the conceptual models to determine the design basis flooding follow the recommendations of RG 1.206 and RG 1.59 and the design basis flooding was determined based on guidance provided in American National Standards Institute/American Nuclear Society standard, ANSI/ANS-2.8-1992, “Determining Design Basis Flooding at Power Reactor Sites.”

The applicant’s analysis of local intense precipitation used the Rational Method to determine runoff. This was appropriate because the area being analyzed is a small developed area. The applicant obtained the precipitation and intensity from the National Oceanic and Atmospheric Administration (NOAA) Hydrometeorological Reports (HMRs) 51 and 52 for a point and assumed the site drainage system would be non-functional during the local intense precipitation event. The applicant estimated the water-surface elevations using the USACE Hydrologic Engineering Center-River Analysis System (HEC-RAS) standard step backwater analysis software. The applicant also stated that flow restrictions were maximized by representing the building structures as obstructions to flow and assuming that they do not provide any flood storage. The applicant also performed a sensitivity analysis by varying the values of Manning’s roughness coefficient.

The applicant stated that the process followed to determine conceptual models for floods from a PMF in the drainage area upstream of the site would be discussed in response to RAI 821, Question 02.04.03-1, those for floods from surges and seiches in response to RAI 823, Question 02.04.05-1, those for floods from tsunami and landslides in response to RAI 824, Question 02.04.06-1, and those for floods from dam failures in response to RAI 822, Question 02.04.04-1.

The applicant consulted the USACE ice jam database and obtained river temperature data from the USGS stream gauge database to determine the conceptual models for floods from ice effects. The applicant stated that because no water is required from the Broad River or from Make-Up Ponds A and B to support safety-related functions of the two proposed units, any potential icing of water supply would have no effects on safety-related facilities.

Subsequently, the applicant decided to install Make-Up Pond C to address low-water conditions related to normal operations of the proposed units. Water stored in Make-Up Ponds B and C would be used, in that order, to provide water to Make-Up Pond A for CWS cooling water during low-flow conditions in the Broad River. Since the water pumped from the Broad River to the three Make-Up Ponds would only provide cooling during normal operations, the staff concluded that none of this water is safety-related. The UHS for the AP1000 units is the atmosphere.

The staff reviewed the applicant’s response to RAI 820, Question 02.04.02-1, and concluded that the applicant provided sufficient description of the process followed to determine conceptual models of flooding at and near the site. Therefore, the staff considers RAI 820, Question 02.04.02-1, resolved. The staff used the information provided by the applicant to evaluate the flooding analyses in subsequent sections of this report.

2.4.2.4.1 Flood History

Information Submitted by the Applicant

The applicant stated that floods on the Broad River occur primarily as a result of precipitation runoff over the watershed. Since dams located upstream of the WLS site are used for water supply and not for flood control, peak discharges in the Broad River near the WLS site are not affected significantly by the dams.

The Gaffney USGS streamflow gauge, (Gauge Number 02153500 with contributing area of 3,859 km^2 (1,490 mi^2)), is located about 8 river km (5 river mi) upstream of the WLS site. The applicant reported that the contributing area of the Broad River upstream of the WLS site is about 4,014 km^2 (1,550 mi^2). The applicant stated that the highest water elevation near the WLS site caused by historical floods (159.3 m (522.5 ft) at USGS Gaffney Station on August 14, 1940, and 156.6 m (513.6 ft) at the Ninety-Nine Islands Reservoir during May 1972) are substantially below the designed nuclear island finished floor elevation of 180.7 m (593 ft) above MSL. The applicant also stated that no historical data exist regarding flooding due to surges, seiches, tsunamis, dam failures, or landslides.

NRC Staff's Technical Evaluation

The staff reviewed the data presented by the applicant in WLS COL FSAR Section 2.4.2 regarding historical flooding and conducted its own analysis. The staff obtained peak streamflow data for USGS streamflow gauges in the Upper Broad River Basin. There are 30 gauges where peak streamflow data are available in the Upper Broad River Basin. Of these 30 gauges, 14 are located upstream of the site (Figure 2.4.2-1 of this report). Table 2.4.2-1 of this report shows the historical maximum peak streamflow reported for each of these streamflow gauges and the corresponding date. The historical maximum peak discharge at the USGS Gaffney Station, 3,373 m^3/s (119,100 cfs), occurred on August 14, 1940. Based on these data, the staff concluded that the flood history presented by the applicant is accurate.

The staff examined a hazard mitigation study conducted by Gaston County (2005). The hazard mitigation study mentions that within Gaston County tsunami and storm surge events are unlikely, landslides (mass earth movements) are unlikely, and snow and ice events are possible; however, with an average annual snowfall of approximately 7.8 cm (3 in.) flooding due to snow and ice events are unlikely. Based on this study and its independent review of historical data, the staff agreed with the applicant that floods due to tsunami, storm surge, landslide, or snow and ice events are unlikely to pose credible flooding hazards at the proposed WLS nuclear reactor site.

The staff reviewed the flood history information provided by the applicant in WLS COL FSAR Section 2.4.2 and independently obtained data from USGS to conclude that the information provided is sufficient to establish the history of flooding at and near the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated hydrological features of the site. Since the flood history provided by the applicant can be used as baseline information to compare with the estimated design bases for safety-related SSCs, the staff also concluded that the applicant adequately determined that the hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been recorded are met.

2.4.2.4.2 Flood Design Considerations

Information Submitted by the Applicant

The applicant stated that the design basis flood elevation at the WLS site was determined from several scenarios including the effects of local intense precipitation, PMF on streams and rivers, and potential dam failures, and that these flood scenarios are described in their respective WLS COL FSAR sections. The applicant also considered the combinations of appropriate conditions with flooding scenarios such as wind-generated waves. The applicant stated that because of the inland location of the WLS site, consideration of ocean-front surges, seiches, and tsunamis is not necessary. The applicant also stated that consideration of snowmelt and ice effects is not necessary because the WLS site is located in a temperate region.

The applicant estimated that the maximum flood water-surface elevation at the WLS site would result from a local intense precipitation event; the maximum flood water-surface elevation at the WLS site would be 180.6 m (592.6 ft) above MSL. The safety-related plant elevation is 180.7 m (593 ft) above MSL. The applicant has stated that this water-surface elevation, 179.72 m (589.62 ft) above MSL, is identified as a site characteristic.

NRC Staff's Technical Evaluation

The staff reviewed the description of flooding mechanisms provided by the applicant in WLS COL FSAR Sections 2.4.2, 2.4.3, 2.4.4, 2.4.5, 2.4.6, and 2.4.7. The staff's review of these individual flooding mechanisms and their flooding potential is described in detail in the associated sections herein. The staff observed that in the November 22, 2011, revised flooding analysis the applicant changed the design basis flood source mechanism from probable maximum flooding in the watershed of Make-Up Pond B with coincident wind waves to onsite flooding from local intense precipitation. The staff agreed with the applicant that the design basis flood elevation would be caused by local intense precipitation near the site and would be below ground-floor elevation of safety-related SSCs at the WLS site. More details of the design basis flood are described in Section 2.4.3.4.5 of this report.

Based on a review of the applicant's information contained in the WLS COL FSAR, the staff concluded that the applicant appropriately considered flood-causing phenomena and their combinations that are relevant for the WLS site. Based on the reasons given above, the staff found that the requirements of 10 CFR 100.20(c), as they relate to identifying and evaluating hydrological features of the site, are met. The staff agreed that the combinations of flood-causing phenomena considered by the applicant are appropriate for the WLS site. Based on the reasons given above, the staff concluded that the requirements of 10 CFR 52.79(a)(1)(iii) are met, as they relate to the determination of hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.2.4.3 Effects of Local Intense Precipitation

Information Submitted by the Applicant

The applicant estimated the local intense PMP for the WLS site by following the guidance in HMRs 51 and 52. The applicant obtained the 2.6 km^2 (1 mi^2) PMP values from HMR 52 for durations of 1 hour and less. For durations of 6 to 72 hours, the applicant obtained the PMP values from HMR 51 for a 25.6 km^2 (10 mi^2) area. The applicant's estimate of local intense precipitation at the WLS site is shown in Table 2.4.2-2 below.

Table 2.4.2-2 COL Applicant's Estimates of Cumulative Local Intense Precipitation Depths at the WLS Site

	Duration								
	5 min	15 min	30 min	1 hr	6 hr	12 hr	24 hr	48 hr	72 hr
PMP (cm [in.])	15.7 (6.2)	24.6 (9.7)	35.6 (14.0)	48.0 (18.9)	75.9 (29.9)	90.2 (35.5)	102.6 (40.4)	112.5 (44.3)	118.9 (46.8)

The applicant noted that the AP1000 site parameter for PMP is 52.6 cm (20.7 in.) per hour. Therefore, the local intense precipitation depth at the WLS site is lower than the AP1000 site parameter.

The applicant stated that elevations immediately adjacent to the nuclear power block areas enclosed by a roadway, range from the nominal plant grade of 180.4 m (592 ft) to 179.8 m (590 ft) above MSL. Farther away from this area, the grade is flat from the roadway to the plant side of the vehicle barrier system at 179.8 m (590 ft) above MSL. The outer bank of the vehicle barrier system is at an elevation of 179.2 m (588 ft) above MSL. Farther outside the vehicle barrier system, the WLS site is flat at an approximate elevation of 179.2 m (588 ft) above MSL before steeper slopes that form the banks of the adjacent water bodies including Make-Up Ponds A and B, Hold-Up Pond A, and the Broad River. The WLS site drainage area is shown in Figure 2.4.2-2 of this report.

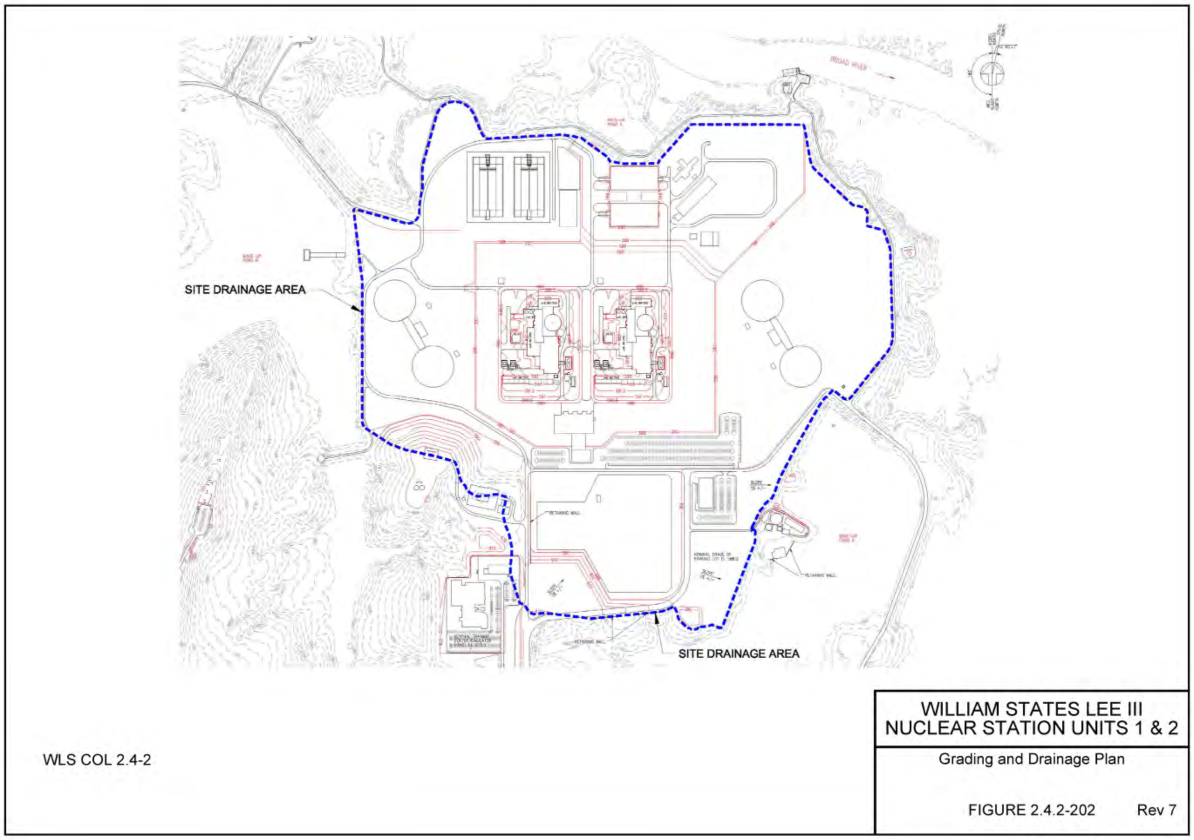

Figure 2.4.2-2 The Site Drainage Area at the WLS Site (Adapted from WLS COL FSAR Revision 7, Figure 2.4.2-202)

The applicant represented the WLS site areas at an elevation of 179.2 m (588 ft) above MSL as an idealized dry reservoir with an elevation-discharge-storage relationship. The applicant refers to this idealized reservoir as the idealized reservoir for the overall site. The storage was estimated using the elevation-area relationship within the drainage area excluding nuclear power block areas that are bounded by the vehicle barrier system, an area north of WLS Unit 2 that slopes from 179.8 m (590 ft) to 179.2 m (588 ft) above MSL, and areas where plant structures and the switchyard are located. The applicant developed the discharge relationship for this reservoir by representing its outer boundary, at an elevation of 179.2 m (588 ft) above MSL, as a broad-crested weir. The weir length is the total length of the 179.2 m (588 ft) above MSL contour minus the length of sections that are deemed ineffective because of less steep downstream slopes. The water-surface elevations in the downstream water bodies provide the downstream boundary conditions for the weir flow. The applicant stated that tailwater conditions would not affect the discharge over the weir; however, the applicant stated that it selected a conservatively low weir discharge coefficient of 2.0. The idealized dry reservoir model was implemented in the USACE Hydrologic Engineering Center Hydrologic Modeling System (HEC-HMS) software Version 3.5.

The applicant simulated two local intense precipitation storms. The first storm used PMP depths for a 72-hour duration with a precipitation interval of 1 hour and the second storm used PMP depths for a 6-hour duration with a precipitation interval of 5 minutes. The applicant estimated the runoff discharge by multiplying the precipitation intensity during each interval by the drainage area; the applicant noted that this approach is equivalent to using the Rational Method with a runoff coefficient of 1 where no losses occur. The applicant used the estimated runoff discharge as inflow to the overall site reservoir model and simulated the resulting water-surface elevation in the reservoir using level-pool routing with the outflow from the reservoir determined by the broad-crested weir equation. The applicant used the water-surface elevation resulting from the 72-hour duration storm as the starting reservoir elevation for the 6-hour duration storm. The applicant reported that the maximum water-surface elevation in the overall site idealized reservoir would be 179.5 m (588.8 ft) above MSL. The applicant used this water-surface elevation as the downstream boundary condition to analyze the WLS site area upstream of the vehicle barrier system.

Similar to the overall site idealized reservoir, the applicant developed an idealized reservoir model for the WLS site area upstream of the vehicle barrier system. The nuclear power block areas bounded by the 179.8 m (590 ft) above MSL contour are not included and all structures provide no storage. The applicant used the broad-crested weir equation to estimate the outflow from the reservoir with the length of the weir determined by the length of the 178.9 m (590 ft) above MSL contour, reduced by the lengths of sections that were deemed ineffective because of the presence of structures. The applicant used a weir discharge coefficient of 2.0. In its analysis, the applicant did not identify any tailwater effects.

Similar to the overall site idealized reservoir, the applicant used two local intense precipitation storms for the idealized reservoir model representing the WLS site area upstream of the vehicle barrier system. Estimation of runoff discharge included no losses. The applicant used the water-surface elevation resulting from the 72-hour duration storm as the starting reservoir elevation for the 6-hour duration storm. Using level-pool routing, the applicant estimated that the maximum water-surface elevation in the reservoir for the 6-hour duration storm would be 180 m (590.6 ft) above MSL. The applicant used this water-surface elevation as the downstream boundary condition to analyze the nuclear power block area of the two units.

For the nuclear power block areas of the two units, the applicant analyzed the runoff from local intense precipitation using four channels within each nuclear power block area (Figure 2.4.2-3 of this report), using a steady-state, backwater analysis in HEC-RAS software version 4.1.0. The applicant did not allow any precipitation losses; the peak runoff discharge used in the steady-state, backwater analysis results from a PMP intensity of 15.7 cm (6.2 in.) in 5 min. The applicant obtained the four channels' cross-section characteristics from the site grading and drainage plan. Structures in the nuclear power block area provide no storage and act as obstructions to open-channel flow. The applicant used a Manning's roughness coefficient of 0.026, appropriate for gravel-lined channels, as a bounding value for ground-cover types in the nuclear power block areas. The applicant reported that the maximum water-surface elevation at the upstream cross section occurred in channels B1 and B2 of the two nuclear power block areas, respectively. The applicant estimated the maximum water-surface elevation to be 180.6 m (592.6 ft) above MSL. The applicant noted that all safety-related structures are located at or above an elevation of 180.7 m (593 ft) above MSL.

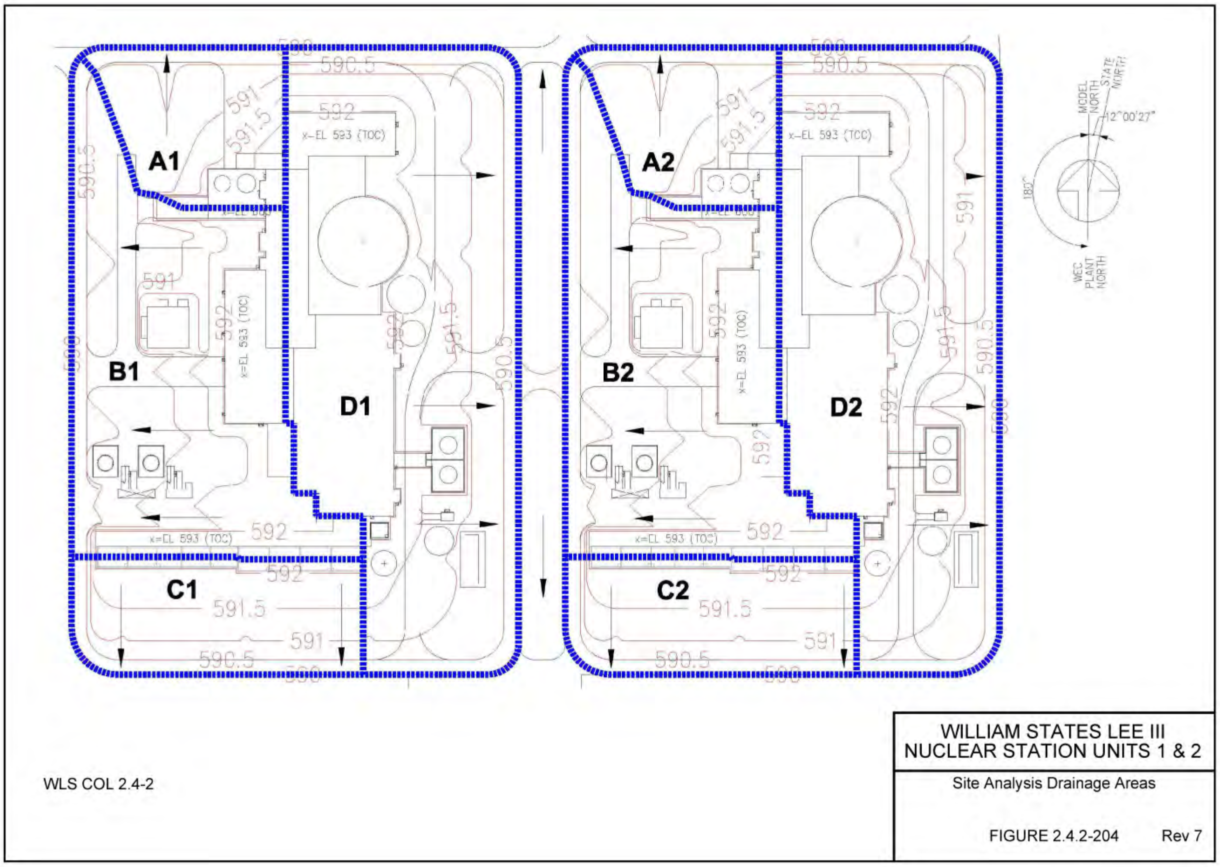

Figure 2.4.2-3 Drainage Pattern within the Nuclear Power Block Areas of the Two Units

NRC Staff's Technical Evaluation

The staff independently estimated the local intense precipitation at the site from NOAA HMRs 51 and 52. The staff-estimated values are shown in Table 2.4.2-3 of this report. The staff compared its independently estimated values of the local intense precipitation at the site to those stated by the applicant and determined that there are small differences in the two estimates. The largest of these differences, approximately 1.6 percent, occurred for the cumulative precipitation depth corresponding to the duration of 48 hours. The staff concluded that these differences are minor and would not significantly affect the estimation of water-surface elevations during site flooding under the local intense precipitation. The staff concluded, therefore, that the applicant's estimate of the local intense precipitation, shown in Table 2.4.2-2 of this report, is acceptable and would be used as a site characteristic.

Table 2.4.2-3 Cumulative Local Intense Precipitation Depths Independently Estimated by the Staff

	Duration								
	5 min	15 min	30 min	1 hr	6 hr	12 hr	24 hr	48 hr	72 hr
PMP (cm [in.])	15.7 (6.2)	24.4 (9.6)	35.6 (14.0)	48.0 (18.9)	76.2 (30.0)	90.7 (35.7)	104.1 (41.0)	114.3 (45.0)	119.4 (47.0)

The following discussion tracks the staff's review of the applicant's local intense precipitation-induced analysis in WLS COL FSAR Revisions 0 through 11. As described above in the subsection, "Information Submitted by the Applicant," the applicant has updated its analysis of flooding in the WLS site area under local intense precipitation after the nominal site grade for WLS Units 1 and 2 nuclear power block and the nuclear island finished floor elevations were raised to 180.4 m (592 ft) and 180.7 m (593 ft) above MSL, respectively.

To understand the analysis performed by the applicant related to the runoff from and water-surface elevations on site drainage areas under local intense precipitation, in RAI 820, Question 02.04.02-2, the staff requested that the applicant: (1) provide input files used in the HEC-RAS analysis described in WLS COL FSAR Section 2.4.2.3; (2) provide details of the iterative process used with the HEC-RAS model to determine water-surface elevations during the local intense precipitation event described in WLS COL FSAR Section 2.4.2.3; (3) provide details of how the times of concentration for the site drainage areas were determined; and (4) provide the locations of safety-related structures where the maximum water-surface elevations for each of the site drainage areas occurred. In an October 27, 2008, response to RAI 820, Question 02.04.02-2, the applicant stated that HEC-RAS and HEC-HMS electronic input and output files were provided to the NRC. The staff used these files to review the applicant's analysis described in WLS COL FSAR Section 2.4.2 and to perform independent confirmatory analyses. The applicant stated that the AP1000 safety-related structures are the containment building and the auxiliary building. The applicant identified these structures on a figure provided with the RAI response.

The staff evaluated the applicant's responses to the RAIs and determined that the applicant has adopted a reasonable approach to identify the effects of local intense precipitation. The staff reviewed the proposed post-construction elevation contour map of the site extending out from the nuclear power block area and determined that the identification of the four subareas based on the site grading plan and the location of safety-related SSCs conform to the elevation contours. The applicant used the Rational Method with an assumption of no losses to estimate the discharges in the four subareas. The applicant used the HEC-RAS hydraulic simulation software to estimate water-surface elevations under steady conditions. The staff concluded that these are conservative approaches and therefore, the applicant's methods for determination of discharges and water-surface elevations during the local intense precipitation event are adequate. Accordingly, the staff considers RAI 820, Question 02.04.02-2, resolved.

However, the staff noted that the applicant's use of the values of Manning's roughness coefficients for grass and for gravel, 0.035 and 0.015, respectively, were potentially not conservative for the corresponding groundcover. A higher value of Manning's roughness coefficient typically results in a greater depth of flow for the same discharge and same channel geometry. Chow (1959) suggested that the value of Manning's roughness coefficient ranges from 0.025 to 0.035 for short grass and from 0.030 to 0.050 for high grass. Since the applicant did not specify which grass type would be prevalent in the grassed areas on the site, the staff conservatively selected a Manning's n value of 0.048. Similarly, because the recommended value for lined or built-up channels with gravel bottom and formed concrete side ranges from 0.017 to 0.025 (1959), the staff selected the value of 0.025 as a conservative value. The applicant used values of 0.035 for grass and 0.015 for paved surfaces. The staff independently performed a HEC-RAS simulation for the northeast subarea of the local site drainage using the input files provided by the applicant. In this analysis, the staff started with the final, converged HEC-RAS simulation performed by the applicant. The only changes made to the HEC-RAS inputs were the Manning's roughness coefficients for grass and for gravel. The staff did not perform any iteration to accurately estimate the time of concentration. The staff's analysis was only meant to estimate how much, if any, effect conservatively selected Manning's roughness coefficients may have on the simulated velocities and water-surface elevations. Table 2.4.2-4 of this report shows the difference in HEC-RAS predictions for flow velocities and those for water-surface elevations for all subareas at cross sections near which safety-related SSC would be located.

Table 2.4.2-4 Difference in Simulated Flow Velocities and Water-Surface Elevations at Cross Sections Near Safety-Related SSCs Due to Change in Manning's Roughness Coefficient

Sub-area	Cross Section	Flow Velocities (m/s [(ft/s])		Water-Surface Elevations (m [ft] Above MSL)	
		COL Applicant	Staff	COL Applicant	Staff
NE	XS10	0.08 (0.25)	0.06 (0.2)	179.47 (588.82)	179.53 (589.01)
NW	XS7	0.17 (0.55)	0.14 (0.45)	179.52 (588.96)	179.58 (589.18)
SE	XS9	0.11 (0.37)	0.10 (0.33)	179.44 (588.7)	179.49 (588.87)
SW	XS8	0.02 (0.06)	0.02 (0.05)	179.63 (589.34)	179.70 (589.58)

As shown in Table 2.4.2-4 above, although the water-surface elevations did not change significantly, the velocities did change by up to 20 percent (at cross-section XS10 in the northeast (NE) subarea), which in turn would require iterations to refine the estimate of the time of concentration. The staff noted, based on the results described above, that the effects of local intense precipitation on the safety-related facilities should be re-evaluated by the applicant using more appropriate values for Manning's roughness coefficient or provide a justification why the base values of Manning's roughness coefficient used in the WLS COL FSAR analysis are conservative. Therefore, in supplemental RAI 72, Question 02.04.02-3, the staff requested that the applicant re-evaluate the effects of local intense precipitation based on more appropriate values of Manning's roughness coefficient, or to justify why the base values of Manning's roughness coefficient used in the WLS COL FSAR analysis were conservative.

In a July 17, 2008, response to RAI 72, Question 02.04.02-3, the applicant stated that a re-evaluation of the effects of the local intense precipitation analysis had been performed with a Manning's roughness coefficient value of 0.050 for grass cover areas and a value of 0.025 for paved and gravel cover areas. The applicant acknowledged the minor increase of the maximum water-surface elevation (from 179.63 m (589.34 ft) above MSL to 179.70 m (589.57 ft) above MSL for the southwest drainage area) due to the local intense precipitation effects. The re-estimated maximum water-surface elevation remained below the plant elevation of all WLS safety-related structures (179.8 m (590 ft) above MSL).

The staff evaluated the applicant's responses to the RAIs and concluded that the applicant has adopted a conservative approach by using the larger values for Manning's roughness coefficient in the HEC-RAS model. Therefore, the staff considers RAI 72, Question 02.04.02-3, resolved.

As described above, the applicant revised the analysis for site flooding under local intense precipitation in response to the staff's RAI 484, Question 10.04.05-2. The staff reviewed the applicant's description of changes to site grading and the applicant's calculations to support the updated site flood analysis. The staff concluded that the applicant's revised analysis that idealizes the site as a dry and shallow reservoir is reasonable because the site area is characterized by gentle slopes and the nuclear power block areas are surrounded by raised roadway that the accumulated runoff would overtop. The staff also concluded that the applicant's analysis to determine water-surface elevations in the nuclear power block areas adjacent to SSCs important to safety is conservative because of the following assumptions and their effects on the water-surface elevation in the idealized reservoir.

- The estimation of runoff ignores all precipitation losses to maximize volume of storage and corresponding water-surface elevation in the idealized reservoir.

- Depression storage was ignored, thereby maximizing the volume of runoff and increase water-surface elevation in the idealized reservoir.

- Plant structures provided obstruction to the flow but no storage, thereby minimizing surface area of the idealized reservoir that would result in higher water-surface elevation for the same storage volume.

- The sheet flow after overtopping could run off the site in all directions, but was assumed to be restricted to three channels that convey runoff to Make-Up Pond B, and the Broad River would result in reduced conveyance and therefore increase storage and corresponding water-surface elevation in the idealized reservoir.

- The downstream boundary conditions in Make-Up Pond B and the Broad River were assumed to be results of their respective PMF events even though the two PMF events would be extremely unlikely to occur concurrently.

The staff also reviewed the parameters the applicant used in the analysis to specify downstream boundary conditions (Manning's n and weir discharge coefficients) and finds them reasonable and conservative. The applicant also used multiple temporal distributions for the local intense precipitation and chose the most conservative results. Therefore, the staff concluded that the applicant's revised analysis for the effects of local intense precipitation on the water-surface elevation within and near the nuclear power block areas is reasonable and conservative. The staff concluded that the applicant-estimated water-surface elevation of 179.72 m (589.62 ft) above MSL that would occur on the west side of each of the proposed units in the area between the Annex Building and the Diesel Generator Building is conservative and acceptable as a site characteristic maximum water-surface elevation. For comparison, this estimate is slightly higher than that reported by the applicant, 179.70 m (589.57 ft) above MSL, in its original analysis.

After raising the nominal site grade for WLS Units 1 and 2 nuclear power block and the nuclear island finished floor elevation to 180.4 m (592 ft) and 180.7 m (593 ft) above MSL, respectively, the applicant updated its analysis of flooding in the WLS site area under a local intense precipitation event. The staff described the applicant's updated analysis above in the subsection, "Information Submitted by the Applicant." The staff reviewed the information provided in the WLS COL FSAR and reviewed the applicant's calculation packages in the reading room.

The staff reviewed the applicant's description of the revised analysis and concluded that the applicant implemented the WLS site area in hydrologic and hydraulic modeling software that is currently accepted in standard engineering practice. The applicant's models incorporate several conservative assumptions:

- No runoff losses are allowed, thereby maximizing the runoff volume, discharge, and the resulting water-surface elevations.
- The two areas modeled using idealized dry reservoirs promote detention of runoff within the reservoirs resulting in higher water-surface elevation.
- The selected value of the weir discharge coefficient would result in smaller discharge from the reservoirs and therefore maximize water-surface elevations within the reservoirs.
- The initial water-surface elevations for the two idealized reservoirs were set to an elevation that would result from a 72-hour-duration local intense precipitation before using the 6-hour, 5-minute local intense precipitation inflow into the reservoirs; this assumption is equivalent to assuming that a 72-hour PMP event was followed by a 6-hour PMP event at the WLS site, which is extremely conservative because it assumes two extreme precipitation events occurring in sequence.
- The Manning's roughness coefficient value of 0.026 is an appropriate maximum value for gravel bottom built-up channels with sides that have random stones in mortar; this assumption would result in a higher water-surface elevation within the nuclear power block areas.

Therefore, the staff concluded that the applicant's revised local intense precipitation-induced flood analysis is reasonable and conservative and would result in conservatively estimated water-surface elevations near the safety-related SSCs. Based on a review of the applicant's information in WLS COL FSAR Revisions 0 through 11, the staff concluded that the applicant has appropriately considered flood-causing phenomena related to local intense precipitation for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated hydrological features of the site. The staff agreed that the flood-causing phenomena associated with local intense precipitation considered by the applicant are appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.2.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.2.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information related to individual types of flood-producing phenomena, and combinations of flood-producing phenomena, considered in establishing the flood design bases for safety-related plant features. The information also covered the potential effects of local intense precipitation. The staff also confirmed that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.2 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This partially addresses COL Information Item 2.4-2. The staff concludes that the applicant has provided sufficient information with respect to the flood history, flood design considerations, and the effects of local intense precipitation to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.3 Probable Maximum Flood (PMF) on Streams and Rivers

2.4.3.1 *Introduction*

WLS COL FSAR Section 2.4.3 describes the hydrologic site characteristics affecting any potential hazard to the plant's safety-related facilities as a result of the effect of the PMF on streams and rivers.

Section 2.4.3 herein provides a review of the following specific areas: (1) regional PMPs and their losses; (2) runoff and stream course models; (3) PMF; (4) flood water-surface elevations including effects of coincident wind waves; (5) consideration of other site-related evaluation criteria; and (6) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts of 10 CFR Part 52.

2.4.3.2 *Summary of Application*

This section of the WLS COL FSAR describes the site-specific PMFs on streams and rivers. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to PMF as follows:

AP1000 COL Information Item

- WLS COL 2.4-2

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.2, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information about historical flooding and potential flooding factors, including the effects of local intense precipitation.
>
> - PMF on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.
> - Dam Failures – Site-specific information about potential dam failures.
> - Probable Maximum Surge and Seiche Flooding – Site-specific information about probable maximum surge and seiche flooding.
> - Probable Maximum Tsunami Loading – Site-specific information about probable maximum tsunami loading.
> - Flood Protection Requirements – Site-specific information about flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.3, the applicant addressed the effects of PMF on streams and rivers. Other causes of floods and their effects are discussed in related WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.3.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification of floods and flood design considerations, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.3.

The applicable regulatory requirements for identifying probable maximum flooding on streams and rivers are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirements to consider physical site characteristics in site evaluations are specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), "Geologic and Seismic Siting Factors," sets forth the criteria to determine the siting factors for plant design bases with respect to seismically induced floods and water waves at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.3:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, "Flood Protection for Nuclear Power Plants," as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.3.4 *Technical Evaluation*

In this section, the staff reviewed the applicant's analysis of PMF on streams and rivers near the WLS site including in the Broad River, in the McKowns Creek and Make-Up Pond B, in the Intermittent Stream and Make-Up Pond A, and in the London Creek and Make-Up Pond C. The staff's independent analysis is also described.

The staff reviewed COL Information Item 2.4-2 related to the provision of site-specific information about the PMF at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.2. 2.4.4, 2.4.5, 2.4.6, 2.4.7, and 2.4.10 of this report.

To ensure that the design basis flood is based on the most conservative of plausible conceptual models, in RAI 821, Question 02.04.03-1, the staff requested that the applicant describe the process followed to determine the conceptual models for floods in streams and rivers and in the site drainage system. In an October 27, 2008, response to RAI 821, Question 02.04.03-1, the applicant stated that conceptual models used to determine the design basis flood are consistent with the guidance of RG 1.206 and RG 1.59. The applicant stated that the flood estimation approach is consistent with the current state of the practice guidance described in ANSI/ANS-2.8-1992.

The applicant estimated the effects of flooding in Make-Up Ponds A and B using the point PMP values from HMRs 51 and 52. The applicant analyzed several time distributions of the PMP to estimate the most severe flooding effects in the makeup ponds. The applicant used the Soil Conservation Service (SCS) unit hydrograph method to estimate runoff. The applicant maximized the runoff by assuming wet antecedent conditions and no precipitation losses.

The applicant stated that the PMP for the Broad River Basin was estimated using HMRs 51 and 52 and that the PMP over the Broad River Basin was maximized by evaluating several storm centers, storm sizes, and storm orientations. The applicant derived the unit hydrographs for use in the PMF estimation from USGS unit hydrographs for the region. The applicant stated that antecedent storm conditions were chosen to maximize runoff and noted that a PMF in the Broad River Basin was combined with coincident wind-wave activity.

The staff reviewed the applicant's October 27, 2008, response to RAI 821, Question 02.04.03-1, and concluded that the description of the process followed to arrive at conceptual models of floods in streams and rivers is adequate. Therefore, the staff considers RAI 821, Question 02.04.031, resolved. The staff's review of flooding on the WLS site and the nuclear power block areas due to local intense precipitation is described in Section 2.4.2 of this report.

2.4.3.4.1 Probable Maximum Precipitation

Information Submitted by the Applicant

The applicant estimated the PMP for the watershed above the WLS site defined by HMRs 51 and 52 based on an existing study for Ninety-Nine Islands Dam. The applicant optimized the orientation of the PMP storm over the Broad River Basin using the HMR 52 computer software. The applicant used 18 sub-basins in the Broad River Basin upstream of the WLS site. The applicant modified the PMP analysis to include antecedent storm conditions, as specified by RG 1.59, Appendix A and estimated the critical 72-hour storm PMP rainfall total to be 64.7 cm (25.5 in.) for the entire watershed. The applicant used HMR 53 to estimate the winter PMP for the Broad River Basin. The applicant examined the combined event of winter PMP coincident with a 100-year snowpack and stated that snowmelt is not considered to be a factor in modeling the PMF event because the sum of winter PMP and 100-year snowpack is approximately 70 percent of the all-season PMP.

The applicant stated that the PMP for the McKowns Creek and Make-Up Pond B watershed, the Intermittent Stream and Make-Up Pond A watershed, and the London Creek and Make-Up Pond C watershed is the local intense precipitation previously estimated in WLS COL FSAR Section 2.4.2.3.

NRC Staff's Technical Evaluation

To understand the analysis performed by the applicant related to the estimation of PMP on the drainage basin above the Ninety-Nine Islands Dam, in RAI 821, Question 02.04.03-2, the staff requested that the applicant describe the relevance of HMR 53 for determination of the PMP in the Broad River Basin.

In an October 27, 2008, response to RAI 821, Question 02.04.03-2, the applicant stated that the winter PMP for the Broad River Basin is estimated by multiplying the all-season PMP value obtained from HMR 52 by the ratio of the 25.9 km^2 (10 mi^2) winter PMP obtained from HMR 53 to the 25.9 km^2 (10 mi^2) all-season PMP obtained from HMR 51. The applicant estimated the ratio to be approximately 0.567 (66.3 cm/116.8 cm [26.1 in/46.0 in]). Using this ratio, the applicant estimated that the winter PMP over the Broad River Basin for a 72-hour duration would approximately be 36.7 cm (14.5 in.) (0.567 × 64.7 cm (25.5 in.)). The applicant further stated that the 100-year snowpack is estimated to be 43.2 cm (17.0 in.) of snow with a water equivalent of 8.6 cm (3.4 in.) and is described in WLS COL FSAR Section 2.3.1.2.7.1. The applicant subsequently estimated, assuming that the 100-year antecedent snowpack would completely melt during the winter PMP event, that the combined potential runoff during the PMP-on-snowpack event would be 45.5 cm (17.9 in.) (36.0 cm (14.5 in.) winter PMP + 8.6 cm (3.4 in.) 100-year snowpack water equivalent), which is approximately 70 percent of the estimated all-season, 72-hour PMP depth of 64.7 cm (25.5 in.) over the whole Broad River Basin. The applicant concluded, therefore, that snowmelt would not be a significant factor in generation of a controlling PMF event in the Broad River Basin.

The staff evaluated the procedure used by the applicant for the estimation of winter PMP in the Broad River Basin. The applicant's approach is based on the assumption that the ratio of the 25.9 km^2 (10 mi^2) winter precipitation (given in HMR 53) to the 25.9 km^2 (10 mi^2) all-season PMP (given in HMR 51) at a given location remains the same for other drainage areas and times of occurrences. The staff independently obtained the 25.9 km^2 (10 mi^2) PMP depths for the months of December through April from HMR 53 for durations equal to 6, 24, and 72 hours at the WLS site. The staff also independently obtained the all-season PMP depths from HMR 51 for the same durations at the WLS site. These values are shown in Table 2.4.3-1. The staff estimated the ratios of HMR 53 PMP for the months of December through April to the HMR 51 all-season PMP depth. These values are shown in Table 2.4.3-2 of this report.

Based on the data shown in Tables 2.4.3-1 and 2.4.3-2 of this report, the staff concluded that the month-wise ratios of HMR 53 PMP depend on the selected duration of the PMP. There is a clear increasing trend for the value of the ratio with increasing duration of the PMP. The staff also noted that the mean of these ratios for the winter months for the 72-hour duration, 0.569, is very close to that used by the applicant, 0.567.

Table 2.4.3-1 Seasonal PMP Depths from HMR 53 and All-Season PMP Depths from HMR 51 at the WLS Site

Duration (hr)	HMR 53 PMP Depth (cm [in.])					HMR 51 All-Season PMP Depth (cm [in.])
	December	January	February	March	April	
6	36.3 (14.3)	33.0 (13.0)	33.0 (13.0)	36.3 (14.3)	43.2 (17.0)	75.7 (29.8)
24	53.6 (21.1)	50.8 (20.0)	50.8 (20.0)	54.9 (21.6)	61.0 (24.0)	102.1 (40.2)
72	68.1 (26.8)	63.5 (25.0)	63.5 (25.0)	68.1 (26.8)	74.2 (29.2)	118.6 (46.7)

Table 2.4.3-2 Ratio of Seasonal PMP Depths from HMR 53 to the All-Season PMP Depths from HMR 51 at the WLS Site

Duration (hr)	HMR 53 to HMR 51 PMP Depth Ratio					
	December	January	February	March	April	Mean
6	0.480	0.436	0.436	0.480	0.570	0.481
24	0.525	0.498	0.498	0.537	0.597	0.531
72	0.574	0.535	0.535	0.574	0.625	0.569

The staff also noted that the winter PMP values obtained from HMR 53 are appropriate for a 25.9 km^2 (10 mi^2) drainage area. Since the PMP depth for a given duration at a given location decreases with increasing drainage area, the staff concluded that the use of 25.9 km^2 (10 mi^2) winter PMP depths for the Broad River Basin, which is approximately 4,014 km^2 (1,550 mi^2) in size above the Ninety-Nine Islands Dam, is conservative. Therefore, the staff concluded that the applicant's approach for estimation of winter PMP depths over the Broad River Basin is conservative. Accordingly, the staff considers RAI 821, Question 02.04.03-2, resolved.

The staff also determined that the addition of the 100-year snowpack, which is assumed to completely melt during the winter PMP event, to the winter PMP depth over the Broad River Basin results in a combined PMP-on-snow event depth that is less than the all-season PMP depth estimated below. Therefore, the staff agreed with the applicant that the flood generated by a PMP-on-snow event would be less severe than the all-season PMF estimated for the Broad River Basin and does not require further consideration.

The staff independently estimated the all-season PMP over the Broad River Basin using the HMR 52 software developed by the USACE. The staff used a GIS layer of the Broad River Basin and its sub-basin boundaries to estimate normalized coordinates for input to the HMR 52 software. The depth-area-duration values from the all-season PMP for durations of 6, 12, 24, 48, and 72 hours, and drainage areas of 25.9, 518, 2,590, 12,950, 25,900, 51,800 km^2 (10, 200, 1,000, 5,000, 10,000 and 20,000 mi^2) from HMR 51 were also input into the software. The

HMR 52 software automatically finds the optimal orientation of the PMP storm pattern over the input drainage basin. The staff-estimated PMP storm pattern and PMP depths closely agreed with those reported by the applicant. Therefore, the staff considers the applicant's PMP estimates acceptable.

Based on a review of the applicant's information in WLS COL FSAR Revisions 0 through 11, the staff concluded that the applicant has appropriately considered the local intense precipitation for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme precipitation events at the site. The staff agreed that the local intense precipitation considered by the applicant is appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determinated hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.3.4.2 Precipitation Losses

Information Submitted by the Applicant

The applicant estimated the precipitation losses for Broad River sub-basins and London Creek watershed upstream of Make-Up Pond C based on an existing study using the USDA SCS (now the NRCS) curve number method. The precipitation losses for each sub-basin are provided in the WLS COL FSAR. The applicant's precipitation losses range from approximately 2.5 to 7.3 cm (1 to 2.9 in.) during the 72-hour PMP event. For McKowns Creek watershed upstream of Make-Up Pond B and the Intermittent Stream watershed upstream of Make-Up Pond A, the applicant assumed that no precipitation loss occurs and therefore all rainfall is transformed to runoff.

NRC Staff's Technical Evaluation

The staff reviewed the method followed by the applicant to estimate precipitation loss rates for the PMF estimation in the Broad River Basin and in the watersheds of Make-Up Ponds A, B, and C. The staff determined that the method used to estimate loss rate for the Broad River Basin and the London Creek watershed upstream of Pond C is commonly used in practice. However, the applicant stated that this method resulted in rainfall losses ranging from 37 to 71 percent with a mean of 51 percent during the antecedent storm and in precipitation losses ranging from 3 to 19 percent with an average of 8 percent during the full PMP storm.

The staff evaluated the effect of loss rates estimated by the applicant on the predicted PMF water-surface elevations near the site by independently estimating the sensitivity of the predictions to this parameter. The staff used the HEC-HMS input files provided by the applicant to perform an analysis for the Broad River Basin such that no precipitation losses were allowed. The staff's analysis resulted in a peak discharge of 22,342 m^3/s (789,000 cfs) at the Ninety-Nine Islands Dam compared to the approximately 21,011 m^3/s (742,000 cfs) discharge estimated by the applicant. The staff used the discharges estimated by HEC-HMS model in the HEC-RAS model provided by the applicant to estimate the corresponding water-surface elevations under the no-loss scenario. The staff's evaluation of the Broad River PMF water-surface elevations is described in Section 2.4.3.4.5 of this report.

The staff agreed with the applicant that the no-loss approach used for the drainage areas of Make-Up Ponds A and B is an appropriately conservative approach for determination of the PMF water-surface elevations in the makeup ponds.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately considered precipitation losses at and near the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the precipitation losses considered by the applicant are appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.3.4.3 Runoff and Stream Course Models

Information Submitted by the Applicant

The applicant developed the Broad River runoff and stream course model based on an existing HEC-1 study with modifications to include the antecedent rainfall conditions. The applicant used the USACE HEC-HMS Version 3.0.1 modeling software for estimating the runoff and routing calculations and USACE HEC-RAS Version 3.1.3 modeling software to route hydrographs from above Gaston Shoals Dam to Lockhart Dam.

To account for nonlinear basin response at high rainfall rates, the applicant increased the peak of the unit hydrograph by 20 percent and reduced the time to peak by approximately 33 percent. The applicant used the SCS unit hydrograph method as a basis for a modified unit hydrograph to transform rainfall to runoff for the Make-Up Pond C sub-basin. The applicant obtained the HEC-RAS cross sections from an existing study and modified as necessary and used Manning's roughness coefficients given in published tables by Chow.

For McKowns Creek and Make-Up Pond B, the applicant used the USACE HEC-HMS modeling software for estimating runoff and storage routing calculations. To account for nonlinear basin response at high rainfall rates, the applicant increased the peak of the unit hydrograph by 20 percent and reduced the time to peak by approximately 33 percent. The applicant used the SCS unit hydrograph method as a basis for a modified unit hydrograph to transform rainfall to runoff. The applicant estimated the drainage area, length of watercourse, and average slope of the watershed from aerial topography of the area and calculated the lag time using the standard SCS curve number regression equation. The applicant estimated the base flow to have a constant rate of 0.05 m^3/s (1.8 cfs) using the minimum average monthly flow of the Gaffney and Ninety-Nine Island gauges (USGS No. 02153500 and 02153551) with correction on the basis of a ratio of drainage basin areas. The applicant developed the Make-Up Pond B outflow structure rating curve using standard weir and orifice flow equations with coefficients of 3.5 and 0.8, respectively and estimated the available storage based on aerial topography. The applicant assumed a full pond elevation of 174 m (570 ft) above MSL for antecedent conditions.

For McKowns Creek and Make-Up Pond B, the applicant used the USACE HEC-HMS modeling software for estimating runoff and storage routing calculations. To account for nonlinear basin response at high rainfall rates, the applicant increased the peak of the unit hydrograph by 20 percent and reduced the time to peak by approximately 33 percent. The applicant used the SCS unit hydrograph method as a basis for a modified unit hydrograph to transform rainfall to runoff. The applicant estimated the drainage area, length of watercourse, and average slope of the watershed from aerial topography of the area and calculated the lag time using the standard SCS curve number regression equation. The applicant estimated the base flow to have a constant rate of 0.05 m^3/s (1.8 cfs) using the minimum average monthly flow of the Gaffney and Ninety-Nine Island gauges (USGS No. 02153500 and 02153551) with correction on the basis of a ratio of drainage basin areas. The applicant developed the Make-Up Pond B outflow structure rating curve using standard weir and orifice flow equations with coefficients of 3.5 and 0.8, respectively and estimated the available storage based on aerial topography. The applicant assumed a full pond elevation of 174 m (570 ft) above MSL for antecedent conditions.

NRC Staff's Technical Evaluation

In RAI 821, Question 02.04.03-3, the staff requested that the applicant explain why unit hydrographs calibrated using observed runoff events produced by precipitation depths much smaller than the PMP event in the Broad River Basin were appropriate to estimate the PMF in the basin or to update the PMF analysis with techniques recommended by other Federal agencies or those used in standard practice.

In an October 28, 2008, response to RAI 821, Question 02.04.03-3, the applicant stated that the impact of nonlinear basin response is examined as a sensitivity study for Make-Up Pond B watershed. The applicant stated that the SCS unit hydrograph, used to transform rainfall to runoff, was modified to increase the peak discharge by 20 percent and to decrease the time base by approximately 33 percent. The applicant stated that the intermediate ordinates of the unit hydrograph were adjusted to maintain the area under the curve equal to 2.5 cm (1 in.) of rainfall excess. The applicant estimated that the maximum water-surface elevation in Make-Up Pond B would be higher using the modified unit hydrographs. The applicant stated that there would be no significant change in wind-wave activity because the increase in the water-surface elevation in Make-Up Pond B was not large enough to significantly affect wind-wave characteristics. The applicant stated that the higher maximum water-surface elevation estimate in Make-Up Pond B for PMP and coincident wind-wave effects was only provided as a sensitivity analysis and would not supersede the flood elevation previously reported.

The staff evaluated the applicant's response to RAI 821, Question 02.04.03-3, and determined that accounting for nonlinearity of basin response should not be viewed only as a sensitivity effect. The final water-surface elevation used for the design basis must be based on an appropriate analysis that includes the effects of nonlinear basin response to account for the most conservative plausible runoff generation scenario. In RAI 69, Question 02.04.03-6, the staff requested that the applicant provide an analysis of Make-Up Pond B flood water-surface elevation that included the effects of nonlinear basin response.

The staff also noted that the coincident wind-wave activity described above was based on the previously estimated water-surface elevation in Make-Up Pond B. The staff concluded that the new estimate of water-surface elevation should be used to re-estimate wind waves. Therefore, in RAI 69, Question 02.04.03-7, the staff requested that the applicant re-estimate coincident wind waves with the flood stillwater-surface elevation estimated from the analysis that includes the effects of nonlinear basin response. In an October 27, 2008, response to RAI 821, Question 02.04.03-3, the applicant stated that a comparison of maximum flood water-surface elevation in the Broad River and the Make-Up Pond B with the maximum flood water-surface elevation in Make-Up Pond B showed a significant amount of freeboard. Based on this significant amount of freeboard, the applicant concluded that accounting for nonlinear basin response in the Broad River Basin would not increase the maximum flood water-surface elevation in the river or in the Make-Up Pond A enough to exceed the maximum flood water-surface elevation estimated for the Make-Up Pond B.

The staff agreed with the applicant that there appears to be a significant amount of freeboard available between the maximum flood water-surface elevation estimated for the Make-Up Pond B and the maximum flood water-surface elevations estimated for the Broad River and the Make-Up Pond A. The staff determined that it is likely, if nonlinear basin response were accounted for in runoff generation during the Broad River Basin PMF event that the flood water-surface elevation would be higher and therefore, would result in a longer fetch length in the inundated areas of the river floodplain. The staff concluded therefore, that a more detailed analysis that includes the effects of nonlinear basin response and the effects of coincident wind waves is needed to conclusively determine that the design basis flood would result from a PMF in the Make-Up Pond B watershed and not in the Broad River Basin. Therefore, in RAI 69, Question 02.04.03-8, the staff requested that the applicant re-estimate wind waves in the Broad River and in Make-Up Pond A with the flood stillwater-surface elevation that accounted for the nonlinear basin response.

In a June 19, 2009, response to RAI 69, Questions 02.04.03-6, 02.04.03-7, and 02.04.03-8, the applicant re-analyzed the flooding scenario for Make-Up Pond B by calculating the effects of wind-driven waves from a still water elevation that includes the nonlinear basin response effects. The staff examined the applicant’s analysis and concluded that the applicant’s new flood analysis includes nonlinear basin response for Make-Up Pond A and coincident wind-wave effects and, therefore, finds that the applicant’s analysis is conservative. Accordingly, the staff considers RAI 820, Question 02.04.03-3 and RAI 69, Questions 02.04.03-6, 02.04.03-7, and 02.04.03-8, resolved.

Based on a review of the applicant’s information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately considered the characteristics of the streams and rivers near the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the local intense precipitation considered by the applicant is appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.3.4.4 Probable Maximum Flood Flow

Information Submitted by the Applicant

The applicant estimated the peak PMF discharge at the WLS site as 23,311 m^3/s (823,212 cfs) resulting from the 2,590 km^2 (1,000 mi^2) storm centered near the centroid of the Gaston Shoals Dam drainage basin.

The applicant estimated the peak PMF runoff to be 567 m^3/s (20,039 cfs) and the routed discharge to be 183 m^3/s (6,471 cfs) from a 6-hour two-thirds peaking storm event for the McKowns Creek watershed upstream of Make-Up Pond B. However, the applicant stated that the controlling water-surface elevation occurred during a 72-hour end-peaking storm event with a peak PMF runoff of 536 m^3/s (18,937 cfs) and a routed discharge of 237 m^3/s (8,386 cfs).

The applicant estimated the peak PMF runoff to be 330 m^3/s (11,644 cfs) and a routed discharge to be 279 m^3/s (9,847 cfs) from a 6-hour storm event for the Intermittent Stream watershed upstream of Make-Up Pond A.

The applicant estimated the peak PMF runoff to be 826 m^3/s (29,167 cfs) and a routed discharge to be 300 m^3/s (10,577 cfs) from a 72-hour end-peaking storm event for the London Creek watershed upstream of Make-Up Pond C.

NRC Staff's Technical Evaluation

The staff reviewed the HEC-HMS model files provided by the applicant and determined that the approach used by the applicant for estimating the PMF flood discharge is appropriate. The staff performed a sensitivity analysis on the PMF discharge by changing the loss rate for the Broad River Basin PMF estimation as described in Section 2.4.3.4.2 of this report. As expected, the PMF discharge near the site increased under the no-loss scenario investigated by the staff. The water-surface elevations corresponding to the no-loss scenario were also estimated by the staff. The staff's evaluation is described in Section 2.4.3.4.5 of this report.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately estimated the PMF discharge in streams and rivers near the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the PMF discharge estimated by the applicant is appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.3.4.5 Water-Elevation Determinations

Information Submitted by the Applicant

The applicant estimated that the maximum stillwater flood elevation near the WLS site from a PMF in the Broad River Basin would be 168.1 m (551.5 ft) above MSL. The applicant estimated that the maximum flood elevation near the WLS site from a PMF in the McKowns Creek watershed upstream of Make-Up Pond B would be 178.1 m (584.4 ft) above MSL. The applicant stated that Make-Up Pond B is not located on a large river or stream and that the impoundment is confined within a small watershed area. The applicant also stated that it did not consider blockage of the outlet structure in its analysis of the PMF routed through Make-Up Pond B because the outlet structure is sized adequately and there is minimal potential for significant amount of debris to be picked up by floodwaters during the PMF event and subsequently transported to the outlet structure. The applicant stated that its shoreline management program would consist of removing trees from the area around the perimeter of Make-Up Pond B extending 15.2 m (50 ft) beyond contour elevation of 178.3 m (585 ft) above MSL. The applicant stated that this area would be maintained as a grassed, paved, or covered by some other suitable material throughout the operational life of the plant. The maximum water-surface elevation in Make-Up Pond B results from the Upper Arm culvert being non-functional while allowing overtopping and discharge into Make-Up Pond B. During the same event, the applicant estimated that the maximum water-surface elevation in the Upper Arm Pond would be 180.5 m (592.3 ft). The ridges on the east of the Upper Arm Pond separate it from the WLS site.

The applicant estimated the maximum water-surface elevation of Make-Up Pond A from a PMF in the Intermittent Stream watershed as 170.1 m (558.2 ft). The applicant stated that because the PMF discharge flow from Make-Up Pond C is bounded by the PMF discharge in the Broad River Basin, spillover from Make-Up Pond C during a PMF event is not a limiting event for flooding at the WLS site when taken as an isolated event.

NRC Staff's Technical Evaluation

To understand the applicant's rationale behind the selection of the design basis flood elevation at the WLS site and whether any special safety-related structures or systems, particularly a debris collection boom near the Make-Up Pond B spillway, may be needed for flood protection, the staff issued RAI 821, Question 02.04.03-4. In an October 27, 2008, response to RAI 821, Question 02.04.03-4, the applicant stated that the maximum flood water-surface elevation from a PMF event in the watershed of Make-Up Pond B and the coincident effects of wind-induced waves would be significantly below the WLS site grade. The applicant also provided a description of a shoreline management plan with this RAI response. The applicant stated that the shoreline management program would remove trees from the water's edge around Make-Up Pond B. The applicant also stated that this area would be maintained as grassy, paved, or with other suitable cover throughout the operational life of the plant. The applicant concluded that because of the shoreline management plan, blockage of Make-Up Pond B's outlet structure from debris during a PMF event would not be credible.

The staff evaluated the applicant's October 27, 2008, response to RAI 821, Question 02.04.03-4, and concluded that the proposed shoreline management program would limit debris accumulation at the outlet structure during the PMF event in the watershed of Make-Up Pond B. Therefore, the staff concluded that the approach and the method adopted for estimation of the PMF in the watershed of Make-Up Pond B is adequate. However, the staff noted that the applicant needed to include details of the Shoreline Management Plan in WLS COL FSAR Section 2.4.3 because it provides important information related to the justification of the PMF estimation approach for the watershed of Make-Up Pond B. Therefore, in RAI 69, Question 02.04.03-10, the staff requested that the applicant address this need. In a June 19, 2009, response to RAI 69, Question 02.04.03-10, the applicant stated that the details provided in response to the staff's RAI 821, Question 02.04.03-4, were included in WLS COL FSAR Revision 1. The applicant stated that the shoreline management program would remove all trees from the water's edge. The applicant stated that this area would be maintained as paved or grassed or covered with other suitable alternative material throughout the operational life of the plant. The staff reviewed the applicant's response and determined that sufficient detail regarding the shoreline management program has not been provided in the WLS COL FSAR. Because the success of the shoreline management program is essential for maintaining the PMF water-surface elevation in Make-Up Pond B below the AP1000 DCD maximum flood level, the staff determined that the applicant needs to provide additional details of the shoreline management program in the WLS COL FSAR including frequency of inspection, criteria for determination of the need to perform maintenance, and the frequency of maintenance throughout the operational life of the plant. The applicant did not provide any additional details of the shoreline management program in Revision 5 of the WLS COL FSAR. In Revision 7 of the WLS COL FSAR, the applicant stated that the shoreline management program would annually inspect the shoreline around Make-Up Pond B and remove trees that may have fallen on the ground and trees that may be about to fall. The applicant would also inspect the spillway for debris after rainfall events that exceed an intensity of 7.6 cm/hr (3 in/hr). The applicant would install a secondary debris barrier system, approximately 107 m (350 ft) from the Make-Up Pond B spillway. The staff reviewed the details of the applicant's shoreline management program and the secondary barrier system. Since an effective implementation of the shoreline management program would minimize debris available for transport with the PMF and the secondary debris barrier system would be in place, the staff concluded that the combination of the shoreline management program and the debris barrier system would prevent the blockage of the Make-Up Pond B spillway. The staff considers implementation of the shoreline management program and the installation of debris barrier system commitments on the part of the applicant. Accordingly, the staff considers RAI 821, Question 02.04.03-4, and RAI 69, Question 02.04.03-10, resolved.

The staff estimated the PMF discharges in the Broad River Basin under a no precipitation loss HEC-HMS scenario performed to investigate the sensitivity of the PMF water-surface elevations near the site to the value of the selected loss rate. The discharge hydrographs predicted by HEC-HMS were input by the staff into the HEC-RAS model of the Broad River Basin provided by the applicant. The staff's HEC-RAS simulation used combined inflow into the Gaston Shoals Dam as the upstream unsteady boundary condition. Flood discharges from reaches and sub-basins located downstream from the Gaston Shoals Dam were input into the HEC-RAS model as lateral inflows. The staff was able to successfully perform the unsteady simulation. However, based on the description of the HEC-RAS model in the WLS COL FSAR and the additional details provided in RAI responses, the staff was unable to determine location of the cross section near the site. The staff required more information regarding the HEC-RAS model setup to verify the sensitivity of the PMF water-surface elevation to precipitation loss rates. Therefore, in RAI 69, Question 02.04.03-9, the staff requested that the applicant identify the cross section in the HEC-RAS setup that is located directly across from the WLS site.

In a June 19, 2008, response to RAI 69, Question 02.04.03-9, and in a subsequent telephone conversation with the applicant, the staff obtained clarification on the location of the above-mentioned cross section and withdrew RAI 69, Question 02.04.03-9. Accordingly, the staff considers RAI 69, Question 02.04.03-9, resolved. During the staff's simulation of a no precipitation loss scenario, the maximum PMF water-surface elevation in the Broad River at the HEC-RAS cross section located directly across from the WLS site was 168.7 m (553.4 ft) above MSL. The increase in the PMF water-surface elevation near the WLS site under the no precipitation loss scenario was relatively minor, about 0.6 m (1.9 ft), compared to the difference between the PMF water-surface elevation and the WLS site grade, which is about 12.2 m (40 ft). Therefore, the staff concluded that the PMF in the Broad River would not cause water-surface elevations near the WLS site that would affect the safety of the WLS units.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately estimated the PMF water-surface elevations in streams and rivers near the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the PMF water-surface elevations estimated by the applicant are appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.3.4.6 Coincident Wind-Wave Activity

Information Submitted by the Applicant

The applicant evaluated the coincident wind-wave activity for the Broad River, Make-Up Pond A, Make-Up Pond B, and Make-Up Pond C. The applicant stated that effects of wind waves for Broad River, Make-Up Pond A, and Make-Up Pond B are addressed in WLS COL FSAR Section 2.4.4.

The applicant stated that Make-Up Pond C is located on a tributary of the Broad River such that wind waves in the pond would not affect the WLS site. The applicant reported that wind-wave activity coincident with PMF in the Broad River Basin and a concurrent failure of Make-Up Pond C Dam is evaluated in WLS COL FSAR Section 2.4.4, which bounds the wind-wave activity in Make-Up Pond C.

NRC Staff's Technical Evaluation

To obtain estimates of coincident wind-wave activity to be included in the estimation of the design basis flood water-surface elevation, the staff issued RAI 821, Question 02.04.03-5.

In an October 27, 2008, response to RAI 821, Question 02.04.03-5, the applicant stated that the effects of wind-wave activity were estimated for flood events in the Broad River and Make-Up Ponds A and B.

The applicant provided an update to the WLS COL FSAR Section 2.4.3.6. The applicant estimated fetch lengths using the longest straight-line fetch from USGS topographic maps. The applicant stated that wave height, wave setup, and wave runup were estimated using the procedures described by USACE. The applicant estimated the 2-year annual extreme mile wind speed using ANSI/ANS-2.8-1992 guidance to be 22.4 m/s (50 mph). The applicant updated the WLS COL FSAR text to reflect changes in wind-wave estimation in response to RAI 69, Questions 02.04.03-6, 02.04.03-7, and 02.04.03-8. The staff evaluated the applicant's response to RAI 821, Question 02.04.03-5, and concluded that the process used to estimate the coincident wind-wave activity is currently used in standard engineering practice and is therefore adequate. Therefore, the staff considers RAI 821, Question 02.04.03-5, resolved.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately estimated the effects of coincident wind waves in streams and rivers near the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the coincident wind-wave activity estimated by the applicant is appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.3.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.3.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information relevant to PMF on streams and rivers, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.3 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addresses COL Information Item 2.4-2 with regard to the PMF. The staff concludes that the applicant has provided sufficient information on hydrologic site characteristics affecting any potential hazard to the plant's safety-related facilities as a result of the effect of the PMF on streams and rivers to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.4 Potential Dam Failures

2.4.4.1 *Introduction*

WLS COL FSAR Section 2.4.4 describes potential dam failures to ensure that any potential hazard to safety-related structures due to failure of onsite, upstream, and downstream water-control structures is considered in the plant design.

Section 2.4.4 of this report presents the staff's review of the estimation of flood level caused by different dam failures. The specific areas of review are as follows: (1) dam-failure permutations; (2) unsteady-flow analysis of potential dam failures; (3) water-level determination; and (4) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.4.2 *Summary of Application*

This section of the WLS COL FSAR describes the site-specific information about floods from potential dam failures. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to potential dam failures as follows:

AP1000 COL Information Item

- WLS COL 2.4-2

In addition, this section addresses the following COL Information Item 2.4-2 (COL Action Item 2.4.1-1) identified in AP1000 DCD Section 2.4.1.2.

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information on historical flooding and potential flooding factors, including the effects of local intense precipitation.
>
> - PMF on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.
> - Dam Failures – Site-specific information on potential dam failures.
> - Probable Maximum Surge and Seiche Flooding – Site-specific information on probable maximum surge and seiche flooding.
> - Probable Maximum Tsunami Loading – Site-specific information on probable maximum tsunami loading.
> - Flood Protection Requirements – Site-specific information on flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.4, the applicant addressed the effects of floods caused by potential dam failures. Other causes of floods and their effects are discussed in related WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.4.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification of floods, flood design considerations and potential dam failures, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.4.

The applicable regulatory requirements for identifying the effects of dam failures are as follows:

- 10 CFR 52.79(a)(1)(iii), “Contents of applications; technical information in final safety analysis report,” as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, “Reactor Site Criteria,” as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), “Geologic and seismic siting factors,” sets forth the criteria to determine the siting factors for plant design bases with respect to seismically induced floods and water waves at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.4:

- RG 1.59, “Design Basis Floods for Nuclear Power Plants,” supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, “Flood Protection for Nuclear Power Plants,” as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” as it relates to the contents of a COL application

2.4.4.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.4.4 and checked the referenced AP1000 DCD to ensure that the combination of the AP1000 DCD and the COL application represents the complete scope of information relating to this review topic. The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to the potential dam failure.

The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 2.4-2

In its independent review, the staff also considered a breach of the proposed CCW Dam and subsequent flows and resulting water-surface elevation in the Broad River adjacent to the site. The staff concluded that these scenarios were conservative and neither scenario would exceed the design-basis flood elevation. The applicant and the staff used the guidance provided in ANSI/ANS-2.8-1992 to quantify flood water elevations at the site resulting from postulated dam failures.

To ensure that the most conservative of plausible conceptual models has been identified, in RAI 822, Question 02.04.04-1, the staff requested that the applicant describe the process to determine the conceptual models for flood waves from severe breaching of upstream dams, domino-type or cascading failures of dams, dynamic effects on safety-related SSCs, loss of safety-related water supplies, sediment deposition and erosion, and failure of onsite water control or storage structures.

In an October 27, 2008, response to RAI 822, Question 02.04.04-1, the applicant stated that the conceptual models to determine flood waves generated from failures of water-control structures conform to the guidance of RG 1.206 and RG 1.59 and the determination of the flood follows the recommendations of ANSI/ANS-2.8-1992.

The applicant maximized the flood generated by upstream failure of dams by assuming that the failures were coincident with the peak discharge of the PMF and were further enhanced by coincident wind-wave activity. The applicant stated that it selected the dam breach parameters conservatively based on USACE guidance. The applicant assumed that Tuxedo and Turner Shoals dams would fail in a cascade because they are located on the same tributary.

The applicant noted that no water is required for any safety-related purpose for the proposed units from the Broad River or from Make-Up Ponds A, B, and C and therefore, no safety-related facilities would be affected by sediment deposition and erosion. The applicant also stated that there are no onsite water-control or -storage structures, failures of which may produce floods that may affect safety-related SSCs.

The staff reviewed the applicant's October 27, 2008, response to RAI 822, Question 02.04.04-1, and concluded that the approach for determination of upstream single and cascading dam-failure-generated floods near the site is sufficiently conservative because the applicant assumed that the dam failures would coincide with the peak discharge at those locations during the PMF event. The staff also concluded that the applicant's evaluation of cascading failure combinations is adequate because a cascading failure of dams on the same tributary is used. Accordingly, the staff considers RAI 822, Question 02.04.04-1, resolved.

The staff conducted a hydrology site audit during the period of May 18 to 20, 2008. The site audit included a visit to the WLS site and a tour of Make-Up Pond B, the dam impounding the south section of the east arm of Make-Up Pond B, Make-Up Pond A, and the Ninety-Nine Islands Dam. The applicant and staff also reconnoitered the Broad River in the vicinity of the site during a boat tour. The staff did not visit any of the dams located upstream of the WLS site in the Broad River Basin.

2.4.4.4.1 Dam-Failure Permutation

Information Submitted by the Applicant

The applicant stated that the overtopping failure of upstream dams during the PMF event in the Broad River Basin would result in more severe flooding than that caused by seismic failures (failure of dams under safe shutdown earthquake coincident with a 25-year flood and failure of dams under the operating basis earthquake coincident with a one-half PMF or the 500-year flood) because the PMF event is a more severe flood than the coincident floods used for seismic failure scenarios. Therefore, the applicant did not evaluate floods resulting from seismic failure of dams coincident with floods that are lesser in magnitude than the PMF.

The applicant assumed that both Cherokee Falls and Gaston Shoals dams would be overtopped during the PMF event and the dam failure would coincide with the peak PMF discharge. The applicant assumed Cherokee Falls Dam to fail completely in 0.5 hour and the middle section of the Gaston Shoals Dam to fail in 0.5 hour along with the failure of embankment abutments separating the latter dam's three sections.

The applicant estimated that failure of the Gaston Shoals Dam only, coincident with the peak PMF discharge, would result in a discharge of 2,333 m^3/s (824,000 cfs) and a corresponding water-surface elevation of 168.1 m (551.5 ft) above MSL at the WLS site. The applicant also estimated that failures of both Gaston Shoals and the Cherokee Dams, coincident with the peak PMF discharge, would result in the same discharge and water-surface elevation at the WLS site because of small reservoir volumes compared to the PMF discharge.

The applicant reported that major upstream structures include Lake Lure, impounded by a dam on the Broad River; Lake Summit, impounded by the Tuxedo Dam on Green River; Lake Adger, impounded by the Turner Shoals Dam; Kings Mountain Reservoir Dam or Moss Lake Dam located on Buffalo Creek; and Lake Whelchel Dam located approximately 12.9 km (8 mi) northwest of the WLS site on Cherokee Creek. The applicant stated that Lake Lure Dam, Tuxedo Dam, and Turner Shoals Dam are designed to withstand overtopping and assumed that dam failure during overtopping would coincide with the peak PMF discharge. For Kings Mountain Reservoir Dam, the applicant postulated a piping failure with the consequent dam failure coinciding with the peak PMF discharge.

The CCW has applied for a permit to construct a water-supply reservoir on the First Broad River approximately 1.6 km (1 mi) north of Lawndale, North Carolina, approximately 42 km (26 mi) northeast of the WLS site. The proposed dam is expected to be approximately 379 m (1,245 ft) long and 25 m (83 ft) high with an impoundment surface area of approximately 908.5 hectare (2,245 ac) and may inundate areas lower in elevation than 262 m (860 ft) above MSL. The applicant stated that its storage would be approximately 58,590,386 m^3 (47,500 ac-ft). The applicant assumed that the dam would be designed to not fail during a PMF event. Since the proposed dam and reservoir are comparable to the Kings Mountain Reservoir, the applicant assumed that seismic failure of the proposed dam coincident with floods of magnitudes lesser than the PMF would be no worse than that estimated for the Kings Mountain Reservoir. Since the dam-failure analysis includes the failure of Kings Mountain Reservoir, the applicant assumed that the effects of failure of the proposed dam would be less than those estimated for existing dams.

The applicant stated that Make-Up Pond C is located on London Creek. The applicant also stated that Lake Cherokee is located on a tributary to London Creek upstream of Make-Up Pond C. The applicant considered the dams impounding Lake Cherokee and Make-Up Pond C to fail in a cascade. The applicant has considered the failures of Lake Lure Dam, Tuxedo Dam, Turner Shoals Dam, Lake Whelchel Dam, Kings Mountain Reservoir Dam, Lake Cherokee Dam, and Make-Up Pond C Dam coincident with the PMF as the critical dam-failure event in the Broad River Basin upstream of the WLS site. The applicant estimated that the peak dam-failure discharge coincident with a PMF event in the Broad River Basin would be 52,386 m^3/s (1,850,000 cfs).

The applicant also analyzed the failures of Lake Cherokee Dam and Make-Up Pond C Dam during a PMF event in the Make-Up Pond C watershed. The PMF event in the Make-Up Pond C watershed would result from a more intense PMP event compared to the Broad River Basin PMP because of the smaller drainage area of Make-Up Pond C watershed. The applicant determined that the peak discharge during this dam-failure permutation would be 37,831 m^3/s (1,336,000 cfs), which is less than the peak discharge estimated for the Broad River with the postulated upstream dam failures. Therefore, the applicant did not consider the cascading failure of Lake Cherokee and Make-Up Pond C Dams further. The applicant considered the failure of Upper Arm Pond Dam located within Make-Up Pond B. The maximum peak discharge resulting from a 6-hour tail end-peaking storm was 672 m^3/s (23,726 cfs).

The applicant stated that there are no safety-related facilities that would be affected by loss of water supply due to failures of dams and there are no onsite water-control or -storage structures that are located above site grade.

NRC Staff's Technical Evaluation

The staff evaluated the applicant's October 27, 2008, response to RAI 822, Question 02.04.04-1, and concluded that the process used by the applicant to determine dam-failure permutations upstream of the site is adequate. Lake Summit Dam (also called the Tuxedo Dam) and Lake Adger Dam (also called the Turner Shoals Dam) are located on the Green River and their impoundments have storage capacities of 10,410,586 m^3 (8,440 ac-ft) and 14,431,737 m^3 (11,700 ac-ft), respectively at their corresponding normal pool elevations. Lake Lure Dam is located on the Broad River with a storage of approximately 39,835,295 m^3 (32,295 ac-ft) at normal pool elevation. Green River flows downstream from Lakes Summit and Adger and joins the Broad River that flows downstream of Lake Lure. Therefore, the staff concluded that a cascading failure of Lake Summit and Lake Adger dams on the Green River is possible.

Downstream of the confluence of the Green River with the Broad River, Gaston Shoals Dam and Cherokee Falls Dam are located on the Broad River with storage capacities of approximately 3,083,705 m^3 (2,500 ac-ft) and 246,696 m^3 (200 ac-ft), respectively. Two more dams, the Kings Mountain Reservoir Dam on Buffalo Creek, with a storage capacity of approximately 54,273,199 m^3 (44,000 ac-ft) and the Lake Whelchel Dam on Cherokee Creek, with a storage capacity of approximately 7,154,194 m^3 (5,800 ac-ft), are located upstream of the Cherokee Falls Dam. However, the creeks that flow downstream from these two dams join the Broad River downstream of the Gaston Shoals Dam but upstream of the Cherokee Falls Dam. Therefore, staff noted that cascading failures of Kings Mountain Reservoir Dam and Cherokee Falls Dam and those of Lake Whelchel Dam and Cherokee Falls Dam are also plausible. However, the staff concluded that the small impoundment capacity of Cherokee Falls Dam would not significantly enhance the cascading effects of any flood generated by a dam failure upstream of it.

Since the dam impounding Lake Cherokee is located upstream on a tributary to London Creek on which Make-Up Pond C is located, the staff concluded that a cascading failure of these two dams is possible. On the mainstem of the Broad River, a cascading failure of Gaston Shoals and Cherokee Falls Dams is also possible. However, because these dams have small storage impoundments, the increase in the discharge that causes overtopping, especially that of the PMF would be minor. Therefore, the staff concluded that the dam-failure scenario analyzed by the applicant, in which Lake Lure Dam, Lake Summit Dam, Lake Adger Dam, Kings Mountain Reservoir Dam, and Lake Whelchel Dam failed coincident with peak discharges at those locations during the PMF event, is conservative.

The applicant considered the failure of the Upper Arm Pond Dam, which is located within Make-Up Pond B. Since there are no other dams upstream of Make-Up Pond B dam, no other dam-failure permutations need evaluation. Based on the above review, the staff considers RAI 822, Question 02.04.04-1, resolved.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately considered dam-failure permutations in the Broad River upstream of the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the dam-failure permutations considered by the applicant are appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.4.4.2 Unsteady-Flow Analysis of Potential Dam Failures

Information Submitted by the Applicant

The applicant used the same HEC-RAS unsteady-flow model previously used in the PMF water-surface elevation calculations, but modified it to use the HEC-RAS dam breach feature. The applicant used the peak PMF discharge, estimated by the HEC-HMS model at the Ninety-Nine

Islands Dam, as input into the HEC-RAS model to perform a steady-state analysis to determine the water-surface elevation at the WLS site.

NRC Staff's Technical Evaluation

The steady-state simulations performed by the applicant with the peak PMF discharge would result in a water-surface elevation that would be asymptotically approached by an unsteady-flow simulation performed with the complete discharge hydrograph. Therefore, the staff determined that the methods used by the applicant are adequately conservative and the water-surface elevation in the Broad River near the site would be conservatively determined by the approach adopted by the applicant.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed dam-failure flood flow in the Broad River upstream of the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the dam-failure flood flow analyzed by the applicant is appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.4.4.3 Water Level at the Plant Site

Information Submitted by the Applicant

The applicant used the HEC-RAS model described above to estimate the water-surface elevation near the WLS site corresponding to a steady-state discharge of 52,386 m^3/s (1,850,000 cfs) in the Broad River near the WLS site. The applicant reported an estimated stillwater-surface elevation of 175.7 m (576.5 ft) above MSL, approximately 5 m (16.5 ft) below the safety-related plant grade of 180.7 m (593 ft) above MSL.

The applicant evaluated the wind-wave activity during the PMF event in the Broad River near the WLS site using the USACE Coastal Engineering Manual. The applicant used a 2-year coincident wind speed of 80 km/h (50 mph), a fetch length of 4.5 km (2.8 mi), and a slope of 40 percent to estimate a combined flood water-surface elevation of 178.2 m (584.8 ft) above MSL.

The applicant used the HEC-HMS model to determine the maximum water-surface elevation in Make-Up Pond B considering failure of the Upper Arm Pond Dam. The maximum water-surface elevations in Make-Up Pond B and Upper Arm Pond were 178.3 m (585.1 ft) and 180.5 m (592.3 ft) above MSL, respectively. The applicant stated that the ridge on the east of Upper Arm Pond separates it from the WLS site and at water-surface elevations above 179.8 m (590 ft) above MSL, discharge from Upper Arm Pond occurs directly to Make-Up Pond B.

NRC Staff's Technical Evaluation

As stated above, the staff concluded that the methods used by the applicant are adequately conservative and the water-surface elevation in the Broad River near the site would be conservatively determined by the approach adopted by the applicant. To assess the impact of wind-induced waves on the flood water-surface elevation under the multiple dam-failure scenarios described by the applicant, in RAI 822, Question 02.04.04-2, the staff requested that the applicant provide wind-induced wave heights coincident with the controlling dam breach flooding scenario.

In an October 27, 2008, response to RAI 822, Question 02.04.04-2, the applicant stated that WLS COL FSAR Section 2.4.4.3 was updated to provide the effects of wind-wave activity coincident with the dam breach scenario investigated for the Broad River. The applicant also included two new figures in the WLS COL FSAR that showed the fetch lengths for the Broad River and Make-Up Pond A during the dam breach flooding scenario.

The applicant stated in the updated WLS COL FSAR text that the wind-wave activity was evaluated for the Broad River to coincide with the PMF including the effects of dam failures. The applicant estimated the critical, longest straight-line fetch length to be approximately 4.5 km (2.8 mi). The applicant stated that the maximum water-surface elevation in the Broad River from the PMF, including the effect of dam failures and the effect of wind-wave activity, would be approximately 178.2 m (584.8 ft) above MSL. Since the safety-related plant grade is at 180.7 m (593 ft) above MSL, the applicant concluded that the site would be safe from flooding due to a PMF including the effects of upstream dam failures and coincident wind-wave activity in the Broad River.

The applicant further stated that during severe flooding events, Make-Up Pond A is inundated by backwaters of the Broad River. Therefore, the applicant evaluated the effects of wind-wave activity in Make-Up Pond A during the PMF event that included the effects of dam failure. The applicant estimated the critical, straight-line fetch length to be approximately 4.3 km (2.7 mi). The applicant reported the 2-year annual extreme mile wind speed to be 22.4 m/s (50 mph) based on the recommendations of ANSI/ANS-2.8-1992. The applicant estimated the critical duration to be 53 minutes and adjusted the wind speed to be 22.3 m/s (49.9 mph). The applicant estimated the significant wave height to be 0.8 m (2.8 ft) and the maximum wave height to be 1.4 m (4.6 ft). The applicant estimated the wind setup to be approximately 0.02 m (0.07 ft) and the maximum runup, using the 47 percent slope along the banks of the Make-Up Pond A near the site, to be approximately 2.88 m (8.9 ft). Therefore, the applicant considered the total wind-wave activity to be approximately 2.7 m (9.53 ft) for Make-Up Pond A. The applicant stated that the maximum water-surface elevation in the Make-Up Pond A from the Broad River PMF including the effect of dam failures and the effect of wind-wave activity would be approximately 178.4 m (585.4 ft) above MSL. Since the safety-related plant grade is at 180.7 m (593 ft) above MSL, the applicant concluded that the site would be safe from flooding due to the Broad River PMF including the effects of upstream dam failures and coincident wind-wave activity in the Make-Up Pond A.

The staff evaluated the applicant's October 27, 2008, response to RAI 822, Question 02.04.04-2, and subsequent changes to the WLS COL FSAR up to and including Revision 7 with respect to the methods used to determine the maximum flood water-surface elevation in the Broad River. The staff concluded that the applicant has used appropriate and conservative methods to estimate the flood water-surface elevation in the Broad River. Accordingly, the staff considers RAI 822, Question 02.04.04-2, resolved. Since the dam failures were postulated to coincide with the peak discharge of the PMF, the staff concluded that this scenario is more conservative than the flood generated only by dam failures or only by a PMF in the Broad River Basin.

The staff noted that a dam is proposed by the CCW (the CCW Dam) on the First Broad River in Cleveland County, NC. The estimated storage of the CCW Dam impoundment would be approximately 58,590,386 m^3 (47,500 ac-ft). Downstream of the proposed CCW Dam, the First Broad River joins the Broad River upstream of the Gaston Shoals Dam. The applicant assumed that the dam would be designed to not fail during a PMF event. The applicant stated in the WLS COL FSAR that because the proposed dam and reservoir are comparable in size to the Kings Mountain Reservoir, a hypothetical seismic failure of the proposed dam coincident with floods of magnitudes lesser than the PMF would be no worse than those estimated for the Kings Mountain Reservoir. The applicant assumed that the effects of failure of the proposed dam would be less than those estimated for existing dams. The staff investigated a hypothetical dam-failure scenario for the proposed CCW Dam, similar to that used for the other dams in the Broad River Basin, as a sensitivity study to determine if the flood water-surface elevation in the river near the site would be significantly affected. As stated in Section 2.4.1.4.2 of this report, the staff received information regarding the proposed CCW Dam from McGill Associates on January 31, 2012, and from the USACE on January 2, 2014.

The staff reviewed the HEC-HMS and HEC-RAS files provided by the applicant and performed an independent simulation to estimate the sensitivity of the flood water-surface elevation by specifying no precipitation loss during the PMP event to maximize the PMF. The staff also used the modified unit hydrographs for the sub-basins of the Broad River Basin to account for nonlinear runoff generation response during the PMF and included a hypothetical failure scenario for the proposed CCW Dam.

Using the HEC-HMS input files provided by the applicant, the staff added a hypothetical CCW Dam located on the First Broad River to modify the Broad River model used by the applicant for dam breach simulations. The staff used the applicant-reported dam height of 25.3 m (83 ft) in the simplified dam breach equation to estimate the peak dam breach discharge of 20,763 m^3/s (733,242 cfs). The height of the CCW Dam according to information received by the staff from McGill Associates on January 31, 2012, is approximately 24.4 m (80 ft). Since the staff used a larger value of dam height, 25.3 m (83 ft), the estimate of peak dam breach discharge is conservative. The staff simulated the modified Broad River dam breach model with concurrent PMF conditions similar to the applicant's approach. The other dams in the Broad River Basin upstream of the WLS site were assumed to fail in a manner identical to the approach used by the applicant.

The staff independently estimated the peak outflow near the WLS site due to dam breaches concurrent with a PMF in the Broad River Basin to be approximately 1,019 m^3/s (36,000 cfs) larger than that estimated by the applicant. The staff used the HEC-RAS model to simulate the water-surface elevation near the WLS site resulting from a steady-state, but increased, discharge. The staff-estimated stillwater elevation near the WLS site was approximately 0.3 m (1 ft) higher than the applicant's estimate.

The staff also evaluated the coincident wind-wave activity for the Broad River with the maximum water-surface elevation resulting from the dam failures concurrent with a PMF event. Using the USGS topographic quadrangles near the WLS site, the staff estimated the longest straight-line fetch length as 4.7 km (2.9 mi).

Using the procedures described by USACE, the staff estimated the maximum wave runup to be 1.6 m (5.1 ft) and a wind setup to be 0.03 (0.1 ft). Therefore, the staff estimated the total dam failure with concurrent PMF water-surface elevation including the effects of coincident wind-wave activity to be 1.9 m (6.1 ft) higher than the applicant's estimate. The staff's conservatively estimated water-surface elevation in the Broad River during the postulated dam-failure permutation, combined with the postulated failure of the CCW Dam and wind waves, was 3.2 m (10.4 ft) lower than the safety-related WLS site grade of 180.7 m (593 ft) above MSL.

As stated in Section 2.4.1.4.2 of this report, the USACE is reviewing the CCW proposal at this time. As stated in this section, the staff evaluated the CCW's proposed site for the First Broad River Reservoir. In a June 1, 2009, letter to the CCW, the USACE identified three alternative reservoir locations in addition to the proposed CCW location. These alternative locations were on Knob Creek, Upper Crooked Run Creek, and Lower Crooked Run Creek. In a more recent communication to the staff, the USACE stated that in its current review, an alternative side stream reservoir on the Upper Crooked Run Creek is being evaluated.

It is possible that the USACE, during its review of the CCW proposal and preparation of an environmental impact statement, may find the alternative Upper Crooked Run Creek site to be environmentally preferable to the CCW's proposed site. To allow for this possibility, the staff evaluated the potential flood at the WLS site produced by a hypothetical failure of a dam similar in characteristics to the CCW Dam located in the Upper Crooked Run Creek drainage. Since the proposed location of the CCW Dam is below the confluence of the Upper Crooked Run Creek and the First Broad River, the staff concluded that the alternative dam location would be farther upstream than the proposed location of the CCW Dam in the First Broad River drainage. The staff also noted that the alternative reservoir being evaluated by the USACE would be an off-stream storage reservoir and therefore may not require construction of a dam on the Upper Crooked Run Creek. However, the staff conservatively assumed that a dam similar to the proposed CCW Dam would be constructed on the Upper Crooked Run Creek because a hypothetical failure of a dam on the Upper Crooked Run Creek would generate a more severe flood in the First Broad River and at the WLS site.

Since the alternative dam location on the Upper Crooked Run Creek is upstream of the CCW Dam's proposed location that the staff analyzed previously in this section and the characteristics of the dam at the two locations are assumed to be similar, the dam failure-generated flood discharge at the two locations would be similar. However, the dam failure-generated flood discharge would need to travel downstream from the two locations to the WLS site via the First Broad River and the Broad River. Since the distance the flood wave would have to travel to the WLS site is greater for the Upper Crooked Run Creek alternative site than for the CCW's proposed site, the attenuation of the peak discharge for the Upper Crooked Run Creek alternative site would be greater. Therefore, the flood effects would be greater if the CCW Dam were located at the CCW's proposed site. Based on this review and analysis, the staff concluded that its analysis of the flood effects from a hypothetical failure of a future CCW Dam described earlier in this section is conservative.

Since the conservatively estimated flood water-surface elevation near the WLS site from dam failures with a concurrent PMF event and coincident wind waves in the Broad River Basin is lower than the safety-related site grade of 180.7 m (593 ft) above MSL, the staff concluded that the safety-related SSCs of the proposed units at the WLS site are unaffected by flooding due to dam failures.

The staff reviewed the applicant's analysis of the failure of the Upper Arm Pond Dam. The staff determined that the applicant used conservative assumptions to estimate the highest water-surface elevations in Make-Up Pond B and the Upper Arm Pond. Since the ridge on the east side of the Upper Arm Pond prevents flood waters from spilling over into the WLS site area without first draining over the Upper Arm Pond Dam into Make-Up Pond B, the staff concluded that the failure of the culvert or overtopping failure of the Upper Arm Pond would not affect the WLS site.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed dam-failure flood water-surface elevations in the Broad River upstream of the WLS site, Make-Up Pond B, and Upper Arm Pond using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the dam-failure flood water-surface elevations estimated by the applicant are appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.4.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.4.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information relevant to potential dam failures, and that no outstanding information is expected to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.4 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addressed potential dam failures in COL Information Item 2.4-2. The staff concludes that the applicant provided sufficient information on hazards from extreme flooding events at the site to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.5 Probable Maximum Surge and Seiche Flooding

2.4.5.1 *Introduction*

WLS COL FSAR Section 2.4.5 describes probable maximum surge and seiche flooding to ensure that any potential hazard to the safety-related SSCs at the proposed site has been considered in compliance with NRC regulations.

Section 2.4.5 of this report presents the evaluation of the following topics based on data provided by the applicant in the WLS COL FSAR and information available from other sources: (1) probable maximum hurricane (PMH) that causes the probable maximum surge as it approaches the site along a critical path at an optimum rate of movement; (2) probable maximum wind storm (PMWS) from a hypothetical extratropical cyclone or a moving squall line that approaches the site along a critical path at an optimum rate of movement; (3) a seiche near the site, and the potential for seiche wave oscillations at the natural periodicity of a water body that may affect flood water-surface elevations near the site or cause a low water-surface elevation affecting safety-related water supplies; (4) the potential effects of seismic and non-seismic information on the postulated design bases and how they relate to a surge and seiche in the vicinity of the site and the site region; and (5) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

As stated in Section 2.4 above, hydrologic characteristics associated with conditions that would result in a loss of external water supply and seismic design considerations of water-supply structures are not relevant for the AP1000 design. Therefore, the low-water aspect of item (3) above was not part of the staff's review.

2.4.5.2 *Summary of Application*

This section of the WLS COL FSAR describes the site-specific information on probable maximum surge and seiche flooding in terms of effects on structures and water supply. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to probable maximum surge and seiche flooding as follows:

<u>AP1000 COL Information Item</u>

- WLS COL 2.4-2

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.2, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information about historical flooding and potential flooding factors, including the effects of local intense precipitation.
>
> - PMF on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.

- Dam Failures – Site-specific information about potential dam failures.

- Probable Maximum Surge and Seiche Flooding – Site-specific information about probable maximum surge and seiche flooding.

- Probable Maximum Tsunami Loading – Site-specific information about probable maximum tsunami loading.

- Flood Protection Requirements – Site-specific information about flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.5, the applicant addressed the effects of floods caused by probable maximum surge and seiche. Other causes of floods and their effects are discussed in related WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.5.3 *Regulatory Basis*

The relevant requirements of NRC regulations for consideration of the effects of probable maximum surge and seiche, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.5.

The applicable regulatory requirements for identifying surge and seiche hazards are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), "Geologic and seismic siting factors," sets forth the criteria to determine the siting factors for plant design bases with respect to water levels at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.5:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, "Flood Protection for Nuclear Power Plants," as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.5.4 *Technical Evaluation*

In this section of the report, the staff reviewed the applicant's assessment of the probable maximum surge and seiche flooding. The staff's independent analysis, where needed for the review, is also described.

Information Submitted by the Applicant

The applicant followed the regulatory guidance prescribed by RG 1.59, which describes the probable maximum surge and seiche based on a PMH, a PMWS, or a moving squall line. The applicant stated that RG 1.59 recommends consideration of a PMH for areas within 322 km (200 mi) of coastal areas and the WLS site is located approximately 282 km (175 mi) from the Atlantic Ocean on the southeast bank of the Broad River.

Following the recommendation for Folly Island in RG 1.59, the applicant estimated the PMH storm surge to be 8.1 m (26.5 ft) above MSL, which includes a 0.3 m (1.0 ft) sea level anomaly known to occur for predicted tides at Charleston, SC. The applicant also reported that the maximum storm surge along the Atlantic Coast since 1975, the most recent year for which data was included in RG 1.59, caused by hurricane Hugo, was approximately 6.1 m (20 ft) high.

Since the safety-related plant grade at 180.7 m (593 ft) above MSL is approximately 25 m (81.9 ft) higher than the normal water-surface elevation in the Broad River near the WLS site, (511.1 ft) above MSL, the applicant concluded that the PMH surge of 8.1 m (26.5 ft) would not flood the site, even if the surge were to translate to the site from the coast without any attenuation. The applicant also concluded that based on the location of the site and its elevation, safety-related facilities at the WLS site would not be affected by surge and seiche flooding.

The applicant stated resonance at natural periodicity, lake reflection, and harbor resonance are characteristics of harbors, estuaries, and large lakes and are generally not associated with river sites. The COL applicant did not present any specific descriptions and analyses of wave action during surge and seiche events.

The applicant used the USACE approach to estimate surge in Make-Up Ponds A and B under extreme winds. The COL applicant used the 100-year water-surface elevations, 169.5 m (556.1 ft) and 175.6 m (576.2 ft) above MSL for Make-Up Ponds A and B, respectively, as the initial elevations. Using the maximum wind speeds identified in WLS COL FSAR Section 2.3.1.2.8, the applicant estimated maximum crest-to-trough wave heights of 1.2 m (3.8 ft) and 2.1 m (6.9 ft) for Make-Up Ponds A and B, respectively. The total high-speed wind-wave activity for Make-Up Ponds A and B were 1.7 m (5.6 ft) and 2.4 m (7.8 ft), respectively. Therefore, the applicant estimated that the flood water-surface elevation in Make-Up Ponds A and B during extreme wind events would be 171.2 m (561.7 ft) and 178 m (583.9 ft) above MSL, respectively. The applicant concluded that the high-speed wind-wave activity would not affect the WLS site because the maximum water-surface elevations in Make-Up Ponds A and B during the extreme wind events would be below the safety-related plant grade of 180.7 m (593 ft) above MSL.

The applicant stated that Make-Up Pond C is located on a tributary of the Broad River, west of the WLS site. The applicant further stated that a postulated failure of the dam impounding Make-Up Pond C would release waters to the Broad River and not directly to the WLS site and therefore flooding from surges and seiches in Make-Up Pond C would be bounded by the postulated failure of Make-Up Pond C Dam described in WLS COL FSAR Section 2.4.4.

NRC Staff's Technical Evaluation

The staff reviewed COL Information Item 2.4-2 related to the provision of site-specific information about the PMF at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.2. 2.4.3, 2.4.4, 2.4.6, 2.4.7, and 2.4.10 of this report. To ensure that the most conservative of plausible conceptual models has been identified, in RAI 823, Question 02.04.05-1, the staff requested that the applicant describe the process followed to determine the conceptual models for PMH, PMWS, seiche and resonance, wave runup, and sediment erosion and deposition.

In an October27, 2008, response to RAI 823, Question 02.04.05-1, the applicant stated that the conceptual models to determine floods from PMH, PMWS, seiche and resonance, and wave runup are consistent with the guidance of RG 1.206 and RG 1.59 and the estimation methods used conform to the guidance provided by ANSI/ANS-2.8-1992. The applicant stated that the maximum hurricane storm surge produced on the Atlantic Coast was transposed to the site without accounting for the travel distance and the presence of any instream structures. The applicant stated that maximum wind speeds were used in the determination of wind-wave effects for water bodies adjacent to the site. The applicant stated that the resulting flood waves did not exceed the water-surface elevation produced by the design basis flood.

The applicant also stated that the natural fundamental periods of oscillation of the water bodies adjacent to the site are determined to be significantly shorter than meteorologically induced wave periods. The applicant concluded, therefore, that there is no potential for resonance of the seiche in the water bodies near the site that could result in flooding at the site. The applicant further stated that no safety-related water is required by the proposed units from the Broad River or from Make-Up Ponds A and B. The applicant concluded, therefore, that no safety-related SSCs of the proposed units would be affected by sediment deposition or erosion.

The staff evaluated the applicant's October 27, 2008, response to RAI 823, Question 02.04.05-1, and concluded that the approach adopted by the applicant in the evaluation of storm surge and seiche hazards at the site is appropriate and sufficiently conservative. Accordingly, the staff considers RAI 823, Question 02.04.05-1, resolved.

Seiches can be caused in lakes and reservoirs by meteorological or seismic forcing. To review the effects of meteorologically or seismically induced seiches near the WLS site, in RAI 823, Question 02.04.05-1, the staff requested that the applicant provide an assessment of meteorologically and seismically induced seiches in Make-Up Ponds A and B. In and October 27, 2008, response to RAI 823, Question 02.04.05-2, the applicant stated that an assessment of meteorologically induced waves in Make-Up Ponds A and B is carried out by estimating the wave periods for high-speed wind waves and the natural fundamental periods of oscillation for the two ponds. The applicant stated that the natural fundamental periods of oscillation of Make-Up Ponds A and B are 2.7 and 8 minutes, respectively. The applicant also reported that the wave periods of high-speed wind waves for Make-Up Ponds A and B, estimated coincident with a 100-year water-surface elevation within the ponds, are 1.8 and 2.7 seconds, respectively. The applicant stated that the wave periods are much shorter than the natural fundamental period of oscillation of the two ponds.

The applicant further stated that the natural fundamental periods of oscillation of the two ponds are significantly shorter than meteorologically induced wave periods such as synoptic storm pattern frequency and dramatic reversal in steady wind direction. The applicant concluded therefore, that a meteorologically induced seiche would not be set up in the two makeup ponds. The applicant also considered the possibility of seismically induced seiches in Make-Up Ponds A and B in response to the staff's RAI 823, Question 02.04.05-2, but provided the details with its response to the staff's RAI 824, Question 02.04.06-2,. The applicant stated that there are no capable tectonic sources within a 25 mile radius of the site as described in WLS COL FSAR Section 2.5.3. The applicant concluded, therefore, that a seismically generated seiche in Make-Up Ponds A and B is unlikely.

The staff evaluated the October 27, 2008, response to RAI 823, Question 02.04.05-2, and updates to the WLS COL FSAR up to and including Revision 7 to determine that the methods used by the applicant to postulate seiching mechanisms and resulting water-surface elevations near the site are adequate. The staff agreed with the applicant that if the natural fundamental periods of oscillation of the two ponds are significantly different from those that can be induced by meteorological events, that meteorologically induced seiches in the two ponds are not likely. The staff agreed with the applicant that in absence of a nearby capable tectonic source, a seismically generated seiche in the makeup ponds is unlikely.

The staff concluded that, due to the location of the site, approximately 282 km (175 mi) inland from the Atlantic Coast any hurricane-induced storm surge in the Atlantic Ocean would dissipate before reaching the site and, therefore, would not affect the site. Due to of the location of Make-Up Pond C on a tributary of the Broad River away from the WLS site, the staff also agreed with the applicant that surge and seiche flooding in the pond would be bounded by the flood generated by a postulated failure of its dam. Accordingly, the staff considers RAI 823, Question 02.04.05-2, resolved.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed flood water-surface elevations caused by surge and seiche near the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. The staff agreed that the surge and seiche flood water-surface elevations estimated by the applicant are appropriate for the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.5.5 *Post Combined License Activities*

There are no post COL activities related to this section

2.4.5.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information relevant to probable maximum surge and seiche flooding, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section/

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.5, herein, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addressed the probable maximum surge and seiche flooding in WLS COL Information Item 2.4-2. The staff concludes that the applicant provided sufficient information on flood hazards related to storm surge and seiches to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.6 Probable Maximum Tsunami Hazards

2.4.6.1 *Introduction*

WLS COL FSAR Section 2.4.6 describes probable maximum tsunami hazards to ensure that any potential tsunami hazard to the safety-related SSCs at the proposed site has been considered in compliance with NRC regulations.

Section 2.4.6 of this report presents an evaluation of the following topics based on data provided by the applicant in the WLS COL FSAR and information available from other sources: (1) historical tsunami data; (2) probable maximum tsunami (PMT) that may pose hazards to the site; and (3) any additional information requirements prescribed in the “Contents of Application” sections of the applicable subparts to 10 CFR Part 52.

2.4.6.2 *Summary of Application*

This section of the WLS COL FSAR addresses the site-specific information about PMT hazards in terms of effects on structures and water supply. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to PMT hazards as follows:

AP1000 COL Information Item

- WLS COL 2.4-2

In addition, this section of the WLS COL FSAR addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.2, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information about historical flooding and potential flooding factors, including the effects of local intense precipitation.
>
> - PMF on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.
> - Dam Failures – Site-specific information about potential dam failures.
> - Probable Maximum Surge and Seiche Flooding – Site-specific information about probable maximum surge and seiche flooding.
> - PMT Loading – Site-specific information about PMT loading.
> - Flood Protection Requirements – Site-specific information about flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.6, the applicant addressed the effects of floods caused by PMT. Other causes of floods and their effects are discussed in related WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.6.3 *Regulatory Basis*

The relevant requirements of NRC regulations on consideration of the effects of PMT hazards, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.6.

The applicable regulatory requirements for tsunami hazards are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.
- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).
- 10 CFR 100.23(d), "Geologic and seismic siting factors," sets forth the criteria to determine the siting factors for plant design bases with respect to water levels at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.6:

- RG 1.59, “Design Basis Floods for Nuclear Power Plants,” supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, “Flood Protection for Nuclear Power Plants,” as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” as it relates to the contents of a COL application

2.4.6.4 *Technical Evaluation*

In this section of the report, the staff reviewed the applicant’s analysis of PMT. The staff’s independent analysis, where needed for the review, is also described.

Information Submitted by the Applicant

The applicant stated that no specific tsunami hazard maps are available for the east coast of the United States. The applicant used a general tsunami risk map developed by the USACE to identify a tsunami wave height of 1.5 m (5 ft) for the east coast of the United States. The applicant reported that NOAA tsunami database includes a maximum recorded tsunami height of 6.1 m (20 ft) at Daytona Beach, FL, on July 3, 1992, which was probably meteorologically induced. The applicant stated that the WLS site is located approximately 282 km (175 mi) inland from the Atlantic Ocean and the safety-related plant elevation is 180.7 m (593 ft) above MSL. Based on historical tsunami data and the location and elevation of the WLS site, the applicant concluded that safety-related facilities would not be affected by tsunami flooding.

The applicant stated that hill-slope failure-induced landslides that generate significant waves in Make-Up Ponds A and B are implausible. The applicant stated that field investigations reported in WLS COL FSAR Section 2.5.1.1 noted no irregular weathering conditions or natural landslide hazards and there is no documented evidence of significant landslides at the WLS site or adjacent to the Make-Up Ponds. The applicant stated that landslides of limited size in shallow soil or fill may occur, but would be of insufficient volume and would occur at too low of velocities to cause any significant water waves. The applicant further stated that the slopes around Make-Up Ponds A and B are either natural and have existed since the Holocene age or resulted from cut and fill during the Cherokee Nuclear Station construction. The applicant stated that these slopes are stable and show no visual evidence of groundwater seepage, past failures, or movement or creep.

The applicant stated that because there are no capable tectonic sources within 40 km (25 mi) of the WLS site, surface fault ruptures from seismic waves are not plausible. The applicant concluded that seismically generated water waves in Make-Up Ponds A and B would be insignificant compared to the freeboard in these ponds.

The applicant stated that Make-Up Pond C is located on a tributary of the Broad River, west of the WLS site. The applicant further stated that a postulated failure of the dam impounding Make-Up Pond C would release waters to the Broad River and not directly to the WLS site and, therefore, flooding from seismically induced water waves in Make-Up Pond C would be bounded by the postulated failure of Make-Up Pond C Dam described in WLS COL FSAR Section 2.4.4.

NRC Staff's Technical Evaluation

The staff reviewed COL Information Item 2.4-2 related to the provision of site-specific information about the PMF at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.2. 2.4.3, 2.4.4, 2.4.5, 2.4.7, and 2.4.10, herein.

To ensure that the most conservative of plausible conceptual models have been identified, in RAI 824, Question 02.04.06-1, the staff requested that the applicant describe the process followed to determine the conceptual models for PMT, tsunami propagation, wave runup, inundation and drawdown, hydrostatic and hydrodynamic forces, debris and water-borne projectiles, and sediment erosion and deposition. In an October 27, 2008, response to RAI 824, Question 02.04.06-1, the applicant stated that the conceptual models used to determine flood waves generated by PMT and other tsunami-like waves follow the requirements of RG 1.206 and RG 1.59. The applicant compared the historical maximum recorded tsunami wave heights and the maximum wave heights reported in a tsunami risk map for the east coast of the U.S. to the available freeboard of the WLS site above the Broad River. The applicant concluded that the resulting flood waves are less than the design-basis flood. Therefore, the applicant concluded that there is no potential for inundation, hydrostatic and hydrodynamic forces, debris, or water-borne projectiles that may affect safety-related facilities.

The applicant also stated that there are no capable tectonic sources in the vicinity of the site as described in WLS COL FSAR Section 2.5.3. The applicant concluded, therefore, that a seismically induced water wave near the site is not plausible. The applicant further stated that there are no irregular conditions or natural landslide hazards in the vicinity of the site. The applicant concluded, therefore, that landslide-induced tsunami-like waves near the WLS site are not plausible.

Based on a review of the applicant's October 27, 2008, response to RAI 824, Question 02.04.06-1, the staff concluded that the process used to determine the conceptual models for tsunamis and tsunami-like waves in the vicinity of the WLS site is adequately described. Accordingly, the staff considers RAI 824, Question 02.04.06-1, resolved. The staff used this information in its safety review combined with observations made during the site audit.

The staff performed a search of the NOAA National Geophysical Data Center (NGDC) Historical Tsunami Database for tsunami runup events reported on the east coast of the U.S. The maximum runup reported in the database on the east coast of the United States is 6.0 m (19.7 ft) above MSL at Daytona Beach, FL, on July 3, 1992, due to a meteorological cause. The staff concluded, based on its independent search and the applicant's RAI responses that credible seismic and landslide tsunamigenic sources in the vicinity of the site do not exist. The staff also determined that the site is located approximately 282 km (175 mi) from the Atlantic Ocean. For a tsunami generated by a near or a far-field oceanic source to affect the site, the runup would need to travel this distance, 282 km (175 mi), inland from the coast. Historically, maximum horizontal extent of inundation is reported to be less than approximately 8.1 km (5 mi). Since the site is located at least one order of magnitude farther than the maximum horizontal inland distance reported for historical tsunamis, the staff concluded that a PMT in the Atlantic Ocean would not pose a hazard at the site.

In RAI 824, Question 02.04.06-2, the staff requested that the applicant provide an assessment of landslide and slope-failure potential on the shores of Make-Up Ponds A and B and an assessment of tsunami-like waves that may be generated by the potential landslides or slope failures in these ponds. In an October 27, 2008, response to RAI 824, Question 02.04.06-2, the applicant stated that no irregular weathering or natural landslides were identified during field investigations in the region. Therefore, the applicant concluded that landslide-generated tsunami-like waves are not plausible for Make-Up Ponds A and B.

The staff determined that there are no active or passive volcanoes located near the site the eruption of and resulting pyroclastic flows from which may generate a tsunami-like wave in any water bodies near the site. The staff evaluated the applicant’s information in the WLS COL FSAR and concluded that the process used by the applicant to estimate source generator characteristics with respect to landslide-generated tsunami-like waves is adequate. The staff also agreed with the applicant’s assessment that a landslide-generated tsunami-like wave in the water bodies near the site is not likely. The staff concluded that a tsunami or a tsunami-like wave in the vicinity of the site is an unlikely event. Therefore, the staff determined that a more detailed tsunami analysis is not needed. Based on its review, the staff considers RAI 824, Question 02.04.06-2, resolved.

Based on a review of the applicant’s information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed the potential for floods caused by tsunamis near the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.6.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.6.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information relevant to PMT hazards, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.6 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a) (1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addressed the probable maximum tsunami hazard in COL Information Item 2.4-2. The staff concludes that the applicant has provided sufficient information on PMT hazards to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.7 Ice Effects

2.4.7.1 *Introduction*

WLS COL FSAR Section 2.4.7 describes ice effects to ensure that safety-related facilities and water supply are not affected by ice-induced hazards.

Section 2.4.7 of this report presents an evaluation of the following topics based on data provided by the applicant in the WLS COL FSAR and information available from other sources: (1) regional history and types of historical ice accumulations (i.e., ice jams, wind-driven ice ridges, floes, frazil ice formation, etc.); (2) potential effects of ice-induced, high- or low-flow levels on safety-related facilities and water supplies; (3) potential effects of ice to produce forces on, or cause blockage of, safety-related facilities; and (4) any additional information requirements prescribed in the “Contents of Application” sections of the applicable subparts to 10 CFR Part 52.

As stated in Section 2.4 above, hydrologic characteristics associated with conditions that would result in a loss of external water supply and seismic design considerations of water-supply structures are not relevant for the AP1000 design. Therefore, low-water conditions related to topics listed above were not part of the staff’s review.

2.4.7.2 *Summary of Application*

This section of the WLS COL FSAR addresses the site-specific information on ice effects. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to ice effects as follows:

AP1000 COL Information Item

- WLS COL 2.4-2

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.2, Revision 19:

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information about historical flooding and potential flooding factors, including the effects of local intense precipitation.

- Probable Maximum Flood (PMF) on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.

- Dam Failures – Site-specific information about potential dam failures.

- Probable Maximum Surge and Seiche Flooding – Site-specific information about probable maximum surge and seiche flooding.

- Probable Maximum Tsunami Loading – Site-specific information about probable maximum tsunami loading.

- Flood Protection Requirements – Site-specific information about flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.7, the applicant addressed ice effects on high water at the site. Other causes of floods and their effects were discussed in subsequent WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.7.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification and evaluation of ice effects, and the associated acceptance criteria, are described in NUREG—800, Section 2.4.7.

The applicable regulatory requirements for identifying ice effects are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), "Geologic and seismic siting factors," sets forth the criteria to determine the siting factors for plant design bases with respect to water levels at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.7:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, “Flood Protection for Nuclear Power Plants,” as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” as it relates to the contents of a COL application

2.4.7.4 *Technical Evaluation*

In this section of the report, the staff reviewed the applicant’s analyses regarding ice effects. The staff’s independent analysis, where needed for the review, is also described.

Information Submitted by the Applicant

The applicant reported that winter water temperatures range from 0 to 9 ºC (32 to 48.2 ºF) between 1962 and 1981 at 10 USGS gauging stations on the Broad River and tributaries upstream of the WLS site. The applicant also reported that the lowest recorded water temperature near the WLS site from 1959 to 2005 is 2 ºC (35.6 ºF) according to the EPA STORET database and the values vary from 1 to 4 ºC (33.8 to 39.2 ºF) from 1995 to 2000 as stated in the measurements by the North Carolina Department of Environmental and Natural Resources at nine stations located near the 10 USGS stations. Based on these water temperature records, the applicant concluded that historical observations suggest the Broad River water temperatures consistently remain above freezing. The applicant also concluded that flooding of the WLS site from an ice jam is a remote possibility based on historical data from the USACE Cold Regions Research and Engineering Laboratory historical ice jam database. Since no safety-related water storage is required for WLS, the applicant concluded that ice-induced low flow would not affect its safety.

NRC Staff’s Technical Evaluation

The staff reviewed COL Information Item 2.4-2 related to the provision of site-specific information about the PMF at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.2. 2.4.3, 2.4.4, 2.4.5, 2.4.6, and 2.4.10 of this report.

The staff searched the NOAA National Climatic Data Center (NCDC) Storm Events database to search for snow and ice events for the counties in which the majority of the Upper Broad River Basin lies. This search yielded the storm and ice events listed in Table 2.4.7-1 of this report.

Table 2.4.7-1 Snow and Ice Events in the Upper Broad River Basin and Its Adjoining Areas Between 1993 and 2008

County	Number of Snow and Ice Events	Number of Ice Storms
Buncombe Co., NC	144	8
Henderson Co., NC	87	13
Polk Co., NC	50	7
McDowell Co., NC	79	12
Rutherford Co., NC	51	6
Cleveland Co., NC	44	7
Gaston Co., NC	37	8
Lincoln Co., NC	43	9
Cherokee Co., SC	50	10

Based on the storm and ice events in the Upper Broad River Basin, the staff determined that ice events are frequent during winters near the WLS site. The staff also searched the USACE ice jam database for ice jam or ice dam formation on the Broad River. No historical records exist of ice jams or dams on the Broad River. As stated in the USACE ice jam database, there are only two records of ice jam or ice dam formation in the State of North Carolina. An ice jam formed in the Neuse River upstream of the USGS streamflow gauge at Kinston, NC, on January 26, 1940, that lasted for 4 days. An ice gorge was reported in the Missouri River at Williston, NC, on February 24, 1925. The ice jam database does not list any events for the State of South Carolina.

Based on the search of the USACE ice jam database, the staff concluded that formation of ice jams and ice dams has not been reported for the Broad River. Therefore, the staff concluded that ice dams and ice jams are not a credible hazard near the WLS site.

The staff downloaded air temperature data for three cooperative stations located near the WLS site from NOAA NCDC. These three stations are Shelby 2 NNE, Gastonia, and Ninety-Nine Islands. The period of record at these stations are 1893−1895 and 1936-present (Shelby), 1930-present (Gastonia), and 1960-present (Ninety-Nine Islands). Using this air temperature data, the staff performed independent analysis to determine some characteristics of minimum daily mean air temperature near the site. These characteristics for the three stations are shown in Table 2.4.7-2 of this report.

Table 2.4.7-2 Some Characteristics of Mean Daily Air Temperature at NOAA NCDC Cooperative Stations Near the Site

Characteristic	Shelby 2 NNE	Gastonia	Ninety-Nine Islands
Minimum daily mean air temperature (date)	-13ºC (8ºF) (02/08/1895)	-12ºC (11ºF) (01/21/1985)	-12ºC (11ºF) (01/21/1985)
Number of days below freezing (total number of days for which data are available)	768 (27,818)	1076 (26,678)	740 (17,566)
Maximum number of consecutive days daily mean air temperature remains at freezing or below	13	11	9
Maximum number of consecutive days daily mean air temperature remains at 18ºF or below	3	2	2

The minimum daily mean air temperature at Shelby, Gastonia, and the Ninety-Nine Islands stations are -13ºC, -12ºC, -12ºC (8ºF, 11ºF, and 11ºF), respectively. The average number of days per year that the stations' daily mean air temperature was below freezing are approximately 10, 15, and 15, respectively. The longest sequences of days that the daily mean air temperature was at or below freezing for the three stations are 13, 11, and 9 days for Shelby, Gastonia, and Ninety-Nine Islands stations, respectively. Based on these characteristics of the daily mean air temperature, the staff concluded that the air temperature near the WLS site can fall below freezing for moderately long periods of time. However, the sequences are not long enough to cause extensive freezing of water bodies near the WLS site.

The staff also concluded the length of sequences of days during which the daily mean air temperature remained at or below -8ºC (18ºF). The reason for choosing the threshold of -8ºC (18ºF) is that frazil ice forms in turbulent, non-snow covered waters that undergo supercooling when the air temperature falls to or below -8ºC (18ºF). The staff noted that at Gastonia and Ninety-Nine Islands stations, the maximum span of such sequences was just 2 days and at Shelby it was 3 days. Based on this data, the staff concluded that frazil ice formation at and near the WLS site is possible, although unlikely, given the short duration during which supercooling can occur. However, the proposed reactors at the WLS site would not depend on any external source of water supply for safe shutdown. Therefore, the staff concluded that the safety of the plants will not be affected by formation of frazil ice at and near the WLS site.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed the potential for ice effects near the WLS site using approaches currently used in standard practice. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.7.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.7.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed site characteristics and other hydrometeorological parameters related to ice formation at or near the plant site, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.7 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addressed ice effects in COL Information Item 2.4-2. The staff concludes that the applicant has provided sufficient information on flood hazards from ice effects to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.8 Cooling Water Canals and Reservoirs

2.4.8.1 *Introduction*

WLS COL FSAR Section 2.4.8 describes cooling-water supply, made up of canals and reservoirs, used to transport and impound water supplied to the safety-related SSCs.

Section 2.4.8 of this report presents an evaluation of the applicant's submittal related to cooling-water canals and reservoirs. As stated in Section 2.4 above, hydrologic characteristics associated with conditions that would result in a loss of external water-supply and seismic design considerations of water-supply structures are not relevant for the AP1000 design. Therefore, flooding and low-water conditions for canals and reservoirs were not part of the staff's review.

2.4.8.2 *Summary of Application*

This section of the WLS COL FSAR addresses the site-specific information on cooling-water canals and reservoirs. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.3, Revision 19 related to cooling-water canals and reservoirs as follows:

AP1000 COL Information Item

- WLS COL 2.4-3

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Tier 2, Section 2.4.1.3, Revision 19.

> Combined License applicants will address the water supply sources to provide makeup water to the service water system cooling tower.

2.4.8.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification of design considerations for cooling-water canals and reservoirs, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.8.

The applicable regulatory requirements for cooling-water canals and reservoirs are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), "Geologic and seismic siting factors," sets forth the criteria to determine the siting factors for plant design bases with respect to water levels at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.8:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG1.102, "Flood Protection for Nuclear Power Plants" as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.8.4 *Technical Evaluation*

In this section of the report, the staff reviewed the applicant's analyses related to cooling-water canals and reservoirs. The staff's independent analysis, where needed for the review, is also described.

Information Submitted by the Applicant

The applicant stated that there are no safety-related cooling-water canals or reservoirs proposed for the WLS site because the UHS is provided by the atmosphere for the proposed AP1000 units.

NRC Staff's Technical Evaluation

The staff reviewed COL Information Item 2.4-3 related to the provision of site-specific information about the cooling-water canals and reservoirs at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.9. 2.4.11, and 2.4.12 of this report.

The staff reviewed the functioning of the AP1000 UHS. The passive cooling system of the proposed units is assisted by a water spray on the containment vessel provided by a passive containment cooling-water storage tank located on top of the containment building, which holds a 3-day supply of water following a design basis accident. Additional water is stored in a passive containment cooling ancillary water storage tank for an additional 4 days. Technical specifications would ensure that this 7-day supply of water to assist in cooling is always available. The proposed reactors at the WLS site would not depend on any external source of water supply for safe shutdown.

The staff concluded that there are no safety-related cooling-water canals or reservoirs are required for the safe operation of the WLS and, therefore, no further evaluation of safety-related water canals and reservoirs are necessary.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed the potential for floods caused by cooling-water canals and reservoirs near the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.8.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.8.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information relevant to design basis for canal and reservoirs used to transport and impound water supplied to the SSCs, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information relative to the design bases of canals and reservoirs important to the design and siting of the plant. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.8 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79, and 10 CFR Part 100, with respect to determining the acceptability of the site. The information provided on the cooling-water canals and reservoirs addressed COL Information Item 2.4-3. The staff concludes that the applicant has provided sufficient information to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.9 Channel Diversions

2.4.9.1 *Introduction*

WLS COL FSAR Section 2.4.9 describes channel diversions. It includes hydrogeologic and geomorphologic descriptions of the Broad River Basin and an evaluation of the likelihood of diversion of Broad River away from its present course.

Section 2.4.9 of this report presents the staff's evaluation of the applicant's submittal related to channel diversions. As stated in Section 2.4 above, hydrologic characteristics associated with conditions that would result in a loss of external water supply and seismic design considerations of water-supply structures are not relevant for the AP1000 design. Therefore, low-water conditions from channel diversions were not part of the staff's review.

2.4.9.2 *Summary of Application*

This section of the WLS COL FSAR addresses information about site-specific channel diversions. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.3, Revision 19 related to channel diversions as follows:

AP1000 COL Information Item

- WLS COL 2.4-3

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Tier 2, Section 2.4.1.3, Revision 19.

> Combined License applicants will address the water supply sources to provide makeup water to the service water system cooling tower.

2.4.9.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification and evaluation of channel diversions, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.9.

The applicable regulatory requirements for identifying and evaluating channel diversions are as follows:

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), "Geologic and seismic siting factors," sets forth the criteria to determine the siting factors for plant design bases with respect to water levels at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.9:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, "Flood Protection for Nuclear Power Plants," as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.9.4 *Technical Evaluation*

In this section of the report, the staff reviewed the applicant's analyses related to channel diversions. The staff's independent analysis, where needed for the review, is also described.

Information Submitted by the Applicant

The applicant stated that there is no evidence to suggest diversions or realignments of the Broad River in the past, no unstable steep side slopes are present and there is no record of ice-induced channel diversions. The applicant noted that several shoals are located in the basin but are confined within the natural banks of the river. The applicant concluded that channel diversion due to geothermal activity is not expected in the region. The applicant also concluded that any potential channel diversion would not affect safety-related structures or systems at the WLS site because the passive cooling system for the AP1000 design uses the atmosphere as the UHS and the cooling system does not rely directly on the Broad River for water.

NRC Staff's Technical Evaluation

The staff reviewed COL Information Item 2.4-3 related to the provision of site-specific information about the channel diversions at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.8, 2.4.11 and 2.4.12 of this report.

Based on the applicant's description of the cooling system of the proposed units at the WLS site, the staff concluded that the Broad River would serve as the source for makeup water for normal plant operation of the proposed units. The staff reviewed the functioning of the AP1000 UHS. The passive cooling system of the proposed units is assisted by a water spray on the containment vessel provided by a passive containment cooling-water storage tank located on top of the containment building, which holds a 3-day supply of water following a design basis accident. Additional water is stored in a passive containment cooling ancillary water storage tank for an additional 4 days. Technical specifications would ensure that this 7-day supply of water to assist in cooling is always available. The proposed reactors at the WLS site would not depend on any external source of water supply for safe shutdown.

The staff concluded that no safety-related cooling-water sources required for the safe operation of the WLS. Therefore, the staff determined that a diversion of the Broad River away from the site for any reason would not affect the safety of the plant. Based on the applicant's description of the geology and geomorphology of the Broad River Basin and the available freeboard between normal water-surface elevation in the river and the grade elevation of the WLS site, the staff also determined that a diversion of the Broad River toward the WLS site is unlikely. Therefore, the staff concluded that flooding of the WLS site from a diversion of the Broad River toward the WLS site is not a plausible hazard.

Based on a review of the applicant's information in WLS COL FSAR Revision 11, the staff concluded that the applicant has appropriately analyzed the potential for channel diversions near the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.9.5 *Post Combined License Activities*

There are no post COL activities related to this section

2.4.9.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information to demonstrate that the characteristics of the site fall within the site parameters specified in the AP1000 DC rule, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description ensuring that the plant and essential water supplies will not be adversely affected. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.9 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This section addressed channel diversions in COL Information Item 2.4-3. The staff concludes that the applicant has provided sufficient information to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.10 Flooding Protection Requirements

2.4.10.1 *Introduction*

WLS COL FSAR Section 2.4.10 describes locations and elevations of safety-related facilities and those of structures and components required for protection of safety-related facilities. These requirements are then compared with design-basis flood conditions to determine whether flood effects need to be considered in the plant's design or in emergency procedures.

Section 2.4.10 of this report presents an evaluation of the flooding protection for the proposed plant site.

2.4.10.2 *Summary of Application*

This section of the WLS COL FSAR addresses the needs for site-specific information on flooding protection requirements. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to flooding protection requirements as follows:

AP1000 COL Information Item

- WLS COL 2.4-2

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address the following site-specific information about historical flooding and potential flooding factors, including the effects of local intense precipitation.
>
> - Probable Maximum Flood (PMF) on Streams and Rivers – Site-specific information that will be used to determine the design basis flooding at the site. This information will include the PMF on streams and rivers.
>
> - Dam Failures – Site-specific information about potential dam failures.
>
> - Probable Maximum Surge and Seiche Flooding – Site-specific information about probable maximum surge and seiche flooding.

- Probable Maximum Tsunami Loading – Site-specific information about probable maximum tsunami loading.

- Flood Protection Requirements – Site-specific information about flood protection requirements or verification that flood protection is not required to meet the site parameter for flood level.

In WLS COL FSAR Section 2.4.10, the applicant addressed the flood protection requirements at the site. The causes of floods and their effects were discussed in other WLS COL FSAR sections. No further action is required for sites within the bounds of the site parameter for flood level.

2.4.10.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the identification and evaluation of flooding protection requirements, and the associated acceptance criteria, are described in NUREG-0800. Section 2.4.10

- 10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in final safety analysis report," as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, "Reactor Site Criteria," as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), "Geologic and seismic siting factors," sets forth the criteria to determine the siting factors for plant design bases with respect to water levels at the site.

The staff also used the following regulatory guides for the acceptance criteria identified in NUREG-0800, Section 2.4.10:

- RG 1.59, "Design Basis Floods for Nuclear Power Plants," supplemented by best current practices, as it relates to providing assurance that natural flooding phenomena that could potentially affect the site have been appropriately identified and characterized

- RG 1.102, "Flood Protection for Nuclear Power Plants," as it relates to providing assurance that SSCs important to safety have been designed to withstand the effects of natural flooding phenomena likely to occur at the site

- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," as it relates to the contents of a COL application

2.4.10.4 *Technical Evaluation*

In this section of the report, the staff reviewed the applicant's analyses related to flooding protection requirements. The staff's independent analysis, where needed for the review, is also described.

Information Submitted by the Applicant

The applicant stated that all safety-related facilities at the WLS site are located above the maximum flood level based on the design-basis flood evaluate in earlier sections of the WLS COL FSAR. Therefore, the applicant concluded that flood protection measures and emergency procedures are not required.

NRC Staff's Technical Evaluation

The staff reviewed COL Information Item 2.4-2 related to the provision of site-specific information about the PMF at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.2. 2.4.3, 2.4.4, 2.4.5, 2.4.6, and 2.4.7 of this report.

The staff determined that the site characteristic maximum flood water-surface elevation near the WLS site from several flooding mechanisms described in earlier sections of this report remains below the site grade and meets the AP1000 DCD site parameter. Therefore, the staff concluded that flooding protection of safety-related SSCs at the WLS site is not needed.

Based on a review of the applicant's information in WLS COL FSAR Revisions 0 through 11, the staff concluded that the applicant has appropriately analyzed the need for flooding protection at the WLS site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately identified and evaluated extreme flood events at the site. Therefore, based on the reasons given above, the staff concluded that the applicant adequately determined hydrologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

2.4.10.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.10.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information to demonstrate that the characteristics of the site fall within the site parameters specified in the AP1000 DC rule, and that no outstanding information is required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information relative to the flood protection measures important to the design and siting of this plant. The staff concluded that the applicant considered the appropriate site phenomena in establishing the flood protection measures for SSCs. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.10 of this report, whether the applicant met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addressed flooding protection requirements in COL Information Item 2.4-2. The staff concludes that the applicant provided sufficient information to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.11 Low Water Considerations

2.4.11.1 *Introduction*

WLS COL FSAR Section 2.4.11 describes natural events that may reduce or limit the available safety-related cooling-water supply. The applicant ensures that an adequate water supply will exist to shut down the plant under conditions requiring safety-related cooling.

Section 2.4.11 of this report presents an evaluation of the effects of low water-surface elevations caused by various hydrometeorological events.

As stated in Section 2.4 above, hydrologic characteristics associated with conditions that would result in a loss of external water supply and seismic design considerations of water-supply structures are not relevant for the AP1000 design. Therefore, low-water conditions were not part of the staff's review.

2.4.11.2 *Summary of Application*

This section of the WLS COL FSAR addresses the impacts of low water on water supply. The applicant addressed the information item identified in AP1000 DCD Tier 2, Section 2.4.1.2, Revision 19 related to low-water considerations as follows:

<u>*AP1000 COL Information Item*</u>

- WLS COL 2.4-3

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.3, Revision 19.

> Combined License applicants will address the water supply sources to provide makeup water to the service water system cooling tower.

2.4.11.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the low-water considerations, and the associated acceptance criteria, are described in NUREG-0800, Section 2.4.11.

The applicable regulatory requirements for identifying the effects of low water are as follows:

- 10 CFR 52.79(a)(1)(iii), “Contents of applications; technical information in final safety analysis report,” as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, “Reactor Site Criteria,” as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), “Geologic and seismic siting factors,” sets forth the criteria to determine the siting factors for plant design bases with respect to seismically induced floods and water waves at the site.

2.4.11.4 *Technical Evaluation*

The following material in this section describes the staff’s review of information provided and analyses carried out by the applicant in its WLS COL FSAR. The staff’s independent analysis, where needed for the review, is also described.

The staff reviewed COL Information Item 2.4-3 related to the provision of site-specific information about low-water considerations at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Sections 2.4.8, 2.4.9, and 2.4.12 of this report.

To ensure that the site characteristics related to low-water events are based on the most conservative of plausible conceptual models, in RAI 825, Question 02.04.11-1, the staff requested that the applicant describe the process followed to determine the conceptual models for low water from drought and from other phenomena and the effects of low water on safety-related water supplies under possible water-use limits. In an October 27, 2008, response to RAI 825, Question 02.04.11-1, the applicant stated that it characterized low-flow conditions in the Broad River using the 10-year return period 7-day flow (7Q10) at the Gaffney, SC, USGS streamflow gauge. The applicant noted that it supplemented the available streamflow record at the Gaffney gauge by additional periods of streamflow data from two upstream gauges at Blacksburg, SC and Boiling Springs, NC. The applicant estimated the 7Q10 flow from a Log-Pearson Type III distribution fitted to the annual 7-day low flow for each year in the record. The applicant stated that the estimated 7Q10 flow for the Broad River at the Gaffney gauge is 13.6 m^3/s (479 cfs), which is approximately the same as the Federal Energy Regulatory Commission (FERC) minimum flow requirement of 13.7 m^3/s (483 cfs) for the Ninety-Nine Islands Hydroelectric Station.

The applicant defined a minimum discharge of 15.2 m^3/s (538 cfs), the sum of the minimum FERC requirement of 13.7 m^3/s (483 cfs) and the expected consumptive water use of 1.6 m^3/s (55 cfs) for the proposed units, which are needed to support current water use and quality downstream of the site. When the Broad River discharge falls below 15.2 m^3/s (538 cfs), onsite water storage would supplement makeup water from the Broad River for the proposed units. When the Broad River discharge falls below 13.7 m^3/s (483 cfs), only Make-Up Ponds B and C would supply makeup water to the proposed units. The staff reviewed the applicant's October 27, 2008, response to RAI 825, Question 02.04.11-1, and subsequent updates to the WLS COL FSAR up to and including Revision 11 to conclude that the applicant's process to determine the conceptual models for low flow are adequately described. The staff also determined that there are no safety-related systems that can be affected by low water at the WLS site. Accordingly, the staff considers RAI 825, Question 02.04.11-1, resolved.

Low Flow in Rivers and Streams

Information Submitted by the Applicant

The applicant stated that the passive cooling system of the AP1000 design does not rely on the Broad River as a source of water and therefore, no safety-related facilities of the WLS would be affected by low-water conditions in the river.

NRC Staff's Technical Evaluation

There are no safety-related systems that can be affected by low water at the WLS site.

Low Water Resulting from Surges, Seiches, or Tsunami

Information Submitted by the Applicant

The applicant stated that no safety-related systems can be affected by low water at the WLS site.

NRC Staff's Technical Evaluation

The staff agreed with the applicant that no safety-related systems can be affected by low water at the WLS site.

Historical Low Water

Information Submitted by the Applicant

The applicant stated that no safety-related systems can be affected by low water at the WLS site.

NRC Staff's Technical Evaluation

The staff agreed with the applicant that no safety-related systems can be affected by low water at the WLS site.

Future Controls

Information Submitted by the Applicant

The applicant stated that no safety-related systems can be affected by low water at the WLS site.

NRC Staff's Technical Evaluation

The staff agreed with the applicant that no safety-related systems can be affected by low water at the WLS site.

Plant Requirements

Information Submitted by the Applicant

The applicant stated that no safety-related systems can be affected by low water at the WLS site.

NRC Staff's Technical Evaluation

The staff agreed with the applicant that no safety-related systems can be affected by low water at the WLS site.

Heat Sink Dependability Requirements

Information Submitted by the Applicant

The applicant reported that the atmosphere provides the UHS for the AP1000 design and the passive containment cooling system does not rely on water from the Broad River. The applicant also stated that no water from the Broad River or from other outside sources is required for safe emergency shutdown because the passive containment cooling-water storage tank stores water required for 72 hours of containment wetting and the passive containment cooling ancillary water storage tank has the capacity to provide containment wetting for an additional 4 days.

NRC Staff's Technical Evaluation

In RAI 825, Question 02.04.11-2, the staff requested that the applicant describe the term "normal plant shutdown" and to clarify whether any safety-related water would be needed during normal plant shutdown.

In an October 27, 2008, response to RAI 825, Question 02.04.11-2, the applicant stated that a normal plant shutdown is a non-emergency procedure and does not require any safety-related water. The normal shutdown would require approximately 130,749 m^3 (106 ac-ft) of water for the two proposed units and an additional 176,388 m^3 (143 ac-ft) to maintain shutdown conditions for 90 days after a normal shutdown. The applicant stated that Make-Up Pond A, with its usable storage capacity of approximately 1,480,178 m^3 (1,200 ac-ft), would have sufficient water to support a normal plant shutdown and to maintain shutdown conditions for durations that are significantly longer than those of any recorded period of low flow. The applicant also stated that it has no plans to draw down Make-Up Pond A to support plant water needs during power production. The staff notes that the applicant has updated the WLS COL FSAR text.

The staff reviewed the functioning of the AP1000 UHS. The passive cooling system of the proposed units is assisted by a water spray on the containment vessel provided by a passive containment cooling-water storage tank located on top of the containment building, which holds a 3-day supply of water following a design-basis accident. Additional water is stored in a passive containment cooling ancillary water storage tank for an additional 4 days. Technical specifications would ensure that this 7-day supply of water to assist in cooling is always available. The proposed reactors at the WLS site would not depend on any external source of water supply for safe shutdown. The staff evaluated the applicant's October 27, 2008, response to RAI 825, Question 02.04.11-2, and concluded that the process used by the applicant to determine heat sink dependability requirements is adequate. The staff concluded that there are no safety-related systems that can be affected by low water at the WLS site. Accordingly, the staff considers RAI 825, Question 02.04.11-2, resolved.

2.4.11.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.11.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information required and that no site characteristics related to low-water conditions apply to the AP1000 design.

As set forth above, the applicant has presented and substantiated information relative to the low-water effects important to the design and siting of this plant. The staff found that the applicant has considered the appropriate site phenomena in establishing the design bases for SSCs. The staff reviewed the information provided and, for the reasons given above, concluded that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.11 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This addressed low-water considerations in COL Information Item 2.4-3. The staff concludes that the applicant has provided sufficient information to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.12 Groundwater

2.4.12.1 *Introduction*

This section of the WLS COL FSAR describes the hydrogeological characteristics of the site. One of the key objectives of groundwater investigations and monitoring at this site is to evaluate the maximum groundwater-surface elevation at the site, which is used in Section 2.5 of this report to determine the effects of groundwater on the stability of the plant foundations and slopes. The evaluation is performed to ensure that the maximum groundwater-surface elevation remains less than the 29.9 m (98.0 ft) plant elevation. Other significant objectives are to examine whether groundwater provides any safety-related water supply, to determine whether dewatering systems are required to maintain groundwater-surface elevations below the required elevation, and to describe subsurface pathways for potential groundwater contaminants.

The specific areas of review are as follows: (1) identification of the aquifers, types of onsite groundwater use, sources of recharge, present withdrawals and known and likely future withdrawals, flow rates, travel time, gradients, and other properties that affect movement of accidental contaminants in groundwater, groundwater-surface elevations beneath the site, seasonal and climatic fluctuations, monitoring and protection requirements, and man-made changes that have the potential to cause long-term changes in local groundwater regime; (2) effects of groundwater-surface elevations and other hydrodynamic effects of groundwater on the design bases of plant foundations and those of other SSCs important to safety; (3) reliability of groundwater resources and related systems used to supply safety-related water to the plant; (4) reliability of dewatering systems to maintain groundwater conditions within the plant's design bases; (5) potential effects of seismic and non-seismic information about the postulated worst-case groundwater conditions for the proposed plant site; and (6) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts of 10 CFR Part 52.

2.4.12.2 *Summary of Application*

This section of the WLS COL FSAR addresses groundwater conditions in terms of impacts on structures and water supply. The applicant addressed information related to groundwater as follows:

AP1000 COL Information Item

- WLS COL 2.4-4

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.4, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address site-specific information on groundwater. No further action is required for the sites within the bounds of the site parameter for groundwater.

License Condition

- Part 10, License Condition 15, "Removal of Legacy Stormwater Drain Line"

The applicant proposed a license condition requiring that a single legacy Cherokee project stormwater drain line (designed to transfer stormwater from the Cherokee power block area to Hold-Up Pond A) and any associated bedding material representing a potential preferential groundwater pathway be removed and the excavation backfilled with compacted native soils.

2.4.12.3 *Regulatory Basis*

The relevant requirements of NRC regulations for groundwater, and the associated acceptance criteria, are specified in NUREG-0800, Section 2.4.12.

The applicable regulatory requirements for groundwater are set forth in the following:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

The staff also used the acceptance criteria identified in NUREG-0800, Section 2.4.12:

- Local and Regional Groundwater Characteristics and Use: The applicant should supply a complete description of regional and local groundwater characteristics and groundwater use, groundwater monitoring and protection requirements, and any man-made changes with a potential to affect regional groundwater characteristics over a long period of time.

- Effects on Plant Foundations and other Safety-Related Structures, Systems, and Components: The applicant should supply a complete description of the effects of groundwater-surface elevations and other hydrodynamic effects on the design bases of plant foundations and other SSCs important to safety.

- Reliability of Groundwater Resources and Systems Used for Safety-Related Purposes: The applicant should supply a complete description of all SSCs important to safety that depends on groundwater, as well as data and analysis regarding the reliability of the groundwater source.

- Reliability of Dewatering Systems: The applicant should supply a complete description of the site dewatering system, including its reliability to maintain groundwater conditions within the groundwater design bases of SSCs important to safety.

- Consideration of Other Site Related Evaluation Criteria: The applicant should supply an assessment of the potential effects of seismic and non-seismic information about the postulated worst-case scenario related to groundwater effects for the proposed plant site.

The regulatory basis of the information incorporated by reference will be addressed in the staff's final safety evaluation report (FSER) related to the AP1000 certified design.

2.4.12.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.4.12 Revisions 0 to 7; corrections and additions to the WLS COL FSAR submitted by the applicant as letters; and associated applicant responses to RAIs issued by the staff. The conclusions of the review are current with, and apply to, WLS COL FSAR Revision 11. However, frequent references are made to earlier WLS COL FSAR revisions where necessary to explain the reasons for RAIs. The staff also checked the referenced AP1000 DCD and departures and supplements specified in the WLS COL FSAR.

The staff reviewed COL Information Item 2.4-4 related to the provision of site-specific information about groundwater at the plant site included under WLS COL FSAR Section 2.4.

For clarity, the technical evaluation is organized into six subsections, each addressing a specific issue: conceptual model; offsite wells; aquifer properties; alternative pathways; maximum water table level; and monitoring. Each subsection describes (1) the staff's review of information and analyses that the applicant provided in the WLS COL FSAR, (2) RAIs issued by the staff and the applicant's responses, and (3) the staff's independent analysis, where needed for the review.

Conceptual Model

Information Submitted by the Applicant

The applicant described its conceptual model of the hydrogeology of the site in WLS COL FSAR Sections 2.4.12.1, 2.4.12.2, and 2.4.12.3. The site is located in the Piedmont physiographic province and is underlain by metamorphic rocks of volcanic, intrusive, and sedimentary origin. Groundwater may be obtained from fractures within the bedrock, but near the surface it occurs under unconfined conditions in artificial fill materials, soil and saprolite that overlie bedrock, and (partially weathered rock (PWR)). The PWR tends to have the highest hydraulic conductivity. Groundwater originates from precipitation, which infiltrates in upland areas, then flows mostly within the near-surface materials toward lower areas where it discharges to the Broad River, the makeup ponds, and other small bodies of surface water. Groundwater supplies mostly domestic wells in the area near the site. The applicant does not currently use or plan to use onsite groundwater.

In response to four staff RAIs, the applicant provided additional details and clarifications related to the rationale for the conceptual model, the impact of variable precipitation on groundwater flow and direction, the role of seeps and springs, and the definition of the word "preferential."

NRC Staff's Technical Evaluation

The staff reviewed the applicant's description of the site conceptual model. To better understand the applicant's rationale and support for the conceptual model, the staff issued RAI 826, Question 02.04.12-1. In a December 11, 2008, response, the applicant provided an overview of the methodology it used to develop the conceptual model of the site. The applicant utilized regional data, Cherokee-era site data, and data collected as part of the WLS characterization effort to characterize the key materials (i.e., fill; saprolite; residual soil; PWR). When site-specific data did not exist, the applicant used literature values. Using the conceptual model and groundwater well data, the applicant identified five potential flow paths between a postulated leak at the nuclear island and the site boundary. In the initial WLS COL FSAR, the applicant had identified only one path; in the current WLS COL FSAR, because of site grading changes, the applicant reduced the number of plausible pathways from five to four. The applicant provided additional details related to the flow paths in response to other WLS COL FSAR RAIs. The applicant proposed to update the WLS COL FSAR with this new information about conceptual model identification. The staff notes that applicant included this information in WLS COL FSAR Section 2.4.12.2, “Sources.” The staff concluded that the applicant’s December 11, 2008, response to RAI 826, Question 02.04.12-1, was acceptable and considers the question resolved.

To help understand how groundwater elevation and flow direction responded spatially and temporally to precipitation, the staff issued RAI 826, Question 02.04.12-3. In a December 11, 2008, response, the applicant supplemented the onsite precipitation data for December 2005 to November 2006 with data from 1950 to 2008 from the Greenville-Spartanburg Airport, located 72 km (45 mi) to the west. The applicant noted that precipitation was relatively evenly distributed throughout the year, yet groundwater levels increased during the winter, reaching a maximum in April and May, and decreased in summer, reaching a minimum in October and November. The applicant attributed the seasonal effect to evapotranspiration, which is lowest in winter and highest in summer. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, “Sources.” The staff concluded that the applicant’s December 11, 2008, response to RAI 826, Question 02.04.12-3, was acceptable and considers the question resolved.

Using precipitation data from the Greenville-Spartanburg Airport, the staff concluded that precipitation in 2005 was 8 percent above average (for the period 1950-2007), 15 percent below average in 2006, and 37 percent below average in 2007. The applicant monitored groundwater levels from April 2006 to April 2007. The staff concluded that those groundwater levels are reflective of drier than average conditions. This issue is discussed further under the topic “Maximum Water Table Level.”

To help understand the role of springs and seeps in groundwater discharge, the staff issued RAI 826, Question 02.04.12-9. In a December 11, 2008, response, the applicant provided a figure showing the locations of springs and seeps in relation to the WLS nuclear island. The applicant stated that, in 1973, springs and seeps were observed in various locations across the site, but predominantly in drainage channels. Cut-and-fill activities associated with the Cherokee Nuclear Plant buried most of those locations. In 2006, springs and seeps were much less prevalent and none was near the proposed site for the nuclear island. The applicant also stated that the number of springs and seeps observed in 2006 may have been affected by the excavation dewatering, which began in December 2005. The figure provided by the applicant helped the staff to recognize the association of seeps with drainages and the proximity of those drainages to the WLS nuclear island. This information was sufficient for the staff to perform and complete its review. The staff concluded that the applicant’s December 11, 2008, response to RAI 826, Question 02.04.12-9, was acceptable and considers the question resolved.

To clarify the applicant’s usage of the technical term “preferential” with regard to groundwater flow, the staff issued RAI 70, Question 02.04.12-17. In a July 31, 2009, response, the applicant agreed to use the term “limiting” in place of “preferential” when referring to the groundwater flow path that represents the shortest travel time, and to revise the WLS COL FSAR accordingly. The applicant also acknowledged the potential for buried Cherokee pipes to act as preferential flow paths, in the sense that they may provide high-permeability paths for groundwater flow. The applicant evaluated the expected post-construction groundwater surface and determined that the pipe that runs from the nuclear power block area north to Hold-Up Pond A could be below the future groundwater surface and therefore could act as a preferential pathway. The applicant proposed to update the WLS COL FSAR to explain the issue and stated that the buried pipe and bedding material would be removed. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, “Sources.” The staff concluded that the applicant’s July 31, 2009, response to RAI 70, Question 02.04.12-17, was acceptable and considers the question resolved.

Offsite Wells

Information Submitted by the Applicant

The applicant provided information about offsite wells in WLS COL FSAR 2.4.12.2. This information was provided for the staff to identify potential groundwater pathways and determine whether construction and operation of the WLS nuclear plants could affect offsite wells. In response to two staff RAIs, the applicant provided additional information about the locations of groundwater users near the site.

NRC Staff’s Technical Evaluation

The staff reviewed the applicant’s information about offsite wells. The staff concluded that additional information was required to complete its evaluation of risks to offsite groundwater users.

To help understand the locations of groundwater users near the site who might be at risk, the staff issued RAI 826, Question 02.04.12-2. In a December 11, 2008, response, the applicant provided information about well depth, well abandonment, and conversion to municipal water. The applicant reported that only 3 of the 50 wells identified in the Cherokee Nuclear Station Environmental Report were drilled deeper than 45.7 m (150 ft). Since 1985, the State of South Carolina reported 22 wells drilled deeper than 45.7 m (150 ft) within 1.6 km (1 mi) of the WLS site property boundary. The applicant provided information from the Draytonville Water District showing that 55 percent of residents within 3.2 km (2 mi) of the reactor buildings had connected to the public water supply and that, based on planned expansion, service would be available to 83 percent of residents in 2009. The applicant stated that it did not detect a trend to abandon existing wells.

The staff noted that all of the public wells are more than 0.8 km (0.5 mi) from the proposed nuclear island. In addition, all of the 22 wells drilled to deeper than 45.7 m (150 ft) since 1985 are more than 1.6 km (1 mi) from the proposed nuclear island and all are separated from the WLS nuclear island by a water body (i.e., the Broad River; Make-Up Pond A; Make-Up Pond B). Therefore, the staff concluded that it is unlikely that groundwater uptake would be directly involved in a groundwater radionuclide pathway. The staff concluded that the applicant’s December 11, 2008, response to RAI 826, Question 02.04.12-2, was acceptable and considers the question resolved.

To help understand potential risks to groundwater users near the site, the staff issued RAI 826, Question 02.04.12-7. In a December 11, 2008, response, the applicant stated that WLS COL FSAR Figure 2.4.12-202 was developed using data from the period from 1976 to 1985 during which the Cherokee Nuclear Station was dewatering the excavation. The staff notes that annual precipitation during this period ranged from 72 to 134 percent of normal, suggesting that the groundwater observations span a reasonable range of precipitation conditions. The applicant stated that the [name withheld] well is located 1,524 m (5,000 ft) south of the nuclear island. At that distance, the well is outside the zone of influence of the construction dewatering. The applicant stated that the Piedmont aquifer consists of porous material above continuous bedrock and because there are no confining layers, the [name withheld] well likely produces water from the same unconfined aquifer as that which exists at the WLS site. The applicant proposed adding the offsite well information to the WLS COL FSAR to support the assumptions that offsite wells are not a potential contaminant transport pathway and that the wells would not be affected by construction and operation of the WLS reactors. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, “Sources.” The staff concluded that the applicant’s December 11, 2008, response to RAI 826, Question 02.04.12-7, was acceptable and considers the question resolved.

Aquifer Properties

Information Submitted by the Applicant

The applicant provided information about the properties of aquifers at the site in WLS COL FSAR Section 2.4.12.2.4, and additional information in WLS COL FSAR 2.5.4. Aquifer materials described were the artificial fill, soil and saprolite, PWR, and fractured bedrock. Properties of particular interest to the staff were hydraulic conductivity, total porosity, and effective porosity. These properties are primary influences on the direction and velocity of groundwater movement in the subsurface, and are among the major influences on movement of radionuclides that move with groundwater. Retardation of radionuclide movement by interaction with aquifer materials is discussed below in Section 2.4.13. In response to four staff RAIs, the applicant provided additional information about the methods used to determine porosity and effective porosity, the decrease of hydraulic conductivity with increasing depth, and the selection of a conservative hydraulic conductivity value for calculations of groundwater velocity.

NRC Staff’s Technical Evaluation

The staff reviewed information provided by the applicant about the hydraulic properties of aquifer materials. The staff concluded that additional information about aquifer properties was required to support its evaluation of maximum groundwater levels and the direction and velocity of radionuclide movement with groundwater.

To clarify the methods used by the applicant to determine porosity, and to allow staff to evaluate the reasonableness of measured and estimated porosity values, the staff issued RAI 826, Question 02.04.12-4. In a December 11, 2008, response and subsequent May 12, 2009, response, the applicant stated that it had estimated the effective porosity for fill and a mix of residual soil and saprolite to be 0.09 and 0.20, respectively, using a USGS method that required particle size data. The applicant estimated the effective porosity for the PWR to be 0.08 by measuring the liquid drained from a single PWR sample. The staff reviewed and confirmed the calculations. The applicant compared the average hydraulic conductivity and effective porosity values of soil/saprolite and PWR at the WLS site to those at the Catawba Nuclear site, which is located in a similar piedmont region about 32 km (20 mi) to the east. Average hydraulic conductivities at the WLS site were 17 and 55 percent less for soil/saprolite and PWR, respectively, than at the Catawba site. The average effective porosity of the soil/saprolite at the WLS site was 77 percent of the value at Catawba. The average effective porosity of the PWR at WLS was 45 percent greater than that at Catawba. The applicant proposed to update WLS COL FSAR Tables 2.4.12-203 and 2.4.12-204. Subsequently, the applicant deleted WLS COL FSAR Table 2.4.12-203 because the information was contained in the text and in WLS COL FSAR Table 2.5.4-211. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, “Sources,” and WLS COL FSAR Section 2.5.4, “Stability of Subsurface Materials and Foundations.” The staff concluded that the applicant’s December 11, 2008, and May 12, 2009, responses to RAI 826, Question 02.04.12-4, were acceptable and considers these questions resolved.

The applicant estimated the effective porosity of the PWR by saturating the sample, then allowing it to drain; the volume of the liquid that drains provides a measure of the effective porosity. This method is typically unable to drain all liquid that would normally drain in a field setting, thus the method underestimates effective porosity. The staff notes that the effective porosity of the PWR material is based on the measurement results for a single sample. However, comparison with the effective porosity at other sites shows it to be consistent. The staff concluded that using the effective porosity value, determined using the method described above, would be conservative for use in calculating travel time.

To clarify the source and validity of certain parameter values presented by the applicant, the staff issued RAI 826, Question 02.04.12-5. In the December 11, 2008, response, the applicant identified grain size distribution, specific gravity, unit weight of soil and hydraulic conductivity as parameters that were measured using American Society for Testing and Materials procedures. The applicant identified total porosity and effective porosity as parameters that were calculated or estimated based on the values of other parameters. Total porosity was estimated using the dry unit weight and specific gravity of the soil and unit weight of water. Effective porosities of fill, soil, and saprolite were estimated using grain size distribution. The effective porosity of PWR was estimated using the saturated and drained unit weights. The staff reviewed the procedures and confirmed the calculations. The applicant proposed to update the WLS COL FSAR with this information about porosity estimation. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, “Sources,” and WLS COL FSAR Section 2.5.4, “Stability of Subsurface Materials and Foundations.” The staff concluded that the applicant’s December 11, 2008, response to RAI 826, Question 02.04.12-5, was acceptable and considers the question resolved.

To clarify the basis for an observed decrease in hydraulic conductivity with increasing depth, the staff issued RAI 826, Question 02.04.12-10. In a December 11, 2008, response, the applicant provided two figures, one showing the 1970s hydraulic conductivity data and the other the 2006 data. Both sets of data show that hydraulic conductivity of the PWR decreases with increasing depth. The applicant did not adjust or rectify the depths for different ground-surface elevation during these two periods. The applicant identified conservative values of hydraulic conductivity to be used in calculating travel time. For each material, the applicant defined the conservative hydraulic conductivity to be the geometric mean of all values above the median value for that material. For the PWR, the applicant used a slightly higher value (1.4×10^{-3} cm/s versus 1.0×10^{-3} cm/s (3.97 ft/day to 2.83 ft/day)) that was obtained in 2006 from an aquifer test conducted along the flow path expected to have the shortest travel time (i.e., the one going north from the proposed Unit 2 to the Broad River). The staff examined the figures provided by the applicant and confirmed that conductivity in the PWR decreases with depth. The staff considered the conductivity data and agreed that the value used for the PWR is conservative for travel-time calculations. The applicant proposed to update the discussion of hydraulic conductivity in the WLS COL FSAR. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, "Sources." The staff concluded that the applicant's December 11, 2008, response to RAI 826, Question 02.04.12-10, was acceptable and considers the question resolved.

To clarify what value of hydraulic conductivity should be used for conservative calculations of groundwater velocity, the staff issued RAI 70, Question 02.04.12-16. In a July 31, 2009, response, the applicant explained that tests conducted in the 1970s for the Cherokee site investigation provided results for unconsolidated material, which was a label that referred to the aquifer material without discriminating between soil, alluvium, saprolite, and PWR. The applicant described the current site conceptual model in terms of specific material (e.g., saprolite, PWR) rather than the bulk "unconsolidated material." The applicant further explained that the PWR was the most transmissive material and that the hydraulic conductivity value of 1.4×10^{-3} cm/s (3.97 ft/day) was nine times greater than the median value. The applicant proposed to update the discussion of hydraulic conductivity in the WLS COL FSAR and clarify the data support and property estimates. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, "Sources." The staff concluded that the applicant's July 31, 2009, response to RAI 70, Question 02.04.12-16, was acceptable and considers the question resolved.

Alternative Flow Paths

Information Submitted by the Applicant

The applicant identified a single bounding groundwater pathway that could carry radionuclides from a postulated release to locations where groundwater could discharge to surface water by which members of the public could be exposed. Groundwater originates from precipitation that infiltrates into soil in upland areas. It then moves generally down slopes toward the Broad River and other surface-water bodies. The applicant did not describe how the bounding pathway was identified and did not evaluate alternative pathways.

In response to four staff RAIs, the applicant provided additional details regarding alternative groundwater pathways, the geologic materials along those pathways, and the impact of temperature and dissolved solids on flow along groundwater pathways, and hydraulic gradients along those pathways.

NRC Staff's Technical Evaluation

To ensure that all possible groundwater flow paths are being considered, the staff issued RAI 826, Question 02.04.12-8. In a December 11, 2008, response, the applicant stated that WLS COL FSAR Figure 2.4.12-204, Sheet 8, which shows post-construction water table conditions, was produced from knowledge of 1973 groundwater conditions and the current water table. Using the same figure, the applicant identified five alternative conceptual flow paths from the nuclear island to the accessible environment. Subsequently, after revising the site layout and drainage plan, the applicant reduced the number of pathways to the four shown in WLS COL FSAR Table 2.4.12-1. The applicant identified Pathway 1 as the limiting flow path, meaning the most conservative pathway with respect to predicting the fastest contaminant movement. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.3, "Groundwater Movement." The staff concluded that the applicant's December 11, 2008, response to RAI 826, Question 02.04.12-8, was acceptable and considers the question resolved.

The staff determined that there was uncertainty in the geologic materials that are present along each plausible groundwater pathway. The staff also determined that the major materials, the soil, saprolite, and PWR, were all exposed in the existing excavation and that a postulated leak could enter any of these materials. To address these issues, the staff issued RAI 70, Question 02.04.12-15. In a December 18, 2009, response, the applicant assumed the presence of PWR (the most highly conductive of the three materials) for all pathways. Table 2.4.12-1 of this report shows the corresponding travel-time estimates are shorter and that Pathway 1, from Unit 2 to Hold-Up Pond A, has the shortest travel time and would therefore represent the most conservative pathway to use for the transport analysis in WLS COL FSAR Section 2.4.13. The applicant stated that a storm drain system (DRS) would be designed to route runoff from the nuclear power block area to reduce the potential for flooding. The applicant does not expect the DRS to cause any other groundwater pathway to have a shorter travel time than Pathway 1. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, "Sources."

Table 2.4.12-1 Pathway Descriptions and Travel-Time Estimates (for WLS COL FSAR Revision 1, actual geology was used; for WLS COL FSAR Revision 7, the geology for all pathways was assumed to be the PWR material)

Pathway Number	Groundwater Pathway Description	Estimated Travel Time (yr)	
		WLS COL FSAR Revision 1	WLS COL FSAR Revision 7
1	Unit 2 to Hold-Up Pond A	7.2	1.6
2	Unit 2 to the Broad River	2.8	2.7
3	Unit 2 to Make-Up Pond A	23	4.0
4	Unit 1 to Make-Up Pond B	9.8	5.5

The staff evaluated the pathways identified by the applicant and determined that they adequately represent the plausible pathways to each of the major water bodies. The travel paths are conservatively evaluated as straight lines rather than the curved flow paths indicated by the groundwater contour map. Post-construction water table elevations might cause slight differences in groundwater flow and direction, but any change from a straight line would only elongate the travel path and lengthen the travel time. Groundwater gradients would also be affected by post-construction water table elevations. For the travel-time estimates in Table 2.4.12-1 of this report, the applicant used its estimate of the maximum water table elevation of 178 m (584 ft) above MSL to calculate the gradient. The staff considers this choice conservative with respect to calculation of the groundwater gradient. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.3, "Groundwater Movement." The staff concluded that the applicant's December 18, 2009, response to RAI 70, Question 02.04.12-15, was acceptable and considers the question resolved.

Liquid released from the liquid waste management system could have a higher temperature and different content of dissolved solids than ambient groundwater. To address the possibility that this might affect groundwater flow paths, the staff issued RAI 826, Question 02.04.12-12. In a December 11, 2008, response, the applicant responded that the leaked fluid would have a total dissolved solids (TDS) content of less than 1 ppm. The applicant stated that any physical properties of the leaked fluid that differed from groundwater conditions would quickly dissipate relative to the travel time. That is, the leaked fluid would quickly take on the physical characteristics of groundwater and, therefore, would neither preferentially rise nor sink as it moved away from the nuclear island.

The staff examined AP1000 DCD Table 5.2-2, which lists the reactor coolant water chemistry specifications. AP1000 DCD Table 5.2-2 suggests the TDS could be as high as 2 parts per million (ppm) if all constituents were at their maximum values. Even if the TDS was 2 ppm, the concentration would still be much lower than the average groundwater TDS of 107 ppm. At the average groundwater temperature of 17ºC (63ºF), the density difference between liquids with 2 and 107 ppm would be less than 0.01 percent. However, the temperature in the effluent holding tank could be much higher than the ambient groundwater temperature. AP1000 DCD Table 11.2-2 lists the design temperature of the effluent hold-up tanks as 65.6ºC (150ºF). The density of a liquid at that temperature and with a TDS of 2 ppm would be almost 2 percent less than the density of groundwater at the WLS site. Such a density difference could lead to buoyancy and affect hydraulic conductivity until the temperature difference dissipated. During that time, the buoyant leaked fluid could rise into shallower aquifer material and potentially travel via an alternate pathway. The staff considered the finite volume of leaked fluid and believes the temperature difference would dissipate quickly such that the fluid properties would resemble those of the ambient groundwater. Furthermore, if the initial properties of the leaked liquid caused it to flow upward or downward into an alternate flow path, the aquifer materials above and below are less transmissive than the PWR, which is the only material considered in the flow paths analyzed by the applicant. Since the leaked fluid properties exist for a limited time and only in the vicinity of the reactor buildings, and because alternate pathways would have less transmissive properties, the staff concludes that including a separate alternative pathway is not warranted. The staff concluded that the applicant's December 11, 2008, response to RAI 826, Question 02.04.12-12, was acceptable and considers the question resolved.

To clarify what groundwater elevations and travel distances should be used in calculating groundwater gradients, the staff issued RAI 826, Question 02.04.12-13. In a December 11, 2008, response, the applicant revised its estimate of the maximum groundwater elevation upward from 176.5 to 178.0 m (579 to 584 ft) above MSL based on the maximum height of water in the excavation, 176.5 m (579 ft) above MSL, and its expectation that seasonal groundwater variation would be approximately 1.5 m (approximately 5 ft). In subsequent updates to the WLS COL FSAR, the applicant estimated the distance from Unit 2 to the nearest edge of Hold-Up Pond A to be 405 m (1,330 ft). The applicant estimated the groundwater gradient to be 0.0368 between Unit 2 and Hold-Up Pond A and 0.036 between Unit 2 and the Broad River. The staff notes that the applicant updated WLS COL FSAR Figure 2.4.12-208 with the information necessary to calculate groundwater gradients. The staff concluded that the applicant's December 11, 2008, response to RAI 826, Question 02.04.12-13, was acceptable and considers the question resolved.

Maximum Groundwater Elevation

Information Submitted by the Applicant

The maximum allowable groundwater elevation is specified as a site parameter in the AP1000 DCD and is defined in the WLS COL FSAR to be less than plant elevation 29.87 m (98 ft). The initial WLS COL FSAR established the plant elevation to be equivalent to the local elevation of 179.83 m (590 ft) above MSL. Therefore, the maximum allowable groundwater elevation was limited by the AP1000 DCD requirement to be less than 179.22 m (588 ft) above MSL. Throughout most of the staff review period, the maximum allowable groundwater elevation remained unchanged, thus, most of the following discussion refers to maximum groundwater elevation of 179.22 m (588 ft) above MSL.

Due to of changes to the site layout and grading, the current WLS COL FSAR establishes plant elevation to be 180.7 m (593 ft) above MSL. Therefore, the maximum allowable groundwater elevation is limited by the AP1000 DCD requirement to be less than 180.14 m (591 ft) above MSL.

In the earlier versions of the WLS COL FSAR, the applicant stated that the maximum actual groundwater elevation was expected to be 178.00 m (584 ft) above MSL. The applicant based this maximum actual groundwater elevation on the pre-development groundwater elevations, anticipated land-surface elevations, elevations of surface-water bodies such as the make-up ponds, water elevation in the excavation left after Cherokee plant construction, and seasonal groundwater levels observed in monitoring wells.

In response to five staff RAIs, the applicant provided additional information about establishing the maximum groundwater elevation, characterizing the post-construction groundwater elevations, site grading and drainage. Based on all the information made available, the applicant conducted groundwater modeling to estimate the maximum groundwater elevation. The highest modeled groundwater elevations near the plant were 179.0 and 179.1 m (587.2 and 587.5 AP1000 DCD ft) above MSL.

NRC Staff's Technical Evaluation

The staff reviewed the applicant's information and analysis related to groundwater levels. The staff paid particular attention to the approach that the applicant used to estimate maximum post-construction groundwater levels. The staff concluded that this approach, while valid in a broad sense, relied too much on generalizations and individual judgment to predict maximum groundwater levels accurately enough to ensure that the AP1000 DCD requirement would be met. To obtain more exact information, the staff issued a series of RAIs to examine the bases of the applicant's groundwater level estimates and to examine the applicability of alternative calculation techniques. Discussion of these RAIs is organized into the four following unnumbered sections corresponding to the principal topics addressed by the RAIs.

Initial Non-Modeling Estimates of Groundwater Elevations

To examine the value of using water marks left by water in the excavation as indicators of groundwater level, and related topics, the staff issued RAI 826, Question 02.04.12-6. In a December 11, 2008, response, the applicant stated it did not have a precise record of the dewatering activities previously carried out during the construction of the Cherokee Nuclear units, and did not know whether there were any dewatering activities during the period after Cherokee construction ceased and before December 2005, when the applicant initiated dewatering of the Cherokee excavation pit. The applicant provided aerial photographs for two dates, February 1994 and February 2005, which show water levels in the excavation pit relative to the Cherokee structures. The applicant used a topographic survey conducted in 2006 to estimate that water-surface elevation in the excavation pit varied between 175.0 and 176.5 m (574 and 579 ft) above MSL from 1994 through 2005. The applicant noted that the average groundwater level fluctuation during the period from April 2006 to April 2007 was 1.4 m (4.5 ft). The applicant estimated, given that the high-water mark in the excavation was determined to be 176.48 m (579 ft) above MSL, the design groundwater elevation to be 176.5±1.5 m (579±5 ft) above MSL, which allows for a 1.5 m (5 ft) seasonal variation over the high-water mark. The current WLS COL FSAR contains this information.

The applicant presented evidence of water levels in the excavation to justify the selection of 178.0 m (584 ft) above MSL as the maximum water table elevation. The staff concluded that the water levels were controlled by the net lateral flux of groundwater and by precipitation and open-water evaporation. Groundwater flow away from the excavation has been facilitated, in part, by the presence of preferential flow paths created by the stormwater drains emplaced during Cherokee-era construction. The applicant acknowledged such preferential paths exist and committed to removing those drains.

- WLS Proposed License Condition 15: Prior to fuel load, the licensee shall confirm that a single legacy Cherokee project stormwater drain line (designed to transfer stormwater from the Cherokee power block area to Hold-Up Pond A) and any associated bedding material representing a potential preferential groundwater pathway have been removed and the excavation has been backfilled with compacted native soils.

Due to of uncertainty in the water balance of the excavation, the staff does not consider information regarding water levels sufficient to estimate the maximum water table level.

To understand how the applicant had estimated the post-construction configuration of the groundwater surface, and the factors that would control the post-construction groundwater surface at the site, the staff issued RAI 826, Question 02.04.12-14. In a December 11, 2008, response, the applicant reiterated that its estimated post-construction groundwater levels are based on the current water table and pre-construction water table. Water table elevations are expected to conform generally to the surface topography, as modified by WLS construction. The applicant did not recommend modeling of groundwater at the time of the response. The applicant expected to implement a groundwater monitoring program after construction.

To obtain additional information necessary for understanding the data and methods that the applicant used to estimate the post-construction configuration of the groundwater surface, the staff issued RAI 17, Question 02.04.12-19. In a September 30, 2010, response, the applicant provided information about its conceptual model of the post-construction conditions, backfill materials, site grading and drainage, ground cover and stormwater management, and post-construction groundwater flow conditions and maximum groundwater level.

The applicant reiterated that the site conceptual model would be consistent with the Piedmont Master Conceptual Model of LeGrand. In that conceptual model, groundwater is controlled by surface drainages and a two-layer slope-aquifer system in which the aquifer consists of residual soil and saprolite overlying weathered and unweathered bedrock.

The applicant stated that the excavation would be filled with engineered backfill around each of the two nuclear islands and extending outward to form the foundation support of the adjacent buildings. Although the exact properties of the engineered fill are yet to be determined, the applicant stated that the hydraulic conductivity would be 10 to 100 times greater than that of in situ residual soil and saprolite. In WLS COL FSAR Section 2.5.4, the applicant stated that the hydraulic conductivity of the engineered fill would fall between 0.00501 cm/s (14.2 ft/day) and 0.0750 cm/s (212.6 ft/day). This range of values is greater than the conservative value of 0.00140 cm/s (3.97 ft/day) for the hydraulic conductivity of the PWR. The applicant provided WLS COL FSAR Figure 2 to show the area receiving the engineered fill. Backfill in the areas beyond the engineered fill would be compacted residual soil and saprolite material with conductivity slightly lower than undisturbed residual soil and saprolite, so somewhat less than 1.1×10^{-4} cm/s (0.32 ft/day). The staff considers these values sufficiently similar to values for the surrounding material such that groundwater conditions would not be appreciably altered.

The applicant stated that the surface around the WLS site is relatively flat and gently slopes away from the plant. The applicant stated that surface topography would be graded to facilitate stormwater runoff away from safety-related structures.

The applicant stated that the 179.2 m (588 ft) above MSL contour that surrounds the nuclear power block areas would enclose an area of 26.5 ha (65.4 ac). Of that, 15.4 percent (4.1 ha (10.1 ac)) would be impervious surfaces such as roads and parking lots and 20 percent (5.2 ha (12.9 ac)) would be semi-impervious compacted gravel (or similar hardscaped material) that reduces infiltration and promotes runoff. Stormwater runoff from the impervious and semi-impervious areas would be collected in the DRS and routed away from the nuclear power block area to reduce the potential for flooding. About 11.8 percent (3.1 ha (7.7 ac)) of the area would be buildings. Precipitation that falls on those buildings would be collected by a roof drain collection system and routed through downspouts into the DRS piping network. The remaining area, about 53 percent (14 ha (34.7 ac)), would be a grass surface cover. The applicant provided a figure that shows that the grass area would surround, but not occur within, the nuclear power block area.

The applicant considered post-construction groundwater conditions and concluded that the structures would not significantly affect groundwater flow. The applicant stated that the high conductivity of the engineered backfill would help equilibrate any local groundwater perturbation. The applicant reiterated that Cherokee-era drains that could affect groundwater would be removed. The applicant concluded that the post-construction groundwater flow would return to conditions consistent with the Piedmont Master Conceptual Model. The applicant proposed to update the WLS COL FSAR with this information about the data and methods used to estimate the post-construction configuration of the groundwater surface. The staff confirmed that the changes were included in WLS COL FSAR.

The staff reviewed the material provided by the applicant. The key reference, LeGrand, provides a synthesis of knowledge related to natural conditions in the Piedmont and can be used to understand the hydrology of the WLS site prior to Cherokee construction. LeGrand does not provide guidance when a site has been significantly altered. The cut-and-fill operations that occurred during Cherokee construction reworked the topography and hydrogeology so extensively that it no longer resembles a typical Piedmont setting. The buildings and extensive impervious surfaces of the WLS site will further diminish the resemblance to a typical Piedmont setting. Thus, generalizations based on LeGrand are not entirely applicable to the WLS site.

The staff considered the post-construction surface conditions provided by the applicant. Runoff and roof drainage are routed to the DRS network, but the terminus of the network is unknown. The termination of the DRS network in the drainages that surround the plant could lead to increased recharge in these areas. The applicant stated that 20 percent of the nuclear power block area would be semi-impervious and 53 percent of the area around the nuclear power block would be grass, but no estimate of recharge was provided for either area. Given the properties of residual soil and saprolite, an average recharge rate of 5.1 cm/yr (2 in/yr) could be sufficient for groundwater to rise to the surface.

The applicant proposed to update the WLS COL FSAR with respect to water table elevation calculations, backfill properties, qualitative descriptions of surface conditions, and a description of a roof drainage system. The staff reviewed the WLS COL FSAR and confirmed that the applicant made the proposed changes. However, staff considered the issue of the maximum water table elevation unresolved; with the resolution of this issue is discussed below.

Recharge Rates and Initial Modeling of Groundwater Elevations

The staff requested estimates of the maximum post-construction groundwater level that is based on anticipated post-construction recharge rates associated with the main surface features and potential groundwater mounds beneath the cooling towers and drainage ditches to better understand how the post-construction groundwater surface would respond.

To obtain additional information needed for the staff's review of the maximum groundwater level, the staff issued RAI 94, Question 02.04.12-20. In a May 18, 2011, response, the applicant provided information to support the view that the post-construction groundwater elevation would not exceed 179.2 m (588 ft) above MSL. The new information consisted of (1) estimates of annual average and maximum recharge rates, (2) a one-dimensional (1-D) analytical method to estimate water table fluctuations in response to recharge, and (3) a quasi two-dimensional (2-D) semi-analytical method to estimate water table fluctuations in response to recharge.

The applicant used annual values of precipitation, evaporation, and runoff to estimate an average annual recharge rate of 13 cm/yr (5.1 in/yr) and a maximum post-construction recharge rate of 21 cm/yr (8.2 in/yr). Recharge is a very site-specific process and the rate of recharge must be estimated for specific soil and vegetation conditions. For example, recharge into an unvegetated surface material (e.g., each of the semi-impervious materials described in the WLS COL FSAR) is expected to differ from recharge into grass-covered fill material. Recharge is also dependent on event-specific weather conditions and could be underestimated if processes such as precipitation, evaporation, runoff, and transpiration are represented as annual average values. Given the information presented by the applicant, the staff could not determine whether the proposed values are appropriate to represent the post-construction conditions at the proposed WLS site.

The applicant used a 1-D analytical method based on specific yield to estimate groundwater fluctuation. The applicant noted that the specific yield estimate for well MW-1215 was 0.0041, but claimed that it would underestimate recharge and substituted effective porosity for specific yield in the analysis. For fill, soil/saprolite, and PWR, the effective porosities are 0.09, 0.2, and 0.08, respectively. Using the average effective porosity of 0.145 for fill and soil/saprolite ((0.09+0.20)/2) = 0.145), the COL applicant estimated a 1.43 m (4.7 ft) groundwater rise for the maximum recharge event of 21 cm (8.2 in.) (i.e., the entire annual recharge amount occurred in a single event). Assuming the event occurred when the water table started at 175.7 m (576.5 ft) above MSL (pre-construction elevation in excavation), the final groundwater elevation was estimated by the applicant to be 177.2 m (581.2 ft) above MSL. Had the applicant used the actual specific yield of 0.0041 (from well MW-1215), the estimated rise in groundwater level would have been more than 30 m (100 ft) in excess of the AP1000 DCD level of 179.2 m (588 ft) above MSL. The applicant did not address possible variations in specific yield and did not justify the conservativeness in its estimate of specific yield. The staff identified additional questions relating to specific yield or effective porosity is the appropriate parameter by which to characterize water table fluctuation when groundwater as near the soil surface.

The applicant also used a 2-D semi-analytical method described by Park and Parker to estimate groundwater fluctuations in response to precipitation that varies over time. The applicant applied the method by representing the maximum recharge event (21 cm/yr (8.2 in/yr)) with four 5.21 cm (2.05 in.) events on four separate days distributed somewhat evenly throughout the year. The applicant estimated the model parameters but did not calibrate the model to the actual WLS site. The applicant estimated the maximum water table rise to be 0.37 m (1.2 ft). The applicant’s analysis appeared to assume that temporary mounding above the AP1000 DCD value for maximum groundwater level was not a problem, whereas the regulatory requirement is that the maximum groundwater elevation must be less than AP1000 DCD value at all times.

<u>Groundwater Modeling Using MODFLOW: Model Conditions</u>

After the initial estimation of maximum groundwater elevations as described above, the applicant estimated post-construction groundwater elevations by conducting computer modeling using the MODFLOW program.

Additional information relevant to groundwater modeling was provided in the applicant’s November 22, 2011, response to RAI 484, Question 10.04.05-2. Although this RAI requested information about Standard Review Plan (SRP) Section 10.04.05, Circulating Water System, the response also contained information about changes to site surface grading and drainage. This information is relevant because the configuration of the land surface is one of the inputs for groundwater modeling. In this response, the applicant stated that the ridge to the northwest of Unit 1 and the two cooling-tower berms would be removed. Site grading in the area of the nuclear power block would be reshaped to promote drainage away from the nuclear island. The surface would grade down to the 178.8 m (586.5 ft) elevation of the vehicle barrier system that would surround the two units. Beyond the vehicle barrier system, the surface would grade down 0.3 to 0.5 m (1 to 1.5 ft) before it engages steeper slopes to the adjacent water bodies.

The applicant provided a second response to RAI 94, Question 02.04.12-20, on November 22, 2011, in which the applicant used groundwater simulations to demonstrate that the AP1000 DCD requirement regarding the maximum groundwater level would be met. The applicant conducted seven groundwater simulations using MODFLOW 2000, Version 1.19.01, embedded in the pre- and post-processing package called Groundwater Vistas.

For the simulations, the applicant established an initial potentiometric surface, an extreme precipitation event, model domain, material properties, boundary conditions, a base case and set of sensitivity cases, and six observation points around the perimeter of both units.

Based on the new site grading and drainage plan, the placement of impervious surfaces, and knowledge of groundwater hydrology in the Piedmont and at the WLS site, the applicant updated the post-construction potentiometric surface map. The new map shows groundwater levels grading from 176.8 m (580 ft) above MSL along the south end of the reactor area to 173.7 m (570 ft) above MSL along the north end.

For the extreme event, the applicant chose Tropical Storm Jerry, which occurred in August 1995. The total precipitation received at the Greenville-Spartanburg Airport during the 47-hour storm was 36.75 cm (14.47 in.). During a single day of that storm, 31.29 cm (12.32 in.) of rain was received, which is the highest 24-hour total in the 45-year record and far exceeds the next highest 24-hour amount of 15.77 cm (6.21 in.) received in September 1972.

The applicant set up the model domain as a square, 914 m (3,000 ft) on each side, centered on the two units and encompassing the vehicle barrier system. Table 2.4.12-2 of this report shows the hydraulic parameters were assigned according to the geologic descriptions in the WLS COL FSAR. For each material, the applicant used the median values for hydraulic conductivity and specific yield. For building foundations and vehicle barrier system, the applicant assumed values that were much lower than those for the geologic materials.

Table 2.4.12-2 Hydraulic Parameters Used in the MODFLOW Simulations

Material	Hydraulic Conductivity (cm/s [ft/day])	Specific Yield (-)
Building Foundations	3.53×10^{-8} (0.0001)	0.001
Granular Backfill	0.011 (31.18)	0.20
Soil Backfill	5.39×10^{-5} (0.1528)	0.09
Soil/Saprolite	1.14×10^{-4} (0.3232)	0.20
Partially Weathered Rock	1.53×10^{-4} (0.4337)	0.08

The boundary conditions were defined for the base of the domain, the sides (groundwater inflow and outflow), and the top in the form of recharge. The base of the model domain was assumed to be no flow. The sides of the model domains were represented with a constant head boundary on the south side of the domain and general head boundaries along the remainder of the domain.

Water input at the top of the model domain was defined by the precipitation event and the runoff-recharge relationship for each surface condition. The precipitation event was modeled as three events. First, a 47-hour storm was applied at rates equivalent to 40 percent of those for Tropical Storm Jerry. Second, a period of 72 hours with no precipitation was imposed to allow the groundwater to equilibrate to the precipitation just received. Finally, the hourly precipitation record of Tropical Storm Jerry was applied.

Precipitation received at the surface was partitioned into runoff according to methodology described by the USDA. The USDA method relies on knowledge of the surface condition, soil type, and vegetation. For each of the 22,576 model cells, the applicant assigned one of the following surface types: buildings; roads; vehicle barrier system; hardscape; grass; and brush. For each surface type, the applicant selected a runoff curve number from the tables provided by USDA and used it to represent the percentage precipitation that would run off. In the case of the grass cover, the applicant added the runoff from buildings, roads, and vehicle barrier system to the amount of precipitation before calculating runoff from grass.

The applicant assumed no interim water storage on the surface such that water that did not run off infiltrated the surface. The applicant assumed no evapotranspiration and no time delay as water moved through the vadose zone to the groundwater. Thus, the applicant used the infiltration rate to define the upper recharge boundary condition.

Groundwater Modeling Using MODFLOW: Results of Simulations

The applicant conducted seven simulations. For the base case (Run 1), it used the projected post-construction potentiometric surface, median hydraulic parameters, and Type B soils (per USDA). The six sensitivity cases examined the impact of a higher initial potentiometric surface (Run 2), lower conductivity values (Run 3), minimum specific yield values (Run 4), maximum specific yield values (Run 5), Type A (instead of Type B) soils (Run 6), and a combination that included lower conductivities and specific yields and Type A soils (Run 7).

The base case results showed that the highest groundwater elevations occurred at the two observation points on the south side of the units. The highest elevation, 177.4 m (582.2 ft) above MSL, occurred just to the southwest of Unit 1. Just to the north of the units, the groundwater elevations are around 175.3 m (575 ft) above MSL. For the sensitivity cases, the highest groundwater elevations always occurred at the two southern observation points. Runs 2 and 7 yielded the highest overall elevations, 179.0 and 179.1 m (587.2 and 587.5 ft) above MSL, respectively. The applicant stated that its analysis demonstrated compliance with the AP1000 DCD site parameter criteria for maximum groundwater level of 149 m (588 ft) above MSL. The applicant provided a copy of all MODFLOW input files to the staff.

The staff examined the proposed site grading and drainage plans and believes it would significantly enhance the ability of the site to increase runoff, reduce recharge, and reduce the potential for groundwater to rise above the AP1000 DCD limit of 179.2 m (588 ft) above MSL. High elevations to the northwest, west, and east that could have increased groundwater levels have been removed. Surface topography slopes down from the units in all four directions, thus facilitating runoff removal in all directions. The maximum elevation of the surface drainage to the southwest is 178.8 m (586.5 ft) above MSL; this ensures that higher groundwater levels further south would not propagate northward to the nuclear islands.

The staff examined the proposed post-construction potentiometric surface. In contrast to the previous map, the new map does not show two groundwater divides on either side of the reactor area. Consistent with that change, the new groundwater levels are about 1.5 m (5 ft) lower than previous estimates. The staff notes that the proposed map appears to be reasonable and consistent with knowledge of the area.

The staff examined the MODFLOW analysis. The use of the precipitation record from Tropical Storm Jerry to evaluate maximum water table rise is appropriate. The event far exceeds the 100-year storm of 18 cm (7.2 in.) predicted for the Cherokee County. Including a pre-storm that adds 40 percent of tropical storm Jerry precipitation adds conservatism. In fact, the total precipitation added (51.46 cm (20.26 in.)) in the 7-day simulation far exceeds all monthly precipitation records.

The staff examined the model domain. Cell sizes are smaller in the reactor areas and larger away from the reactors. The extent of the domain does not extend to natural boundaries such as Make-Up Pond B and the Broad River. Instead, the applicant chose to focus the analysis on a smaller domain. Doing so required establishing head boundary conditions at interim locations. The analysis only addresses a short period of 7 days. In that time, any effects from lateral boundary conditions would not be discernible. As a result, the staff performed confirmatory analyses as described below.

The staff examined the material properties and confirmed they are reasonable to somewhat conservative with respect to hydraulic conductivity. The applicant's groundwater modeling was based on the median hydraulic conductivity for the well-graded gravel granular material (1.1×10^{2} cm/sec (11,381 ft/year)). In WLS COL FSAR Table 2.5.4-211, the minimum value of hydraulic conductivity reported for the poorly graded gravel granular fill materials is stated as "<~5.0E-03" cm/sec ("<~5,173" ft/year). The MODFLOW sensitivity case Run 3 examined the impact of using minimum conductivity values. The result was an increase in the maximum groundwater elevation to 177.2 m (581.47 ft), which is only 0.02 m (0.08 ft) above the base case (Run 1) and far below the assumed maximum groundwater elevation of 178.0 m (584 ft).

The staff examined the boundary conditions. Using a no-flow bottom boundary is consistent with data from the site. Even if there was a small amount of flow, up or down, the fluxes would be too small to affect a 7-day simulation. Therefore, the lateral boundary conditions are not ideal, so the staff ran the base case with different lateral boundary conditions and confirmed that these boundaries do not measurably affect the results of the short 7-day simulations.

The staff examined the methodology used to calculate runoff and establish recharge rates. It appears to the staff that the applicant treated the runoff curve numbers as runoff coefficients (i.e., percentages) rather than as parameters in the USDA's Equation 2.3. The staff used Equation 2.3 to calculate the true runoff percentage, which yielded a runoff fraction that was slightly higher than the value determined by the applicant. The applicant's calculation resulted in slightly higher recharge rates, which its analysis revealed would not cause the site to exceed the AP1000 DCD requirement. Repeating the applicant's analysis with the slightly lower but correct recharge rates would yield the same result.

Table 2.4.12-3 of this report lists the runoff coefficients used to establish recharges rates for the MODFLOW simulations. The staff examined the applicant's choices of runoff curve numbers to represent surface conditions at the site and identified some differences from how the staff would parameterize the site. The practice is to route the runoff from buildings and roads to hardscape, and runoff from hardscape to grass.

Using the runoff curve numbers and runoff routing method described above, the staff repeated the base-case simulation. The results at the observation points showed very little difference from the applicant's results. This lack of sensitivity is due in part to the relatively low recharge rates in the hardscape and to the high conductivity of the engineered fill, which quickly dissipates local groundwater mounds caused by variations in recharge rates.

The staff's review confirmed that groundwater would not exceed an elevation of 179.2 m (588 ft) MSL. As noted above, because recent changes to the site grading yielded a higher plant elevation, the current WLS COL FSAR requires the maximum groundwater elevation to be less than 180.1 m (591 ft). Since all other conditions remain the same, the staff affirms that the site groundwater would not exceed an elevation of 180.1 m (591 ft) MSL.

In summary, the applicant described changes to the site grading and drainage plan and provided groundwater modeling results to support its assessment that the site meets the AP1000 DCD requirement relative to the maximum groundwater elevation. The staff evaluated the site grading changes and the modeling analysis and conducted confirmatory modeling analyses. Since the applicant used a very extreme storm event, did not account for evaporation or transpiration, and did not account for runoff that would be routed well away from the site before it could infiltrate, the staff concluded that the site would be able to meet the AP1000 DCD requirement. The staff notes that the applicant included a description of the latest site grading and drainage plan, the vehicle barrier system, and the groundwater modeling analysis in WLS COL FSAR Section 2.4.12.2, "Sources." The staff concluded that the applicant's responses to RAI 826, Questions 02.04.12-6, and 02.04.12-14; RAI 17, Question 02.04.12-19; RAI 94, Question 02.04.12-20; and RAI 484, Question 10.04.05-2, were acceptable. Accordingly, the staff considers these questions resolved.

Table 2.4.12-3 Runoff Curve Numbers Used to Estimate Recharge

Surface Condition	Runoff Curve Numbers				Comments
	Applicant		NRC Staff		
	Type B Soils	Type A Soils	Type B Soils	Type A Soils	

Buildings	100	100	100	100	A value of 100 is not provided in USDA (1986), but staff judged it to be sufficient given the stated intent of the applicant to manage all precipitation that falls on buildings. The applicant routed runoff to grass, the staff routed runoff to hardscape
Roads	100	98	89	83	The applicant used USDA (1986) values associated with curbed roads; the staff used values associated with uncurbed roads. The applicant routed runoff to grass; the staff routed runoff to hardscape
Hardscape	85	76	85	76	Both the applicant and the staff routed runoff to grass
VBS	100	98	98	98	The applicant used value of 100 for Type B soil; the staff used value of 98. Both the applicant and the staff routed runoff to grass
Brush	82	72	48	30	The applicant used values for dirt (Table 2-2a, USDA 1986); the staff used values for brush (Table 2-2c, USDA 1986)
Grass	61	61	61	39	Applicant used value for Type A soil that is not consistent with USDA (1986)

Monitoring

<u>*Information Submitted by the Applicant*</u>

The applicant stated that a groundwater monitoring program would be developed. The applicant provided a list of three areas within the site to be considered for monitoring and a list of generalized considerations for implementation of the program. In response to a staff RAI requesting details, the applicant provided additional information about post-construction monitoring plans to reduce uncertainties in groundwater flow paths used for WLS COL FSAR Section 2.4.13.

<u>*NRC Staff's Technical Evaluation*</u>

In the December 11, 2008, response to RAI 826, Question 02.04.12-11, the applicant described post-operational monitoring activities that address traditional monitoring goals as well as goals related to reducing uncertainties about the plausible groundwater pathways. The activities include placement of near-field and far-field wells to detect early releases and to verify that there is no offsite migration, and placement of both shallow and deep wells to monitor plausible flow paths close to the facilities. The applicant stated that the post-construction groundwater monitoring program would be consistent with the guidance provided by the Nuclear Energy Institute (NEI 2009), which references NEI and EPRI. The staff reviewed those references and confirmed they would form the basis for an adequate monitoring program. The staff notes that the applicant included this monitoring information in WLS COL FSAR Section 2.4.12.4, "Monitoring or Safeguard Requirements." The staff concluded that the applicant's December 11, 2008, response to RAI 826, Question 02.04.12-11, was acceptable and considers the question resolved.

2.4.12.5 *Post Combined License Activities*

For the reasons discussed in the technical evaluation section above, the staff proposes to include the following license condition:

- License Condition (2-1) – Prior to fuel load, the licensee shall confirm that a single legacy Cherokee project stormwater drain line (designed to transfer stormwater from the Cherokee power block area to Hold-Up Pond A) and any associated bedding material representing a potential preferential groundwater pathway have been removed and the excavation has been backfilled with compacted native soils.

2.4.12.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant addressed the information relevant to groundwater, and that there is no outstanding information required to be addressed in the WLS COL FSAR related to this section. As set forth above, the applicant presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concludes that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.12, herein, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. This applicant addressed groundwater in COL Information Item 2.4-4. The staff concludes that the applicant provided sufficient information on groundwater characteristics to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.13 Accidental Release of Radioactive Liquid Effluent in Ground and Surface Waters

2.4.13.1 *Introduction*

This section of the WLS COL FSAR provides a characterization of the attenuation, retardation, dilution, and concentrating properties governing transport processes in the surface-water and groundwater environment at the site. The goal of this section is not to provide an assessment of the effects of a specific release scenario but to provide a suitable conceptual model of the hydrological environment for other assessments. Since it would be impractical to characterize all the physical and chemical properties (e.g., hydraulic conductivities, porosity, and mineralogy) of a time-varying and heterogeneous environment, the section characterizes the environment in terms of the projected transport of a postulated release of radioactive waste. The accidental release of radioactive liquid effluents in ground and surface waters is evaluated using information about existing uses of groundwater and surface water and their known and likely future uses as the basis for selecting a location to summarize the results of the transport calculation. The source term from a postulated accidental release is reviewed under NUREG-0800, Section 11.2, following the guidance in Branch Technical Position (BTP) 11-6, "Postulated Radioactive Releases Due to Liquid-containing Tank Failures."

The source term is determined from a postulated release from a single tank outside of the containment. The results of a radionuclide transport analysis are evaluated against SRP Section 11.2 and BTP 11-6 guidance and effluent concentration limits (ECLs) as acceptance criteria to meet the requirements of 10 CFR Part 20, Appendix B, as SRP acceptance criteria. Under SRP guidance, the effluent concentration limits of 10 CFR Part 20, Appendix B, are applied as acceptance criteria only for the purpose of assessing the acceptability of the results of the consequence analysis and are not intended for demonstrating compliance with ECLs.

The following specific areas are reviewed by the staff: (1) alternative conceptual models of the hydrology at the site that reasonably bound the site's hydrogeological conditions to the degree that these conditions affect the transport of radioactive liquid effluent in the groundwater and surface-water environment; (2) a bounding set of plausible surface and subsurface pathways from potential points of an accidental release to determine the critical pathways that may result in the most severe effect on existing uses and known and likely future uses of groundwater and surface-water resources in the vicinity of the site; (3) the ability of the groundwater and surface-water environments to delay, disperse, dilute, or concentrate accidentally released radioactive liquid effluents during transport; and (4) the assessment of scenarios wherein an accidental release of radioactive effluents is combined with potential effects of seismic and non-seismic events.

2.4.13.2 *Summary of Application*

This section of the WLS COL FSAR addresses the accidental release of radioactive liquid effluents in groundwater and surface waters. The applicant addressed information related to accidental release of radioactive liquid effluents as follows:

AP1000 COL Information Item

- WLS COL 2.4-5

In addition, this section addresses the following COL-specific information identified in AP1000 DCD Section 2.4.1.5, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address site-specific information on the ability of the ground and surface water to disperse, dilute, or concentrate accidental releases of liquid effluents. Effects of these releases on existing and known future use of surface water resources will also be addressed.

2.4.13.3 *Regulatory Basis*

The relevant requirements of NRC regulations for the pathways of liquid effluents in ground and surface waters, and the associated acceptance criteria, are specified in NUREG-0800, Section 2.4.13.

The applicable regulatory requirements for evaluating accidental release of radioactive liquid effluents in ground and surface waters are set forth in the following:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

The staff also used the acceptance criteria identified in NUREG-0800, Section 2.4.13:

- Alternate Conceptual Models: Alternate conceptual models of hydrology in the vicinity of the site are reviewed.

- Pathways: The bounding set of plausible surface and subsurface pathways from the points of release are reviewed.

- Characteristics that Affect Transport: Radionuclide transport characteristics of the groundwater environment with respect to existing and known and likely future users should be described.

- Consideration of Other Site-Related Evaluation Criteria: The COL applicant’s assessment of the potential effects of site-proximity hazards, seismic, and non-seismic events on the radioactive concentration from the postulated tank failure related to accidental release of radioactive liquid effluents to ground and surface waters for the proposed plant site is needed.

- BTP 11-6 provides guidance in assessing a potential release of radioactive liquids after the postulated failure of a tank and its components, located outside of containment, and effects of the release of radioactive materials at the nearest potable water supply, located in an unrestricted area, for direct human consumption or indirectly through animals, crops, and food processing.

In addition, the hydrologic characteristics should conform to appropriate sections from RG 1.113, “Estimating Aquatic Dispersions of Effluents from Accidental and Routine Reactor Releases for the Purpose of Implementing Appendix I.”

The staff used best current practices to analyze groundwater transport of radioactive liquid effluents. The regulatory basis of the information incorporated by reference is addressed in the staff's FSER for the AP1000 certified design, NUREG-1793.

2.4.13.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.4.13 Revisions 0 to 11; corrections and additions to the WLS COL FSAR submitted by the applicant as letters; and associated applicant responses to RAIs issued by the staff. The staff also checked the referenced AP1000 DCD and departures and supplements specified in the WLS COL FSAR.

The staff reviewed COL Information Item 2.4-5 related to the provision of site-specific information about accidental release of liquid effluents into ground and surface water at the plant site included under WLS COL FSAR Section 2.4. Additional aspects of this information item are addressed in Section 2.4.12 of this report.

The staff reviewed the specific items related to the assessment of an accidental release of radioactive liquid effluents in groundwater and surface water included in the WLS COL FSAR and associated RAI responses. To improve readability, the staff's discussion of these items is organized into the following sections, which correspond to the sections of WLS COL FSAR Section 2.4.13, Revision 11.

Groundwater

<u>*Information Submitted by the Applicant*</u>

In WLS COL FSAR Section 2.4.13, the applicant provided information that described movement of accidentally released effluents from the nuclear island area to the nearest potable water supply in an unrestricted area. The applicant identified the groundwater pathway from Unit 2 to Hold-Up Pond A (Pathway 1) as the bounding pathway because of its higher groundwater velocity and shorter travel time. The failure of a Unit 2 effluent hold-up tank, located below ground level in the auxiliary building, was identified as the appropriate scenario for analysis of a postulated accidental release of radioactive liquid effluent. The radioactive source term for this release was described based on AP1000 DCD, Tables 11.1-2 and 11.1-8. The conceptual model of the release is that one of the effluent hold-up tanks, having a capacity of 106,000 L (28,000 gal), ruptures and releases 80 percent of the volume, which equates to 84,800 L (22,400 gal) of liquid effluent. Radionuclides in the effluent travel with groundwater to Hold-Up Pond A where they enter Hold-Up Pond A and flow directly into the Broad River. The applicant used RESRAD-OFFSITE Version 2.0 to calculate the transport rates and determine the radionuclide concentrations in the Broad River.

The applicant stated that three soil samples were collected from a depth range of 13.7 to 22.3 m (45 to 73 ft) below ground in two wells. The samples were analyzed for soil distribution coefficients (i.e., K_d values) for colbalt (Co)-60, cesium (Cs)-137, iron (Fe)-55, iodine (I)-129, nickel (Ni)-63, plutonium (Pu)-242, strontium (Sr)-90, technetium (Tc)-99, and uranium (U)-235.

In response to three staff RAIs, the applicant provided additional information and clarification related to the K_d values for the three main geologic materials.

NRC Staff's Technical Evaluation

The staff reviewed the applicant's information about accidental releases. Because of the subsurface location of the release, transport by surface water away from the release location was not considered feasible, and was not considered further. The staff reviewed the applicant's information regarding the groundwater pathway, and concluded that additional information was required to complete its evaluation of the risks from radionuclide transport by this pathway.

To clarify the suitability of the onsite K_d measurements for the evaluation of accidental releases, the staff issued RAI 828, Question 02.04.13-10. In the November 25, 2008, response, the applicant described the soil K_d values with respect to the effluent chemistry, site geochemistry, and the relationship to radionuclide migration. The applicant stated that the water in the effluent hold-up tanks is slightly acidic, has a TDS content of less than 1 ppm, and would not vary significantly from the ambient groundwater conditions in pH, salts, metals, or organics. Given those conditions, the applicant stated that the effluent would not alter the groundwater chemistry outside the range under which the K_d values were determined. The applicant stated that the K_d values determined for three samples at the WLS site are sufficient to represent the range of values within each of the alternative flow pathways. The applicant bounded its calculations by using the lowest measured K_d value regardless of media. The applicant used a K_d value of 0 for tritium and stated that tritium contributes 99 percent of the dose. The applicant also analyzed the sensitivity of the RESRAD-OFFSITE results to variations in K_d values. The staff evaluated the RESRAD-OFFSITE analyses and confirmed the results. The applicant updated the WLS COL FSAR to explain in more detail the nature of the K_d values and to describe the results of the sensitivity tests. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-10, was acceptable and considers the question resolved.

The staff noted that the three samples tested included one from fill material and two from soil/saprolite. There were no measurements of K_d in the PWR, which is the material considered in the most conservative pathway. To evaluate the significance of this data gap, the staff issued RAI 828, Question 02.04.13-12. In a November 25, 2008, response, the applicant stated that PWR samples were not analyzed because of the difficulty of working with a representative sample. Therefore, the applicant assumed that K_d values for fill and soil/saprolite were reasonable alternatives for PWR. Partly because of this assumption, the applicant evaluated the sensitivity of its analysis to variations in the distribution coefficients (see Section 2.4.13.4.5 herein). The staff considered this to be a reasonable approach. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.13.1, "Groundwater." The staff concluded that the applicant's November 12, 2009, response to RAI 828, Question 02.04.13-12, was acceptable and considers the question resolved.

The staff noted that, in the proposed revision to Section 2.4.13.4, the applicant referred to the "lowest uncertainty corrected K_d values." In a broad sense, the term "uncertainty" was intended to capture all aspects that contribute to uncertainty, many of which would never be known. The applicant defined the conservative K_d value as the lowest of three (3) measured K_d values minus one standard deviation. Calling any value the "lowest uncertainty corrected value" implies that all uncertainty has been removed and that the value is known with certainty. That is not the case for K_d values. To clarify the description of K_d, the staff issued RAI 73, Question 02.04.13-23. In a November 12, 2009, response, the applicant stated that the K_d values are indeed the mean values minus one standard deviation and concurred that the phrase "uncertainty corrected" could be misinterpreted. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.13.1, "Groundwater." The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-23, was acceptable and considers the question resolved.

Accident Scenario

Information Submitted by the Applicant

The applicant described the limiting accident scenario as the failure of a Unit 2 effluent hold-up tank, located in the Unit 2 auxiliary building, and resulting transport of radioactive contaminants to the Broad River. The applicant chose this scenario because the hold-up tank of Unit 2 was closest to the closest point of exposure: Hold-Up Pond A and the Broad River. The applicant ruled out other tanks because they had lower volumes and lower isotope inventories relative to the effluent hold-up tanks. Following BTP 11-6, March 2007, the applicant assumed that 80 percent of the effluent tank capacity (a release volume of 84,800 L (22,400 gal)) was immediately released through cracks in the auxiliary building walls and floor into the surrounding subsurface soil.

In response to three staff RAIs, the applicant provided additional information and clarification related to the identification of plausible alternative conceptual models.

NRC Staff's Technical Evaluation

The staff reviewed the applicant's information about the accidental release scenario. This information identified the assumed source of the release and the groundwater pathway that the applicant believed would be most probable. The staff identified certain missing or incomplete information needed for evaluation of the applicant's analysis of the accident scenario.

To understand the process used to identify subsurface pathways that affect the transport of radioactive liquid effluents so as to ensure that the most conservative of plausible conceptual models has been identified, the staff issued RAI 828, Question 02.04.13-3. In a November 25, 2008, response, the applicant increased the number of plausible flow paths from two to five (in subsequent WLS COL FSAR updates, the applicant reduced the number of flow paths from five to four). Despite the greater number of plausible pathways, the applicant stated that Pathway 1, the pathway that had been chosen previously for the RESRAD-OFFSITE modeling analysis, remained the most conservative pathway. Therefore, the applicant determined that a RESRAD-OFFSITE analysis of another pathway was not necessary. The staff concluded that this explanation was reasonable. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.13.3, "Groundwater Movement." The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-3, was acceptable and considers this question resolved.

To understand the impact of the post-construction water table (which may differ from the pre-construction water table) on the selection of alternative pathways, the staff issued RAI 828, Question 02.04.13-18. The staff examined the November 25, 2008, response and concluded that the process and the methods used by the applicant to determine the bounding set of plausible surface and subsurface pathways were reasonable. As discussed in WLS COL FSAR

Section 2.4.12, the applicant has generated a post-construction water table that is consistent with the recharge-affecting surface conditions. The new estimate of the post-construction water table does not alter the potential pathways and thus does not change the selection of the primary pathway for the transport analysis, which is from Unit 2 to the Broad River. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-18, was acceptable and considers the question resolved.

The staff examined the responses to these RAIs and determined that the process and the methods used by the applicant to determine alternate conceptual models of the site hydrology are reasonable but potentially incomplete. The applicant did not evaluate the impact of a failure of the dams associated with Make-Up Ponds A and B. Such an event could increase the hydraulic gradient substantially and shorten travel times. The applicant did not evaluate alternative geohydrologic features such as continuous PWR along all pathways. The applicant did not evaluate the potential for preferential flow paths (e.g., buried pipes, or coarse bedding material beneath them) created by Cherokee construction activities. To address these issues, the staff issued RAI 73, Question 02.04.13-19.

In a November 12, 2009, response, the applicant stated that the transport calculation was changed to assume PWR occurred along all potential transport pathways. This change eliminated any concern that the occurrence of PWR would be underestimated. The changed calculation also led the applicant to confirm the Pathway 1 (from Unit 2 to Hold-Up Pond A) as the limiting pathway. The applicant considered the impact of dam failure and demonstrated that, because of distance, Pathway 1 would remain the limiting pathway. The applicant acknowledged the potential for Cherokee-era drainage piping to be a preferential flow pathway in the event of an effluent tank release. The applicant reviewed the Cherokee piping system and identified the piping corridor from the nuclear power block area north to Hold-Up Pond A as the only one having the potential to affect flow and transport. The applicant committed to removing this piping system and associated bedding materials. The staff notes that the applicant included this information in WLS COL FSAR Section 2.4.12.2, "Sources." The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-19, was acceptable and considers the question resolved.

Source Term

Information Supplied by the Applicant

The applicant identified the source-term concentrations per the information in the AP1000 DCD Tables 11.1-8 (H-3), 11.1-2 (corrosion products chromium (Cr)-51, manganese (Mn)-54, manganese (Mn)-56, Fe-55, Fe-59, Co-58, and Co-60), and 11.1-2 for the other isotope concentrations after adjusting them by the factor 0.12/0.25 in accordance with BTP 11-6, March 2007. The applicant described the two pathways that were considered in WLS COL FSAR Revision 0. Travel time to the Broad River was shorter (because of hydrogeology) than to Hold-Up Pond A. Unit 2 was closer to the Broad River than Unit 1. Thus, transport of the Unit 2 effluent tank contents directly to the Broad River was identified as the limiting scenario because it minimized the transport distance and time. The applicant assumed the contents of the failed effluent tank entered the subsurface environment at a depth of 10.2 m (33.5 ft) and completely filled the soil pore space in an area large enough to contain 84,791 L (22,400 gal) of effluent.

In response to four staff RAIs, the applicant provided additional information and clarification related to the use of RESRAD-OFFSITE to calculate contaminant transport.

NRC Staff's Technical Evaluation

In RAI 828, Question 02.04.13-14, the staff requested that the applicant provide the calculation package used to convert source concentration values in AP1000 DCD Tables 11.1-2 and 11-1-8 to RESRAD-OFFSITE input values (with units of pCi/g water). In a November 25, 2008, response, the applicant summarized the steps used to convert source concentrations to RESRAD-OFFSITE input values. The activities listed in AP1000 DCD Table 11.1-2 for non-corrosion products were stated to be corrected by 0.12/0.25 as recommended by AP1000 DCD Section 2.1 (the staff noted that the WLS COL FSAR incorrectly cites NRC BTP 11-6 as the source for this correction). The activities for the corrosion products were taken directly from AP1000 DCD Table 11.1-2. The resulting activities for all constituents were adjusted by a factor of 1.01 and then converted from microcuries to picocuries by multiplying by 1×10^6. The applicant proposed no changes to the WLS COL FSAR.

The staff's review of the calculation package showed that the applicant used the uncorrected values, i.e., the applicant did not modify the values in DCD Table 11.1-2 by the factor 0.12/0.25. The applicant did not explain the reason for adjusting concentrations by a factor of 1.01, but such an adjustment increases concentrations slightly and therefore could be viewed as being conservative. The staff noted that the table of concentrations in the RAI response from the applicant contained a xenon (Xe)-133 concentration of 1.2×10^{-2} µCi/g. The AP1000 DCD value is 1.2×10^2 µCi/g. The applicant did not include Xe-133 in its RESRAD-OFFSITE groundwater analysis. The staff issued two more RAIs related to the source term, as discussed below.

In RAI 828, Question 02.04.13-16, the staff requested that the applicant explain more fully the conceptual model of the accidental release with respect to soil volume occupied, duration of leak, and impact on surrounding groundwater. In a November 25, 2008, response, the applicant stated that the release to groundwater was assumed to be instantaneous and that the leaked fluid immediately occupied a rectangular plume volume that was 2.0 m (6.6 ft) high and 6.5 m (21.4 ft) wide on each side. Although the leak was considered to be instantaneous, the applicant assumed that the release mechanism was sufficiently gradual that there was no perturbation to the groundwater surface, flow rate, and flow direction. The applicant assumed that aspects of a real leak event, such as potential groundwater flow into the auxiliary building and the time delay for contaminants to exit the building, were inconsequential; this assumption makes the release analysis more conservative. The applicant proposed no changes to the WLS COL FSAR. The staff considered the assumptions and agreed with the applicant's assessment. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-16, was acceptable and considers the question resolved.

To address questions raised by the staff's review of the applicant's response to RAI 828, Question 02.04.13-14, as described above, the staff issued RAI 73, Question 02.04.13-26. In the November 12, 2009, response to RAI 73, Question 02.04.13-26, the applicant stated that it would apply the 0.12/0.25 factor correctly and repeat the RESRAD-OFFSITE analysis. The applicant stated that the modification by a factor of 1.01 is just a conservative adjustment. The staff noted that the table of concentrations in the RAI response from the applicant contained a Xe-133 concentration of 1.2×10^{-2} µCi/g, whereas the correct value from the AP1000 DCD is

1.2 x 10^2 µCi/g. The applicant indicated that the 1.2x10^{-2} value was only a typographical error. The applicant did not include Xe-133 in its RESRAD-OFFSITE groundwater analysis because it is a gas and because it has a short half-life of 0.014 years. The staff noted that the other source-term gases listed in WLS COL FSAR Section 2.4.13.3 also have short half-lives (much less than 0.1 years) except for krypton (Kr)-85, which has a half-life of 10.8 years. However, Kr-85 is a noble gas and would partition rapidly into the atmosphere, both at the time of the release and if it reaches the Broad River. Therefore, significant exposure by way of groundwater and surface water appears unlikely. The staff notes that the applicant updated WLS COL FSAR Section 2.4.13.3, "Source Term." The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-26, was acceptable and considers the question resolved.

To clarify the handling of tritium in the applicant's evaluation of accidental releases, the staff issued RAI 73, Question 02.04.13-27. In a November 12, 2009, response the applicant stated that the AP1000 vendor (Westinghouse) recognized that tritium was not in AP1000 DCD Table 11.1-2 and indicated that the best available value for tritium was in AP1000 DCD Table 11.1-8, Realistic Source Terms. The staff notes that the applicant updated WLS COL FSAR Section 2.4.13.3, "Source Term." The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-27, was acceptable and considers the question resolved. The staff also concluded that that the applicant's November 12, 2009, response to RAI 73, Questions 02.04.13-26 and 02.04.13-27, provides information to find the applicant response to RAI 828, Question 02.04.13-14, acceptable and considers the question resolved.

Conceptual Model

<u>*Information Submitted by the Applicant*</u>

The applicant stated in WLS COL FSAR Revision 0 that the conceptual model was conservative because it used the shortest travel time, did not credit dilution in the Broad River, assumed a straight travel path, and assumed the entire domain had the properties of PWR (which has a high permeability). The applicant used RESRAD-OFFSITE to determine radionuclide concentrations in the Broad River for an evaluation period of 50 years. The applicant provided a list of parameters used in its analysis. The applicant calculated the maximum radionuclide concentration for each isotope in the Broad River during the evaluation period and compared it to the limiting concentrations defined in 10 CFR Part 20, Appendix B, Table 2, Column 2. The applicant reported that all concentrations were below the limits. In addition, the applicant calculated the sum of fractions of effluent concentrations using all maximum radionuclide concentrations and showed it to be well below a value of 1.0. The applicant stated that this result was conservative because the maximum concentration of each radionuclide occurred at a different time due to variations in transport time to the Broad River.

In response to 12 staff RAIs, the applicant provided additional information and clarification related to the conceptual model and parameter choices affecting the RESRAD-OFFSITE calculation of contaminant transport.

NRC Staff's Technical Evaluation

The staff reviewed the applicant's conceptual model for groundwater transport of radionuclide contaminants from a release. The staff determined the applicant's conceptual model generally reasonable, but required much additional information and analysis from the applicant to support the staff's review. Therefore, in RAI 828, Question 02.04.13-5, the staff requested that the applicant clarify why different values of porosity were used in each section. If this was done for conservatism, the staff requested that the applicant explain why each is conservative. In a November 25, 2008, response, the applicant set the total porosity of the PWR equal to its estimate of 0.08 for the effective porosity. The applicant stated that the lowest porosity values are the most conservative values because they result in the shortest travel time and, thus, the highest concentration of radionuclides in the receptor water body. The staff notes that the applicant updated WLS COL FSAR Table 2.4.13-203. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-5, was acceptable and considers the question resolved.

To clarify the conservatism of the hydraulic conductivity value used for the PWR, the staff issued RAI 828, Question 02.04.13-6. In a November 25, 2008, response, the applicant changed the statement from "highest measured" to "conservative" hydraulic conductivity. The staff notes that the applicant updated WLS COL FSAR Section 2.4.12.2, "Sources." The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-6, was acceptable and considers the question resolved.

In RAI 828, Question 02.04.13-7, the staff requested that the applicant define the nature of the contaminated zone; namely, describe the materials that make up the contaminated zone. In a November 25, 2008, response the applicant stated that the contaminated zone consists of PWR with some portions of residual soils and fill. The applicant considers use of PWR to represent the most conservative approach for estimating transport. The applicant set both total and effective porosity of PWR to the value of 0.08. This value is much lower than the WLS COL FSAR Revision 0 value of 0.44 and the applicant considers it much more conservative. The staff notes that the applicant updated WLS COL FSAR Table 2.4.13-203 to the revised porosity values for the partially weathered zone. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-7, was acceptable and considers the question resolved.

To gain a clearer understanding of the significance of precipitation, runoff, evapotranspiration, and recharge with respect to radionuclide transport, the staff issued RAI 828, Question 02.04.13-11. In a November 25, 2008, response, the applicant revised its estimate of average annual precipitation from 1.01 to 1.23 m/yr (39.8 to 48.4 in/yr) based on precipitation data from Gaffney, SC, for the years from 1944 to 2007. The applicant described the calculation process in which it used the SCS curve number method to estimate the runoff coefficient. For the watershed containing Make-Up Pond A and Hold-Up Pond A, the applicant calculated annual runoff to be 53 percent of precipitation. For the watershed containing Make-Up Pond B, it calculated annual runoff to be 39 percent of precipitation. For the RESRAD-OFFSITE analysis, the applicant used the value of 39 percent for both watersheds, which is realistic for the Make-Up Pond B watershed and conservative for the watershed containing Make-Up Pond A and Hold-Up Pond A. Using this analysis, the applicant revised its runoff coefficient from 0.36 to 0.39.

Given that the average annual precipitation is 123.0 cm (48.41 in.), runoff amounts to 48.0 cm (18.88 in.). The applicant calculated evaporation using regional pan evaporation data, which showed an annual pan evaporation rate of 132 cm (51.8 in.). Pan evaporation data tend to overestimate actual evaporation, so the applicant used a correction factor of 0.7 to adjust the pan data, yielding an estimate of annual evaporation of 91 cm (36 in.). In the RESRAD-OFFSITE analysis, the applicant specified an evaporation factor of 0.74. RESRAD-OFFSITE uses the evaporation factor to estimate how much of the infiltration water (i.e., precipitation - runoff, or P-R) is lost to evaporation (which includes transpiration from vegetation). In this case, annual evapotranspiration (E) is estimated to be 55.5 cm (21.85 in.). Annual net infiltration, also called groundwater recharge, is thus 19.5 cm (7.68 in.) (i.e., (P-R)-E). The staff notes that the applicant updated WLS COL FSAR Table 2.4.13-203 to include the above runoff coefficient and evaporation factor. The staff concluded that the COL applicant's November 25, 2008, response to RAI 828, Question 02.04.13-11, was acceptable and considers the question resolved.

To review the appropriateness of contaminant transport modeling methods used by the applicant, the staff issued RAI 828, Question 02.04.13-13. In a November 25, 2008, response, the applicant sent the input and output files. The staff reviewed the RESRAD-OFFSITE input file and noted that the dry bulk density of the saturated zone material is 1.51 g/cm^3 (94.3 pcf). The applicant stated that this value should be 1.59 g/cm^3 (99.3 pcf). The RESRAD-OFFSITE model requires the user to specify the initial radionuclide concentration on a picocurie per gram of soil basis. Instead of providing the appropriate soil-based concentrations, the applicant used the liquid-based concentrations that are identified in AP1000 DCD, Table 11.1-2. Since RESRAD-OFFSITE assumes the input concentrations are soil based, RESRAD-OFFSITE multiplies the input concentrations by a factor equal to the bulk density divided by the porosity to yield the initial groundwater concentration. The net effect is that the RESRAD-OFFSITE groundwater concentrations are much higher (by the factor bulk density divided by porosity) than the liquid concentrations specified in the AP1000 DCD. The staff notes that the applicant updated the RESRAD-OFFSITE analysis to use the correct porosity and appropriate method for initializing the contaminant concentration. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-13, was acceptable and considers the question resolved.

In RAI 828, Question 02.04.13-15, the staff requested that the applicant explain how contaminant concentrations were affected by mixing in the Broad River as part of the RESRAD-OFFSITE analyses. In a November 25, 2008, response, the applicant stated that it used a mixing volume of 150,000 m^3 (5,297,200 ft^3) in the Broad River. That volume is the default volume used by RESRAD-OFFSITE to represent a lake. The volume represents 17.5 percent of the static pool that would reside behind the Ninety-Nine Islands Dam if there were no flow. The volume does not take into account the daily flow of water past the site. That flow is on the order of 6.2×10^6 m^3/day (2.2×10^8 ft^3/day), which, on a daily basis, is equivalent to 41 mixing volumes. The applicant stated that a residence time of 1 year was chosen to standardize the exposure duration to the accumulation duration. Actual residence time would be less than 1 day. The applicant stated that groundwater concentrations were not evaluated at the river edge because no regulatory basis exists for an intermediate release point. The applicant described the rationale for the mixing volume in the Broad River in WLS COL FSAR Section 2.4.13.4, "Conceptual Model." The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-15, was acceptable and considers the question resolved.

To explain the period used for evaluating radionuclide concentrations, the staff issued RAI 828, Question 02.04.13-17. In a November 25, 2008, response, the applicant expanded the evaluation period from 50 to 1,000 years. The applicant stated that this time period was sufficient for all radionuclides to either appear in the receptor body or disappear through radioactive decay. The staff notes that the applicant updated WLS COL FSAR Section 2.4.13.4, "Conceptual Model," to reflect the change in the length of the evaluation period. The staff concluded that the applicant's November 25, 2008, response to RAI 828, Question 02.04.13-17, was acceptable and considers the question resolved.

To clarify the initial dimensions assumed for the contaminant plume, the staff issued RAI 73, Question 02.04.13-20. In a November 12, 2009, response, the applicant stated that it would use the effective porosity to define the plume size and would update the WLS COL FSAR accordingly. The applicant approximated the plume as a cube with dimensions of 10.2 m (33.5 ft) on each side. The staff confirmed this dimension was consistent with the effective porosity. The staff notes that the applicant updated WLS COL FSAR Section 2.4.13.4, "Conceptual Model," and WLS COL FSAR Table 2.4.13-203 to reflect the change in the plume size. The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-20, was acceptable and considers the question resolved.

The staff agreed that travel times decrease as the effective porosity is reduced. However, the staff noted that as the total porosity is decreased, the retardation factor is increased, which means that travel times are increased. Bulk density (p_b), water density (p_w), total porosity (n), and soil distribution coefficient (K_d) affect the retardation of contaminants in the following manner.

$$\text{Retardation (R)} = 1+((p_b/p_w)/n)K_d$$

Therefore, it is imperative that appropriate values of total and effective porosity be used for any contaminant that has the potential to be absorbed. Therefore, in RAI 73, Question 02.04.13-21, the staff requested that the applicant justify why a total porosity value of 0.08 is conservative for contaminants that sorb to the sediments. In a November 12, 2009, response, the applicant identified appropriate site-specific values for total porosity and effective porosity for PWR of 27 percent and 8 percent, respectively. The applicant used these values in revised RESRAD-OFFSITE transport analyses. Additional discussion is included below in the applicant's response to RAI 73, Question 02.04.13-29. The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-21, was acceptable and considers the question resolved.

The staff noted that the applicant's proposed revision to WLS COL FSAR Section 2.4.13 described the annual precipitation used in the RESRAD-OFFSITE analysis as being the highest annual precipitation rate. Since average annual precipitation is used, the description is incorrect in both the proposed text and in WLS COL FSAR Table 2.4.13-203 and needs to be corrected in both locations. The staff also noted that the recharge rate of 19.5 cm/yr (7.68 in/yr) is lower than expected. In WLS COL FSAR Section 2.4.1.2.4, the applicant stated that, because surface materials in many areas are relatively impermeable, recharge is only 25 to 38 cm/yr (10 to 15 in/yr). In Environmental Report Section 2.3.1.1.5, the applicant stated that the recharge rate ranges from 22 to 33 percent of annual precipitation, which translates to 27.2 to 40.6 cm/yr (10.7 to 16.0 in./yr). Since recharge is used in RESRAD-OFFSITE to leach contaminants from the contaminated zone into the groundwater, the staff issued RAI 73, Question 02.04.13-24.

In a November 12, 2009, response to RAI 73, Question 02.04.13-24, the applicant stated that the value of 19.5 cm/yr (7.68 in/yr) is conservative. However, the applicant provided a more conservative value for the RESRAD-OFFSITE analyses. The input value for annual precipitation was updated to 1.27 m (i.e., approximately 50 in. as stated in WLS COL FSAR Section 2.3.1.1) and the evapotranspiration coefficient was revised to a value of 0.64, based on regional information. The runoff coefficient was assigned a value of zero to maximize the recharge rate. These three changes increased the effective recharge rate for the RESRAD-OFFSITE analyses to approximately 46 cm/yr (18 in./yr). The staff notes that the applicant updated WLS COL FSAR, Table 2.4.13-203, to reflect the changes. The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-24, was acceptable and considers the question resolved.

To understand the rationale for using the default mixing volume in RESRAD-OFFSITE, the staff issued RAI 73, Question 02.04.13-28. In a November 12, 2009, response, the applicant defined the mixing volume as 856,036 m^3 (30,230,600 ft^3), which it determined to be the volume of the Broad River reservoir from the postulated release point downstream to the Ninety-Nine Islands Dam. The applicant determined the residence time of radionuclides in the reservoir to be 0.00397 years (1.5 days) by assuming only 50 percent of the FERC license requirement for minimum flow (13.7 m^3/s [483 cfs]) passing the Ninety-Nine Islands Dam. The staff notes that the applicant updated WLS COL FSAR Table 2.4.13-203 to reflect the changes. The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-28, was acceptable and considers the question resolved.

In RAI 73, Question 02.04.13-29, the staff requested that the COL applicant clarify the choice of parameters used to initialize the RESRAD-OFFSITE analyses and explain how leaked fluid concentrations were transformed into initial radionuclide concentration on a picocurie per gram of soil basis. In a November 12, 2009, response, the applicant provided a revised RESRAD-OFFSITE analysis. The contaminated zone was assumed by the applicant to be a cube composed of PWR having an effective porosity of 0.08 and a dry bulk density of 1.98 g/cm^3 (124 pcf). The initial source-term concentrations were converted to a soil mass basis by using the dry bulk density; this method yielded the final concentration input to RESRAD-OFFSITE in picocuries per gram. Although the WLS site geology is variable, all five pathways (subsequently reduced to the current four pathways) were conservatively evaluated by the applicant by assuming the pathway was composed entirely of PWR, which has the highest conductivity and yields the shortest travel time.

The limiting pathway was from Unit 2 to Hold-Up Pond A. Contaminant transport to Hold-Up Pond A was via groundwater. Once at the Hold-Up Pond A, the applicant assumed all groundwater entered the surface water in the pond, travel over the spillway, and enter the Broad River. Dilution in the Broad River was described previously in this report in the response to RAI 73, Question 02.04.13-28. The applicant reported that the radionuclide concentrations were below the limits in 10 CFR Part 20, Appendix B, Table 2, Column 2. In addition, the total sum of fractions was also less than 1.0 for both the hypothetical well (approximately 0.8) and the surface-water analyses (approximately 4 x 10^{-5}). The nearest potable water supply is located approximately 34 km (21 mi) downstream of the outfall from Hold-Up Pond A. The staff expects that the Broad River concentrations and sum of fractions would be even lower at that location. The staff notes that the applicant updated WLS COL FSAR Section 2.4.13, Table 2.4.13-203, and WLS COL FSAR Table 2.4.13-204 to reflect the changes. The staff concluded that the applicant's November 12, 2009, response to RAI 73, Question 02.04.13-29, was acceptable and considers the question resolved.

Sensitive Parameters

Information Submitted by the Applicant

The applicant did not provide any sensitivity analyses in WLS COL FSAR Revision 0. Partly because of the RAI process, the applicant included sensitivity analyses in WLS COL FSAR Revision 1 and all subsequent revisions. The applicant examined the RESRAD-OFFSITE sensitivities for selected parameters, including total porosity, effective porosity, hydraulic conductivity, hydraulic gradient, and K_d values for those radionuclides that were evaluated for site soils. The applicant stated that no variation in any single parameter had sufficient impact to cause the concentrations to exceed 10 CFR Part 20, Appendix B, Table 2, Column 2 limits or for the sum of fractions calculation to exceed 1.0.

In response to one staff RAI, the applicant provided additional clarification related to the nature of the K_d values used for the PWR.

NRC Staff's Technical Evaluation

The staff examined the sensitivity cases and determined they covered a sufficient range of parameter variation to conclude that reducing parameter uncertainty would not alter the results.

With respect to the sensitivity analysis of the K_d values, the lower values affected the results for two radionuclides, namely, I-129 and Tc-99. Predicted concentrations were 10 and 5.8 percent higher, respectively. The applicant stated that, in both cases, the higher concentrations were still well below limits listed in 10 CFR Part 20, Appendix B, Table 2, Column 2.

The staff determined that the K_d value for PWR had the potential to be less than that for the soil/saprolite zone, which was the only material tested. Therefore, the staff issued RAI 73, Question 02.04.13-25. In a November 12, 2009, response, the applicant stated that the PWR material is a transition material between the saprolite above and the underlying bedrock and that the measurements on samples from the soil/saprolite are representative and appropriate for the accidental release analysis. The staff recognizes the difficulty of measuring K_d values directly on PWR and agrees that, as an alternative, using the lowest K_d values of all three samples and the results of the sensitivity tests (i.e., no impact) provides sufficient information to conclude that the WLS site meets the 10 CFR Part 20 concentration and sum of fractions requirements. The staff concluded that the applicant's November 23, 2009, response to RAI 70, Question 02.04.13-25, was acceptable and considers the question resolved.

Regulatory Compliance

Information Submitted by the Applicant

The applicant stated that meeting the concentration limits of 10 CFR Part 20 Appendix B, Table 2, Column 2 results in a dose of less than 0.05 Roentgen equivalent man (REM) and, therefore, demonstrates that the requirements of 10 CFR 20.1301 and 10 CFR 20.1302 are met.

NRC Staff's Technical Evaluation

The staff evaluated and confirmed the applicant's demonstration that radionuclide concentrations and sum of fractions in the Broad River would be well below the requirements of 10 CFR Part 20.

2.4.13.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.4.13.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant addressed the relevant information and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. As set forth above, the applicant presented and substantiated information to establish the potential effects of accidental releases from the liquid waste management system. The staff reviewed the information provided and, for the reasons given above, concludes that the applicant has provided sufficient details about the site description, and about the design of the liquid waste management system, to allow the staff to evaluate, as documented in this section, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site, and with respect to 10 CFR 20 as it relates to ECLs. This addresses, and closes, COL information item 2.4-5. The staff concluded that the applicant provided sufficient information to satisfy the applicable requirements of 10 CFR Part 20, 10 CFR Part 52, and 10 CFR Part 100.

2.4.14 Technical Specifications and Emergency Operation Requirements

2.4.14.1 *Introduction*

WLS COL FSAR Section 2.4.14 describes technical specifications and emergency operation requirements as necessary. The requirements described implement protection against floods for safety-related facilities to ensure that an adequate supply of water for shutdown and cool-down purposes is available.

Section 2.4.14 of this report presents the staff's evaluation of required technical specifications and emergency operations for the proposed plant site.

2.4.14.2 *Summary of Application*

This section of the WLS COL FSAR addresses technical specifications and emergency operation requirements. The applicant addressed information related to technical specifications and emergency operation requirements as follows:

AP1000 COL Information Item

- WLS COL 2.4-6

In addition, this section addresses the following COL-specific information identified in AP1000 Tier 2, Section 2.4.1.6, Revision 19.

> Combined License applicants referencing the AP1000 certified design will address any flood protection emergency procedures required to meet the site parameter for flood level.

2.4.14.3 *Regulatory Basis*

The relevant requirements of NRC regulations for consideration of emergency protective measures, and the associated acceptance criteria, are described in NREG-0800, Section 2.4.14.

The applicable regulatory requirements for technical specifications and emergency operation requirements are set forth in the following:

- 10 CFR 50.36, "Technical Specifications," as it relates to identifying technical specifications related to all emergency procedures required to ensure adequate plant safety from controlling hydrological events by the organization responsible for the review of issues related to technical specifications.

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 100, as it relates to identifying and evaluating hydrological features of the site. The requirement to consider physical site characteristics in site evaluations is specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d) sets forth the criteria to determine the siting factors for plant design bases with respect to seismically induced floods and water waves at the site.

2.4.14.4 *Technical Evaluation*

Information Submitted by the Applicant

The applicant stated that the maximum flood water-surface elevation at the WLS site is 178.3 m (584.8 ft) above MSL, resulting from a PMF event in the watershed of Make-Up Pond B. The applicant noted that the safety-related plant grade at the WLS site is 179.8 m (590 ft) above MSL. Therefore, the applicant concluded that a freeboard of over 1.5 m (5 ft) is available under the worst flooding scenario. The applicant stated that based on the description provided in WLS COL FSAR Section 2.4.12.5, the maximum expected groundwater elevation would not exceed the design criteria for the chosen reactor design. The applicant stated that no safety-related facilities would be affected by low flow or drought conditions in the Broad River. The applicant concluded that, based on site-specific conditions at the WLS site, no emergency protective measures designed to minimize the impact of hydrologic events on safety-related facilities are needed.

As described in Section 2.4.2.4 of this report, the applicant revised the analysis for site flooding under local intense precipitation in response to the staff's RAI 484, Question 10.04.05-2. The applicant's revised analysis established a slightly higher maximum water-surface elevation of 179.72 m (589.62 ft) above MSL caused by the effects of the local intense precipitation.

NRC Staff's Technical Evaluation

The staff reviewed COL Information Item 2.4-6 related to the provision of site-specific information about flood protection emergency operation procedures at the plant site included under WLS COL FSAR Section 2.4.

As stated in Section 2.4.10 of this report, the staff concluded that the site characteristic maximum flood water-surface elevation near the WLS site from several flooding mechanisms described in earlier sections herein remains below the site grade and meets the AP1000 DCD site parameter. As stated in Section 2.4.11 of this report, the staff concluded that there are no safety-related systems that can be affected by low water at the WLS site. Therefore, the staff concluded that no emergency operation requirements for flooding and water availability are needed for the WLS site.

2.4.14.5 *Post Combined License Activities*

There are no post COL activities related to this section

2.4.14.6 *Conclusion*

The staff reviewed the application and confirmed that the applicant has addressed the information relevant to technical specification and emergency operations requirements, and there is no outstanding information required to be addressed in the WLS COL FSAR related to this section.

As set forth above, the applicant has presented and substantiated information to establish the site description. The staff reviewed the information provided and, for the reasons given above, concludes that the applicant has provided sufficient details about the site description to allow the staff to evaluate, as documented in Section 2.4.14 of this report, whether the applicant has met the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100 with respect to determining the acceptability of the site. The WLS COL FSAR addressed flood protection emergency operation procedures in COL Information Item 2.4-6. The staff concluded that the applicant provided sufficient information to satisfy the applicable requirements of 10 CFR Part 52 and 10 CFR Part 100.

2.4.15 Combined License Information

The applicant also identified the following AP1000 DCD Tier 2 departure:

> STD DEP 1.1-1 within FSAR Section 2.4.1, “Hydrologic Description,” identifies instances where the FSAR sections are renumbered to include content consistent with Regulatory Guide 1.206, as well as NUREG-0800. Here, Subsections in Section 2.4.15 of the DCD are renumbered as Section 2.4.1, 2.4.2, 2.4.3, 2.4,4, 2.4.5, 2.4.6, 2.4.7, 2.4.8, 2.4.9, 2.4.10, 2.4.11, 2.4.12, 2.4.13, and 2.4.14.

The applicant’s evaluation, in accordance with 10 CFR Part 52, Appendix D, Section VIII.B.5, determined that this departure did not require prior NRC approval. The staff concluded that it is reasonable that the departure does not require prior NRC approval. The applicant’s process for evaluating departures and other changes to the AP1000 DCD are subject to NRC inspections. The NRC evaluated the AP1000 DCD Tier 2 departure in the aforementioned renumbered sections.

2.5 Geology, Seismology, and Geotechnical Engineering

In William States Lee III Nuclear Station (WLS) Combined License (COL) Final Safety Analysis Report (FSAR) Section 2.5, “Geology, Seismology, and Geotechnical Engineering,” Revision 9, the applicant described the geologic, seismic, and geotechnical engineering characteristics of the proposed COL site. Following NRC guidance in RG 1.206, “Combined License Applications for Nuclear Power Plants - LWR Edition,” and Regulatory Guide (RG) 1.208, “A Performance-Based Approach to Define Site-Specific Earthquake Ground Motion,” the applicant defined the following four zones around WLS and conducted technical investigations in the zones that became progressively more detailed passing from site region to site location.

- Site region – Area within a 320-km (200-mi) radius of the site location
- Site vicinity – Area within a 40-km (25-mi) radius of the site location
- Site area – Area within an 8-km (5-mi) radius of the site location
- Site location – Area within a 1-km (0.6-mi) radius of proposed Units 1 and 2

The applicant referred to the 1974 Preliminary Safety Analysis Report (PSAR) for the former Cherokee Nuclear Station (CNS) to provide information deemed pertinent for understanding geologic setting and characteristics of the WLS site. The information about the CNS site is pertinent for the WLS site because site locations coincide. However, most material in Final Safety Analysis Report (FSAR) Section 2.5 draws on information developed from sources published since the 1974 CNS PSAR, as well as data derived from investigations specifically performed for geologic, seismic, and geotechnical characterization of WLS.

The staff reviewed WLS COL FSAR Section 2.5, interacted with the applicant during public meetings, and issued requests for additional information (RAIs) to confirm the assertions made by the applicant in the WLS COL FSAR. In early versions of the WLS COL FSAR, the applicant used the Electric Power Research Institute (EPRI) base seismic source models for seismic hazard analysis. The applicant replaced those models with the new seismic source characterization (SSC) model for the central and eastern United States (CEUS) published in NUREG-2115, "Central and Eastern United States Seismic Source Characterization for Nuclear Facilities."

Following the 2011 Fukushima Dai-ichi nuclear power plant accident in Japan, which occurred as a result of the Great Tohoku earthquake and the subsequent tsunami, the NRC Near-Term Task Force (NTTF) issued a series of recommendations for reevaluating and improving nuclear power plant safety in the United States (U.S.). Consequently, on March 12, 2012, the NRC issued an information letter requesting that licensees of all operating nuclear power plants in the U.S. reevaluate the seismic hazard at their respective plants using the most recent data and evaluation methodologies available. That information letter also requested that licensees of operating plants in the CEUS use the seismic source model provided in NUREG-2115 to characterize seismic hazard at their respective plants. Consistent with existing guidance in Regulatory Guide (RG) 1.208, "A Performance-Based Approach to Define the Site-Specific Earthquake Ground Motion" pertaining to the need to consider the latest information in the evaluation of seismic hazard, the NRC also requested that all COL and Early Site Permit (ESP) applicants in the CEUS address seismic hazard for their respective proposed plant sites using information in NUREG-2115 and modify the ground motion response spectra (GMRS), if needed. The staff issued this request to WLS in RAI 105, Question 01.05-1.

In a January 30, 2014, response to RAI 105, Question 01.05-1, the applicant stated that it replaced the previous EPRI seismic source models with the CEUS SSC model presented in NUREG-2115 as the starting point for developing GMRS for the WLS site. With this change in the base seismic source model, some RAIs the staff had previously issued became moot as specified in Section 2.5.2.4 of this report. Accordingly, the following sections of this report describe only the most recent version of the WLS COL FSAR, as well as additional WLS COL FSAR markups provided by the applicant in the January 30, 2014, response to RAI 105, Question 01.05-1. The technical evaluations undertaken by the staff do not discuss the obsolete portions of the WLS COL FSAR that were replaced by the CEUS SSC model. The RAIs discussed below in detail are the RAIs that remained applicable to the staff's review following the change in the base seismic source model, along with the new RAIs developed by the staff related to the most recent version of the WLS COL FSAR.

This section of the report is divided into five main parts, Sections 2.5.1 through 2.5.5, which parallel the five main WLS COL FSAR sections prepared by the applicant for the WLS COL application. The five sections are Section 2.5.1, "Basic Geologic and Seismic Information"; Section 2.5.2, "Vibratory Ground Motion"; Section 2.5.3, "Surface Faulting"; Section 2.5.4, "Stability of Subsurface Materials and Foundations"; and Section 2.5.5, "Stability of Slopes." These sections summarize the content of the WLS COL FSAR, as well as present the staff's evaluations, conclusions, and findings with regard to the geologic, seismic, and geotechnical engineering characteristics of WLS Units 1 and 2.

2.5.1 Basic Geologic and Seismic Information

2.5.1.1 *Introduction*

In WLS COL FSAR Section 2.5.1, the application describes basic geologic and seismic information collected by the applicant during site characterization investigations. This information addresses both regional and site-specific geology and seismicity. The investigations included surface and subsurface field studies, performed at progressively greater levels of detail closer to the site, within each of four circumscribed areas corresponding to site region, site vicinity, site area, and site location, as previously defined. The applicant conducted these investigations to assess the geologic and seismic suitability of WLS to determine whether new geologic or seismic data exist that could significantly affect seismic design based on the results of the probabilistic seismic hazard analysis (PSHA) for the site, and to provide the geologic and seismic data appropriate for plant design.

2.5.1.2 *Summary of Application*

WLS COL FSAR Section 2.5 incorporates by reference AP1000 DCD, Revision 19. Section 2.5.1. In addition, in WLS COL FSAR Section 2.5.1, the applicant provided site-specific supplemental information to address the following:

AP1000 COL Information Item

- WLS COL 2.5-1

The applicant provided additional information in WLS COL 2.5-1 to address COL Information Item 2.5-1 (COL Action Item 2.5.1-1). WLS COL 2.5-1 addresses the provision of regional and site-specific geologic, seismic, and geophysical information, as well as conditions caused by human activity. This information specifically includes the following topics: structural geology; seismicity; geologic history; evidence of paleoseismicity; site stratigraphy and lithology; engineering significance of geologic features; site groundwater conditions; dynamic behavior during prior earthquakes; zones of alteration, irregular weathering, or structural weakness; unrelieved residual stresses in bedrock; materials that could be unstable because of mineralogy or physical properties; and the effects of human activities in the site area.

Two main sections comprise WLS COL FSAR Section 2.5.1. WLS COL FSAR Section 2.5.1.1, “Regional Geology,” discusses physiography, geomorphology, and stratigraphy; tectonic setting, including tectonic structures that are possibly Quaternary in age (i.e., 2.6 million years ago, or 2.6 Ma, to present); and seismicity and paleoseismicity within the site region. WLS COL FSAR Section 2.5.1.1 also describes specific seismic sources inside the site region (i.e., the Charleston, SC area, the Giles County Seismic Zone of southwestern Virginia (GCVSZ), and the Eastern Tennessee Seismic Zone (ETSZ)), as well as significant seismic sources outside the site region, including the New Madrid and Central Virginia Seismic Zones. WLS COL FSAR Section 2.5.1.2, “Site Geology,” addresses physiography and geomorphology, geologic setting and history, stratigraphy and lithology, and structural geology within the site vicinity and site area. WLS COL FSAR Section 2.5.1.2 also discusses physiography and geomorphology, geologic setting and history, stratigraphy and lithology, structural geology, and geologic mapping at the site location, as well as engineering geology (including the effects of human activities), seismicity and paleoseismicity, and groundwater conditions in the site area.

The applicant developed WLS COL FSAR Section 2.5.1 for WLS based on information derived from geologic maps and reports published by State and Federal agencies and research scientists; aerial photographs and digital elevation models; communications with experts in geology, seismology, and tectonics of the site region, site vicinity, site area, and site location; and geologic field investigations performed specifically for characterization of the WLS vicinity, site area, and site location. These field investigations included geologic field reconnaissance; lineament studies; analysis of test pits, trenches, and boreholes located at WLS; and geologic mapping of bedrock exposures in the excavations for former CNS Units 2 and 3. The applicant also used information presented in the PSAR for the former CNS site to supplement data derived from geologic and seismic investigations conducted specifically for the WLS application. That action was possible because the former CNS site and the proposed WLS site are coincident. As noted by the applicant in WLS COL FSAR Sections 2.5.4.5.3.2 and 2.5.4.7.4.1, sound concrete placed over previously mapped continuous bedrock during construction of CNS Unit 1 entirely underlies the coincident WLS Unit 1 nuclear island. The existing excavation for former CNS Unit 2, which lies between WLS Units 1 and 2, exposes foundation grade level bedrock. CNS Unit 3 coincides with WLS Unit 2, the excavation for which currently reaches top of sound rock and not foundation grade level bedrock. It should be noted that, to avoid an area of deeply weathered saprolitic (i.e., soft, typically clay-rich, thoroughly decomposed rock formed in place by chemical weathering that characteristically preserves geologic structures present in the unweathered parent rock) bedrock at the northwest corner of former CNS Unit 1, the applicant moved the WLS Unit 1 nuclear island footprint 20.1 meters (m) (66 feet (ft)) south and 15.2 m (50 ft) east of CNS Unit 1. The applicant also moved the WLS Unit 2 nuclear island footprint 20.1 m (66 ft) south to maintain the spacing between WLS Units 1 and 2. Due to the short distances involved, proposed WLS Units 1 and 2 remain coincident with former CNS Units 1 and 3, respectively. The applicant included boring logs for seven boreholes placed to characterize subsurface geology in the relocated nuclear island footprints in Attachment 6 of WLS COL FSAR Appendix 2AA (“Lee Nuclear Station Field Exploration Data”).

To confirm previous geologic mapping of foundation bedrock exposures in excavations at the CNS site, the applicant performed geologic mapping of foundation grade level bedrock surfaces exposed in a small portion of the CNS Unit 2 excavation and compared that geologic map to archived scanned records for the CNS site. In addition, to supplement that confirmatory mapping effort and document lithologies and geologic features (including faults, shear and breccia zones, and fractures) that occur in concrete-covered foundation grade level bedrock underlying CNS Unit 1, the applicant compiled a detailed geologic map of the foundation grade level bedrock surface in the CNS Unit 1 excavation from original field notes and geologic maps initially prepared in the 1970s to characterize site location geology in that excavation. As explained in WLS COL FSAR Section 2.5.1.2.5.5, the applicant digitized the original geologic maps and prepared a detailed map compilation report containing copies of the original geologic maps and the digitized map data, detailed descriptions of the quality assurance controls exercised to produce the digitized geologic map compilation, and discussions of lithologies and geologic structures that occur in the CNS and WLS Unit 1 excavation. The applicant documented the similarity of rock types and orientations and ages of tectonic structures in the excavations for former CNS Units 1, 2, and 3 and proposed WLS Units 1 and 2 in the map compilation report.

Based on the geologic and seismic investigations performed for WLS Units 1 and 2, the applicant concluded in WLS COL FSAR Section 2.5.1 that no geologic or seismic conditions exist at the site that would negatively affect construction or operation of safety-related structures. With regard to the assessment of evidence for capable tectonic sources in WLS COL FSAR Section 2.5.1, based on the definition in RG 1.208, in WLS COL FSAR Section 2.5.3 the applicant stated that a capable tectonic source is a tectonic structure that can generate both tectonic surface deformation (e.g., faulting or folding) and vibratory ground motion in the present seismotectonic setting. The following sections of this report summarize the basic geologic and seismic information provided by the applicant in WLS COL FSAR Section 2.5.1: Sections 2.5.1.2.1, "Regional Geology," and 2.5.1.2.2, "Site Geology."

2.5.1.2.1 Regional Geology

WLS COL FSAR Section 2.5.1.1 discusses the physiography, geomorphology, stratigraphy, tectonic setting, and seismicity and paleoseismicity of the site region, defined as the area that lies within a 320 km (200 mi) radius of WLS. Under the discussion of regional tectonic setting, the applicant specifically addressed potential regional tectonic structures of Quaternary (2.6 Ma to present) age. Under regional seismicity and paleoseismicity, the applicant also presented information on seismic sources located both inside and outside the site region. The following subsections of this report summarize the information provided by the applicant in WLS COL FSAR Section 2.5.1.1.

2.5.1.2.1.1 *Regional Physiography, Geomorphology, and Stratigraphy*

WLS COL FSAR Section 2.5.1.1.1 describes the physiography, geomorphology, and stratigraphy of the site region. The applicant stated that, from northwest to southeast, the site region encompasses parts of five physiographic provinces, including the Appalachian Plateau, Valley and Ridge, Blue Ridge, Piedmont, and Atlantic Coastal Plain provinces. Figure 2.5.1-1 of this report shows the location of WLS in relation to these five provinces. WLS lies in the Piedmont physiographic province.

2.5.1.2.1.1.1 Appalachian Plateau, Valley and Ridge, Blue Ridge, and Atlantic Coastal Plain Physiographic Provinces

The applicant reported that unmetamorphosed, slightly deformed sedimentary rocks of Permian (299 to 251 Ma) to Cambrian (542 to 488 Ma) age underlie the Appalachian Plateau province, which extends from New York State to Alabama; that folded and faulted sedimentary rocks of Paleozoic (542 to 251 Ma) age underlie the Valley and Ridge province, which extends from New York State through Pennsylvania, Maryland, and Virginia; and that the Blue Ridge province extends from Pennsylvania into northern Georgia and consists of intensely folded and faulted metamorphosed basement and cover rocks intruded by igneous bodies. The applicant stated that the Atlantic Coastal Plain province extends southwest from Massachusetts to south-central Georgia, where it merges with the Gulf section of the Coastal Plain province. This province exhibits a low, gently rolling topography and contains semi-consolidated sedimentary rocks of Cretaceous (145.5 to 65.5 Ma) age and younger.

2.5.1.2.1.1.2 Piedmont Physiographic Province

The applicant reported that the Piedmont physiographic province, which contains WLS, lies between the Blue Ridge and Atlantic Coastal Plain provinces. The Piedmont province extends from New York State into Alabama and contains two distinct lithotectonic elements, defined based on the occurrence of different rock types and field evidence for a different tectonic history in each element (i.e., the Piedmont Zone to the northwest and the Carolina Zone to the southeast). A series of faults referred to as the Central Piedmont Shear Zone (CPSZ), a Paleozoic (> 251 Ma) structure located about 8 km (5 mi) northwest of WLS (Figure 2.5.1-2 of this report), separate the Piedmont Zone and the Carolina Zone. WLS lies in the Carolina Zone of the Piedmont physiographic province, specifically in the Charlotte terrane of that zone, as shown in Figure 2.5.1-2 of this report. The applicant reported that late Proterozoic (1000 to 54 Ma) to early Paleozoic (> 488 Ma) plutonic rocks intrude a suite of metamorphosed igneous rocks and make up the dominant lithology in the Charlotte terrane, and that sediments of the Atlantic Coastal Plain unconformably overlie rocks of the Carolina Zone southeast of WLS.

2.5.1.2.1.1.3 Mesozoic Extensional Basin

The applicant also discussed early to middle Mesozoic (251 to 145.5 Ma) extensional basins in WLS COL FSAR Section 2.5.1.1.1. The applicant indicated that these basins, which occur in the site region in both the Piedmont and Atlantic Coastal Plain physiographic provinces but do not underlie the site (Figure 2.5.1-1 of this report), formed in response to continental rifting associated with formation of the existing Atlantic Ocean basin.

2.5.1.2.1.2 *Regional Tectonic Setting*

WLS COL FSAR Section 2.5.1.1.2 describes the regional tectonic setting of WLS, including regional geologic history, tectonic stress in the mid-continent region, site region and site vicinity gravity and magnetic data, and principal regional tectonic structures. The following subsections of this report provide a summary of the information presented by the applicant in WLS COL FSAR Section 2.5.1.1.2, including a discussion of principal regional tectonic structures that are possibly Quaternary (2.6 Ma to present) in age.

2.5.1.2.1.2.1 Regional Geologic History

In the description of geologic history in WLS COL FSAR Section 2.5.1.1.2.1, the applicant stated that WLS lies in the southern part of the Appalachian Mountains orogenic belt, which developed during Paleozoic time (542 to 251 Ma) as a result of four compressional orogenic episodes related to continental collisions and the associated opening and closing of the proto-Atlantic Ocean. The applicant reported that the middle Ordovician (472 to 461 Ma) Taconic orogeny, the second regional tectonic deformation event to affect the Appalachian orogenic belt during the Paleozoic, is the earliest tectonic event that deformed rocks in the WLS region. The applicant noted that the fourth and final orogenic event, the Alleghanian orogeny, which occurred during late Paleozoic time between 359 and 251 Ma, is the most significant collisional tectonic event of the Appalachian orogenic belt. The applicant stated that this collisional event closed the Paleozoic proto-Atlantic Ocean basin; created the fold and thrust fault belt of the Valley and Ridge physiographic province at the latitude of WLS; and transported the ancestral North American basement westward to form the western part of the Blue Ridge physiographic province. The applicant indicated that, at the latitude of WLS, ancestral North American basement rocks underlie the Valley and Ridge, Blue Ridge, and Inner Piedmont physiographic provinces at depths of less than 10 to 14 km (6 to 9 mi). The applicant also reported that a basal décollement (i.e., a large-displacement, shallow-dipping to subhorizontal, regional shear zone that truncates all rock units above it) developed along the top of the ancestral North American basement and formed the source of the Paleozoic thrust sheets in these three physiographic provinces.

The applicant noted further that the early to middle Mesozoic (251 to 145.5 Ma) rift basins of the modern continental margin record the start of extension and continental rifting leading to the formation of the current Atlantic Ocean basin. The applicant pointed out that Wheeler suggested many earthquakes that occur in the eastern part of the Piedmont physiographic province and beneath the Coastal Plain may be spatially associated with reactivated buried normal faults initially developed during Mesozoic rifting. However, the applicant indicated that no definitive correlation of seismicity with Mesozoic normal faults has been demonstrated to date. The applicant stated that, after continental extension and rifting during early to middle Mesozoic time, deposition of Cretaceous (145.5 to 65.5 Ma) and Cenozoic (65.5 Ma to present) sediments of the Coastal Plain occurred along a passive continental margin.

2.5.1.2.1.2.2 Tectonic Stress in the Mid-Continent

WLS COL FSAR Section 2.5.1.1.2.2 discusses tectonic stress in the mid-continent region. The applicant stated that data compiled for the CEUS SSC model (NUREG-2115) confirmed previous work indicating a prevailing east-northeast to northeast orientation of maximum horizontal compressive stress in the mid-continent. This orientation is consistent with the theoretical trend of compressive forces exerted on the North America plate by seafloor spreading at the mid-Atlantic ridge as proposed by Zoback.

2.5.1.2.1.2.3 Gravity and Magnetic Data

WLS COL FSAR Section 2.5.1.1.2.3 presents gravity and magnetic data for the site region and vicinity. In WLS COL FSAR Section 2.5.1.1.2.3.1, the applicant reviewed the regional gravity data, including reprocessed data in the CEUS SSC database (NUREG-2115), and concluded that long wavelength anomalies observed in the vicinity of WLS are also characteristic of large parts of the Appalachian orogenic belt. The applicant also concluded that short wavelength characteristics noted in the WLS vicinity are gravity highs and lows related to mafic and granitic igneous intrusive rock bodies, respectively. The applicant further concluded that the gravity data do not show any evidence of Cenozoic (65.5 Ma to present) tectonic activity or specific Cenozoic tectonic structures in the site region or site vicinity.

In WLS COL FSAR Section 2.5.1.1.2.3.2, the applicant reviewed the regional magnetic data, also including reprocessed data in the CEUS SSC database (NUREG-2115), and concluded that first-order magnetic anomalies mainly reflect regional terranes of the Paleozoic Appalachian orogen, which trend northeast-southwest. The applicant associated superimposed anomalies having wavelengths of 5 to 19 km (3 to 12 mi) with igneous intrusive rock bodies or ore deposits. The applicant further concluded that the magnetic data generally are not of sufficient resolution to identify discrete faults.

2.5.1.2.1.2.4 Principal Regional Tectonic Structures

WLS COL FSAR Section 2.5.1.1.2.4 discusses principal regional tectonic structures within 320 km (200 mi) of WLS. The discussion included geophysical anomalies and lineaments and Paleozoic, Mesozoic, Cenozoic, and Quaternary tectonic structures.

Regional Geophysical Anomalies and Lineaments

In WLS COL FSAR Section 2.5.1.1.2.4.1, the applicant discussed geophysical anomalies and lineaments found within the site region. From southeast to northwest, these features are the East Coast Magnetic Anomaly (ECMA); the southeastern limit of Iapetan (i.e., late Proterozoic, 1,000 to 542 Ma, to early Paleozoic, > 488 Ma, in age) normal faulting; the Clingman, Ocoee, and New York-Alabama (NYAL) lineaments; the Appalachian gravity gradient; the northwestern boundary of Iapetan normal faulting; the Appalachian thrust front; and the Grenville Front. The applicant documented an age of > 65.5 Ma for these anomalies and lineaments.

Regional Paleozoic Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4.2, the applicant discussed the following 13 Paleozoic (542 to 251 Ma) tectonic structures that occur in the WLS region, associating them with thrust faulting that occurred during compressional Appalachian orogenic events:

- Kings Mountain Shear Zone – 8 km (5 mi) north of the site
- Tinsley Bridge Fault – 8 km (5 mi) southwest of the site
- Cross Anchor Fault – 16 km (10 mi) west of the site
- Southwest extension of the Boogertown Shear Zone – 13 km (8 mi) east of the site
- Reedy River Thrust Fault – 29 km (18 mi) west-northwest of the site
- Gold Hill-Silver Hill Shear Zone – 48 km (30 mi) south of the site
- Middleton-Lowdensville Shear Zone – 64 km (40 mi) south of the site
- Modoc Shear Zone – 121 km (75 mi) south of the site
- Brevard Fault Zone – 89 km (55 mi) northwest of the site
- Chappells Shear Zone – 92 km (57 mi) south of the site
- Hyco Shear Zone – 225 km (139 mi) northeast of the site
- Brindle Creek Thrust Fault – 64 km (40 mi) north of the site

- Beaver Creek Shear Zone – 64 km (40 mi) south of the site

The applicant indicated that the majority of these regional tectonic structures dip eastward, shallowing in dip as they merge into the basal décollement. Based on interpretations by researchers who determined that most of the seismicity in eastern North America occurs in basement rocks below the décollement surface, the applicant stated that seismicity in the Southern Appalachian Mountains is likely unrelated to shallow thrust faults mapped at the surface. The applicant did not attribute any seismicity to Paleozoic faults in the site region, and indicated that published literature does not report any evidence for associated late Cenozoic (23 Ma to present), including Quaternary (2.6 Ma to present), deformation related to these faults. Therefore, the applicant concluded that none of the Paleozoic structures found in the site region are capable tectonic features.

Regional Mesozoic Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4.3, the applicant described the following six Mesozoic (251 to 65.5 Ma) tectonic features that occur in the WLS region:

- Wateree Creek Fault – 89 km (55 mi) south of the site
- Summers Branch Fault – 89 km (55 mi) south of the site
- Ridgeway Fault – 96.6 km (60 mi) southeast of the site
- Longtown Fault – 96.6 km (60 mi) southeast of the site
- Mulberry Creek Fault – 89 km (55 mi) southwest of the site
- Mesozoic Rift Basins – located in the site region

The applicant stated that no known correlation exists between seismicity and these Mesozoic structures, and that published literature does not indicate any late Cenozoic, including Quaternary (2.6 Ma to present), deformation associated with the structures. Therefore, the applicant concluded that none of the Mesozoic structures found in the site region are capable tectonic features. However, the applicant noted that the Extended Continental Crust-Atlantic Margin (ECC-AM) seismotectonic zone of the CEUS SSC model (NUREG-2115), one of the multiple zones included in the seismic hazard calculation for WLS, contains Mesozoic tectonic structures of the site region. The applicant discussed the ECC-AM seismotectonic zone in WLS COL FSAR Section 2.5.2.2.3.2.

Regional Quaternary Tectonic Structure

In WLS COL FSAR Section 2.5.1.1.2.4.5, based on the catalogue of known or suggested Quaternary (2.6 Ma to present) tectonic structures in the CEUS developed by Crone and Wheeler and Wheeler, the applicant identified 15 potential Quaternary tectonic features in the WLS region, including faults, liquefaction features, and seismic zones. Crone and Wheeler and Wheeler classified potential tectonic features in regard to strength of evidence for Quaternary faulting and related deformation features based on evaluation of published information, not on a direct field examination of the actual geologic features. Their four classification categories for tectonic features are as follows:

- Class A – Geologic evidence demonstrates the existence of a Quaternary fault of tectonic origin, whether inferred from liquefaction or other deformation features or exposed at the ground surface.
- Class B – Geologic evidence demonstrates the existence of a fault or suggests Quaternary deformation, but the fault may not cut deep enough into the crust to be a potential source of significant earthquakes or the available evidence is not strong enough to assign the feature to Class A, but is too strong to assign it to C.
- Class C – Geologic evidence is insufficient to demonstrate the existence of a tectonic fault or Quaternary deformation associated with the feature.
- Class D – Geologic evidence demonstrates that the feature is not a tectonic fault.

The 15 potential Quaternary tectonic structures identified and described by the applicant within the WLS region include the Class A Charleston area, Bluffton, and Georgetown liquefaction features; the Class B Pembroke faults; and the Class C Fall Lines of Weems, Belair fault zone, Pen Branch fault, Cape Fear arch, Hares Crossroads fault, Lindside fault zone, Stanleytown-Villa Heights faults, Cooke fault, East Coast fault system, and Giles County and Eastern Tennessee seismic zones. Figure 2.5.1-3 of this report shows the locations of these potential Quaternary features relative to WLS.

The applicant discussed Charleston, SC area tectonic features (i.e., proposed source faults, seismic zones, and seismically-induced liquefaction and paleoliqefaction features) in FSAR Section 2.5.1.1.3.2.1; the Cape Fear arch in WLS COL FSAR Section 2.5.1.1.2.4.4; the ETSZ in WLS COL FSAR Section 2.5.1.1.3.2.2; and the GCVSZ in WLS COL FSAR Section 2.5.1.1.3.2.3. Other sections of this report summarize the information provided by the applicant in these four WLS COL FSAR sections related to the specific regional Quaternary tectonic structures defined above. The applicant described the remaining seven potential Quaternary tectonic structures (i.e., the Fall Lines of Weems, the Belair and Lindside fault zones, and the Pen Branch, Hares Crossroads, Stanleytown-Villa Heights, and Pembroke faults) in WLS COL FSAR Section 2.5.1.1.2.4.5. The following paragraphs summarize the information provided by the applicant in WLS COL FSAR Section 2.5.1.1.2.4.5 related to these seven potential Quaternary faults.

<u>Fall Lines of Weems (Class C)</u>

The applicant described the Fall Lines of Weems as alignments of rapids or anomalously steep sections of rivers draining the Piedmont and Blue Ridge physiographic provinces of North Carolina and Virginia (Figure 2.5.1-3 of this report), and stated that the features lie as close as 8 km (5 mi) to WLS. Based on published literature, field reconnaissance, and a review of the staff's evaluation of these features for the North Anna ESP application as presented in NUREG-1835, "Safety Evaluation Report for an Early Site Permit (ESP) at the North Anna ESP Site," issued September 2005, the applicant concluded that the Fall Lines of Weems developed due to a contrast in resistance to erosion of adjacent rock types and are not tectonic in origin.

Belair Fault Zone (Class C)

The applicant stated that a series of northeast-striking, southeast-dipping, oblique-slip faults comprise the Belair fault zone, which lies about 201 km (125 mi) south of WLS (Figure 2.5.1-3 of this report), and indicated that information provided by Prowell and O'Connor constrains last movement on the Belair fault zone to between late Eocene (< 33.9 Ma) and 26,000 years before present. The applicant concluded that, although the available data do not preclude Quaternary deformation along the fault zone, the data do not unequivocally demonstrate Quaternary movement in the zone.

Pen Branch Fault (Class C)

The applicant reported that the Pen Branch fault, located about 241 km (150 mi) south of WLS (Figure 2.5.1-3 of this report), is a northeast-striking structure that bounds the northwestern side of the buried Mesozoic (251 to 65.5 Ma) Dunbarton Basin, but has no surface expression. The applicant stated that seismic reflection and borehole data collected at the Savannah River Site, as well as investigations performed for the Vogtle ESP application to assess the age of the youngest strata deformed by the Pen Branch fault, show no evidence of fault movement younger than Eocene (55.8 to 33.9 Ma). The applicant concluded that the Pen Branch fault is not a capable tectonic structure.

Hares Crossroads Fault (Class C)

The applicant reported that Prowell postulated an offset of Coastal Plain strata by the Hares Crossroads fault based on field observations in a single roadcut at a location approximately 322 km (200 mi) east-northeast of WLS (Figure 2.5.1-3 of this report). Because the postulated fault occurs at a single location, the applicant concluded that it is most likely a local feature produced by landsliding and not a tectonic structure.

Lindside Fault Zone (Class C)

The applicant stated that the Lindside fault zone, located about 274 km (170 mi) north of WLS (Figure 2.5.1-3 of this report), is a northeast-striking normal fault, which does not exhibit any evidence for Quaternary movement.

Stanleytown-Villa Heights Faults (Class C)

The applicant indicated that the postulated Stanleytown-Villa Heights faults, located approximately 241 km (150 mi) northeast of WLS (Figure 2.5.1-3 of this report), mark the juxtaposition of Quaternary (2.6 Ma to present) alluvium and rocks of Cambrian (542 to 488 Ma) age. The applicant stated that field evidence summarized by Crone and Wheeler indicates these features are short, down-dropped in a downhill slope direction, and not associated with any other faults. The applicant concluded that field evidence suggests the faults most likely resulted from landsliding and are not tectonic structures.

Pembroke Faults (Class B)

The applicant reported that the postulated Pembroke faults lie about 241 km (150 mi) north of WLS (Figure 2.5.1-3 of this report) in alluvial deposits of probable Quaternary age, but exhibit no geomorphic expression and are possibly the result of dissolution collapse rather than tectonism.

2.5.1.2.1.3 *Regional Seismicity and Paleoseismology*

WLS COL FSAR Section 2.5.1.1.3 discusses the seismicity and paleoseismicity of the CEUS related to seismic sources that lie within the WLS region, as well as selected seismogenic tectonic sources that occur outside the site region. The applicant emphasized the discussion of tectonic features in the area around Charleston, SC, including postulated faults and possible seismic zones, because a currently unknown tectonic structure in that area produced the 1886 Charleston earthquake, one of the largest historical earthquakes ever to occur in the CEUS. The following subsections of this report summarize the information presented by the applicant in WLS COL FSAR Section 2.5.1.1.3 related to seismicity and paleoseismicity in and beyond the WLS region.

2.5.1.2.1.3.1 Seismic Source Zones and Potential Source Faults

In WLS COL FSAR Sections 2.5.1.1.3.1 and 2.5.1.1.3.2, the applicant addressed the seismicity of the CEUS and seismic sources defined by regional seismicity, respectively. In WLS COL FSAR Section 2.5.1.1.3.2, the applicant identified and discussed five principal areas of concentrated seismicity within 320 km (200 mi) of WLS and ten postulated buried source faults for the 1886 Charleston, SC earthquake. The applicant described the ten potential source faults for the 1886 Charleston, SC earthquake and three of the five areas of concentrated seismicity in the WLS region, specifically the three areas within 80 km (50 mi) of Charleston (i.e., the Middleton Place-Summerville, Bowman, and Adams Run seismic zones), in WLS COL FSAR Section 2.5.1.1.3.2.1. WLS COL FSAR Sections 2.5.1.1.3.2.2 and 2.5.1.1.3.2.3 address the remaining two areas of concentrated seismicity in the site region, the ETSZ and the GCVSZ, respectively. In WLS COL FSAR Section 2.5.1.1.3.2.4, the applicant discussed two areas of concentrated seismicity outside the site region, specifically the New Madrid and Central Virginia seismic zones. Figure 2.5.1-4 of this report shows the locations of all five principal areas of concentrated seismicity within WLS region and the two seismic zones located outside the site region. Based on data presented in the CEUS SSC model (NUREG-2115), the applicant considered only Charleston and the New Madrid seismic zone (NMSZ) as sources of repeated (i.e., two or more) large magnitude (i.e., M > 6.5) earthquakes, or RLMEs, in the PSHA for WLS as described in WLS COL FSAR Section 2.5.2.2.4.

Charleston Tectonic Features

In WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant reported that the 1886 Charleston earthquake generated a Modified Mercalli Intensity (MMI) X shaking in the epicentral area of the earthquake. This earthquake, with an expected moment magnitude (E[M]) of 6.9 (i.e., estimated given the uncertainty in earthquake magnitude), was the largest historical seismic event to occur in the eastern United States. The applicant stated that liquefaction and paleoliquefaction features discovered in coastal South Carolina provide evidence that the Charleston seismic source exhibits characteristics of an RLME source as discussed in the CEUS SSC model (NUREG-2115). The applicant acknowledged that there is no identifiable primary tectonic surface deformation feature associated with the 1886 earthquake, such that researchers infer an earthquake source based on the geology, geomorphology, and instrumental seismicity of the site region. The applicant noted that the CEUS SSC model (NUREG-2115) includes three alternative geometries for the Charleston seismic source, as discussed in WLS COL FSAR Section 2.5.2.2.4.1, since there is no known causative tectonic feature associated with the 1886 earthquake.

Charleston Area Seismic Zones and Potential Source Faults

In WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant discussed three zones of increased seismicity identified in the Charleston area, specifically the Middleton Place-Summerville, Bowman, and Adams Run seismic zones, as well as seismically-induced liquefaction features that occur in the Charleston area. Figure 2.5.1-4 of this report shows the locations of these three seismic zones. Since a specific source fault has not been defined for the 1886 Charleston earthquake, the applicant discussed ten postulated buried source faults for this earthquake, with all the faults located in or near the meizoseismal area (i.e., the area of maximum observed earthquake-induced damage due to shaking) of the earthquake. These ten postulated source faults include the East Coast Fault System (ECFS); the Helena Banks fault zone, located offshore southeast of Charleston and outside the meizoseismal area of the 1886 earthquake; and the Adams Run, Ashley River, Charleston, Cooke, Sawmill Branch, Dorchester, Summerville, and Woodstock faults. Figure 2.5.1-5 of this report shows the locations of these postulated source faults and the seismically-induced liquefaction features found in the Charleston area.

Charleston Area Seismically-Induced Liquefaction Features

In WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant also discussed spatial distribution and ages of seismically-induced liquefaction features that occur in the Charleston area and along the South Carolina coast to constrain possible locations and recurrence rates for large earthquakes related to a Charleston area seismic source. The applicant noted that the meizoseismal area for the 1886 Charleston area contains the heaviest concentration of liquefaction features (Figure 2.5.1-5 of this report), and that the presence of liquefaction features associated with the 1886 Charleston earthquake and paleoliquefaction features attributed to pre-1886 earthquakes demonstrate the occurrence of repeated large magnitude earthquakes (RLMEs) in the Charleston area.

Eastern Tennessee Seismic Zone

In WLS COL FSAR Section 2.5.1.1.3.2.2, the applicant described the ETSZ. The applicant noted that this zone, located about 241 km (150 mi) west-northwest of WLS (Figure 2.5.1-4 of this report), is one of the most active seismic zones in eastern North America in terms of small magnitude (i.e., **M** < 5) earthquakes, and that no damaging historical earthquakes have occurred in the zone. The applicant indicated that earthquakes in the ETSZ occur in Precambrian (> 542 Ma) crystalline basement rocks at a mean focal depth of about 14 km (9 mi), which is well below the 5 km (3 mi) depth of the Appalachian basal décollement separating Precambrian basement from younger rocks in the overlying thrust sheets. The applicant reported that earthquakes within the ETSZ cannot be related to any known capable tectonic structure, but that the western margin of the zone is coincident with the prominent magnetic gradient defined by the NYAL magnetic lineament. Although the CEUS SSC model (NUREG-2115) did not define the ETSZ as an RLME, the applicant reported that, based on field data, Hatcher and others have suggested one or more prehistoric earthquakes of M 6.5 may have occurred in the ETSZ within the last 73,000 to 200,000 years. The applicant explained how the CEUS SSC model (NUREG-2115) incorporates the ETSZ into the Paleozoic Extended Crust (PEZ) seismotectonic zone in WLS COL FSAR Section 2.5.2.2.3.5, and discussed geologic investigations conducted in the zone more extensively in WLS COL FSAR Section 2.5.2.2.5.1.

Giles County Seismic Zone

In WLS COL FSAR Section 2.5.1.1.3.2.3, the applicant discussed the Giles County seismic zone (GCVSZ), which lies in Virginia approximately 257 km (160 mi) north of WLS (Figure 2.5.1-4 of this report). The applicant stated that the largest earthquake to occur in the seismic zone was an **M** 5.9 event in 1897. The applicant noted that earthquakes in this zone occur in Precambrian crystalline basement rocks lying beneath the Appalachian thrust sheets at depths of 5 to 26 km (3 to 16 mi). The applicant stated that no capable tectonic structures have been identified in the GCVSZ. The applicant explained how the CEUS SSC model (NUREG-2115) incorporates this seismic zone into the PEZ seismotectonic zone in WLS COL FSAR Section 2.5.2.2.3.5.

Concentrated Seismicity Outside the Site Region

In WLS COL FSAR Section 2.5.1.1.3.2.4, the applicant described two areas of concentrated seismicity outside the WLS region, specifically the New Madrid and Central Virginia seismic zones. Figure 2.5.1-4 of this report shows the locations of these two seismic zones.

The NMSZ extends from southeastern Missouri to southwestern Tennessee and lies more than 724 km (450 mi) west of WLS. The applicant reported that three large-magnitude historical earthquakes occurred in this zone between December 1811 and February 1812, with magnitudes interpreted by area experts ranging from **M** 7.2 to **M** 8.1. The applicant noted that recent published paleoseismic data suggest a mean earthquake recurrence interval of 500 years for the NMSZ. However, the applicant also noted that paleoseismic studies suggest seismic activity in this zone during the Holocene (0.01 Ma to present) may not be indicative of the long-term recurrence rate based on information provided in the CEUS SSC model (NUREG-2115). The applicant discussed temporal clustering models and uncertainties associated with the paleoliquefaction record and recurrence and explained how the CEUS SSC model (NUREG-2115) incorporated this zone as an RLME in WLS COL FSAR Section 2.5.2.2.4.2.

The Central Virginia seismic zone (CVSZ) is an area of persistent, low-level seismicity located more than 402 km (250 mi) north-northeast of WLS. This zone extends about 120 km (75 mi) in a north-south direction and about 144 km (90 mi) in an east-west direction from Richmond, VA, to Lynchburg, VA. The applicant noted that no causative surface faults have been identified in the zone. The applicant reported that the largest historical earthquake in the CVSZ occurred near Mineral, VA, in August 2011 with a magnitude (M_w) of 5.8, and discussed the investigations conducted for the Mineral earthquake in more detail in WLS COL FSAR Section 2.5.2.2.5.2.

2.5.1.2.2 Site Geology

WLS COL FSAR Section 2.5.1.2 describes geologic characteristics of the WLS area and site location, defined as the areas lying within an 8 km (5 mi) and a 1 km (0.6 mi) radius of the site, respectively. These characteristics include physiography and geomorphology, geologic setting and history, stratigraphy and lithology, structural geology, engineering geology, seismicity and paleoseismicity, and groundwater conditions. For the discussion of seismicity and paleoseismicity, the applicant also included the area lying within a 40 km (25 mi) radius of the site (i.e., the site vicinity). The following subsections of this report summarize the information provided by the applicant in WLS COL FSAR Section 2.5.1.2.

2.5.1.2.2.1.1 Site Area Physiography and Geomorphology

In WLS COL FSAR Section 2.5.1.2.1, the applicant described the physiography and geomorphology of the WLS area. The applicant indicated that the site lies within the Piedmont physiographic province of central South Carolina on the western side of the Broad River, bounded by the Coastal Plain province to the southeast and the Blue Ridge province to the northwest (Figure 2.5.1-1 of this report). The Broad River is the primary drainage in the site area. The applicant reported that gently to moderate rolling hills and well-drained mature valleys characterize topography of the site area, with elevations ranging from about 122 m to 305 m (400 to 1,000 ft) above mean sea level (MSL).

The applicant stated that residual soils and saprolite overlie igneous and metamorphic bedrock in the site area. The applicant noted that prominent lineaments associated with topographic ridges in the site area reflect patterns of stream erosion controlled by erosion-resistant rock units, rather than by surface displacement along tectonic structures, and concluded that no topographic features in the site area suggest surface faulting related to tectonic deformation.

2.5.1.2.2.2 *Site Area Geologic Setting and History*

In WLS COL FSAR Section 2.5.1.2.2, the applicant described the geologic setting and history of the WLS area. The applicant stated that metamorphosed and complexly deformed plutonic and volcanic rocks and associated metasedimentary rock units underlie the site area, which lies in the western part of the Charlotte terrane of the Carolina Zone (Figure 2.5.1-2 of this report). The applicant indicated that rocks comprising the Charlotte terrane exhibit a long and complex geologic history from Neoproterozoic (1000 to 542 Ma) through Triassic (251 to 201.6 Ma), including magmatic activity related to the opening of the modern Atlantic Ocean basin. The applicant reported that Charlotte terrane rocks in the site area show the effects of early Cambrian (542 to 535 Ma) metamorphism and deformation; tectonic and thermal events during Silurian (444 to 416 Ma), Devonian (416 to 359 Ma) and Carboniferous-Permian (the Alleghanian orogeny at 359 to 251 Ma) time; and Mesozoic (specifically Triassic-Jurassic, 251 to 145.5 Ma) extension and magmatism.

2.5.1.2.2.3 *Site Area Stratigraphy and Lithology*

In WLS COL FSAR Section 2.5.1.2.3, the applicant discussed site area stratigraphy and lithology. The applicant stated that rock units in the WLS area generally belong to the Battleground Formation, defined by Horton as Neoproterozoic (1,000 to 542 Ma) in age, with younger cross-cutting Triassic and Jurassic (251 to 145.5 Ma) intrusive igneous dikes. The applicant described the Battleground Formation as a volcaniclastic sequence intruded by its own parent magma, made up of metamorphosed felsic to intermediate composition rocks, metavolcaniclastic sequences with metaigneous intrusions of similar compositions, and interlayered metasedimentary rock units. The applicant explained that few primary features remain in this lithologic sequence for determining stratigraphic relationships, due primarily to metamorphism and intense deformation of the rock units. The applicant described individual rock units of the Battleground Formation in WLS COL FSAR Section 2.5.1.2.3, and reported that one of the metamorphosed intrusive igneous bodies of that formation, rock unit "Zto" (Figure 2.5.1-6 of this report), is the foundation unit for WLS. The applicant also stated that Quaternary alluvium made up of gravel, sand, and silt deposits occurs in river and stream valleys in the site area.

2.5.1.2.2.4 *Site Area Structural Geology*

In WLS COL FSAR Section 2.5.1.2.4, the applicant discussed the structural geology of the site area. The applicant stated that geologic structures observed in the site area and at the site location include deformation features that developed during five regional deformational episodes, D1 through D5, and affected rock units in the site vicinity and site area and at the site location. Based on observed field relationships, the applicant indicated geologic structures that developed during deformational episodes D1 and D2 formed during a metamorphic event about 549 to 535 Ma ago. The applicant reported that radiometric dates constrain the age of the D3, D4 and D5 deformational episodes to be no younger than 296 Ma. The following sections of this report summarize the information presented by the applicant in WLS COL FSAR Sections 2.5.1.2.4 on geologic structures in the WLS area.

2.5.1.2.2.4.1 Structures in the Site Area

In WLS COL FSAR Section 2.5.1.2.4, the applicant discussed site area geologic structures, including the Cherokee Falls and Draytonville synforms (i.e., folds with limbs closing downward, applied when the stratigraphic order of the folded sequence is unknown) and minor surfaces exhibiting slickensides (i.e., surficial striations that typically occur on a fault plane, which indicate direction, but not amount, of displacement along the fault). Based on field relationships, the applicant interpreted the Cherokee Falls and Draytonville synforms, both located about 7 km (4.5 mi) northwest of WLS, as D2 deformation features. The applicant also reported that several small-scale minor faults described in the CNS PSAR, located 6.4 km (4 mi) north and 9.7 km (6 mi) northwest of WLS in rocks that are Neoproterozoic to Cambrian in age (> 535 Ma), could not be traced laterally and are typical of older, minor geologic structures commonly found in the Piedmont.

The applicant discussed minor slickensided surfaces that occur at Cherokee Falls, SC, 4.8 km (3 mi) northwest of the site, and Draytonville, SC, 6.4 km (4 mi) west of the site, as described in the CNS PSAR. The applicant stated that these surfaces exhibiting slickensides could not be traced beyond a single exposure, a field observation suggesting the slickensides do not mark a through-going fault. The applicant also stated that field work performed for the WLS application did not reveal these reported slickensided surfaces. Therefore, the applicant concluded that the slickensided surfaces represent minor, localized structures similar to those found throughout the

Piedmont, and that they do not provide any evidence for Quaternary (2.6 Ma to present) fault movement.

2.5.1.2.2.5 *Site Location Geology*

In WLS COL FSAR Section 2.4.1.2.5, the applicant discussed the geology of the WLS location, which is the area located within a 1-km (0.6-mi) radius of the site. The applicant specifically addressed physiography and geomorphology, geologic setting and history, stratigraphy and lithology, structure, and geologic mapping in relation to site location.

2.5.1.2.2.5.1 Site Location Physiography and Geomorphology

In WLS COL FSAR Section 2.5.1.2.5.1, the applicant described the physiography and geomorphology of the site location. The applicant reported that the physiography and geomorphology observed at the site location are typical of the site area as described in WLS COL FSAR Section 2.5.1.2.1. Elevations at the site location range from 155 m to 250 m (510 to 820 ft) above MSL, with the observed relief primarily the result of stream drainage incision. The applicant indicated that an erosion-resistant quartzite unit holds up McKown's Mountain, the north-northeast-trending linear ridge located northwest of WLS (Figure 2.5.1-6 of this report).

2.5.1.2.2.5.2 Site Location Geologic Setting and History

In WLS COL FSAR Section 2.5.1.2.5.2, the applicant discussed the geologic setting and history of the site location. The applicant indicated that site location setting and history are generally congruent with the site area as described in WLS COL FSAR Section 2.5.1.2.2. However, the applicant noted that, of the five regional deformation episodes (D1 through D5) documented in the site area, rock units at the site location most strongly record only two of the five events (i.e., D1 and D2). The applicant stated that variations in strength and anisotropy between the metaplutonic rock mass comprising foundation unit Zto and the surrounding metavolcanic and metasedimentary country rocks resulted in the development of different tectonic structures in the different rock units, making it difficult to distinguish structures produced by deformation events D1 and D2.

2.5.1.2.2.5.3 Site Location Stratigraphy and Lithology

In WLS COL FSAR Section 2.5.1.2.5.3, the applicant described the stratigraphy and lithology of the WLS location. The applicant indicated that rock unit Zto (Figure 2.5.1-6 of this report) is the foundation unit for WLS, and that saprolite, with a maximum thickness of 30 m (100 ft), is typically 12 to 24 m (40 to 80 ft) thick at the site location. The applicant noted that Quaternary alluvium composed of gravel, sand, and silt deposits occurs in river and stream valleys.

2.5.1.2.2.5.4 Site Location Structure

In WLS COL FSAR Section 2.5.1.2.5.4, the applicant discussed the geologic structures mapped at the site location. These structures include the McKown's Creek antiform (i.e., a fold with limbs closing upward, applied when stratigraphic order of the folded sequence is unknown), shear and breccia zones, dilation fractures, joints, and slickensides. The applicant indicated that, although foundation rock unit Zto is generally massive, the unit locally exhibits discrete geologic structures expressed as fractures, joints, and shear and breccia zones at the site location.

McKown's Creek Antiform

Based on Schaeffer, the applicant interpreted the McKown's Creek antiform as a D2 deformation structure that developed around 542 Ma ago. The applicant noted that WLS foundation unit Zto lies in the nose of this proposed fold. The applicant reported that the more recent geologic map of Nystrom does not include the McKown's Creek antiform, and that most of the folds reflected in geologic map patterns at the site location resulted from deformation D2.

Shear and Breccia Zones, Dilation Fractures, and Joints

The applicant stated that shear and breccia zones, which occur at the site location in foundation rock unit Zto, show preferential development in smaller mafic dikes and along the margins of larger mafic dikes that intrude the foundation unit. The applicant indicated that the best-developed shear and breccia zones, initially studied during investigations performed for the Cherokee site, strike a few degrees east of north and dip steeply to the southeast, while a secondary set strikes northwest and dips moderately to the southwest. The applicant reported that the shear and breccia zones exhibit an early ductile fabric overprinted by a later-stage brittle fabric, and that a potassium-argon (K-Ar) radiometric age date constrains timing of the shearing and brecciation to be older than 219 Ma. The applicant obtained the K-Ar age date on potassium feldspar, collected during site characterization of the Cherokee site from an undeformed igneous vein cutting across one shear zone.

The applicant indicated that igneous veins containing undeformed minerals, including potassium feldspar, in rock unit Zto cut across the shear and breccia zones as dilation fractures (i.e., fractures opened by expansion perpendicular to the walls of the fracture, rather than by shearing parallel to the fracture). The applicant reported that the K-Ar radiometric age date discussed in the above paragraph also constrains timing of development of the dilation fractures to be older than 219 Ma. The applicant reported that steeply-dipping (i.e., 60 degrees to vertical) joints are common at the site location and exhibit a range of strike directions.

Slickensides

The applicant reported the occurrence of slickensides on joint surfaces and along contacts between different rock types at the site location, and stated that the slickensides post-date the dilation fractures and shear and breccia zones since the slickensided surfaces cross-cut the dilation fractures and shear and breccia zones. The applicant noted the common occurrence of chlorite mica on the slickensided surfaces, and concluded that minor movement along the surfaces must have occurred more than 219 Ma ago in connection with the metamorphic event that produced the chlorite (i.e., a greenschist facies metamorphic event, interpreted to occur within a temperature range of 300-500 degrees centigrade). The applicant indicated that slickensides also occur on discontinuous surfaces in partially weathered rock and saprolite.

2.5.1.2.2.5.5 Site Location Geologic Mapping

In WLS COL FSAR Section 2.5.1.2.5.5, the applicant summarized geologic mapping efforts conducted for WLS to document geologic characteristics of foundation bedrock at the site location. To confirm the results of previous geologic mapping of bedrock exposures in excavations at the CNS site as part of the investigations for the WLS application, the applicant performed geologic mapping to define lithologies and major tectonic features in foundation grade level bedrock exposed in a portion of the CNS Unit 2 excavation and compared that geologic map to scanned records for the CNS site located in the Duke archives. The applicant reported agreement between this confirmatory map and the original CNS Unit 2 geologic map of foundation grade level bedrock. The applicant also mapped available exposures of the top of sound rock (i.e., not foundation grade level bedrock) in the CNS Unit 3 excavation to preliminarily assess lithologies and major tectonic features at WLS Unit 2, which is coincident with CNS Unit 3.

The applicant likewise documented lithologies and tectonic features (i.e., faults, shear and breccia zones, and fractures) that occur in foundation grade level bedrock underlying CNS Unit 1, which coincides with WLS Unit 1. The documentation materials included detailed geologic maps of the foundation grade level bedrock surface in the CNS Unit 1 excavation that now lies under concrete, produced by digitizing and compiling the original field maps prepared for CNS Unit 1, and a report containing the compiled digital maps and associated data. Based on these materials for CNS Unit 1, the confirmatory mapping of a portion of CNS Unit 2, and the preliminary mapping of exposures at CNS Unit 3, the applicant confirmed the similarity of rock types and orientations and ages of tectonic structures in the excavations for WLS/CNS Unit 1, CNS Unit 2, and WLS Unit 2/CNS Unit 3. Regarding the age of tectonic features, based on undeformed mineral assemblages associated with a prominent fault zone (initially designated as “Fault Zone 6”) mapped in the excavation for the CNS Unit 1 reactor and auxiliary buildings, the applicant concluded that the fault zone must have developed prior to 170 Ma (i.e., middle Mesozoic). Closure temperatures and age relationships determined by the applicant for undeformed minerals in other minor fault zones also generally indicated that tectonic deformation at WLS is older than early Mesozoic (i.e., > 201.6 Ma). Therefore, based on results of the geologic mapping conducted at the site location as described above in combination with information on mineral closure temperatures and age dates, the applicant concluded that foundation bedrock at WLS does not contain any tectonic structures of Quaternary age (i.e., potentially capable tectonic structures).

2.5.1.2.2.6 *Site Area Engineering Geology*

In WLS COL FSAR Section 2.5.1.2.6, the applicant discussed the engineering geology of the WLS area and site location. The applicant indicated that unweathered crystalline rock of the Battleground Formation underlies the site area and site location, and that the foundation unit is a metamorphosed igneous intrusive rock body (i.e., Unit Zto, shown in Figure 2.5.1-6 of this report). The applicant stated that average shear wave velocities greater than 2,804 m/sec (9,200 ft/sec) characterize unweathered rock materials underlying the site. The applicant also stated that no mining operations, excessive extraction or injection of groundwater, or impoundments of water occur within the site area that could detrimentally affect geologic conditions, and that bedrock at the site is not susceptible to settlement or subsidence due to groundwater withdrawal. The applicant cross-referenced WLS COL FSAR Section 2.5.4 for additional details related to the engineering geology of the site area and site location. In WLS COL FSAR Section 2.5.4.5.3.1, the applicant specifically indicated that geologic mapping of the final exposed foundation-bearing rock surface would be performed upon completion of subsequent excavations related to the nuclear islands.

2.5.1.2.2.7 *Site Area Seismicity and Paleoseismology*

In WLS COL FSAR Section 2.5.1.2.7, the applicant discussed site area and site vicinity seismicity and paleoseismology. Based on the updated seismicity catalog used for the CEUS SSC model (NUREG-2115), the applicant noted that the largest earthquake within 40 km (25 mi) of the site was an E[M] 4.13 event in 1886. The applicant stated that the January 1913 E[M] 4.54 earthquake in Union County, SC, which does not have a well-defined epicenter but occurred at the margin of the site vicinity about 40 km (25 mi) south-southwest of WLS, produced an estimated Rossi-Forel shaking intensity at the site of VI. The applicant indicated that no causative tectonic feature has been identified for the Union County earthquake. The estimated Modified Mercalli Intensity at the site for the 1886 Charleston earthquake was VI.

Concerning geologic features that may indicate paleoseismic events occurred in the site area, the applicant stated that no published data indicate the presence of paleoseismic features in the site area. Based on extensive studies of outcrops during field reconnaissance investigations for WLS, the applicant also stated that no evidence exists for post-Miocene (< 5.3 Ma) earthquake activity in the site area.

2.5.1.2.2.8 *Site Area Groundwater Conditions*

WLS COL FSAR Section 2.5.1.2.8 cross-references WLS COL FSAR Section 2.4.12 for the detailed discussion of groundwater conditions presented by the applicant for WLS.

2.5.1.3 *Regulatory Basis*

NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design,” and its supplements address the regulatory basis for information incorporated by reference.

The applicable regulatory requirements for geologic and seismic information are as follows:

- Title 10 of the *Code of Federal Regulations* (10 CFR) 52.79(a)(1)(iii), “Contents of Applications: Technical Information in Final Safety Analysis Report,” as it relates to including in the WLS COL FSAR information on seismic and geologic characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR 100.23, “Geologic and Seismic Siting Criteria,” for evaluating the suitability of a proposed site based on the consideration of geologic, geotechnical, geophysical, and seismic characteristics of the proposed site. Geologic and seismic siting factors must include the safe shutdown earthquake ground motion (SSE) for the site and the potential for surface tectonic and non-tectonic deformation.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for basic geologic and seismic information are given in NUREG-0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants,” Section 2.5.1, as follows:

- Regional Geology: Requirements of General Design Criterion (GDC) 2 of 10 CFR Part 50, Appendix A, 10 CFR 52.17 and 10 CFR 100.23(c) are met and guidance in RG 1.206, RG 1.208, and RG 4.7 followed for this area of review if a complete and documented discussion is presented for the geologic setting, tectonic framework and conditions caused by human activities, that have the potential to affect the safe siting and design of the plant. This section should contain a review of regional stratigraphy, lithology, structural geology, geologic and tectonic history, tectonic features (with emphasis on the Quaternary period), seismology, geomorphology, paleoseismology, and physiography within the 320-km (200-mi) site region or beyond as necessary to provide a framework within which significance to safety can be evaluated concerning geology, seismology, and conditions caused by human activities. Geologic maps and cross-sections constructed at scales adequate to illustrate relevant regional features should be included in the application.

- Site Geology: Requirements of GDC 2 in 10 CFR Part 50, Appendix A, 10 CFR 52.17 and 10 CFR 100.23 (c) are met and guidance in RG 1.206, RG 1.208, and RG 4.7 followed for this area of review if it contains a description and evaluation of geologic features, tectonic features, and conditions caused by human activities at appropriate levels of detail for determining any potential natural hazards that might affect the design and operation of the proposed facility. This subsection should contain the following information:

    a. Structural geology, including identification and characterization of faults, joints, and other tectonic deformation features and discussion of the relationships between these features and regional tectonic structures.

    b. Geologic maps and cross-sections constructed at scales adequate to clearly illustrate pertinent features in the site vicinity, area and location shall be included in the application.

    c. Stratigraphy and lithology of rock units and discussion of their relationships to the regional lithostratigraphic framework.

    d. Geomorphologic features as tectonic strain markers or indicators of other potentially hazardous natural phenomena (e.g., landslides, karst development and dissolution collapse, growth faults).

    e. Geologic and tectonic history, particularly for the Quaternary Period, and discussion of the relationship to regional geologic and tectonic history.

f. Tectonic framework description, including identification of historical and instrumentally-recorded earthquakes; identification and characterization of any local tectonic features as they might be related to seismicity; discussion of the relationships between local and regional tectonic structures and any relationship to seismicity; and the nature of the crust beneath the site.

g. Evidence for paleoseismic features, including a description of investigations performed by the applicant to verify the presence or absence of the features.

h. Geologic features that have significance for geotechnical engineering:

    1) Zones of mineralization, alteration, irregular or deep weathering, or structural weakness in surface or subsurface materials

    2) Surface and subsurface dissolution features in soluble rock such as limestone, gypsum, or salt

Geologic characteristics should also be consistent with the appropriate sections from RG 1.132, Revision 2, “Site Investigations for Foundations of Nuclear Power Plants”; RG 1.138, Revision 2, “Laboratory Investigations of Soils and Rocks for Engineering Analysis and Design of Nuclear Power Plants”; RG 1.198, “Procedures and Criteria for Assessing Seismic Soil Liquefaction at Nuclear Power Plant Sites”; RG 1.206; and RG 1.208.

2.5.1.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.5.1 and the referenced DCD to ensure that the combination of information presented in the WLS COL FSAR and the DCD completely represents the required information related to basic geologic and seismic characteristics. The staff confirmed, as described below, that information contained in the application or incorporated by reference addresses the information required for this review topic. NUREG-1793 and its supplements document the results of the staff’s evaluation of information incorporated by reference into the WLS application.

The staff reviewed the following information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 2.5-1

The staff reviewed WLS COL 2.5-1 regarding the geologic, seismic, and geophysical information included in WLS COL FSAR Section 2.5.1. The COL information item in AP1000 DCD Section 2.5.1 states:

> Combined License applicants referencing the AP1000 certified design will address the following regional and site-specific geological, seismological, and geophysical information as well as conditions caused by human activities: (1) structural geology of the site, (2) seismicity of the site, (3) geologic history, (4) evidence of paleoseismicity, (5) site stratigraphy and lithology, (6) engineering

significance of geologic features, (7) site groundwater conditions, (8) dynamic behavior during prior earthquakes, (9) zones of alteration, irregular weathering, or structural weakness, (10) unrelieved residual stresses in bedrock, (11) materials that could be unstable because of mineralogy or physical properties, and (12) effect of human activities in the area.

WLS COL FSAR Section 2.5.1 contains geologic and seismic information collected by the applicant in support of the vibratory ground motion analysis and the site-specific GMRS provided in WLS COL FSAR Section 2.5.2. RG 1.208 recommends that applicants update the geologic, seismic, and geophysical database and evaluate any new data to determine whether revisions to the existing seismic source models are necessary. Consequently, the staff focused on geologic and seismic data published since the middle to late 1980s (i.e., after the original studies conducted by EPRI), including information in the CEUS SSC model as presented in NUREG-2115, to assess whether these data required updates of existing seismic source models. Through its review of WLS COL FSAR Section 2.5.1 and the report presenting the compiled geologic map for WLS/CNS Unit 1 excavation, the staff determined whether the applicant had complied with the applicable regulations and conducted the investigations at an appropriate level of detail in accordance with RG 1.208.

As part of the technical evaluation of WLS COL FSAR Section 2.5.1, the staff visited WLS between April 27 and May 2, 2008, on January 27 and 28, 2009, on July 12 to 14, 2011, and on February 10, 2014, to meet with the applicant regarding the geologic, seismic, geophysical, and geotechnical investigations conducted to characterize the site. Technical experts from the U.S. Geological Survey (USGS) accompanied the staff during the January 2009 site visit to assist with the evaluation of the geologic and seismic data.

During the site visits conducted in April to May 2008 and January 2009, the staff examined site location bedrock exposures in the excavations for the original CNS Unit 3 (i.e., WLS Unit 2 with the top of sound rock, not foundation grade level bedrock, exposed) and CNS Unit 2 (with foundation level bedrock exposed), and around the original CNS Unit 1 (WLS Unit 1) where no concrete had been previously placed. The staff also examined saprolite in the walls of the CNS excavations, core samples collected during site characterization investigations for the WLS application, and select bedrock exposures in the site area to assist with understanding the complex tectonic deformation history reflected in rock units at the site location.

The July 2011 site visit occurred after the applicant had provided Version 0 of the compiled geologic map report for the foundation grade level bedrock surface in the CNS/WLS Unit 1 excavation. The staff conducted a data documentation audit of Version 0 of the Duke report presenting the compiled geologic map and associated data for CNS Unit 1 on June 6, June 9, and June 10, 2011. The staff also audited Version 1 of the Duke report between October 25 and 27, 2011, to ensure that the final version of the report contained the necessary information related to documenting similarities in both lithologies and geologic features found in the CNS Unit 1 (proposed WLS Unit 1) excavation and in the adjacent excavations for CNS Unit 3 (proposed WLS Unit 2) and CNS Unit 2. During the site visit, the staff focused on analyzing lithologies and geologic structures shown on the compiled geologic map for the CNS Unit 1 excavation, which now lies under concrete. The staff directly examined lithologies and geologic structures in the existing adjacent excavations for the original CNS Unit 3 (i.e., WLS Unit 2 excavated to the top of sound rock) and CNS Unit 2 (located between WLS Units 1 and 2 and excavated to foundation grade level) and confirmed that the compiled geologic map accurately represents lithologies and geologic structures found in the CNS/WLS Unit 1 excavation. The data documentation audits and July site visit also enabled the staff to verify that lithologies and geologic features are similar among WLS/CNS Unit 1, WLS Unit 2/CNS Unit 3, and CNS Unit 2 and that no capable tectonic structures or other potentially detrimental geologic features occur in the concrete-covered excavation for proposed WLS Unit 1 (previous CNS Unit 1) or in the existing open excavations for CNS Unit 3 (proposed WLS Unit 2) and CNS Unit 2.

During the site visit in February 2014, the staff directly examined core from the following four select boreholes placed at the modified locations of the nuclear islands for WLS Unit 1, which is coincident with the previous CNS Unit 1, and WLS Unit 2, which is coincident with previous CNS Unit 3: B-2000 (total depth, or TD, = 38.4 m (126.0 ft)) and B-2002 (TD = 68.8 m (225.6 ft)) for Unit 1; B-2005 (TD = 68.6 m (225.0 ft)) and B-2006 (TD = 30.8 m (101.0 ft)) for Unit 2. The applicant moved the Unit 1 nuclear island footprint 20.1m (66 ft) south and 15.2 m (50 ft) east of CNS Unit 1 to avoid an area of deeply weathered saprolitic bedrock at the northwest corner of old CNS Unit 1. The applicant also moved the Unit 2 nuclear island footprint 20.1 m (66 ft) south. The site visit occurred after the staff had reviewed core logs and core images for all seven bore holes placed to characterize subsurface geologic conditions in the relocated nuclear island footprints in order to determine which cores were most appropriate for direct examination. The purpose of the site visit was to verify that lithologic units and tectonic deformation features intercepted by the boreholes in the subsurface at the locations of the relocated footprints were similar to what had been observed in boreholes from the previous footprint locations and in the foundation rock units exposed in the existing original excavations for the CNS site, including lithologic units and tectonic deformation structures previously mapped in the foundation grade level bedrock of the CNS Unit 1 excavation. Based on a detailed examination of the four cores and field observation of the locations of the new boreholes combined with consideration of the information derived from previous boreholes, examination of exposed bedrock that will comprise the foundation grade level units for WLS, and review of the geologic maps of the CNS Unit excavation, the staff concluded that lithologic units and tectonic deformation features similar to those previously described occur in the cores from the relocated footprints. Furthermore, B-2000 clearly illustrates that the applicant has avoided the zone of deeply weathered rock at the northwest corner of the original WLS Unit 1 since the core shows that, at 2.96 m (9.7 ft) depth, the borehole passes from the tightly-bonded concrete-bedrock interface into only slightly weathered bedrock.

Since tectonic deformation features (specifically ductile and brittle shear zones and other older tectonic features associated with the complex deformation history of the site) occur in bedrock in the site area and at the site location, on February 23 and July 20, 2009, the staff also audited materials used by the applicant to constrain the timing of the development of minor ductile and brittle shear zones mapped in the excavations at the original CNS site as part of the technical evaluation of WLS COL FSAR Section 2.5.1. These materials contained data on radiometric age dates previously acquired by the applicant for characterization of the original CNS site. Understanding the constraints on the timing of deformation provided by these original age dates is important because the applicant did not obtain additional radiometric ages during site characterization investigations for WLS, but rather relied on the previously acquired age dates to document the timing of the development of tectonic deformation features in the WLS application. In addition, the staff audited Revision 0 and Revision 1 of the report discussing the compiled geologic map and associated data on June 6, June 9 and 10, and October 25 through 27, 2011. The Duke report documented the characterization of the foundation grade level bedrock surface in the WLS Unit 1 excavation based on the previous geologic mapping of foundation grade level bedrock conducted in the co-located CNS Unit 1 excavation.

Through the multiple site visits and data documentation audits described above, the staff assessed the interpretations, assumptions, and conclusions made by the applicant regarding basic geologic and seismic information for WLS and acceptability of geologic conditions at WLS Units 1 and 2, particularly with regard to age constraints for the ductile and brittle shear zones. The staff confirmed that no geologic features found in foundation bedrock units represent capable tectonic structures.

Based on the discussion of the basic geologic and seismic information presented in WLS COL FSAR Section 2.5.1, and the independent staff evaluation described in Section 2.5.1.4 of this report, the staff concludes that the applicant provided the information required to satisfy COL Information Item 2.5-1.

Sections 2.5.1.4.1, "Regional Geology," and 2.5.1.4.2, "Site Geology," of this report present the staff's technical evaluation of the information provided by the applicant in WLS COL FSAR Section 2.5.1 and the applicant's responses to RAIs for WLS COL FSAR Section 2.5.1.
In addition to RAIs addressing specific technical issues related to regional and site geology of WLS, discussed in detail below, the staff prepared several editorial RAIs to clarify certain descriptive statements made by the applicant in the WLS COL FSAR and to qualify geologic features illustrated in WLS COL FSAR figures. This technical evaluation does not discuss these editorial RAIs because they do not alter the substantive technical information provided by the applicant. Also, this evaluation does not discuss RAIs related to geologic issues resolved in FSARs previously prepared for other sites in the CEUS, but rather addresses these issues by reference to and a summary of the information used to resolve them in those FSARs.

2.5.1.4.1 Regional Geology

The staff focused the review of WLS COL FSAR Section 2.5.1.1 on the descriptions provided for physiography, geomorphology, stratigraphy, tectonic setting, seismicity, and paleoseismology within a 320 km (200 mi) radius of WLS. The staff specifically focused on geologic features in the site region interpreted to be Quaternary (2.6 Ma to present) in age.

2.5.1.4.1.1 *Regional Physiography, Geomorphology, and Stratigraphy*

WLS COL FSAR Section 2.5.1.1.1 discusses the regional physiography, geomorphology, and stratigraphy of WLS, including the geologic setting of the Piedmont physiographic province in which WLS lies. Figure 02.05.01-1 of this report shows the location of WLS in relation to the parts of the five physiographic provinces that occur in the site region (i.e., the Appalachian Plateau, Valley and Ridge, Blue Ridge, Piedmont, and Atlantic Coastal Plain).

The staff focused the review of WLS COL FSAR Section 2.5.1.1.1 on the applicant's discussion of the Carolina Zone of the Piedmont physiographic province in which WLS lies. In RAI 59, Questions 02.05.01-3 and 02.05.01-4, the staff requested that the applicant clearly distinguish the Carolina Zone from adjacent lithotectonic terranes, and to incorporate pertinent information from more recent published references for describing the lithologic, stratigraphic, and tectonic characteristics of the Carolina Zone because WLS COL FSAR Section 2.5.1.1.1 lacked the information derived from these references. In response to RAI 59, Questions 02.05.01-3 and 02.05.01-4, the applicant clearly distinguished the Carolina Zone from the adjacent lithotectonic terranes by modifying WLS COL FSAR Figures 2.5.1-202a and 2.5.1-202b, as well as by including new WLS COL FSAR Figure 2.5.1-235 to show the correlations between physiographic provinces and recent classifications of lithotectonic terranes in the site region. The applicant also presented information derived from the more recent published references that describe the lithologic, stratigraphic, and tectonic characteristics of the Carolina Zone. The applicant incorporated the three figures and the updated descriptions of the Carolina Zone into WLS COL FSAR Section 2.5.1.

Based on review of the responses to RAI 59, Questions 02.05.01-3 and 02.05.01-4 and the figures and descriptions provided in WLS COL FSAR Section 2.5.1, as well as an independent examination of the current literature cited by the applicant, the staff concludes that the applicant adequately distinguished and characterized the Carolina Zone in which the site lies. The staff draws this conclusion because the applicant incorporated information from up-to-date references into WLS COL FSAR Section 2.5.1. Accordingly, the staff considers RAI 59, Questions 02.05.01-3 and 02.05.01-4 resolved.

Based on review of F WLS COL FSAR Section 2.5.1.1.1, the responses to RAI 59, Questions 02.05.01-3 and 02.05.01-4, and an independent examination of current literature cited by the applicant, the staff finds that the applicant provided a thorough and accurate description of regional physiography, geomorphology, and stratigraphy in support of the WLS application.

2.5.1.4.1.2 *Regional Tectonic Setting*

WLS COL FSAR Section 2.5.1.1.2 discusses the regional tectonic setting of WLS, including regional geologic history, tectonic stress in the mid-continent region, gravity and magnetic data of the site region and site vicinity, and principal regional tectonic structures. The following paragraphs present the staff's evaluation of WLS COL FSAR Sections 2.5.1.1.2.1 through 2.5.1.1.2.4. The staff performed the most detailed evaluation for the 15 potential Quaternary tectonic structures identified in the site region because these structures represent potentially capable tectonic features.

2.5.1.4.1.2.1 Regional Geologic History

In WLS COL FSAR Section 2.5.1.1.2.1, the applicant discussed geologic history of WLS region. The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.1 on the applicant's discussion of the possibility that earthquakes in the eastern part of the Piedmont physiographic province and beneath the Coastal Plain province may be spatially associated with buried normal faults that initially developed during the early and middle Mesozoic rifting of the continental crust. The applicant indicated that there is no definitive spatial correlation of seismicity with any faults known to bound Mesozoic rift basins in the site region. The staff evaluated this interpretation further as described in Section 2.5.1.4.1.2.4 below.

Based on review of WLS COL FSAR Section 2.5.1.1.2.1 and an independent examination of references cited by the applicant, the staff concludes that the applicant presented information pertinent for describing the geologic history of the WLS region. The staff makes this conclusion because the applicant included information to adequately address the geologic history for the region including WLS from Paleozoic (542 to 251 Ma) to Quaternary (2.6 Ma to present) time.

Based on review of WLS COL FSAR Section 2.5.1.1.2.1 and an independent examination of references cited by the applicant, the staff finds that the applicant provided a thorough and accurate description of regional geologic history in support of the WLS application.

2.5.1.4.1.2.2 Tectonic Stress in the Mid-Continent Region

In WLS COL FSAR Section 2.5.1.1.2.2, the applicant discussed tectonic stress in the mid-continent region, including data from the CEUS SSC model (NUREG-2115) compilations. The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.2 on information used by the applicant to document that no new concerns exist regarding the potential for tectonic activity along geologic structures in the site region due to changes in orientation of the regional stress field. Based on review of WLS COL FSAR Section 2.5.1.1.2.2 and an independent examination of the references cited by the applicant in that WLS COL FSAR section, the staff concludes that the data presented by the applicant document a continuing northeast-southwest orientation for maximum horizontal compressive stress in the site region. The staff draws this conclusion because all published regional stress data presented by the applicant and independently reviewed by the staff fully support it.

Based on review of WLS COL FSAR Section 2.5.1.1.2.2 and an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff finds that the applicant provided a thorough and accurate description of tectonic stress in the mid-continent region in support of the WLS application.

2.5.1.4.1.2.3 Gravity and Magnetic Data

In WLS COL FSAR Section 2.5.1.1.2.3, the applicant discussed gravity and magnetic data for the site region and site vicinity, including those data reprocessed and published as part of the CEUS SSC model (NUREG-2115) database. The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.3 on the applicant's statements related to determining the presence of Cenozoic tectonic structures based on regional gravity and magnetic data because the applicant did not provide any explanation of how these regional data sets can be used to determine that a specific tectonic feature is Cenozoic in age. In RAI 59, Question 02.05.01-5, the staff requested that the applicant define the criteria applied for determining the presence of Cenozoic tectonic structures based on regional gravity and magnetic data, and to discuss the significance of magnetic anomalies in the site vicinity in relation to geologic structure and rock type. In the response to RAI 59, Question 02.05.01-5, the applicant indicated that the statements made about gravity and magnetic data in WLS COL FSAR Section 2.5.1.1.2.3 should not be interpreted to imply that these data can be used to explicitly define the ages of geologic features. The applicant incorporated revised text into WLS COL FSAR Section 2.5.1.1.2.3 to correct this misconception. Also in the response to RAI 59, Question 02.05.01-5, the applicant explained that the low magnetic anomalies, which occur in Charlotte terrane rocks of the site vicinity both southeast and northeast of WLS, reflect the presence of Paleozoic (542 to 251 Ma) intrusive igneous bodies that are relatively non-magnetic, rather than faults or shear zones. The applicant provided two additional figures to illustrate magnetic anomaly patterns in the site vicinity and site area, and incorporated revised text and the two new figures into the WLS COL FSAR to better describe the magnetic anomalies.

Based on review of the response to RAI 59, Question 02.05.01-5, figures and descriptions provided in WLS COL FSAR Section 2.5.1.1.2.3, and an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff concludes that the applicant corrected the statement implying that regional gravity and magnetic data could be used to define the presence of Cenozoic structures and qualified that low magnetic anomalies in the site vicinity generally reflect lithologies rather than tectonic structures. The staff draws this conclusion with regard to the magnetic anomalies because published field evidence cited by the applicant in the FSAR and reviewed by the staff shows that intrusive igneous bodies occur at the locations of the magnetic lows southeast and northeast of the site.

Based on review of WLS COL FSAR Section 2.5.1.1.2.3, an independent examination of references cited by the applicant in that WLS COL FSAR section, and the response to RAI 59, Question 02.05.01-5, the staff finds that the applicant provided a thorough and accurate description of regional gravity and magnetic data in support of WLS application. Accordingly, the staff considers RAI 59, Question 02.05.01-5 resolved.

2.5.1.4.1.2.4 Principal Regional Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4, the applicant discussed Paleozoic (542-251 Ma), Mesozoic (251-65.5 Ma), Cenozoic (65.5 Ma to present), and Quaternary (2.6 Ma to present) tectonic structures that occur within 320 km (200 mi) of WLS (i.e., the site region). The applicant specifically assessed the 15 potential Quaternary tectonic structures postulated to occur in the site region.

The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.4 primarily on the Quaternary tectonic structures postulated to occur in the site region since they represent potentially capable tectonic features. The staff also focused on understanding age constraints proposed by the applicant for the regional faults interpreted to be pre-Quaternary in age. This secondary focus was important for documenting the timing of last displacement on these structures to ensure that none are Quaternary in age (i.e., potentially capable tectonic features).

Regional Geophysical Anomalies and Lineaments

In WLS COL FSAR Section 2.5.1.1.2.4.1, the applicant discussed the geophysical anomalies and lineaments that occur in the site region. From southeast to northwest, these features include the ECMA; the southeastern limit of Iapetan normal faulting; the Clingman and Ocoee lineaments; the NYAL; the Appalachian gravity gradient; the northwest boundary of Iapetan normal faulting; the Appalachian thrust front; and the Grenville Front.

Based on review of the information presented in WLS COL FSAR Section 2.5.1.1.2.4.1 regarding the association of regional geophysical anomalies and lineaments with old tectonic features, as well as an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff concludes that none of the anomalies or lineaments represent a capable tectonic structure. The staff draws this conclusion because the preponderance of available data strongly supports the interpretation that the anomalies and lineaments show an association with tectonic features that initially developed more than 65.5 Ma ago. In addition, the staff notes that WLS COL FSAR Section 2.5.2.2.3 explains how the CEUS SSC model incorporated regional gravity and magnetic anomalies to define the boundaries of seismotectonic zones in and adjacent to the site region. Therefore, the staff further concludes that the applicant considered the latest regional geophysical data by using the CEUS SSC model in the PSHA for WLS.

Based on review of WLS COL FSAR Section 2.5.1.1.2.4.1 and an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff finds that the applicant provided a thorough and accurate description of regional geophysical anomalies and lineaments in support of the WLS application.

Regional Paleozoic Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4.2, the applicant discussed 13 regional tectonic structures of Paleozoic (542 to 251 Ma) age, which occur in the WLS region, specifically the Kings Mountain, Gold Hill-Silver Hill, Middleton-Lowdensville, Beaver Creek, Modoc, Chappells, Hyco and Boogertown-Southwest Extension shear zones and the Tinsley Bridge, Brevard, Cross Anchor, Brindle Creek, and Reedy River faults. The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.4.2 on the information used to document ages of the faults and shear zones interpreted to be Paleozoic in age, which occur in the site region, to ensure that none of these structures have any potential for reactivation as capable tectonic features. In RAI 59, Questions 02.05.01-11 through 02.05.01-14, the staff requested that the applicant provide the published information used to document a Paleozoic age for the faults and shear zones discussed in WLS COL FSAR Section 2.5.1.1.2.4.2, but also include some tectonic structures interpreted to be Paleozoic in age that the applicant did not specifically discuss in that WLS COL FSAR section. In the responses to RAI 59, Questions 02.05.01-11 through 02.05.01-14, the applicant provided additional information and updated references to clearly document a Paleozoic age for the last movement on the faults and shear zones interpreted to be Paleozoic. The applicant also modified WLS COL FSAR Figures 2.5.1-209 and 2.5.1-210 to locate certain structures and incorporated changes in WLS COL FSAR Section 2.5.1.1.2.4.2, to present the additional information, updated references, and modified figures.

Based on review of the applicant's responses to RAI 59, Questions 02.05.01-11 through 02.05.01-14 and the revisions made in WLS COL FSAR Section 2.5.1.1.2.4.2, including both text and WLS COL FSAR Figures 2.5.1-209 and 2.5.1-210, as well as independent examination of references cited by the applicant in that WLS COL FSAR section, the staff concludes there is strong evidence that these faults and shear zones are Paleozoic in age and that none are capable tectonic structures. The staff makes this conclusion because the age dates presented by the applicant constrain the last displacements along these regional tectonic structures to Paleozoic time, and because the structures commonly exhibit deformation fabrics indicative of a deep-seated, high-temperature metamorphic environment (i.e., the geologic environment in which Paleozoic deformational events occurred in the site region).

Based on review of WLS COL FSAR Section 2.5.1.1.2.4.2, the applicant's responses to RAI 59, Questions 02.05.01-11 through 02.05.01-14, the revisions incorporated into WLS COL FSAR

Section 2.5.1.1.2.4.2, and an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff finds that the applicant provided a thorough and accurate description of regional Paleozoic tectonic structures in support of the WLS application. Accordingly, the staff considers RAI 59, Questions 02.05.01-11 through 02.05.01-14 resolved.

Regional Mesozoic Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4.3, the applicant discussed six regional tectonic structures of Mesozoic (251 to 65.5 Ma) age that occur in the WLS region, specifically Mesozoic rift basins and the Wateree Creek, Summers Branch, Ridgeway, Longtown, and Mulberry Creek faults. The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.4.3 on the information used by the applicant to document the ages of the structures interpreted to be Mesozoic in age to ensure that none of these structures have any potential for reactivation as capable tectonic features. The staff also focused on the data used by the applicant to conclude that faults bounding Mesozoic rift basins do not show any spatial relationship with seismicity.

<u>Wateree Creek, Summers Branch, and Ridgeway Faults</u>

In RAI 59, Question 02.05.01-16, the staff requested that the applicant summarize the information used to constrain the timing of fault displacement along the Summers Branch and Ridgeway faults since the applicant interpreted these two faults to be Mesozoic (251 to 65.5 Ma) in age based primarily on their association with the Wateree Creek fault. In response to RAI 59, Question 02.05.01-16, based on field data from Secor and others, the applicant reported that igneous dikes of probable Triassic (251 to 201.6 Ma) to early Jurassic (201.6 to 176 Ma) age cross the Wateree Creek fault without offset, constraining the age of last movement on that fault to be older than 176 Ma. The applicant stated that Secor and others noted strong similarities between the Wateree Creek and Ridgeway faults, including fault length and a northerly strike direction. In addition, the applicant pointed out that Secor and others presented field data showing the Ridgeway fault does not offset an overlying Mesozoic (specifically Upper Cretaceous, 99.6 to 65.2 Ma) stratigraphic unit, indicating that the last movement on the Ridgeway fault is older that Upper Cretaceous. The applicant stated that, while evidence for the Summers Branch fault is speculative, the strike direction and length of this fault are similar to the strike direction and length of the Wateree Creek and Ridgeway faults as defined by Secor and others. The applicant reported that a more recent geologic map prepared by Maher and others, which included Secor as a co-author, did not show the Summers Branch fault. Based on field observations that suggest strong similarities between the Summers Branch (if it exists), Wateree Creek, and Ridgeway faults, the applicant concluded that the last displacements on these three faults are not younger than Mesozoic (i.e., > 65.5 Ma).

Based on review of the applicant's response to RAI 59, Question 02.05.01-16 and direct field examination of the Wateree Creek Fault performed by the staff with USGS geologists during a March 2009 site visit related to the review of the FSAR for the V.C. Summer site, the staff concludes that existing field evidence strongly supports the interpretation that these three faults are Mesozoic in age and none represent capable tectonic structures. The staff draws this conclusion because of the well-defined Mesozoic age constraint on the Wateree Creek fault; the similarities between the three faults described by the applicant; and the field characteristics of the Wateree Creek fault observed by the staff, which indicate that this fault offsets older

Paleozoic rock units and does not exhibit a deformation fabric clearly related to late-stage brittle failure. Accordingly, the staff considers RAI 59, Question 02.05.01-16 resolved.

<u>Longtown and Mulberry Creek Faults</u>

In WLS COL FSAR Section 2.5.1.1.2.4.3, based on Barker and Secor, the applicant reported that four igneous dikes of probable Triassic (251 to 201.6 Ma) age cross the Longtown fault without offset, establishing a minimum age of Triassic for this fault. Regarding the Mulberry Creek fault, the applicant noted that silicified breccia and microbreccia characterize this fault and suggested a Late Triassic to Early Jurassic (235 to176 Ma) age for the fault based on the fact that, as documented by West, silicified fault zones found in North and South Carolina are most commonly Mesozoic in age. The staff concludes that the applicant provided sufficient information to document a Mesozoic age for both the Longtown and Mulberry Faults because published field data cited by the applicant and reviewed by the staff clearly constrain timing of the last displacement along these two structures to Mesozoic.

<u>Mesozoic Rift Basins</u>

In WLS COL FSAR Section 2.5.1.1.2.4.3, the applicant reported that Mesozoic rift basins have long been considered potential earthquake sources in the CEUS. Although the applicant concluded, in WLS COL FSAR Section 2.5.1.1.2.4.3, that no correlation exists between seismicity and Mesozoic rift basins in the site region, the applicant stated in WLS COL FSAR Section 2.5.3.1.5 that two September 2006 earthquakes, which occurred near Bennettsville, SC, about 121 km (75 mi) east-southeast of the site, showed a spatial association with a small Mesozoic extensional basin lying beneath the Coastal Plain as mapped by Benson. In RAI 59, Question 02.05.01-17, the staff requested that the applicant provide information to support the conclusion that faults bounding Mesozoic rift basins do not exhibit any spatial association with seismicity, and to summarize the logic for stating that Mesozoic structures in the site region are not capable tectonic sources. In response to RAI 59, Question 02.05.01-17, the applicant stated that, based on the most current data available, no positive correlation exists between earthquakes and Mesozoic rift basins in the site region; that there is a definitive lack of spatial correlation between Mesozoic basins and seismicity within 80.5 km (50 mi) of WLS, based on an assessment of tectonic features and seismicity within that area; and that no data demonstrate Quaternary reactivation of any Mesozoic basin-bounding faults in the site region. The applicant also stated that the two September 2006 earthquakes that occurred near Bennettsville had large uncertainties in location and could not be definitively correlated with any specific tectonic feature.

Based on review of the applicant’s response to RAI 59, Question 02.05.01-17, the staff concludes that faults bounding Mesozoic rift basins do not exhibit any definitive spatial association with seismicity and that no Mesozoic structures that occur in the site region represent capable tectonic sources. The staff draws these conclusions because a preponderance of data independently reviewed by the staff strongly supports these two interpretations. In addition, staff notes that the Extended Continental Crust-Atlantic Margin (ECC-AM) seismotectonic zone of the CEUS SSC model (NUREG-2115), one of the multiple zones included in the seismic hazard calculation for WLS, contains Mesozoic tectonic structures of the site region. The applicant discussed the ECC-AM seismotectonic zone in WLS COL

FSAR Section 2.5.2.2.3.2. Accordingly, the staff considers RAI 59, Question 02.05.01-17 resolved.

Based on review of WLS COL FSAR Section 2.5.1.1.2.4.3, an independent examination of references cited by the applicant in that WLS COL FSAR section, and the applicant's responses to RAI 59, Questions 02.05.01-16 and 02.05.01-17, the staff finds that the applicant provided a thorough and accurate description of regional Mesozoic tectonic structures in support of the WLS application.

Regional Cenozoic Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4.4, the applicant discussed regional tectonic structures of Cenozoic (65.5 Ma to present) age that occur in WLS region. The applicant stated that only a few structures in the site region show possible evidence of Cenozoic activity, including the Camden fault, the Prowell faults, and the Cape Fear and Yamacraw arches.

The staff focused the review of WLS COL FSAR Section 2.5.1.1.2.4.4 on the data used by the applicant to conclude that the Cape Fear and Yamacraw arches are not active tectonic features. In RAI 59, Question 02.05.01-19, the staff requested that the applicant refer to the primary sources of data that render this conclusion about these features plausible, rather than relying on the data compilation of Crone and Wheeler. In response to RAI 59, Question 02.05.01-19, the applicant cited information from the published literature and stated that there is only limited evidence to constrain timing of the most recent movement on the Cape Fear and Yamacraw arches. The applicant used the most recent field data from Gohn to state that warping related to the Cape Fear arch did not affect stratigraphic units younger than late Tertiary (i.e., > 2.6 Ma, so pre-Quaternary in age), and that tectonic history of the Yamacraw arch is likely analogous since they both represent broad structural upwarps formed by the same processes. The applicant incorporated changes into the WLS COL FSAR to present the information derived from Gohn.

Based on review of the applicant's response to RAI 59, Question 02.05.01-19, independent examination of the references cited by the applicant, and text revisions in WLS COL FSAR Section 2.5.1.1.2.4.4, the staff concludes that the Cape Fear and Yamacraw arches likely do not represent active tectonic structures. The staff draws this conclusion because the most recent field data support the interpretation that upwarping related to the Cape Fear and Yamacraw arches did not affect stratigraphic units younger than late Tertiary. Accordingly, the staff considers RAI 59, Question 02.05.01-19 resolved.

Based on a review of WLS COL FSAR Section 2.5.1.1.2.4.4, independent examination of references cited by the applicant in that WLS COL FSAR section, and the applicant's response to RAI 59, Question 02.05.01-19, the staff finds that the applicant provided a thorough and accurate description of regional Cenozoic tectonic structures in support of the WLS application.

Regional Quaternary Tectonic Structures

In WLS COL FSAR Section 2.5.1.1.2.4.5, the applicant identified fifteen potential Quaternary tectonic features postulated to occur in WLS region based on data compiled by Crone and Wheeler and Wheeler. These authors classified potential Quaternary features as Class A, B, C, or D based on strength of evidence for Quaternary deformation derived from published information. These 15 potential Quaternary tectonic features include the Class A Charleston area, Bluffton, and Georgetown liquefaction features; the Class B Pembroke faults; and the Class C Fall Lines of Weems, Belair and Lindside fault zones, Giles County and Eastern Tennessee seismic zones, East Coast fault system, Cape Fear arch, and Pen Branch, Hares Crossroads, Stanleytown-Villa Heights, and Cooke faults. Figure 2.5.1-3 of this report shows the locations of these potential Quaternary features in relation to WLS.

The staff's technical evaluations of the information provided by the applicant in the WLS COL FSAR and in responses to RAIs in regard to the Cape Fear arch, Charleston area features (i.e., the Cooke fault, East Coast Fault System, and Charleston, Bluffton, and Georgetown liquefaction features), and the Eastern Tennessee and Giles County seismic zones are in various parts of this report. The paragraphs that immediately follow present the staff's evaluations of information provided by the applicant in the WLS COL FSAR and in responses to RAIs related to the Fall Lines of Weems, the Belair and Lindside fault zones, and the Pen Branch, Hares Crossroads, Stanleytown-Villa Heights, and Pembroke faults. The staff focused the review on information used by the applicant to determine that none of these features represent capable tectonic structures.

<u>Fall Lines of Weems (Class C)</u>

For the Fall Lines of Weems, based on published literature, field reconnaissance, and review of the staff's detailed evaluation of these features for the North Anna ESP application as dodumented in NUREG-1835, the applicant concluded that these features developed because of contrasting resistance to erosion of adjacent rock types. The detailed evaluation performed by the NRC for the North Anna ESP application (NUREG-1835) provided the primary basis for staff to also conclude that the Fall Lines of Weems are not tectonic in origin and do not represent capable tectonic structures.

<u>Belair Fault Zone (Class C)</u>

Based on information from Prowell and O'Connor, the applicant constrained the timing of last movement on the Belair fault zone to between 33.9 Ma (i.e., late Eocene) and 26,000 years ago. The applicant stated that the Belair fault zone may be related to the regional Augusta fault zone and, although available data do not clearly demonstrate Quaternary movement along the Belair zone, these data also do not preclude Quaternary displacement on the Belair fault zone. In RAI 59, Question 02.05.01-20, the staff requested that the applicant discuss how the inference of possible Quaternary movement on the Belair fault zone, coupled with a possible structural relationship to the Augusta fault zone, might affect seismic hazard at WLS. In response to RAI 59, Question 02.05.01-20, the applicant noted that existing data do not confirm a common slip history or similar sense of slip for the Augusta and Belair fault zones. The applicant also noted that none of the faults in the site region exhibiting Cenozoic reactivation show any evidence of Quaternary displacement and, therefore, are not capable tectonic features that must be specifically assessed in regard to seismic hazard at WLS.

Based on the applicant's response to RAI 59, Question 02.05.01-20 and an independent examination of references cited by the applicant, the staff concludes that there is no definitive evidence to document Quaternary displacement on the Belair or Augusta fault zones and that the Belair fault zone is not a capable tectonic structure. The staff draws these conclusions because the published field data cited by the applicant and independently reviewed by the staff support the interpretation that the Belair fault does not show conclusive evidence for Quaternary movement. Accordingly, the staff considers RAI 59, Question 02.05.01-20 resolved.

Pen Branch Fault (Class C)

Based on information collected for the Savannah River site and the results of investigations performed for the Vogtle ESP application, the applicant concluded that no evidence exists for post-Eocene (i.e., < 33.9 Ma) displacement along the Pen Branch fault and the fault is not a capable tectonic structure. Based on an independent review of the information presented by Cumbest and others and data included in Vogtle ESP application, the staff also concludes that the Pen Branch fault does not represent a capable tectonic structure. The staff makes this conclusion because timing of last movement on the fault is constrained by field data to be older than Quaternary (i.e., > 2.6 Ma).

Hares Crossroads Fault (Class C)

The applicant noted that the postulated Hares Crossroads fault occurs in a single roadcut exposure in Coastal Plain sediments and concluded that this structure is a local feature that most likely formed as a result of landsliding rather than tectonic faulting. Because this postulated fault occurs in a single exposure of Coastal Plain sediments and is not laterally continuous, the staff concludes that this feature is non-tectonic in origin and does not represent a capable tectonic structure.

Lindside Fault Zone (Class C)

The applicant reported that the Lindside fault zone does not exhibit any evidence of Quaternary displacement, and that orientation of the fault zone is unfavorable for reactivation in the current stress field. Based on a lack of field data suggesting Quaternary slip on the fault zone, the staff concludes that the Lindside fault zone is not a capable tectonic structure.

Stanleytown-Villa Heights Faults (Class C)

The applicant stated that field evidence derived from published literature suggests the postulated Stanleytown-Villa Heights faults are likely the result of landsliding, rather than a tectonic event. These postulated faults juxtapose Quaternary (2.6 Ma to present) alluvium against Cambrian (542 to 488 Ma) rock units and occur as short features characterized by downslope displacements along the surfaces which define the postulated fault surfaces. In RAI 59, Question 02.05.01-21, the staff requested that the applicant concisely summarize the primary evidence for a non-tectonic, landslide mechanism for these postulated faults since they affect Quaternary age deposits. In response to RAI 59, Question 02.05.01-21, based on Conley and Toewe, the applicant reported that these proposed faults do not exhibit any shear fabrics and have a limited lateral extent, and that the juxtaposition of Quaternary and Cambrian units can be readily interpreted as a depositional contact between alluvium and bedrock. The applicant also pointed out that no publications more recent than that of Conley and Toewe address these features.

Since a preponderance of published field evidence cited by the applicant and reviewed by the staff suggests that the postulated Stanleytown-Villa Heights faults are likely non-tectonic in origin and related either to landsliding or a depositional contact between Quaternary alluvium and weathered Cambrian bedrock, the staff concludes that these features are not capable tectonic structures. Accordingly, the staff considers RAI 59, Question 02.05.01-21 resolved.

Pembroke Faults (Class B)

The applicant reported that the postulated Pembroke faults exhibit no geomorphic expression, occur in alluvial terrace deposits of latest Pliocene (3.6 to 2.6 Ma) to Quaternary (2.6 Ma to present) age, and overlie dissolution-prone Ordovician (488 to 444 Ma) carbonate rocks. The applicant stated that these features may be directly related to collapse over subsurface dissolution features rather than a tectonic event. In RAI 59, Question 02.05.01-22, the staff requested that the applicant summarize the primary information on fault geometry and fault length, and to present evidence regarding whether the postulated Pembroke faults are tectonic or non-tectonic (i.e., related to dissolution collapse) in origin. In response to RAI 59, Question 02.05.01-22, the applicant stated that, because these features occur in a single roadcut, fault length cannot be determined. Based on Peavy and Sayer, the applicant reported that numerous sinkholes attributed to dissolution of underlying Ordovician carbonates occur in the area. The applicant also noted Law and others suggested that subsurface cavities detected in sandy clays developed as a result of dissolution collapse and consequent upward migration of collapse structures from underlying carbonate bedrock into the overlying sediments.
In addition, the applicant reported that the same researchers who initially proposed that the Pembroke faults formed in response to tectonic processes more recently suggested karst dissolution as an equally viable origin for these features. Therefore, the applicant did not interpret the Pembroke faults as capable tectonic structures.

Based on the response to RAI 59, Question 02.05.01-22 and an independent review of references cited by the applicant, the staff concludes that the postulated Pembroke faults are likely related to collapse of alluvial terrace deposits as a result of dissolution of underlying carbonate bedrock. The staff draws this conclusion because carbonate rocks underlie the terrace deposits at the location of these features, and researchers who initially interpreted the Pembroke faults as tectonic in origin more recently suggested dissolution collapse as the causative mechanism. Accordingly, the staff considers RAI 59, Question 02.05.01-22 resolved.

Based on review of WLS COL FSAR Section 2.5.1.1.2.4.5, an independent examination of references cited by the applicant in that WLS COL FSAR section, and the applicant's responses to RAI 59, Questions 02.05.01-20 through 02.05.01-22, the staff finds that the applicant provided a thorough and accurate description of the Fall Lines of Weems, the Belair and Lindside fault zones, and the Pen Branch, Hares Crossroads, Stanleytown-Villa Heights, and Pembroke faults, all of which are potential Quaternary tectonic structures postulated to occur in the site area, in support of the WLS application.

2.5.1.4.1.3 *Regional Seismicity and Paleoseismology*

WLS COL FSAR Section 2.5.1.1.3 discusses seismicity and paleoseismology of WLS region, with emphasis on the Charleston, East Tennessee, and Giles County seismic zones. WLS COL FSAR Section 2.5.1.1.3 also addresses two seismic zones that lie outside the site region, the

New Madrid and Central Virginia seismic zones. The applicant noted that only Charleston and the New Madrid seismic zone are RLME sources as defined in the CEUS SSC model (NUREG-2115). Figure 2.5.1-4 of this report shows the locations of these 5 seismic source zones relative to WLS. Sections 2.5.1.4.1.3.1 through 2.5.1.4.1.3.1.5 of this report present the staff's technical evaluation of the information provided by the applicant in WLS COL FSAR Section 2.5.1.1.3 related to regional seismicity and paleoseismology.

2.5.1.4.1.3.1 Charleston Tectonic Features

In WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant discussed ten source faults and three seismic source zones postulated to occur in the Charleston area, as well as seismically-induced liquefaction features. The applicant noted that, although the 1886 Charleston earthquake is the largest historic seismic event in the eastern United States, researchers have not yet identified a causative fault, but rather infer an earthquake source based on geomorphology, geologic features, and instrumented seismicity.

Potential Charleston Area Source Faults and Seismic Zones

In WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant discussed ten potential source faults for the 1886 Charleston earthquake (i.e., the postulated East Coast Fault system, Helena Banks fault zone, and Adams Run, Ashley River, Charleston, Cooke, Sawmill Branch, Dorchester, Summerville, and Woodstock faults). All of these structures lie within the meizoseismal area of the 1886 earthquake, except the Helena Banks fault zone, as shown in Figure 2.5.1-5 of this report. Also in WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant described three zones of increased seismicity identified in the Charleston area as possible source zones for the 1886 earthquake, specifically the Middleton Place-Summerville, Bowman, and Adams Run seismic zones. Figure 2.5.1-4 of this report shows the locations of these three seismic zones.

The applicant noted that the CEUS SSC model (NUREG-2115) includes three alternative geometries for the Charleston seismic source (i.e., Charleston Local, Charleston Narrow, and Charleston Regional), as discussed in WLS COL FSAR Section 2.5.2.2.4.1. These three alternatives encompass the ten causative source faults and the three seismic source zones postulated for the 1886 Charleston earthquake.

The staff acknowledges that the alternate source zone geometries of the CEUS SSC model (NUREG-2115) contain all potential source faults and postulated seismic source zones for the 1886 Charleston earthquake. Therefore, because the applicant used the CEUS SSC model to analyze seismic hazard at WLS, the staff concludes that the applicant took into account the ten potential source faults and the three postulated seismic source zones.

Charleston Area Seismically-Induced Liquefaction Features

In WLS COL FSAR Section 2.5.1.1.3.2.1, the applicant discussed seismically-induced liquefaction features in the Charleston area, including liquefaction features related to the 1886 Charleston earthquake and paleoliquefaction features found along the South Carolina coast which pre-date the 1886 earthquake. Figure 2.5.1-5 of this report shows the locations of these liquefaction and paleoliquefaction features. The three alternate source zone geometries of the CEUS SSC model encompass the locations of all seismically-induced liquefaction and paleoliquefaction features found in the Charleston area. As discussed in WLS COL FSAR Section 2.5.2.2.4.1, the Charleston Local seismic source geometry specifically encompasses the area with the densest concentration of liquefaction features associated with the 1886 earthquake and prehistoric earthquakes, as well as the meizoseismal area of the 1886 earthquake and the majority of local tectonic features. The Charleston Narrow geometry captures location and orientation of postulated faults and tectonic features in the Charleston area. The Charleston Regional seismic source geometry includes the Local and Narrow zones, along with outlying paleoliquefaction sites and other proposed tectonic features. It was not necessary for the applicant to define a specific causative tectonic structure for any of the liquefaction or paleoliquefaction features because the three alternate source zones used in the PSHA analysis for WLS captured these seismically-induced features.

The staff acknowledges that the CEUS SSC model used by the applicant to assess seismic hazard at WLS incorporates the most recent information on earthquake recurrence interval derived from analysis of the liquefaction and paleoliquefaction features found in the Charleston area, as discussed by the applicant in WLS COL FSAR Section 2.5.1.1.3.2.1. Therefore, because the applicant used the CEUS SSC model to analyze seismic hazard at WLS, the staff concludes that the applicant took into account liquefaction data related to the 1886 event, as well as paleoliquefaction data that suggest three to five possible prehistoric seismic events going back to 5500 years before present.

2.5.1.4.1.3.2 Eastern Tennessee Seismic Zone

The applicant addressed the ETSZ in WLS COL FSAR Section 2.5.1.1.3.2.2 and also discussed the geologic investigations conducted in the zone in WLS COL FSAR Section 2.5.2.2.5.1. Figure 2.5.1-4 of this report shows the location of the ETSZ, which is not a RLME source as defined in the CEUS SSC model (NUREG-2115) but rather lies in the PEZ seismotectonic zone of that model. The applicant concluded that no new information requires treating the ETSZ as a RLME, including the data discussed by Hatcher and others who interpreted initial field evidence to suggest that one or more pre-historic earthquakes of M 6.5 may have occurred in the zone within the last 73,000 to 200,000 years.

Based on review of WLS COL FSAR Sections 2.5.1.1.3.2.2 and 2.5.2.2.5.1 and an independent examination of references cited by the applicant in those WLS COL FSAR sections, the staff concludes that the applicant properly included the ETSZ within the PEZ seismotectonic zone as defined in the CEUS SSC model (NUREG-2115). The staff makes this conclusion because there is no firm evidence as yet that the ETSZ should be included as a RLME for assessment of seismic hazard at WLS.

Based on review of WLS COL FSAR Sections 2.5.1.1.3.2.2 and 2.5.2.2.5.1 and an independent examination of references cited by the applicant in those WLS COL FSAR sections, the staff finds that the applicant provided a thorough and accurate description of the ETSZ in support of the WLS application.

2.5.1.4.1.3.3 Giles County Seismic Zone

In WLS COL FSAR Section 2.5.1.1.3.2.3, the applicant discussed the GCVSZ, reporting that no geologic evidence exists to demonstrate the occurrence of prehistoric earthquakes larger than any historical events known to have occurred in this seismic zone. Consequently, the applicant concluded that there is no new information requiring the zone to be treated in a manner other than incorporating it into the PEZ seismotectonic zone as defined in the CEUS SSC model (NUREG-2115).

Based on review of WLS COL FSAR Section 2.5.1.1.3.2.3 and an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff concludes that the applicant correctly determined that no new data exist to warrant consideration of the GCVSZ differently than including the zone within the PEZ seismotectonic zone as defined for the CEUS SSC model (NUREG-2115). The staff draws this conclusion because no new information exists that requires the seismic zone to be characterized differently.

Based on review of WLS COL FSAR Section 2.5.1.1.3.2.3 and an independent examination of references cited by the applicant in that WLS COL FSAR section, the staff finds that the applicant provided a thorough and accurate description of the Giles County seismic zone in support of the WLS application.

2.5.1.4.1.3.4 Areas of Concentrated Seismicity Outside the Site Region

In WLS COL FSAR Section 2.5.1.1.3.2.4, the applicant discussed two areas of concentrated seismicity outside WLS region, namely, the NMSZ and CVSZ. Figure 2.5.1-4 of this report shows the locations of these two seismic zones. The applicant also discussed detailed information related to characterization of the NMSZ as a RLME in the CEUS SSC model (NUREG-2115) in WLS COL FSAR Section 2.5.2.2.4.2, and investigations of the 2011 Mineral, VA earthquake that occurred in the CVSZ in WLS COL FSAR Section 2.5.2.2.5.2.

For the NMSZ, the applicant presented data in WLS COL FSAR Sections 2.5.1.1.3.2.4 and 2.5.2.2.4.2 documenting that this seismic zone can be characterized as a RLME for assessment of seismic hazard at WLS. Based on a review of WLS COL FSAR Sections 2.5.1.1.3.2.4 and 2.5.2.2.4.2 and an independent examination of references cited by the applicant in those WLS COL FSAR sections, the staff concludes that sufficient data exist to characterize the NMSZ as a RLME. The staff makes this conclusion because there are considerable data presented in the CEUS SSC model (NUREG-2115) to support it.

For the CVSZ, the applicant presented data in WLS COL FSAR Sections 2.5.1.1.3.2.4 and 2.5.2.2.5.2 documenting that the ECC-AM seismotectonic zone of the CEUS SSC model (NUREG-2115) captures seismicity in this zone. The applicant concluded that no new data, including information related to the 2011 Mineral, VA earthquake, required revision to the CEUS SSC model for the CVSZ. Based on review of WLS COL FSAR Sections 2.5.1.1.3.2.4 and 2.5.2.2.5.2 and an independent examination of references cited by the applicant in those WLS COL FSAR sections, the staff concludes that there is no new information requiring revision to how the CEUS SSC model incorporates the CVSZ. The staff draws this conclusion because no evidence exists that the CVSZ represents a RLME.

Based on review of WLS COL FSAR Sections 2.5.1.1.3.2.4, 2.5.2.2.4.2, and 2.5.2.2.5.2 and an independent examination of references cited by the applicant in those WLS COL FSAR sections, the staff finds that the applicant provided a thorough and accurate description of areas of concentrated seismicity outside the site region in support of the WLS application.

2.5.1.4.1.4 *Staff Conclusions on Regional Tectonic Setting, Seismicity, and Paleoseismology*

Based on review of WLS COL FSAR Sections 2.5.1.1.2 and 2.5.1.1.3 and the applicant's responses to RAIs on those two WLS COL FSAR Sections, as well as independent examination of references cited by the applicant in those two sections, the staff finds that the applicant provided thorough and accurate descriptions of the regional tectonic setting and regional seismicity and paleoseismology for WLS, including regional geologic history, tectonic stress in the mid-continent region, gravity and magnetic data in the site region and site vicinity, principal regional tectonic structures, and seismic sources defined by regional seismicity in the CEUS both inside and outside the site region. The staff also finds that the descriptions provided in WLS COL FSAR Sections 2.5.1.1.2 and 2.5.1.1.3 reflect the current literature and state of knowledge and meet the requirements of 10 CFR 52.79 and 10 CFR 100.23.

2.5.1.4.2 Site Geology

The staff focused the review of WLS COL FSAR Section 2.5.1.2 on descriptions provided by the applicant for physiography and geomorphology, geologic setting and history, stratigraphy and lithology, structural geology, engineering geology, seismicity and paleoseismology, and ground water conditions in the WLS vicinity and site area. The staff also focused on descriptions provided by the applicant in WLS COL FSAR Section 2.5.1.2.5 related to certain of these topics specifically for WLS location.

2.5.1.4.2.1 *Site Area Physiography and Geomorphology*

WLS COL FSAR Section 2.5.1.2.1 discusses physiography and geomorphology of the WLS vicinity and site area. The applicant described five lineaments that occur in the site vicinity, one of which, Lineament 1, extends into the site area. The applicant interpreted these lineaments to be non-tectonic in origin, with development controlled by stream drainage patterns and varying resistance of bedrock units to erosion, and concluded that the lineaments do not represent capable tectonic structures. However, Lineament 1 parallels a northeast-striking ridge held up by a resistant quartzite unit, and the orientation of this ridge parallels the northeastern orientation of regional geologic structures that are characteristic of the Appalachian orogenic belt.

The staff focused the review of WLS COL FSAR Section 2.5.1.2.1 on determining that the lineaments occurring in the site vicinity and site area do not represent capable tectonic structures. In RAI 59, Question 02.05.01-29, the staff requested that the applicant discuss the possibility that certain lineaments may reflect regional joint trends, if not capable tectonic features. In RAI 59, Question 02.05.01-31, the staff requested that the applicant discuss the influence of geologic features on development of Lineament 1. In response to RAI 59, Question 02.05.01-29, the applicant stated that, while some exceptions exist, drainage orientations commonly exhibit local control due to variable resistance of bedrock units to erosion, rather than control by jointing, and that no field evidence exists to suggest the five lineaments described in WLS COL FSAR Section 2.5.1.2.1 have a tectonic origin. The applicant compared orientations of regional joint patterns with drainage systems, and determined that joints and structural fabrics strike N25E to N60E, while drainages have a predominant strike of N30W to N60W. In response to RAI 59, Question 02.05.01-31, based on field observations made for the WLS application and information provided in the WLS COL PSAR for the CNS site, the applicant documented that Lineament 1 parallels an erosion-resistant quartzite ridge and terminates to the northeast along strike at the Broad River. Therefore, the applicant concluded that none of these lineaments represent capable tectonic structures.

Based on review of WLS COL FSAR Section 2.5.1.2.1 and the responses to RAI 59, Questions 02.05.01-29 and 02.05.01-31, staff examination of quartzite ridges in the field during the January 2009 site visit, and an independent review of information presented in the CNS PSAR, the staff concludes that erosion-resistant rock units, and not capable tectonic structures, controlled development of the five lineaments discussed in WLS COL FSAR Section 2.5.1.2.1, including Lineament 1, which occurs in the site area. The staff makes this conclusion because field data reported by the applicant and field observations made by the staff during the January 2009 site visit support the interpretation that the lineaments developed along stream drainages aligned parallel to ridges capped by erosion-resistance rock units, and that Lineament 1 is a relatively local feature which terminates along strike at the Broad River. Accordingly, the staff considers RAI 59, Questions 02.05.01-29 and 02.05.01-31 resolved.

Based on review of WLS COL FSAR Section 2.5.1.2.1, the responses to RAI 59, Questions 02.05.01-29 and 02.05.01-31, examination of quartzite ridges in the field, and an independent review of information presented in the CNS PSAR, the staff finds that the applicant provided a thorough and accurate description of site area physiography and geomorphology in support of the WLS application.

2.5.1.4.2.2 *Site Area Geologic Setting and History*

WLS COL FSAR Section 2.5.1.2.2 describes geologic setting and history of the WLS vicinity and site area, specifically addressing the Charlotte terrane in which the site lies and summarizing the deformation and metamorphic history of the site area. However, WLS COL FSAR Section 2.5.1.2.2 presents an inconsistent terminology for the rock units that comprise the Charlotte terrane, making it difficult to correlate rock units described in WLS COL FSAR Section 2.5.1.2.2 with those shown on the geologic maps included in the WLS COL FSAR. In addition, WLS COL FSAR Section 2.5.1.2.2 does not concisely summarize the complete deformation history of the site area, but leaves out Ordovician (488 to 444 Ma) history and any discussion of Mesozoic (251 to 145.5 Ma) cataclasites (i.e., rocks which developed as a result of pervasive fracturing, crushing, and grinding by brittle faulting).

The staff focused the review of WLS COL FSAR Section 2.5.1.2.2 on clarifying both terminology for the rock units comprising the Charlotte terrane in which the site occurs and deformation history of the Charlotte terrane in the site area. In RAI 59, Question 02.05.01-32, the staff requested that the applicant delineate the lithologic units that make up the Charlotte terrane to enable correlation with geologic maps presented in the WLS COL FSAR. In RAI 59, Question 02.05.01-35, the staff requested that the applicant summarize the complete deformation history of the site area to aid with assessing potential geologic hazard at WLS. In the responses to RAI 59, Questions 02.05.01-32 and 02.05.01-35, the applicant indicated that the confusion about site area lithologies results largely from the fact that different researchers have applied different classification schemes and terminologies over time. The applicant provided changes to WLS COL FSAR Section 2.5.1.2.2 that clarified terminology for the rock units occurring in the site area and more completely summarized site area deformation history to include all orogenic events proposed for the Charlotte terrane based on information in Hibbard and others.

Based on review of WLS COL FSAR Section 2.5.1.2.2, the responses to RAI 59, Questions 02.05.01-32 and 02.05.01-35, and an independent examination of the clarifying references cited by the applicant, the staff concludes that the applicant clearly delineated the lithologic units that make up the Charlotte terrane and adequately discussed the deformation history of that terrane. The staff makes this conclusion because the applicant incorporated additional information from appropriate published sources prepared by area experts. Accordingly, the staff considers RAI 59, Questions 02.05.01-32 and 02.05.01-35 resolved.

Based on review of WLS COL FSAR Section 2.5.1.2.2, the responses to RAI 59, Questions 02.05.01-32 and 02.05.01-35, and an independent examination of the references cited by the applicant, the staff finds that the applicant provided a thorough and accurate description of site area geologic history and setting in support of WL application**.**

2.5.1.4.2.3 *Site Area Stratigraphy and Lithology*

WLS COL FSAR Section 2.5.1.2.3 describes site area stratigraphy and lithology. The applicant indicated that rock units in WLS area are part of the Battleground Formation, defined by Horton as Neoproterozoic (1000 to 542 Ma) in age. A Neoproterozoic metamorphosed plutonic rock mass, Zto, intrudes the metavolcanic sequence and comprises the foundation rock unit for WLS Units 1 and 2.

The staff focused the review of WLS COL FSAR Section 2.5.1.2.3 on understanding the extent of foundation rock unit Zto and the relationships between the various rock units that occur in the site area and at the site location. In RAI 59, Question 02.05.01-36, the staff requested that the applicant provide a consistent nomenclature and description for rock unit Zto since this is the foundation rock mass for WLS Units 1 and 2. In RAI 59, Question 02.05.01-37, the staff requested that the applicant discuss in more detail the relationships between rock units found in the site area and at the site location, to include specifying locations of the geologic structures interpreted to deform, and consequently influence the observed relationships between, rock units in the site area and at the site location. In response to RAI 59, Question 02.05.01-36, the applicant stated that variations in descriptive terminology for the Battleground Formation and rock unit Zto occur because different researchers mapped the Battleground Formation and Zto at different times using different map scales in adjacent quadrangles. The applicant incorporated changes into WLS COL FSAR Section 2.5.1.2.3 to more concisely describe the Battleground Formation and foundation rock unit Zto, including multiple references clarifying the variations in nomenclature for Zto. The applicant stated that, while the composition of Zto is spatially variable, the most abundant rock type is metagranodiorite based on petrographic analyses presented in the CNS PSAR. In response to RAI 59, Question 02.05.01-37, the applicant further modified WLS COL FSAR Section 2.5.1.2.3 by locating the South Fork and McKowns Creek antiforms on the site area geologic map shown in WLS COL FSAR Figure 2.5.1-219a to accompany the text changes provided in response to RAI 59, Question 02.05.01-36. These text changes clarified the relationships between rock units in the site area and at the site location as influenced by the intense deformation which accompanied development of the antiformal folds, leading to the interpretation that rock units are relatively younger to the northwest across the site area.

Based on review of WLS COL FSAR Section 2.5.1.2.3, the responses to RAI 59, Questions 02.05.01-36 and 02.05.01-37, and an independent examination of references cited by the applicant related to rock nomenclature and the relationships between rock units in the site area and at the site location, the staff concludes that the applicant clarified the nomenclature for and description of foundation rock unit Zto and qualified the relationships between the different rock units in the site area and at the site location. The staff makes this conclusion because the applicant provided information documenting the primary rock type that characterizes rock unit Zto and the effects of deformation on the relationships between rock units in the site area and at the site location. Accordingly, the staff considers RAI 59, Questions 02.05.01-36 and 02.05.011-37 resolved.

Based on review of WLS COL FSAR Section 2.5.1.2.3, the responses to RAI 59, Questions 02.05.01-36 and 02.05.01-37, and an independent examination of references cited by the applicant related to rock nomenclature and relationships between rock units in the site area and at the site location, the staff finds that the applicant provided a thorough and accurate description of site area stratigraphy and lithology in support of the WLS application.

2.5.1.4.2.4 *Site Area Structural Geology*

WLS COL FSAR Section 2.5.1.2.4 describes structural geology of the site area, including deformation history. WLS COL FSAR Section 2.5.1.2.4.1 discusses the relevant geologic structures that occur within WLS area, specifically the Cherokee Falls and Draytonville synforms and slickensides.

The staff focused the review of WLS COL FSAR Sections 2.5.1.2.4 and 2.5.1.2.4.1 on the applicant's discussions of the Cherokee Falls and Draytonville synforms and slickensides. Sections 2.5.1.4.2.4.1 through 2.5.1.4.2.4.3 of this report present the staff's technical evaluation of the information provided by the applicant in WLS COL FSAR Sections 2.5.1.2.4 and 2.5.1.2.4.1 related to site area structural geology and structures within the site area.

2.5.1.4.2.4.1 Deformation History

In WLS COL FSAR Section 2.5.1.2.4, based on Schaeffer, the applicant discussed the field evidence for five regional deformation episodes, D1 through D5, which occurred during development of the Appalachian orogenic belt and affected WLS area as well as the site region, site vicinity, and site location. The applicant presented field evidence documenting that D1 and D2 structures formed during deformation accompanied by a metamorphic event around 542 Ma ago, and radiometric age dates constraining the timing of D3, D4 and D5 structures to be more than 296 Ma old.

Based on review of the information presented in WLS COL FSAR Section 2.5.1.2.4 regarding ages of deformation episodes D1 through D5, independent review of the references cited by the applicant in that WLS COL FSAR section, four data documentation audits conducted by the staff in February 2009, July 2009, June 2011, and October 2011, and the staff's direct examination of deformation features during four site visits conducted in April-May 2008, January 2009, July

2011, and February 2014, the staff concludes that deformation events D1 through D5 are all older than 296 Ma. The staff draws this conclusion because field evidence related to growth of metamorphic minerals associated with the deformation events supports the interpretation that none of these events are younger than 296 Ma.

2.5.1.4.2.4.2 Cherokee Falls and Draytonville Synforms

In WLS COL FSAR Section 2.5.1.2.4.1, the applicant presented field evidence documenting that the Cherokee Falls and Draytonville synforms are D2 deformation features. The applicant also indicated that more recent mapping by Nystrom did not include either of these synforms, although the portion of the geologic map shown in WLS COL FSAR Figure 2.5.1-219a as being based on Nystrom includes the synforms. In RAI 59, Questions 02.05.01-40 and 02.05.01-41, the staff requested that the applicant clarify why these two structures are shown on the map derived from Nystrom even though he did not include them on his map. In response to RAI 59, Questions 02.05.01-40 and 02.05.01-41, the applicant stated that the map prepared by Nystrom did not include structural data, including fold axes, and the portion of the geologic map in WLS COL FSAR Figure 2.5.1-219a attributed to Nystrom actually presents geologic data derived from multiple sources, certain of whom mapped the axial traces of the Cherokee Falls and Draytonville synforms. The applicant revised notation on WLS COL FSAR Figure 2.5.1-219a to indicate that geology came from Nystrom, Howard, and Horton and Dicken; that Hibbard and others provided information on fault locations; and that Murphy and Butler provided the locations of fold axes.

Based on review of WLS COL FSAR Section 2.5.1.2.4.1, including the modifications to WLS COL FSAR Figure 2.5.1-219 and the responses to RAI 59, Questions 02.05.01-40 and 02.05.01-41, the staff concludes that the applicant clarified the basis for including the axial traces of the Cherokee Falls and Draytonville synforms on WLS COL FSAR Figure 2.5.1-219a. The staff draws this conclusion because the applicant documented the various sources of information compiled to develop this figure, including the mapping of Murphy and Butler that defined these two structures, and the staff reviewed the cited information and finds it reliable and sufficient. Accordingly, the staff considers RAI 59, Questions 02.05.01-40 and 02.05.01-41 resolved.

2.5.1.4.2.4.3 Slickensides

Slickensides are potentially important structural features because they provide evidence for at least minor displacement along the surfaces on which they occur. Based on the CNS PSAR, the applicant stated that, although slickensided surfaces occur in the site area, none could be readily traced beyond a single exposure, which suggests the lack of a through-going fault. The applicant also reported that similar minor, locally-developed slickensided surfaces are common throughout the Piedmont. Since the applicant did not show the slickenside locations on a geologic map in the WLS COL FSAR, it is uncertain whether they may define a single extended linear trace. It is also uncertain whether unsheared minerals occur on all slickensided surfaces, indicating that the slickensides represent old and deep-seated, rather than young (i.e., Quaternary, 2.6 Ma to present in age) and near-surface, deformation. Therefore, to enable an assessment of whether the slickensided surfaces may indicate the presence of a capable tectonic structure, in RAI 59, Question 02.05.01-42, the staff requested that the applicant summarize information taken from the CNS PSAR and used to conclude that the slickensides are old and do not indicate the existence of a potentially capable Quaternary tectonic structure of finite length in the site area. The staff also requested that the applicant provide a reference for the statement that slickensided surfaces and other similar minor, locally developed features with no tectonic significance occur throughout the Piedmont. In response to RAI 59, Question 02.05.01-42, the applicant cited the CNS PSAR and stated that no features associated with the locations of the slickensides exhibited any topographic expression, as may be expected for an active tectonic structure, and that orientation of the slip surfaces varied at the different locations, making them inconsistent with a single tectonic feature. The applicant also noted that the mineral epidote occurred on at least one of slickensided surfaces, and deformation history of the Piedmont, including the site area, indicates the conditions required to grow this mineral have not occurred in the site area since late Paleozoic time (> 251 Ma). The applicant cited Garihan and others, who reported the widespread occurrence of brittle deformation features that commonly show no correlation with active faults throughout the Piedmont.

Based on review of WLS COL FSAR Section 2.5.1.2.4.1, the response to RAI 59, Question 02.05.01-42, and an independent examination of references cited by the applicant, the staff concludes that the slickensides found in the site area do not suggest the presence of any capable tectonic structures. The staff makes this conclusion because the applicant documented the local, discontinuous nature of the slickensided surfaces. Accordingly, the staff considers RAI 59, Question 02.05.01-42 resolved.

Based on review of WLS COL FSAR Sections 2.5.1.2.4 and 2.5.1.2.4.1 and the responses to RAI 59, Questions 02.05.01-40 through 02.05.01-42, the staff finds that the applicant provided a thorough and accurate description of site area structural geology, including deformation history and structures within the site area, in support of the WLS application.

2.5.1.4.2.5 *Site Location Geology*

WLS COL FSAR Section 2.5.1.2.5 discusses geology of the WLS location, including physiography and geomorphology, geologic setting and history, stratigraphy and lithology, structure, and geologic mapping. Sections 2.5.1.4.2.5.1 through 2.5.1.4.2.5.5 of this report present the staff's technical evaluation of the information provided by the applicant in WLS COL FSAR Section 2.5.1.2.5. In Section 2.5.1.4.2.5.5 of this report, the staff also evaluated the compiled geologic map and associated data for the CNS Unit 1 site (i.e., proposed WLS Unit 1) excavation, which documented lithologies and the absence of capable tectonic structures or other potentially detrimental geologic features in the foundation rocks of proposed WLS Unit 1. The staff focused the review of WLS COL FSAR Section 2.5.1.2.5 on understanding timing of deformation at the site location in light of the information presented by the applicant in WLS COL FSAR Section 2.5.1.2.4 related to the five regional deformation episodes that affected the site area, and on assessment of the compiled geologic map of the CNS/WLS Unit 1 excavation.

2.5.1.4.2.5.1 Site Location Physiography and Geomorphology

In WLS COL FSAR Section 2.5.1.2.5.1, the applicant discussed physiography and geomorphology of WLS location. The applicant reported that physiography and geomorphology at the site location are similar to these same characteristics as observed in the site area.

Based on review of the information presented in WLS COL FSAR Section 2.5.1.2.5.1 regarding physiography and geomorphology of WLS location, as well as field observations made during site visits conducted by the staff in April-May 2008, January 2009, July 2011, and February 2014, the staff concludes that physiographic and geomorphic characteristics of the site location are similar to these same characteristics as described for the site area. The staff draws this conclusion because field observations made during the four site visits confirm that physiography and geomorphology at the site location are typical of the site area and no unique physiographic or geomorphic features occur at the site location.

Based on review of WLS COL FSAR Section 2.5.1.2.5.1 and the field observations made during the four site visits, the staff finds that the applicant provided a thorough and accurate description of site location physiography and geomorphology in support of the WLS application.

2.5.1.4.2.5.2 Site Location Geologic Setting and History

In WLS COL FSAR Section 2.5.1.2.5.2, the applicant discussed geologic setting and history of the site location. The applicant stated that geologic setting and history of the site location are the same as the geologic setting and history of the site area even though, of the five regional deformation episodes (D1 through D5) documented in the site area, rock units at the site location most strongly exhibit only the first two of the five events (i.e., D1 and D2, with D2 being the most prominent).

Based on review of WLS COL FSAR Section 2.5.1.2.5.2 and field observations made during site visits conducted by the staff in April-May 2008, January 2009, July 2011, and February 2014, the staff concludes that the metavolcanic and metasedimentary country rock sequence responded differently to deformation than did foundation rock unit Zto due to rheological differences between these different lithologies. The staff makes this conclusion because field evidence observed during the site visits listed above documents the imprint of all five deformation events, D1 through D5, in the country rock sequence and corroborates the applicant’s statement that rock unit Zto best exhibits deformation events D1 and D2, with D2 being the most obvious.

Based on review of WLS COL FSAR Section 2.5.1.2.5.2 and the field observations made during the four site visits, the staff finds that the applicant provided a thorough and accurate description of site location geologic setting and history in support of the WLS application.

2.5.1.4.2.5.3 Site Location Stratigraphy and Lithology

In WLS COL FSAR Section 2.5.1.2.5.3, the applicant discussed stratigraphy and lithology of the site location. The applicant indicated that stratigraphy and lithology at the site location are the same as stratigraphy and rock types in the site area.

Based on review of WLS COL FSAR Section 2.5.1.2.5.3 and field observations made during site visits conducted by the staff in April-May 2008, January 2009, July 2011, and February 2014, the staff concludes that stratigraphy and lithology at the site location are congruent with site area stratigraphy and lithology. The staff makes this conclusion because field evidence observed by the staff documents that stratigraphy and lithology at the site location are the same as the stratigraphy and rock types described for the site area.

Based on review of WLS COL FSAR Section 2.5.1.2.5.3 and the field observations made during the four site visits, the staff finds that the applicant provided a thorough and accurate description of site location stratigraphy and lithology in support of the WLS application.

2.5.1.4.2.5.4 Site Location Structure

In WLS COL FSAR Section 2.5.1.2.5.4, the applicant addressed structural geology of the site location. The applicant discussed geologic structures that occur at the site location, including the McKown's Creek antiform, shear and breccia zones, joints and dilation fractures, and slickensides.

McKown's Creek Antiform

The applicant reported that, while regional deformation episodes D1 through D5 characterize deformation style in the site area, geologic structures at the site location, including the McKown's Creek antiform, largely reflect geologic structures and rock fabrics resulting from deformation D2. The applicant noted that foundation unit Zto is a massive metamorphosed intrusive igneous body and does not contain good marker horizons for registering deformation events. Therefore, although the applicant provided a chronological listing of regional deformation events that affected the site area in WLS COL FSAR Section 2.5.1.2.5.4, it is not completely clear to the staff which deformation event produced a given geologic structure (e.g., foliation surfaces, shear and breccia zones, dilation fractures and joints, and slickensides) at the site location. In RAI 59, Question 02.05.01-46, the staff requested that the applicant clarify which deformation event produced which geologic structure and rock fabric at the site location. In response to RAI 59, Question 02.05.01-46, the applicant incorporated new Table 2.5.1-204 into WLS COL FSAR Section 2.5.1.2.5.4 to correlate structures developed at the site location with site area deformation episodes, including a summary of age constraints for the deformation events and structures. This table clarified the relationships described by the applicant between site location structures and site area deformation episodes, and equated the latest stage of fracture development with Mesozoic (251 to 145.5 Ma) extension. All other tectonic structures (i.e., folds, shear and breccia zones, dilation fractures, and joints mineralized by chlorite and calcite and often slickensided) are older than 219 Ma based on radiometric age date results.

Shear and Breccia Zones, Dilation Fractures, Joints, and Slickensides

Shear and breccia zones, dilation fractures, joints, and slickensides occur at the site location in rock mass Zto, the foundation unit for proposed WLS Unit 1 and Unit 2. The applicant reported that a K-Ar radiometric age date constrains timing of the shearing, brecciation, dilation fracturing, and development of slickensides on joint surfaces coated with chlorite mica in unweathered rock to be older than 219 Ma.

Based on review of WLS COL FSAR Section 2.5.1.2.5.4, including WLS COL FSAR Table 2.5.1-204, and the response to RAI 59, Question 02.05.01-46, as well as direct field observations made by the staff during site visits in April-May 2008, January 2009, July 2011, and February 2014 and review of information during data documentation audits conducted by NRC staff in February and July 2009 and June and October 2011, the staff concludes that the applicant provided information sufficient to enable correlation of structures developed at the site location with site area deformation episodes. The staff makes this conclusion because information reviewed during the data documentation audits, which included radiometric age dates, and field evidence examined during the site visits documented the deformation history presented by the applicant for the site location and confirmed that none of the structures produced by the deformation episodes represent capable tectonic features. Accordingly, the staff considers RAI 59, Question 02.05.01-46 resolved.

Based on review of WLS COL FSAR Section 2.5.1.2.5.4 and the response to RAI 59, Question 02.05.01-46, as well as field observations made during the four site visits and examination of data during the four data documentation audits, the staff finds that the applicant provided a thorough and accurate description of site location structure in support of the WLS application.

2.5.1.4.2.5.5 Site Location Geologic Mapping

WLS COL FSAR Section 2.5.1.2.5.5 discusses geologic mapping performed at the site location.

Based on geologic mapping results for both WLS and the original CNS site, including detailed geologic maps of CNS Unit 1 foundation grade level bedrock produced by digitizing and compiling the original field maps prepared for CNS Unit 1, as well as in-situ and laboratory test results summarized in WLS COL FSAR Section 2.5.1.2.6 and cross-referenced in WLS COL FSAR Section 2.5.1.2.5.5, the applicant concluded that the foundation rock mass at WLS is suitable. Since the applicant used information in the CNS PSAR to supplement geologic data for WLS, WLS COL FSAR Section 2.5.1.2.5.5 also discusses confirmatory testing of the original CNS geologic map of CNS Unit 2, implemented by the applicant as part of site characterization for WLS. The applicant did not provide a geologic map of that part of the CNS Unit 2 excavation used to confirm the accuracy of previous mapping at the original CNS site. In RAI 59, Question 02.05.01-47, the staff requested that the applicant summarize the data collected during previous geologic mapping at the CNS site being used to supplement geologic data for WLS. The staff also requested that the applicant provide a geologic map documenting the reported confirmation of the previous geologic mapping at the CNS site. Also in WLS COL FSAR Section 2.5.1.2.5.5, the applicant concluded that the western boundary of plutonic rock mass Zto, the foundation unit at WLS, is a lithologic contact with surrounding country rock rather than a fault, although Nystrom mapped this boundary as a straight line segment that could be interpreted as a fault. The applicant did not provide a summary of the pertinent information that made the conclusion about the non-tectonic character of this contact possible. In RAI 59, Question 02.05.01-49, the staff requested that the applicant summarize the data used to determine that the western boundary of foundation unit Zto is not a fault or shear zone in light of the fact that Nystrom mapped this boundary as a straight line that could be interpreted as a fault.

In response to RAI 59, Question 02.05.01-47, the applicant indicated that the primary objective of the confirmatory mapping was to validate the historical final foundation geologic mapping records developed for the original CNS site. The applicant used these records to supplement geologic data collected for the WLS application. The applicant noted that this mapping was particularly important for validating the unpublished historical geologic map data for CNS Unit 1, which now lies under concrete, because the original CNS Unit 1 site coincides with the proposed WLS Unit 1 site. The applicant stated that the most prominent lithologies, shear zones, and individual shears appear on both the historical CNS and WLS geologic maps. The applicant provided a geologic map showing WLS mapping results overlain on the part of the historical CNS Unit 2 final foundation geologic map being validated to support this statement. Careful examination of these two sets of geologic map data by staff documented that the most prominent lithologies, shear zones, and individual shears occur on both the historical CNS Unit 2 and the confirmatory WLS geologic maps.

In response to RAI 59, Question 02.05.01-49, using field evidence derived from trenches located to investigate geologic characteristics of the western boundary of metamorphosed plutonic rock mass Zto and from boreholes drilled for CNS site investigations and the WLS application, the applicant determined that this boundary is lithologic contact between the pluton and the adjacent country rock and not a fault. The applicant modified WLS COL FSAR Figure 2.5.1-226 to show the irregular nature of this boundary and correct the misconception that it is a straight line, which could be interpreted as related to faulting.

Based on review of WLS COL FSAR Section 2.5.1.2.5.5, the responses to RAI 59, Questions 02.05.01-47 and 02.05.01-49, and information in the CNS PSAR, as well as field observations made by the staff during the site visits and examination of data by the staff during the data documentation audits, including review of the report presenting the compiled geologic map and associated data for the WLS/CNS Unit 1 excavation, the staff makes the following conclusions: (1) the most prominent lithologies, shear zones, and individual shears appear in both the historical CNS and WLS geologic maps; (2) the western boundary of foundation rock unit Zto is an irregular intrusive contact rather than a fault; (3) similarities exist in both lithologies and geologic features found in the CNS Unit 1 (proposed WLS Unit 1) excavation and the adjacent excavations for CNS Unit 2 and CNS Unit 3 (proposed WLS Unit 2); and (4) no capable tectonic structures or other potentially detrimental geologic features occur in the excavation for proposed WLS Unit 1. The staff makes these conclusions for the following reasons with field evidence based on observations made by the staff and independent evaluation of data presented by the applicant: (1) field data shown on the historical CNS Unit 2 and the confirmatory WLS geologic maps document that lithologies and major geologic features are similar between the two maps; (2) field evidence indicates the western boundary of foundation unit Zto is not a fault; (3) the data documentation audits and site visits confirm that similarities exist in both lithologies and geologic features found in the CNS Unit 1 (proposed WLS Unit 1) excavation and in the adjacent excavations for CNS Unit 2 and CNS Unit 3 (proposed WL Unit 2); and (4) field evidence indicates that no capable tectonic structures or other potentially detrimental geologic features occur in the excavation for proposed WLS Unit 1. Accordingly, the staff considers RAI 59, Questions 02.05.01-47 and 02.05.01-49 resolved.

Based on review of WLS COL FSAR Section 2.5.1.2.5.5 and the responses to RAI 59, Questions 02.05.01-47 and 02.05.01-49, as well as the field observations made during the site visits and examination of data during data documentation audits, including the report presenting the compiled geologic map for CNS Unit 1/WL Unit 1, the staff finds that the applicant provided a thorough and accurate description of site location geologic mapping in support of the WLS application.

2.5.1.4.2.6 *Site Area Engineering Geology*

In WLS COL FSAR Section 2.5.1.2.6, the applicant described engineering geology of the site area. The applicant indicated that, although further excavation will likely expose weathered zones, joints, and fractures in the foundation rock unit (Zto), the weathered rock would be treated and removed as described in WLS COL FSAR Section 2.5.4.12. Based on in-situ and laboratory test results summarized in WLS COL FSAR Section 2.5.1.2.6, as well as information derived from geologic mapping at the site location, the applicant concluded that the foundation rock unit at WLS is suitable.

Based on review of WLS COL FSAR Section 2.5.1.2.6, in-situ and laboratory results, and results of geologic mapping at the site location, the staff finds that the applicant provided a thorough and accurate description of site area engineering geology in support of the WLS application**.**

2.5.1.4.2.7 *Site Area Seismicity and Paleoseismology*

In WLS COL FSAR Section 2.5.1.2.7, the applicant discussed site area seismicity and paleoseismology. The applicant stated that no published reports identified paleoseismic features in the site area, and that, based on extensive new studies performed for the WLS application, there is no evidence for post-Miocene (< 5.3 Ma) earthquake activity in the site area. However, the applicant did not present any information to support the statement about the new studies.

The staff focused the review of WLS COL FSAR Section 2.5.1.2.7 on the applicant’s statement that no evidence exists for post-Miocene (< 5.3 Ma) earthquake activity in the site area. In RAI 59, Question 02.05.01-50, the staff requested that the applicant provide information documenting that field investigations performed for the WLS application did not reveal any evidence for post-Miocene earthquake activity. In response to RAI 59, Question 02.05.01-50, the applicant stated that the new studies included comprehensive literature reviews and interviews with site area experts; interpretation of aerial photographs; and geologic investigations comprising aerial and ground reconnaissance of the site area, including examination of Quaternary alluvial surfaces and deposits that are potentially subject to earthquake-induced liquefaction and outcrops along the Broad River and its tributaries. The applicant stated that none of these efforts revealed paleoliquefaction features, other indicators of post-Miocene earthquake activity, or evidence for Miocene or younger faulting in the site area.

Based on review of WLS COL FSAR Section 2.5.1.2.7 and the applicant’s response to RAI 59, Question 02.05.01-50, the staff concludes that no evidence exists for earthquake-induced paleoliquefaction, other indicators of post-Miocene earthquake activity, or Miocene or younger faulting. The staff makes this conclusion because the applicant applied the standard field methods necessary for assessing the presence of paleoseismic features such as those that would be represented by earthquake-induced liquefaction or young (i.e., post-Miocene, including Quaternary age) faulting.

Based on review of WLS COL FSAR Section 2.5.1.2.7 and the fact that the applicant applied standard field methods to assess the presence of paleoseismic features, the staff finds that the applicant provided a thorough and accurate description of site area seismicity and paleoseismology in support of the WLS application.

2.5.1.4.2.8 *Site Area Groundwater Conditions*

WLS COL FSAR Section 2.5.1.2.8 cross-references WLS COL FSAR Section 2.4.12, for the detailed discussion of groundwater conditions presented by the applicant for WLS.

2.5.1.5 *Post Combined License Activities*

There are no post COL activities related to WLS COL FSAR Section 2.5.1. However, Section 2.5.3.4.8 of this report identifies a geologic mapping License Condition for WLS Unit 2 as the responsibility of the applicant and explains why a geologic mapping License Condition is not necessary for WLS Unit 1. Section 2.5.3.5 of this report defines the applicant's responsibility for geologic mapping at WLS Unit 2 as License Condition (2-2).

2.5.1.6 *Conclusion*

The staff reviewed the WLS COL FSAR and the referenced DCD. Based on these reviews, the staff confirmed that the applicant addressed the required information related to basic geologic and seismic characteristics, and that no additional outstanding information must be discussed in WLS COL FSAR related to these characteristics. NUREG-1793 and its supplements document the results of the staff's technical evaluation of the information incorporated by reference into the WLS application.

As set forth above, the staff has reviewed the information in WLS 2.5-1 and finds that the applicant provided a thorough characterization of basic geologic and seismic information for WLS, as required by 10 CFR 100.23 and 10 CFR 52.79(a)(1)(iii). In addition, the staff concludes that the applicant identified and appropriately characterized all seismic sources significant for determining the GMRS, or SSE, for this COL site, in accordance with NRC regulations provided in 10 CFR 100.23 and 10 CFR 52.79(a)(1)(iii) and guidance provided in RG 1.208. Based on the applicant's geologic investigations performed for the site region, site vicinity, site area, and site location, the staff concludes that the applicant properly characterized regional and site lithology, stratigraphy, geologic and tectonic history, and structural geology, as well as subsurface soil materials and rock units at WLS. The staff also concludes that there is no potential for effects of human activity (i.e., mining activity or ground water injection or withdrawal) to compromise site safety. Therefore, the staff concludes that the proposed WLS site is acceptable from the standpoint of geologic and seismic information and meets the requirements of 10 CFR 100.23 and 10 CFR 52.79(a)(1)(iii).

WLS COL 2.5-1 addresses the provision of regional and site-specific geologic, seismic, and geophysical information, as well as conditions caused by human activity. Based on the discussion of the basic geologic and seismic information presented in WLS COL FSAR Section 2.5.1, and the technical evaluation presented above in FSER Section 2.5.1.4, the staff concludes that the applicant provided the information required to satisfy WLS COL 2.5-1.

2.5.2 Vibratory Ground Motion

2.5.2.1 *Introduction*

The vibratory ground motion is evaluated based on seismological, geological, geophysical, and geotechnical investigations carried out to determine the site-specific GMRS, which must meet the regulations for SSE provided in 10 CFR 100.23. The GMRS is defined as the free-field horizontal and vertical ground motion response spectra at the plant site. The development of the GMRS is based upon a detailed evaluation of earthquake potential, taking into account the regional and local geology, Quaternary tectonics, seismicity, and site-specific geotechnical engineering characteristics of the site subsurface material. The specific investigations necessary to determine the GMRS include the seismicity of the site region and the correlation of earthquake activity with seismic sources. Seismic sources are identified and characterized, including the rates of occurrence of earthquakes associated with each seismic source. Seismic sources that have any part within 320 km (200 mi) of the site must be identified. More distant sources that have a potential for earthquakes large enough to affect the site must also be identified. Seismic sources can be capable tectonic sources or seismogenic sources. The review covers the following specific areas: (1) seismicity; (2) geologic and tectonic characteristics of the site and region; (3) correlation of earthquake activity with seismic sources; (4) probabilistic seismic hazard analysis and controlling earthquakes; (5) seismic wave transmission characteristics of the site; (6) site-specific ground motion response spectrum; and (7) any additional information requirements prescribed within the "Contents of Application" sections of the applicable Subparts to 10 CFR Part 52, "Licenses, certifications, and approvals for nuclear power plants."

2.5.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.5, incorporates by reference AP1000 DCD, Revision 19, Section 2.5.2.

In addition, in WLS COL FSAR Section 2.5.2, the applicant provided site-specific information to address the following:

AP1000 COL Information Item

- WLS COL 2.5-2

The applicant provided additional information in WLS COL 2.5-2 to address COL Information Item 2.5-2. WLS COL 2.5-2 addresses the provision for site-specific information related to vibratory ground motion aspects of the site including: seismicity, geologic and tectonic characteristics, correlation of earthquake activity with seismic sources, probabilistic seismic hazard analysis (PSHA), seismic wave transmission characteristics and the SSE ground motion.

- WLS COL 2.5-3

The applicant provided additional information in WLS COL 2.5-3 to resolve COL Information Item 2.5-3, which addresses the provision for performing site-specific evaluations, if the site-specific GMRS at foundation level exceed the response spectra in AP1000 DCD Figures 3.7.1-1 and 3.7.1-2 at any frequency, or if soil conditions are outside the range evaluated for the AP1000 DCD.

2.5.2.2.1 Seismicity

WLS COL FSAR Section 2.5.2.1 states that the applicant used the most recent earthquake catalog published as part of NUREG-2115, "Central and Eastern United States Seismic Source Characterization for Nuclear Facilities," in its seismic hazard assessment at the WLS Site. The NUREG-2115 earthquake catalog covers earthquakes in the CEUS region from 1568 through 2008. The applicant indicated that since the compilation of the NUREG-2115 earthquake catalog, the moment magnitude (**M**) 5.8, 2011, Virginia earthquake was the most significant earthquake. The epicenter of this earthquake was located approximately 450 km (280 mi) from the WLS site. Although this earthquake falls outside the WLS Site region, the applicant discussed the earthquake as part of the discussion of the Central Virginia seismic zone (WLS COL FSAR Section 2.5.1.1.3.2.4) and in the source characterization (WLS COL FSAR Section 2.5.2.2.5.2). Figure 2.5.2-1 of this report shows the seismicity of the WLS site region and its surroundings. The largest earthquake within 40 km (25 mi) of the WLS Site in the NUREG-2115 earthquake catalog is the 1886 E[**M**] 4.13 event.

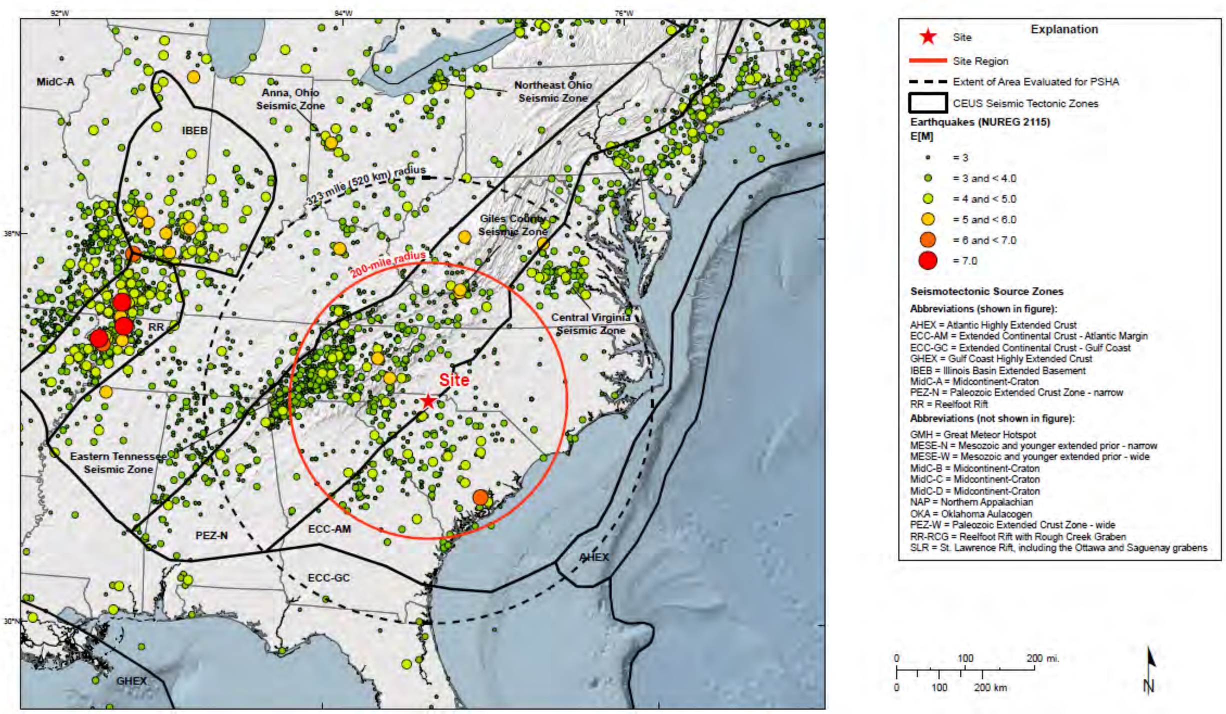

Figure 2.5.2-1 Map Showing The Earthquake Activity in The CEUS Region and The WLS Site (Ref. WLS COL FSAR Revision 8, Figure 2.5.2-248)

2.5.2.2.1.1 *Reservoir-Induced Seismicity*

In WLS COL FSAR Section 2.5.2.1.3, the applicant evaluated the potential for Reservoir-Induced Seismicity (RIS) associated with the construction and operation of Make-Up Pond C. The applicant stated that no documented RIS is associated with the Make-Up Pond B constructed as a part of the former Cherokee Nuclear Station, but noted that factors controlling the presence or absence of RIS are strongly dependent on local geologic properties, including reservoir rock type, fault and fracture characteristics, local and regional tectonics, and reservoir operation characteristics.

Following NUREG/CR-5503, the applicant stated the importance of making a distinction between triggered seismicity in regions of active faulting that are characterized by tectonic earthquakes of **M** greater than 5 in the historical record, such as the region west of the Rocky Mountains, and RIS in regions that are not associated with ongoing seismic activity and generally lack historical seismicity of **M** greater than 4. Triggered seismicity implies that a tectonic earthquake that was likely to occur at a later date is triggered and occurs earlier as a result of perturbations of elastic stresses and/or pore pressures associated with reservoir operations.

The applicant summarized the documented cases of RIS for reservoirs with hydraulic heights less than 60 m (196 ft) considering all U.S. Bureau of Reclamation reservoirs located in metamorphic terranes and all earthquakes located within 30 km (18 mi) of the reservoirs. In those cases post-impoundment maximum magnitudes have been less than **M**4 for reservoirs located in regions of low historical seismicity and have been less than or equal to **M**5 for reservoirs located in regions where historical pre-impoundment maximum magnitudes were greater than or equal to **M**5.5.

In the event that RIS associated with Make-Up Pond C occurs, the applicant concludes that it is unlikely that the induced magnitudes would exceed a **M** greater than 4, well below the short-period controlling earthquake. The applicant concluded that the potential for RIS associated with the Make-Up Pond C impoundment is low with a negligible risk to safe operations for WLS Units 1 and 2.

2.5.2.2.2 Geologic and Tectonic Characteristics of the Site and Region

WLS COL FSAR Section 2.5.2.2 describes the seismic sources and seismic model parameters that the applicant used to calculate the seismic ground motion hazard at the WLS site. The applicant used the NUREG-2115 regional seismic source characterization model developed for the CEUS region as a starting point for its seismic ground motion hazard analysis. The NUREG-2115 seismic source model is a model published in January 2012. The model development followed the Senior Seismic Hazard Analysis Committee (SSHAC) Level 3 procedures as outlined in NUREG/CR-6372, “Recommendations for Probabilistic Seismic Hazard Analysis: Guidance on Uncertainty and Use of Experts,” and NUREG-2117, “Practical Implementation Guidelines for SSHAC Level 3 and 4 Hazard Studies.” The NUREG-2115 model is a regional seismic source model to be used as a starting model in seismic hazard calculations for nuclear facilities in the CEUS region. The applicant stated that it conducted a review of the NUREG-2115 model to identify whether there is a need to update any of the seismic sources. Based on its review results, the applicant stated that the regional model, as published, is adequate for use in seismic hazard calculations for the WLS site. The following describes a summary of the NUREG-2115 model.

2.5.2.2.2.1 *Summary of NUREG-2115 Seismic Source Model*

The applicant stated that the CEUS SSC model described in NUREG-2115 contains two types of seismic sources: (1) distributed seismicity sources; and (2) repeated large magnitude earthquake sources. While the distributed seismicity sources were developed based on available earthquake locations and regional geologic/tectonic characterizations, the RLME sources were based on geologic and paleo-earthquake records. The RLME sources represent the zones of repeated (two or more) large magnitude earthquakes (**M** > 6.5) in the CEUS region.

The NUREG-2115 model categorizes the distributed seismicity sources into two subgroups: Mmax zones and seismotectonic zones. These subgroups represent uncertainties in source characterizations and differences of opinions in seismic source identification in this region. In hazard estimates, the Mmax and seismotectonic sources are weighted by 40 percent and 60 percent, respectively, to determine their contributions to the total seismic hazard at the site. The Mmax zones are broad seismic sources identified based on limited tectonic information and represent potential seismic sources of future earthquakes. The seismotectonic sources are those developed by extensive analyses of regional geology, tectonics, and seismicity in the CEUS region. Both the Mmax and the seismotectonic zones also include alternative source geometries, accommodating inherent uncertainty in seismic source characterization. The RLME sources are superimposed on the distributed seismicity sources.

2.5.2.2.2.2 *Post-NUREG-2115 Seismic Source Characterization Studies*

In WLS COL FSAR Section 2.5.2.2.5, the applicant discussed geologic and seismic investigations of the site region and beyond that provide information that could be used to evaluate and potentially update the NUREG-2115 model relevant to the WLS site PSHA. Specifically, the applicant discussed ongoing investigations of the: (1) Eastern Tennessee seismic zone (ETSZ); and (2) **M**5.8, 2011, Virginia earthquake.

Geologic Investigations of the Eastern Tennessee Seismic Zone

The ETSZ can be identified as a narrow trend of concentrated seismicity east of the New York-Alabama magnetic lineament and seismicity associated with the ETSZ is located within the WLS site region. The applicant stated that in spite of the high rate of seismic activity in the ETSZ, the largest historical earthquake in the region is magnitude 4.6 (magnitude scale unspecified). The applicant stated that recent geologic studies of the ETSZ either post-date the NUREG-2115 model or were published during development of the NUREG-2115 model. These studies suggest that the ETSZ may have produced large prehistoric earthquakes.

The applicant discussed the findings of Vaughn (2010), Obermeier (2010), Howard (2011), Warrell (2012), and Hatcher (2012). Vaughn (2010) found minor surface faulting, fracturing, and disrupted features in terrace alluvium, along with minor paleoliquefaction, northeast of Knoxville, TN. Similarly, Obermeier (2010) documented Douglas Reservoir fracture systems and sandy intrusions in terrace deposits that they interpret as paleoseismic in origin, although the applicant stated the significance of these features is unclear. Howard (2011) and Warrell (2012) document fractures, small faults, and displacements in Quaternary alluvium along Douglas Reservoir that they suggest resulted from earthquakes with magnitudes greater than 6.0 and 6.5 (magnitude scale unspecified). The applicant explained that Hatcher (2012) continued studying the Douglas Reservoir by coupling geologic observations with preliminary optically stimulated luminescence age dating of Quaternary deposits. Hatcher concluded that one or more "probable minimum" **M**6.5 earthquakes could be associated with the ETSZ within the last 73 to approximately 200 ka.

The applicant stated that while these recent studies strengthen the argument that the ETSZ has experienced at least one moderate-sized earthquake in the late Quaternary, the studies do not quantify parameters such as recurrence interval and magnitude, which are necessary parameters to demonstrate that the ETSZ produces repeating large-magnitude events as defined in NUREG-2115. Therefore, the applicant concluded that the ETSZ is best modeled within its NUREG-2115 host seismic source zones, the Mesozoic-and-younger extended crust Mmax zone (MESE) and the Paleozoic extended seismotectonic zones (PEZ), and that creation of an ETSZ RLME source is not warranted.

Investigations of the **M**5.8, 2011, Virginia Earthquake

The **M**5.8, 2011, Virginia earthquake was the largest historical event in the region and the largest instrumentally recorded earthquake in eastern North America since the 1988 **M**5.84 Saguenay earthquake. The **M**5.8, 2011, event occurred after completion of the NUREG-2115 earthquake catalog and is not included in the applicant's earthquake catalog. Numerous scientific studies have been conducted to identify the surface rupture associated with the earthquake, but the applicant reports that the consensus results of these investigations suggest that the earthquake occurred on a previously unrecognized structure, the dimensions of which are unknown and not observable at the ground surface. Therefore, the applicant did not include the **M**5.8, 2011, earthquake as a new fault or RLME source in the WLS site PSHA. The applicant stated that without slip-rate, recurrence, or maximum magnitude constraints for the structure defined by the distribution of aftershock hypocenters that likely produced the earthquake, it is most appropriate to consider it as an event captured by the host seismic source zones (ECC-AM, MESE-N, MESE-W, and Study Region) in the NUREG-2115 model framework. In addition, the applicant stated that because of the distance to the WLS site (approximately 450 km (280 mi)), and the buffer between the earthquake magnitude and lower end of the host seismic source zones' maximum magnitude distribution. The applicant concluded that no changes to the NUREG-2115 model were required due to the **M**5.8, 2011, event.

2.5.2.2.3 Correlation of Earthquake Activity with Seismic Sources

In WLS COL FSAR Section 2.5.2.3, the applicant discussed the correlation of the NUREG-2115 earthquake catalog to the specific NUREG-2115 seismic sources used by the applicant. Since the applicant did not update the NUREG-2115 earthquake catalog or seismic sources, the applicant chose to rely on the correlation of earthquake activity with seismic sources defined in NUREG-2115.

2.5.2.2.4 Probabilistic Seismic Hazard Analysis and Controlling Earthquakes

WLS COL FSAR Section 2.5.2.4 presents the results of the applicant's PSHA for the WLS site. In performing this analysis, the applicant followed the guidance provided in RG 1.208 to determine the seismic hazard curves and controlling earthquakes for the WLS site. The applicant based its analyses on the NUREG-2115 seismic source model and the EPRI (2013) ground motion prediction equations. The PSHA curves generated by the applicant represent generic hard rock conditions characterized by a shear wave velocity (V_S) in excess of 2.8 kilometers per second (km/s) (9,200 feet per second (fps)). The applicant also described the earthquake potential for the site in terms of a uniform hazard response spectra (UHRS) and the controlling earthquakes, the most likely earthquake magnitudes and source-site distances. The applicant determined the low- and high-frequency controlling earthquakes by deaggregating the PSHA curves at selected probability levels. The summary of the applicant's PSHA study is described below.

2.5.2.2.4.1 *PSHA Inputs*

To conduct the PSHA and obtain the UHRS at the site, it is necessary to study the site location and its surrounding regions to determine geological and seismological properties, as outlined in

RG 1.208. This requires determinations of active seismic source zones in the area, the seismic sources' model parameters, and appropriate ground motion models (GMM) for the region. The following subsections summarize the applicant's efforts in these areas.

2.5.2.2.4.1.1 Seismic Source Models and Parameters

The input model for the WLS PSHA study is the NUREG-2115 seismic source model. The applicant stated that it included all Mmax zones defined by the NUREG-2115 model in its hazard calculation for the WLS Site, truncated at a distance from the site of approximately 520 km (325 mi). The seismotectonic zones that the applicant included in the hazard calculation for the WLS site are the Atlantic Highly Extended Crust (AHEX), Extended Continental Crust-Atlantic Margin (ECC-AM), Extended Continental Crust-Gulf Coast (ECC-GC), Illinois Basin Extended Basement (IBEB), Paleozoic Extended Crust (PEZ), Midcontinent-Craton (MidC) seismotectonic zones (MidC-A through MidC-D), and Reelfoot Rift zone-Rough Creek graben (RR-RCG) zones. The applicant truncated each seismotectonic zone at a distance of 520 km (325 mi) from the site. The applicant determined that the RLME sources that contribute significantly to hazard at the WLS site are Charleston and New Madrid RLME sources, so the applicant included the Charleston and New Madrid RLME sources in its hazard calculations.

2.5.2.2.4.1.2 Ground Motion Models

In WLS COL FSAR Section 2.5.2.4.1, the applicant stated that it used the CEUS ground motion prediction model published in 2013 by EPRI for its PSHA calculations. These models were reviewed by the staff. In an August 28, 2013, letter to the Nuclear Energy Institute, the staff concluded that the EPRI (2013) GMM is an acceptable ground motion attenuation model for use by CEUS plants in developing plant-specific GMRS until such time as the Next Generation Attenuation project for eastern North America (NGA-East) project is completed and has been reviewed and approved by the staff. The NGA-East project is being conducted as a higher level SSHAC project than the EPRI (2013) GMM and will benefit from the development of the new GMM based on an expanded suite of earthquake recordings and simulations. Once complete, the NGA-East GMM will replace this EPRI (2013) GMM.

2.5.2.2.4.2 *PSHA Methodology and Calculation*

Using the updated NUREG-2115 seismic source characteristics and the EPRI (2013) GMM, the applicant performed PSHA calculations for peak ground acceleration (PGA) and spectral acceleration at ground motion frequencies of 0.5, 1.0, 2.5, 5, 10, and 25Hz. The applicant performed PSHA calculations for the WLS site assuming generic hard rock conditions at the site with V_S of 2.8 km/s (9,200 fps). The applicant first calculated mean and fractile rock seismic hazard curves at seven particular spectral frequencies (0.5, 1.0, 2.5, 5, 10, 25, and PGA (100 Hz)) and annual frequencies of exceedance (10^{-4}, 10^{-5}, and 10^{-6}). Then, the applicant deaggregated the results as described in RG 1.208 to calculate the controlling earthquakes for low- and high-frequency ground motions. Finally, the applicant used the WLS controlling earthquakes, and hard rock spectral shapes for CEUS earthquake ground motions recommended in NUREG/CR-6728 to calculate the final WLS generic hard rock UHRS.

2.5.2.2.4.3 *PSHA Results*

In WLS COL FSAR Section 2.5.2.4.2, the applicant stated that the local background, Charleston and New Madrid seismic sources contribute to seismic hazard at the WLS site. The applicant plotted its deaggregation results in WLS COL FSAR Figures 2.5.2-231 through -236. For a 10^{-4} annual frequency of exceedance, the applicant stated that the background and Charleston sources are the largest contributors to seismic hazard at both low- (1 and 2.5 Hz) and high-frequencies (5 and 10 Hz). For a 10^{-5} annual frequency of exceedance, the applicant obsevered that the background and Charleston sources are the largest contributor to seismic hazard for low-frequencies and the background source is the largest contributor to seismic hazard at high-frequencies. For a 10^{-6} annual frequency of exceedance, the applicant stated that the Charleston contribution is smaller at low-frequencies and is absent for high-frequencies and that the local background sources representing seismicity dominate for all annual frequencies of exceedance for high-frequencies.

The applicant also calculated the controlling earthquakes' distances and magnitudes for the low- and high-frequency earthquakes using the generic rock hazard curves. Table 2.5.2-1 of this report shows the results of the applicant's calculations.

Table 2.5.2-1 Controlling Earthquakes for the WLS Site
(Ref. WLSA COL FSAR Revision 8, Table 2.5.2-218)

	Mean 10^{-4}	Mean 10^{-5}	Mean 10^{-6}
Low Frequency **M** (R>100 km)	7.2	7.3	7.4
Low Frequency R (R>100 km)	250 km	230 km	190 km
High Frequency **M**	6.1	6.0	6.2
High Frequency R	35 km	16 km	12 km

Following the calculations of the controlling earthquake distances and magnitudes, the applicant calculates PSHA results using the NUREG-2115 seismic source model and the EPRI (2013) ground motion prediction models at the seven defined frequencies. The applicant determined the smoothed UHRS at the generic rock level and the applicant's UHRS curves for 10^{-4}, 10^{-5}, and 10^{-6} annual exceedance levels are shown as the blue, red, and green curves, respectively, in Figure 2.5.2-2 of this report.

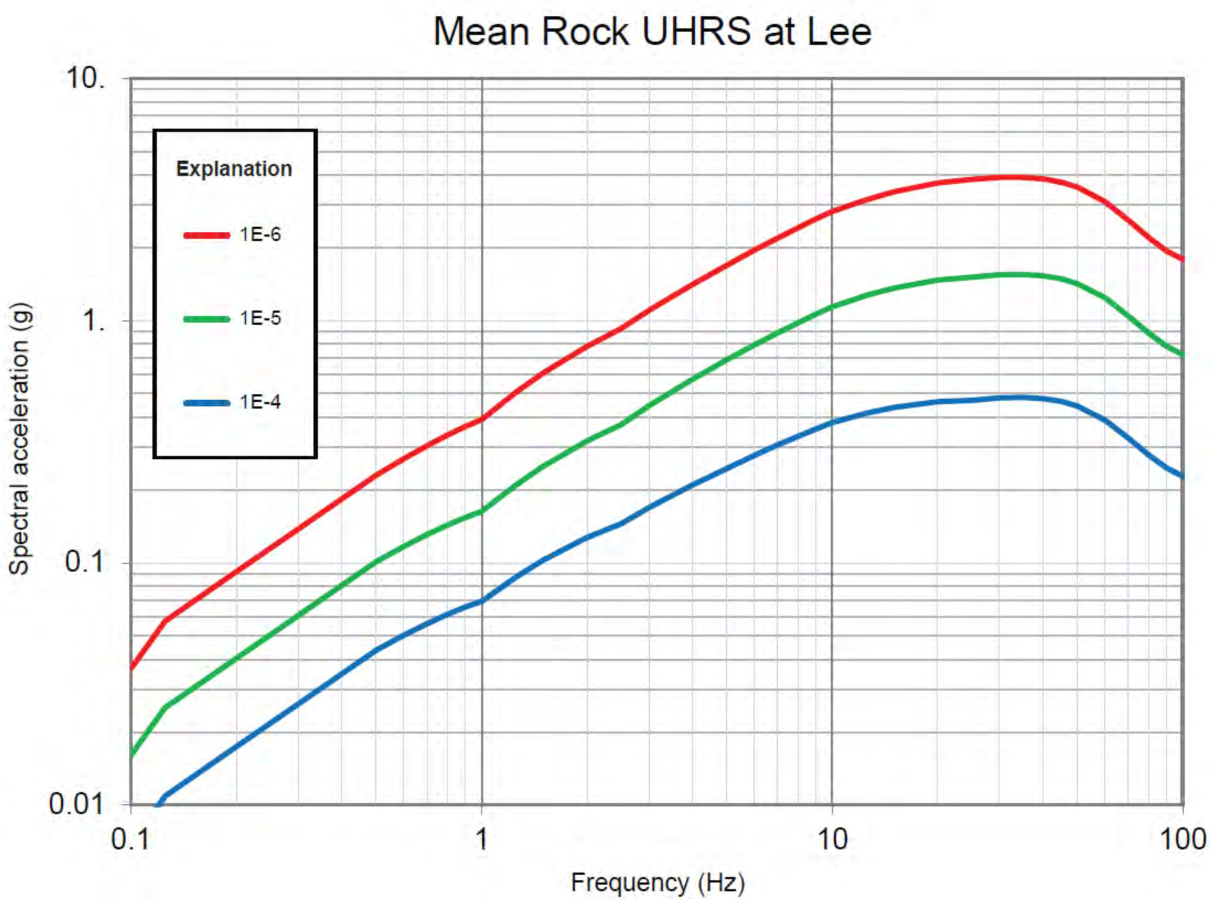

Figure 2.5.2-2 Smoothed Uniform Hazard Response Spectra For the Generic Rock Conditions at the WLS Site. (Ref. WLS COL FSAR Revision 8, Figure 2.5.2-266b)

2.5.2.2.5 Seismic Wave Transmission Characteristics of the Site

In WLS COL FSAR Section 2.5.2.5, the applicant characterized the WLS site as a hard rock site located on igneous and metamorphic rocks of Paleozoic age. WLS COL FSAR Section 2.5.1.2 describes the geology of the site area. The applicant referred to WLS COL FSAR Section 2.5.4 for a detailed discussion of dynamic and static properties of the site foundation materials. The majority of V_s measurements at the site exceed 2.8 km/s (9,200 fps), the hard rock definition used by CEUS attenuation relationships (2.83 km/s (9,282 fps)). Some near-surface V_s measurements fall below 2.8 km/s (9,200 fps). The applicant stated that variation in V_s measurements of several hundred feet per second centered at the hard rock condition result in a negligible variation in site response calculation results.

Based on the majority of near-surface V_s exceeding 2.8 km/s (9,200 fps), the applicant concluded that the WLS site is a hard rock site and therefore the EPRI (2013) ground motion equations were used directly, without calculation of site response. The UHRS reflects this hard rock condition.

2.5.2.2.6 Ground Motion Response Spectra

WLS COL FSAR Section 2.5.2.6 describes the method used by the applicant to develop the horizontal and vertical site-specific GMRS. The applicant first developed the horizontal GMRS and then obtained the vertical GMRS using vertical-to-horizontal (V/H) ratios. The applicant stated that it did not use the cumulative absolute velocity (CAV) model in its final hazard calculation.

2.5.2.2.6.1 *Horizontal GMRS*

The applicant calculated a horizontal, site-specific, performance-based GMRS using the method described in RG 1.208. The performance-based method achieves the annual target performance goal (PF) of 10^{-5} per year for frequency of onset of significant inelastic deformation. This damage state represents a minimum structural damage state, or essentially elastic behavior, and falls well short of the damage state that would interfere with functionality. The GMRS is calculated using the following relationship.

$$\text{GMRS} = \text{UHRS} * \text{DF}$$

Where

$$\text{UHRS} = \text{Mean } 10^{-4} \text{ UHRS}$$

$$\text{DF} = \max \{1.0, 0.6\ (\text{AR})^{0.8}\}$$

$$\text{AR} = 10^{-5} \text{ UHRS} / 10^{-4} \text{ UHRS}$$

RG 1.208 also states, if AR as defined above is greater than 4.2, then this relationship is no longer valid. In this case, RG 1.208 recommends setting the GMRS to 45 percent of the 10^{-5} site-specific surface UHRS curve. Figure 2.5.2-3 of this report shows the horizontal GMRS curve calculated for the WLS Site.

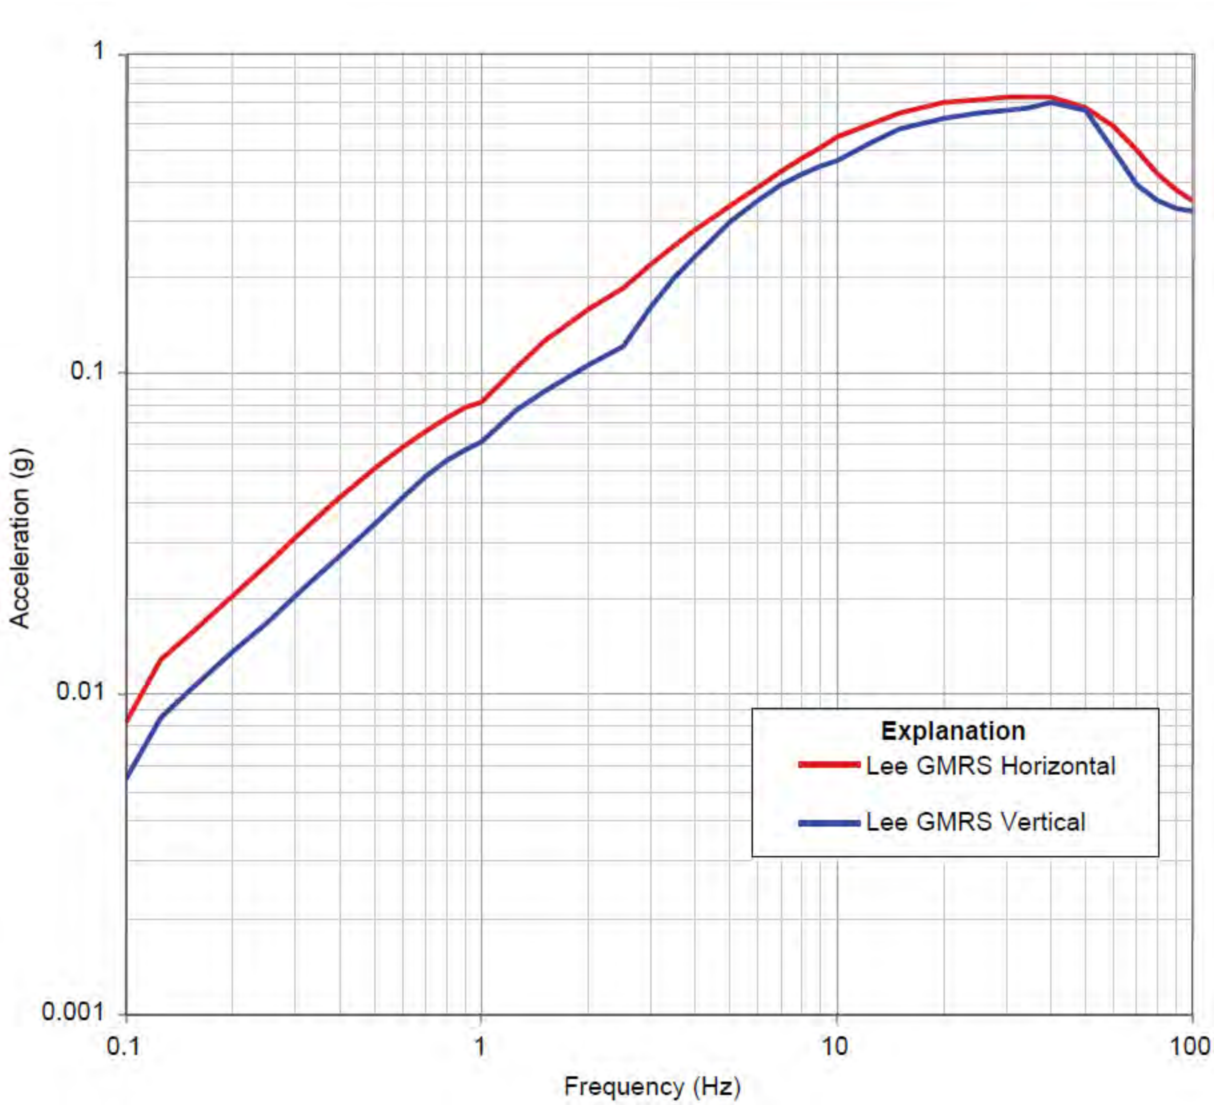

Figure 2.5.2-3 GMRS For Horizontal and Vertical Motion
(Ref. WLS COLFSAR Revision 8, Figure 2.5.2-239)

2.5.2.2.6.2 *Vertical GMRS*

In WLS COL FSAR Section 2.5.2.6, the applicant calculated the vertical GMRS by integrating the horizontal hazard curves with distributions of V/H ratios, which the applicant used to maintain the same exceedance probability as the horizontal hazard. V/H ratios can vary with source distance, so the range of ratios used by the applicant was intended to cover the deaggregation distances. The applicant presented a subset of the median estimates of the computed V/H ratios and demonstrated that there is little change at distances beyond about 10 to 15 km (6 to 9 mi), with an abrupt jump in the ratios within about 10 km (6 mi). The ratios are largely independent of frequency with a peak near 60 Hz, and range in amplitude from about 0.5 to about 1 as distance decreases. These values, at low frequency, are lower than empirical hard rock central and eastern North America (CENA) V/H ratios, which average about 0.8, decreasing from about 0.9 at 1 Hz to about 0.7 at 10 Hz. While these empirical V/H ratios are for Fourier amplitude spectra and not 5 percent damped response spectra and are dominated by small earthquakes of **M** less than or equal to 4, and large distances greater than or about 201 km (125 mi), the results illustrate the large uncertainty in vertical hard rock hazard for CENA and suggest large distant ratios may be greater than model predictions at low frequency. The applicant adopted a minimum V/H ratio of 0.7, the average of the empirical and simulations. To accommodate the change in source distance with both annual exceedance probability and structural frequency shown in the deaggregation plots (WLS COL FSAR Figures 2.5.2-231 through -236), V/H ratios computed at a suite of distances were given relative weights. The distances selected are 27, 6.4, and 0 km (17, 4, and 0 mi) to cover ratios reflecting distant, intermediate, and near source contributions. The resulting vertical GMRS is shown in Figure 2.5.2-3 of this report.

2.5.2.2.7 Development of FIRS for Units 1 and 2

In WLS COL FSAR Section 2.5.2.7, the applicant described how it preformed analyses to develop the site-specific foundation input response spectra (FIRS). While the applicant described development of FIRS in WLS COL FSAR Section 2.5.2.7, the staff's summary and technical evaluation of the FIRS is described in Section 3.7.1 of this report.

2.5.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed within the FSER related to the AP1000 DCD.

In addition, the applicable regulatory requirements for reviewing the applicant's discussion of vibratory ground motion are as follows:

- 10 CFR 100.23, as it relates to obtaining geologic and seismic information necessary to determine site suitability and ascertain that any new information derived from site-specific investigations does not impact the GMRS derived by a probabilistic seismic hazard analysis. In complying with this regulation, the applicant also meets guidance in RG 1.132 and RG 1.208.

- 10 CFR 52.79(a)(1)(iii), as it relates to consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity and period of time in which the historical data have been accumulated.

The related acceptance criteria from NUREG-0800, Section 2.5.2 are summarized as follows:

- Seismicity: To meet the requirements in 10 CFR 100.23, this subsection is accepted when the complete historical record of earthquakes in the region is listed and when all available parameters are given for each earthquake in the historical record.

- Geologic and Tectonic Characteristics of Site and Region: Seismic sources are identified and characterized.

- Correlation of Earthquake Activity with Seismic Sources: To meet the requirements in 10 CFR 100.23, acceptance of this subsection is based on the development of the relationship between the history of earthquake activity and seismic sources of a region.

- Probabilistic Seismic Hazard Analysis and Controlling Earthquakes: For CEUS sites relying on NUREG-2115 methods and data bases, the staff will review the applicant's PSHA, including the underlying assumptions and how the results of the site investigations are used to update the existing sources in the PSHA, how they are used to develop additional sources, or how they are used to develop a new data base.

- Seismic Wave Transmission Characteristics of the Site: In the PSHA procedure described in RG 1.208, the controlling earthquakes are determined for generic rock conditions.

- Ground Motion Response Spectra: In this subsection, the staff reviews the applicant's procedure to determine the GMRS.

In addition, the geologic and seismic characteristics should be consistent with appropriate sections from: RG 1.60, "Design Response Spectra for Seismic Design of Nuclear Power Plants"; RG 1.132, "Site Investigations for Foundations of Nuclear Power Plants"; RG 1. 206, "Combined License Applications for Nuclear Power Plants (LWR Edition)"; and RG 1.208, "A Performance-Based Approach to Define the Site-Specific Earthquake Ground Motion."

2.5.2.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.5.2 and checked the referenced DCD to ensure that the combination of the DCD and the information in the COL represent the complete scope of information relating to this review topic. The staff's review confirmed that the information contained in the application and incorporated by reference addresses the required information relating to the vibratory ground motion. AP1000 DCD, Revision 19, Section 2.5.2 was reviewed by the staff under Docket Number 56-006. The staff's technical evaluation of the information incorporated by reference related to the vibratory ground motion is documented in the staff's safety evaluation report on the DC application for the AP1000 design.

The staff reviewed the following information contained in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 2.5-2

The staff reviewed WLS COL 2.5-2 related to COL Information Item 2.5-2, which addresses the provision for site-specific information related to the vibratory ground motion aspects of the site including: seismicity; geologic and tectonic characteristics; correlation of earthquake activity with seismic sources; probabilistic seismic hazard analysis; seismic wave transmission characteristics and the SSE ground motion.

- WLS COL 2.5-3

The staff reviewed WLS COL 2.5-3 related to COL Information Item 2.5-3, which addresses the provision for performing site-specific evaluations, if the site-specific GMRS at foundation level exceed the response spectra in AP1000 DCD Figures 3.7.1-1 and 3.7.1-2 at any frequency, or if soil conditions are outside the range evaluated for the AP1000 DCD.

Section 2.5.2.4 of this report provides the staff's evaluation of the seismic, geologic, geophysical, and geotechnical investigations carried out by the applicant to determine the site-specific GMRS, or the SSE ground motion for the site. The development of the GMRS is based upon a detailed evaluation of earthquake potential, taking into account the regional and local geology, Quaternary tectonics, seismicity, and site-specific geotechnical engineering characteristics of the WLS site subsurface material.

During the early site investigation stage, the staff visited the site and interacted with the applicant regarding the geologic, seismic and geotechnical investigations conducted for the WLS application. To thoroughly evaluate the geologic, seismic and geophysical information presented by the applicant, the staff visited the WLS site over April 27 to May 2, 2008, and January 27 and 28, 2009, Technical experts from the USGS accompanied the staff during the January 2009 site visit to assist with evaluation of the geologic and seismic data. The staff's evaluation of the information the applicant presented in WLS COL FSAR Section 2.5.2 and in the applicant's responses to RAIs is presented below.

As discussed at the beginning of this report (Section 2.5, "Geology, Seismology, and Geotechnical Engineering"), the staff issued several RAIs to the applicant and evaluated the responses received during the review process. However, following the Fukushima accident in Japan in March 2011, and the subsequent NRC NTTF recommendations as well as the NRC March 12, 2012, letter, "Request for information pursuant to Title 10 of the *Code of Federal Regulations* 50.54(f) regarding recommendations 2.1, 2.3, and 9.3 of the near term task force review of insights from the Fukushima Dai-ichi accident," requesting the operating nuclear power plants to re assess seismic hazards at their sites using the most recent seismic source models, the staff issued an RAI to all COL and ESP applicants (RAI 105, Question 01.05-1 was issued to WLS) to reassess the seismic hazard at their sites using the new seismic source models. In a January 30, 2014, response, the applicant revised the WLS COL FSAR significantly, especially WLS COL FSAR Section 2.5.2 related to seismic hazard calculations. As part of this WLS COL FSAR revision, the applicant replaced the EPRI (1986, 1989) seismic source models previously used in the seismic hazard calculations at the site with the newly published NUREG-2115 CEUS SSC model. With this change in the base seismic source model, and the move of the Unit 1 nuclear island footprint 20.1 m (66 ft) south and 15.2 m (50 ft) east of CNS Unit 1 to avoid an area of deeply weathered saprolitic bedrock at the northwest corner of the old CNS Unit 1, many of the earlier RAIs became irrelevant and were closed without any specific resolution. The staff's evaluations of these earlier RAIs are not part of this report. However, new RAIs that the staff developed in response to the revised WLS COL FSAR are applicable to the staff's review and are discussed below.

2.5.2.4.1 Seismicity

WLS COL FSAR Section 2.5.2.1 states that the earthquake catalog used for the WLS site seismic hazard assessment is the NUREG-2115 earthquake catalog. The earthquake catalog published as part of the NUREG-2115 seismic source model covers the entire CEUS region from 1568 through 2008 and includes a uniform moment magnitude scale for all earthquakes listed in the catalog. The NUREG-2115 earthquake catalog covers the seismicity in the WLS site region through 2008 and provides critical data to assess seismic source model parameters used in the WLS PSHA study. Seismic source model parameters, such as maximum magnitude and earthquake recurrence rates, are primarily determined based on information available in the earthquake catalog. Since the staff reviewed the NUREG-2115 earthquake catalog previously, the staff's technical evaluation of WLS COL FSAR Section 2.5.2.1 focused on whether earthquakes that have occurred since completion of the NUREG-2115 earthquake catalog should be used to update the catalog for use in the WLS site PSHA.

As part of its review of WLS COL FSAR Section 2.5.2.1, the staff performed confirmatory analysis by developing a supplemental earthquake catalog covering the CEUS region from 2009 through September 15, 2014. The staff used this supplemental earthquake catalog to determine whether there are new earthquakes in the CEUS region since the development of the NUREG-2115 earthquake catalog that might impact the parameters of seismic sources identified in the NUREG-2115 model used in the WLS site PSHA study. The staff used the USGS Advanced National Seismic Network earthquake catalog (ANSS)[23] for this analysis. The staff searched for earthquakes with magnitudes 3.0 and above within the time window covering 2009 through September 15, 2014, throughout the CEUS as defined by NUREG-2115. The staff's supplemental earthquake catalog confirmed that the applicant's use of the NUREG-2115 earthquake catalog without updates adequately characterizes seismicity for the WLS site.

The staff's supplemental catalog showed that there are 912 earthquakes in the CEUS region (Figure 2.5.2-4 of this report) that occurred between 2009 and September 15, 2014. Five of these earthquakes are greater than or equal to **M**5.0. The earthquake with a **M** greater than or equal to **M**5.0 that is the closest to the WLS site is also the largest of these five events and it is the **M**5.8, 2011, Virginia earthquake, which is located approximately 450 km (280 mi) from the WLS site. The other large magnitude events occurred in November 2011, in Oklahoma and August 2011, in southern Colorado. The staff identified 60 earthquakes in the range between **M**4.0 and 4.9 distributed over the CEUS region. The majority of the earthquakes (847 of the 912) in the updated catalog are small magnitude earthquakes (**M** < 4.0).

[23] Advanced National Seismic System (ANSS), ANSS Catalog Search, http://www.ncedc.org/anss/catalog-search.html.

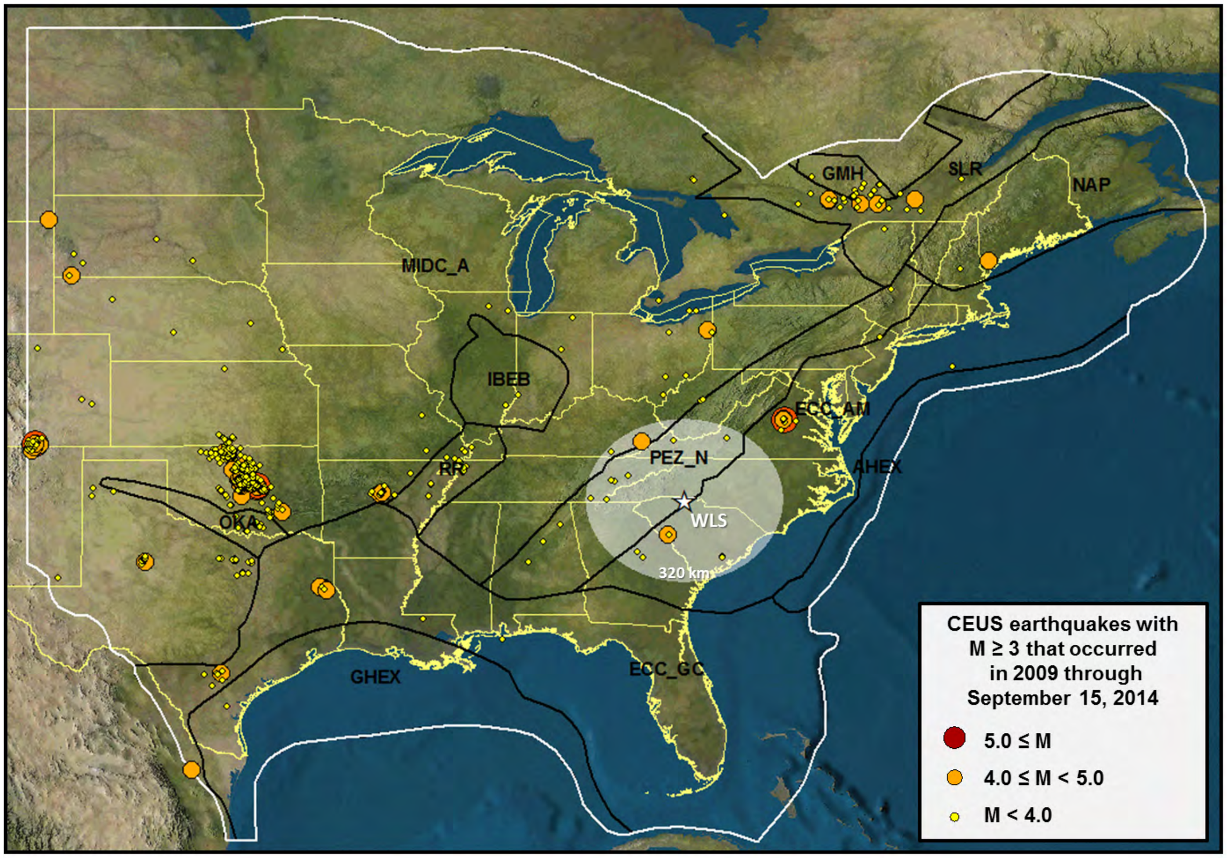

Figure 2.5.2-4 Earthquakes With Moment Magnitudes (M) Greater Than Or Equal to 3.0 In The CEUS That Occurred Between 2009 and September 15, 2014. The Outer White Polygon Defined the NUREG-2115 CEUS Region and the Black Lines and Labels Identify the NUREG-2115 CEUS-SS

Within the WLS site region, there were 15 earthquakes that occurred during 2009 through September 15, 2014. Of the 15 earthquakes within the WLS site region, there was a **M**4.2 on November 10, 2012, northeast of the WLS site in southeastern Kentucky and a **M**4.1 on February 15, 2012, southeast of the WLS site in eastern South Carolina. The other 13 earthquakes within the WLS site region that appear in the staff's supplemental earthquake catalog are all less than or equal to **M**3.3.

There are ten NUREG-2115 seismic sources zones that occur within the WLS site region. Those seismic source zones are modeled using maximum magnitude distributions that range from **M**5.6 through **M**8.1. The maximum magnitude distributions of the NUREG-2115 seismic sources zones that occur with the WLS site region are well above the 15 earthquake magnitudes that appear in the staff's supplemental earthquake catalog and occur within the WLS site region. Since all the large magnitude events (**M** > 5.0) are located outside of the WLS site region and all earthquakes in the supplemental catalog occurred within existing seismic sources with maximum magnitude distributions larger than the magnitudes of the observed events, the staff concludes from its confirmatory analysis that the earthquakes in the staff's supplemental earthquake catalog do not add any new information that might impact the parameters of the seismic sources of the seismic sources used in the WLS site PSHA study and, therefore, the applicant's use of NUREG-2115 earthquake catalog without updates adequately characterizes seismicity for the WLS site.

Reservoir-Induced Seismicity

Reservoir-induced seismicity is the triggering of earthquakes by the physical processes that accompany the impoundment of reservoirs (i.e., the effect of the mass of the added water on the underlying rocks, or the pore-fluid pressure changes from the added water). The applicant evaluated the potential for RIS associated with the construction and operation of Make-Up Pond C. To do this, the applicant reviewed worldwide cases of RIS near reservoirs with equivalent or greater hydraulic heights to Make-up Pond C, RIS near reservoirs in the Carolina Piedmont, and the U.S. Bureau of Reclamation records of RIS near reservoirs located in metamorphic terranes with equivalent or greater hydraulic heights to Make-up Pond C. Make-Up Pond C will be located in the Carolina Piedmont on metamorphic terrane, so the information the applicant reviewed is analogous to conditions at Make-Up Pond C and can be used to inform the analysis of the potential for RIS associated with the impoundment of that reservoir. Additionally, the applicant followed NUREG/CR-5503, "Techniques for Identifying Faults and Determining Their Origins," to analyze the relationships between faults, fault activity, and associated RIS.

The applicant conducted a thorough global review of reservoirs similar to or larger than Make-up Pond C. Since there are no active seismogenic faults near the location of Make-Up Pond C and historical seismic activity is low, any triggered seismicity associated with the impoundment of that reservoir is likely to be **M** < 5. Specifically for RIS associated with reservoirs located in the Carolina Piedmont on metamorphic terrane in regions of low historical seismicity, RIS magnitudes are **M** < 4. Additionally, no documented RIS was associated with the impoundment of Make-up Pond B during the construction of the former CNS located next to the WLS site. Lastly, as shown in Table 2.5.2-1 of this report, the local earthquakes that control the short-period hazard at the WLS are larger than potential RIS (minimum controlling earthquake **M** is equal to 6.0 for 10^{-4}, 10^{-5}, and 10^{-6} annual frequencies of exceedance). Therefore, the staff concludes it is unlikely that seismicity induced from the impoundment of Make-Up Pond C at the WLS site would exceed the **M** of the short-period controlling earthquakes and the potential for RIS associated with the Make-Up Pond C impoundment is low with a negligible risk to safe operations at the WLS site.

Staff Conclusions Regarding Seismicity

Based upon its review of the applicant's WLS COL FSAR Section 2.5.2.1 and the staff's confirmatory analysis, the staff concludes that the applicant used a complete and accurate earthquake catalog for the region surrounding the WLS site. The staff concludes that the seismicity catalog as described by the applicant in WLS COL FSAR Section 2.5.2.1 forms an adequate basis for the seismic hazard characterization of the site and meets the requirements of 10 CFR 52.79 and 10 CFR 100.23.

2.5.2.4.2 Geologic and Tectonic Characteristics of the Site and Region

WLS COL FSAR Section 2.5.2.2 describes the seismic sources and seismicity parameters used by the applicant to calculate the seismic ground motion hazard for the WLS site. Specifically, the applicant described the seismic source model published as part of NUREG-2115 in 2012. The staff previously reviewed the NUREG-2115 seismic source model and approved its use as a starting regional model for nuclear power plant applications. However, the NUREG-2115 model is a regional model and NUREG-2115 specifically states that it should be compared against the local data and information, and if needed, appropriate local adjustments must be conducted. As such, the staff primarily focused on the applicant's investigation of potential local seismic source and source parameter adjustments to the NUREG-2115 model.

2.5.2.4.2.1 *Modifications to NUREG-2115 model due to Post-NUREG-2115 Seismic Source Characterization Studies*

In WLS COL FSAR Section 2.5.2.2.5, the applicant discussed geologic and seismic investigations of the site region and beyond that provide information that could be used to potentially update the NUREG-2115 model relevant to the WLS site PSHA. Specifically, the applicant discussed ongoing investigations of the: (1) ETSZ; and (2) **M**5.8, 2011, Virginia earthquake. The following describes the staff's assessment of the applicant's evaluations of post-NUREG-2115 model seismic source characterization studies and their relevance to the WLS site PSHA.

<u>Geologic Investigations of the Eastern Tennessee Seismic Zone</u>

In WLS COL FSAR Section 2.5.2.2.5, the applicant discussed recent geologic studies of the ETSZ that either post-date the NUREG-2115 model or were published during development of the model. The seismicity associated with the ETSZ is located within the WLS site region. These studies suggest that the ETSZ may have produced large prehistoric earthquakes. Specifically, the applicant discussed the findings of Vaughn (2010), Obermeier (2010), Howard (2011), Warrell (2012), and Hatcher (2012). The applicant stated that while these recent studies strengthen the argument that the ETSZ has experienced at least one moderate-sized earthquake in the late Quaternary, the studies do not quantify parameters such as recurrence interval and magnitude, which are necessary parameters to demonstrate that the ETSZ produces repeating large-magnitude events as defined in NUREG-2115. Therefore, the applicant concluded that the ETSZ is best modeled within its NUREG-2115 host seismic source zones and that creation of an ETSZ RLME source is not warranted.

During the staff's review of the applicant's discussion of the ETSZ, the staff noted that the applicant focused on whether the findings of the new studies should be integrated into the NUREG-2115 model's characterization of seismic sources, but did not evaluate the potential significance of recent studies on the site-specific seismic hazard analysis. The new information suggests that the ETSZ might represent a site-specific seismic source that is not appropriately represented by the regional model. Since the applicant did not evaluate the potential significance of recent studies on the site-specific seismic hazard analysis, in RAI 117, Question 02.05.02-53, the staff requested that the applicant assess and evaluate the effects of such recent ETSZ research results on the site-specific seismic hazard analysis at the WLS site and to provide a thorough description of the assessment and evaluation, and provide the basis to explain and justify the conclusions.

In response to RAI 117, Question 02.05.02-53, the applicant performed hazard sensitivity studies to assess and evaluate the effects of the recent research results on the site-specific seismic hazard analysis at the WLS site. The applicant evaluated the ETSZ as a hypothetical RLME source as defined in NUREG-2115, sources that represent zones of repeated (two or more) large magnitude earthquakes (**M**>6.5) in the CEUS region. The applicant used the ETSZ source zone boundary defined by the USGS National Seismic Hazard Mapping Program (Peterson et al., 2008), as shown in Figure 2.5.2-5 of this report, for its sensitivity studies. The applicant performed two hazard sensitivity studies: (1) evaluated the sensitivity of the maximum magnitude distribution of the ETSZ source; and (2) evaluated the magnitude-frequency distribution for ETSZ. The applicant provided comparisons of its sensitivity studies to FSAR hazard results at the WLS site.

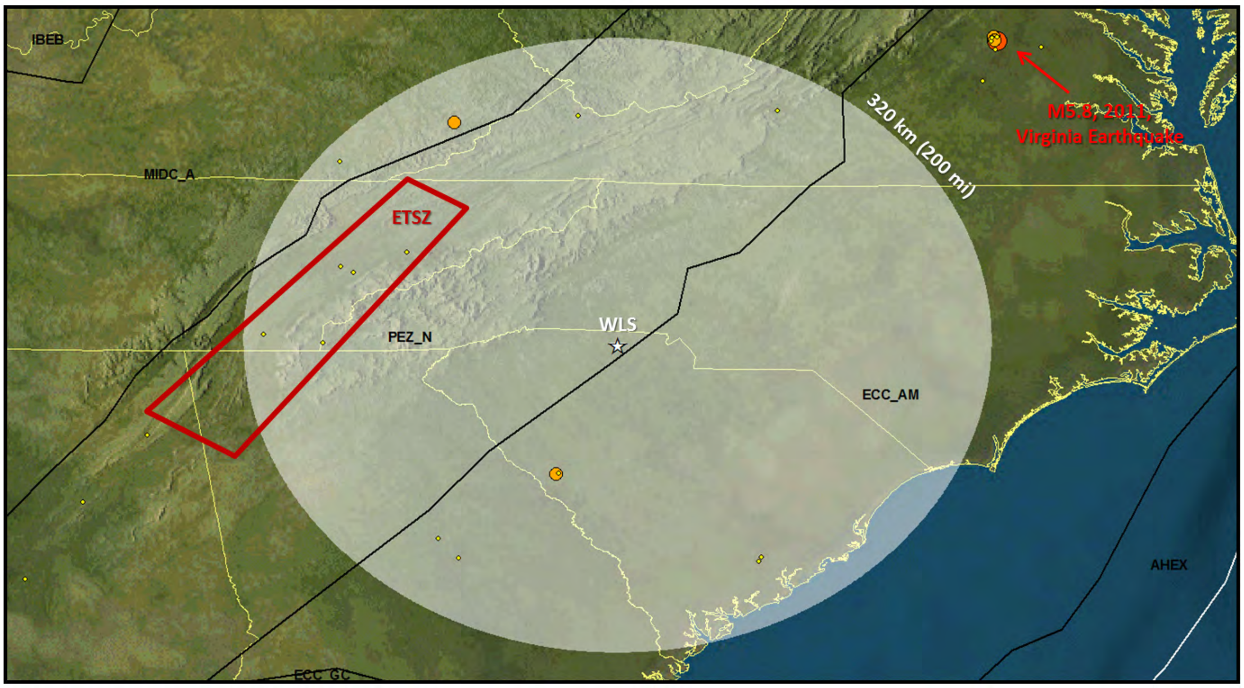

Figure 2.5.2-5 Approximate Representation of the USGS National Seismic Hazard Mapping Program (Peterson et al., 2008) ETSZ (Red Polygon) and The Black Lines and Labels Identify The NUREG-2115 CEUS-SSC Seismotectonic Zones (Model A)

To evaluate the sensitivity of the maximum magnitude distribution of ETSZ seismic sources, the applicant first assumed that the ETSZ had a maximum magnitude distribution equal to that of the PEZ-N seismic source, the host source for the WLS site. The applicant then assumed that a **M**6.5 earthquake occurred during the historical period within the ETSZ and re-assessed its maximum magnitude distribution, as shown in Table 2.5.2-2 of this report. The applicant then applied these updated, or sensitivity, maximum magnitude values to its ETSZ source and calculated the hazard for the ETSZ using both the PEZ-N maximum magnitude distributions and the updated maximum magnitude distributions. The applicant's calculations showed that the percent difference in total hazard using the two different ETSZ at spectral frequencies 1 and 10 Hz increased by 0.3 percent or less at the WLS site, as shown in Figure 2.5.2-6 of this report. The staff considers the differences calculated in this sensitivity study to be within the uncertainty in the overall PSHA calculations.

Table 2.5.2-2 Comparison Between Original (PEZ-N) and Updated Sensitivity Maximum Magnitude Distributions for The WLS ETSZ and Associated Weights (Ref. RAI 117, Question 02.05.02-53 Response Table 1)

CEUS SSC HID (M)	5.9	6.4	6.8	7.2	7.9
Sensitivity (M)	6.6	6.8	7.1	7.6	8.1
Weights	0.101	0.244	0.309	0.244	0.101

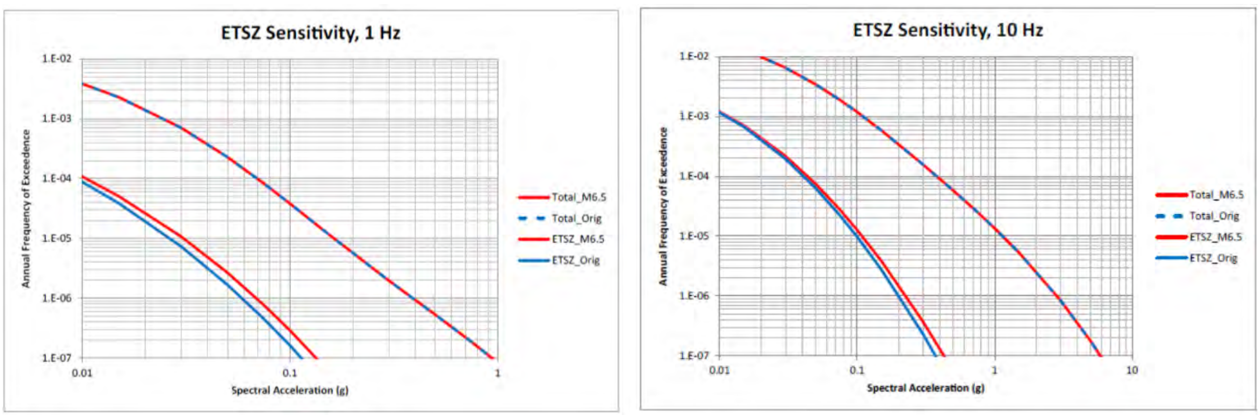

Figure 2.5.2-6 Comparison of Total Hazard and Hazard From The WLS ETSZ at 1 Hz (Left) and 10 Hz (Right). Blue Lines Show Hazard Using The PEZ-N Maximum Magnitude Distribution For The WLS ETSZ and The Red Lines Use The Updated Maximum Magnitude Distribution. (Ref. RAI 117, Question 02.05.02-53 Response Figure 2 and 3)

To evaluate the magnitude frequency distribution, or recurrence parameters, for the ETSZ, the applicant calculated magnitude frequency distributions for cell centers associated with the WLS ETSZ. Specifically, the applicant calculated magnitude frequency distributions for cell centers of the PEZ-N zone that lie within the boundary of the WLS ETSZ. The applicant stated that its magnitude frequency distribution calculations used the NUREG-2115 seismicity rates (a-values), b-values, and extracted parameters of rate per cell area, cell-area, and beta values for each source. The applicant developed the final weighted magnitude frequency distribution by applying the NUREG-2115 global logic tree weights to the calculated magnitude frequency distributions from each source. The applicant's calculated mean recurrence intervals for earthquakes occurring in the ETSZ with magnitudes ranging from 6.0 to 7.5 are tabulated in Table 2.5.2-3 of this report. The applicant stated that results show that the NUREG-2115 model indicates a mean recurrence interval for large earthquakes (**M**>6.5) in the ETSZ of 14,900 years. The applicant noted that this mean recurrence interval is consistent with the hypothetical occurrence of several such earthquakes in the late Pleistocene and Holocene (the last 130,000 years), as hypothesized by Hatcher (2012). The applicant concludes that these sensitivity results indicate that the NUREG-2115 model generates moderate to large events (**M** > 6.5) with sufficient frequency in the ETSZ area to explain the interpretation presented in Hatcher (2012) of field observations that imply the occurrence of two events of **M** > 6.5 or larger in the late Quaternary Period. The applicant stated that, without any modification, the NUREG-2115 model generates about seven **M**6.5 events and one **M**7.0 event in the ETSZ about every 100,000 years.

Table 2.5.2-3 Applicant's Estimated Mean Recurrence Intervals For Hypothetical ETSZ Large-Magnitude Events (Ref. RAI 117, Question 02.05.02-53 Response Table 4)

Magnitude (M)	Recurrence Interval (yrs)
≥6.0	3,200
≥6.5	14,900
≥7.0	103,000
≥7.5	1,000,000

The staff evaluated the applicant's response to RAI 117, Question 02.05.02-53 and its sensitivity studies. Because the applicant's sensitivity calculations showed that incorporating a **M**6.5 earthquake into the ETSZ magnitude distribution resulted in increases in total hazard of 0.3 percent or less at spectral frequencies 1 and 10 Hz at the WLS site and because the staff considers differences in total hazard of 0.3 percent as within the uncertainty in the overall PSHA calculations, the staff concludes that the applicant adequately assessed and evaluated the effects of recent research results on maximum magnitude distributions for the site-specific seismic hazard analysis at the WLS site. Additionally, because the applicant evaluated the magnitude-frequency distribution for the ETSZ and showed that the NUREG-2115 model generates **M**>6.5 events with sufficient frequency in the ETSZ area to explain the interpretation presented in recent research, the staff concludes that the applicant adequately assessed and evaluated the effects of recent research results on magnitude-frequency distributions for the site-specific seismic hazard analysis at the WLS site. Accordingly, the staff considers RAI 117, Question 02.05.02-53 resolved.

Investigations of the **M**5.8, 2011, Virginia Earthquake

The **M**5.8, 2011, Virginia earthquake occurred approximately 450 km (280 mi) northeast of the WLS site (Figure 2.5.2-5 of this report). The applicant did not include the **M**5.8, 2011, earthquake in its seismicity catalog or modify the NUREG-2115 model to incorporate the event in the WLS site PSHA. The staff reviewed updating the NUREG-2115 model to include the **M**5.8, 2011, Virginia earthquake in the WLS site PSHA. The staff previously reviewed the effect of the earthquake on site-specific PSHA parameters for a nuclear power plant application site located 180 km (112 mi) closer to the earthquake than the WLS site. Specifically, the staff reviewed the effect of the **M**5.8, 2011, Virginia earthquake on the PSEG site, which is located approximately 270 km (170 mi) from the earthquake. The staff's conclusion from review of the effect of the **M**5.8, 2011, Virginia earthquake on the PSEG site was that the effect of the **M**5.8, 2011, Virginia earthquake on the mean background hazard and the total mean site hazard at the PSEG site was negligible and that the PSEG applicant's use of the original NUREG-2115 model earthquake recurrence parameters was acceptable. Since the WLS site is located 180 km (112 mi) farther from the earthquake than the PSEG, the effect of the earthquake at the WLS site would be less than that assessed at the PSEG site. Therefore, the staff concludes that the applicant's use of the NUREG-2115 model earthquake recurrence parameters is acceptable for use in the WLS site PSHA.

2.5.2.4.2.2 *Staff Conclusions on Geologic and Tectonic Characteristics of the Site and Region*

Based upon its review of WLS COL FSAR Sections 2.5.2.2.5 and 2.5.2.4 and the applicant's response to RAI 117, Question 02.05.02-53, the staff concludes that the applicant adequately assessed the NUREG-2115 seismic sources as the input to its PSHA for the WLS site. In addition, the staff concludes that the applicant adequately considered modifications to the NUREG-2115 seismic sources for the WLS site. The staff concludes that the applicant's use of NUREG-2115 seismic source models as described by the applicant in WLS COL FSAR Sections 2.5.2.2.5 and 2.5.2.4 forms an adequate basis for the seismic hazard characterization of the site and meets the requirements of 10 CFR 52.79 and 10 CFR 100.23.

2.5.2.4.3 Correlation of Earthquake Activity with Seismic Sources

WLS COL FSAR Section 2.5.2.3 describes the correlation of seismicity in the region with the seismic source model used in the WLS PSHA study. The applicant discussed the correlation of the NUREG-2115 earthquake catalog to the specific NUREG-2115 seismic sources used by the applicant. The staff previously reviewed the NUREG-2115 seismic source model and approved its use as a starting regional model for nuclear power plant applications. Since the applicant did not update the NUREG-2115 earthquake catalog or seismic sources, the applicant chose to rely on the correlation of earthquake activity with seismic sources made in NUREG-2115. Based on the applicant's assessment in FSAR Section 2.5.2.3, the applicant's response to RAI 117, Question 02.05.02-53, and the staff's confirmatory analysis described in Section 2.5.2.4.1 of this report, the staff concludes that the applicant's characterization of the correlation of earthquake activity is adequate. Since the applicant adequately correlated the seismic activity in the WLS site region with the appropriate seismic source zones, the staff concludes that the applicant's analysis meets the requirements of 10 CFR 52.79 and 10 CFR 100.23.

2.5.2.4.4 Probabilistic Seismic Hazard Analysis and Controlling Earthquakes

In WLS COL FSAR Section 2.5.2.4, the applicant stated that it used the NUREG-2115 seismic model in the probabilistic seismic hazard calculations at the WLS site and the procedures outlined therein. Using the NUREG-2115 CEUS-SSC model sources and the EPRI (2013) GMM, the applicant calculated generic hard rock seismic hazard curves at the seven frequencies defined by the EPRI (2013) GMM. Using the hard rock seismic hazard curves, the applicant obtained UHRS at the annual frequency of exceedances of 10^{-4}, 10^{-5}, and 10^{-6}. Using the procedures outlined in RG 1.208, the applicant also developed the controlling earthquakes' magnitudes and distances. The following describes the staff's assessment of the applicant's PSHA calculations and the determination of the controlling earthquakes and their parameters.

2.5.2.4.4.1 *PSHA Inputs*

As described in Section 2.5.2.2.4 of this report, the applicant implemented the entire NUREG-2115 model with no modifications. The applicant stated that it included all Mmax zones defined by the NUREG-2115 model in its hazard calculation for the WLS site, truncated at a distance from the site of approximately 520 km (325 mi). The seismotectonic zones that the applicant included in the hazard calculation for the WLS site are the Atlantic Highly Extended Crust (AHEX), Extended Continental Crust-Atlantic Margin (ECC-AM), Extended Continental Crust-Gulf Coast (ECC-GC), Illinois Basin Extended Basement (IBEB), Paleozoic Extended Crust (PEZ), Midcontinent-Craton (MidC) seismotectonic zones (MidC-A through MidC-D), and Reelfoot Rift zone-Rough Creek graben (RR-RCG) zones. The applicant truncated each seismotectonic zone at a distance of 520 km (325 mi) from the site. The applicant determined that the RLME sources that contribute significantly to hazard at the WLS site are Charleston and New Madrid RLME sources, so the applicant included the Charleston and New Madrid RLME sources in its hazard calculations. The staff previously reviewed the NUREG-2115 seismic source model and approved its use as a starting regional model for nuclear power plant applications. Therefore, the applicant's PSHA inputs are consistent with RG 1.208 and the staff concludes that the applicant's PSHA inputs are adequate.

2.5.2.4.4.2 *PSHA Software Audit and Confirmatory Analysis*

During the development of the applicant's response to RAI 105, Question 01.05-1, the staff conducted software audits to distinct seismic hazard calculation software being used by the industry to respond to the NTTF Recommendation 2.1 seismic RAIs submitted to all COL and ESP applicants. The purpose of these audits was to review seismic hazard software and examine the implementation of the new seismic source models described in NUREG-2115. The objective was to gain in-depth understanding of the seismic software being used and review the implementation of the new seismic source model into the existing codes. The applicant contracted with ENERCON, who contracted with Lettis Consultants International, Inc. (LCI), formerly known as William Lettis & Associates, Inc., to perform its seismic hazard calculations. The LCI software audit took place on August 20 and 21, 2012. During the software audit, the staff reviewed software runs and reviewed several quality assurance documents related to LCI seismic hazard code.

As part of its confirmatory analysis, the staff used the NUREG-2115 CEUS-SSC model Mmax, seismotectonic, and RLME sources and independently calculated the seismic hazard curves at the WLS site for all seven ground motion frequencies defined in the EPRI (2013) ground motion prediction models. From the NUREG-2115 seismic source model, the staff included all Mmax and seismotectonic sources zones defined by the NUREG-2115 model in its hazard calculation for the WLS site and truncated the zones' hazard contributions at a distance from the site of 500 km (310 mi). The staff also included all RLME source zones from NUREG-2115 and truncated the RLMEs' hazard contributions at a distance from the WLS site of 1000 km (621 mi). Figure 2.5.2-7 of this report shows the staff's results as compared to the applicant's for the generic hard rock UHRS at the annual frequency of exceedances of 10^{-4} and 10^{-5}.

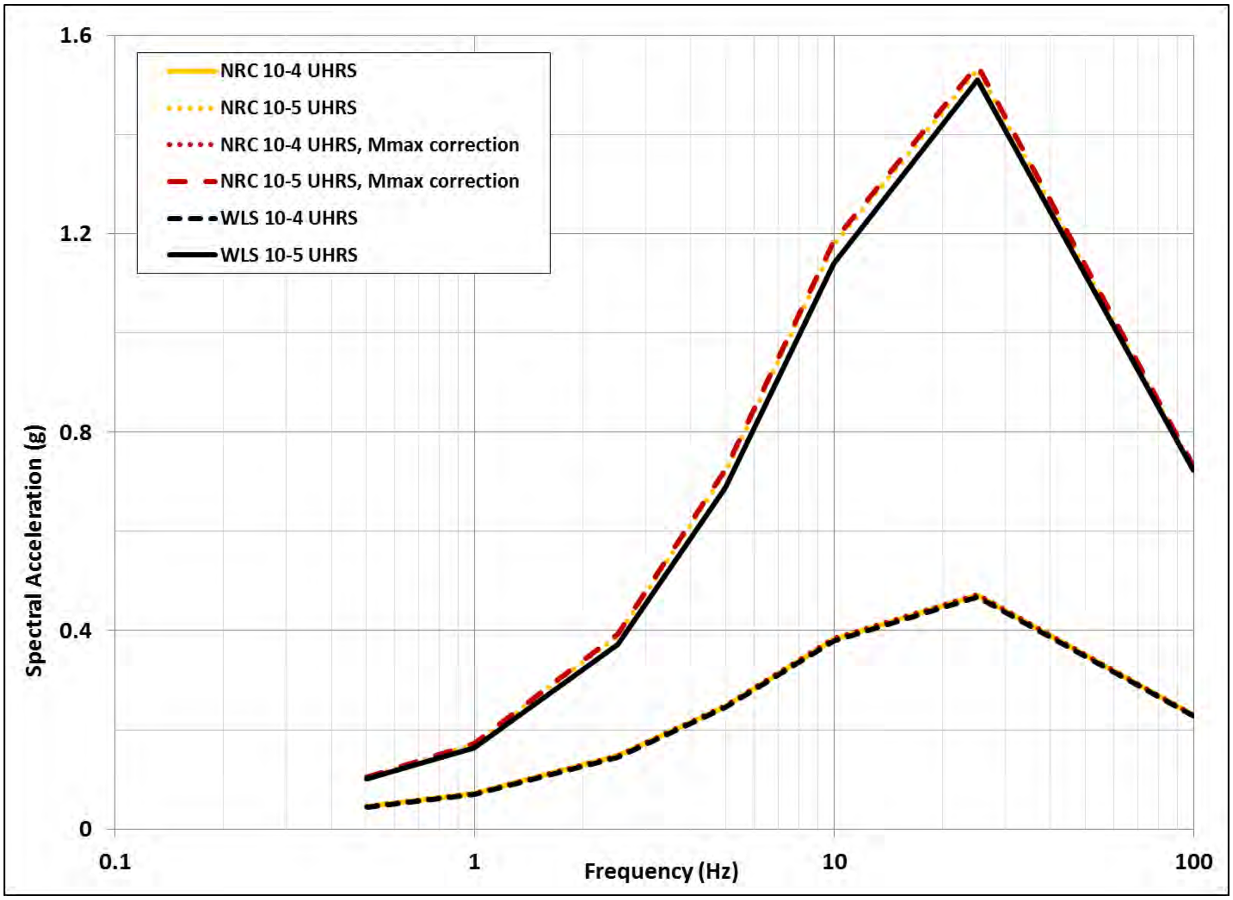

Figure 2.5.2-7 Staff Confirmatory Analysis of Hard Rock UHRS Calculations for Seven Spectral Frequencies at the Annual Frequency of Exceedances of 10^{-4} and 10^{-5}. The Black Lines Are the WLS UHRS, the Yellow Lines Are the Staff's Confirmatory UHRS, and the Red Lines Are the Staff's Confirmatory, Sensitivity Study UHRS Performed to Test and Possible Error in Maximum Magnitude Distributions in the NUREG-2115 Documentation

On July 28, 2014, EPRI wrote a letter (Agencywide Documents Access Management System (ADAMS) Accession No. ML14260A280), to the NRC notifying the agency of errors that EPRI identified in the NUREG-2115 documentation. The error is that maximum magnitude distributions for three of the seismotectonic model zones are incorrect. Table 2.5.2-4 of this report shows the published and corrected maximum magnitude values for the affected seismotectonic zones (PEZ-N, PEZ-W, and IBEB). As shown in Figure 2.5.2-4 of this report, the WLS Site is located with the PEZ-N seismotectonic zone in the NUREG-2115 seismotectonic zone model A. Alternative models in NUREG-2115 designate PEZ-W as the host seismotectonic zone for the WLS Site. Seismotectonic zone IBEB, however, is located approximately 534 km (332 mi) from the WLS Site (Figure 2.5.2-4 of this report) and is not included in the applicant's WLS Site PSHA. The staff performed confirmatory analysis to test the effect of these errors in maximum magnitudes on the seismic hazard analysis at the WLS site. The staff performed separate PSHA calculations using the corrected maximum magnitude distributions for PEZ-N, PEZ-W, and IBEB, as shown in Table 2.5.2-4 of this report. The results are shown in Figure 2.5.2-7 of this report and are labeled in that figure as "NRC…UHRS, Mmax correction." When the staff compared its original confirmatory UHRS at seven frequencies (yellow lines in Figure 2.5.2-7 of this report) to the "NRC…UHRS, Mmax correction" in Figure 2.5.2-7 of this report, the percent difference between the spectra range from 0.4 to 1.0 percent change. These percent differences are similar to those calculated by EPRI in its July 28, 2014, letter. In that letter, EPRI showed preliminary sensitivity study results for the NUREG-2115 Chattanooga test site. Like the WLS Site, the Chattanooga test site is located in the PEZ-N and PEZ-W seismotectonic zones. EPRI's preliminary sensitivity study results showed that at the NUREG-2115 Chattanooga test site the effect of the errors in maximum magnitude result in percent differences ranging from 0.6 to 1.5 percent for the generic hard rock UHRS at the annual frequency of exceedances of 10^{-4} and 10^{-5}. Both the staff's and EPRI's results show that the errors in maximum magnitude distributions in the NUREG-2115 PEZ-N, PEZ-W, and IBEB seismotectonic zones do not significantly affect the PSHA results at the WLS Site.

Table 2.5.2-4 Published And Corrected Maximum Magnitude Values For Seismotectonic Zones PEZ-N, PEZ-W, and IBEB. (Ref. Table in July 28, 2014, EPRI Letter)

PEZ-N		PEZ-W		IBEB	
CEUS SSC Report	Corrected Value	CEUS SSC Report	Corrected Value	CEUS SSC Report	Corrected Value
5.9	6.0	5.9	6.0	6.5	6.4
6.4	6.5	6.4	6.4	6.9	6.7
6.8	6.9	6.8	6.9	7.4	7.0
7.2	7.4	7.2	7.4	7.8	7.3
7.9	8.0	7.9	8.0	8.1	7.9

Based on review of WLS COL FSAR Section 2.5.2.4 and the staff's confirmatory analysis, the staff concludes that the applicant adequately characterized the mean seismic hazard at the WLS Site.

2.5.2.4.4.3 *Controlling earthquakes*

To determine the low- and high-frequency controlling earthquakes' magnitudes and distances, the applicant used a procedure called deaggregation of the seismic hazard. The applicant followed the deaggregation procedures outlined in RG 1.208, Appendix D. The deaggregation results showed that local seismic sources within 35 km (21 mi) of the WLS Site are the primary contributors to the high-frequency seismic hazard at the site, while the RLME sources as well as regional sources were contributors to the low-frequency seismic hazard at the WLS Site. Table 2.5.2-1 of this report shows the applicant's deaggregation results for the mean 10^{-4}, 10^{-5}, and 10^{-6} PSHA results. The applicant calculated the controlling earthquakes for two different cases: hazard from earthquakes located less than 100 km (62 mi) away and hazard from earthquakes located beyond 100 km (62 mi). As shown in the deaggregation, Table 2.5.2-1 of this report, for the high-frequency hazard, the controlling earthquakes are those with magnitudes about **M**6 occurring at short distances. For the low frequency hazard, the controlling earthquakes are several hundred kilometers away with magnitudes greater than **M**7.

Since the applicant used the guidance outlined in RG 1.208 to determine the controlling earthquakes and their magnitudes and distances, the staff concludes that the procedures used by the applicant are adequate and the resultant controlling earthquake parameters are representative of the controlling earthquakes in this region.

2.5.2.4.4.4 *Staff Conclusions Regarding PSHA and Controlling Earthquakes*

After its review of the applicant's PSHA and controlling earthquake determination, the staff's confirmatory calculations, and the staff's review of the code used by WLS during the software audit, the staff concludes that the applicant's PSHA adequately characterizes the seismic hazard for the WLS Site and that the controlling and deaggregation earthquakes determined by the applicant are representative of earthquakes that would be expected to contribute the most to the hazard. The staff concludes that the applicant's PSHA and controlling earthquake analysis meets the requirements of 10 CFR 52.79 and 10 CFR 100.23.

2.5.2.4.5 Seismic Wave Transmission Characteristics of the Site

WLS CIK FSAR Section 2.5.2.5 describes the WLS Site as a hard rock site located on igneous and metamorphic rocks of Paleozoic age with the majority of V_S measurements exceeding 2.8 km/s (9,200 fps) and variation in V_S measurements of several hundred feet per second centered at the hard rock condition considered to be a negligible variation in site response calculations. Therefore, the EPRI (2013) ground motion prediction equations are used directly, without calculation of site response and the UHRS reflects this hard rock condition. Based on the applicant's V_S analysis and the staff's review, the staff concludes that the applicant's use of the hard rock UHRS adequately characterizes the WLS Site. The applicant appropriately followed the guidance in RG 1.208, which meets the requirements of 10 CFR 52.79 and 10 CFR 100.23.

2.5.2.4.6 Ground Motion Response Spectra

WLS COL FSAR Section 2.5.2.6 describes the method used by the applicant to develop the horizontal and vertical, site-specific, GMRS. To obtain the horizontal GMRS, the applicant used the performance based approach described in RG 1.208 and American Society of Civil Engineers/Structural Engineering Institute (ASCE/SEI) Standard 43-05, "Seismic Design Criteria for Structures, Systems, and Components in Nuclear Facilities." WLS COL FSAR Section 2.5.2.6, states that the horizontal GMRS (for each spectral frequency), is obtained by scaling the 10^{-4} soil UHRS by the design factor specified in RG 1.208. The final GMRS is shown in Figure 2.5.2-3 of this report.

In WLS COL FSAR Section 2.5.2.6., the applicant stated that to accommodate the change in source distance with both annual exceedance probability and structural frequency, the applicant's computed V/H ratios at a suite of distances are given relative weights, as shown in WLS COL FSAR Table 2.5.2-223. The probabilistic method, Approach 3, used by the applicant is described in NUREG/CR-6728. Since the applicant used an accepted methodology presented in NUREG/CR-6728, the staff concludes that the applicant's V/H ratios are adequate for the use of the WLS Site vertical GMRS. The applicant's horizontal and vertical GMRS are shown in Figure 2.5.2-3 of this report. Since the applicant used the standard procedure outlined in RG 1.208 and NUREG/CR-6728 to develop both the horizontal and vertical GMRS, the staff concludes that the applicant's GMRS adequately represents the WLS Site ground motion. This information addresses WLS COL 2.5-2 to resolve COL Information Item 2.5-2 and WLS COL 2.5-3 to resolve COL Information Item 2.5-3. In conclusion, the applicant provided sufficient information for satisfying 10 CFR 52.79 and 10 CFR 100.23.

2.5.2.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.5.2.6 *NRC Conclusions Regarding Vibratory Ground Motion*

The staff reviewed the application and checked the referenced DCD. The staff confirmed that the applicant has addressed the required information relating to vibratory ground motion, and that there is no outstanding information expected to be addressed in the WLS COL FSAR related to this subsection. Accordingly, the staff considers RAI 105, Question 01.05-1, which is the RAI issued after the NTTF recommendation following the Fukushima accident in Japan in March 2011, resolved.

As set forth above, the staff reviewed the seismic information submitted by the applicant in WLS COL FSAR Section 2.5.2. On the basis of its review of WLS COL FSAR Section 2.5.2, the staff finds that the applicant provided a thorough characterization of the seismic sources surrounding the site, as required by 10 CFR 100.23. In addition, the staff finds that the applicant adequately addressed the uncertainties inherent in the characterization of these seismic sources through a PSHA, and that this PSHA follows the guidance provided in RG 1.208. The staff concludes that the controlling earthquakes and associated ground motion derived from the applicant's PSHA are consistent with the seismogenic region surrounding the COL site. In addition, the staff finds that the applicant's GMRS, which was developed using the performance-based approach, adequately represents the regional and local seismic hazards and accurately includes the effects of the local site subsurface properties. The staff concludes that the proposed WLS COL site is acceptable from a geologic and seismologic standpoint and meets the requirements of 10 CFR 100.23.

2.5.3 Surface Faulting

2.5.3.1 *Introduction*

WLS COL FSAR Section 2.5.3 discusses information related to the potential for tectonic (i.e., due to faulting) and non-tectonic surface and near-surface deformation collected by the applicant during site characterization investigations. This information provided by the applicant addresses the following specific topics: geologic, seismic, and geophysical investigations; geologic evidence, or absence of evidence, for surface deformation; correlation of earthquakes with capable tectonic sources; ages of most recent deformations; relationships between tectonic structures in the site area and regional tectonic structures; characterization of capable tectonic sources; designation of zones of Quaternary (2.6 million years (Ma) to present) deformation in the site region; and the potential for surface tectonic and non-tectonic deformation at the site.

2.5.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 2.5 incorporates by reference AP1000 DCD, Revision 19, Section 2.5.3. In addition, in WLS COL FSAR Section 2.5.3, the applicant provided site-specific supplemental information to address the following:

AP1000 COL Information Item

- WLS COL 2.5-4

The applicant provided additional information in WLS COL 2.5-4 to address COL Information Item 2.5-4 (COL Action Item 2.5.3-1). WLS COL 2.5-4 addresses the evaluation of site-specific surface and subsurface geologic, seismic, and geophysical information related to the potential for surface and near-surface faulting at the site.

The applicant developed FSAR Section 2.5.3 for WLS based on information derived from review of published literature and geologic maps; interpretation of aerial photographs and satellite imagery; discussions with experts familiar with the geology, seismology, and tectonic history of the site region, site vicinity, site area, and site location; review of historical and recorded seismicity data; field geologic and aerial reconnaissance investigations performed specifically for the WLS application; analysis of test pits, trenches, and boreholes located at WLS; geologic mapping of bedrock exposures in the excavations for former CNS Unit 3 (WLS Unit 2) and CNS Unit 2; and the central and eastern U.S. seismic source characterization (CEUS SSC) report, provided as NUREG-2115, that contains the most recent seismic source models for the CEUS. The applicant also used information presented in the PSAR for the CNS site to develop FSAR Section 2.5.3 for WLS. In addition, as part of the site characterization studies performed for the WLS application to assess results of previous geologic mapping of foundation bedrock exposures in excavations at the CNS site, the applicant performed confirmatory geologic mapping of foundation grade level bedrock exposed in a small portion of the CNS Unit 2 excavation and compared that geologic map to archived scanned records for the CNS site.

As discussed in more detail in Section 2.5.1.2 of this report, to support the confirmatory geologic mapping effort described above and document lithologies and geologic features (including tectonic faults, shear and breccia zones, and fractures) that occur in foundation grade level bedrock underlying CNS Unit 1(WLS Unit 1), the applicant compiled a detailed geologic map of the foundation grade level bedrock surface in the CNS Unit 1 excavation from original field notes and geologic maps prepared in the 1970s to characterize site location geology in that excavation. The applicant provided a report containing the compiled geologic map and associated data, which documented the similarity of rock types and orientations and ages of tectonic structures in the WLS Unit 1/CNS Unit 1, CNS Unit 2, and WLS Unit 2/CNS Unit 3 excavations.

Based on information derived from the sources defined above, the applicant concluded in FSAR Section 2.5.3 that no evidence exists for Quaternary faults or capable tectonic sources within the site vicinity or at the site location, and that the potential for non-tectonic surface or near-surface deformation at the site location is negligible. With regard to assessment of evidence for capable tectonic sources, based on the definition in RG 1.208, the applicant stated that a capable tectonic source is a tectonic structure that can generate both tectonic surface deformation (e.g., faulting or folding) and vibratory ground motion in the present seismotectonic setting. Sections 2.5.3.2.1 through 2.5.3.2.8 of this report summarize the information provided by the applicant in FSAR Section 2.5.3 related to surface and near-surface tectonic deformation due to faulting, as well as surface and near-surface non-tectonic deformation.

2.5.3.2.1 Geologic, Seismic, and Geophysical Investigations

FSAR Section 2.5.3.1 outlines the geologic, seismic, and geophysical investigations performed by the applicant to assess the potential for tectonic and non-tectonic surface and near-surface deformation in the WLS vicinity and site area and at the site location. Sections 2.5.3.2.1.1 through 2.5.3.2.1.6 of this report summarize these investigations and the conclusions made by the applicant based on them in regard to tectonic and non-tectonic surface and near-surface deformation at WLS.

2.5.3.2.1.1 *Previous Site Investigations*

FSAR Section 2.5.3.1.1 discusses previous investigations conducted at WLS in connection with preparation of the PSAR for the former co-located CNS site. The applicant reported that detailed excavation mapping at the CNS site did not reveal any evidence for active or geologically recent (i.e., Quaternary) tectonic faulting in the WLS area. The applicant indicated that minor shear zones mapped in the CNS excavations commonly occurred near the contacts of metamorphosed mafic dikes that intrude metamorphosed plutonic intrusive body Zto, which comprises the foundation unit at WLS. The applicant cross-referenced FSAR Sections 2.5.1.2 and 2.5.4.1 for a detailed discussion of these minor geologic features that occur in foundation bedrock at WLS.

2.5.3.2.1.2 *Published Geologic Mapping*

FSAR Section 2.5.3.1.2 discusses the results of geologic mapping conducted in the site area by the USGS, the South Carolina Geological Survey, and other researchers. The applicant reported that these published geologic maps do not show any evidence for geologically recent or active faulting in the site area. The applicant noted that the geologic maps developed for the CNS site in the 1970s are the most detailed maps documenting geologic characteristics of WLS.

2.5.3.2.1.3 *Current Geologic Mapping*

FSAR Section 2.5.3.1.3 discusses current geologic mapping at WLS. The applicant indicated that the published geologic maps discussed in FSAR Section 2.5.3.1.2 formed the basis for the geologic maps presented in FSAR Section 2.5.1. The applicant conducted field reconnaissance of the site location, site area, and site vicinity for the WLS application to refine these geologic maps as necessary. In addition, the applicant analyzed the contact between the western margin of metamorphosed plutonic intrusive rock mass Zto, the foundation unit at WLS, and the adjacent metavolcanic country rock that the plutonic body intrudes to determine if any evidence for faulting exists along this contact. The applicant investigated the contact using geologic mapping, boreholes, test pits, and trenches and concluded that the irregular map pattern and intrusive character of the contact precluded a fault along the western margin of foundation unit Zto.

2.5.3.2.1.4 *Previous Seismicity Data*

FSAR Section 2.5.3.1.4 discusses previous seismicity data within and beyond the site vicinity. The applicant stated that, based on the earthquake catalog included in the CEUS SSC report (NUREG-2115), the largest earthquake in the site vicinity was an 1886 event with an expected moment magnitude (E[M]) of 4.13 (i.e., estimated given the uncertainty in earthquake magnitude) located south-southwest of WLS as shown in Figure 2.5.3-1 of this report. The E[M] 4.54 January 1913 Union County, South Carolina earthquake, also located south-southwest of WLS just outside the site vicinity (Figure 2.5.3-1 of this report), had an estimated Rossi-Forel shaking intensity of VI at WLS. A Rossi-Forel VI is approximately equivalent to a shaking intensity of VI in the more commonly used Modified Mercalli Intensity (MMI) scale, indicating an earthquake felt by all but causing only slight damage. The applicant stated that the 1886 Charleston earthquake, which occurred in the site region with an epicenter likely more than 240 km (150 mi) from WLS, produced a shaking intensity at the site of MMI VI. The applicant noted that the Union County and Charleston earthquakes have not been related to known causative faults.

2.5.3.2.1.5 *Current Seismicity Data*

WLS COL FSAR Section 2.5.3.1.5 discusses current seismicity data within and beyond WLS vicinity, including data from the updated CEUS SSC earthquake catalog (NUREG-2115) covering earthquakes that occurred within the CEUS between 1568 and 2008. The applicant cross-referenced WLS COL FSAR Section 2.5.2.1 for a more detailed description of this earthquake catalog.

The applicant reported that four minor earthquakes not included in the CEUS SSC catalog occurred in northeastern South Carolina in 2006. Two of these earthquakes occurred on January 24 and 25, 2006, approximately 32 km (20 mi) southwest of the site location with body-wave magnitudes (m_b) of 2.5 and 1.5, respectively. The applicant noted that the epicenters of these two small earthquakes have not been accurately located due to their small magnitudes. The other two 2006 earthquakes occurred in September more than 121 km (75 mi) east-southeast of WLS, as shown in Figure 2.5.3-1, with m_b values of 3.5 (September 22) and 3.7 (September 25). The applicant stated that the two September earthquakes appear to be spatially related to a small Mesozoic (25 to 145.5 Ma) extensional basin lying beneath the Coastal Plain as mapped by Benson (1992). Talwani (2006) suggested that the earthquakes may be spatially related to the regional Eastern Piedmont fault system (EPFS) of Hatcher and others (1977), which lies beneath the Coastal Plain at the estimated epicentral locations of the two earthquakes. The applicant reported that there is no definitive correlation of the September 2006 earthquakes with the EPFS because of the uncertainty in their epicentral locations.

2.5.3.2.1.6 *Current Aerial and Field Reconnaissance*

WLS COL FSAR Section 2.5.3.1.6 discusses current aerial and field reconnaissance studies performed using aerial photographs, satellite imagery, and topographic maps. The applicant indicated that no information acquired from the reconnaissance studies showed any evidence of active tectonic surface deformation (i.e., surface fault rupture, warping, or offset of geomorphic features) within the site.

The applicant reported that a northeast-trending topographic lineament, which occurs about 3 km (2 mi) northwest of the WLS location (i.e., Lineament 1), resulted from localized erosion along a tributary of the Broad River that flows parallel to an erosion-resistant, northeast-trending, quartzite-capped ridge. Although this lineament has the same trend as the regional northeastern structural grain of the Appalachian orogenic belt, it does not extend across the Broad River and the applicant concluded that it is non-tectonic in origin.

2.5.3.2.2 Geologic Evidence, or Absence of Evidence, for Surface Deformation

WLS COL FSAR Section 2.5.3.2 addresses the presence or absence of evidence for surface deformation within the WLS vicinity and at the site location. The applicant reviewed existing literature, performed aerial and field reconnaissance studies, and examined aerial photographs and satellite imagery for evidence of Quaternary (2.6 Ma to present) surface deformation along six mapped fault traces, interpreted to be Paleozoic (> 251 Ma) in age, which occur in the site vicinity. These structures include the Kings Mountain shear zone; the southwestern extension of the Boogertown shear zone; an unnamed fault north of Gaffney; and the Tinsley Bridge, Brindle Creek, and Reedy River faults. Figure 2.5.3-1 of this report shows the locations of these six faults relative to the WLS location. The applicant documented a Paleozoic age for these six tectonic features based on geologic field relationships, and concluded that no evidence exists for Quaternary surface deformation associated with these faults.

Based on geologic field relationships, the applicant also stated that strain markers comprising two elongated, north-striking quartzite units in the western part of the site area and the northerly-striking western margin of the metamorphosed pluton comprising foundation unit Zto do not show any displacement along northeast-striking faults. A northeastern orientation is the predominant trend of regional tectonic features in the WLS vicinity and site region. The applicant stated that the quartzite units and the metamorphosed pluton are Precambrian (> 542 Ma) in age and provide reliable strain markers for determining that no major faults project into or across the WLS location.

2.5.3.2.3 Correlation of Earthquakes with Capable Tectonic Sources

WLS COL FSAR Section 2.5.3.3 discusses correlation of earthquakes with capable tectonic sources within the WLS vicinity. Based on the epicentral data shown in Figure 2.5.3-1 of this report, the applicant concluded that there is no spatial correlation of earthquake epicenters with known or postulated faults or other tectonic features within the site vicinity. The applicant stated that no historical earthquakes have been associated with bedrock faults in the WLS vicinity, and concluded that none of the faults in the site vicinity are capable tectonic structures.

2.5.3.2.4 Ages of Most Recent Deformation

WLS COL FSAR Section 2.5.3.4 discusses ages of most recent deformations within the WLS vicinity. Based on geologic field relationships as discussed above in Section 2.5.3.2.2 of this report, the applicant documented a Paleozoic age for the six faults mapped in the site vicinity (i.e., the Kings Mountain shear zone; the southwestern extension of the Boogertown shear zone; an unnamed fault north of Gaffney; and the Tinsley Bridge, Brindle Creek, and Reedy River faults). The applicant reported that Garihan and others (1993) suggested the Kings Mountain shear zone may have experienced localized reactivation during Mesozoic (251 to 65.5 Ma) time. However, based on information presented in WLS COL FSAR Section 2.5.3.2 and summarized above in Section 2.5.3.2.2 of this report, no evidence exists for Quaternary (2.6 Ma to present) deformation associated with any of these structures.

2.5.3.2.5 Relationships of Site Area Tectonic Structures to Regional Tectonic Structures

WLS COL FSAR Section 2.5.3.5 addresses the relationships of the six faults identified in the site vicinity with regional tectonic structures. The applicant indicated that four of these faults (i.e., the Kings Mountain shear zone, the Tinsley Bridge fault, the southwest extension of the Boogertown shear zone, and the Reedy River thrust fault) are part of the regional Central Piedmont shear zone (CPSZ) of Paleozoic (> 251 Ma) age, which separates the Western Piedmont Zone from the Charlotte terrane of the Carolina Zone in which WLS lies. The applicant stated that the relationship of the unnamed fault north of Gaffney and the CPSZ is not clear, and concluded that none of the six faults represents a capable tectonic structure.

2.5.3.2.6 Characterization of Capable Tectonic Sources

WLS COL FSAR Section 2.5.3.6 discusses characterization of capable tectonic sources within the WLS vicinity. Based on review of published literature, interviews with technical experts knowledgeable about the geology and seismology of the site region and site vicinity, and investigations performed by the applicant for the WLS application, the applicant concluded that no evidence exists for the existence of capable tectonic sources within the WLS vicinity. The applicant noted that this interpretation is fully consistent with data derived from previous investigations performed for the CNS site.

2.5.3.2.7 Designation of Quaternary Deformation Zones in the Site Region

WLS COL FSAR Section 2.5.3.7 addresses zones of Quaternary deformation in the site region. Based on review of published literature, interviews with technical experts knowledgeable about the geology and seismology of the site region and site vicinity, and investigations performed for the WLS application, the applicant concluded that no evidence exists for zones of Quaternary deformation within the WLS region or site vicinity.

2.5.3.2.8 Potential for Surface Tectonic Deformation at the Site

WLS COL FSAR Section 2.5.3.8 addresses the potential for surface tectonic and non-tectonic deformation at the site. The applicant stated that detailed geologic mapping of the former CNS site revealed no evidence of geologically recent or active (i.e., Quaternary) faulting at WLS. Based on review of published literature, interviews with technical experts knowledgeable about the geology and seismology of the site region and site vicinity, and investigations performed for the WLS application, the applicant concluded that no Quaternary faults or capable tectonic sources occur within the WLS vicinity and the potential for surface tectonic deformation at the site is negligible.

Since lithologies in the site vicinity and site area and at the site location are metamorphosed igneous, volcanic, and sedimentary rock units, the applicant also stated that none of these rock units are susceptible to dissolution collapse or subsidence due to fluid withdrawal. The applicant indicated that no evidence exists to suggest there is any potential for non-tectonic surface deformation within the WLS area, and concluded that the potential for non-tectonic surface deformation within the site area and at the site location is negligible. The applicant evaluated the potential for RIS in WLS COL FSAR Section 2.5.2.1.3 and concluded in WLS COL FSAR Section 2.5.3.8 that the potential for non-tectonic surface deformation due to RIS is also negligible.

2.5.3.3 *Regulatory Basis*

The regulatory basis for the information incorporated by reference is addressed in NUREG-1793 and its supplements. The applicable regulatory requirements for surface faulting are as follows:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying geologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity and period of time in which the historical data have been accumulated

- 10 CFR 100.23, as it relates to determining the potential for surface tectonic and non-tectonic deformation at and in the region surrounding the site

In addition, the related acceptance criteria associated with relevant requirements of NRC regulations for surface deformation are given in NUREG-0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants,” Section 2.5.3 as follows:

- Geologic, Seismic, and Geophysical Investigations: Requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi),or 10 CFR 52.79(a)(1)(iii) and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), are met and guidance in RG 1.208, and RG 4.7 followed for this area of review if discussions of Quaternary tectonics, structural geology, stratigraphy, geochronologic methods used for age dating, paleoseismology, and geologic history of the site vicinity, site area, and site location are complete, compare reasonably with studies conducted by others in the same area, and are supported by detailed investigations performed by the applicant. Site vicinity, site area, and site location-specific geologic maps and cross-sections constructed at scales adequate to clearly illustrate surficial and bedrock geology, structural geology, topography, and relationship of power plant foundations and site boundaries to these features should be included in the application. For sites located near bodies of water, the application should address how investigations have been conducted to detect possible surface deformation features that might be located beneath water.

- Geologic Evidence for Surface Deformation: Requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), are met and guidance in RG 1.208, and RG 4.7 followed for this area of review if the applicant provides sufficient surface and subsurface information for the site vicinity, area, and location to confirm and characterize presence or absence of surface deformation (e.g., faulting, growth faulting, subsidence or collapse related to dissolution of limestone, salt or gypsum deposits, or salt diapirism and paleoliquefaction) features. The applicant should also take into account the potential for blind faults.

- Timing of Deformation: Requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), are met for this area of review if recognized surface deformation features (e.g., tectonic faults and non-tectonic features including growth faults) and features associated with a blind fault, are investigated in sufficient detail to constrain the age of the most recent surface deformation event, and, if applicable, the ages of preceding deformation events. The application shall also provide an acceptable evaluation of sensitivity and resolution of the exploratory geologic and geophysical techniques used to determine whether or not appropriate techniques were applied to assess the age of the most recent displacement.

- Correlation of Earthquakes with Tectonic Feature: Requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi or 10 CFR 52.79(a)(1)(iii)), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), are met for this area of review if the applicant evaluates all reported historical earthquakes within the site vicinity with respect to accuracy of hypocenter location and source of origin, and with respect to correlation to tectonic features. The applicant shall evaluate the potential for historical activity on tectonic features in the site vicinity. The application should include a plot of earthquake epicenters superimposed on a map showing tectonic features in the site vicinity.

- Relationship of Geologic Features in the Site Vicinity to Regional Geologic Features: Requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), are satisfied for this area of review if the applicant evaluates the relationships between faults or other deformation features in the site vicinity and the regional framework. The application should provide an acceptable evaluation of the relationships between the regional (tectonic and non-tectonic) framework and deformation features in the site vicinity, including growths faults and growth fault systems. The applicant should show how this information is used in the evaluation of potential for future surface deformation at the site.

- Potential for Surface Deformation at the Site: To meet requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), for this area of review, the applicant shall assess the potential future tectonic and nontectonic surface deformation at the site. The applicant should provide sufficient geological, seismological, and geophysical information to clearly establish whether there is a potential for future surface deformation at the site. If the potential for future surface deformation exists at the site, the application must provide information that demonstrates the potential effects of surface deformation are within the design basis of the proposed facility. NRC regulations do not restrict building in an area with surface faulting potential, but if that potential exists, the regulations require that surface deformation must be taken into account in the design

> and operation of the proposed nuclear power plant. It is questionable whether it might be feasible to design for surface deformation with any degree of confidence that safety-related structures, systems, and components would maintain their safety functions if surface displacements occur in the future. Consequently, it is NRC policy (e.g. RG 1.208) to recommend that any site located on a surface or near-surface feature with a potential for future displacement be re-located to an alternate site.

Geologic characteristics should also be consistent with the related guidance from appropriate sections of RG 1.132, Revision 2, RG 1.198, RG 1.206, and RG 1.208.

2.5.3.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 2.5.3 and checked the referenced DCD to ensure that the combination of information presented in the WLS COL FSAR and the AP1000 DCD completely represents the required information related to tectonic (i.e., faulting) and non-tectonic surface and near-surface deformation. The staff's review confirmed that information contained in the application or incorporated by reference addresses the information required for this review topic. NUREG-1793 and associated supplements document the results of the staff's evaluation of information incorporated by reference into the WLS application. The staff reviewed the following information in the WLS COL FSAR.

AP1000 COL Information Item

- WLS COL 2.5-4

The staff reviewed WLS COL 2.5-4 included in WLS COL FSAR Section 2.5.3. WLS COL FSAR Section 2.5.3 addresses the potential for surface or near-surface tectonic and non-tectonic deformation within the site vicinity and site area and at the site location. The COL information item from the AP1000 DCD, Section 2.5.3, states:

> Combined License applicants referencing the AP1000 certified design will address the following surface and subsurface geological, seismological, and geophysical information related to the potential for surface or near-surface faulting affecting the site: (1) geological, seismological, and geophysical investigations; (2) geological evidence, or absence of evidence, for surface deformation; (3) correlation of earthquakes with capable tectonic sources; (4) ages of most recent deformations; (5) relationship of tectonic structures in the site area to regional tectonic sources; (6) characterization of capable tectonic sources; (7) designation of zones of Quaternary deformation in the site region; and (8) potential for surface tectonic deformation at the site.

Based on the discussion of the potential for tectonic and non-tectonic surface deformation at the site presented in WLS COL FSAR Section 2.5.3, the staff concludes that the applicant provided the information required to satisfy WLS COL 2.5-4.

Section 2.5.3.2 above specifies the data sources used by the applicant to develop WLS COL FSAR Section 2.5.3, which contains information related to the potential for tectonic and non-tectonic surface and near-surface deformation within the site vicinity and site area and at the site location. Through the review of WLS COL FSAR Section 2.5.3, the staff determined whether the applicant had complied with the applicable regulations and conducted the investigations at an appropriate level of detail in accordance with RG 1.208.

As part of the technical evaluation of WLS COL FSAR Section 2.5.3, the staff visited WLS on April 27 to May 2, 2008 (ML120320233); January 27 and 28, 2009 (ML120320258); July 12 through 14, 2011 (ML11216A256); and February 10, 2014 (ML14126A584), to interact with the applicant and its consultants in regard to the geologic, seismic, geophysical, and geotechnical investigations being conducted to characterize the site. Technical experts from the USGS accompanied the staff during the January 2009 site visit to assist with evaluation of geologic and seismic data collected by the applicant. On February 23 and July 20, 2009 (ML120270235), the staff audited information used by the applicant to constrain timing of development of minor ductile and brittle shear zones mapped in the excavations at the original CNS site. The staff also audited Revisions 0 and 1 of the report discussing the compiled geologic map for the CNS Unit 1 (i.e., WLS Unit 1) excavation on June 6, 9, and 10, 2011 and October 25 through 27, 2011 (ML120270246). The Duke report documented geologic characteristics of foundation grade level bedrock at WLS Unit 1 based on previous geologic mapping of foundation grade bedrock conducted in the former co-located CNS Unit 1 excavation, which lies under concrete poured during initial construction activities at the CNS site. Section 2.5.1.4 of this report presents details about the site visits and data documentation audits that enabled staff to assess conclusions made by the applicant regarding the potential for surface and near-surface tectonic and non-tectonic deformation at WLS and confirm that no geologic features occurring in foundation bedrock represent capable tectonic structures.

Sections 2.5.3.4.1 through 2.5.3.4.8 of this report present the staff's evaluation of information provided by the applicant in WLS COL FSAR Section 2.5.3 and the applicant's responses to RAIs for WLS COL FSAR Section 2.5.3. In addition to RAIs addressing specific technical issues related to tectonic and non-tectonic surface and near-surface deformation at the site, discussed in detail below, the staff also prepared editorial RAIs to further clarify certain descriptive statements made by the applicant in the WLS COL FSAR and to qualify geologic features illustrated in WLS COL FSAR figures. This detailed technical evaluation does not discuss these editorial RAIs.

2.5.3.4.1 Geologic, Seismic, and Geophysical Investigations

WLS COL FSAR Section 2.5.3.1 describes geologic, seismic, and geophysical investigations performed by the applicant to assess the potential for tectonic (i.e., due to faulting) and non-tectonic surface and near-surface deformation within the site vicinity and site area, as well as the potential for surface fault rupture at the WLS location. Based on these investigations, the applicant concluded that no evidence exists for active or geologically recent (i.e., Quaternary age, 2.6 Ma to present) faulting within the site vicinity and site area or at the site location. Sections 2.5.3.4.1.1 through 2.5.3.4.1.4 of this report present the staff's evaluations of the geologic, seismic, and geophysical investigations performed by the applicant for WLS.

2.5.3.4.1.1 *Previous Site Investigations and Published Geologic Mapping*

WLS COL FSAR Sections 2.5.3.1.1 and 2.5.3.1.2 discuss, respectively, previous WLS area and site location investigations and published geologic maps for the site vicinity and site area. The applicant concluded that no evidence exists for active or geologically recent (i.e., Quaternary, 2.6 Ma to present) faulting or shearing in the site area, but did not summarize information in the WLS COL FSAR to qualify this conclusion.

The staff focused the review of WLS COL FSAR Sections 2.5.3.1.1 and 2.5.3.1.2 on documentation of the sources used by the applicant to conclude that previous detailed geologic mapping at the CNS site revealed no evidence for active or geologically recent faulting, and on clarifying the timing of deformation along the brittle shear zones that occur at the margins of mafic dikes that intrude foundation unit Zto at the site location. In RAI 26, Question 02.05.03-1, the staff requested that the applicant summarize data derived from geologic investigations performed at the CNS site used to conclude that no evidence exists for active or geologically recent faulting in the site area. In RAI 85, Question 02.05.03-11, the staff requested that the applicant provide the information considered for constraining time of development of the brittle shear zones observed along the margins of mafic intrusive dikes at the site location and documenting that the zones are much older than Quaternary.

In response to RAI 26, Question 02.05.03-1, the applicant summarized the information acquired at the CNS site and re-evaluated during geologic characterization of WLS. The applicant stated that radiometric age dates on deformed and undeformed mineral samples, collected adjacent to or within minor faults and shear zones at the CNS site, confirmed that no fault movement or shearing younger than Mesozoic (251 to 65.5 Ma) had occurred at the site. The applicant reported that geologic investigations performed for the WLS application, including the confirmatory mapping of lithologies and geologic features in the northern portion of the CNS Unit 2 foundation excavation and comparison of those mapping results with the original geologic map prepared for CNS Unit 2, supported the interpretation of a pre-Quaternary (> 2.6 Ma) age for tectonic deformation features at WLS. Therefore, the applicant concluded that the historical CNS geologic map data can be used for characterization of foundation grade level bedrock at WLS to establish a pre-Quaternary age for the latest shearing and faulting observed at the site.

In response to RAI 85, Question 02.05.03-11, the applicant cross-referenced WLS COL FSAR Section 2.5.1.2.5.4, which presents radiometric age dates that constrain timing of development of the shear zones to be no younger than Mesozoic (251 to 65.6 Ma) based on the presence of undeformed potassium feldspar minerals in veins that cross-cut the shear zones. The applicant also indicated that the shear zones may be older than 300 Ma based on the presence of undeformed post-tectonic metamorphic minerals. Therefore, the applicant concluded that the shear zones are much older than Quaternary and do not reflect active or recent faulting at WLS.

The staff concludes that the shear zones are minor and much older than Quaternary, and that no evidence exists for active or geologically recent faulting or shearing in the site area or at the site location. The staff makes these conclusions based on information derived from the following activities: review of WLS COL FSAR Sections 2.5.3.1.1 and 2.5.3.1.2 and the applicant’s responses to RAI 26, Question 02.05.03-1 and RAI 85, Question 02.05.03-11; direct field observation of minor shear zones in the CNS excavations during site visits in April-May 2008 (ML120320233), January 2009, and July 2011 (ML11216A256) , including the southeastern end of a prominent, northwest-trending shear zone in the excavation for CNS Unit 2 (originally mapped as Shear Zone 6 at the CNS site) that extends beneath the concrete covering the CNS Unit 1 (i.e., WLS Unit 1) excavation; direct examination of core from the relocated footprints of WLS Units 1 and 2 in February 2014; and review of radiometric age dates and the compiled geologic map prepared by Duke for CNS/WLS Unit 1, including data specifically related to Shear Zone 6, during data documentation audits in June and October 2011. Accordingly, the staff considers RAI 26, Question 02.05.03-1 and RAI 85, Question 02.05.03-11 resolved.

2.5.3.4.1.2 *Current Geologic Mapping*

WLS COL FSAR Section 2.5.3.1.3 describes current geologic mapping in the site vicinity and site area and at the site location. The applicant stated that field investigations conducted for the WLS application enabled refinement of previous geologic maps and provided support for the conclusions that foundation grade level bedrock in CNS Unit 1 (WLS Unit 1) and CNS Unit 2 does not contain capable tectonic features or exhibit any evidence to suggest a potential for tectonic or non-tectonic surface or near-surface deformation. The applicant did not summarize the map refinements or present the refined geologic maps in the WLS COL FSAR.

The staff focused the review of WLS COL FSAR Section 2.5.3.1.3 on clarifying the refinements made by the applicant to previous geologic maps based on field investigations conducted for the WLS application. In RAI 26, Question 02.05.03-4, the staff requested that the applicant summarize the geologic map refinements and present them in the WLS COL FSAR. In response to RAI 26, Question 02.05.03-4, the applicant explained the refinements made to geologic maps previously presented in the WLS COL FSAR, which contain the western boundary of the metamorphosed pluton that comprises foundation unit Zto. The applicant documented that this boundary is an intrusive contact separating the plutonic rock body from the surrounding metamorphosed country rock based on field data derived from borings, test pits, and trenches located to investigate the geologic characteristics of the boundary. The applicant used these data to conclude that the contact boundary is more irregular than initially shown on earlier geologic maps and does not exhibit any characteristics indicative of faulting and revised WLS COL FSAR Figure 2.5.1-226 to more clearly illustrate locations of the field data sources.

Based on review of WLS COL FSAR Section 2.5.3.1.3 and the applicant’s response to RAI 26, Question 02.05.03-4, particularly the definitive field evidence derived from borings, test pits, and trenches used to investigate geologic characteristics of the western boundary of the pluton comprising foundation unit Zto, the staff concludes that the western boundary of the pluton is an intrusive contact with the surrounding county rock and not a fault. The staff notes that the applicant’s revisions to WLS COL FSAR Figure 2.5.1-226 reinforce the interpretation that the western margin of the pluton is irregular, rather than planar, and not a fault. The staff draws this conclusion based on the field data that show no evidence for faulting along the western boundary of the pluton that forms foundation unit Zto. Accordingly, the staff considers RAI 26, Question 02.05.03-4 resolved.

2.5.3.4.1.3 *Previous and Current Seismicity Data*

WLS COL FSAR Sections 2.5.3.1.4 and 2.5.3.1.5 discuss previous and current seismicity within the WLS vicinity, respectively. The staff focused the review of WLS COL FSAR Section 2.5.3.1.5 on understanding the age of last deformation along the EPFS and on statements made by the applicant that two September 2006 earthquakes with epicenters about 121 km (75 mi) east-southeast of WLS may have been related to either the EPFS or a Mesozoic extensional basin proposed by Benson to underlie Coastal Plain sediments. In RAI 26, Question 02.05.03-5 and RAI 85, Question 02.05.03-12, the staff requested that the applicant locate the EPFS on an appropriate map in the WLS COL FSAR; to document the age of last movement on this proposed fault system, including assessment of the interpretation by Nystrom that post-Miocene (< 5.3 Ma) displacement may have occurred along it; and to discuss the possible spatial correlation of the two earthquakes with the EPFS, as suggested by Talwani, and with the buried Mesozoic basin defined by Benson.

In response to RAI 26, Question 02.05.03-5 and RAI 85, Question 02.05.03-12, the applicant modified WLS COL FSAR Figures 2.5.1-209 and 2.5.1-210 to clearly show the location of the multiple segments comprising the EPFS. The applicant stated that field evidence generally constrains timing of last movement on the EPFZ to Paleozoic (i.e., > 251 Ma), since a granitic intrusive body, located in Georgia and dated at 269 Ma, and Mesozoic dikes (suggesting an age > 65.5 Ma) in South Carolina cross-cut different segments of the EPFS without any deformation. The applicant reported that Nystrom (2006) proposed local reactivation of some segments of the EPFS during the Cenozoic (65.5 Ma to present) based on inferred offset of mapped geologic units. The applicant noted that Nystrom also identified silicified breccias along some parts of the EPFS, a field relationship generally characteristic of Mesozoic (251 to 65.5 Ma) faulting in the Piedmont. The applicant summarized the existing field data, which documents that some of the offsets interpreted by Nystrom (2006) to suggest possible post-Miocene reactivation of the EPFS have not been observed along all segments of the ECFS and that the outcrop patterns of some geologic units mapped by Nystrom (2006) actually preclude Cenozoic movement along the entire length of the EPFS. The applicant stated that no definitive evidence exists to demonstrate that the two September 2006 earthquakes show any causative relationship with the EPFS or the Mesozoic basin proposed by Benson (1992) in light of the lack of focal mechanism data for these seismic events and the large uncertainty associated with their epicentral locations. Based on these collective data, the applicant concluded that the EPFS is most likely not younger than Paleozoic in age, and that no definitive evidence exists for any relationship between the two September 2006 earthquakes and either the EPFS or the buried Mesozoic extensional basin.

Based on the review of WLS COL FSAR Sections 2.5.3.1.4 and 2.5.3.1.5, the applicant's responses to RAI 26, Question 02.05.03-5 and RAI 85, Question 02.05.03-12, and an independent examination of the information sources discussed by the applicant in the WLS COL FSAR and the RAI responses, the staff concludes that no existing data suggest the two small September 2006 earthquakes resulted from displacement along either the EPFS or a fault bounding the proposed buried Mesozoic basin. The staff draws this conclusion because of the large uncertainty in the epicentral locations of these two earthquakes, making even a spatial correlation between them and either of the structures difficult to establish. The staff also concludes that existing field data do not indicate Cenozoic (65.5 Ma to present), including post-Miocene (< 5.3 Ma), deformation characterizes the entire length of the EPFS, but rather show that this fault system is generally not younger than Mesozoic (> 65.5 Ma), because the granite body in Georgia dated at 269 Ma and Mesozoic dikes in South Carolina dated at > 65.5 Ma cross-cut the EPFS without any deformation. Accordingly, the staff considers RAI 26, Question 02.05.03-5 and RAI 85, Question 02.05.03-12 resolved.

2.5.3.4.1.4 *Current Aerial and Field Reconnaissance*

WLS COL FSAR Section 2.5.3.1.6 discusses current aerial and field reconnaissance conducted by the applicant to assess the presence of active tectonic surface deformation in WLS area. The applicant concluded that no geomorphic evidence exists for active faulting in the site area, including along Lineament 1, the northeast-trending topographic feature that lies 3.2 km (2 mi) northwest of the site location.

The staff focused the review of WLS COL FSAR Section 2.5.3.1.6 on documenting a non-tectonic origin for Lineament 1. In RAI 26, Question 02.05.03-6, the staff requested that the applicant summarize the information used to conclude that Lineament 1 is the result of erosion. In response to RAI 26, Question 02.05.03-6, the applicant stated that previous geologic maps show no faults associated with Lineament 1; field reconnaissance conducted for WLS did not reveal any evidence for faulting along the lineament; erosion-resistant metasedimentary rocks cap the ridges lying adjacent to the lineament; streams flowing along the base of the ridges result in strong topographic enhancement of the lineament; and the lineament does not extend across the Broad River to the northeast. Based on these field observations, the applicant concluded that Lineament 1 is non-tectonic in character and the result of localized stream erosion controlled by erosion-resistant, ridge-forming metasedimentary rock units.

Based on review of the applicant’s response to RAI 26, Question 02.05.03-6 and field observations made during site visits in April-May 2008 (ML120320233) and January 2009 (ML120320258), the staff concludes that Lineament 1 is the result of erosion rather than faulting. The staff draws this conclusion because field evidence demonstrates that Lineament 1 reflects localized stream erosion controlled by a resistant ridge-forming quartzite and does not extend across the Broad River to the northeast. Accordingly, the staff considers RAI 26, Question 02.05.03-6 resolved.

Based on the review of WLS COL FSAR Sections 2.5.3.1.1 through 2.5.3.1.6 and the applicant’s responses to RAI 26, Questions 02.05.03-1, 02.05.03-4 through 02.05.03-6, RAI 85, Question 02.05.03-11 and Question 02.05.03-12, as well as field observations made during the site visits, the staff finds that the applicant presented thorough and accurate descriptions of the geologic, seismic, and geophysical investigations performed to assess the potential for tectonic and non-tectonic surface and near-surface deformation within the site vicinity and site area and at the site location in support of the WLS application.

2.5.3.4.2 Geologic Evidence, or Absence of Evidence, for Surface Deformation

WLS COL FSAR Section 2.5.3.2 discusses geologic evidence, or lack of evidence, for surface deformation within the WLS vicinity and at the site location. Based on field relationships and radiometric age dates, the applicant concluded that the six bedrock faults reported to occur in the site vicinity, shown in Figure 2.5.3-1 of this report, are Paleozoic (> 251 Ma) in age, and that no faults oriented parallel to the northeastern trend of regional tectonic structures extend through the WLS location because good lithologic strain markers show no deformation related to faulting.

The staff focused the review of WLS COL FSAR Section 2.5.3.2 on the evidence presented by the applicant to document that the six faults mapped in the vicinity of WLS, including those that strike toward the site location, do not exhibit any evidence for Quaternary surface or near-surface tectonic deformation. Based on review of WLS COL FSAR Section 2.5.3.2, independent examination of references cited by the applicant, and direct observations made during site field audits conducted in April-May 2008 (ML120320233), January 2009 (ML120320258), July 2011 (ML11216A256), and February 2014 (ML14126A584), the staff concludes that these faults are all pre-Quaternary in age and do not exhibit any characteristics suggesting a potential for Quaternary surface or near-surface tectonic deformation at WLS. The staff draws this conclusion based on the field evidence and radiometric age dates presented by the applicant that limit the timing of displacements on these tectonic features to pre-Quaternary (> 2.6 Ma).

Based on the review of WLS COL FSAR Section 2.5.3.2, independent examination of references cited by the applicant, and direct observations made during site field audits, the staff finds that the applicant presented thorough and accurate descriptions of information related to geologic evidence, or lack of evidence, for surface deformation due to faulting within the site vicinity and at the site location in support of the WLS application.

2.5.3.4.3 Correlation of Earthquakes with Capable Tectonic Sources

WLS COL FSAR Section 2.5.3.3 addresses the correlation of earthquakes with capable tectonic sources in the WLS vicinity. The applicant concluded that there is no correlation of earthquakes with capable tectonic sources in the WLS vicinity.

The staff focused the review of WLS COL FSAR Section 2.5.3.3 on information used by the applicant to document that there is no correlation of earthquakes with capable tectonic sources in the WLS vicinity. Based on review of WLS COL FSAR Section 2.5.3.3 and an independent examination of data sources referenced in WLS COL FSAR Section 2.5.2, the staff concludes that no correlation exists between earthquakes and capable tectonic sources in the WLS vicinity because no data demonstrate any correlation.

Based on the review of WLS COL FSAR Section 2.5.3.3 and an independent examination of references cited by the applicant in WLS COL FSAR Section 2.5.2, the staff finds that the applicant presented a thorough and accurate description of information related to correlation of earthquakes with capable tectonic sources in support of the WLS application.

2.5.3.4.4 Ages of Most Recent Deformations

WLS COL FSAR Section 2.5.3.4 discusses ages of most recent deformations in the vicinity of WLS. The applicant concluded that the six faults mapped within the site vicinity, shown in Figure 2.5.3-1 of this report, only exhibit evidence for pre-Quaternary (> 2.6 Ma) deformation.

The staff focused the review of WLS COL FSAR Section 2.5.3.4 on information used by the applicant to document that all faults mapped within the WLS vicinity are pre-Quaternary in age. Based on review of WLS COL FSAR Section 2.5.3.4 and related information presented in WLS COL FSAR Section 2.5.3.2, as well as independent examination of references cited by the applicant and site visits conducted in April-May 2008 (ML120320233), January 2009 (ML120320258), July 2011 (ML11216A256), and February 2014 (ML14126A584), the staff concludes that tectonic deformation in the site vicinity is pre-Quaternary in age. The staff draws this conclusion because field data presented in the WLS COL FSAR and field observations made by staff during the site visits document a lack of Quaternary deformation in the WLS vicinity and site area and at the site location.

Based on the review of WLS COL FSAR Section 2.5.3.4, independent examination of references cited by the applicant, and field observations made during site visits, the staff finds that the applicant presented a thorough and accurate description of ages of most recent deformations in support of the WLS application.

2.5.3.4.5 Relationships of Site Area Tectonic Structures to Regional Tectonic Structures

WLS COL FSAR Section 2.5.3.5 discusses the relationships of tectonic structures in the site area to regional tectonic structures. The applicant stated that four of the six faults mapped in the site vicinity (specifically the Kings Mountain shear zone, the southwestern extension of the Boogertown shear zone, and the Tinsley Bridge and Reedy River faults shown in Figure 2.5.3-1 of this report) are segments of the regional CPSZ. Based on constraining age dates and observed field relationships summarized in WLS COL FSAR Section 2.5.3.2, which document that the CPSZ and these four tectonic structures are Paleozoic (> 521 Ma) in age, the applicant concluded that none of the structures are capable tectonic features.

The staff focused the review of WLS COL FSAR Section 2.5.3.5 on the information used by the applicant to document that four of the six faults mapped within the WLS vicinity and site area are segments of the regional CPSZ, which is Paleozoic in age. The staff concludes that these faults are not capable tectonic features based on the Paleozoic age constraint for the faults and the CPSZ as summarized in WLS COL FSAR Section 2.5.3.2.

Based on the review of WLS COL FSAR Section 2.5.3.5, the staff finds that the applicant presented a thorough and accurate description of the relationship of tectonic structures in the site area to regional tectonic structures in support of the WLS application.

2.5.3.4.6 Characterization of Capable Tectonic Sources

WLS COL FSAR Section 2.5.3.6 addresses the characterization of capable tectonic sources within the WLS vicinity. Based on constraining age dates and observed field relationships summarized in WLS COL FSAR Section 2.5.3.2, the applicant concluded that no evidence exists for any capable tectonic sources in the vicinity of WLS.

The staff focused the review of WLS COL FSAR Section 2.5.3.6 on the information used by the applicant to document that no capable tectonic sources exist in the site vicinity. Based on the constraining age dates and observed field relationships summarized in WLS COL FSAR Section 2.5.3.2, as well as field observations made during site visits in April-May 2008 and January 2009, the staff concludes that no capable tectonic sources exist in WLS vicinity. The staff draws this conclusion because the age dates and observed field relationships document a lack of capable tectonic sources in the site vicinity. The staff notes the suggestion of Garihan and others (1993) that the Kings Mountain shear zone may have experienced localized Mesozoic (251 to 65.5 Ma) reactivation does not alter the conclusion about the absence of capable tectonic sources in the site vicinity.

Based on the review of WLS COL FSAR Section 2.5.3.6 and field observations made during the site visits, the staff finds that the applicant presented a thorough and accurate description of information related to characterization of capable tectonic sources in support of the WLS application.

2.5.3.4.7 Designation of Zones of Quaternary Deformation in the Site Region

WLS COL FSAR Section 2.5.3.7 discusses the designation of Quaternary (2.6 Ma to present) deformation zones in the WLS region. Based on information presented in WLS COL FSAR Section 2.5.1 and cross-referenced in WLS COL FSAR Section 2.5.3.7, the applicant concluded that no zones of Quaternary deformation requiring further investigation occur in the site region.

The staff focused the review of WLS COL FSAR Section 2.5.3.7 on the data presented by the applicant, mainly in WLS COL FSAR Section 2.5.1, to document that no zones of Quaternary deformation occur in the site region. The staff concludes that no evidence exists for zones of Quaternary deformation in the site region based on independent review of the data sources presented by the applicant in the WLS COL FSAR, which document a lack of Quaternary deformation in the site region.

Based on the review of WLS COL FSAR Section 2.5.3.7 and an independent review of references cited by the applicant, the staff finds that the applicant presented a thorough and accurate description of information related to designation of zones of Quaternary deformation in the site region in support of the WLS application.

2.5.3.4.8 Potential for Surface Tectonic Deformation at the Site

WLS COL FSAR Section 2.5.3.8 discusses the potential for surface and near-surface tectonic and non-tectonic deformation at WLS. The applicant documented that no Quaternary (2.6 Ma to present) faults or capable tectonic structures occur in the site vicinity or site area, and that rock units in the site area and at the site location are not susceptible to dissolution collapse or subsidence related to fluid withdrawals. Therefore, the applicant concluded that the potential for tectonic and non-tectonic surface and near-surface deformation is negligible at the site location.

The staff focused the review of WLS COL FSAR Section 2.5.3.8 on information presented by the applicant to document that no evidence exits to indicate any potential for surface or near-surface tectonic or non-tectonic deformation at WLS. The staff concludes that the potential for surface or near-surface tectonic or non-tectonic deformation at WLS is negligible based on results of the following activities: Review of WLS COL FSAR Section 2.5.3.8; examination of lithologic units and tectonic features in the CNS excavations during site visits in April-May 2008, January 2009, July 2011, and February 2014; data documentation audits conducted in February and July 2009 and June and October 2011; and an independent review of published sources cited by the applicant. The staff draws this conclusion because direct field observations made by staff during site visits, the data documentation audits, and the independent review of the information sources cited by the applicant strongly support it.

Based on the review of WLS COL FSAR Section 2.5.3.8, independent review of published sources cited by the applicant, results of the data documentation audits, and field observations made during the site visits, the staff finds that the applicant presented a thorough and accurate description of the potential for surface tectonic deformation at the site in support of the WLS application.

With regard to evaluating the potential for surface and near-surface tectonic and non-tectonic deformation in foundation bedrock units at WLS Unit 1, (i.e., former CNS Unit 1, the excavation for which lies under concrete poured during initial CNS construction activities), the staff deemed it necessary to document lithologies and geologic features that occur in foundation grade level bedrock in WLS Unit 1/CNS Unit 1 excavation. To accomplish this task, the staff performed the June and October 2011 data documentation audits described in Section 2.5.1.4 of this report specifically to review the report containing the compiled geologic map and associated data for CNS Unit 1. The staff also conducted the site visit in July 2011, as described in Section 2.5.1.4 of this report, to directly examine existing exposures in CNS Unit 2 and CNS Unit 3 (WLS Unit 2) for determining whether lithologies and geologic features mapped in the CNS Unit 1 (WLS Unit 1) excavation are similar to the rock units and geologic features that occur in the existing adjacent CNS site excavations. Based on the results of these activities, specifically focused on assessment of the compiled geologic map data presented in the Duke report and with due consideration for results of the data documentation audits performed in February and July 2009 and the site visits conducted in April-May 2008 and January 2009, the staff concludes that the applicant essentially satisfied the requirements for a geologic mapping License Condition for WLS Unit 1,. The staff makes this conclusion because field relationships observed during all site visits and field data reviewed during all data documentation audits fully support the premise of similarity of lithologies and geologic features in excavations for CNS Unit 1, Unit 2, and Unit 3, and, consequently, for WLS Unit 1,. Also, in support of the staff's conclusion regarding how the applicant satisfied the requirements for a geologic mapping License Condition for WLS Unit 1, the site visits and data documentation audits confirm that no capable tectonic structures or other potentially detrimental geologic features occur in the foundation rocks of WLS Unit 1, and that the potential for surface or near-surface tectonic and non-tectonic deformation at WLS Unit 1, is negligible.

Although the staff concludes that the applicant essentially satisfied the requirements for a geologic mapping License Condition for WLS Unit 1, based on all geologic data examined and the direct field observations made, it is the responsibility of the applicant to perform detailed geologic mapping of the WLS Unit 2 excavation for nuclear island structures. Section 2.5.3.5 of this report defines this responsibility as License Condition (2-2).

2.5.3.5 *Post-Combined License Activities*

The staff identified the following geologic mapping License Condition in Section 2.5.3.4.8 of this report as the responsibility of the COL licensee:

- License Condition (2-2) – The licensee shall perform detailed geologic mapping of the excavation for WLS Unit 2 nuclear island structures; examine and evaluate geologic features discovered in excavations for safety-related structures other than those for the Unit 2 nuclear island; and notify the Director of the Office of New Reactors, or the Director's designee, once excavations for Unit 2 safety-related structures are open for examination by the staff.

2.5.3.6 *Conclusions*

The staff reviewed the WLS COL FSAR and the referenced DCD. Based on these reviews, the staff confirmed that the applicant addressed the required information related to surface and near-surface tectonic (i.e., due to faulting) and non-tectonic deformation, and there is no additional outstanding information related to these types of deformation that must be discussed in the WLS COL FSAR. NUREG-1793 and associated supplements document the results of the staff's technical evaluation of information incorporated by reference into the WLS application.

As set forth above, the staff has reviewed the information in COL Information Item WLS COL 2.5-4 and concludes that the applicant thoroughly characterized the potential for surface and near-surface tectonic and non-tectonic deformation at WLS, as required by 10 CFR 10.23 and 10 CFR 52.79(a)(1)(iii). Based on the applicant's geologic investigations performed for the site vicinity, site area, and site location, the staff also concludes that the applicant properly addressed information related to the following specific topics for WLS: Geologic, seismic, and geophysical investigations; geologic evidence, or absence of evidence, for surface deformation; correlation of earthquakes with capable tectonic sources; ages of most recent deformations; relationships between tectonic structures in the site area and regional tectonic structures; characterization of capable tectonic sources; designation of zones of Quaternary (2.6 Ma to present) deformation in the site region; and the potential for surface tectonic and non-tectonic deformation at the site. In addition, the staff concludes that the applicant performed all investigations in accordance with 10 CFR 100.23 and 10 CFR 52.79(a)(1)(iii) and followed guidance provided in RG 1.208. Finally, the staff concludes that the applicant established an adequate basis to state that no known capable tectonic sources exist which could cause surface or near-surface tectonic deformation at WLS and no known sources exist for non-tectonic deformation at the site. Therefore, the staff finds that the proposed WLS site is acceptable in regard to surface and near-surface tectonic and non-tectonic deformation and meets the requirements of 10 CFR 10.23 and 10 CFR 52.79(a)(1)(iii).

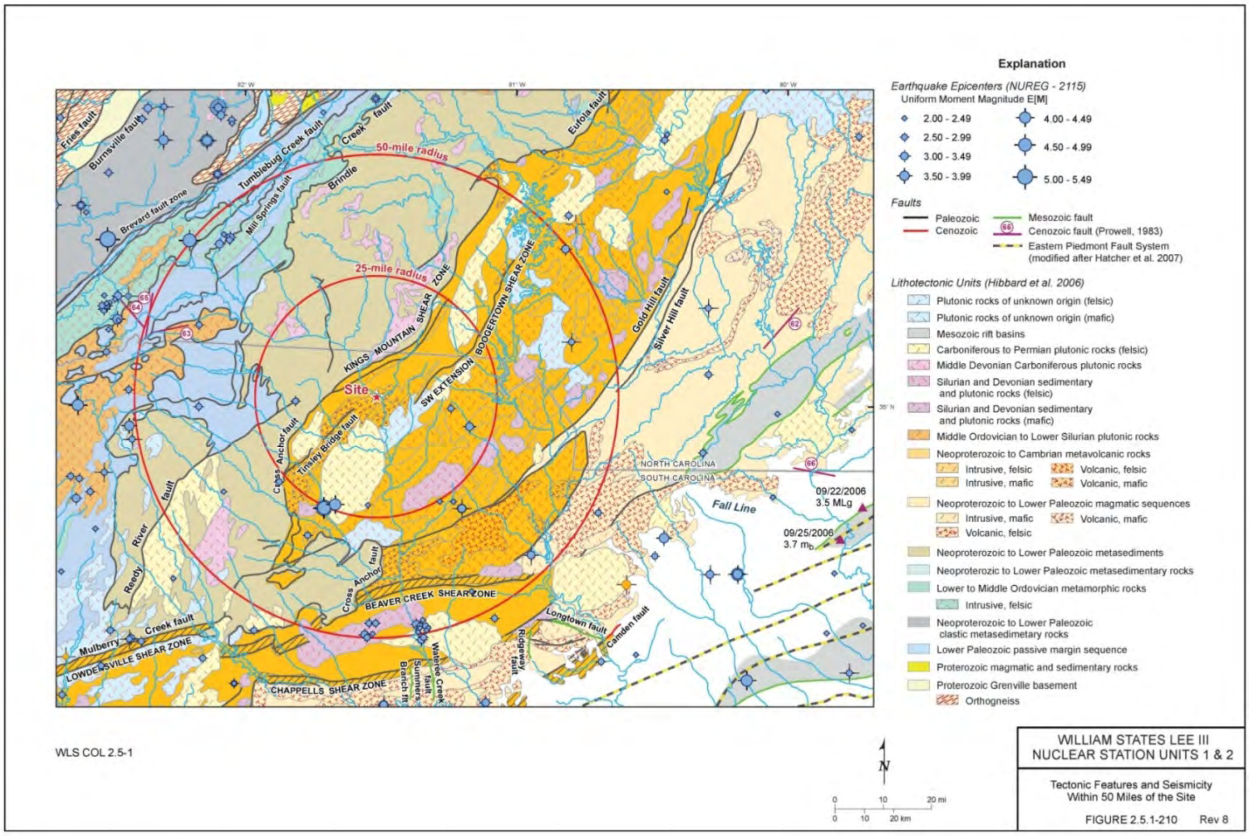

Figure 2.5.3-1 Tectonic Features And Seismicity Within 80.5 km (50 mi) of WLS (Reproduced from WLS COL FSAR Revision 8, Figure 2.5.1-210)

2.5.4 Stability of Subsurface Materials and Foundations

2.5.4.1 *Introduction*

WLS COL FSAR Section 2.5.4 presents the applicant's evaluation of the stability of subsurface materials and foundations that relate to the WLS site. The properties and stability of the soil and rock underlying the site are important to the safe design and siting of the plant. The information provided by the applicant in WLS COL FSAR Section 2.5.4 addresses: (1) geologic features in the site vicinity; (2) static and dynamic engineering properties of soil and rock strata underlying the site; (3) the interface between the foundations for safety-related facilities and the engineering properties of underlying materials; (4) results of the geophysical surveys performed to provide the velocity profiles underneath foundation footprints; (5) excavation and backfill plans and engineered earthwork analysis and criteria for safety-related structure foundations; (6) groundwater conditions at the site and associated testing monitoring and analyses; (7) responses of site soils or rocks to dynamic loading; (8) soil liquefaction potential analysis and evaluation; (9) earthquake design bases; (10) results of investigations and analyses conducted to determine foundation material stability, deformation, and settlement under static and dynamic loading conditions; (11) criteria, references, and design methods used in static and dynamic analyses of subsurface materials and foundation stability; (12) techniques and specifications to improve subsurface conditions, which are to be used at the site to provide suitable foundation conditions; and any additional information deemed necessary in accordance with 10 CFR Part 52.

2.5.4.2 *Summary of Application*

WLS COL FSAR Section 2.5.4 incorporates by reference AP1000 DCD, Revision 19, Section 2.5.4.

In addition, in WLS COL FSAR Section 2.5.4, the applicant provided site-specific information to address the following:

AP1000 COL Information Items

- WLS COL 2.5-1

The applicant provided additional information in WLS COL 2.5-1, to resolve COL Information Item 2.5-1. WLS COL 2.5-1 addresses the provision of regional and site-specific geological, seismological, and geophysical information, as well as conditions caused by human activities; structural geology; seismicity of the site; geological history; evidence of paleoseismicity; site stratigraphy and lithology; engineering significance of geological features; site groundwater conditions; dynamic behavior during prior earthquakes; zones of alteration, irregular weathering, or structural weakness; unrelieved residual stresses in bedrock; materials that could be unstable because of mineralogy or unstable physical properties; and effect of human activities in the area. This COL information item is also addressed in WLS COL FSAR Sections 2.5.1, 2.5.4.1, 2.5.4.3, 2.5.4.3.3, 2.5.4.3.5 and 2.5.4.8, Appendix 2AA, Appendix 2BB.

- WLS COL 2.5-2

The applicant provided additional information in WLS COL 2.5-2, to resolve COL Information Item 2.5-2. WLS COL 2.5-2 addresses the provision for the collection of site-specific geological, seismological, and geotechnical data and demonstration that the proposed site meets the specified requirements. This COL information item is addressed in WLS COL FSAR Sections 2.5, 2.5.2, and 2.5.4.3.3.

- WLS COL 2.5-3

The applicant provided additional information in WLS COL 2.5-2, to resolve COL Information Item 2.5-3. WLS COL 2.5-3 addresses the provision for the performance of site-specific geological, seismological, and geotechnical evaluation; if the site-specific spectra at foundation level exceed the response spectra in AP1000 DCD Figures 3.7.1-1 and 3.7.1-2 at any frequency, or if soil conditions are outside the range evaluated for AP1000 design certification. This COL information item is addressed in WLS COL FSAR Section 2.5.4.3.3.

- WLS COL 2.5-5

The applicant provided additional information in WLS COL 2.5-5, to resolve COL Information Item 2.5-5. WLS COL 2.5-5 addresses the provision of site-specific information underlying site conditions and geologic features, including site topographic features and locations of Seismic Category I structures. This COL information item is addressed in WLS COL FSAR Sections 2.5.4.1, 2.5.4.3.5, and 2.5.4.5.

- WLS COL 2.5-6

The applicant provided additional information in COL Information Item 2.5-6, resolve WLS COL 2.5-6. WLS COL 2.5-6 addresses the provision that the properties of the foundation materials are within the range of the properties considered for the design of the nuclear island basemat. This COL information item is addressed in WLS COL FSAR Sections 2.5.4.2, 2.5.4.2.1, 2.5.4.3.6, 2.5.4.4, 2.5.4.5.1, 2.5.4.5.2, 2.5.4.5.3, 2.5.4.7, 2.5.4.9, and 2.5.4.10.

- WLS COL 2.5-7

The applicant provided additional information in WLS COL 2.5-7, to resolve COL Information Item 2.5-7. WLS COL 2.5-7 addresses the provision of data concerning the extent (horizontally and vertically) of all Seismic Category (SC) I excavations, fills, and slopes, conditions and geologic features. This COL information item is addressed in WLS COL FSAR Section 2.5.4.3.6, 2.5.4.5.1, 2.5.4.5.2, and 2.5.4.5.3.

- WLS COL 2.5-8

The applicant provided additional information in WLS COL 2.5-8, to resolve COL Information Item 2.5-8. WLS COL 2.5-8 addresses the provision of addressing groundwater conditions relative to the foundation stability of the safety-related structures at the site. This COL information item is addressed in WLS COL FSAR Section 2.5.4.5.4 and 2.5.4.6.4.

- WLS COL 2.5-9

The applicant provided additional information in WLS COL 2.5-9, to resolve COL Information Item 2.5-9. WLS COL 2.5-9 addresses the provision of demonstration that the potential for liquefaction is negligible. This COL information item is addressed in WLS COL FSAR Section 2.5.4.8.

- WLS COL 2.5-10

The applicant provided additional information in WLS COL 2.5-10, to resolve COL Information Item 2.5-10. WLS COL 2.5-10 addresses the verification that the site-specific allowable soil bearing capacities are equal to or greater than the values documented in the standard design, or will provide a site-specific evaluation as described in AP1000 DCD Section 2.5.4.2 under all combined loads, including the safe shutdown earthquake, for static and dynamic loads. This COL information item is addressed in WLS COL FSAR Section 2.5.4.10.1.

- WLS COL 2.5-11

The applicant provided additional information in WLS COL 2.5-11, to resolve COL Information Item 2.5-11. WLS COL 2.5-11 addresses the design of static and dynamic lateral earth pressures and hydrostatic pressures acting on safety-related facilities using site-specific seismic loading and soil parameters. This COL information item is addressed in WLS COL FSAR Section 2.5.4.10.3

- WLS COL 2.5-12

The applicant provided additional information in WLS COL 2.5-12, to resolve COL Information Item 2.5-12. WLS COL 2.5-12 addresses soil characteristics affecting the stability of the nuclear island including foundation rebound, settlement and differential settlement. This COL information item is addressed in WLS COL FSAR Section 2.5.4.10.2.

- WLS COL 2.5-13

The applicant provided additional information in WLS COL 2.5-13, to resolve COL Information Item 2.5-13. WLS COL 2.5-13 addresses the provision of data on instrumentation, if any, proposed for monitoring the performance of the foundations of the nuclear island; including the type, location, and purpose of each instrument, as well as significant details of installation methods, along with the location and installation procedures for permanent benchmarks and markers for monitoring settlement. This COL information item is addressed in WLS COL FSAR Section 2.5.4.10.

- WLS COL 2.5-16

The applicant provided additional information in WLS COL 2.5-16, to address COL Information Item 2.5-16. WLS COL 2.5-16 addresses the provision of data on short-term (elastic) and long-term (heave and consolidation) settlement for soil sites for the history of loads imposed on the foundation consistent with the construction sequence. The resulting time-history of settlements includes construction activities such as dewatering, excavation, bearing surface preparation, placement of the basemat, and construction of the superstructure. This COL information item is addressed to the extent that the applicant stated that this is a rock site.

In addition, this WLS COL FSAR section addresses AP1000 DCD Interface Item 2.12 related to the seismic parameters peak ground acceleration, response spectra and shear wave velocity and Interface Item 2.13 related to the required bearing capacity of foundation materials.

AP1000 COL Supplements

- COL SUP 2.5-2

The applicant provided supplemental information in COL SUP 2.5-2 regarding the backfilling of exploratory boreholes for monitoring wells. This supplement is addressed in WLS COL FSAR Section 2.5.4.2.1.2.

- COL SUP 2.5-3

The applicant provided supplemental information in WLS COL Supplement 2.5-2 regarding the grouting of polyvinyl chloride (PVC) monitoring well locations that were left open for continued monitoring. This supplement is addressed in WLS COL FSAR Section 2.5.4.2.1.2.

Interface Items

- Interface Item 2.12

The WLS COL FSAR addresses Interface Item 2.12 of the AP1000 DCD related to the seismic parameters peak ground acceleration, response spectra and shear wave velocity.

- Interface Item 2.13

The WLS COL FSAR addresses Interface Item 2.13 related to the required bearing capacity of foundation materials.

2.5.4.2.1 Geologic Features

WLS COL FSAR Section 2.5.4.1 evaluates the non-tectonic processes and features that may cause permanent ground deformation or foundation instability at the WLS site. In particular, the applicant focused on areas of actual or potential surface or subsurface subsidence, uplift or collapse and the causes of these potential conditions. The applicant also considered potential zones of alteration, irregular weathering profiles, zones of structural weakness, geologic history, unrelieved residual stresses in the bedrock at the site, and rocks or soils that may be unstable due to physical or chemical properties. The applicant concluded that that there are no geologic processes or features that would be detrimental to the stability of the proposed WLS site.

2.5.4.2.2 Properties of Subsurface Materials

WLS COL FSAR Section 2.5.4.2 details the various field and laboratory methods used to sample and test soil and rock to determine material properties needed for the site safety evaluation. The applicant stated that the field investigations for determining the engineering properties of soil and rock materials conform to RG 1.132. WLS COL FSAR Sections 2.5.4.2.1 and 2.5.4.2.2 provide more complete details of the soil and rock sampling programs, respectively. The applicant used the guidelines of RG 1.138 to plan and conduct the laboratory testing program. The applicant also summarized the static and dynamic laboratory tests performed, and reported the results from tests carried out on disturbed samples, undisturbed samples and remolded samples.

2.5.4.2.2.1 *Site Explorations*

WLS COL FSAR Section 2.5.4.2.1 describes the methods and equipment used to perform the site exploration. The applicant described soil and rock borings, groundwater monitoring wells, cone penetration test (CPT) soundings, surface geophysical surveys, geotechnical test pits, geologic trench excavations, and downhole deformation testing and seismic and non-seismic logging of the site soils and rock performed for the WLS investigations.

The site investigation plan was developed based on the evaluations of historic field explorations performed in the 1970’s for the CNS that is within the site boundary of the WLS. The site investigation for this application was first conducted between early 2006 and mid-2007. Since the relocation of the power plant footprint, additional field work was performed in 2012 to obtain additional geotechnical data at the revised nuclear island locations to confirm the applicability of the 2006-2007 data. The applicant provided CNS exploratory work as a supplement in WLS COL FSAR Appendix 2BB. Figure 2.5.4-01 of this report shows the exploration locations for the WLS power blocks and adjacent areas, as well as the soil and rock borings from the previous investigations for the CNS.

2.5.4.2.2.1.1 Soil and Rock Borings

The applicant obtained the soil and rock core borings using conventional drilling equipment and procedures. WLS COL FSAR Appendix 2AA presents the results of the WLS field exploration. For selected borings, the applicant presented summary borehole sheets. Figure 2.5.4-2 of this report shows the summary sheet for boring B-1004 as an example and includes the depths from which samples were taken for the shear wave velocity (V_s), compression wave velocity (V_p), Young's modulus and unconfined compression tests. In addition, the figure shows the percent recovery and the Rock Quality Designation (RQD), an index that reflects the soundness of the rock mass, in histogram fashion along the length of the boring length. The rock type is designated in the lithology column and Goodman Jack test results. The petrographic sample locations are also shown in the figure.

2.5.4.2.2.1.2 Groundwater Monitoring Wells

The applicant installed groundwater monitoring wells to obtain hydrologic data and performed a pump test to determine mass permeability to compliment the borehole slug tests and packer tests to obtain permeability within different material types within the boreholes. Groundwater flow at the WLS site occurs mainly in the saprolite, partially weathered rock and joints within the bedrock. The applicant left some groundwater monitoring wells open for continued monitoring. WLS COL FSAR Section 2.4.12 provides additional information regarding the groundwater monitoring wells and a detailed summary and evaluation of those wells.

2.5.4.2.2.1.3 Surface Geophysical Testing

The applicant performed surface geophysical testing at the site using the Spectral Analysis of Surface Waves (SASW) technique at 15 locations to compliment the downhole geophysical testing and to obtain geophysical data to depths that ranged from several meters (tens of feet) to approximately 45.7 m (150 ft) below the ground surface. The applicant stated the SASW surface geophysical testing compared favorably to down-hole geophysical testing methods, however, the SASW methodology was limited in its penetration depth and useful information was typically limited to several meters (tens of feet) below the ground surface.

2.5.4.2.2.1.4 In-Situ Testing

The applicant performed several different methods of in-situ testing in boreholes to estimate soil and rock properties. The applicant measured the deformation properties of the rock using the Goodman Jack and the borehole pressuremeter tests. Additional borehole geophysical tests in soil and rock using downhole geophysical techniques included optical televiewer, acoustic televiewer, P-S (compression and shear waves) suspension logging, downhole seismic velocity logging and seismic cone penetration test.

Goodman Jack Testing

The applicant performed 14 Goodman Jack tests in two boreholes at multiple depth intervals to measure the rock elastic modulus using the procedures described in American Society for Testing and Materials (ASTM) Standard D4971-02, "Standard Test Method for Determining in Situ Modules of Deformation of Rock Using Diametrically Loaded 76-mm (3 in.) Borehole Jack."

Borehole Pressuremeter Testing

The applicant performed 24 pressuremeter tests in two boreholes at multiple depth intervals following the procedures described in ASTM D4719-00, "Standard Test Methods for Prebored Pressuremeter Testing in Soils," to measure the elastic modulus of soil and rock. WLS COL FSAR Table 2.5.4-209 provides the results of the pressuremeter tests.

Borehole Geophysical Testing

The applicant performed borehole geophysical testing in 19 boreholes, including 16 P-S suspension logging tests, four downhole seismic velocity logging tests performed in P-S suspension logging borings for comparison purposes, and 17 borehole televiewer logging tests using optical and/or acoustic methods to develop the rock seismic profiles for the determination of the GMRS and FIRS in WLS COL FSAR Section 2.5.2. WLS COL FSAR Section 2.5.4.2.4 presents the results of the borehole geophysical testing in more details.

2.5.4.2.2.1.5 Petrographic Testing

The applicant collected 15 rock core samples from nine borings for petrographic testing. Using standard 27 by 46 mm (1.0 by 1.8 in.) covered thin sections, the applicant performed petrographic analyses and photomicrography at magnifications ranging from 25X to 500X and used the results to classify the bedrock.

2.5.4.2.2.2 *Soil and Rock Sampling*

The applicant performed Standard Penetration Tests (SPT) to determine the properties of soils that would be supporting non-safety-related structures. The SPT thick-walled sampler was used to collect disturbed samples for classification, and measurements of the resistance of soil to penetration, or N-value, was recorded.

The applicant performed rock coring when soil drilling methods met refusal to obtain intact rock cores for laboratory strength testing. Each rock core was photographed in the field and core logs prepared noting joints and fractures and other pertinent data. The percent recovery and RQD were recorded on the boring logs.

The applicant determined that rock having a RQD of 65 percent or greater is suitable foundation material and designated this material as "continuous rock," but noted that the continuous rock surface is uneven due to differential depths of weathering. Excavation to continuous rock is required at WLS Unit 2. The applicant's interpretation of the surface elevation of continuous rock across the site is depicted in Figure 2.5.4-3 of this report. The contour map shown in

Figure 2.5.4-3 of this report also reveals the uneven continuous rock surface across the site. The applicant stated that it will take down the high points and backfill the low areas with concrete under the foundation support zone of the nuclear island.

2.5.4.2.2.2.1 Static Properties of Geotechnical Materials

Table 2.5.4-1 of this report summarizes the static properties of the continuous rock based on laboratory testing of intact rock specimens and shows that rock core unconfined compressive strengths range from 68.9 to 193 Meganewtons/square meter (MPa) (10.0 to 28 kilopounds/square inch (ksi)) for the various metamorphic rocks identified at the site. Young's modulus determined from stress-strain measurements made during unconfined compressive strength (UCS) tests on instrumented samples ranged from 42,000 to 55,800 MPa (6,100 to 8,100 ksi). The applicant used data from the CNS Preliminary Safety Analysis Report (PSAR) to supplement the WLS geotechnical data for soils, such as the lightly weathered rock, where limited data was available.

The applicant provided the engineering properties of the pre-existing CNS concrete and underlying rock in a supplemental pre-demolition concrete basemat evaluation report. This report included a description of the field and laboratory activities, test results, and an evaluation of the concrete-rock interface. The UCS of the existing concrete generally exceeded 27.5 MPa (4,000 psi), and the V_s was typically greater than 2,286 m/s (7,500 fps). The applicant concluded that the field and laboratory V_s are consistent with the values used in the WLS Unit 1 FIRS.

Table 2.5.4-1 Summary of Laboratory Test Results for Intact Rock Cores (WLS COL FSAR Table 2.5.4-213)

	Meta Granodiroite	Meta Quartz Diorite	Meta Diorite	All Rock Types
Unit Weight, pcf	168 +/- 1 [19]	169 +/- 3 [14]	177 +/- 2 [8]	170 +/- 4 [41]
Unconfined Compressive Strength, ksi	23 +/- 5 [19]	17 +/-7 [14]	22 +/- 6 [8]	21 +/- 7 [41]
Young's Modulus, x10^6 psi	7.8 +/- 0.3 [3]	7.1 +/- 1.0 [7]	8.1 [1]	7.4 +/- 0.9 [11]
Poisson's Ratio	0.29 +/- 0.06 [3]	0.27 +/- 0.05 [7]	0.23 [1]	0.27 +/- 0.05 [11]

The number in brackets is the number of tests performed.

2.5.4.2.3 Foundation Interfaces

WLS COL FSAR Section 2.5.4.3 compiles the information gathered during the WLS site exploration into a geological representation of the foundation conditions at the site.

2.5.4.2.3.1 *Geotechnical Profiles*

The WLS COL FSAR includes geotechnical profiles along seven geologic cross-sections through the WLS nuclear islands and adjacent areas. Figure 2.5.4-1 of this report shows the locations where these cross sections were cut and from which is it possible to depict the former and existing ground surface, plant and yard grade, nuclear island and non-safety-related structures locations, geologic features, and relevant boring and geophysical test data. Figure 2.5.4-4 of this report shows the cross-section BB-BB', a West-East profile passes through the centerlines of the WLS. Figure 2.5.4-5 of this report shows the cross-section UU-UU', a West-East profile through the north end of the Units 1 and 2 nuclear island. The cross-sections show the extent of the existing concrete from the CNS construction at Unit 1 and the geologic interpretation of the foundation conditions underlying the structures.

2.5.4.2.4 Geophysical Surveys

WLS COL FSAR Section 2.5.4.4 describes the exploratory geophysical surveys that the applicant performed to determine the soil and rock low strain seismic characteristics within the power block areas and pre-existing concrete and soil fills. The applicant stated that it conducted the investigations using the methods described in RG 1.132. The applicant also used a combination of surface and borehole geophysical surveys to characterize the subsurface conditions. The geophysical tools used to characterize the existing concrete, soil and rock including SASW, seismic cone penetration tests (SCPT), P-S (compressional wave - shear wave) suspension logging, downhole seismic velocity logging and acoustic and optical televiewer logging. The applicant noted that the redundancy of state-of-the-art methods provides confidence in the results.

2.5.4.2.4.1 *Spectral Analysis of Surface Waves Surveys*

SASW surveys were conducted at 15 locations with survey depths ranging from several meters (tens of feet) to approximately 30.5 m (100 ft) below ground surface. The applicant concluded that the SASW technique yielded average V_s that compare favorably with borehole P-S suspension and downhole seismic velocity logs.

2.5.4.2.4.2 *Seismic Cone Penetration Tests*

The applicant performed SCPTs at 10 locations in the site soils and saprolite and used the results for the design of non-safety-related structures.

2.5.4.2.4.3 *Suspension and Downhole Seismic Velocity Logging*

The applicant performed suspension velocity logging in a total of 16 boreholes and companion downhole seismic velocity tests in 4 of the 16 boreholes for comparison. The applicant concluded that downhole velocity measurements compared favorably with the P-S suspension logging measurements and developed velocity profiles from the results of the seismic testing. Figures 2.5.4-06 through 2.5.4-07 of this report show a representative boring summary sheet for the WLS powerblock areas. These boring logs show consistent hard rock V_s of greater than 2,438 m/s (8,000 fps), particularly at depths below an El. of 162 m (533 ft).

2.5.4.2.4.4 *Acoustic and Optical Televiewer Logging*

The applicant conducted acoustic and optical televiewer logging in 17 boreholes to correct soil, rock and geophysical log depths to true depths, and provide acoustic images of the borehole wall to determine the dip and azimuth of fractures. The applicant used the fracture orientation data to estimate the Rock Mass Rating and evaluate discontinuity characteristics.

2.5.4.2.5 Excavation and Backfill

WLS COL FSAR Section 2.5.4.5 describes the excavation and backfilling required to reach foundation grade and plant grade for WLS. The applicant proposed using a combination of excavation slopes and temporary retaining structures to excavate to the bottom of unsuitable materials. The purpose of the retaining structures is to minimize disturbance of the slopes.

The applicant described the foundation for the nuclear islands as consisting of continuous rock at variable elevations below the basemat foundation level at an El. of 168.7 m (553.5 ft). The applicant noted that all of the WLS Unit 1 foundation support zone is underlain by pre-existing CNS concrete overlying continuous rock from the former construction activities associated with the CNS. The applicant performed pre- and post-demolition studies of the CNS structural and fill concrete to determine its static and dynamic properties. The existing rock and concrete surface at WLS Unit 1 is below the basemat founding elevation. In order to bring the site to basemat foundation grade, the applicant plans to use concrete fill. The applicant proposed to use a fill concrete mix design based on American Concrete Institute (ACI) Standard 318-02 with minimum design UCS of 17.2 MPa (2,500 psi). Figure 2.5.4-9 of this report, cut along cross-section BB-BB', shows the relationship between the excavation, concrete fill, engineered granular fill, Units1 and 2 Annex Building, Unit 1 and 2 nuclear island, existing CNS concrete fill and CNS structural fill (basemat).

2.5.4.2.5.1 *Extent of Excavation*

The applicant noted that it will enlarge the extent of the excavation an additional 3.05 m (10 ft) laterally into the fill and natural soil materials removing softened, sloughed, or other loose soil and rock materials in the slopes of the existing CNS excavation. Under the nuclear islands, the excavations will be taken down as necessary to reach continuous rock, defined as having a RQD of 65 percent. The applicant determined the limits of the excavation based on the core borings distributed across the site.

The WLS Unit 1 excavation is made to a foundation subgrade elevation of approximately 164.5 to 165.1 m (540 to 545 ft), corresponding to the elevation of the pre-existing CNS structural elements where they exist. The applicant stated that the foundation support zone for the WLS Unit 1 nuclear island is entirely underlain by the existing concrete of CNS Unit 1, which is underlain by continuous rock. Figure 2.5.4-8 of this report conceptually shows the WLS excavation depths to reach continuous rock and concrete fill to be placed underneath and surrounding the nuclear island. The applicant also stated that the existing CNS concrete foundation has several local pits with horizontal and vertical waterproofing membranes.
In those locations, excavation will be performed to remove those membranes and then be continued to reach the continuous rock, or the top of the fill concrete layer that is resting on the continuous rock. The new fill concrete will be placed underneath and surrounding planned Seismic Category I structures.

The WLS Unit 2 excavation will be made mostly in continuous rock with the exception of the east side of the Reactor Building. The applicant noted that boring B-1014 indicates that the continuous rock surface is approximately 4.8 m (16 ft) below the basemat foundation elevation. The applicant proposed the use of fill concrete in this and any other areas requiring backfill.

2.5.4.2.5.1.1 Concrete Fill

The applicant noted that variable depths of concrete fill and dental concrete are needed to construct a uniform and smooth subgrade for the placement of the basemat foundation at El. 168.7 m (553.5 ft). Several meters to 7.6 m (several feet to 25 ft) of concrete backfill are needed at WLS Unit 1 and approximately 4.8 m (16 ft) of concrete fill are needed at the east side of WLS Unit 2. The applicant stated that the concrete fill mix design will be in accordance with ACI 318-02 and will have a minimum unconfined compressive strength of 17.2 MPa (2,500 psi) and V_s of 2,286 m/s (7,500 fps). The applicant assumed V_s equal to 2,286 m/s (7,500 fps) in the dynamic analyses to correspond with the average V_s determined for the existing CNS concrete fill and structural concrete.

The applicant stated that it will prepare the existing concrete left in place from the CNS construction by cleaning and scoring the surface 0.64 cm (0.25 in.) deep to provide for adhesion between the existing concrete and new concrete fill. As described in Section 2.5.4.4.5.1.2 the applicant stated these properties will be ensured through testing of the mix design.

2.5.4.2.5.2 *Soil Backfill Sources and Quantities*

WLS COL FSAR Section 2.5.4.5.1 describes the use of both on- and off-site granular material sources for backfilling the area around the below-grade nuclear island walls out to the limits of the excavation slope. The offsite granular backfill will be used to support the non-safety-related and Seismic Category II structures surrounding the nuclear island. The applicant described steps for verification of foundation conditions and placement of proper backfill materials. The applicant proposed using South Carolina Department of Transportation (SCDOT) standard gravel or sand gradations readily available from state-approved borrow sources. The applicant did not identify the source for the granular fill but stated that the granular fill material would likely be obtained from an off-site source such as an operating rock quarry. The granular fill to be placed adjacent to Seismic Category I structures or beneath other important adjacent facilities would be verified to have the properties used in site response analyses and compatible with the material properties described in WLS COL FSAR Section 3.7.2.8.4.

2.5.4.2.5.3 *Specifications and Control*

WLS COL FSAR Section 2.5.4.5.3 describes the methods and procedures used for verification and quality control of the nuclear island foundation materials and the fill concrete beneath the nuclear island foundation limits. The applicant noted that these methods and procedures will verify that all unsuitable material has been removed down to continuous rock and will be verified by geologic mapping of the final exposed excavation surface prior to placement of concrete. The staff discusses the requirement for a geologic mapping and proposed a license condition in Section 2.5.3 of this report.

In pre- and post- demolition reports, the applicant verified that the concrete fill materials and reactor building basemat slab remaining from the CNS are suitable for support of the WLS nuclear island foundation. Fill concrete beneath the nuclear island foundation limits will be designed in accordance with ACI 318-02 to attain a V_s of 2,286 m/s (7,500 fps). The applicant stated surfaces to receive concrete fill will be intentionally roughened according to the guidance in ACI 349.

The applicant plans to prepare the foundation materials beyond the limits of the nuclear island footprint for support of engineered granular backfill. The applicant also stated that it will verify proper foundation conditions and any depressions or cavities in the surface of the foundation soil or rock will be backfilled with fill concrete or properly compacted soil fill materials. Engineered backfill to support Seismic Category II and non-safety-related buildings will be granular fill conforming to SCDOT gradation limits obtained from approved quarries. The applicant further stated that it will compact the backfill to a minimum of 96 percent of the maximum density determined by the modified Proctor compaction method as described in ASTM D1556, “Standard Test Method for Density and Unit Weight of Soil in Place by Sand-Cone Method.” Finally, the applicant stated that in areas where backfill is placed over saprolite, the saprolite will have N_{60} values of at least 15 blows per foot.

2.5.4.2.5.4 *Groundwater Control*

The applicant plans to accomplish temporary groundwater control during excavation and backfill by deep dewatering wells placed outside of the excavation limits, combined with sump pumps within low areas in the excavation. The applicant proposed a dewatering scheme similar to that used for the CNS.

2.5.4.2.6 Groundwater Conditions

The applicant noted that the groundwater conditions at the WLS nuclear island consist of a permanent ground water table elevation which ranges from 175 to 178 m (574 to 584 ft) MSL. The standard design plant maximum water table is at El. 180 m (591 ft), and the basemat foundation is at El. 168.7 m (553.5 ft) MSL. The applicant noted that, although the structure is below the long term static groundwater elevation, permanent dewatering systems are not required as the foundation basemat and below grade walls are waterproofed and designed for hydrostatic pressure as part of the AP1000 standard design.

2.5.4.2.7 Response of Soil and Rock to Dynamic Loading

WLS COL FSAR Section 2.5.4.7 presents the response of the soil and rock to dynamic loading. The applicant determined the dynamic material properties in rock and existing site soils by various means including geophysical borehole logging surveys, and by estimating the dynamic properties of borrow materials for engineered fill based on engineering experience with compacted fill and dynamic property research conducted on granular soils by Menq (2003).

2.5.4.2.7.1 *Field Dynamic Measurements*

The applicant established representative dynamic velocity profiles based on the seismic survey results obtained from downhole and surface seismic surveys performed across the site. Figure 2.5.4-9 of this report shows the locations of the dynamic profiles and the individual seismic surveys used to develop the dynamic profiles. Representative velocity profiles from the footprints of WLS were previously presented in the summary boring data sheets in Section 2.5.4.2.4 and Figures 2.5.4-6 and -7 of this report.

2.5.4.2.7.2 *Dynamic Profiles*

The applicant used the seismic velocity profiles to develop three velocity profiles representing the WLS Unit 1 centerline (smoothed dynamic Profile A), the WLS Unit 2 centerline (smoothed dynamic Profile C) and generic engineered granular fill (best estimate layer velocity Profile G). The applicant used Profile A to develop the site GMRS, and Profile C to evaluate possible differences in site response between WLS as a result of the spatial separation and possible lateral variability in the rock properties. The applicant developed Profile G to represent engineered granular fill placed over the bedrock and around the plant nuclear islands to develop the plant grade. Coinciding with the location of Profile A is the dynamic profile Base Case A1, which includes the layered CNS fill and structural concrete, and WLS concrete fill, which the applicant used for the Unit 1 FIRS analysis. The base Case A5 (CNS Unit 1 Pump Rooms) defines the GMRS and localized condition of the WLS Unit 1 nuclear island that will overlie legacy CNS pump rooms at approximately 161 m (527 ft) at the North American Vertical Datum of 1988 (NAVD). The site GMRS and WLS Unit 1 FIRS A1 dynamic analyses are summarized and evaluated in Sections 2.5.2 and 3.7.1 of this report, respectively.

2.5.4.2.7.2.1 WLS Unit 1 Nuclear Island

The applicant stated that the foundation rock consists primarily of slightly weathered to fresh rock that exhibits high average V_s, in the typical range of 2,743 to 3,048 m/s (9,000 to 10,000 fps). The applicant indicated that the Unit 1 nuclear island footprint initially proposed in its COL application was approximately 90 percent underlain by concrete, but the relocated plant footprint will be fully underlain by concrete placed on top of continuous rock during the CNS construction. The construction of WLS Unit 1 will require the placement of additional concrete fill ranging from several feet to as much as 7.6 m (25 ft) thick to bring the subgrade to basemat grade. For the development of the WLS dynamic velocity model, the applicant assumed that the Unit 1 concrete material properties were of similar composition, strength, quality and dynamic properties as the CNS concrete. Figure 2.5.4-10 of this report shows the WLS Unit 1 centerline dynamic Profile A, which the applicant used in determining the GMRS summarized and evaluated in Section 2.5.2 of this report.

2.5.4.2.7.2.2 WLS, Unit 2 Nuclear Island

The applicant stated that it will found the WLS Unit 2 nuclear island basemat on sound, massive metamorphic bedrock that fully complies with the criteria for a uniform site as described in AP1000 DCD Section 2.5.4.5. At locations where the bedrock is below the foundation grade, the applicant will use concrete fill. The maximum thickness of concrete fill is about 6.1 m (20 ft) beneath the east portion of the nuclear island. Figure 2.5.4-11 of this report shows the dynamic Profile C established under the centerline of Unit 2. The applicant compared the dynamic analyses using Profile C (Unit 2 centerline) to the dynamic response obtained using Profile A (Unit 1 centerline) to evaluate ground motion variability between Units 1 and 2. Figure 2.5.4-12 of this report shows the dynamic profile Base Case A5 and C4 that consider site variability within the foundation rock, the existing CNS concrete materials and WLS concrete fill, assuming a V_s of 2,286 m/s (7,500 fps) in the concrete materials. The WLS Unit 2 FIRS C4 analyses are described in Sections 2.5.2 and 3.7.1 of this report.

2.5.4.2.7.3 *Laboratory Dynamic Testing*

Although the final selection of the borrow area has not been made, the applicant stated that the laboratory dynamic testing program will consist of resonant column torsional shear (RCTS) testing of the selected borrow materials. The applicant estimated soil dynamic properties of the proposed granular fill types: well-graded gravel (GW), poorly-graded gravel (GP), or well-graded sand (SW) based on the relationships of Menq (2003) and developed generic fill dynamic profiles for the range of potential backfill types that may be used to support the Seismic

Category II and non-safety-related structures adjacent to the nuclear island. As an example, Figure 2.5.4-13 of this report presents the estimated V_s profile and the shear modulus degradation ratio and damping ratio as function of shear strain for the well-graded sand granular fill (SW). The applicant used the generic fill dynamic profiles and estimated dynamic soil properties in the soil structure interaction analyses and liquefaction potential evaluations.

2.5.4.2.8 Liquefaction Potential

WLS COL FSAR Section 2.5.4.8 states that all Seismic Category I safety-related plant foundations for WLS will bear on rock, or fill concrete over rock, neither of which are susceptible to liquefaction. The applicant further stated that it will place engineered fill under structures adjacent to Seismic Category I structures to 96 percent of maximum density in accordance with modified Proctor compaction specifications, and that these materials will have a very low potential for liquefaction. The applicant made this conclusion based on an evaluation of the liquefaction potential of granular soils (SW) placed in a very dense condition, where 96 percent modified Proctor density is equivalent to 80 percent relative density, according to Lee and Singh (1971). The estimated normalized SPT blow count number $(N_1)_{60}$ for densely compacted engineered fill is approximately 30 (Idriss and Boulanger, 2008), while gravel soils would have a $(N_1)_{60}$ of 45 (Rollins et al., 1998. The applicant conducted similar liquefaction analyses for the saprolite that underlies the engineered fill supporting non-safety-related structures and concluded that no liquefaction hazards exist for Seismic Category I safety-related structures, or the adjacent Seismic Category II and non-safety-related structures.

2.5.4.2.9 Earthquake Site Characteristics

WLS COL FSAR Section 2.5.4.9 summarizes the procedures used to determine the performance-based site-specific GMRS and FIRS developed for the WLS site. The applicant determined the methodology and the development of the Unit 2 location-specific GMRS and Unit 1 location-specific FIRS in accordance with RG 1.208. Site response analysis results are described in WLS COL FSAR Section 2.5.2.

2.5.4.2.10 Static Stability

WLS COL FSAR Section 2.5.4.10 evaluates the stability of the WLS for foundation bearing capacity, foundation settlement, and lateral pressures against below-grade walls. The applicant compared the bearing capacity and settlement estimates obtained for WLS with the design criteria in the AP1000 DCD. Additionally, the applicant estimated the bearing capacity and settlement of the non-safety-related structures surrounding the nuclear island to ensure that differential settlements between the nuclear island and the non-safety-related structures did not exceed the limit of 7.6 cm (3 in.) given in the AP1000 DCD. The applicant concluded that bearing capacity factors of safety and settlement of the Seismic Category I, Seismic Category II, and non-safety-related structures were within AP1000 DCD requirements.

2.5.4.2.10.1 *Bearing Capacity*

WLS COL FSAR Section 2.5.4.10.1 evaluates the bearing capacity of the WLS Units 1 and 2 nuclear island foundations separately. The applicant used the method of Peck, Hanson and Thornburn (1974) for allowable bearing pressure based on rock RQD, and determined the ultimate bearing capacity based on the Terzaghi (1943) bearing capacity equation and the strength of the rock mass from the Hoek-Brown (2002) criteria.

The applicant stated that the Peck, Hanson, and Thornburn (1974) method estimated a minimum allowable bearing pressure of 9,097 kPa (190,000 psf) at Unit 1 and 11,587 kPa (242,000 psf) at Unit 2. The Terzaghi method (1943) determined ultimate bearing capacities by utilizing Hoek-Brown parameters of the rock mass to establish the Mohr-Coulomb (1900) parameters of friction angle and cohesion for the rock, and the bearing capacity factors as developed in EM 1110-1-2908 (USACE, 1994) and by Sowers (1979), of at least 121,000 kPa (2,539,000 psf) under static conditions and 117,000 kPa (2,444,000 psf) under combined (static plus seismic) loading conditions. The applicant concluded that the ultimate static bearing capacity of the foundation materials at the WLS site exceeds the AP1000 DCD average static bearing capacity requirement of 425 kPa (8,900 psf) and the combined static and seismic bearing demand of 1,675 kPa (35,000 psf) by factors of safety of at least 3.0 for the static case and 1.5 for the dynamic case.

2.5.4.2.10.2 *Settlement*

WLS COL FSAR Section 2.5.4.10.2 estimates the post-construction settlement calculated separately for Unit 1 and Unit 2, and the surrounding Seismic Category II and non-safety-related structures. The applicant used three methods based on the theory of elasticity to calculate settlement: (1) the Steinbrenner equation (Bowles, 1988), (2) the United States Army Corps of Engineers equation (USACE, 1990), and (3) the Boussinesq equation (Li, 1995). The applicant also estimated settlement using an empirical approach described by Peck, Hanson, and Thornburn (1974), which is based on the RQD of the rock. The applicant assumed the nuclear island foundation bears directly on rock or on a depth of fill concrete resting on rock and, using the elastic methods, determined that the settlement is less than 0.25 cm (1/10 of an inch). The maximum estimated settlements beneath Units 1 and 2 are 0.119 and 0.121 cm (0.047 and 0.048 in.), respectively. Using the empirical RQD method, the applicant estimated a maximum settlement of 0.180 cm (0.071 in.) beneath Unit 1 and 0.140 cm (0.055 in.) beneath Unit 2. The applicant concluded that the calculated tilt settlements were within the limits allowed by the AP1000 DCD design parameter of 1.27 cm in 15.2 m (0.5 inches in 50 ft).

Additionally, the applicant computed the settlement of the adjacent Seismic Category II and non-safety-related structures to ensure that the differential settlement, settlement of the Seismic Category II and non-safety-related structures as compared to the settlement of the nuclear island, was within the AP1000 DCD criteria. The applicant calculated a total settlement of less than 5.1 cm (2 in.) for each of the Seismic Category II and non-safety-related structures; which, when compared to the nil settlement of the nuclear island, results in differential settlement of less than the allowable 7.6 cm (3 in.) between the adjacent Seismic Category II and non-safety-related structures and the nuclear island.

2.5.4.2.10.3 *Lateral Pressures*

WLS COL FSAR Section 2.5.4.10.3 addresses the lateral pressures that develop against the below grade nuclear island walls resulting from backfill placement. The applicant used the Rankine earth pressure theory to calculate earth pressure envelopes for the cases of active, at-rest and passive pressure conditions at both minimum and maximum groundwater elevations.

The applicant stated that because the walls are unyielding, the at-rest pressure case governs the design. The applicant also computed the additional lateral load induced by the compaction effort of the hand-operated equipment and heavy rollers operating within 1.5 m (5 ft) of the below ground walls. Finally, the applicant computed the dynamic lateral stresses on the walls using the method in American Society of Civil Engineers (ASCE) 4-98, "Seismic Analysis of Safety-Related Nuclear Structures and Commentary," assuming a peak ground acceleration of 0.3 g applied uniformly to the wall. Figure 2.5.4-14 of this report depicts the static at-rest lateral earth pressures, combined with the excess earth pressures created by compaction equipment operating within 1.5 m (5 ft) of the below ground nuclear island walls.

2.5.4.2.11 Design Criteria

WLS COL FSAR Section 2.5.4.11 summarizes the AP1000 DCD site parameter criteria and compares them to the site-specific parameters presented in the WLS COL FSAR. Table 2.5.4-2 of this report summarizes the critical parameters.

Table 2.5.4-2. Comparison of AP1000 Design Criteria to WLS Site Characteristics (Based on WLS COL FSAR Table 2.0-201)

	AP1000 DCD	WLS Site	WLS FSAR	WLS within Site Parameter
Static Bearing Capacity	425 kPa (8,900 psf)	9,097 to 11,587 kPa 190 to 242 ksf	2.5.4.10.1	Yes
Dynamic Bearing Capacity	1,675 kPa 35,000 psf	9,097 to 11,587 kPa 190 to 242 ksf	2.5.4.10.1	Yes
Shear Wave Velocity	305 m/s (1,000 fps)	2,743 to 3,048 m/s 9,000 to 10,000 fps	2.5.4.7	Yes
Lateral Variability	CASE 1, uniform layer thickness dips no more than 20 degrees, and less than 20% shear wave velocity variation in any layer.	CASE 1, non-dipping massive plutonic rock with less than 20% shear wave velocity variation.	2.5.4.7.4	Yes
Liquefaction Potential	No liquefaction considered beneath the SC I and SC II structures and immediate surrounding area.	None: nuclear Island founded on rock or concrete over rock; adjacent structures have negligible liquefaction potential.	2.5.4.8	Yes
Minimum Angle of Internal Friction of Foundation Soils	Greater than 35 degrees.	Founded on rock meeting the criteria	Not applicable	Yes

WLS COL FSAR Section 2.5.4.11 does not specify any departures from or supplements to the AP1000 DCD. However, because of the reevaluation of the site-specific seismic loading, the applicant addressed a departure of lateral earth pressure under one load combination in WLS COL FSAR Sections 2.5.4.10 and 3.8.4.4.4.

2.5.4.2.12 Techniques to Improve Subsurface Conditions

WLS COL FSAR Section 2.5.4.12 addresses the methods and means for preparing the rock surface to ensure that the WLS Units 1 and 2 nuclear island foundation mat is supported by continuous rock, or by fill concrete that is supported on continuous rock.

The applicant stated that it will remove the soil, weathered rock, and concrete within the nuclear island area and above the design foundation subgrade, down to continuous rock, described as rock having a RQD equal to or greater than 65 percent. The applicant noted that it will not remove some relatively minor zones of lower quality rock (RQD < 65 percent). Figure 2.5.4-3 of this report shows the contours of the continuous rock surface. The applicant planned to verify the foundation improvement by geologic mapping of the final excavation surface prior to foundation treatment or placement of any fill materials. The applicant also stated that the foundation preparation in advance of concrete placement involves removing loose soil and rock, or other materials from the foundation surface, removing protrusions and overhangs within the rock or concrete, washing the exposed rock or concrete surface with air and/or water, treating isolated depressions or cracks in the rock or concrete surface with fill concrete, and roughening exposed concrete surfaces. The applicant also planned to seal the CNS Unit 1 under slab drainage system with concrete to prevent the migration of fill materials.

Figure 2.5.4-15 of this report shows one example of how the applicant will backfill drainage channels in the existing CNS foundation, while Figure 2.5.4-16 of this report shows how the applicant will improve severely weathered localized zones of rock found in the continuous rock subgrade.

2.5.4.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in the FSER related to the AP1000 DCD and its supplements and in NUREG-1923.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for stability of subsurface materials and foundations are given in NUREG-0800, Section 2.5.4.

The applicable regulatory requirements for reviewing the applicant's FSAR on the stability of subsurface materials and foundations are as follows:

- 10 CFR Part 50, Appendix A, GDC 1, “Quality Standards and Records,” as it relates to the requirement that SSCs important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. It also requires that appropriate records of the design, fabrication, erection, and testing of SSCs important to safety be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit.

- 10 CFR Part 50, Appendix A, GDC 2, "Design Bases for Protection Against Natural Phenomena,” as it relates to consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants," establishes quality assurance requirements for the design, construction, and operation of those SSCs of nuclear power plants that prevent or mitigate the consequences of postulated accidents that could cause undue risk to the health and safety of the public.

- 10 CFR Part 50, Appendix S, "Earthquake Engineering Criteria for Nuclear Power Plants," as it applies to the design of nuclear power plant structures, systems, and components important to safety to withstand the effects of earthquakes.

- 10 CFR 100 provides the criteria that guide the evaluation of the suitability of proposed sites for nuclear power and testing reactors.

- 10 CFR 100.23 provides the nature of the investigations required to obtain the geologic and seismic data necessary to determine site suitability and identify geologic and seismic factors required to be taken into account in the siting and design of nuclear power plants.

The related review acceptance criteria from NUREG-0800, Section 2.5.4 are as follows:

- Geologic Features: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the section defining geologic features is acceptable if the discussions, maps, and profiles of the site stratigraphy, lithology, structural geology, geologic history, and engineering geology are complete and are supported by site investigations sufficiently detailed to obtain an unambiguous representation of the geology.

- Properties of Subsurface Materials: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the description of properties of underlying materials is considered acceptable if state-of-the-art methods are used to determine the static and dynamic engineering properties of all foundation soils and rocks in the site area to sufficient depth that impact behavior during construction and over the life of the facility, including during postulated seismic events.

- Foundation Interfaces: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the discussion of the relationship of foundations and underlying materials is acceptable if it includes (1) a plot plan or plans showing the locations of all site explorations, such as borings, trenches, seismic lines, piezometers, geo logic profiles, and excavations with the locations of the safety-related facilities superimposed thereon; (2) profiles illustrating the detailed relationship of the foundations of all Seismic Category I and other safety-related facilities to the subsurface materials; (3) logs of core borings and test pits; and (4) logs and maps of exploratory trenches in the application for an early site permit or COL.

- Geophysical Surveys: To meet the requirements of 10 CFR 100.23, the presentation of the dynamic characteristics of soil or rock is acceptable if geophysical investigations have been performed at the site and the results obtained there from are presented in detail.

- Excavation and Backfill: To meet the requirements of 10 CFR Part 50, the presentation of the data concerning excavation, backfill, and earthwork analyses is acceptable if: (1) the sources and quantities of backfill and borrow are identified and are shown to have been adequately investigated by borings, pits, and laboratory property and strength testing (dynamic and static); long term solubility properties and dissolution behavior during the life of the facility have been determined; and these data are included, interpreted, and summarized; (2) the extent (horizontally and vertically) of all Seismic Category I excavations, fills, and slopes are clearly shown on plot plans and profiles; (3) compaction specifications and embankment and foundation designs are justified by field and laboratory tests and analyses to ensure stability and reliable performance over the life of the plant; (4) the impact of compaction methods are incorporated into the structural design of the plant facilities; (5) quality control methods are discussed and the quality assurance program described and referenced. If backfill is to be placed under safety-related structures, proper inspections, tests, analyses and acceptance criteria (ITAAC) should be specified in the applicant’s technical submittal to ensure that the static and dynamic properties of in-place backfill material will be the same as, or better than the design parameters. In case cementitious construction material is to be placed under safety -related structures, proper ITAAC should be specified in the applicant technical submittal to ensure that the cementitious backfill placed underneath any Seismic Category I structures to a thickness greater than five feet, meets the design, construction and testing of applicable ACI standards; (6) control of groundwater during excavation to preclude degradation of foundation materials and properties is described and referenced. In addition, the long-term behavior of the backfill subjected to any aggressive groundwater characteristics is evaluated; and (7) for sites where deeply embedded structures are involved, deep excavation techniques will likely utilize wall retaining systems rather than a sloped excavation of the soil. A description of the planned excavation technique(s) and design of the wall retention system with sufficient details is provided and it should be able to demonstrate that the excavation technique used will not significantly affect the surrounding soil properties that are relied upon in the analysis and design of the foundation and plant structures.

- Ground Water Conditions: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the analysis of groundwater conditions is acceptable if the following are included in this subsection or cross-referenced to the appropriate subsections in Section 2.4 of the applicant’s technical submittal: (1) discussion of critical cases of groundwater conditions relative to the foundation settlement and stability of the safety-related facilities of the nuclear power plant; (2) plans for dewatering during construction and the impact of the dewatering on temporary and permanent structures. This includes consideration of the potential for substantial head and volume of water due to the deep excavation for the plant structures; (3) analysis and interpretation of seepage and potential piping conditions during construction; (4) records of field and laboratory permeability tests as well as dewatering induced settlements; (5) history of groundwater fluctuations as determined by periodic monitoring of an adequate number of local wells and piezometers. Flood conditions should also be considered; and (6) evaluation of chemical properties of the groundwater that may impact long-term behavior of the rock/soil/fill materials as well as structural elements (concrete and steel materials).

- Response of Soil and Rock to Dynamic Loading: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, descriptions of the response of soil and rock to dynamic loading are acceptable if: (1) an investigation has been conducted and discussed to determine the effects of prior earthquakes on the soils and rocks at the site. Evidence of liquefaction and sand cone formation should be include; (2) field seismic surveys (surface refraction and reflection and in-hole and cross-hole seismic explorations) have been accomplished and the data presented and interpreted to develop bounding P and S wave velocity profiles; and (3) dynamic tests have been performed in the laboratory on undisturbed samples of the foundation soil and rock sufficient to develop strain-dependent modulus-reduction and hysteretic damping properties of the soils and the results included. If generic soil degradation properties are used in the related preliminary analyses (e.g., site seismic response and soil structure interaction analyses), then reconciliation of the generic properties and laboratory testing results should be performed. The section should be cross-referenced with WLS COL FSAR Section 2.5.2.5.

- Liquefaction Potential: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, if the foundation materials at the site adjacent to and under Seismic Category I structures and facilities are saturated soils and the water table is above bedrock, then an analysis of the liquefaction potential at the site is required.

- Static and Dynamic Stability: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the discussions of static and dynamic analyses are acceptable if the stability of all safety-related facilities has been analyzed from a static and dynamic stability standpoint including bearing capacity, rebound, settlement, and differential settlements under dead loads of fills and plant facilities, dynamic loads including "live" and seismic loads with consideration of loading sequences and combinations.

- Design Criteria: To meet the requirements of 10 CFR Part 50, the discussion of criteria and design methods is acceptable if the criteria used for the design, the design methods employed, and the factors of safety obtained in the design analyses are described and a list of references presented.

- Techniques to Improve Subsurface Conditions: To meet the requirements of 10 CFR Part 50, the discussion of techniques to improve subsurface conditions is acceptable if plans, summaries of specifications, and methods of quality control are described for all techniques to be used to improve foundation conditions (such as grouting, vibroflotation, bridging mats, dental work, rock bolting, or anchors).

In addition, the geotechnical engineering characteristics should be consistent with appropriate sections from: RG 1.27, "Ultimate Heat Sink for Nuclear Power Plants"; RG 1.28, "Quality Assurance Program Requirements (Design and Construction)"; RG1.132, "Site Investigations for Foundations of Nuclear Power Plants"; RG 1.138, "Laboratory Investigations of Soils And Rocks for Engineering Analysis and Design of Nuclear Power Plants"; RG 1.198, "Procedures and Criteria for Assessing Seismic Soil Liquefaction at Nuclear Power Plant Sites"; and RG 1.206, "Combined License Applications for Nuclear Power Plants."

2.5.4.4 *Technical Evaluation*

2.5.4.4.1 Description of Site Geologic Features

WLS COL FSAR Section 2.5.4.1 presents an overview of the site geologic features and refers to WLS COL FSAR Sections 2.5.1.1 and 2.5.1.2 for a more detailed description of the regional and site geology, respectively. The technical evaluation of site geologic features is presented in Section 2.5.1.4 of this report. The technical evaluation for vibratory ground motion is presented in Section 2.5.2.4 of this report, and the technical evaluation of the potential for surface faulting at the WLS site is located in Section 2.5.3.4 of this report. These sections of this report, respectively, present the WLS COL FSAR summaries and conclusions regarding the site geologic features. The applicant provided geotechnical and geological data in the form of boring logs from the WLS site investigation and the CNS site investigation in Appendices 2AA and 2BB to resolve WLS COL 2.5-1.

2.5.4.4.2 Properties of Subsurface Materials

WLS COL FSAR Section 2.5.4.2 describes the field investigation and subsurface material properties at the WLS site. Section 2.5.4.2.2 of this report provides a summary of the information presented in the WLS COL FSAR. The staff reviewed the geotechnical data presented and evaluated the WLS exploration and laboratory testing programs in accordance with the guidelines presented in RG 1.132 and RG 1.138. The main focus of the review was to ensure that the soil and rock profile was adequately characterized in order to evaluate the ability of the subsurface to support the nuclear island statically and dynamically.

2.5.4.4.2.1 *Site Explorations*

The applicant relied on 189 borings completed in support of the CNS exploration program to locate and drill a total of 131 geotechnical borings for the WLS site exploration. Figure 2.5.4-1 of this report shows the locations of the borings in the power block and adjacent areas. Additionally, the applicant made test pits and seismic CPT soundings in the soil profile at many locations, cored the existing CNS concrete and supporting rock, and provided the results of in-situ and laboratory engineering tests in pre- and post- demolition reports. In several boreholes and at various depths, the applicant performed downhole deformation testing with two testing devices in order to evaluate the engineering properties of the rock mass. The applicant continuously sampled additional holes for dynamic rock mass properties using P-S suspension logging and downhole seismic velocity logging methods. The applicant obtained acoustic and televiewer data to study the lithology and stratification of the rock. Samples collected for strength testing and petrographic analysis were handled in accordance with ASTM D4220-95, "Standard Practices for Preserving and Transporting Soil Samples."

In general and prior to the construction activities associated with the CNS, the site consists of residual soils overlying saprolite, overlying partially weathered rock, overlying bedrock. The staff noted that the depth of the overburden is variable due to differential weathering across the site and, particularly where the WLS will be located, the overburden has been partially or completely removed to expose the bedrock. The staff notes that the applicant estimated soil properties for the support of the non-safety-related structures. Since the estimated soil properties are not used in the design of safety-related structures, the staff concludes that the estimated soil data is adequate for the design of non-safety-related structure foundations and lateral stresses against the nuclear island below ground walls.

The staff noted that the WLS will be founded on continuous rock having a RQD of 65 percent or greater. The applicant cored the rock continuously to depths of up to approximately 77.7 m (255 ft) within the nuclear island footprints and between the WLS nuclear island locations. Selected core samples were tested in the laboratory for strength and deformation characteristics in unconfined compression and unconfined compression with stress-strain measurements. The applicant concluded that the materials were consistently high strength with high elastic modulus. The staff also observed that the applicant performed in-situ deformation tests in selected boreholes using the Goodman Jack test and pressuremeter. The results of those tests were lower than the results of tests on intact samples due to the discontinuities in the rock mass, but still indicated high strength and low deformation. The staff notes that with the exception of some local pockets of rock with lower strength and stiffness, this site is characterized by a rock mass having a high UCS and high elastic modulus, and consequently high bearing capacity and negligible deformation. Since the number of tests indicating lower strength was small and from few locations in a limited number of borings, the staff concludes that those areas with lower strength are not representative of the rock mass on the whole, and therefore it should not affect the static stability of the nuclear units. The staff further concludes that the exploratory program is sufficient to adequately characterize the subsurface profile and assign material properties to the geotechnical model.

2.5.4.4.2.2 *Existing Concrete at WLS Unit 1*

The applicant performed a pre-demolition exploration of the existing concrete to investigate the quality of the concrete and concrete/rock interface for concrete strength, V_s and adherence between the concrete and underlying bedrock. Documentation for the exploration was submitted as a supplement to the WLS COL FSAR.

The staff compared the results of the pre-demolition report to the concrete material property assumptions made in the WLS COL FSAR and concludes that the measured values of the pre-demolition exploration envelop the assumed UCS and V_s values of the concrete used in the design.

2.5.4.4.2.3 *Staff Conclusions Regarding the Properties of Subsurface Materials*

Based on the types of tests performed, the numbers and locations of tests, the redundancy of data collected by various methods, the consistency in strength and stiffness data, and the replication of data from previous exploration programs, the staff concludes that the exploratory program for the WLS site followed the guidance of RG 1.132 and RG 1.138, and collected sufficient information to provide the key geotechnical parameters required to perform the necessary engineering analyses. The staff also concludes that the applicant provided adequate geological, geotechnical and geophysical field and laboratory test results and engineering analyses to close COL Information Item 2.5-6. Furthermore, the staff concludes that the data from the geotechnical site investigation addressed the provision that the properties of the foundation materials are within the range of the properties considered for the certified design of the structures and foundations. The staff further concludes that the material properties are reasonable representatives of in-situ conditions at the WLS site. Accordingly, the staff concludes that the exploration program meets the requirements of 10 CFR Part 50 and 10 CFR Part 100.

2.5.4.4.3 Foundation Interfaces

WLS COL FSAR Section 2.5.4.3 describes the foundation conditions existing under the WLS nuclear islands and non-safety-related structures surrounding the nuclear islands.

The staff focused its review on the geologic interpretations made by the applicant by reviewing the individual boring logs, boring summary sheets, and geologic profiles relative to the foundation embedment depths of the nuclear island and the uniformity requirements of the AP1000 DCD.

The applicant stated that it will found the safety-related structures on continuous rock having an RQD of at least 65 percent representing a fair rock mass quality index. The staff reviewed the RQD values recorded on the CNS and WLS site borings, and concludes that the RQD values are consistently greater that 65 percent over most of the site area.

All or portions of the annex building, turbine building and radwaste building will be founded on engineered backfill resting on competent, non-liquefiable residual soils, saprolite, partially weathered rock, concrete or continuous rock depending on the category of the structure and its location. The staff reviewed the SPT borings penetrating the residual soil, saprolite and into the partially weathered rock and concludes the borings are adequate to determine the limits to which the excavation must be carried to ensure removal of all unstable soil and soil-like material. Figures 2.5.4-04 and 2.5.4-09 of this report illustrate the rock and soil boring information used to evaluate foundation conditions and excavation requirements under the footprints of the nuclear island and non-safety-related structures and also present SPT data for the residual soils and saprolite used in assessing the stability of the natural soils and the required depth of excavation.

Based on the review of WLS COL FSAR Section 2.5.4.3, the staff concludes that the applicant provided adequate information to illustrate the interface of foundation and subsurface materials. The cross-sections of the site in the power block and adjacent areas show the geological condition and excavation and backfill plan, and the soil profiles and boring summary sheets present geotechnical and site uniformity data. As the applicant also presented the detailed results of geotechnical, geological and geophysical field testing obtained during the WLS site investigation in Appendix 2AA, the staff further concludes that this information closes COL Information Items 2.5-2 and COL Information Item 2.5-3. The applicant provided cross-sections showing geologic profiles of WLS borings with structures superimposed at their locations and embedment depths. The staff concludes that the applicant provided sufficient information on the underlying site conditions, topographic features, and locations of Seismic Category I structures in WLS COL FSAR Section 2.5.4.3 to close COL Information item 2.5-5. Finally, the staff concludes that the applicant provided sufficient foundation interface data to satisfy the requirements of 10 CFR Part 50 and 10 CFR Part 100.

2.5.4.4.4 Geophysical Surveys

The applicant described surface and borehole geophysical surveys conducted on the WLS site in WLS COL FSAR Section 2.5.4.4. The staff focused its review on the methods used to determine the V_s, the level of agreement between the various surface and downhole testing methods used, and the site conformity with respect to the minimum acceptable V_s and uniformity requirements described in the AP1000 DCD.

The AP1000 DCD requires a minimum small strain V_s of 305 m/s (1,000 fps) within the footprint of the nuclear island at its excavation depth, and the V_s measured in any given layer must be within 20 percent of the average V_s of that layer, or a site-specific soil-structure interaction (SSI) analysis must be performed. The staff noted that of the three geophysical survey methods performed to measure the V_s, P-S suspension logging is the most accurate due to its near continuous record of discreet measurements made throughout the depth of the borehole.

The staff reviewed the V_s profiles and observed that the basemat bottom elevation of the nuclear island at both WLS will be at an elevation (El.) of 168.7 m (553.5 ft). The staff also observed that the borings typically originated below the basemat bottom elevation in the WLS Unit 1 powerblock area, and above the basemat bottom elevation at WLS Unit 2. Since the existing WLS Unit 1 subgrade is already below an El. of 168.7 m (553.5 ft), the applicant planned to add concrete fill with an assumed V_s of 2,286 m/s (7,500 fps) at WLS Unit 1 to raise the existing grade to the bottom of the basemat.

2.5.4.4.4.1 *WLS Unit 1 V_s Profiles*

At WLS Unit 1, V_s profiles taken at B-1002 and B-1004 indicate that the average V_s typically exceed 2,286 m/s (7,500 fps) below the existing ground surface, with the exception of the originally planned location for the northwest corner. At the original northwest corner location, V_s profiles shown in B-1074A and 1075A had an average V_s in the range of 1,219 to 1,828 m/s (4,000 to 6,000 fps) down to an El. of 155 m (509 ft), below which the V_s increased to 2,286 to 2,743 m/s (7,500 to 9,000 fps). However, the staff noted that the original northwest corner location for WLS Unit 1 represents a softer rock condition than the remainder of the site. Therefore, in RAI 44, Question 02.05.04-9, the staff requested that the applicant justify site uniformity given the much lower V_s in this area.

However, in Revision 7 of the application, dated May 9, 2013, as reflected in Revision 9, the applicant moved the footprint 15 m (50 ft) to the east for WLS Unit 1 and 20 m (66 ft) to the south for both units. Due to the relocation of the footprints, the planned location of WLS Unit 1 avoids the originally planned “northwest corner” where the uniformity of the subsurface material is less desirable than other areas within the footprint and, therefore, the concern of the subsurface material uniformity underneath the Seismic Category I structure no longer exists. Accordingly, the staff considers RAI 44, Question 02.05.04-9 resolved.

2.5.4.4.4.2 *Existing CNS Concrete*

The staff reviewed the supplemental pre-demolition CNS concrete report prepared and submitted by the applicant. The applicant investigated the existing CNS concrete that overlies the WLS Unit 1 footprint using SASW surveys and cross-hole seismic surveys performed in boreholes drilled in the existing concrete into the underlying bedrock. From the pre-demolition report results, the staff notes that V_s values from cross hole surveys and SASW testing indicated good agreement in the range of 2,286 m/s (7,500 fps) or greater. The staff concludes that the V_s of the existing CNS concrete are consistent with values assumed in the geotechnical model for the Unit 1 FIRS.

2.5.4.4.4.3 *WLS Unit 2 V_s Profiles*

At WLS Unit 2, the staff noted that the V_s profiles typically started above an El. of 168.7 m (553.5 ft), except for boring B-1014, where more extensive weathering created a depression under the East side of the Reactor building and no V_s profile was available. At this location, the continuous rock surface begins below about El. 165.6 m (543.5 ft). The staff noted that the V_s results in borings B-1012, B-1015 and B-1017 show V_s on the order of 2,438 to 3,048 m/s (8,000 to 10,000 fps). The depression underlying the Unit 2 Reactor, location of B-1014, will require placement of concrete fill to bring the subgrade to an El. of 168.7 m (553.5 ft). The staff concludes that the concrete fill will require at least V_s of 2,286 m/s (7,500 fps) to match the properties assumed in the applicant's dynamic analysis. In WLS COL FSAR Table 2.5.4-220, "Quality Control Recommendations for Nuclear Island Fill Concrete," the applicant stated that the compressive strength as determined from the preconstruction mix design and testing program will ensure that the fill concrete will exhibit an average shear wave velocity greater than or equal to 2,286 m/s (7,500 fps), which will meet design requirements.

2.5.4.4.4.4 *Conclusions Regarding Geophysical Surveys*

The staff concludes that WLS COL FSAR Section 2.5.4.4 was thorough and that the results obtained by various state-of-the-art methods were complementary and consistent. The staff further concludes that the geophysical surveys used to reliably determine dynamic properties of soil and rock were appropriate and the resulting data is sufficient for use in the determination of the GMRS and FIRS for structures, performance of SSI analyses, and determination of the liquefaction potential in the soil profiles at the site. Accordingly, the staff considers the information provided in WLS COL FSAR Section 2.5.4.4 acceptable to satisfy the criteria of 10 CFR Part 100.

2.5.4.4.5 Excavation and Backfill

The applicant presented information regarding excavations and backfill for the WLS site. Section 2.5.4.2.5 of this report summarizes this information. The staff focused its review in the applicant's description of excavations for safety-related structures, sources for backfill materials, properties of materials, temporary slopes, and quality control for backfill and excavations.

2.5.4.4.5.1 *Sources and Quantities*

Although the applicant has yet to select the offsite borrow source it will use to backfill the excavation, in WLS COL FSAR Section 2.5.4.5.3.5, committed to using a qualified quarry to obtain granular fill that meet the SCDOT gradation limits to support Seismic Category II and non-safety-related structures. Support of the nuclear island foundations will be on rock or concrete fill where rock elevations are below the basemat founding level.

2.5.4.4.5.1.1 Granular Backfill

Initially, the applicant planned to use on-site materials to backfill against the below ground nuclear island walls and as support for surrounding non-safety-related structures. However, the staff reviewed the engineering data presented for the on-site backfill and, in RAI 60, Question 02.05.04-10, requested that the applicant clarify how to ensure the static and dynamic properties of backfill materials are equal or exceed that used in design and analyses. In May 15, 2009, and October 30, 2009, responses to RAI 60, Question 02.05.04-10, the applicant stated that the original data from construction of the CNS plant backfill was no longer available, but that the backfill was not required for sliding stability of the nuclear island, and therefore is non-safety-related. However, to add defense in depth, the applicant decided to use an offsite backfill source for the support of the non-safety-related structures. The applicant also planned to use the on-site backfill, but only in areas where structural support is not required.

The gradations of the off-site borrow materials are approved by SCDOT and produced at South Carolina-approved borrow pits. The potential gradations of granular backfill proposed by the applicant consist of a well-graded gravel, poorly-graded gravel, or well-graded sand. The off-site granular backfill is planned to be placed and compacted to reach 96 percent modified Proctor density. The applicant estimated the static and dynamic properties of the three gradations from correlations, but planned to perform laboratory tests to confirm the estimated properties. The applicant also determined a “best estimate” seismic velocity profile for each of the proposed gradations for use in dynamic analyses. Shear modulus and damping ratio versus strain relationships estimated based on research by Menq on granular materials will be verified by the applicant using RCTS tests on the selected borrow materials.

The staff reviewed the proposed offsite backfill materials, the testing plans, placement requirements and quality control plans and concludes that the use of the uniform materials available from SCDOT-approved borrow sources placed to 96 percent modified Proctor density meets the stability requirements for support of the non-safety-related structures surrounding the nuclear island. The staff further concludes that the use of on-site borrow materials at non-critical locations placed to 95 percent standard Proctor density is also acceptable because there is no backfill requirement for sliding stability or overturning for nuclear islands founded on hard rock. Accordingly, the staff considers RAI 60, Question 02.05.04-10 resolved.

On April 9-11, 2012, the staff audited the site response and SSI calculations performed by Westinghouse Electric Corporation in support of the design of WLS. During the audit, the applicant indicated that the GW, GP, and SW type of soils, as defined by Unified Soil Classification system, were considered as backfill in its site response and SSI analyses. The applicant also planned to utilize a gabion/Mechanically Stabilized Earth (MSE) wall to support fill adjacent to the nuclear island. However, the staff noted that the applicant did not specify the soil classification of the backfill soil to be placed around Seismic Category I and adjacent Seismic Category II structures, and there is no mention of the MSE wall in WLS COL FSAR Section 2.5.4. Therefore, in RAI 106, Question 02.05.04-17, the staff requested that the applicant specify the type of material to be used as backfill with its classification and static and dynamic properties; discuss how to ensure that the as-placed backfill properties are comparable to those assumed in all related site-specific analyses; and provide details of MSE wall design and discuss its impact on side fill compaction and structural stability analyses.

In a June 18, 2012, response to RAI 106, Question 02.05.04-17, the applicant stated that two SCDOT granular products, namely Macadam Base Course (MBC) and Washed Screenings are candidates for backfill material. Two specific gradations within the range for MBC and a third specific gradation within the range for Washed Screenings are to be used to predict static and dynamic properties that are considered to be typical for these materials. Both of these materials will be considered for construction use pending selection of the quarry source and performance of a test program to confirm compatibility with the estimated properties. The selection criterion is that a particular granular quarry aggregate must have static and dynamic properties comparable to those used in design and analyses. The applicant also states that the classification symbol for a given specimen of Washed Screenings could be SW or GP.

The applicant revised WLS COL FSAR Table 2.5.4-222 to present a list of laboratory and field tests that will be conducted to confirm the properties of the chosen backfill material. The applicant also planned to construct a "test fill" pad on-site using the equipment and granular fill materials to be used in construction, and then perform the listed tests on the test fill. The applicant then specified that before the production backfill commences, an engineering report will be provided to the NRC to demonstrate that the equipment and methods used to construct the test fill are capable of producing acceptable and consistent results. A program of in-place measurements of V_s in the granular backfill will be performed to confirm that shear wave velocities of the as-placed granular backfill are comparable to those used in the site-specific analyses.

The applicant stated that for construction convenience, a system of MSE walls will be constructed to surround the nuclear islands. The applicant then described the MSE wall design, including materials to be used, the facing of the wall and construction procedure. This description emphasize that the presence of a MSE wall (with its facing of wire forms and geogrids with geotextile fabric) will have no adverse effect on the structural stability, foundation bearing capacity or settlement analyses of these structures. The applicant then proposed a revision to WLS COL FSAR Section 2.5.4.5.3.5 and WLS COL FSAR Table 2.5.4-222 with a statement of that the moisture content of the fill at the time of compaction should be within approximately 3 percent of the optimum moisture content determined in accordance with ASTM D1557, “Standard Test Methods for Laboratory Compaction Characteristics of Soil Using Modified Effort (56,000 ft-lbf/ft3 (2,700 kN-m/m3)).”

Based on the review of responses to RAI 106, Question 02.05.04-17, the staff concludes that the applicant provided sufficient information on the type of backfill materials to be used, the sources where the backfill soil will be obtained, and a suite of tests that will be performed during backfill construction, and details of the MSE wall design and construction. The staff further concludes that the backfill materials identified by the applicant have properties that can meet the design parameter requirements, and the planned field and laboratory tests are adequate to ensure that the as-placed backfill will have properties as designed. Since the designed MSE wall will have similar properties as the soil surrounding the wall, the staff concludes that the existence of the MSE wall will have no adverse effect on the structural stability, foundation bearing capacity or settlement analysis results of these structures. The staff concludes that the applicant properly addressed the staff’s concerns regarding the compaction of the fills, and confirmed that WLS COL FSAR Revision 11, incorporated proposed changes committed to in the response. Accordingly, the staff considers RAI 106, Question 02.05.04-17 resolved.

2.5.4.4.5.1.2 Concrete Fill

Concrete fill is required at both WLS. The applicant assumed for its dynamic analyses that the WLS concrete fill will have a V_s of 2,286 m/s (7,500 fps) with a design compressive strength of 17.2 MPa (2,500 psi). In RAI 95, Question 02.05.04-16, the staff requested that the applicant provide details on how it would ensure that the in-place concrete fill would have V_s of 2,286 m/s (7,500 fps), while theoretically concrete with compressive strength of 17.2 MPa (2,500 psi) is not normally capable of possessing such a high shear wave velocity.

In a March 17, 2011, response to RAI 95, Question 02.05.04-16, the applicant stated that the concrete mix design would be in accordance with ACI 318-02 and testing of the mix design would be performed to ensure that a V_s of 2,286 m/s (7,500 fps) is reached. The applicant acknowledged that this may be at a higher compressive strength than 17.2 MPa (2,500 psi) and proposed a revision to WLS COL FSAR Table 2.5.4-220 to indicate that an increase in unconfined compressive strength may be required to meet the V_s requirement of 2,286 m/s (7,500 fps).

The staff concludes that the required shear wave velocity for concrete backfill can be obtained by increasing the UCS using the mix design in accordance with ACI 318-02. Therefore, the staff finds the applicant’s response to RAI 95, Question 02.05.04-16 acceptable. The staff further confirms that the proposed changes were incorporated in Revision 9 of the WLS COL FSAR. Accordingly, the staff considers RAI 95, Question 02.05.04-16 resolved.

2.5.4.4.5.2 *Extent of Excavations*

WLS COL FSAR Section 2.5.4.5.2 states that the excavation for the CNS removed much of the surface material above the bedrock within the footprints of the proposed WLS.

At WLS Unit 1, previous excavation for the CNS was completed down to continuous rock under the WLS Unit 1 footprint. The applicant planned to conduct necessary excavation down to continuous rock, and prepare the existing rock and concrete surfaces to receive new concrete fill. Proposed temporary excavation slopes will vary from 1.5 horizontal to 1 vertical in the residual soil to as steep as 0.25 horizontal to 1 vertical in the partially weathered rock. Figure 2.5.4-8 of this report shows a typical excavation cross-section of WLS. The staff noted that the excavation at WLS Unit 2 requires the removal of hard rock down to the basemat grade at El. 168.7 m (553.5 ft) over most of the nuclear island footprint. However, an area underlying the east side of the WLS Unit 2 nuclear reactor is already below grade and contains rock with RQD values less than 65 percent as observed in boring B-1018. This will require removal of unsatisfactory material to reach continuous rock, and then subgrade preparation, prior to placing approximately 4.8 m (16 ft) of concrete fill to bring this area to grade. The concrete fill will have properties that meet the strength and V_s requirements as previously discussed. Prior to the nuclear island footprints being relocated, the staff issued RAI 44, Question 02.05.04-3, requesting that the applicant clarify how it would determine the limits of excavation in the northwest corner given the differences in RQD data between Borings B-1074 and B-1074A.

In a December 23, 2008, response to RAI 44, Question 02.05.04-3, the applicant stated that boring B-1074 encountered difficult drilling conditions and the borehole was abandoned at El. 152.8 m (501.5 ft) and replaced by boring B-1074A, drilled 1.8 m (6 ft) away. The applicant ascribed the differences in RQDs to poorer quality rock and/or mechanical breakage in boring B-1074 due to drilling. The applicant indicated that continuous rock had not been reached until El. 152.8 m (501.5 ft) in boring B-1074. The applicant concluded that this boring represents a local zone of lower quality rock that can be treated with dental concrete as shown in Figure 2.5.4-16 of this report and, therefore, can remain in place without affecting the overall static or dynamic bearing capacity of the northwest corner. In addition, because of the relocation of the WLS Unit 1 footprint, the whole foundation of the nuclear island will be founded on continuous rock, or concrete fill supported by continuous rock.

Figure 2.5.4-17 of this report shows the area in the vicinity of boring B-1018 that is already below foundation grade at Unit 2, and contains rock that does not meet the definition of continuous rock, RQD less than 65 percent. The staff determined that geologic mapping will ensure that rock not meeting the definition of continuous rock is removed down to continuous rock for the nuclear islands of WLS. As a result of the applicant's plan to found the nuclear islands on continuous rock, or concrete supported by continuous rock, the staff considers RAI 44, Question 02.05.04-3 resolved.

2.5.4.4.5.3 *Conclusions Regarding Excavations and Fills*

The applicant provided an excavation plan relative to geologic conditions and features showing the horizontal and vertical extent of excavations, fills, and slopes for Seismic Category I structures. The applicant identified areas underlying Seismic Category I structures that required fill to bring the site to basemat foundation grade and addressed fill quantities, backfill material types, estimated backfill engineering properties, and backfill compaction specifications. Based on the information provided in FSAR Section 2.5.4.5.2 and RAI responses, the staff concludes that the applicant adequately addressed and closed COL Information Item 2.5-7. Further, the dewatering plan the applicant provided for the planned excavation at WLS closes COL Information Item 2.5-8.

The staff concludes that the excavation plan considered the stability of temporary slopes and the details of subgrade preparation and placement of dental concrete for localized soft zones. The staff further concludes that engineered backfill supporting Seismic Category II and non-safety-related structures placed in a very dense condition of 96 percent of the modified Proctor density, and conforming to SCDOT specifications, and the estimated engineering properties verified by future static and dynamic laboratory and field testing, is sufficient to satisfy the requirements of 10 CFR Part 100. Finally, a license condition is required for geologic mapping of the WLS Unit 2 excavation as identified in Section 2.5.3 of this report, and additional information gained during the excavation and mapping operations will allow for modifications to the conceptual excavation plans at WLS Unit 2 to ensure that continuous rock is reached prior to the placement of concrete fill.

2.5.4.4.6 Groundwater Conditions

Details about historic and current groundwater conditions for the WLS site, as well as seepage and groundwater movement information, were provided in WLS COL FSAR Section 2.4.12. WLS COL FSAR Section 2.5.4.6 provides a summary description of the groundwater conditions at the site. The staff focused its review on the proposed plan for dewatering considering groundwater levels, groundwater flow within the saprolite and fractured rock, and proposed dewatering systems to lower the groundwater during excavation and backfill placement. The staff's review and evaluation of permanent groundwater levels, permeability and groundwater flow are provided in Section 2.4.12 of this report. The review in this section is limited to the dewatering of the excavation during construction.

The applicant justified using a range of groundwater elevations between 178 and 175 m (584 and 574 ft) based on the high water marks found on the CNS superstructure after 30 years of exposure. Since the ground water level is below the AP1000 design elevation of 180 m (591 ft) and will not require a permanent dewatering system, the applicant is only concerned with temporarily lowering the groundwater level during excavation and backfill placement.

Through field pumping tests, borehole slug tests and borehole hydraulic packer tests the applicant determined that the seepage into the excavation will occur mostly in the saprolite, partially weathered rock, and open fractures and joints in the bedrock. Based on staff experience in the region, the staff concludes that this is typical of the hydrologic characteristics of the Piedmont soil/rock profile.

The staff reviewed the packer tests and slug tests and found that similar permeability parameters were obtained by different methods. With the inflow occurring mainly in the saprolite and partially weathered rock, the staff concludes that the use of deep wells around the perimeter of the excavation and sumps at selected locations in the excavation will intercept and control seepage and uplift pressures. This plan capitalizes on the construction dewatering experience gained during the excavation for the CNS and takes into consideration the current topography and groundwater conditions. The staff concludes that this dewatering plan will be effective in minimizing lateral flow into the excavation and removing water from within the excavation.

The staff further concludes that because this is a hard rock site, there is no negative groundwater effect on the rock foundation. Erosion, settlement, bearing capacity, and bottom heave of the foundation cannot occur as a result of seepage or groundwater elevation. Although seepage into the excavation from the excavation side walls may occur, this should have minimal effect on the stability of temporary slopes due to the nature of the materials at the site. The staff notes that most of the flow should be cutoff by the exterior deep wells, and surface runoff and seepage entering the excavation can be gathered at the designated sumps and be pumped out. The staff concludes that the experience gained during the construction of the CNS eliminates many of the unknowns regarding potential excavation and dewatering problems.

Therefore, the staff concludes that the groundwater data collected, together with past experience on the site, is sufficient for the design of the temporary dewatering system to allow safe excavation and backfilling operations during the construction of WLS. Based on the review of WLS COL FSAR Section 2.5.4.6, the staff concludes that the applicant adequately described the groundwater conditions to design a temporary dewatering system to meet the construction dewatering demands, and this section meets the requirements of 10 CFR Part 50 and 10 CFR Part 100 and is acceptable.

2.5.4.4.7 Response of Soil, Granular Fill and Rock to Dynamic Loading

WLS COL FSAR Section 2.5.4.7 presents the dynamic properties for hard rock at the WLS site and refers to WLS COL FSAR Section 2.5.2 for the presentation of the development of the GMRS and the FIRS for WLS Unit 1. In this section, the staff reviewed the methods and results used to obtain dynamic profiles of the rock supporting the nuclear island, and the dynamic properties of engineered fill supporting the surrounding structures. The staff focused its review on the field dynamic measurements for the development of the rock dynamic profile underlying the Seismic Category I structures and the existing soil overburden, as well as the estimated soil dynamic material properties for the proposed engineered fill that will support the non-safety-related structures surrounding the WLS nuclear islands.

2.5.4.4.7.1 *Field Dynamic Measurements*

The staff reviewed the field seismic test program and results and the use of the state-of-the-art P-S suspension logging which provides continuous downhole measurements on 0.5 m (1.6 ft) intervals, and the confirmation of the P-S suspension logging results obtained in four of the same boreholes using downhole seismic logging equipment that averages V_s over 3.04 m (10 ft) intervals. The staff concludes that agreement between the two methods was satisfactory, and therefore reliable. Accordingly, the staff concludes that the number and distribution of velocity profiles performed for the nuclear island foundations are adequate to characterize the dynamic properties of the rock and existing concrete across the site.

The staff also considered the selection of borings B-1004, B-2000 and B-2002 for WLS Unit 1, and B-1074A and B-1075A for the previous location of the northwest corner of WLS Unit 1; and B-1015, B-1017 and B-2005 for WLS Unit 2, and concluded that these locations provided consistent results and were deemed representative of those areas for developing dynamic Profiles A and C, respectively. Based on the fact that the densely compacted fills would be supporting Seismic Category II and non-safety-related structures, the staff concludes that the use of the Menq’s relationships is an acceptable method to estimate the soil profiles and dynamic properties of the potential borrow materials until the dynamic properties can be determined by RCTS testing.

2.5.4.4.7.1.1 Foundation Conditions and Uniform

The staff noted that the velocity profiles for the previous location of the northwest corner have lower velocities than the remainder of the site down to approximately El. 155 m (509 ft). In RAI 44, Question 02.05.04-9, the staff requested that the applicant clarify how the WLS site meets the uniformity criteria, given rock not meeting the AP1000 DCD criteria would constitute a soft spot in the subgrade. However, as a result of the revision of application, the applicant moved the Unit 1 footprint about 25 m (82 ft) to the south-east from the originally planned location, which addressed the staff’s uniformity concern for the subsurface materials underneath the nuclear island. Furthermore, dynamic confirmatory sensitivity analyses performed and evaluated in Sections 2.5.2 and 3.7.1 of this report ensure uniform dynamic response. Accordingly, the staff considers RAI 44, Question 02.05.04-9 resolved.

2.5.4.4.7.2 *Conclusions Regarding Response to Dynamic Loading*

On the basis of the sufficiency of the field testing and similar data collected by various test methods, the staff concludes that the applicant adequately determined the dynamic properties of the subsurface rock. The staff also concludes that the applicant addressed Interface Item 2.12 that is related to the seismic parameters for peak ground acceleration, response spectra and shear wave velocity by providing geophysical field test data for input to dynamic analyses performed as presented in WLS COL FSAR Sections 2.5.2 and 3.7.1. Also, the staff concludes that the dynamic properties of the existing soils, proposed engineered fill, and existing concrete were reliably established either by field testing, or estimated by reliable correlations. Future laboratory testing planned by the applicant will confirm the estimated dynamic properties of the engineered fill. Therefore, the staff concludes that the requirements of 10 CFR Part 50 and 10 CFR Part 100 have been adequately addressed.

2.5.4.4.8 Liquefaction Potential

The AP1000 DCD requires that no liquefaction is allowed beneath the Seismic Category I and Seismic Category II structures and the immediate surrounding area. WLS COL FSAR Section 2.5.4.8 states that the WLS site has a liquefaction potential of low to none. The applicant based this conclusion on the fact that the Seismic Category I structures will be constructed on top of either bedrock or concrete fill, and that the non-safety-related structures, including the Seismic Category II annex building adjacent to the nuclear island, will be founded on engineered fill compacted to 96 percent modified Proctor density. The staff reviewed the AP1000 DCD requirements for liquefaction, WLS COL FSAR Section 2.5.4.8, the applicant’s response to liquefaction related RAIs, and considered the foundation conditions underlying the nuclear island and the adjacent non-safety-related and Seismic Category I structures to evaluate the liquefaction potential at the WLS site.

2.5.4.4.8.1 *Nuclear Islands*

The nuclear islands will be founded either on rock or concrete overlying rock and, therefore, the staff concludes that liquefaction is not possible for the materials beneath the nuclear islands of WLS.

2.5.4.4.8.2 *Granular Backfill*

The staff noted that the backfill surrounding the nuclear island will be a granular material with a low percentage of fines that meets the SCDOT gradation requirements and the fill material will be obtained from a SCDOT-approved quarry. The particular gradation has not yet been selected, but the applicant provided data on three fill types; well-graded gravel, poorly-graded gravel, and well graded sand. The engineered fill will be placed in the field with 96 percent of modified Proctor relative compaction, and the granular material will support the non-safety-related structures. In RAI 44, Questions 02.05.04-1 and 02.05.04-5, and RAI 61, Questions 02.05.04-11, 02.05.04-12, 02.05.04-13, and 02.05.04-14, the staff requested that the applicant provide the results of the liquefaction analyses performed for the Group 1 fill material originally cited as the on-site backfill source. However, the applicant subsequently revised its liquefaction analysis when it replaced the Group 1 fill with the SCDOT granular fill, therefore the concerns raised by the staff in those RAIs no longer apply and accordingly, each of those RAIs are closed.

The applicant submitted a second liquefaction analysis using offsite borrow material with a compaction of 96 percent of modified Proctor density (ASTM D1557). The staff reviewed the liquefaction analyses and performed a simplified confirmatory analysis to check the applicant's conclusion. The staff determined that 96 percent relative compaction based on the modified Proctor specification results in a relative density of 80 percent. This was determined by the Lee and Singh relationship given in Equation 2.5.4-1 of this report.

$$RC = 80 + .02D_r \qquad \text{Equation 2.5.4-1}$$

Where: RC is relative compaction with respect to ASTM D1557, and D_r is relative density

Considering that the SW gradation would be the most critical gradation from the standpoint of liquefaction, the staff determined the $(N_1)_{60}$ from Figure 2.5.4-18 of this report to be 38, corresponding to a relative density of 80 percent. The applicant had used a different correlation that gave a more conservative $(N_1)_{60}$ of 30. The relationship between the cyclic stress ratio and $(N_1)_{60}$ published in Youd et al., shown in Figure 2.5.4-19 of this report, indicates that the liquefaction potential of clean granular materials having a $(N_1)_{60}$ of 30 or greater is nil. This is concluded because data points to the right of the "SPT Clean Sand Base Curve" shown in the figure are in the "no liquefaction" portion of the plot. Therefore, a $(N_1)_{60}$ of 30 or greater always resides to the right of the liquefaction/no liquefaction boundary. Therefore, the staff concludes that the applicant made a conservative assumption regarding the strength of the compacted soils, $(N_1)_{60}$ equal to 30, and that engineered fill placed to 96 percent relative compaction will provide adequate resistance to liquefaction under the SSE loading.

2.5.4.4.8.3 *Saprolite*

The applicant also performed liquefaction analyses for the saprolite that will remain to support the engineered fill. The saprolite will be removed from under the safety-related portions of the Seismic Category II structures, but saprolite will be left in place at some locations under non-safety-related buildings or non-safety-related portions of Seismic Category II buildings, specifically the annex and turbine buildings. The applicant found that for corrected N-values, N_{60}, exceeding 15, factors of safety were greater than 2.0. The applicant stated that saprolite exhibiting SPT N_{60}-values less than 15 will be removed.

The staff performed a simplified confirmatory liquefaction analysis based on RG 1.198 and determined that for soil with a N_{60} value of 15, at a depth of roughly 5.6 m (18.5 ft) from the existing ground surface, and 15 percent fines, the cyclic resistance ratio (CRR) was approximately 0.25 from Figure 2.5.4-19 of this report. Since the relationship in Figure 2.5.4-19 of this report is based on a magnitude 7.5 earthquake, and the local earthquake is a magnitude (M_w) 5.1, a Magnitude Scaling Factor (MSF) of 2.68 was applied to yield a CRR of 0.67. The correction factor is a lower bound correction factor recommended in Youd, et al.

$$MSF = {10^{2.24}}\big/{M_w^{2.56}} \qquad \text{Equation 2.5.4-2}$$

The factor of safety is computed as:

$$FS = \frac{CRR}{CSR} \times MSF \qquad \text{Equation 2.5.4-3}$$

A conservative cyclic stress ratio (CSR) for the Magnitude M_w 7.5 earthquake was determined from Equation 2.5.4-4 of this report for the interface at depth of 5.6 m (18.5 ft), because this profile resulted in the greatest peak ground acceleration of 0.345g.

$$CSR = \frac{\tau_{av}}{\sigma'_{vo}} = 0.65\left(\frac{a_{max}}{g}\right)\left(\frac{\sigma_{vo}}{\sigma'_{vo}}\right) r_d \qquad \text{Equation 2.5.4-4}$$

Where:

τ_{av} = average cyclic shear stress

a_{max} = maximum ground acceleration at the ground surface

g = acceleration of gravity

σ_{vo} = total overburden stress

σ'_{vo} = effective overburden stress

r_d = reduction factor based on depth of soil

Based on the above equations, the staff calculated a cyclic stress ratio, CSR, of 0.36, which results in a factor of safety (FS) of 1.86. From this result, the staff concludes that saprolite with N_{60} of 15 or greater provides adequate resistance against liquefaction and may remain to support the engineered fill. The staff also reviewed the excavation plan and boring logs in areas that show saprolite supporting engineered fill below safety-related structures to observe the field N-values that will remain below the excavation line. To convert the field N-values to N_{60} values the staff consulted WLS COL FSAR Appendix 2AA and found that the average energy imparted was 78.1 percent in Boring B-1023. Thus, a N_{60} value of 15 is equivalent to a field N-value of 11.5. The staff determined that the field N values of saprolite that will remain below the planned excavation grade were all greater than 11.5. Based on the results of the confirmatory SPT liquefaction analysis, the staff concludes that the engineered fill placed to the compaction specifications of 96 percent modified Proctor maximum density will not liquefy, and saprolite below the planned excavation grade with N_{60} values of 15 or greater will not liquefy.

However, in Revision 7, submitted on May 9, 2013, WLS COL FSAR Section 2.5.4.8 indicates that the immediate underlying material for some non-seismic portions of the annex and turbine buildings will be saprolite soils, instead of compacted engineered granular fill over saprolite soils as originally planned. Since the SPT N_{60} values of the saprolite soil are between 11 and 30 as listed in WLS COL FSAR Table 2.5.4-211, and the possible maximum groundwater level will be above this layer of soil, this saprolite soil is not totally liquefaction potential free. Therefore, in RAI 112, Question 02.04.05-18, the staff requested that the applicant address the liquefaction potential of the saprolite and the impact of such materials underneath portions of the foundation on the differential settlement between the nuclear island and adjacent buildings.

In an April 24, 2014, response to RAI 112, Question 02.05.04-18, the applicant stated that because of the relocation of WLS, the southernmost area of the non-seismic annex building for Unit 1 lies over existing concrete, which in turn is underlain by continuous rock. Therefore, no saprolite will exist beneath the southernmost area of the non-seismic annex building for WLS Unit 1. The applicant further stated that the existing saprolite material will be removed underneath the non-seismic portion of the WLS Unit 2 turbine building. The only area where saprolite soil will remain beneath the AP1000 non-seismic buildings is beneath the southernmost end of the non-seismic part of the Unit 2 annex building. However, the base of the open excavation has $(N_1)_{60}$ values equal to 26-27, and thus may be considered as highly resistant to liquefaction. Since the liquefaction potential is negligible at the planned site based on the properties of the subsurface materials, the applicant stated that the foundation performance of buildings supported on the granular fill will meet the AP1000 DCD differential settlement criterion. The applicant then proposed changes to the WLS COL FSAR.

Based on the review of the response to RAI 112, Question 02.05.04-18, the staff concludes that the liquefaction potential at the planned site is negligible because the whole power block and non-seismic annex building of Unit 1 will be founded over existing concrete, which in turn is underlain by continuous rock; and the remaining saprolite soil underneath a portion of the Unit 2 annex building has properties that are highly resistant to liquefaction. The staff confirmed that WLS COL FSAR Revision 11, incorporated proposed changes to ensure the standard design requirement on liquefaction potential at the proposed site are met. Accordingly, the staff considers RAI 112, Question 02.05.04-18 resolved.

2.5.4.4.8.4 *Conclusion for Liquefaction Potential*

Based upon its review of WLS COL FSAR Section 2.5.4.8 and staff's independent confirmatory calculations, the staff concludes that no liquefaction can occur below the nuclear island as the bedrock formation and concrete fill are non-liquefiable, nor will liquefaction occur in either the engineered fill or the saprolite that support the Seismic Category II and non-safety-related structures. Since the applicant demonstrated that liquefaction was not possible in the rock and concrete foundation materials underlying WLS and demonstrated that liquefaction would not occur in the densely compacted backfill underlying the non-safety-related structures that border the nuclear islands, the staff concludes that the applicant adequately addressed and closed COL Information Item 2.5-9. The staff concludes that the liquefaction analysis described in WLS COL FSAR Section 2.5.4.8 forms an adequate basis for the assessment of the potential for liquefaction at the WLS site, and meets the requirements of 10 CFR Part 50, Appendix S; and 10 CFR 100.23.

2.5.4.4.9 Earthquake Site Characteristics

In WLS COL FSAR Section 2.5.4.9, the applicant summarized the performance-based site-specific GMRS and FIRS, which were completed in accordance with RG 1.208. The technical evaluation of the development of GMRS and FIRS is included in Section 2.5.2 of this report. The history of the surface faulting for the site and evaluation of surface deformation are evaluated in Section 2.5.3 of this report.

2.5.4.4.10 Static Stability

The staff focused its review of WLS COL FSAR Section 2.5.4.10 on the determination of the representativeness of the soil and rock properties used in the analyses, the applicability of the methods of analysis used, and the applicant's statement that the estimated performance was within the AP1000 bounding criteria. The applicant presented the assumptions, methodologies, and technical references used for its evaluation of the foundation conditions relative to the proposed demands created by excavation, structure and backfill loads, and lateral pressures exerted against the exterior walls of the nuclear island.

2.5.4.4.10.1 *Bearing Capacity*

AP1000 DCD, Tier 1, Chapter 5, states that a site is acceptable if its site characteristics fall within the AP1000 plant site design parameters in the AP1000 DCD Tier 1, Table 5.0-1. An extract of this table for bearing capacity is presented in Table 2.5.4-3 of this report. The applicant evaluated the ultimate bearing capacity of the rock foundation for WLS using two methods of analysis. An empirical method based on average RQD, cited in Peck, Hanson, and Thornburn, was used to determine that the allowable bearing pressure provided lower results than using Tezaghi's bearing capacity equation.

Table 2.5.4-3 AP1000 DCD Bearing Capacity Requirements

AP1000 DCD Table 5.0-1	
Average Allowable Static Soil Bearing Capacity	Greater than or equal to 8900 lb/ft^2 over the footprint of the nuclear island at its excavation depth.
Maximum Allowable Dynamic Bearing Capacity For Normal Plus Safe Shutdown Earthquake (SSE)	Greater than or equal to 35,000 lb/ft^2 at the edge of the nuclear island at its excavation depth.

Using the relationship presented in Peck et al., the applicant determined a minimum allowable bearing capacity of 9,097 kPa (190,000 psf) at Unit 1, and 11,587 kPa (242,000 psf) at Unit 2. In RAI 44, Question 02.05.04-6, the staff requested that the applicant clarify if it considered the lower RQD values obtained in the northwest corner of WLS Unit 1 in the determination of the allowable bearing capacity. In a December 23, 2008, response to RAI 44, Question 02.05.04-6, the applicant considered the lower RQD values and provided a summary of the pertinent RQD values. Table 2.5.4-4 of this report summarizes the RQD values the applicant used in the determination of the allowable bearing capacity provided in response to this RAI. In every instance, the allowable bearing capacity, which includes a FS of 3, was greater than the applied maximum bearing pressure.

Table 2.5.4-4 Summary of Minimum RQD and Allowable Bearing Capacity at WLS Unit 1

Boring	Rock Elevation Range, ft MSL		Foundation Width, ft	Minimum RQD_{avg}, %	Allowable Bearing Capacity On Rock, ksf	Comments $q_{allow} > q_{applied}$
	Top	Bottom				
B-1001	524.1	459	91	86	349	Yes
B-1001A	550.0	459	91	82	309	Yes
B-1002	535.5	459	91	65	190	Yes
B-1003	533.2	497.2	91	86	349	Yes
B-1004	544.0	459	91	86	349	Yes
B-1004A	528.5	459	91	79	279	Yes
B-1011	537.7	459	91	70	214	Yes
B-1074A	505.2	459	91	95	492	Yes
B-1075A	511.5	459	91	91	422	Yes

The staff performed a bearing capacity confirmatory analysis by first verifying the average RQDs as provided in the boring logs included in WLS COL FSAR Appendix 2AA. The staff noted that, based on the boring logs, the average RQD within the zone of influence (a depth approximately equal to the minimum width of the basemat) was equal to approximately 65 percent at WLS Unit 1 and 80 percent at WLS Unit 2. These values were assumed in the applicant's analysis as shown in Table 2.5.4-4 of this report. Using the Peck relationship shown graphically in Figure 2.5.4-20 of this report, the staff obtained approximate ultimate bearing capacity values of 9.125 and 14 MPa (190,600 and 292,400 psf) at WLS, respectively. These values closely match the values given by the applicant and provide factors of safety of greater than 3 in the static case and greater than 1.5 in the dynamic case. Due to this agreement between the applicant's estimations and the staff's calculations, the staff considers RAI 44, Question 02.05.04-6 resolved.

WLS COL FSAR, Revision 7, submitted on May 9, 2013, WLS COL FSAR Section 2.5.4.10.1.1, states, "[t]he applied seismic loading may exceed, by a relatively small amount, the AP1000 DCD value as a result of the site-specific seismic loading." Since the dynamic bearing capacity site parameter is a Tier 1 requirement, any exceedance will result in a departure. Therefore, in RAI 112, Question 02.05.04-19, the staff requested that the applicant provide details on how the calculated loading differs from the AP1000 DCD value, and properly address this departure in this application. In an April 11, 2014, response to RAI 112, Question 02.05.04-19, the applicant clarified that the site-specific maximum bearing pressure is approximately 1,103 kPa (23,030 psf) based on site-specific structural stability analyses, which is significantly less than the AP1000 DCD site acceptance characteristic of 1,675 kPa (35,000 psf). The site-specific analyses also confirmed that no foundation liftoff is expected when the nuclear islands are subjected to the nuclear island FIRS. The applicant then proposed a revision to the WLS COL FSAR to clearly state the dynamic bearing capacity at the WLS site. As the applicant clarified that the calculated site-specific maximum dynamic bearing pressure is less than that specified in the AP1000 DCD, the staff concludes that there is no departure related to this design parameter. The staff further confirmed that FSAR Revision 11 incorporated proposed changes to properly address the dynamic bearing capacity at the proposed site. Accordingly, the staff considers RAI 112, Question 02.04.05-19 resolved.

Based on the review of WLS COL FSAR Sections 2.5.4.10 and 3.8.5.5, and the applicant's responses to related RAIs, the staff concludes that the applicant showed that the allowable bearing capacity of the rock supporting the nuclear islands of WLS Units 1 and 2 is greater, with FS of 3, than the maximum bearing pressure determined from the analyses described in AP1000 DCD Appendix 3G (35,000 psf (1,675 kPa) under all combined loads including the safe shutdown earthquake). Therefore, the staff finds that COL Information Item 2.5-10 is adequately addressed and is closed. The staff also notes that the applicant used material properties obtained from field and laboratory tests in bearing capacity analyses to satisfy Interface Item 2.13, related to the required bearing capacity of foundation materials. The staff concludes that the allowable bearing capacity as determined from the empirical relationship presented in Peck et al. provides an adequate bearing capacity for both the static and dynamic loading conditions.

2.5.4.4.10.2 *Settlement*

The applicant calculated settlement using three methods proposed by: Steinbrenner (Bowles, 1988), the U.S. Army Corps of Engineers (USACE, 1990), and Boussinesq (Li, 1988). Each of these methods is based on the theory of elasticity. The applicant also used an empirical relationship obtained from Peck et al. (1974) that uses the RQD of the rock to predict settlement. The applicant computed settlements of approximately 0.127 cm (0.05 in.) at WLS Units 1 and 2 using the elastic theory derived methods. Using the empirical method of Peck et al. (1974), the applicant computed settlements of 0.058 cm (0.023 in.) at Unit 1 and 0.038 cm (0.015 in.) at Unit 2. The computed settlements from those methods are small and fall within the design settlement criteria established in the AP1000 DCD: 7.62 cm (3 in.) for total settlement, and 1.27 cm in 15.24 m (0.5 in. in 50 ft) for differential settlement.

The staff inspected the boring logs to verify input data. Based on the strengths of the rock and the computed bearing capacity factors of safety, the staff concludes that the settlements will be small and in the elastic range, which verifies the reasonableness of the applicant's approach. The staff also performed its own confirmatory analysis using elastic theory. The staff selected the four borings with V_s measurements at WLS Unit 1 to estimate possible maximum differential settlement. The average elastic modulus values to a depth of approximately 45.7 m (150 ft), the maximum depth of these borings, were conservatively corrected to account for strain using a correction factor of 0.5. Although settlements were only calculated to a depth of 45.7 m (150 ft) due to the limitation of the boring depths, the staff concludes that this was sufficiently deep because the stresses decrease as depth below the basemat increases, and the rock elastic modulus remains the same or increases as observed by the V_s measurements made in borings taken to depths of 76.2 m (250 ft). The calculated settlements between the four borings were compared: the largest settlement was 0.129 cm (0.051 in.) and the least settlement was 0.058 cm (0.023 in.). The AP1000 assigns an allowable total settlement of 7.62 cm (3.0 in.) and allowable differential settlement of 1.27 cm in 15.24 m (0.5 in. in 50 ft). Accordingly, the staff concludes that the estimated total settlement and differential settlement of the WLS are within the AP1000 DCD criteria.

The staff noted that the AP1000 DCD limits differential settlement between the nuclear island and the surrounding structures to 7.62 cm (3 in.); however, the applicant did not present differential settlement data between structures. Therefore, in RAI 66, Question 02.05.04-15, the staff requested that the applicant provide the differential settlements between the nuclear island and each of the surrounding structures. In June 2, 2009 and October 30, 2009, responses to RAI 66, Question 02.05.04-15, the applicant presented the differential settlements between the nuclear island and the surrounding structures. The applicant based the settlement calculations on the method of Peck et al. (1974). Table 2.5.4-5 of this report summarizes the results.

Table 2.5.4-5 Allowable Bearing Pressure Based on Limiting Settlement (WLS COL FSAR Table 2.5.4-229)

Structure	Subsurface	$q^{(a)}_{allow}$ (k/ft^2)	$q_{applied}$ (k/ft^2)	$q_{allow} > q_{applied}$	Anticipated Settlement (inches)
SW Sand Granular Backfill					
Annex Building	Granular Fill – SW	7.29	2.43	Yes	<2
Turbine Building	Granular Fill – SW	6.96	3.51	Yes	<2
Radwaste Building	Granular Fill – SW	7.24	1.31	Yes	<2
GP Gravel Granular Backfill					
Annex Building	Granular Fill – GP	10.93	2.43	Yes	<2
Turbine Building	Granular Fill – GP	10.44	3.51	Yes	<2
Radwaste Building	Granular Fill – GP	10.86	1.31	Yes	<2
GW Gravel Granular Backfill					
Annex Building	Granular Fill – GW	10.93	2.43	Yes	<2
Turbine Building	Granular Fill – GW	10.44	3.51	Yes	<2
Radwaste Building	Granular Fill – GW	10.86	1.31	Yes	<2

(a) For limiting settlement to 2 inches

The staff reviewed the applicant’s calculations and observed that total settlement is limited to less than 5.08 cm (2 in.) for each of the Seismic Category II or non-safety-related structures irrespective of the engineered fill type assumed in the calculations. The most critical case is associated with the Turbine building and its static bearing pressure of 98.6 kPa (3.51 ksf). The allowable bearing pressure (q_{allow}) for 5.08 cm (2 in.) settlement at the Turbine building is 340.4 kPa (7.11 ksf). Since a 340.4 kPa (7.11 ksf) of pressure is expected to produce 5.0 cm

(2 in.) total maximum settlement, for the actual bearing pressure of 98.6 kPa (2.06 ksf), the applied Turbine building load is expected to produce settlement of less than 5.08 cm (2 in.). This amount of total settlement compared to the negligible settlement of the nuclear island, falls within the 7.62 cm (3 in.) differential settlement criteria between structures imposed by the AP1000 DCD.

The staff concludes that the applicant resolved COL Information Item 2.5-12 by demonstrating through engineering analyses that the rebound, settlement and differential settlement of the Seismic Category I, Seismic Category II and non-safety-related structures were within the range of acceptable settlements required by the AP1000 DCD. Also, because the applicant provided settlement calculations to demonstrate that settlement of the nuclear islands on rock was negligible, the staff concludes that the applicant adequately addressed COL Information Item 2.5-16. The staff further concludes that based on this analysis, the fact that most of the settlement under the Seismic Category II and non-safety-related structures will occur during construction, and given the engineering properties of the granular fill, the differential settlement between the nuclear island and the surrounding structures will be negligible and is acceptable.

2.5.4.4.10.3 *Lateral Pressures*

The applicant calculated lateral earth pressures caused by the placement of backfill against the exterior walls of the nuclear island using Rankine's theory. Earth pressure calculations were made with conservatively assumed soil properties and the range of expected water table elevations. Dynamic lateral earth pressures had not been submitted; therefore, in RAI 44, Question 02.05.04-8, the staff requested that the applicant provide dynamic lateral earth pressures acting on below ground walls of the plant safety-related facilities.

In December 23, 2008, and October 30, 2009, responses to RAI 44, Question 02.05.04-8, the applicant provided the lateral stresses due to dynamic forces imposed by the SSE. The dynamic pressures were calculated in accordance with ASCE 4-98. The staff reviewed the ASCE 4-98 methodology and concludes that this method is a state-of-the-art and widely used method for non-yielding walls and, therefore, acceptable for estimating dynamic lateral earth pressures. The staff also concludes that the input parameters used by the applicant to calculate the dynamic lateral stresses are conservative. Accordingly, the staff considers RAI 44, Question 02.05.04-8 resolved.

However, although in revised WLS COL FSAR Chapter 2, Section 2.5.4.10.3, it states, "Westinghouse has evaluated the WLS site-specific lateral earth pressures and has determined that they are bounded by the standard AP1000 design pressures," there is no related table or figure to show that the site-specific lateral earth pressures are bounded by the standard AP1000 design. Therefore, in RAI 112, Question 02.05.04-20, the staff requested that the applicant provide necessary table(s) or figure(s) to confirm that the site-specific lateral earth pressures are bounded by the standard AP1000 design.

In an April 11, 2014, response to RAI 112, Question 02.05.04-20, the applicant stated that Westinghouse evaluated the WLS site-specific lateral earth pressures by comparing the site-specific pressures on the nuclear island below-grade walls for Load Combinations (LC) 1 through 9 in AP1000 DCD Table 3.8.4-2 to the corresponding pressures that were used in the AP1000 standard design. The analysis results showed that the site-specific lateral pressures on the nuclear island exterior walls below grade are bounded by the AP1000 design pressures for load combinations 1, 2, 3, 4, 5, 6, 8, and 9 in both the east-west (E-W) and north-south (N-S) directions, with the exception that the site-specific lateral pressure in Load Combination 7 (LC7) for the GW backfill material slightly exceeds the standard design lateral pressure. The applicant then indicated that the exceedance of lateral earth pressure under LC7 is mainly attributed to the lower groundwater level at the site and with the assumption of full passive lateral earth pressure. However, the maximum lateral displacement at the base of the nuclear island when subjected to the certified seismic design response spectra (CSDRS) is expected to be 3 to 5 mm (0.12 to 0.19 in.) and such small lateral displacements are not capable of developing the full passive earth pressure. Therefore, the applicant concluded that the site-specific nuclear island below-grade wall pressures resulting from the NI FIRS will be less than those used in the standard AP1000 design for this load combination.

To confirm its conclusion, the applicant presented the results of a sensitivity study that varied the groundwater levels with a conservative assumption of displacement of 5 mm (0.2 in.). This study results show that when varying groundwater levels from 2.44 to 5.49 m (8 to 18 ft) below ground, the maximum fraction of the fully mobilized passive earth pressure is 0.83, or the passive earth pressure on the nuclear island below-grade wall will not be fully mobilized. However, the site-specific pressures on below-grade walls for LC7 exceed those specified in the AP1000 standard design, therefore, this exceedance is identified as a departure from the AP1000 DCD. The applicant then proposed changes to the WLS COL FSAR accordingly and referred to WLS COL FSAR Section 3.8.4.4.4 for a detailed discussion of site-specific lateral earth pressure.

Based on the review of the RAI response and WLS COL FSAR Section 3.8.4.4.4, the staff concludes that the applicant adequately demonstrated that the passive earth pressure on the nuclear island below-grade wall will not be fully mobilized given the very small expected lateral displacement under design seismic loading conditions, and the sensitivity study results confirmed this conclusion. Therefore, the staff concludes that the site-specific maximum lateral earth pressure will be smaller than those calculated in the standard AP1000 design for all load combinations, and the applicant adequately addressed this issue. .

2.5.4.4.10.4 *Conclusions of Bearing Capacity, Settlement and Lateral Earth Pressures*

In WLS COL FSAR Section 2.5.4.10, the applicant considered the static and dynamic bearing capacities, settlement, and lateral stresses at the WLS site. Based on the analytical results, the staff concludes that the bearing capacity of the WLS metamorphic and igneous rock foundation is sufficient to meet both the static and dynamic loading demands imposed by the WLS nuclear islands with adequate factors of safety. The staff also concludes that the settlement of the foundation under the maximum static load imposed by the nuclear island on the bedrock was minimal for either unit, less than 0.129 cm (0.051 in.), and the least settlement was 0.058 cm (0.023 in.); therefore, both the differential and total settlements are smaller than those specified in the standard design. The staff further concludes that the applicant conducted a site-specific lateral earth pressure analysis that used a conservative approach and showed that the expected maximum lateral pressures applied to the nuclear island below grade walls at this site will be smaller than those specified in the standard design.

The staff reviewed WLS COL FSAR Section 2.5.4.10 and concludes that the applicant developed an accurate assessment of the static and dynamic stabilities at the WLS site that address COL Information Items 2.5-10 through 2.5-13, including the minimum static and dynamic bearing capacities, lateral earth pressures, and stability of facilities. The staff further concludes that the applicant resolved COL Information Item 2.5-13 by providing planned instrumentation programs proposed for monitoring the performance of the dewatering system during the excavation phase of the project. Since the nuclear islands are founded on rock, the staff concurs with the applicant that settlement monitoring is not required. The staff also concludes that the information provided with respect to the required bearing capacity of foundation materials is adequate to address Interface Item 2.13. Accordingly, the staff concludes that the applicant's information in WLS COL FSAR Section 2.5.4.10, with the close of all related confirmatory items, forms an adequate basis for the stability of subsurface materials and foundations of Seismic Category I structures at the site and meets the requirements of 10 CFR Part 50, Appendix A and Appendix S, and 10 CFR 100.23.

2.5.4.4.11 Design Criteria

WLS COL FSAR Section 2.5.4.11 describes design criteria considered in the design of the foundations for the WLS nuclear islands. The applicant referred to WLS COL FSAR Table 2.1-201 where the AP1000 DCD site parameter requirements are compared to the WLS site characteristics. The staff focused its review on design criteria used, design assumptions, design methods, calculated factors of safety, and conservatism in the analyses. The staff reviewed the cited references to ensure proper interpretation of the equations, assumptions and limitations on the theory and performed independent confirmatory analyses to check the applicant's results.

The staff concludes that the applicant utilized the AP1000 DCD design criteria in its evaluation of the WLS site, performed calculations for bearing capacity, settlement, static and dynamic lateral earth pressures in accordance with accepted industry standards, and evaluated liquefaction potential in accordance with RG 1.198 and state-of-the-art methodology. The staff further concludes that computed factors of safety for liquefaction of backfill, static and dynamic bearing capacity are acceptable. Accordingly, the staff concludes that the applicant addressed the AP1000 DCD Tier 1 requirements; that the applicant used state-of-the art engineering methodology in determining the engineering behavior of the foundations; and that the site exhibits factors of safety that are in accordance with acceptable nuclear industry standards. Therefore, the staff concludes that the information presented in WLS COL FSAR Section 2.5.4.11 is acceptable to satisfy the applicable criteria of 10 CFR Part 50.

2.5.4.4.12 Techniques to Improve Subsurface Conditions

The applicant stated that with minor exceptions the WLS Units 1 and 2 nuclear islands will be founded on continuous rock having RQD values greater than 65 percent and that rock with lower RQD value will be excavated and replaced with fill concrete. Details for using dental concrete to backfill narrow zones of deeper weathered rock were provided. The applicant also stated that a drainage network under the existing CNS concrete slab will require modification to prevent migration of backfill into the drains. The staff focused its review on the proposed bedrock surface preparation details, including the excavation of unsatisfactory rock, the backfilling of joints (dental concrete), and sealing of the open drainage ways under the CNS foundation.

The rock and existing concrete surfaces will undergo surface preparation in advance of concrete fill placement. This includes cleaning the bedrock surface of loose soil or weak rock, removal of rock protrusions and overhangs, backfilling of open joints with dental concrete, and roughening the surfaces to receive concrete. This procedure is standard practice for bedrock surface preparation for major structures placed on rock foundations. The staff concludes that those techniques are acceptable because they are consistent with the assumptions made in the static and dynamic foundation design. Geologic mapping of the rock surface will provide the documentation needed to ensure that the excavation was advanced to continuous rock, and that no geologic hazardous conditions exist that were not uncovered in the geotechnical exploration. Geologic mapping requirement is evaluated in Section 2.5.3 of this report.

Under the existing CNS foundation basemat, a network of drains exists and the applicant proposed to seal off the drainage system with concrete to prevent migration of backfill into the drains. The staff concludes that the placement of concrete as a plug to block the migration of backfill materials into the drainage system is acceptable. The staff considers the applicant’s plan for improving the subsurface conditions adequate and, therefore, concludes that the information is acceptable to satisfy the applicable criteria of 10 CFR Part 50.

2.5.4.5 *Post Combined License Activities*

There are no post COL activities related to this section.

2.5.4.6 *Conclusions*

Based on its review of WLS COL FSAR Section 2.5.4, the referenced design certification of AP1000 and the applicant’s responses to related RAIs, the staff concludes that the applicant adequately determined the engineering properties of the soil and rock underlying the WLS site through its field and laboratory investigations. The staff concludes that the applicant used the state-of-the-art field and laboratory testing methods, in accordance with RG 1.132, RG 1.138, and RG 1.198, to determine the required site-specific engineering properties for the WLS site and to ensure that these properties met the design criteria specified in the AP1000 DCD.

Based on the information provided in the WLS COL FSAR and related RAI responses from the applicant, the staff concludes that the subsurface profile underlying the WLS site was properly characterized, that state-of-the-art analytical methods were used with conservative input values to determine factors of safety and limits of deformation in subsurface material and foundation stability analyses, and that the applicant considered all aspects of the foundation design that could impact the safety-related SSCs. Specifically, the staff concludes that the applicant adequately determined: (1) the soil and rock static and dynamic properties through its field investigations and laboratory tests; (2) the response of the soil and rock to dynamic loading; (3) the liquefaction potential of the engineered fill; and (4) the static and dynamic stabilities, including the bearing capacity, settlement, and lateral earth pressures of the nuclear island and surrounding non-safety-related structures under static and seismic loading conditions.

The staff concludes that the applicant provided sufficient information in WLS COL 2.5-1 through WLS COL 2.5-13, WLS COL 2.5-16 and WLS COL 2.5-17 to adequately address COL information items pertaining to WLS COL FSAR Section 2.5.4, which met the requirements specified in the AP1000 DCD. Finally, as discussed above, the staff concludes that WLS COL FSAR Section 2.5.4 is acceptable and meets the applicable requirements of 10 CFR Part 50, Appendix A (GDC 2) and Appendix S; and 10 CFR 100.23.

2.5.5 Stability of Slopes

2.5.5.1 *Introduction and Overview*

Stability of slopes addresses the stability of all earth and rock slopes, both natural and man-made (cuts, fill, embankments, dams, etc.), whose failure, under any of the conditions to which they could be exposed during the life of the plant, could adversely affect the safety of the plant. The following subjects are evaluated using the applicant's data in the WLS COL FSAR and information available from other sources: (1) slope characteristics; (2) design criteria and design analyses; (3) results of the investigations including borings, shafts, pits, trenches, and laboratory tests; (4) properties of borrow material, compaction and excavation specifications; and (5) any additional information deemed necessary in accordance with 10 CFR Part 52.

Section 2.5.5 of this report addresses slope stability information related to the WLS site. Section 2.5.5.2 of this report provides a summary of relevant geologic and seismic information contained in WLS COL FSAR Section 2.5.5 of the WLS application. Section 2.5.5.3 of this report provides a summary of the regulations and guidance used by the applicant in its application and by the staff to review the application. Section 2.5.5.4 of this report provides a review of the staff's evaluation of the WLS COL FSAR Section 2.5.5. Section 2.5.5.5 of this report discusses any post combined license activities. Finally, Section 2.5.5.6 of this report provides an overall summary of the applicant's conclusions, as well as the staff's conclusions, restates any bases covered in the application, and confirms that the application meets the requirements defined in NRC regulations.

2.5.5.2 *Summary of Application*

WLS COL FSAR Section 2.5.5 addresses COL Information Items 2.5-14, “Stability of Slopes,” and 2.5-15, “Embankments and Dams,” of the AP1000 DCD, Revision 19.

In addition, in WLS COL FSAR Section 2.5.5, the applicant provided the following:

AP1000 COL Information Items

- WLS COL 2.5-14

The applicant provided additional information in WLS COL 2.5-14 to address COL Information Item 2.5-14, which addresses the provision of site-specific information about the static and dynamic stability of site-specific soil and rock slopes with regard to how their failure could adversely affect the safety of the Seismic Category I structures.

- WLS COL 2.5-15

The applicant provided additional information in WLS COL 2.5-15 to address COL Information Item 2.5-15, which addresses the provision of site-specific information about the static and dynamic stability of site-specific embankments and dams with regard to how their failure could adversely affect the safety of the nuclear power plant facilities.

The applicant developed WLS COL FSAR Section 2.5.5 for the evaluation of slope stability at the WLS site based on information derived from site investigations, geotechnical characterization studies, and excavation and backfill profiles presented in WLS COL FSAR Sections 2.5.4.1 through 2.5.4.5. These investigations and studies included consideration of geologic features and characteristics, site exploration involving soil and rock boring and sampling, groundwater monitoring, surface geophysical testing, in-situ testing, geotechnical test pits, geologic trench excavations, and laboratory testing; and geophysical surveys.

2.5.5.2.1 Slope Characteristics

WLS COL FSAR Section 2.5.5.1 describes the characteristics of existing permanent slopes, both natural and man-made, which exist within 0.4 km (0.25 mi) of the WLS Units 1 and 2 nuclear islands, including properties of the materials that make up these slopes. The applicant cross-referenced detailed information presented in WLS COL FSAR Sections 2.5.4.1 through 2.5.4.5 derived from investigations performed at the site. Based on the results of these investigations, the distance, height, and inclination of the slopes from the nuclear island, the applicant concluded that no slope, either permanent or man-made, exists for which failure will adversely affect the safety-related structures of WLS Units 1 and 2. The following sections provide a summary of the characteristics and material properties of slopes at the site.

2.5.5.2.1.1 *General Discussion*

In WLS COL FSAR Section 2.5.5.1.1, the applicant stated that the natural slopes at the WLS site existed through most or all of Holocene time (i.e., since 10,000 years ago), and the man-made slopes were part of the initial CNS construction. The applicant indicated that all these slopes exhibit acceptable stability with no visual evidence of groundwater seepage, past failure, incipient movement, or major creep. The applicant further stated that the native (i.e., residual and saprolitic) soils and engineered fill at the WLS site are not prone to liquefaction, and that the potential for a liquefaction-induced slope stability hazard does not exist for Seismic Category I structures under either static or dynamic loading conditions.

The applicant described the two permanent slopes nearest to the nuclear island areas, which are labeled as Slopes 5 and 7 in Figure 2.5.5-1 of this report. The applicant identified the highest slope (Slope 5 in Figure 2.5.5-1 of this report) as a natural hill located southwest of the WLS Unit 1 nuclear island. The applicant stated that this hill rises approximately 24.4 m (80 ft) above the yard grade, has a natural slope of approximately 2.5 horizontal to 1 vertical (2.5h:1v), and is located more than 305 m (1,000 ft) from WLS Unit 1.

Another slope (Slope 7 in Figure 2.5.5-1 of this report) identified by the applicant is an engineered slope about 366 m (1,200 ft) north of WLS Unit 2, which descends 26.8 m (55 ft) below the yard elevation. The applicant stated that this slope is approximately 2 horizontal to 1 vertical (2h:1v), and no credible mechanism exists whereby failure of a descending slope of about 26.8 m (55 ft) high and 366 m (1,200 ft) away could affect safety-related structures at the WLS site.

The applicant concluded that, due to the past stable history of the slopes, slope height and inclination, and its distance from the safety-related structures, the slopes at the WLS site do not pose a hazard to the safety of the plant.

2.5.5.2.1.2 *Exploration Program*

WLS COL FSAR Section 2.5.5.1.2 references information in WLS COL FSAR Sections 2.5.4.1 through 2.5.4.3, in which the applicant describes the assessment of the stability of permanent slopes at the WLS site.

2.5.5.2.1.3 *Groundwater and Seepage*

WLS COL FSAR Section 2.5.5.1.3 references the information provided in WLS COL FSAR Sections 2.4.12 and 2.5.4.6. The applicant concluded that groundwater seepage in natural and manmade slopes does not pose a hazard for the WLS site since no slopes are in close proximity to safety-related structures.

2.5.5.2.1.4 *Slope Materials and Properties*

In WLS COL FSAR Section 2.5.5.1.4, the applicant referenced WLS COL FSAR Section 2.5.4.2 for descriptions of the properties of the existing engineered fill and native residual and saprolitic soil that consist of all permanent slopes. The slope stability assessment performed by the applicant consisted of an evaluation of slope locations, geometries, inclinations, past stability, distance from the WLS Units 1 and 2 nuclear island structures, and observed long-term slope performance. The applicant used information on slope materials and properties as a guide regarding the distances between the slopes and safety-related structures. The applicant also noted that permanent slopes show inclinations of about 26.5 degrees (i.e., 2h:1v) or less, which is smaller than the friction angle of the materials comprising the slopes and, therefore, stated that the cohesive component of shear strength of the materials consisting of the slopes increased the perceived inherent stability of the slopes. The applicant further indicated, based on liquefaction potential of the materials that comprise the slopes as discussed in WLS COL FSAR Section 2.5.4.8, that the slope materials are not prone to liquefaction. Therefore, the applicant concluded that no potential slope stability hazard exists under either static or dynamic conditions to adversely affect safety-related structures at the WLS site.

2.5.5.2.2 Design Criteria and Analyses

WLS COL FSAR Section 2.5.5.2 indicates that the applicant limited the assessment of permanent slope conditions to those slopes within 0.4 km (0.25 mi) of the WLS Units 1 and 2 nuclear island structures and based this assessment on past slope performance, slope height and angle, and distance of the slope from safety-related structures. The applicant reported that the nearest permanent slopes are 305 m (1,000 ft) or more away from the WLS Units 1 and 2 nuclear island structures, and concluded that no permanent slopes required further analyses since none were identified in which failure would pose a hazard to the safety-related structures.

2.5.5.2.3 Logs of Borings

WLS COL FSAR Section 2.5.5.3 states that no borings, test pits, or trenches were used for stability analyses of permanent slope conditions surrounding the WLS safety-related nuclear island structures. The applicant indicated that this geotechnical information was not required since no slopes were determined to pose a hazard to the safety-related structures.

2.5.5.2.4 Compacted Fill

In WLS COL FSAR Section 2.5.5.4, the applicant stated that there are no safety-related permanent dams, dikes, or embankments at the WLS site. Therefore, the applicant concluded that design and performance criteria for compacted fills were not required.

2.5.5.3 *Regulatory Basis*

The applicable regulatory requirements for reviewing the applicant's discussion of stability of slopes are:

- 10 CFR 50.55a, "Codes and Standards," as it relates to the requirement that structures, systems, and components shall be designed, fabricated, erected, constructed, tested, and inspected in accordance with the requirement of applicable codes and standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 1, "Quality Standards and Records," as it relates to the requirement that structures, systems, and components important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. This regulation also requires that appropriate records of the design, fabrication, erection, and testing of structures, systems, and components important to safety be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit.

- 10 CFR Part 50, Appendix A, GDC 2, "Design Bases for Protection Against Natural Phenomena," as it relates to consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 50, Appendix S, "Earthquake Engineering Criteria for Nuclear Power Plants," as it applies to the design of nuclear power plant structures, systems, and components important to safety to withstand the effects of earthquakes.

- 10 CFR Part 100, "Reactor Site Criteria," provides the criteria that guide the evaluation of the suitability of proposed sites for nuclear power and testing reactors.

- 10 CFR 100.23, "Geologic and Seismic Criteria," provides the nature of the investigations required to obtain the geologic and seismic data necessary to determine site suitability and identify geologic and seismic factors required to be taken into account in the siting and design of nuclear power plants

The related acceptance criteria are summarized from Standard Review Plan (SRP) Section 2.5.5:

- Slope Characteristics: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the discussion of slope characteristics is acceptable if the section includes: (1) cross sections and profiles of the slope in sufficient quantity and detail to represent the slope and foundation conditions; (2) a summary and description of static and dynamic properties of the soil and rock comprised by Seismic Category I embankment dams and their foundations, natural and cut slopes, and all soil or rock slopes whose stability would directly or indirectly affect safety-related and Seismic Category I facilities; and (3) a summary and description of groundwater, seepage, and high and low groundwater conditions.

- Design Criteria and Analyses: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the discussion of design criteria and analyses is acceptable if the criteria for the stability and design of all Seismic Category I slopes are described and valid static and dynamic analyses have been presented to demonstrate that there is an adequate margin of safety.

- Boring Logs: To meet the requirements of 10 CFR Part 50 and 10 CFR Part 100, the applicant should describe the borings and soil testing carried out for slope stability studies and dam and dike analyses.

- Compacted Fill: To meet the requirements of 10 CFR Part 50, the applicant should describe the excavation, backfill, and borrow material planned for any dams, dikes, and embankment slopes

In addition, the geologic characteristics should be consistent with appropriate sections from: RG 1.28, "Quality Assurance Program Requirements (Design and Construction)"; RG 1.132, "Site Investigations for Foundations of Nuclear Power Plants"; RG 1.138, "Laboratory Investigations of Soils for Engineering Analysis and Design of Nuclear Power Plants"; RG 1.198, "Procedures and Criteria for Assessing Seismic Soil Liquefaction at Nuclear Power Plant Sites"; and RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)."

2.5.5.4 *Technical Evaluation*

The NRC staff reviewed Section 2.5.5 of the WLS COL FSAR and checked the referenced DCD to ensure that the combination of information presented in the FSAR and the DCD completely represents the required information related to the stability of slopes. The staff's review confirmed that information contained in the application or incorporated by reference addresses the information required for this review topic. NUREG-1793 and its supplements document the results of the staff's evaluation of the information incorporated by reference into the WLS COL application.

The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Items

- WLS COL 2.5-14

The staff reviewed the resolution to the COL information items related to the stability of all earth and rock slopes, both natural and man-made (cuts, fill, embankments, dams, etc.), the failure of which, under any of the conditions to which they could be exposed during the life of the plant, could adversely affect the safety of the plant included under WLS COL FSAR Section 2.5.5.

With respect to COL Information Item WLS COL 2.5-14, the applicant stated that there are no soils or rock slopes that the failure of which could adversely affect the safety-related structures at the WLS site. The staff considered the results of site investigations in conjunction with the applicant's conclusion and concurs with the applicant's assessment that the slopes at the site are a sufficient distance from the WLS safety-related structures. The staff concludes that the applicant has met the criteria of COL Information Item 2.5-14 WLS COL 2.5-14.

- WLS COL 2.5-15

Regarding WLS COL 2.5-15, the applicant stated that there are no dams or embankments the failure of which could adversely affect the safety-related structures at the WLS site. The staff considered the results of site investigations, as well as the applicant's assertion and concurs with the applicant that there are no dams or embankments that might adversely affect safety-related structures of the WLS Units 1 and 2. The staff concludes that the applicant adequately addressed the criteria of COL Information Item 2.5-15 WLS COL 2.5-15.

2.5.5.5 *Post Combined License Activities*

There are no post COL activities associated with this section.

2.5.5.6 *Conclusions*

As discussed above, the applicant presented sufficient information on the evaluation of the stability of all earth and rock slopes, both natural and manmade at the proposed site, and adequately addressed COL Information Items WLS COL 2.5-14 and 2.5-15, which met the design criteria and requirements specified in the AP1000 DCD. The staff reviewed the investigations performed for slope stability studies and the evaluation of the stability of all slopes at the proposed site by the applicant, and concludes that the analyses and evaluations demonstrated that natural and manmade slopes will remain stable under the site-specific static and seismic loading conditions and that safety-related earthwork will function reliably at the site to justify the soil and rock characteristics used in the design. The staff further concludes that the design analyses contain adequate margins of safety for construction and operation of the nuclear power plant and meets the requirements of 10 CFR Part 50, Appendix A (GDC 1 and GDC 2); 10 CFR Part 50, Appendices B and S; and 10 CFR 100.23. Accordingly, the staff concludes that the WLS site is suitable with respect to the criteria governing the stability of slopes and, therefore, considers WLS COL FSAR Section 2.5.5 acceptable.

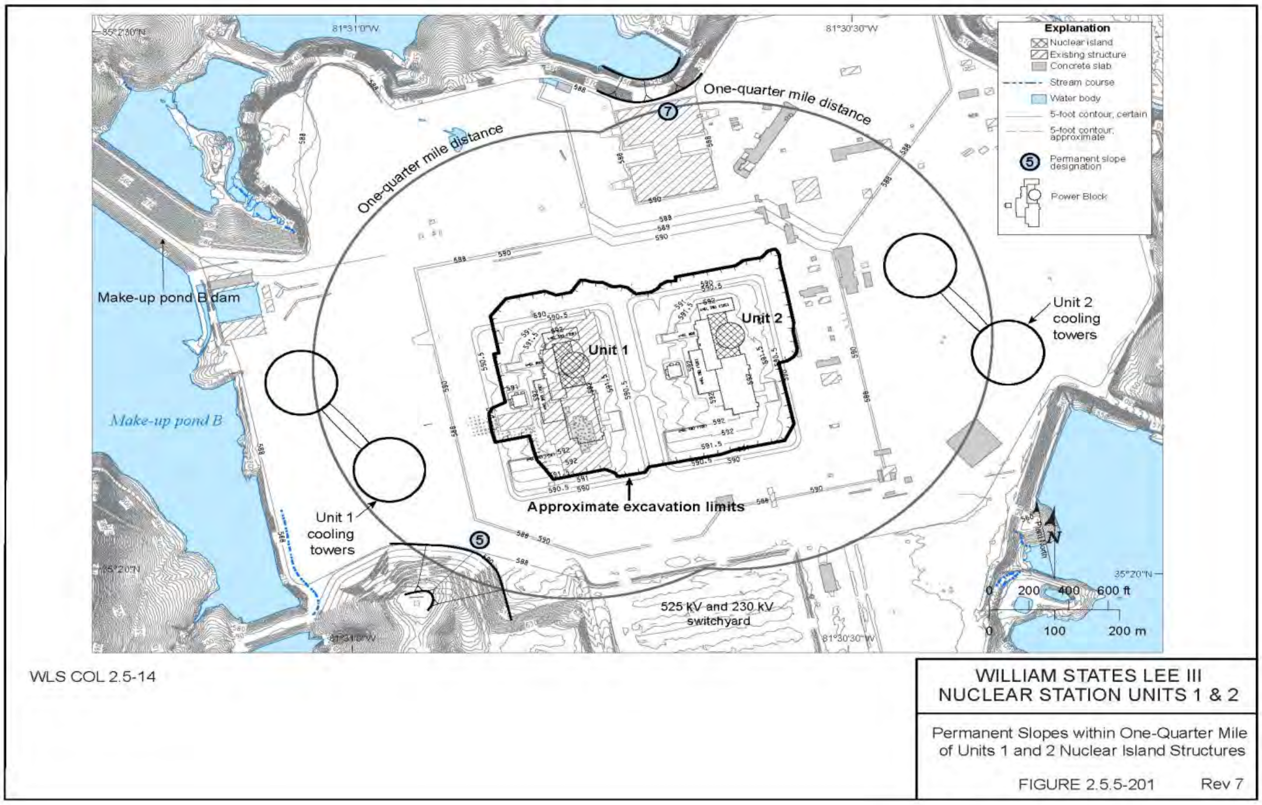

Figure 2.5.5-1 Permanent Slopes at the Lee Nuclear Station Site (WLS COL FSAR Figure 2.5.5-201)

2.5.6 Combined License Information

WLS COL FSAR Section 2.5.6 is an administrative departure from the AP1000 DCD for organization and numbering for the WLS COL FSAR sections. This section provides a list of all COL information items addressed in WLS COL FSAR Section 2.5. Since there is no technical content in this section, no safety evaluation was needed.

4.0 REACTOR

4.1 Introduction

This chapter describes the mechanical components of the AP1000 reactor and reactor core, including the reactor internals, control rod drive and core support structural materials, fuel system design (fuel rods and fuel assemblies), the nuclear design, and the thermal-hydraulic design. It also specifies the principal design criteria with which the mechanical design, the physical arrangement of the reactor components, and the capabilities of reactor control, protection, and emergency cooling systems (when applicable) must comply.

4.2 Summary of Application

Chapter 4 of the William States Lee III Nuclear Station (WLS) combined license (COL) Final Safety Analysis Report (FSAR), Revision 11, incorporates by reference Chapter 4 of the AP1000 Design Control Document (DCD), Revision 19.

In addition, in WLS COL FSAR Section 4.4, the applicant provided the following:

AP1000 COL Information Item

- STD COL 4.4-2

The applicant provided additional information in Standard (STD) COL 4.4-2 to address COL Information Item 4.4-2. This item states that, upon selection of the actual instrumentation, the instrumentation uncertainties of the operating parameters shall be calculated and the validity of the design-limit departure from nucleate boiling ratio (DNBR) values shall be confirmed.

License Condition

Part 10, License Condition 2, Item 4.4-2

The license condition will require the completion of the actions described in STD COL 4.4-2 prior to initial fuel load.

4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793, “Final Safety Evaluation Report [FSER] Related to Certification of the AP1000 Standard Design.”

In addition, the acceptance criteria associated with the relevant requirements of the Commission regulations for the thermal-hydraulic design are identified in Section 4.4 of NUREG-0800, “Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants.”

To resolve the confirmatory item, the Nuclear Regulatory Commission (NRC) staff also used the requirements of Title 10 of the *Code of Federal Regulations* (10 CFR) 50.72, “Immediate notification requirements for operating nuclear power reactors,” and 10 CFR 50.73, “Licensee event report system," and the guidance of NUREG-1022, "Event Reporting Guidelines: 10 CFR 50.72 and 50.73," Revision 2.

4.4 Technical Evaluation

The NRC staff reviewed Chapter 4 of the WLS COL FSAR and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The NRC staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the reactor internals, control rod drive and core support structural materials, fuel system design (fuel rods and fuel assemblies), the nuclear design, and the thermal-hydraulic design. The results of the NRC staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this safety evaluation report (SER) provides a discussion of the strategy used by the NRC to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (Vogtle Electric Generating Plant [VEGP], Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5 to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from requests for additional information (RAIs).
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.
- The staff verified that the site-specific differences were not relevant.

The staff has completed its review and found the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the Bellefonte Nuclear Plant (BLN), Units 3 and 4 COL application.

[1] See Section 1.2.2 for a discussion of the staff's review related to verification of the scope of information to be included in a COL application that references a design certification (DC).

The following portion of this technical evaluation section is reproduced from Section 4.4 of the VEGP SER:

<u>AP1000 COL Information Item</u>

- *STD COL 4.4-2*

The NRC staff reviewed STD COL 4.4-2 related to COL Information Item 4.4-2 and related COL Action Item 4.4-1 (from Appendix F of the NRC staff's FSER for the AP1000 DCD (NUREG-1793)), included under Section 4.4 of the BLN COL FSAR, Revision 1. STD COL 4.4-2 states:

> *Following selection of the actual plant operating instrumentation and calculation of the instrumentation uncertainties of the operating plant parameters as discussed in DCD Subsection 7.1.6, the design limit DNBR values will be calculated. The calculations will be completed using the revised thermal design procedure (RTDP) with these instrumentation uncertainties and confirm that either the design limit DNBR values as described in DCD Section 4.4 remain valid or that the safety analysis minimum DNBR bounds the new design limit DNBR values plus DNBR penalties, such as rod bow penalty. This will be completed prior to fuel load.*

<u>License Condition</u>

Part 10, License Condition 2, Item 4.4-2

The applicant provided a license condition in Part 10 of the BLN COL application, "Proposed Combined License Conditions," which will require the completion of the actions described in STD COL 4.4-2 prior to initial fuel load.

As reported in FSER Section 4.4 related to the DCD, expected instrument uncertainties are included in the methodology used by the applicant in calculating the design limit DNBR values. The final validation of the design limit DNBR values will be based on the actual uncertainties for instrumentations not yet procured. The quantification of instrument uncertainties includes activities that require procurement and installation of the instruments, including evaluation of changes in sensor design and location, and that can only be completed after installation of the instruments. Confirmation of instrument uncertainties after completion of the installation does not alter the methods of evaluation used to establish setpoints in the technical specifications, since the design limit DNBR values were based on the plant specifications for instrumentation uncertainties. The design limit DNBR values are expected to remain valid through plant procurement.

The NRC staff concluded in FSER Section 4.4 that the methodology for calculating the design limit DNBR values complied with the relevant regulatory requirements. The staff further concluded that it was acceptable to complete the *final verification of the design limit DNBR values when the as-built specifications are available.*

Therefore, the staff concludes that the supplemental information described in FSAR Section 4.4 meets COL Information Item 4.4-2 described in AP1000 DCD Subsection 4.4.7.2, complies with COL Action Item 4.4-1, and is acceptable.

The staff also finds the applicant's proposed license condition that will require completing this analysis prior to fuel load acceptable, since the applicant has committed to confirm that either the design limit DNBR values remain valid, or that the safety analysis minimum DNBR bounds the new design DNBR values plus DNBR penalties, such as rod bow penalty.

Conformance to Regulatory Guide 1.133, Revision 1

In BLN COL FSAR Section 1.9, "Compliance with Regulatory Criteria," Section 1.9.1, "Regulatory Guides," the applicant adds Appendix 1AA, which provides an evaluation of the degree of compliance with Division 1 regulatory guides (RGs) as applicable to the content of this FSAR, or to the site-specific design, construction and/or operational aspects, and Table 1.9-201, which identifies the appropriate regulatory guide to FSAR cross-reference. In Appendix 1AA, the applicant provides an evaluation of its loose-part detection program for compliance with RG 1.133, Revision 1, May 1981, "Loose Part Detection Program for the Primary System of Light-Water-Cooled Reactors." It states that conformance of the design aspects is as stated in the DCD. It also documents conformance with the programmatic and/or operational aspects described in paragraphs C.3a and C.6 of RG 1.133, Revision 1.

RG 1.133, Revision 1, describes a method acceptable to the NRC staff for implementing regulatory requirements with respect to detecting a potentially safety-related loose part in light-water-cooled reactors during normal operation. The AP1000 design includes a digital metal impact monitoring system, which is a non-safety-related system provided for monitoring the reactor coolant system for metallic loose parts. AP1000 DCD Section 4.4.6.4 documents the conformance of this monitoring system to RG 1.133. BLN COL FSAR Appendix 1AA documents its conformance to the design aspects described in DCD Section 4.4.6.4, and also states it conforms to Regulatory Position C.3a, regarding manual mode of data acquisition for detection of loose parts and Regulatory Position C.6, regarding notification to NRC of confirmation of the presence of a loose part.

The NRC staff noted that RG 1.133, Revision 1, was not included in Revision 1 of FSAR Table 1.9-201 for a cross-reference to the appropriate FSAR section, although an evaluation of compliance with RG 1.133 is provided in Appendix 1AA. In response to Request for Additional Information (RAI) 1-7, the applicant added RG 1.133, Revision 1, to Table 1.9-201, as part of Revision 1 to the FSAR. In addition, the response to RAI 1-7 was supplemented by adding a conformance discussion for regulatory guide positions related to the procedures and training program (positions 4g, 4h, 4i and 4j) in the proposed revision to BLN

*FSAR Appendix 1AA, "A Conformance with Regulatory Guides." The proposed change to BLN FSAR is acceptable subject to a formal revision to BLN FSAR. Accordingly, this is **Confirmatory Item 4.4-1**. With the conformance of the programmatic and operational aspects of regulatory positions, the staff concludes that the applicant's loose parts detection program will conform to RG 1.133, Revision 1.*

Resolution of Standard Content Confirmatory Item 4.4-1

The staff notes that RAI 1-11 was mistakenly identified as RAI 1-7 in the standard content SER as it relates to the conformance discussion for RG 1.133. The RAI number related to conformance is 1-11. The staff also notes that the BLN SER did not address Position C.6 of RG 1.133.

Confirmatory Item 4.4-1, as modified by the discussion above, is related to the applicant's conformance with the RG 1.133 Positions C.4g, 4h, 4i, 4j, and 6 as documented in Appendix 1AA of the VEGP COL FSAR. The staff's review of the VEGP COL FSAR indicates that the VEGP COL FSAR Appendix 1AA was updated to include all the information identified in the Confirmatory Item 4.4-1 except for Position C.6.

The response to RAI 1-11 included a conformance discussion for RG 1.133, Position C.6, "Notification of a Loose Part." Position C.6 refers to RG 1.16, "Reporting of Operating Information." The applicant took an exception to this position because this RG had been withdrawn. The staff considered this justification to be inadequate. Although the staff agreed it was no longer relevant to refer to RG 1.16, there remained a need to address reporting requirements. In response to this staff concern, the applicant proposed a revision to Appendix 1AA of its FSAR. In a letter dated January 8, 2010, the applicant stated that it would follow reporting requirements in accordance with requirements of 10 CFR 50.72 and 10 CFR 50.73 using guidance of NUREG-1022. The staff considers the applicant's position adequately addresses reporting requirements for loose part notification and therefore considers the exception acceptable. The staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 4.4-1 is now closed.

4.5 Post Combined License Activities

For the reasons discussed in the technical evaluation section above, the staff finds the following license condition proposed by the applicant acceptable:

- License Condition (4-1) – Before initial fuel load, the licensee shall calculate the instrumentation uncertainties of the actual plant operating instrumentation to confirm that either the design limit DNBR values remain valid or that the safety analysis minimum DNBR bounds the new design limit DNBR values plus DNBR penalties, such as rod bow penalty.

4.6 Conclusion

The NRC staff reviewed the application and checked the referenced DCD. The NRC staff's review confirmed that the applicant addressed the required information relating to the reactor internals, control rod drive and core support structural materials, fuel system design (fuel rods and fuel assemblies), the nuclear design, and the thermal-hydraulic design, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this chapter. The results of the NRC staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable. The staff based its conclusion on the following:

- STD COL 4.4-2 is acceptable because it specifies a commitment on the part of the applicant to confirm the validity of the calculations of the design limit DNBR values, which are based on the plant specifications for instrumentation uncertainties. The confirmation of plant instrument uncertainties will be completed when the as-built specifications are available. The methodology for this calculation was previously approved by the staff in NUREG-1793.

3 DESIGN OF STRUCTURES, COMPONENTS, EQUIPMENT AND SYSTEMS

3.1 Conformance to General Design Criteria

Section 3.1 of the William States Lee III Nuclear Station (WLS) combined license (COL) Final Safety Analysis Report (FSAR), Revision 11, incorporates by reference, Section 3.1, "Conformance with NRC General Design Criteria," of Revision 19 of the AP1000 Design Control Document (DCD). In addition, in the WLS COL FSAR, the applicant provided the following:

Departure

- WLS DEP 6.4-1

The applicant provided additional information about WLS DEP 6.4-1 in Section 3.1.2 of the FSAR related to design changes affecting habitability of the main control room and changes to the calculated doses to control room operators. This information, as well as related WLS DEP 6.4-1 information appearing in other chapters of the FSAR, is reviewed in Section 21.2 of this report.

The U.S. Nuclear Regulatory Commission (NRC) staff (the staff) reviewed the application and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this section.[1] The NRC staff's review confirmed that the applicant addressed the required information to satisfy the evaluation criteria. There is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the NRC staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. Section 21.2 of this report evaluates the departure from the DCD provided in WLS DEP 6.4-1.

3.2 Classification of Structures, Components, Equipment, and Systems

3.2.1 Seismic Classification

3.2.1.1 *Introduction*

Nuclear power plant structures, systems, and components (SSCs) important to safety are to be designed to withstand the effects of earthquakes without loss of capability to perform their safety functions. Important to safety SSCs are defined in Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, "Domestic licensing of production and utilization facilities," Appendix A, "General Design Criteria for Nuclear Power Plants," as those SSCs that provide reasonable assurance that the facility can be operated without undue risk to the health and safety of the

[1] See Section 1.2.2 for a discussion of the staff's review related to verification of the scope of information to be included in a COL application that references a design certification (DC).

public. Important to safety SSCs include safety-related SSCs that perform safety-related functions to ensure: (1) the integrity of the reactor coolant pressure boundary (RCPB); (2) the capability to shut down the reactor and maintain it in a safe-shutdown condition; and (3) the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures. The earthquake for which these safety-related plant features are designed is defined as the safe shutdown earthquake (SSE). The SSE is based on an evaluation of the maximum earthquake potential for the site and is an earthquake that produces the maximum vibratory ground motion for which SSCs are designed to remain functional. In a nuclear plant, there may be equipment, considered to be non-safety- related that do not have safety functions, however, they may enhance the ability of the plant to withstand or recover from off-normal conditions. For this equipment that are non-safety-related but said to have a risk-significant function, the regulatory treatment of non-safety systems (RTNSS) process is applied to define seismic requirements for those SSCs.

The methodology in the referenced AP1000 DCD is incorporated by reference in the WLS COL application and classifies SSCs into three seismic categories: Seismic Category I, Seismic Category II and Non-seismic (NS). Those plant features designed to remain functional, if an SSE occurs, are designated Seismic Category I. Seismic Category I applies to both functionality and integrity of equipment for an SSE event, and Seismic Category II applies only to integrity. If the failure of a NS SSC during an SSE could result in the loss of function of safety-related items, then they are designated as Seismic Category II. This methodology is similar to Regulatory Guide (RG) 1.29, “Seismic Design Classification,” Revision 4, except that RG 1.29 does not use the terms Seismic Category II and NS.

3.2.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.2, incorporates by reference AP1000 DCD, Revision 19, Section 3.2. In addition, in WLS COL FSAR Section 3.2, the applicant provided the following:

Departures

- WLS DEP 3.2-1

The applicant provided additional information about WLS DEP 3.2-1 in Section 3.2 of the FSAR related to design modifications to the condensate return portion of the Passive Core Cooling System. This information, as well as related WLS DEP 3.2-1 information appearing in other chapters of the FSAR, is reviewed in Section 21.1 of the SER.

Supplemental Information

- Standard (STD) Supplement (SUP) 3.2-1

The applicant provided supplemental information by adding text to the end of AP1000 DCD Section 3.2.1, “Seismic Classification,” which stated that there are no safety-related SSCs at WLS outside the scope of the AP1000 DCD. The applicant also stated that the non-safety-related SSCs outside the scope of the AP1000 DCD are classified as non-seismic (NS).

3.2.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the seismic classification are given in NUREG-0800, "Standard Review Plan [SRP] for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition," Section 3.2.1.

The regulatory basis for acceptance of the supplemental information of defining the scope of safety-related SSCs is established in 10 CFR Part 50, Appendix A, General Design Criteria (GDC) 2, "Design Bases for Protection Against Natural Phenomena," which requires that all SSCs that are important to safety be designed to withstand the effects of natural phenomena, including earthquakes and guidance on how to meet this requirement is in RG 1.29.

3.2.1.4 *Technical Evaluation*

The staff reviewed Section 3.2 of the WLS COL application and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to seismic classification. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application is documented in NUREG-1793 and its supplements.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the safety evaluation report (SER) for the Reference COL application (i.e., Vogtle Electric Generating Plant (VEGP) Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the WLS COL application, as applicable) resulting from requests for additional information (RAIs).

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the Bellefonte Nuclear Plant (BLN), Units 3 and 4 COL application.

The staff reviewed the following information in the WLS COL FSAR:

Supplemental Information

- STD SUP 3.2-1

The staff reviewed STD SUP 3.2-1, related to the seismic classification of safety-related SSCs included under WLS COL FSAR Section 3.2.1, which states that there are no safety-related SSCs outside the scope of the DCD. Therefore, the seismic classification is acceptable.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.2.1.4 and concludes that the seismic classification is acceptable:

> *Important to Safety SSCs*
>
> *GDC 2 states, in part, that SSCs important to safety shall be designed to withstand the effects of earthquakes. BLN COL FSAR Section 3.2.1 states there are no safety-related SSCs outside the scope of the DCD. In request for additional information (RAI) 3.2.1-1, the applicant was requested to clarify if there is any site-specific non-safety-related SSCs outside the scope of the DCD that are important to safety and, if so, identify the appropriate seismic classification of such SSCs. The applicant's response identified that there are no site-specific non-safety-related SSCs outside the scope of the DCD that are important to safety and that non-safety-related SSCs outside the scope of the DCD are classified as non-seismic. In Revision 1 of the BLN COL FSAR, the applicant added the statement that the non-safety-related SSCs outside the scope of the DCD are classified as non-seismic. The revised BLN COL FSAR is acceptable, and the staff's concern is closed. The staff based its conclusion on the applicant's response that there are no site-specific non-safety-related SSCs outside the DCD that are important to safety.*
>
> *Seismic Classification of Other Site-Specific SSCs*
>
> *Section 1.8 of the AP1000 DCD, Revision 16 identified certain site-specific SSCs that are outside the scope of the AP1000 standard plant, such as the circulating water system (CWS) and its heat sink, for which the COL applicant must provide site-specific information. The seismic classification of the CWS is not identified in DCD Table 3.2-3. Section 1.8 of BLN COL FSAR identifies certain COL items that represent interfaces for the standard design, but the seismic classification is not identified for the CWS.*
>
> *In RAI 3.2.1-2, the applicant was requested to clarify if there are any site-specific SSCs outside the scope of the DCD that are not included in DCD Tables 3.2-2 and 3.2-3 that are to be seismically classified in the COL. For example, site-specific structures, the CWS and miscellaneous items such as reactor vessel insulation are not included in the tables. If so, the applicant was requested to identify the appropriate seismic classification of such SSCs. This concern was also identified in an RAI for the review of AP1000 Revision 16 and the DC applicant clarified that the seismic categorization of CWS and reactor vessel insulation are not plant-specific and are to be classified in the DCD. Therefore, this concern is closed and seismic classification of these components is to be addressed in the DCD rather than the BLN COL FSAR.*

<u>Quality Assurance for Seismic Category II SSCs</u>

It is not clear in the BLN COL FSAR how Title 10 of the Code of Federal Regulations (CFR) 50, Appendix B is applied to seismic Category II SSCs, including those that may be site-specific. DCD Appendix 1A identifies that AP1000 conforms to RG 1.29, Regulatory Position C.4 and Section 1.8 identifies COL Information Item 17.5-1 for quality assurance (QA) in the design phase. DCD Section 17.5.2 identifies that the COL applicant will address its QA program and that the QA program will include provisions for seismic Category II SSCs. In RAI 3.2.1-4, the applicant was requested to clarify the extent that pertinent QA requirements of Appendix B to 10 CFR Part 50 in Regulatory Position C.4 of RG 1.29 apply to those activities affecting the safety-related functions of those portions of SSCs covered under Regulatory Positions 2 and 3 of RG 1.29, including any site-specific SSCs. If this issue will be resolved in the DCD rather than the COL for all plant SSCs, including those that are site-specific, the applicant was requested to advise the NRC staff that this was the case. The RAI response identified that there are no site-specific seismic Category II SSCs and that the application of 10 CFR Part 50, Appendix B is addressed by the DCD. Since there are no site-specific seismic Category II SSCs, this COL concern is closed for the BLN COL FSAR.

<u>Consistency with RG 1.29, Revision 4</u>

Section 3.2.1 of the BLN COL FSAR does not identify any departures relative to seismic classification identified in the DCD and BLN COL FSAR, Appendix 1AA identifies conformance with RG 1.29, Revision 3 as stated in the DCD rather than Revision 4 of RG 1.29, dated March 2007. In RAI 3.2.1-3, the applicant was requested to clarify if seismic classifications of site-specific SSCs are consistent with RG 1.29, Revision 4. The RAI response identified that seismic classification of site-specific SSCs not addressed in the DCD is consistent with RG 1.29, Revision 4. This position is acceptable to the staff, since it represents the current RG revision. The applicant revised Appendix 1AA in Revision 1 of the BLN COL FSAR to indicate conformance to RG 1.29, Revision 4.

3.2.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.2.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to seismic classification, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 50, Appendix A, and GDC 2. The staff based its conclusion on the following:

- WLS DEP 3.2-1, related to design modifications to the condensate return portion of the Passive Core Cooling System, is reviewed and found acceptable by the staff in Section 21.1 of this SER.

- STD SUP 3.2-1 is acceptable because the WLS COL FSAR states that there are no safety-related SSCs outside the scope of the AP1000 DCD. The WLS COL FSAR also states that the non-safety-related SSCs outside the scope of the DCD are classified as NS. Therefore, the requirements of 10 CFR Part 50, Appendix A, GDC 2, the acceptance criteria in NUREG-0800, Section 3.2.1, and the guidelines in RG 1.29 are satisfied.

3.2.2 Classification Systems

3.2.2.1 *Introduction*

The system and component quality group classification addresses, in part, the general design criterion that nuclear power plant SSCs that are important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed. Important to safety SSCs are defined in 10 CFR Part 50, Appendix A as those SSCs that provide reasonable assurance that the facility can be operated without undue risk to the health and safety of the public. Important to safety SSCs include safety-related SSCs that perform one of the following safety-related functions to ensure: (1) the integrity of the RCPB; (2) the capability to shut down the reactor and maintain it in a safe-shutdown condition; and (3) the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures. The RTNSS process is applied to define supplemental quality requirements for SSCs that are non-safety-related but perform risk significant functions.

The system and component quality group classification in combination with the RTNSS process define appropriate classifications, codes and standards and special treatment for important to safety pressure-retaining components and their supports, depending on their safety function. RG 1.26, “Quality Group Classification and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants,” Revision 4, provides the regulatory guidance for classifying SSCs important to safety and the appropriate quality standards.

3.2.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.2, incorporates by reference AP1000 DCD, Revision 19, Section 3.2. In addition, in WLS COL FSAR Section 3.2, the applicant provided the following:

Supplemental Information

- STD SUP 3.2-1

The applicant provided supplemental information by adding text to the end of AP1000 DCD Section 3.2.2, “AP1000 Classification System,” and stated that there are no safety-related SSCs at WLS outside the scope of the AP1000 DCD.

3.2.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the system quality group classification are given in NUREG-0800, Section 3.2.2.

The basis for acceptance is established in RG 1.26, "Quality Group Classification and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants," Revision 4, and applicable American Society of Mechanical Engineers (ASME) Codes and industry standards. RG 1.26 provides regulatory guidance for classifying SSCs important to safety and applying the appropriate quality standards. Conformance to the guidance contained in RG 1.26 is one way to ensure that component quality will be commensurate with the importance of the safety functions of these systems. Thus, this constitutes the basis for satisfying GDC 1, "Quality Standards and Records" for pressure-retaining components and their supports.

3.2.2.4 *Technical Evaluation*

The staff reviewed Section 3.2 of the WLS COL application and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic. The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the system quality group classification. The results of the staff's evaluation of the information incorporated by reference in the WLS application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the COL FSAR.
- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 application.

The staff reviewed the following information in the WLS COL FSAR:

Supplemental Information

- STD SUP 3.2-1

The staff reviewed STD SUP 3.2-1 related to the seismic classification of safety-related SSCs included under WLS COL FSAR Section 3.2.2, which states that there are no safety-related SSCs outside the scope of the AP1000 DCD at WLS.

The staff reviewed STD SUP 3.2-1 related to quality group classification of systems included under WLS COL FSAR Section 3.2.2. The staff notes that STD SUP 3.2-1 is identical to STD SUP 3.2-1 in the BLN FSAR with respect to quality group classification of systems included under WLS COL FSAR Section 3.2.2. The staff noted that additional information was needed to evaluate BLN STD SUP 3.2-1 resulting in RAIs being issued to the BLN COL applicant. The WLS COL applicant endorsed the BLN RAI response in a February 5, 2009, letter. As such, the staff's review of STD SUP 3.2-1 is addressed through the comparison with the BLN SER. As discussed below, there are no site-specific non-safety-related SSCs outside the scope of the AP1000 DCD that are important to safety, so there are no changes to the quality group classifications listed in WLS COL FSAR Section 3.2.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.2.2.4:

> *Special Treatment for Risk-Significant SSCs*
>
> *GDC 1 identifies, in part, that SSCs important to safety shall be designed, fabricated, erected and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be supplemented or modified as necessary to assure a quality product in keeping with the required safety function. Supplemental quality standards and QA programs applicable to passive SSCs used in non-safety-related regulatory treatment of non-safety systems that may be important to safety are not clearly defined in the BLN COL FSAR for site-specific SSCs.*
>
> *In RAI 3.2.2-2, the applicant was requested to clarify what supplemental quality standards are applied to non-safety-related site-specific SSCs that are important to safety to ensure that all SSCs important to safety are designed, fabricated, erected, and tested to quality standards commensurate with the safety function to be performed. Any site-specific SSCs that are considered important to safety may also require special treatment, but the response to RAI 3.2.1-1 identified that there are no site-specific non-safety-related SSCs outside the scope of the DCD that are important to safety. Therefore, this concern is closed.*
>
> *Codes and Standards*
>
> *The Staff Requirements Memorandum (SRM), dated July 21, 1993, concerning SECY-93-087 identified that the staff will review passive plant design applications using the newest codes and standards endorsed by the NRC and unapproved revisions to the codes will be reviewed on a case by case basis. Editions of*

various codes and standards referenced in DCD Section 3.2.6 are not current and newer codes and standards are not referenced in BLN COL FSAR Sections 3.2 or 1.8. In RAI 3.2.2-3, the applicant was requested to clarify if any different or current codes and standards are applied to the design and procurement of site-specific SSCs, other than those identified in the DCD. The RAI response identified that the applicant intends to implement the DCD identified codes and standards and that the codes and standards applied to the design and procurement of non-safety-related site-specific SSCs are those identified in various sections of the BLN COL FSAR. Although codes and standards for site-specific SSCs would be expected to be identified and reviewed in the COL application rather than the DCD, the response to RAI 3.2.1-1 identified that there are no site-specific non-safety-related SSCs outside the scope of the DCD that are important to safety. Therefore, this concern is closed.

Consistency with RG 1.26, Revision 4

Section 3.2.2 of the BLN COL FSAR does not identify any departures relative to quality group classification identified in the DCD and BLN COL FSAR, Appendix 1AA identifies conformance with RG 1.26, Revision 3 in the DCD rather than Revision 4, dated March 2007. In RAI 3.2.2-1, the applicant was requested to clarify if quality group classifications of site-specific SSCs are consistent with RG 1.26, Revision 4. The applicant's response clarified that the quality group classification of site-specific SSCs is consistent with RG 1.26, Revision 4. This position is acceptable to the staff, since it represents the current RG revision. This staff concern is closed and the BLN COL FSAR Appendix 1AA has been revised accordingly to reflect this RAI response.

3.2.2.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.2.2.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the system quality group classification, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 50, Appendix A, GDC 1. The staff based its conclusion on the following:

- STD SUP 3.2-1 is acceptable with regard to quality group classifications because no change was made to the quality group classifications in AP1000 DCD Section 3.2 and there are no site-specific non-safety-related SSCs outside the scope of the AP1000 DCD that are important to safety. Therefore, the staff finds that the requirements of 10 CFR Part 50, Appendix A, GDC 1, the acceptance criteria in NUREG-0800, Section 3.2.2, and the guidelines in RG 1.26 are satisfied.

3.3 Wind and Tornado Loadings

Seismic Category I and II buildings and structures are designed to withstand extreme wind and tornado loading conditions in compliance with the requirements in GDC 2 in Appendix A to 10 CFR Part 50 that states SSCs that are important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. The design bases for these structures shall reflect the appropriate consideration of the most severe of the natural phenomena that have been historically reported in the area of the plant, with sufficient margin to account for limited accuracy, quantity, and period of time for collection of data. In this section of the report, the staff reviewed the Seismic Category I and II structures subjected to wind and tornado loadings. Other natural phenomena effects, such as earthquakes, floods, tsunami, and seiches, are evaluated in Sections 3.4, 3.7 and 3.8 of this report.

3.3.1 Wind Loadings

3.3.1.1 *Introduction*

Seismic Category I structures must withstand the effects of the specified design wind speed for the plant to ensure conformance with 10 CFR Part 50, Appendix A, GDC 2. The specific areas of review are the design wind speed, its recurrence interval, speed variation with height, and applicable dust factors from the standpoint of use in defining the input parameters for the appropriate structural design criteria for wind loading. The staff also reviews the procedures that are used to transform the design wind speed into an equivalent pressure applied to structures taking into consideration the geometrical configuration and physical characteristics of the structures and the distribution of wind pressure on the structures.

3.3.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.3, incorporates by reference AP1000 DCD, Revision 19. In WLS COL FSAR Section 3.3.1, the applicant provided the following:

<u>AP1000 COL Information Items</u>

- WLS COL 3.3-1

The applicant provided information in WLS COL FSAR Section 3.3.1.1, “Design Wind Velocity,” to address COL Information Item 3.3-1 stating that the wind velocity characteristics for the WLS site are given in WLS COL FSAR Section 2.3.1.2.8. The applicant stated that these values are bounded by the design wind velocities specified in AP1000 DCD Section 3.3.1.1 for the standard AP1000 plant design. In addition, the applicant stated, in part, that the effects of wind on the safety-related SSCs due to failures in an adjacent AP1000 plant are bounded by the evaluation of the buildings and structures in a single unit. The portion of WLS COL 3.3-1 relating to tornado loadings is reviewed in Section 3.3.2 of this report.

3.3.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for wind loadings are given in NUREG-0800, Section 3.3.1.

The regulatory basis for WLS COL 3.3-1 is 10 CFR Part 50, Appendix A, GDC 2, that states SSCs that are important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornados, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions and related regulatory guidance in RG 1.76, “Design-Basis Tornado and Tornado Missiles for Nuclear Power Plants,” Revision 1.

3.3.1.4 *Technical Evaluation*

The staff reviewed WLS COL Section 3.3 and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to wind loadings. The results of the staff’s evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 3.3-1

The staff reviewed WLS COL 3.3-1 related to design wind loads applied on safety-related SSCs included under WLS COL FSAR Section 3.3.1.1. The application states in WLS COL 3.3-1 that the wind velocity characteristics for WLS are given in WLS COL FSAR Section 2.3.1.2.8. The COL states that these values are bounded by the DCD design wind velocity values for the standard AP1000 plant.

In Section 2.3.1.4 of this report, the staff concluded that a site characteristic 3-second gust basic wind speed value of 43 meters per second (m/s) (96 miles per hour (mph)) is an acceptable wind speed for this site. Since this value is bounded by the AP1000 design wind speed of 62.8 m/s (145 mph), the staff concludes that the design wind velocities for the WLS site comply with GDC 2 and are acceptable; therefore, WLS COL 3.3-1 is resolved.

3.3.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.3.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff’s review confirmed that the applicant addressed the required information relating to wind loadings, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of GDC 2.

- WLS COL 3.3-1, as it relates to design wind loads, is acceptable based on the site-specific wind velocities, reviewed in Section 2.3 of this report, being bounded by the AP1000 DCD design wind velocities and, therefore, complies with GDC 2.

3.3.2 Tornado Loading

3.3.2.1 *Introduction*

Tornado loadings are considered for design in accordance with AP1000 DCD Section 3.3.2, "Tornado Loadings." AP1000 DCD Section 3.3.2 addresses tornado loadings for Seismic Category I structures using applicable tornado design parameters to determine forces on structures as explained in AP1000 DCD Section 3.3.1.2. Also AP1000 DCD Section 3.3.2.1 states that the estimated probability of tornado wind speeds to be greater than the design basis tornado is between $10E^{-6}$ and $10E^{-7}$ per year at a "worst location" anywhere within the contiguous United States. The WLS COL FSAR discusses and supplements the AP1000 DCD in Sections 3.3.2.1, "Applicable Design Parameters," and 3.3.2.3, "Effect of Failure of Structures or Components Not Designed for Tornado Loads."

3.3.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.3, incorporates by reference AP1000 DCD, Revision 19. In WLS COL FSAR Section 3.3.2, the applicant provided the following:

AP1000 COL Information Items

- WLS COL 3.3-1

The applicant provided information in WLS COL FSAR to resolve COL Information Item 3.3-1. In WLS COL 3.3-1, the applicant stated in WLS COL FSAR Section 3.3.2.1 that tornado characteristics for WLS, given in WLS COL FSAR Section 2.3.1.2.2, are bounded by the tornado design parameters given in AP1000 DCD Section 3.3.2.1 for the standard AP1000 plant. In addition, the applicant stated that the effects of wind and tornado on the safety-related SSCs due to failures in an adjacent AP1000 plant are bounded by the evaluation of the buildings and structures in a single unit. The portion of WLS COL 3.3-1 relating to design wind velocity characteristics is reviewed in Section 3.3.1 of this report.

- STD COL 3.3-1

The information provided in WLS COL FSAR Section 3.3.2.3 to address STD COL 3.3-1 states that the effects of wind and tornado on the safety-related SSCs due to failures in an adjacent AP1000 plant are bounded by the evaluation of the buildings and structures in a single plant.

3.3.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for tornado loading are given in NUREG-0800, Section 3.3.2. Acceptance of WLS COL 3.3-1 is established based on site-specific parameters and verification of bounding conditions for relevant parameters related to the AP1000 DCD interface criteria for tornado, site arrangement, and building construction. The design of AP1000 safety-related SSCs for tornado loads must meet the requirements of 10 CFR Part 50, Appendix A, GDC 2 that states SSCs important to safety shall be designed to withstand the effects of natural phenomena, such as earthquakes, tornados, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions.

3.3.2.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 3.3.2 and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to tornado loading. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 3.3-1

The staff reviewed WLS COL 3.3-1 included under WLS COL FSAR Sections 3.3.2 and 3.5.1. Specific information provided by the applicant includes development of site-specific parameters and verification of bounding conditions, site arrangement and building construction. In WLS COL 3.3-1, the applicant stated that the tornado characteristics for WLS, given in WLS COL FSAR Section 2.3.1.2.2, are bounded by the tornado design parameters given in AP1000 DCD Section 3.3.2.1 for the standard AP1000 plant design. In addition, the applicant stated that the effects of wind and tornado on the safety-related SSCs due to failures in an adjacent AP1000 plant are bounded by the evaluation of the buildings and structures in a single unit. In Section 2.3.1 of this report, the staff concluded that tornado site characteristics chosen by the applicant were acceptable. Since these values match the design tornado site characteristics included in the AP1000 DCD, the staff concludes that the design tornado site characteristics for the WLS site comply with GDC 2.

The scope of WLS COL 3.3-1 also includes the effects of wind and tornado on the safety-related SSCs due to failure of non-safety-related buildings in an adjacent AP1000 plant and WLS. The applicant stated that these effects are bounded by the evaluation of the buildings and structures in a single unit. To assure the failure of structures or components not designed for wind or tornado loadings does not affect the capability of safety-related SSCs to perform their intended safety functions, the COL applicants had the following three options in AP1000 DCD Section 3.3.2.3.

1. design the adjacent non-safety-related structure to the design basis tornado loading

2. analyze the effect of failure of adjacent non-safety-related structures on nuclear island (NI) structures to ensure that no impairment of safety function will result

3. design a structural barrier to protect Seismic Category I SSCs from adjacent structural collapse

The applicant used Option 2 for WLS COL 3.3-1, indicating that the effects of wind and tornado on the safety-related SSCs due to failure of an adjacent non-safety-related building are bounded by the evaluation of the structures in a single unit at WLS. The analysis of the impact of building collapse on the nuclear island (NI) structures is in AP1000 DCD Section 3.7.2.8 and the staff's review of this analysis is provided in NUREG-1793 and its supplements. Based on the above discussion, the staff finds WLS COL 3.3-1 acceptable and resolved.

- STD COL 3.3-1

COL standard information item STD COL 3.3-1 addresses the effect of failure of SSCs not designed for tornado loadings in WLS COL FSAR Section 3.3.2.3. COL standard information item STD COL 3.3-1 involves consideration of a tornado-initiated failure of site-specific structures and components whose failure could compromise the safety of AP1000 safety-related structures and components at WLS site.

The staff reviewed the resolution to the COL Information Item STD COL 3.3-1 relating to the effect of failure of SSCs not designed for tornado loadings included under WLS COL FSAR Section 3.3.2.3. To ensure the failure of structures or components not designed for wind or tornado loadings does not affect the capability of safety-related SSCs to perform their intended safety functions, the COL applicants were offered three options in AP1000 DCD Section 3.3.2.3:

1. design the adjacent non-safety-related structure to the design basis tornado loading

2. analyze the effect of failure of adjacent non-safety-related structures on nuclear island (NI) structures to assure that no impairment of safety function will result

3. design a structural barrier to protect Seismic Category I SSCs from adjacent structural collapse

In STD COL 3.3-1, the applicant used Option 2. Since the applicant has not placed any additional structures adjacent to the standard unit, the original analysis done in AP1000 DCD Section 3.7.2.8 is still valid. The staff's review of this analysis is provided in NUREG-1793 and its supplements. Based on the above discussion, the staff consider STD COL 3.3-1 resolved.

3.3.2.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.3.2.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff’s review confirmed that the applicant addressed the required information relating to tornado loading, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff concludes that the relevant information presented in the WLS COL FSAR Section 3.3.2 is acceptable and meets the requirements of 10 CFR Part 50, Appendix A, GDC 2.

- WLS COL 3.3-1, as it relates to design tornado loads, is acceptable based on the design tornado site characteristics, reviewed in Section 2.3 of this report, matching the AP1000 DCD design tornado site characteristics and, therefore, complying with GDC 2. WLS COL 3.3-1, as it relates to the effects of wind and tornado on the safety-related SSCs due to failure of non-safety-related buildings in an adjacent AP1000 plant and WLS is acceptable because the applicant incorporated by reference acceptable methodology from AP1000 DCD Section 3.7.2.8.

- STD COL 3.3-1, as it relates to the effects of wind and tornado on the safety-related SSCs due to failure of non-safety-related buildings in an adjacent AP1000 plant is acceptable because the applicant incorporated by reference an acceptable assessment methodology from AP1000 DCD Section 3.7.2.8.

3.4 Water Level (Flood) Design

3.4.1 Flood Protection

3.4.1.1 *Introduction*

Seismic Category I SSCs have flood protection measures for both external flooding and postulated internal flooding from plant component failures.

3.4.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.4 incorporates by reference AP1000 DCD, Revision 19, Section 3.4. In WLS COL FSAR Section 3.4, the applicant provided the following:

AP1000 COL Information Item

- WLS COL 3.4-1

The applicant provided information to resolve COL Information Item 3.4-1, which addresses plant-specific information on site-specific flooding hazards protective measures. That information, for WLS COL 3.4-1, in WLS COL FSAR Section 3.4.1.3, “Permanent Dewatering System,” and WLS COL FSAR Section 3.4.3, “Combined License Information,” states that no permanent dewatering system is required because site groundwater levels are 0.6 meters (m) (2 feet (ft) or more below site grade level and the site-specific water levels satisfy the interface requirements identified in AP1000 DCD Section 2.4, respectively.

3.4.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The regulatory acceptance criteria associated with the relevant requirements of NRC regulations for flood protection measures are given in NUREG-0800, Section 3.4.1. The acceptance criteria associated with the relevant requirements of NRC regulations for the identification of floods and flood design considerations are given in NUREG-0800, Section 2.4.12.

3.4.1.4 *Technical Evaluation*

The staff reviewed this application and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to flood protection measures. The results of the staff’s evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff reviewed the following information in the WLS COL FSAR:

AP1000 COL Information Item

- WLS COL 3.4-1

The staff reviewed WLS COL 3.4-1 addressing the permanent dewatering system and site-specific water levels in WLS COL FSAR Sections 3.4.1.3 and 3.4.3, respectively. This site-specific COL item states that the COL applicant will demonstrate that the site satisfies the interface requirements as described in Section 2.4. If these criteria cannot be satisfied because of site-specific flooding hazards, the applicant may propose protective measures as discussed in Section 2.4. In WLS COL FSAR Section 3.4, the applicant provided the following plant-specific information:

- WLS COL FSAR Section 3.4.1.3, “Permanent Dewatering System,” states that no permanent dewatering system is required because site groundwater levels are 0.6 m (2 ft) or more below site grade level as described in WLS COL FSAR Section 2.4.12.5.

- WLS COL FSAR Section 3.4.3, “Combined License Information,” states that the site-specific water levels given in WLS COL FSAR Section 2.4 satisfy the interface requirements identified in AP1000 DCD Section 2.4.

In Section 2.4.12 of this report, the staff accepted the WLS applicant's position that no permanent dewatering system is required and that the site-specific groundwater characteristics for the WLS site fall within the Tier 1 and Tier 2 AP1000 DCD parameter values. Therefore, the staff concludes that the site-specific information in WLS COL 3.4-1 is acceptable.

3.4.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.4.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff’s review confirmed that the applicant addressed the required information relating to flood protection measures, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the regulatory guidance in NUREG 0800, Sections 2.4.12 and 3.4.1. :

- WLS COL 3.4-1, is acceptable based the staff’s conclusions in NUREG-1793 regarding the need for a permanent dewatering system and on the staff’s conclusions in Section 2.4.12 of this report that no permanent dewatering system is required and that the site-specific groundwater characteristics for the WLS site fall within the Tier 1 and Tier 2 AP1000 DCD groundwater parameter values.

3.4.2 Analytical and Test Procedures

Analysis methods and test procedures are described for the design of AP1000 standard plants to assess the maximum water levels due to internal flooding caused by equipment failure or external flooding caused by natural phenomena and make sure that they do not jeopardize the safety of the plant or the ability to achieve and maintain safe shutdown conditions. WLS COL FSAR, Revision 11, Section 3.4 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 3.4.2, “Analytical and Test Procedures.” AP1000 DCD Section 3.4.2 states that the analytical approach for external and internal flooding events is described in AP1000 DCD Section 3.4.1.2, “Evaluation of Flooding Events.” The staff reviewed the application and checked the referenced AP1000 DCD to ensure that no issue relating to this section remained for review.[1] The staff’s review confirmed that there is no outstanding issue related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.5 Missile Protection

Seismic Category I structures are analyzed and designed to be protected from a wide spectrum of missiles (e.g., missiles from rotating and pressurized equipment, gravitational missiles, and missiles generated from tornado winds). When a missile hazard is identified, its statistical significance is determined (a missile is significant when it could cause unacceptable consequences or violate the guidelines of 10 CFR Part 100, “Reactor Site Criteria”).

3.5.1 Missile Selection and Description

3.5.1.1 *Introduction*

The design credits safety-related structures, systems, and components to establish and maintain safe shutdown conditions following a postulated event such as internally generated missiles. The SSCs needed to bring the plant to safe shutdown, including the main control room and the recirculating service water system are located inside the auxiliary building and containment shield building, respectively. Both the auxiliary and containment shield buildings are Seismic Category I NI structures having thick structural concrete walls that provide internal and external missile protection. The missiles generated outside containment by rotating or pressurized (high-energy fluid system) equipment are included. Aircraft hazards and missiles generated by human activities offsite as well as those generated by weather are also considered. SSCs considered “important to safety” are protected against internally generated missiles (outside containment), in accordance with NUREG-0800, Section 3.5.1.1.

3.5.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.5, “Missile Protection,” incorporates by reference AP1000 DCD, Revision 19, with site-specific information and supplements. WLS COL FSAR Section 3.5.1, “Missile Selection and Description,” which includes Sections 3.5.1.1, “Internally Generated Missiles (Outside Containment)”; 3.5.1.2, “Internally Generated Missiles (Inside Containment)”; 3.5.1.3, “Turbine Missiles”; 3.5.1.4, “Missiles Generated by Natural Phenomena”; 3.5.1.5,” Missiles Generated by Events Near the Site”; and 3.5.1.6, “Aircraft Hazards.” In WLS COL FSAR Section 3.5, the applicant provided the following:

AP1000 COL Information Item

- WLS COL 3.5-1

The applicant provided information in the WLS COL FSAR to resolve WLS COL 3.5-1. WLS COL FSAR Section 3.5.1.5, "Missiles Generated by Events Near the Site," states that certain buildings, such as the gate house, administrative building water service building, et al., at the WLS site are common structures located at a nuclear power plant. Therefore, any missiles resulting from a tornado-initiated failure of those common structures are not more energetic than tornado missiles postulated for design of the AP1000. Furthermore, the WLS COL FSAR states that the missiles generated by events near the site are evaluated in accordance with WLS COL FSAR Section 2.2.3. With regard to WLS COL 2.5-1, WLS COL FSAR Section 3.5.1.6, "Aircraft Hazards," states that the approach and methodology from NUREG-0800, Section 3.5.1.6 has been used to calculate the probability of an aircraft crash into areas of safety-related structures. Descriptions of Airports and Airways are addressed in WLS COL FSAR Section 2.2.2.7 and aircraft hazards are evaluated in WLS COL FSAR Section 3.5.1.6.

Supplemental Information

- STD SUP 3.5-1

The applicant provided information in WLS COL FSAR Section 3.5.1.3, "Turbine Missiles," to address STD SUP 3.5-1. This supplemental information states that the potential for a turbine missile from another AP1000 plant in close proximity has been considered for WLS in accordance with RG 1.115, "Protection Against Low-Trajectory Turbine Missiles," Revision 1. The WLS COL FSAR also states that in addition to low potential for turbine missile strike, the design of safety-related structures such as the shield building provide additional protection for safety-related SSCs from this event.

- STD SUP 3.5-2

The applicant provided supplemental information WLS COL FSAR Section 3.5.1.3, "Turbine Missiles," by stating that the turbine system maintenance and inspection program is discussed in WLS COL FSAR Section 10.2.3.6.

3.5.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," September 2004, and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for missile selection and description are given in NUREG-0800, Sections 3.5.1.1 through 3.5.1.6.

The design of safety-related structures for protection against missiles using acceptable procedures must meet the requirements of 10 CFR Part 50, Appendix A, GDC 2.
10 CFR 100.21(e), "Non-seismic site criteria," provides regulatory requirements for potential hazards associated with nearby transportation routes, industrial and military facilities. The regulatory basis for acceptance of WLS COL 3.5-1 is that the applicant developed sufficient site-specific parameters and verification of bounding conditions compared to the AP1000 DCD interface criteria for missile generation, site arrangement, and building construction. Additional regulatory guidance related to the review in this report is contained in RG 1.76 on design-basis

tornado and tornado missiles, RG 1.91 on evaluation of explosions postulated to occur on transportation routes, RG 1.115, Sections C.1 and C.3, on protection against low trajectory turbine missiles, and RG 1.117, Regulatory Positions C.1 through C.3 on tornado design classification.

3.5.1.4 *Technical Evaluation*

The staff reviewed this application and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the WLS COL application and incorporated by reference addresses the required information relating to missile protection of safety-related SSCs. The staff's evaluation of the information incorporated by reference in the WLS COL application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the Reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews.

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting responses to from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the COL FSAR.

- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusions.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application. The staff reviewed the information in the WLS COL FSAR:

AP1000 COL Information Items

- WLS COL 3.5-1

The staff reviewed information related to missiles generated near the site included under WLS COL FSAR Section 3.5.1.5 related to missiles generated by events near the site included under WLS COL FSAR Section 3.5.1.5. The applicant provided site-specific information to resolve the COL information items stating that the effects of explosions have been evaluated and it has been determined that the over pressure criteria of RG 1.91 is not exceeded. Since the staff did not identify any over pressure criteria, no further evaluation of postulated missiles is required as the effect of postulated missiles will be less than those associated with the over-pressure levels considered in RG 1.91.

WLS COL FSAR Section 3.5.1.6, “Aircraft Hazards,” states that based on the description of nearby aircraft handling facilities and air routes in WLS COL FSAR Section 2.2.2.7, and the methodology outlined in NUREG-0800, “Standard Review Plan,” Section 3.5.1.6, “Aircraft Hazards,” the applicant concludes that it can be qualitatively shown that the total aircraft crash hazard probability of for WLS is much lower than was conservatively calculated to be 1.8×10^{-7}/year. Therefore, the applicant concludes the aircraft hazards pose no undue risk to the health and safety of the public.

The applicant evaluated potential aircraft hazards and effects on safety-related structures following the approach and methodology outline in NUREG-0800 Section 3.5.1.6, “Aircraft Hazards.” and determined the effects of an aircraft crash on safety-related structures in the site. The probability of aircraft accidents resulting in radiological consequences that may exceed the 10 CFR Part 100 radiological dose requirements was evaluated by the applicant based on its one Federal airway that passes within 6.4 km (4 mi) of the plant. Low altitude Airway V54 runs between Spartanburg Downtown Memorial Airport (SPA) (located 42 km (26.1 mi) from WLS) and Charlotte/Douglas International Airport (CLT). CLT is located 55 km (34.4 mi) from WLS. Information was provided regarding the number of flights using this airway V54. No airports having flights more than $500D^2$ per year located within 16 km (10 mi) of WLS. There are no military training routes within 16 km (10 mi) of the site.

The staff performed independent confirmatory probability calculations using the most conservative total highest annual flight data within 9 km (5 mi) of the plant obtained from the Federal Aviation Administration (FAA) covering the 5-year period from 2004-2008 and applying to Airway V54. Based on using this FAA annual flight data for the year 2007 conservatively, the staff also concluded the total aircraft accident probability of about 1.8×10^{-7} per year, which is less than the acceptance criteria of 10^{-6} per year in NUREG-0800, Section 3.5.1.6.

On the basis of the confirmatory analysis and the review of the applicant’s assumptions and data used for the estimation of aircraft accident probability, the staff concludes that the operation of the WLS in the vicinity of the CLT does not present an undue risk to the health and safety of the public and meets the relevant requirements of 10 CFR Part 100 and 10 CFR 100.10 (or 10 CFR 100.20, as appropriate) and meets the acceptance criteria provided in NUREG-0800, Sections 3.5.1.5 and 3.5.1.6. This conclusion is based on information provided in the WLS COL FSAR and the staff’s independent verification of the applicant’s assessment of aircraft hazards at the site that resulted in a probability on the order of magnitude of 10^{-7} per year for an accident having radiological consequences worse than the exposure guidelines of 10 CFR Part 100.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.5.1.4:

Supplemental Information

- *STD SUP 3.5-1*

The NRC staff reviewed the standard supplementary information (STD SUP 3.5-1) on the probability of turbine missiles from another AP1000 plant in close proximity affecting SSCs. The applicant proposes to add to the AP1000 DCD, Section 3.5.1.3, a statement that the potential for a turbine missile from another AP1000 plant in close proximity is less than 1×10^{-5} per year, and *that the reinforced concrete shield building and auxiliary building walls, roofs, and floors satisfies the guidance of RG 1.115 for two AP1000 plants side-by-side.*

It should be noted that AP1000 DCD, Section 1.2.2 refers to Figure 1.2 2 of the AP1000 DCD for the building structure orientation with respect to the turbine building and the nuclear island. Figure 1.2 2 illustrates the AP1000 plant as a single unit. Section 1.2.1.3.1 of the AP1000 DCD also states that the turbine orientation minimizes potential interaction between turbine missiles and safety-related structures and components. In addition, Section 3.5.1.3 of the AP1000 DCD states that the turbine generator is located north of the nuclear island with its shaft oriented north-south so that safety-related systems are located outside the high-velocity, low trajectory missile strike zone. With this information, the AP1000 design is considered to favorably orient the turbine building with respect to safety-related SSCs as defined in RG 1.115. However, since BLN Units 3 and 4 will be side-by-side, the staff notes that each turbine generator may not be oriented favorably with respect to the other plant's safety-related SSCs (i.e., BLN Unit 3 turbine generator not favorably orientated to BLN Unit 4 safety-related SSCs, and vice versa).

In Revision 1 of the BLN COL FSAR, the applicant revised STD SUP 3.5-1 to state that when two or more AP1000 units are situated side-by-side, the turbine generators are orientated unfavorably with respect to the other nuclear island which contains safety-related SSCs. The BLN site has two AP1000 units situated side-by-side. Therefore, the staff notes that to meet the guidance of RG 1.115 and Section 3.5.1.3 of NUREG-0800, for an unfavorable turbine generator orientation, the probability of generating a turbine missile must be equal to or less than $1x10^{-5}$ *per year. As stated in the BLN COL FSAR, Section 3.5.1.3, the probability of generating a missile for the AP1000 turbine generator is less than* $1x10^{-5}$ *per year as calculated in the applicable bounding turbine missile analysis topical report referenced in the AP1000 DCD, Sections 3.5.1.3 and 10.2.8. The staff has not completed its review of the DCD with respect to this issue. Therefore, the staff is unable to make final determination. This is Open Item 1-1.*

- *STD SUP 3.5-2*

STD SUP 3.5-2 to BLN COL, Section 3.5.1.3 states, "The turbine system maintenance and inspection program is discussed in Section 10.2.3.6." This statement refers to Section 10.2.3.6 of the BLN COL, for information concerning the turbine maintenance and inspection program. The staff's review of the turbine maintenance and inspection program is included in Section 10.2.3 [sic 10.2] *of this SER.*

Resolution of the Standard Content Evaluation Concerning Open Item 1-1 for Turbine Missiles

The NRC staff identified a statement in the text reproduced above from Section 3.5.1.4 of the BLN SER that requires clarification for the VEGP COL application. The BLN SER states that the review of the AP1000 DCD with respect to the probability of generating a turbine missile was not completed and, *therefore, identified it as Open Item 1-1. The results of the NRC staff's technical evaluation of the AP1000 DC amendment application are documented in NUREG-1793 and its supplements, and include the final staff conclusions on the issue of probability of a missile striking a safety-related component.*

The NRC staff identified a statement in the text reproduced above from Section 3.5.1.4 of the BLN SER that requires clarification for the VEGP COL application. The BLN SER states that the review of the AP1000 DCD with respect to the probability of generating a turbine missile was not completed and, therefore, identified it as Open Item 1-1. The results of the NRC staff's technical evaluation of the AP1000 DC amendment application are documented in NUREG-1793 and its supplements, and include the final staff conclusions on the issue of probability of a missile striking a safety-related component.

3.5.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.5.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the WLS COL applicant addressed the required information relating to missile protection, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the regulatory guidance in NUREG-0800, Sections 3.5.1.1 through 3.5.1.6.

- WLS COL 3.5-1 is acceptable because it meets the regulatory requirements by meeting the acceptance criteria provided in NUREG-0800, Sections 3.5.1.5 and 3.5.1.6.

- STD SUP 3.5-1 is acceptable because the turbine missile evaluation for co-located AP1000 units meets the guidance of NUREG-0800 Section 3.5.1.3; therefore, it ensures that the requirements of 10 CFR Part 50, Appendix A, GDC 4, "Environmental and Dynamic Effects Design Bases," are met for protecting safety-related SSCs against the effects of turbine missiles.

- STD SUP 3.5-2 provides information on the turbine maintenance and inspection program. The staff's review of, and conclusions on, the turbine maintenance and inspection program is included in Section 10.2 of this report.

3.5.2 Protection from Externally Generated Missiles

Systems required for safe shutdown are protected from the effects of missiles. Protection of SSCs from external missiles, including those generated by natural phenomena, is generally provided by the external walls and roof of the Seismic Category I NI structures. The external walls and roofs are generally reinforced concrete. The structural design requirements for the shield building and auxiliary building are outlined in AP1000 DCD Section 3.8.4. Where openings through these walls are provided, they are evaluated on a case-by-case basis to demonstrate that a missile passing through the opening would not prevent safe shutdown and would not result in an offsite release exceeding the limits defined in 10 CFR Part 100.

WLS COL FSAR, Revision 11, Section 3.5, incorporates by reference AP1000 DCD, Revision 19, Section 3.5.2, "Protection from Externally Generated Missiles," without any departures or supplements. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.5.3 Barrier Design Procedures

Missile barriers and protective structures are designed to withstand and absorb missile impact loads to prevent damage to safety-related systems or components. Formulae used for missile penetration calculations into steel or concrete barriers are the Modified National Defense Research Committee formula for concrete and either the Ballistic Research Laboratory or Stanford formulae for steel as documented in AP1000 DCD Section 3.5.3.

WLS COL FSAR, Revision 11, Section 3.5, incorporates by reference AP1000, Revision 19, Section 3.5.3, "Barrier Design Procedures," without any departures or supplements. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.6 Protection against Dynamic Effects Associated with the Postulated Rupture of Piping

3.6.1 Introduction

The design basis and criteria are described to demonstrate that safety-related systems are protected from pipe ruptures. This section also evaluates design bases for locating postulated breaks and cracks in high- and moderate-energy piping systems inside and outside the containment; the procedures used to define the jet thrust reaction at the break location; the procedures used to define the jet impingement loading on adjacent essential SSCs; pipe whip restraint design; and the protective assembly design. Pipe breaks in several high-energy systems, including the reactor coolant loop (RCL) and surge line, are replaced by small leakage cracks when the leak-before-break (LBB) criteria are applied. Jet impingement and pipe whip effects are not evaluated for these small leakage cracks. Mechanistic pipe break evaluations (also referred to as LBB) demonstrate that for piping lines meeting the criteria, sudden catastrophic failure of the pipe is not credible. The evaluations demonstrate that piping that satisfies the criteria leaks at a detectable rate from postulated flaws prior to growth of the flaw to a size that would fail due to applied loads resulting from normal conditions, anticipated transients, and a postulated SSE.

3.6.2 Summary of Application

WLS COL FSAR, Revision 11, Section 3.6, incorporates by reference AP1000 DCD, Revision 19, Section 3.6. In WLS COL FSAR Section 3.6.4, the applicant provided the following additional information:

AP1000 COL Information Items

- STD COL 3.6-1

The applicant provided information in WLS COL FSAR Section 3.6.4.1, "Pipe Break Hazard Analysis," and in 14.3.3, "CDM Section 3.0, Non-System Based Design Descriptions and ITAAC," for STD COL 3.6-1 to address the applicable AP1000 DCD information item. Specifically, the applicant stated: (1) the as-designed pipe rupture hazards evaluation will be in accordance with AP1000 DCD criteria with SSCs identified to be essential targets will be protected, and (2) that a pipe rupture hazard analysis is part of the piping design. It is used to identify postulated break locations and layout changes, support design, whip restraint design, and jet shield design for high- and moderate energy piping. The applicant further stated that the final design of these activities will be completed prior to installation of the piping and connected components. The as-built reconciliation of the pipe rupture hazards evaluation whip restraint and jet shield design will be completed prior to fuel load and will be available for NRC review.

- STD COL 3.6-4

The applicant provided information in STD COL 3.6-4 to address the information item, regarding the use of Alloy 690 and as-built verification of LBB piping.

License Condition

- Part 10, License Condition 2, "COL Holder Items," Item 3.6-1

The applicant proposed a license condition addressing the as-designed pipe rupture hazards analysis completion schedule and the contents of a related design report.

Inspections, Tests, Analyses and Acceptance Criteria (ITAAC)

In a November 3, 2010, letter, the applicant endorsed the April 23, 2010, letter from the VEGP applicant that proposed adding to the AP1000 DCD, Tier 1, Section 3.3, an ITAAC in the WLS COL, Part 10, Appendix B, "Inspections, Tests, Analysis, and Acceptance Criteria," denoted as Table 3.3-8, "Pipe Rupture Hazards Analysis (Sheet 1 of 1)," requiring the completion of an as-designed pipe rupture hazards analysis to demonstrate that SSCs required to be functional during and following a design basis event are protected against or qualified to withstand the dynamic and environmental effects with analyses of postulated pipe failures in high- and moderate-energy piping.

3.6.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations (10 CFR Part 50, Appendix A, GDC 4) for the piping design against pipe breaks, pipe break locations and characteristics in safety-related piping, and LBB evaluation procedures are given in NUREG-0800, Sections 3.6.1, 3.6.2, and 3.6.3.

3.6.4 Technical Evaluation

The staff reviewed this application section and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic. The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the protection against dynamic effects associated with the postulated rupture of piping. The staff's evaluation of the information incorporated by reference in the WLS application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content for the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews.

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (VEGP) contains evaluation material from the SER for the Bellefonte Nuclear Plant, Units 3 and 4 COL application. The staff reviewed the following information in the WLS COL FSAR.

AP1000 COL Information Items

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.6.4:

- *STD COL 3.6.-1*

The staff notes that there are two different actions to be addressed: 1) the COL holder item addresses the as-designed pipe rupture hazard analysis report; and 2) the ITAAC addresses as-built reconciliation of the pipe rupture hazard analysis report. The ITAAC has a stated schedule, prior to fuel load, and a regulatory requirement that the ITAAC schedule be provided one year after the license is granted.

Based on the review of the information included in the BLN COL FSAR, it is unclear to the staff when the as-designed pipe rupture hazard analysis report will be completed by the applicant. As identified in 10 CFR 52.79(d)(3), the applicant should supply the NRC with a schedule for completion of detailed engineering information, in this case, the as-designed pipe rupture hazard analysis report. The applicant is requested to revise the implementation milestone for the License Condition to address the as-designed pipe rupture hazard analysis report (as opposed to as-built reconciliation) to allow coordination of activities with the NRC construction inspection program following the issuance of the COL such that the analysis would be made available to verify the design was completed in accordance with the regulations and DCD prior to fabrication and installation of the piping and connected components. In RAI 3.6.2-1, the staff requested the applicant provide a description pertaining to the closure milestone of the as-designed pipe rupture hazard analysis activities.

The applicant responded to RAI 3.6.2-1, however, based on its review of the applicant's response, the staff determined that it is not acceptable. Specifically, RAI 3.6.2-1 requested that the applicant address the implementation milestone of the as-designed pipe rupture hazard analysis report. However, the applicant's RAI response addressed the as-built rather than the as-designed aspect. Therefore, RAI 3.6.2-1 remains unresolved and will be tracked as Open Item 3.6-1.

- *STD COL 3.6-4*

The BLN COL FSAR replaced the first paragraph of Section 3.6.4.4 of AP1000 DCD with the following text:

> *Alloy 690 is not used in leak-before-break [LBB] piping. No additional or augmented inspections are required beyond the inservice inspection [ISI] program for leak-before-break [LBB] piping. An as-built verification of the leak-before-break piping is required to verify that no change was introduced that would invalidate the conclusion reached in this subsection.*

Based upon its review of the replaced Section 3.6.4.4, the staff determined that additional information was needed by the COL applicant to address whether Alloy 690 material is being used in the BLN-specific LBB piping systems. Accordingly, the staff issued several RAIs.

In RAI 3.6.3-1, the staff noted that it was unclear why Alloy 690 was not used in LBB piping applications. If Alloy 690 base material and Alloy 52/152 weld material was not being used, the staff asked the applicant to identify what material was being used for the piping.

In RAI 3.6.3-2, the staff asked if another base material was being used other than Alloy 690/52/152, then the applicant should provide its reasons for using this material in LBB piping applications based upon operating experience, and provide justification as to why no augmented inspection plans and evaluation criteria were considered necessary. Additionally, the staff requested that the applicant provide a discussion which supports the use of an alternative material *and discuss why concerns for potential PWSCC [primary water stress-corrosion cracking] should not be considered a factor.*

In RAI 3.6.3-3, for piping requiring dissimilar metal welds, the applicant was requested to address that if Alloy 52/152 is not being used for the weld material, then they should identify the weld material and provide justification for its use. In addition, the applicant should provide a discussion which supports the use of an alternative weld material and why concerns regarding the potential for PWSCC should not be considered a factor. The staff noted that there are currently ASME Code cases being developed for dissimilar-metal welds due to PWSCC concerns.

In its response to these RAIs, the applicant provided additional information to clarify the material that is used for LBB piping systems. The applicant stated that there is some limited use of Alloy 690 base material as safe ends in components connected to LBB piping, and there is some limited use of Alloy 52/152 weld material associated with these safe ends. However, the applicant noted that the base material for most of the LBB piping is 316LN stainless steel material. The applicant further stated that the material used in the AP1000 LBB piping is the same material currently used for LBB piping in operating nuclear power plants. Alloy 690 and Alloy 600 are not used as base material for LBB piping in the AP1000 design and are not commonly used in the LBB piping in current operating nuclear power plants. The applicant also stated that even though the material used in the LBB piping for the AP1000 design do not presently require an augmented ISI program, if ASME Code cases are developed and approved to address PWSCC concerns for dissimilar metal welds used in the AP1000 DCD, they will be evaluated and implemented.

The staff notes that in a final rule to amend 10 CFR 50.55a (73 FR [Federal Register] 52730) issued on September 10, 2008, a new requirement was added for licensees to augment their ISI program to use ASME Code Case N-722 for ISI of Alloy 600/182/82 materials to address PWSCC concerns. The applicant stated that there will be no Alloy 600/182/82 material used for new reactor construction of AP1000 plants. The staff notes that the final rule did not impose any additional requirements for augmented ISI of Alloy 690/152/52 materials. Based on the applicant's response discussed above and its commitment to evaluate and implement ASME Code cases that are developed and approved for augmented inspections of Alloy 690/152/52 material to address PWSCC concerns, the staff concludes the applicant's changes to COL Information Item 3.6-4 is consistent with current industry practice and NRC regulations as amended in 10 CFR 50.55a and is thus, acceptable.

<u>Resolution of Standard Content Open Item 3.6-1</u>

To address Open Item 3.6-1 in the BLN SER with open items, the VEGP applicant proposed in its letter dated April 23, 2010, an ITAAC for as-designed pipe rupture hazards analysis in ITAAC Table 3.8-# [where # is the next sequential number] and a revision to the proposed License Condition 2, Item 3.6-1 in Part 10 of the VEGP COL application. In addition, the applicant *proposed to revise VEGP COL FSAR Section 3.6.4.1 and to add VEGP COL FSAR Section 14.3.3related to pipe rupture hazards analysis.*

Specifically, the proposed ITAAC includes a post-COL requirement related to the completion of the as-designed pipe rupture hazards analysis report. The proposed VEGP COL FSAR Section 3.6.4.1 states that the completed as-designed pipe rupture hazards analysis will be in accordance with the criteria outlined in AP1000 DCD Sections 3.6.1.3.2 and 3.6.2.5. The applicant stated that the completed as-designed pipe rupture hazards analysis report will be completed prior to installation of the piping and connected components and will be made available to the NRC staff. The applicant's proposed license condition that will require completion of the as-designed pipe rupture hazards analysis report prior to installation of the piping and connected components in their final location is proposed License Condition 2, Item 3.6-1. In the proposed VEGP COL FSAR Section 14.3.3.# [where # is the next sequential number], the applicant stated that the as-designed pipe rupture hazards analysis completed for the first standard AP1000 plant will be available to subsequent standard AP1000 plants under the "one issue, one review, one position" approach for closure.

The staff reviewed the applicant's April 23, 2010, response to BLN open items for Chapter 3, and has determined that the use of a plant-specific ITAAC to verify that the as-design pipe rupture hazards evaluation has been performed in accordance with the criteria outlined in AP1000 DCD Sections 3.6.1.3.2 and 3.6.2.5 is acceptable. The applicant's proposed license condition requiring completion of the as-designed pipe rupture hazards analysis report prior to installation of the piping and connected components in their final location, through the above discussed ITAAC, will allow the staff sufficient time to review the as-design pipe rupture hazards evaluation in a timely matter in order to identify and address any design issues. Therefore, the staff finds the response acceptable and concludes that Standard Content Open Item 3.6-1 has been satisfactorily resolved. The incorporation of the planned VEGP COL FSAR changes will be tracked as Confirmatory Item 3.6-1.

<u>Resolution of Standard Content Confirmatory Item 3.6-1</u>

Confirmatory Item 3.6-1 is an applicant commitment to revise its FSAR Section 3.6.4.1 and, Section 14.3.3.2, to verify the incorporation of the as-designed pipe rupture hazard analysis and add an ITAAC (Table 3.8-1) for the as-designed pipe rupture hazard analysis. The staff verified that the VEGP COL FSAR and Part 10 of the application (ITAAC Table 3.8-1) were appropriately updated. As a result, Confirmatory Item 3.6-1 is now closed.

- WLS COL 3.6-1

The staff reviewed WLS COL 3.6-1 included under WLS COL FSAR Section 3.6. The applicant replaced the last paragraph in AP1000 DCD Section 3.6.4.1, stating that after a COL is issued, the COL holder will complete an as-designed pipe rupture hazard evaluation that will be available for review. The evaluations will be provided prior to fabrication and installation of the piping and connected parts. In a July 22, 2011, letter, the applicant committed to remove this additional information because the standard content provided in WLS COL FSAR, Revision 2 provides all the necessary information for resolving STD COL 3.6-1. This is being tracked as Confirmatory Item 3.6-2.

Resolution of Confirmatory Item 3.6-2

Confirmatory Item 3.6-2 was an applicant commitment to remove excess information from the WLS COL FSAR Section 3.6.4.1. The staff verified that the information was removed. As a result, Confirmatory Item 3.6-2 is now closed.

3.6.5 Post Combined License Activities

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following ITAAC and license condition acceptable:

- The licensee shall perform and satisfy the pipe rupture hazards analysis described in WLS COLA, Part 10, Appendix B, ITAAC Table 3.3-8, "Pipe Rupture Hazards Analysis (Sheet 1 of 1)."

- License Condition (3-1) – Before commencing installation of individual piping segments and connected components in their final locations, the licensee shall complete the as-designed pipe rupture hazards analysis for compartments (rooms) containing those segments in accordance with the criteria outlined in the AP1000 DCD, Rev. 19, Sections 3.6.1.3.2 and 3.6.2.5, and shall inform the Director of NRO, or the Director's designee, in writing, upon the completion of this analysis and the availability of the as-designed pipe rupture hazards analysis reports.

3.6.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the pipe design against pipe break, pipe break locations, characteristics in safety-related piping, and LBB evaluation procedures and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 50, Appendix A, GDC 4. The staff based its conclusion on the following:

- STD COL 3.6-1 is acceptable because the applicant's proposed resolution in WLS COL FSAR Section 3.6.4.1 meets the relevant guidelines of NUREG-0800, Sections 3.6.1 and 3.6.2 and 10 CFR 52.79(d)(3) and is, thus, acceptable. Conformance to these guidelines provides an acceptable basis to satisfy, in part, the requirements of 10 CFR Part 50, Appendix A, GDC 4.

- STD COL 3.6-4 is acceptable because the applicant's proposed resolution in WLS COL FSAR Section 3.6.4.4 meets the relevant guidelines of NUREG-0800, Section 3.6.3 and RG 1.206, Section C.III.1, Chapter 3, C.I.3.6.3 and is, thus, acceptable. Conformance to these guidelines provides an acceptable basis to satisfy, in part, the requirements of 10 CFR Part 50, Appendix A, GDC 4

3.7 Seismic Design

Section 3.7 of this report focuses on the seismic analyses of NI structures (Seismic Category I) and adjacent Seismic Category II structures. Seismic design of the AP1000 Seismic Category I and II structures, systems, equipment, and components are based on the SSE. Low-level seismic effects are included in the design of certain equipment that are potentially sensitive to a number of low-level events based on a percentage of the responses calculated for the SSE. Criteria for evaluating the need to shut down the plant following an earthquake are established. Seismic Category I SSCs are designed to withstand the effects of the SSE and maintain the specified design functions. Seismic Category II and NS SSCs are designed or physically arranged (or both) so that the SSE would not cause unacceptable structural interaction with or failure of Seismic Category I SSCs.

On April 25, 2012, the staff issued RAI 105, Question 01.05-1 pertaining to the implementation of the Fukushima Near-Term Task Force (NTTF) Recommendations for the WLS. RAI 105, Question 01.05-1 addressed NTTF Recommendation 2.1, requested that the applicant (1) evaluate the potential impacts of the new Central and Eastern United States Seismic Source Characterization model (CEUS-SSC; NUREG-2115) on the seismic hazard curves and the site-specific ground motion response spectra (GMRS)/foundation input response spectra (FIRS) and (2) modify the GMRS/FIRS as necessary.

In a January 30, 2014, response, the applicant addressed the implementation of the CEUS-SSC in updating the site-specific seismic hazards and response spectra for the WLS and the respective effects on the Nuclear Island (NI) structures. In a supplemental response, dated February 28, 2014, the applicant addressed the effects of the updated site-specific hazards on the seismic Category II structures adjacent to the NI. The aforementioned responses also included changes to the WLS FSAR. The staff's review of the development of the updated site-specific hazard is discussed in Section 2.5 of this report. Section 3.7 of this report focuses on the seismic analyses of NI structures and adjacent seismic Category II structures. These seismic analyses are based on the new WLS site-specific seismic hazard. On the basis of the above discussion, the staff considers this RAI resolved

3.7.1 Seismic Design Parameters

3.7.1.1 *Introduction*

In this section, the input seismic design GMRS for the SSE in the free field at plant grade is addressed.

3.7.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.7, incorporates by reference AP1000 DCD, Revision 19, In addition, in WLS COL FSAR Section 3.7, the applicant provided the following:

Departures

- WLS DEP 2.0-1

The seismic design of the AP1000 standard plant is based on the Certified Seismic Design Response Spectra (CSDRS) as addressed in AP1000 DCD Section 3.7.1.1. The AP1000 DCD also includes hard rock high frequency (HRHF) spectra for evaluation of site-specific GMRS. The WLS site-specific horizontal and vertical spectra exceed the CSDRS and HRHF spectra; therefore, constituting a departure from the AP1000 certified design. This departure is identified in WLS COL FSAR Table 2.0-201 and WLS COL FSAR Sections 3.7.1.1.1, 3.7.2.8.4, 3.7.2.15, Appendix 3I, and WLS COL FSAR Section 19.55.6.3. Consistent with the requirements of the AP1000 DCD Tier 1, Table 5.0-1, AP1000 DCD Section 2.5.2.1, paragraph 4b, and AP1000 DCD Section 3.7.2.8.4, the applicant performed site-specific analysis to demonstrate the adequacy of the standard design for the WLS site. The staff's evaluation of WLS DEP 2.0-1 and supporting site-specific analysis is included in Section 3.7.2.4 of this report.

Supplemental Information

- WLS SUP 3.7-3

The applicant provided information in WLS SUP 3.7-3 by adding Section 3.7.1.1.1, "Design Foundation Spectra," to the WLS COL FSAR, with site-specific foundation input response spectra for each WLS unit.

3.7.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the seismic design parameters are given in NUREG-0800, Section 3.7.1 and interim staff guidance (ISG) in the form of DC/COL-ISG-1, "Interim Staff Guidance on Seismic Issues of High Frequency Ground Motion in Design Certification and Combined License Applications."

3.7.1.4 *Technical Evaluation*

The horizontal and vertical design GMRS for the AP1000 were developed based on the response spectra in RG 1.60, "Design Response Spectra for Seismic Design of Nuclear Power Plants," Revision 1, with special consideration of high-frequency amplification effects. The staff reviewed WLS COL FSAR Section 3.7 and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and that incorporated by reference addresses the required information relating to seismic design parameters. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff's review of the information in the WLS COL FSAR is as follows:

Supplemental Information

- WLS SUP 3.7-3

WLS SUP 3.7-3 addresses site-specific NI FIRS for each of the WLS units, separately. The applicant stated that individual foundation response spectra were provided for the certified design portion of the Units 1 and 2 plants based on their unique foundation conditions. WLS COL FSAR Sections 2.5.2.7 and 3.7.1.1.1 describe the applicant's site-specific seismic velocity model and associated calculation of the WLS site-specific FIRS. The applicant developed site-specific dynamic velocity models and used the probabilistic method of random vibration theory (RVT), as described in NUREG/CR-6728 as Approach 3, to compute the location-specific FIRS at the WLS site.

The applicant developed three site-specific dynamic velocity models to represent localized foundation conditions – Unit 1 A1, Unit 1 A5, and Unit 2 C4. WLS COL FSAR Section 2.5.4.7 describes the material dynamic properties and WLS COL FSAR Figures 2.5.4-252a, 2.5.4-252b, and 2.5.4-252c show the dynamic velocity profiles for Base Cases A1, A5, and C4, respectively, which represent the Unit 1 FIRS A1, Unit 1 FIRS A5, and Unit 2 FIRS C4 configurations.

As described in WLS COL FSAR Section 2.5.2.7 the WLS Unit 1, FIRS A1 represents the Unit 1 nuclear island centerline foundation input motion that supports the Unit 1 nuclear island. The applicant based its Unit 1 FIRS A1 on the GMRS developed at the hard rock condition, as defined by CEUS attenuation relationships (2,830 m/s (9,282 fps)), at 161 m (530 ft) (NAVD), transferred up through previously placed Cherokee Nuclear Station (CNS) concrete materials and newly placed WLS concrete materials to the basemat foundation level at 168.7 m (553.5 ft) (NAVD). The applicant's site-specific dynamic velocity model for Unit 1 A1 contains approximately 2.4 m (8 ft) of new fill concrete overlying an average of about 4.5 m (15 ft) of existing fill concrete, structural basemat concrete and native rock from the former CNS foundation. In total, the applicant's Unit 1 FIRS A1 site-specific seismic velocity profile contains 7 m (23.5 ft) of fill concrete material of shear wave velocities of 2286 m/s (7,500 fps) overlying hard rock (WLS COL FSAR Figure 2.5.4-252a).

The applicant also described that the WLS Unit 1 FIRS A5 represents the Unit 1 localized condition where the nuclear island overlies legacy CNS pump rooms. The applicant based its WLS FIRS A5 on the WLS GMRS developed at the hard rock condition and transferred up through 9 m (30.5 ft) of previously placed CNS concrete materials and newly placed WLS concrete materials to the basemat foundation level at 168.7 m (553.5 ft) (NAVD) (WLS COL FSAR Figure 2.5.4-252b).

The applicant described that the WLS Unit 2 FIRS C4 represents the eastern edge of the Unit 2 nuclear island which may be supported by up to 6 m (20 ft) of new leveling fill concrete. The applicant's Unit 2 FIRS C4 is based on the WLS GMRS developed at the top of the hard rock condition fixed at 155 m (509 ft) (NAVD) and transferred up through 6 m (20 ft) of newly placed WLS concrete materials to the basemat foundation level at 168.7 m (553.5 ft) (NAVD) (WLS COL FSAR Figure 2.5.4-252c). The applicant randomly varied each site-specific seismic velocity base profile by ± 1 m (± 3 ft).

The applicant first generated randomized site-specific seismic velocity model profiles and associated shear moduli and damping parameters that represent possible variations from the base seismic mode, consistent with RG 1.208. Then the applicant calculated site-specific response amplification functions for each randomized profile using the RVT methodology. The use of RVT in site response calculations is described in RG 1.208 as a possible methodology that can be used. RG 1.208 specifically states, "…RVT methods are acceptable as long as the strain dependent soil properties are adequately accounted for in the analysis." Similar to the time series methodology, RVT analysis produces an amplification function that is then applied to the rock spectra to obtain the response spectra defined at the ground surface (or at any intermediate point within the soil profile), which accounts for the effects of soil amplification (or deamplification) on the input base hard rock ground motion. To accommodate the possibility of distance-dependent transfer functions in a linear analysis, the applicant used a suite of spectral shapes as control motions at distances of 1, 20, 100, 200, and 400 km (0.6, 12, 62,125, 250 mi). The applicant shows those results in WLS COL FSAR Figures 2.5.2-241a, 2.5.2-241b, and 2.5.2-241c, which display a small site resonance at high frequencies. Following the guidance of RG 1.208, the staff focused its review on the input parameters used in the site amplification functions calculations. Inputs to the RVT method include response spectra which are based on the hard rock UHRS, 60 randomized velocity profiles, effective strain ratio, and strong motion duration. Having reviewed the applicant's input parameters; the staff concludes that the applicant's selection of input parameters is adequate to calculate the FIRS amplification functions at the WLS site.

In WLS COL FSAR Section 3.7.1.1.1, the applicant described that it used the envelope of the Unit 1 and Unit 2 FIRS, referring to the enveloped spectra as NI FIRS. The resulting horizontal NI FIRS is shown in Figure 3.7.1.4-1 of this report and the vertical NI FIRS is shown in WLS COL FSAR Figure 3.7-202.

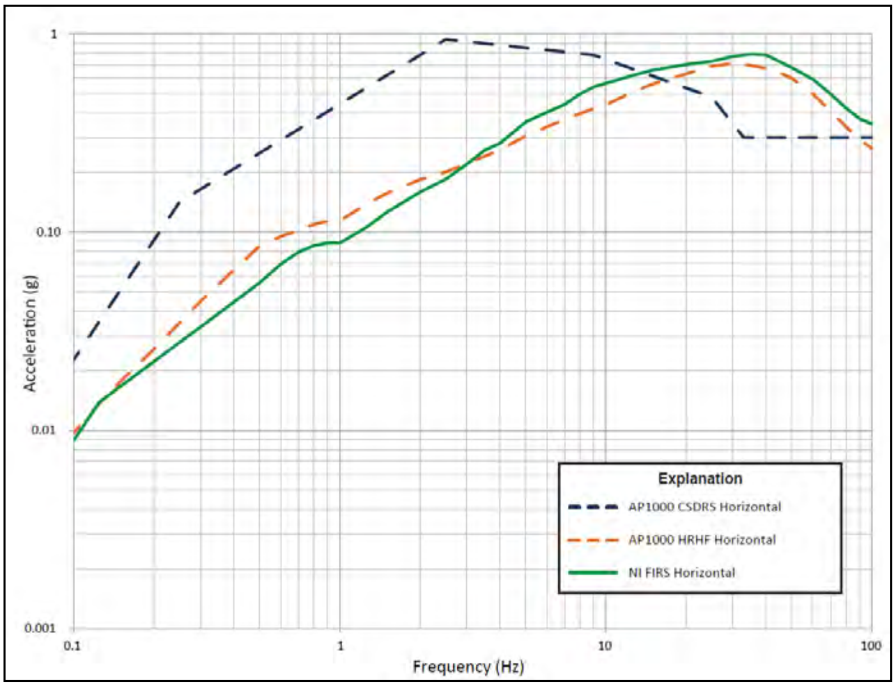

Figure 3.7.1.4-1 The WLS horizontal NI FIRS, the AP1000 horizontal certified seismic design response spectra (CSDRS), and the AP1000 horizontal hard rock high frequency spectra (HRHF). (Ref. WLS COL FSAR Revision 9, FSAR 3.7-201)

To determine the adequacy of the applicant's FIRS calculations, the staff completed confirmatory calculations. As input, the staff used the static and dynamic properties provided in WLS COL FSAR Section 2.5.4 and 2.5.2.7 for base cases A1, A5, and C4. To represent the input rock motions, the staff used the applicant's low- and high-frequency 10^{-4} and 10^{-5} rock spectra. The staff completed its site response calculations using the Strata software (Kottke and Rathje, 2008). The staff compared its calculated horizontal NI FIRS with the applicant's in Figure 3.7.1.4-2 of this report. Figure 3.7.1.4-2 of this report shows that the staff's NI FIRS calculation is similar to the applicant's NI FIRS across the frequency range typically important for engineering purposes (i.e., 0.5 to 10 Hz).

The staff noted a difference between the applicant's and the staff's NI FIRS results at high frequencies (between approximately 40 and 100 Hz). The staff noted the WLS FIRS amplification transfer functions show amplification from approximately 30 to 100 Hz due to the varying fill concrete beneath the WLS proposed structures, which means that at those frequencies the FIRS should have larger spectral accelerations than the WLS site-specific GMRS. In contrast, the WLS NI FIRS is less than the WLS GMRS at high frequencies. To investigate this issue, in RAI 118, Question 03.07.01-6, the staff requested that the applicant assess and evaluate the inconsistency of WLS FIRS amplification transfer functions, FIRS, and the GMRS and to provide a thorough description of the assessment and evaluation. The staff also requested that the applicant explain the basis and justify the conclusions regarding the relationship between the WLS site-specific amplification functions, FIRS, and GMRS.

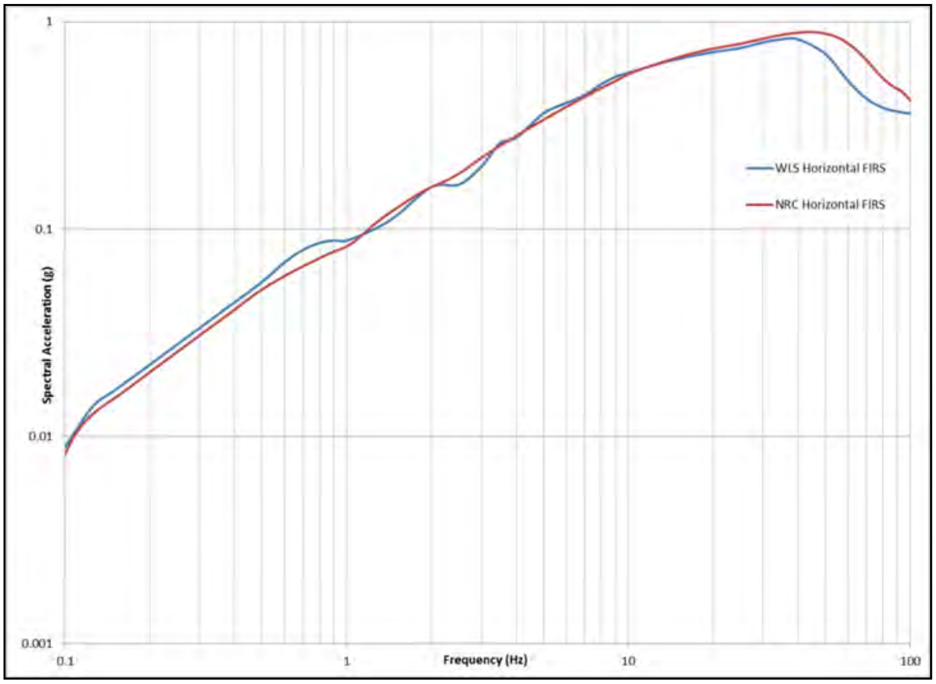

Figure 3.7.1.4-2 The WLS horizontal NI FIRS and the staff's (NRC) horizontal NI FIRS

In a July 24, 2014, response to RAI 118, Question 03.07.01-6, the applicant described that the noted differences in the relationships of the horizontal GMRS and FIRS are attributed to differences in high-frequency interpolation methods used to develop the rock (GMRS) and concrete (FIRS) spectral shapes. In Figure 3.7.1.4-3 of this report, the applicant presented the horizontal GMRS and FIRS A1 from WLS COL FSAR, Sections 2.5.2.6 and 2.5.2.7 (labeled as

"Orig") and compared them to alternative calculations of the horizontal GMRS and FIRS A1 based on the FIRS high-frequency interpolation method ("Altern"). The applicant's RAI response results demonstrated that using the same interpolation methods lead to consistent spectral shapes and resulting in a GMRS that is generally lower than the GMRS presented in WLS COL FSAR Revision 9.

Based on this review, the staff concludes that the WLS COL FSAR Revision 9 horizontal GMRS and FIRS spectra are considered appropriate. Additionally, the staff also concludes that the difference in interpolation methods explains the differences between the WLS NI FIRS and the NRC NI FIRS shown in Figure 3.7.1.4-2 of this report. Accordingly, the staff concludes that the WLS NI FIRS satisfy the acceptance criteria of RG 1.208 and the requirements of 10 CFR 100.23, and considers RAI 118, Question 03.07.01-6 resolved. Based upon its review of WLS COL FSAR Section 2.5.2.7 and 3.7.1.1.1, the applicant's response to RAI 118, Question 03.07.01-6, and the staff's confirmatory analysis, the staff concludes that the applicant's methodology and results for calculations of the site-specific NI FIRS are acceptable and resolved.

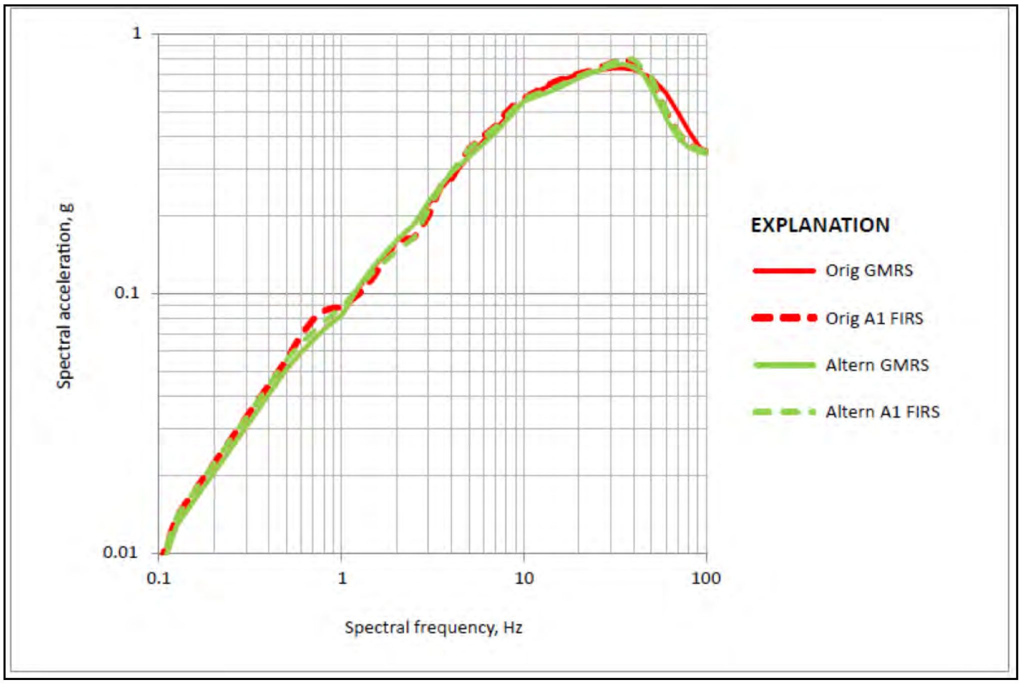

Figure 3.7.1.4-3 Comparison of the horizontal GMRS and FIRS A1 from the FSAR ("Orig") and horizontal GMRS and FIRS A1 using the methodology consistent with that used to develop the FSAR NI FIRS ("Altern"). (Ref. RAI 03.07.01-6 response Figure 9)

As shown in WLS COL FSAR Figures 3.7-201 (Figure 3.7.1.4-1 of this report) and 3.7-202, the horizontal NI FIRS exceeds the standard horizontal AP1000 CSDRS at frequencies above approximately 14 Hertz (Hz) and the vertical NI FIRS exceeds the CSDRS at frequencies above approximately 16 Hz. The peak ground acceleration (PGA) values for horizontal and vertical NI FIRS are 0.35g and 0.32g, respectively. The applicant also provided a comparison of the NI FIRS to the HRHF spectra. The horizontal NI FIRS exceeds the horizontal AP1000 HRHF spectrum above 3 Hz and the vertical NI FIRS exceeds the vertical HRHF at frequencies between about 3 and 55 Hz and between 80 and 100 Hz. The aforementioned exceedances of the NI FIRS to both the CSDRS and the HRHF spectra are identified by the applicant as departure WLS DEP 2.0-1. To address this departure, the applicant stated that consistent with AP1000 DCD Section 2.5.2.1, paragraph 4b, a site-specific analysis of the AP1000 has been performed, similar to the analysis described in AP1000 DCD Appendix 3I, to demonstrate that the high frequency spectra exceedances are within the seismic design margin of the AP1000 certified design and will not adversely affect the structures, systems, or components of the plant.

The WLS site-specific analyses for NI structures are described in WLS COL FSAR Section 3.7.2.15 and discussed in detail in Reference 206 to WLS COL FSAR Section 3.7 (“Effects of William S. Lee Site Specific Seismic Requirements on AP1000 SSCs,” WLG-GW-GLR-815, Revision 0, January 30, 2014). Reference 206, Section 2.0 states that two site-specific Soil Structure Interaction (SSI) models were developed with dynamic soil profiles corresponding to the varied conditions beneath the WLS Unit 1 and 2 NIs. WLS COL FSAR Figures 2.5.4-250 and 2.5.4-252a show the dynamic velocity profiles for Unit 2 and Unit 1 respectively. The shear wave velocity immediately below Unit 2 is greater than 2,500 m/s (8,000 fps) and approximately 2,900 m/s (9,500 fps) at lower depths, whereas Unit 1 has a shear wave velocity of 2,300 m/s (7,500 fps_ (i.e., concrete layer) immediately below its NI foundation and approximately 2,900 m/s (9,500 fps) at lower depths. Reference 206, states that a comparison of the WLS SSI in-structure response spectra (ISRS) at the six key NI locations for Units 1 and 2 was made for both dynamic profiles and determined to be similar. On this basis, the WLS site-specific analyses are based on the SSI model with the Unit 1 dynamic velocity profile, which includes the effects of fill concrete beneath the NI basemat. The staff reviewed Reference 206 and noted that the applicant did not provide the ISRS comparisons for the models with Units1 and Unit 2 dynamic soil profiles. These ISRS comparisons were reviewed by the staff during the May 2014 WLS structural audit. Additionally, the staff issued RAI 119, Question 03.07.01-7, requesting that the applicant provide the ISRS (for Units 1 and 2 dynamic velocity profiles) at the six key NI locations. In an August 14, 2014, response, the applicant provided the ISRS at the six key locations for the two SSI analyses, one based on Unit 1 dynamic soil profile and the other based on Unit 2 dynamic soil profile. The staff also noted that the ISRS at the six key locations corresponding to the SSI models with Units 1 and 2 dynamic soil profiles were consistent in spectral shape with negligible differences in spectral acceleration amplitude. Additionally, the staff noted that the HRHF analyses in AP1000 DCD Appendix 3I are based on a shear wave limitation defined at the bottom of the basemat equal to or higher than 2286 m/s (7,500 fps), while maintaining a shear wave velocity equal to or above 2438 m/s (8,000 fps) at the lower depths. Based on the consistency with the limiting lower bound shear wave velocity for the AP1000 DCD Appendix 3I analyses and the consistent results of the ISRS at the six key locations for Units 1 and 2 dynamic profiles, the staff finds the Unit 1 dynamic profile acceptable for use in the WLS site-specific SSI analyses and considers the RAI resolved.

3.7.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.7.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff’s review confirmed that the applicant addressed the required information relating to the seismic design parameters, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 50, Appendix A, Appendix S, and other pertinent staff guidance. The staff based its conclusion on the following:

- WLS SUP 3.7-3 is acceptable because the applicant addressed the relevant information and performed adequate analyses that meet the acceptance criteria in NUREG-0800, Section 3.7.1 and ISG-1. In conclusion, the applicant has provided sufficient information to comply with the requirements of 10 CFR Part 50, Appendix A, GDC 2; 10 CFR Part 50, Appendix S; and 10 CFR 100.23.

3.7.2 Seismic System Analysis

3.7.2.1 *Introduction*

This section describes seismic analysis methods and acceptance criteria for all Seismic Category I SSCs. The description includes basic assumptions, procedures for modeling, seismic analysis methods, development of ISRS envelopes, consideration of torsional effects, evaluation of overturning and sliding of Seismic Category I structures, and determination of composite damping. The effects of soil structure interaction (SSI) on the seismic responses of the NI structures are included in the section. The staff review also covered design criteria and procedures for evaluating the interaction of NS Category I structures with Seismic Category I structures and the effects of parameter variations on floor response spectra (FRS).

3.7.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.7, incorporates by reference AP1000 DCD, Revision 19. In WLS COL FSAR Section 3.7.2, the applicant provided the following departure and supplements:

Departures

- WLS DEP 2.0-1

The seismic design of the AP1000 certified nuclear plant is based, in part, on the CSDRS as addressed in AP1000 DCD Section 3.7.1.1. The AP1000 DCD also includes HRHF spectra, which provide an alternative set of spectra for evaluation of site-specific GMRS. The WLS site-specific horizontal and vertical spectra exceed the CSDRS and HRHF spectra, constituting a departure from the AP1000 certified design. This departure is identified in WLS COL FSAR Table 2.0-201 and Sections 3.7.1.1.1, 3.7.2.8.4, 3.7.2.15, AP1000 DCD Appendix 3I, and Section 19.55.6.3. Consistent with the requirements of AP1000 DCD Table 5.0-1 (Tier 1), AP1000 DCD Section 2.5.2.1, paragraph 4b, and AP1000 DCD Section 3.7.2.8.4, the applicant performed site-specific analysis to demonstrate the adequacy of the standard design for the WLS site. The staff‘s evaluation of WLS DEP 2.0-1 and supporting site-specific analysis is included in Section 3.7.2.4 of this report.

AP1000 COL Information Items

- WLS COL 3.7-1

The applicant provided information in WLS COL 3.7-1 in WLS COL FSAR Sections 3.7.2.12 and 3.7.5.1, regarding seismic analysis of existing and new dams that could affect the site to address COL Information Item 3.7- discussed in AP1000 DCD Section 3.7.5.1. The information in WLS COL FSAR Section 3.7.5.1 references Section 3.7.2.12 and will be discussed in Section 3.7.2.4 of this report and will not be discussed elsewhere in this report.

- STD COL 3.7-3

The applicant provided information to address STD COL 3.7-3 on the seismic interaction review, which is discussed in AP1000 DCD Section 3.7.5.3. The information added to the AP1000 DCD to address STD COL 3.7-3 is located in WLS COL FSAR Section 3.7.5.3 and is the subject of a proposed license condition (Part 10, License Condition 2, "COL Holder Items," Item 3.7-3, "Seismic Interaction Review," below). STD COL 3.7-3 will not be discussed elsewhere in this report.

- STD COL 3.7-4

The applicant provided information in STD COL 3.7-4 on the reconciliation of seismic analyses of NI structures, which is discussed in AP1000 DCD Section 3.7.5.4. The information added to the AP1000 DCD to address STD COL 3.7-4 is located in WLS COL FSAR Section 3.7.5.4 and is the subject of a proposed license condition (Part 10, License Condition 2, "COL Holder Items," Item 3.7-4, "Reconciliation of Seismic Analyses of Nuclear Island Structures," below). This COL item will not be discussed elsewhere in this report.

Supplemental Information

- WLS SUP 3.7-4

The applicant provided information at the end of AP1000 DCD Section 3.7.2.8.4 regarding seismic modeling and analysis of Seismic Category II building structures.

- WLS SUP 3.7-5

The applicant provided information in WLS SUP 3.7.5 by adding Section 3.7.2.15 to the WLS COL FSAR which addresses site-specific analysis of NI Seismic Category I structures.

- WLS SUP 3.7-6

The applicant added supplemental information to the end of AP1000 DCD Section 3.7.2.1.2 regarding the development of time histories for use in site-specific analyses.

License Conditions

- Part 10, License Condition 2, "COL Holder Items," Item 3.7-3

The applicant proposed a license condition requiring an update to the seismic interaction review for as-built information to be completed prior to initial fuel load. This review is performed in parallel with the seismic margin evaluation and will follow the methodology in AP1000 DCD Section 3.7.5.3. The review is based on as-procured data, as well as the as-constructed condition.

- Part 10, License Condition 2, "COL Holder Items," Item 3.7-4

The applicant proposed a license condition requiring a reconciliation of seismic analysis for detail design changes, such as those due to as-procured or as-built changes in component mass, center of gravity, and support configuration based on as-procured equipment information. Acceptance criteria for deviations are specified. The reconciliation of seismic analysis of NI structures will be completed prior to initial fuel load.

3.7.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the seismic system analysis are given in NUREG-0800, Section 3.7.2 and ISG-1, which provides guidance on implementation of evaluation methodology to determine the effects of high-frequency ground motion.

3.7.2.4 *Technical Evaluation*

The staff reviewed this application and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and that incorporated by reference addresses the required information relating to the seismic system analysis. The staff's evaluation of the information incorporated by reference in the WLS COL application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews.

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (i.e., VEGP) contains evaluation material from the SER for the BLN, Units 3 and 4 COL application. The staff reviewed the following information in the WLS COL FSAR:

Departures

- WLS DEP 2.0-1

The staff's evaluation of WLS DEP 2.0-1 is accomplished through the evaluation of three supplemental information sections: WLS SUP 3.7-4, WLS SUP 3.7-5, and WLS SUP 3.7-6. This supplemental information is evaluated below.

AP1000 COL Information item

- WLS COL 3.7-1

The staff reviewed the resolution to the COL information item related to the evaluation of existing and new dams included under WLS COL FSAR Section 3.7.2.12. WLS COL 3.7-1 addresses the evaluation of existing and new dams whose failure could affect the site interface flood level specified in AP1000 DCD Section 2.4.1.2. The applicant references WLS COL FSAR Section 2.4.4 for the details of the evaluation. The applicant stated that the WLS site is not subject to flooding from dam failures. The staff's review of WLS COL FSAR Section 2.4. found it to be acceptable. Therefore, the staff finds the information in the WLS COL FSAR addressing WLS COL 3.7-1 acceptable.

Supplemental Information

- WLS SUP 3.7-4

WLS SUP 3.7-4 addresses the site-specific seismic modeling and analysis of Seismic Category II building structures (i.e., Turbine Building First Bay (TBFB) and Annex Building). The purpose of the modeling and analysis is to demonstrate that adverse interaction between the Seismic Category II buildings and the adjacent NI is precluded under the site-specific demands. The staff's review focused on the adequacy of the minimum seismic gap, the adequacy of the bearing capacity of the backfill under the Category II buildings, the overall global stability of the Seismic Category II structures, and the adequacy of the Seismic Category II building designs to preclude local member failure and a consequential adverse interaction with the adjacent NI.

In the application, the analyses are also discussed in detail in the, "William S. Lee Site Specific Adjacent Buildings Seismic Evaluation Report," WLG-1000-S2R-804, Revision 3, February 2014 (Reference 205). The applicant's site-specific SSI analysis of these structures is performed with site-specific and building-specific performance-based surface response spectra (PBSRS) at plant grade as input. These PBSRS were developed using the same analytical methods used in calculating the Unit 1 FIRS. Furthermore, these analyses used hazard-consistent, strain-compatible properties for the granular material supporting the Seismic Category II building structures. Three soil profiles were considered in the analyses including a best estimate (BE), lower bound (LB), and upper bound (UP) soil profiles. These analyses, consistent with the AP1000 DCD analyses of Seismic Category II structures, are 2D SSI analyses with lump mass stick models of the Seismic Category II adjacent structures.

Reference 205 provided the calculated site-specific displacements of the Seismic Category II building structures relative to the NI. As stated in Reference 205, Section 6.2, relative displacements were calculated to verify that there would be no contact between the NI and the Seismic Category II adjacent structures. As per AP1000 DCD, Revision 19, Section 3.8.5.1, buildings adjacent to the NI, such as the TBFB and Annex Building are structurally separated from NI structures by a 5-cm (2-in.) gap at and below grade and a minimum gap of 10-cm (4-in.) above grade. The applicant provided the site-specific relative displacements at four locations including, (1) TBFB foundation to NI, (2) top of the TBFB to the NI (El. 52 m (170 ft)), (3) Annex Building foundation to the NI, and (4) top of Annex Building to the NI (El. 55 m (180 ft)). The staff reviewed Reference 205, Section 6.2 and noted that the relative displacements for the TBFB bound those of the Annex Building. The staff notes that the calculated maximum relative displacements for the TBFB are 0.5 cm (0.197 in,) below grade and 1.5 cm (0.576 in.) above grade, which are significantly lower than the aforementioned minimum required gaps between the NI and adjacent structures. On this basis, the staff finds that the minimum required seismic gaps in the AP1000 DCD continue to provide adequate separation to prevent interaction between the NI and the adjacent Seismic Category II structures at the WLS site.

In RAI 120, Question 03.07.02-4, the staff requested that the applicant include in the WLS COL FSAR the site-specific values for the relative displacements between the NI and the adjacent Seismic Category II structures. In addition, the staff requested that the applicant include in the WLS COL FSAR the relative displacements for the 1.67 times the site-specific seismic demand. In an August 7, 2014, response, the applicant provided markups to WLS COL FSAR Section 3.7.2.8.4 that addressed the relative displacement information. On this basis, the staff considered the applicant's response acceptable. Accordingly, the staff considers RAI 120, Question 03.07.02-4 resolved.

In terms of the backfill bearing pressure, Reference 205 provided the site-specific dynamic bearing pressure demand vs capacity comparisons. Consistent with the AP1000 analysis of Seismic Category II structures, these pressure demands combine dead weight and seismic pressures to obtain a total bearing pressure on the soil elements under the basemat of the Seismic Category II structures. These comparisons showed that the bearing capacity of the supporting granular fill is greater than the bearing demand for the seismic Category II structures under the site-specific demands. On this basis the staff finds that the supporting granular fill is adequate for withstanding the bearing demand from the Seismic Category II structures at the WLS site.

To ensure no potential adverse interaction between the NI and the Seismic Category II structures as a result of global sliding or overturning of the Seismic Category II buildings under the effects of the site-specific seismic hazard, in RAI 121, Question 03.08.05-7, the staff requested that the applicant provide the factors of safety against sliding and overturning for the Seismic Category II structures for both the site-specific seismic demand and the 1.67 times the site-specific seismic demand. In an August 14, 2014, response, the applicant provided a qualitative assessment regarding the sliding and overturning stability of the Seismic Category II structures. The staff reviewed the applicant's response and noted that it contained insufficient details pertaining to the stability of the Seismic Category II structures. In a clarification call with the applicant, the staff requested that the applicant provide additional information including the calculation of factors of safety against sliding and overturning of the Seismic Category II structures. In an October 22, 2014, supplemental response, the applicant provided the factors of safety against sliding and overturning for the Seismic Category II structures. The staff's review of the factors of safety for the 1.67 times the site-specific demand is in Section 19.55 of this report. The smallest site-specific factors of safety for demand to resist sliding and overturning were 2.6 and 2.3, respectively. These factors of safety are greater than the

1.1 minimum required factor of safety for the NI specified in AP1000 DCD Table 3.8.5-1. Furthermore, the applicant provided markups to WLS COL FSAR Section 3.7.2.8.4, which addressed the sliding and overturning consideration in the detailed design of Seismic Category II structures. Based on the site-specific factors of safety provided by the applicant, the staff finds sufficient margin exists for Seismic Category II buildings against sliding and overturning as to preclude adverse interaction with the adjacent NI under the site-specific seismic demands. As such, the minimum seismic gap is adequate for the WLS site. Therefore, the staff finds this acceptable and, therefore, considers RAI 121, Question 03.08.05-7 resolved.

In terms of the impact of the site hazard exceedance above the CSDRS and HRHF on the design of the Seismic Category II buildings and the potential for failure leading to an adverse impact on the adjacent NI, the staff reviewed the applicant's approach to address this issue. Consistent with AP1000 DCD Section 3.7.2.8.4, the applicant computed the WLS site-specific Seismic Category II foundation response spectra (FRS) and provided comparisons of the site specific FRS with the corresponding AP1000 generic design envelop spectra. The generic design envelop spectra in AP1000 DCD Section 3.7.2.8.4, are those used in the design of Seismic Category II structures. Comparisons provided by the applicant are found in WLS COL FSAR Figures 3.7-213a and 3.7-213g for the Annex Building and 3.7-214a and 3.7-214b for the TBFB. These figures show that the site-specific horizontal FRS fall beneath the AP1000 envelope FRS for both the TBFB and the Annex Building, except for a minor exceedance between 3 Hz and 5 Hz for the TBFB. In the vertical direction, for both the TBFB and the Annex Building, there are vertical FRS exceedances between approximately 6 Hz and 25 Hz. The staff assessed the impact of the exceedance and concluded that both the horizontal and vertical exceedances have a negligible impact on the global stability of the Seismic Category II buildings, as demonstrated by sufficient margin against sliding and overturning as well as the small displacements of the Seismic Category II building structures relative to the NI. Furthermore, the applicant stated in WLS DEP 2.0-1 and in WLS COL FSAR Section 3.7.2.8.4 that the design of the Seismic Category II buildings will be performed to both the AP1000 generic design demand envelop and the WLS site-specific demands to ensure that the Seismic Category II building members are adequately designed so as not to fail and potentially negatively impact the adjacent NI SSCs. The staff finds that the design of the Seismic Category II buildings to the larger of the demands obtained from the AP1000 generic design envelop spectra and the WLS site-specific spectra to be adequate to ensure that these buildings will have adequate member capacity to preclude failure and avoid negatively impacting the safety-related functions of the adjacent NI SSCs.

Based on its review, the staff finds that the applicant has provided adequate and sufficient information to demonstrate that the Seismic Category II buildings will be supported and designed so as to preclude adverse interactions with the adjacent Seismic Category I SSCs when subjected to the WLS site-specific seismic hazard. Accordingly, WLS SUP 3.7-4 and the associated portion of DEP 2.0-1 are acceptable.

- WLS SUP 3.7-5

WLS SUP 3.7.5 addresses site-specific analyses of the NI Seismic Category I structures. The purpose of the site-specific analysis is to demonstrate that the NI Seismic Category I structures site-specific seismic demands are enveloped by the generic AP1000 DCD seismic demands. The staff's review focused on the adequacy of the modeling approach, the appropriate application of the incoherency function, and the verification of the adequacy of the AP1000 DCD demands for the design of the NI structures. WLS COL FSAR Section 3.7.2.15 describes the NI analyses that included three-dimensional incoherent SSI analysis based on the NI FIRS. The WLS NI FIRS exceeds both the AP1000 CSDRS and HRHF. As such, the applicant stated that site-specific analyses are performed to confirm that the site specific demands will not adversely affect the SSCs of the WLS. This site-specific evaluation implements the evaluation described in AP1000 DCD Appendix 3I, which describes the methodology and criteria used in the evaluation to confirm that the HRHF input is not damaging to the equipment and structures qualified by the analysis for the AP1000 CSDRS. The staff notes that while WLS COL FSAR Section 3.7.2.15 also discusses the applicant's site-specific evaluation for primary coolant loop, piping, and equipment, this report section focuses on the staff's evaluation of the structures. The staff's review of the applicant's evaluation regarding primary coolant loop, piping, and equipment is discussed in Sections 3.9, 3.12, and 3.10 of this report, respectively.

The methodology in the AP1000 DCD, Appendix 3I uses the NI20 nuclear island model described in AP1000 DCD Appendix 3G. The WLS site-specific analyses use an updated version of the NI20 model referred to as the NI20u model. The updates included in NI20u are described in Reference 206 and were discussed in detail during the May 2014 audit. The NI10 model was used in the AP1000 DCD analyses for defining the seismic response for the hard rock site. Additionally, AP1000 DCD Appendix 3G, Section 3G.2.2.2 states that the results of fixed base analyses of the NI20 model were compared to those of the NI10 model to confirm the adequacy of the NI20 model for use in the SSI analyses. In Reference 206, the applicant provided the ISRS at the six AP1000 key locations, comparing the response between the NI20u model and the NI10 model. The results provided were for fixed base analyses. During the May 2014 audit, the staff reviewed additional ISRS (at additional locations) and effective modal mass comparisons between the NI20u and NI10 models. During the review the staff noted that the comparisons included in Reference 206 and the ones presented during the May 2014 audit, demonstrate dynamic equivalence between the models. Additionally, the staff noted that the NI20u model yields responses that are consistent with the NI10 model and conservative with respect to the NI10 response. The staff also reviewed the model updates included in the NI20u model in conjunction with the NI20 model parameters provided in AP1000 DCD Appendix 3G. The staff reviewed the updates included in the NI20u model and noted that the model updates do not deviate from or alter the model parameters provided in AP1000 DCD Appendix 3G and are acceptable. Based on its consistency with the AP1000 DCD and its conservative response prediction discussed above, the staff finds the NI20u model adequate for the WLS site-specific evaluation.

As stated above, the WLS site-specific evaluation implements the three-dimensional incoherent SSI analysis based on the NI FIRS. In Reference 206, Section 5, the applicant stated that ACS SASSI (ACS SASSI by Ghiocel Predictive Technologies Inc. is a program that performs seismic soil-structure interaction (SSI) analysis) is used to perform 25 simulations with the incoherency function using the same methodology described in AP1000 DCD Appendix 3I, which, consistent with the staff guidance in ISG-1, uses the 2007 Abrahamson Hard-Rock coherency model. Additionally, the staff notes that Reference 206 Appendix A provides comparisons of WLS site-specific ISRS using both coherent and incoherent input motions. The staff noted that, while these comparisons identify the impacted frequency ranges due to incoherency and show that the incoherent response is generally lower than the coherent response, these comparisons did not explicitly indicate the percentage reduction to the coherent motion. As such, to assist the staff in its review of the incoherency function's impact on the demands, in RAI 120, Question 03.07.02-3, the staff requested that the applicant quantify the range of reductions to the coherent motion for both the site-specific evaluation and to compare it to the evaluation performed during the AP1000 certification. In an August 7, 2014, response, the applicant provided plots of reductions factors versus frequency for all the locations in Reference 206, Appendix A and for the AP1000 HRHF and the site-specific evaluations. The staff reviewed the applicant's response and noted the maximum levels of site-specific reduction to the coherent motions are consistent with the AP1000 HRHF evaluation. Therefore, based on the similar ISRS reductions of the WLS site-specific evaluation using the three-dimensional incoherent SSI analysis and the AP1000 HRHF calculations, the staff finds the applicant's reduction to coherent motion acceptable and, therefore, considers RAI 120, Question 03.07.02-3 resolved.

WLS COL FSAR Figures 3.7-209a through 3.7-211c compare the ISRS (at the AP1000 six key locations) corresponding to the AP1000 CSDRS, AP1000 HRHF (incoherent response), and the site-specific NI-FIRS (incoherent response). Furthermore, Reference 206, Figures 5.4-1 through 5.4-16 show the ISRS comparisons at additional locations consistent with the locations in the AP1000 DCD Appendix 3I evaluation. The staff reviewed these comparisons and noted that the WLS site-specific ISRS are largely enveloped by either the AP1000 CSDRS or HRHF FRS, except for a few exceedances generally in the high frequency range. As discussed in WLS COL FSAR Section 3.7.2.1.5, additional evaluations are performed to address the effect of site-specific ISRS exceedances. To assess the significance of the exceedances at the ISRS level on the NI structures, the applicant evaluated and compared the loads obtained from the site-specific NI FIRS and those obtained from the AP1000 CSDRS. These evaluations were performed for representative portions of the building structures selected by screening as being potentially sensitive to high frequency input. Moreover, as stated in Reference 206, Section 6.1, the selection of these representative portions of the building structures is based on areas that can experience high seismic demands during a seismic event. These representative portions of the building structures, consistent with AP1000 DCD Appendix 3I, include three locations in the Auxiliary Building, eight locations in the Shield Building, and three areas in the Containment Internal Structures (CIS). Reference 206, Figures 6.1-2 through 6.1-6 and Tables 6.1-1 through 6.1-6 show the locations for the screened representative portion of building structures and the member force comparisons, respectively. The staff reviewed Reference 206, Tables 6.1-1 through 6.1-6 and noted that the member forces resulting from the AP1000 CSDRS are greater than those resulting from the WLS NI FIRS for all the screened representative portions of building structures. On this basis, the staff finds that the member forces resulting from the AP1000 CSDRS envelope those resulting from the WLS NI FIRS and, therefore, the design of the WLS NI structures using the AP1000 CSDRS input is acceptable.

The staff notes that the WLS COL FSAR supplemented information from the AP1000 DCD Appendix 3I. Specifically, the applicant identified WLS DEP 2.0-1 and added information to AP1000 DCD Sections 3I.1, 3I.2, 3I.3, 3I.6, 3I.6.1, 3I.6.2, 3I.6.3, 3I.6.4, and 3I.7. This added information describes the applicant's site-specific analysis supporting WLS DEP 2.0-1.
In relation to the applicant's assessment of structures, the staff noted that the additional information in AP1000 DCD Appendix 3I is consistent with the supplemental information provided in WLS COL FSAR Section 3.7 and, as such, it is addressed by the review and conclusions in Section 3.7 of this report. The staff reviewed the site-specific SSI analyses performed by the applicant to evaluate the exceedances between the WLS NI FIRS and the CSDRS and the HRHF spectra. The staff concludes that the WLS site-specific SSI analyses demonstrate that the AP1000 standard plant structural demands are adequate to use for the design of the NI SSCs at the WLS site. On this basis, the staff finds the WLS SUP 3.7-5 and the associated portions of WLS DEP 2.0-1 acceptable.

- WLS SUP 3.7-6

WLS SUP 3.7-6 addressed the development of time histories for use in site-specific analyses. The earthquake record (CHICHI/ILA031) from the 1999 Chi-Chi earthquake was selected from NUREG/CR-6728 (Magnitude>7, Distance=50-100 km, WUS Rock bin) as the seed time history record for the site-specific analyses. The time histories in this seed record (i.e., two horizontal and one vertical time histories) are modified so as to match the site-specific NI FIRS. As stated in WLS COL FSAR Section 3.7.2.12, the time step interval for the modified time histories is no more than 0.005 seconds and the total duration is no less than 30 seconds. (WLS COL FSAR Figures 3.7-203a to 3.7-203c show a total duration of about 90 seconds.) Furthermore, WLS COL FSAR Table 3.7-201 indicates strong motion duration greater than 6 seconds and cross correlation coefficient lower than 0.16 for the 3 time history components. During the May 2014 audit, the staff reviewed the development of the time histories for use in site-specific analyses including response spectra matching and power spectral density (PSD) calculations. The staff confirmed that the development of the time histories was performed in accordance with SRP Section 3.7.1, Option 1 - Approach 2. The staff finds that the developed time histories provide an acceptable representation of the WLS NI FIRS and, as such, acceptable for use in WLS site-specific analyses. Accordingly, WLS SUP 3.7-6 and the associated portions of WLS DEP 2.0-1 are acceptable.

The following portion of this technical evaluation section is reproduced from Section 3.7.2.4 of the VEGP SER:

<u>License Conditions</u>

- *Part 10, License Condition 2, Item 3.7-3*

The applicant has proposed a license condition requiring a seismic interaction review by the licensee for as-built information. This review is performed in parallel with the seismic margin evaluation. The review is based on as-procured data, as well as the as-constructed condition. The as-built seismic interaction review is to be completed prior to fuel load. The Staff has reviewed and approved this review methodology in Section 3.7.5.3 of the AP1000 DCD. Therefore, the staff finds the proposed License Condition 2 acceptable.

- *Part 10, License Condition 2, Item 3.7-4*

The applicant has proposed a license condition requiring a seismic analysis for detail design changes, such as those due to as-procured or as-built changes in component mass, center of gravity, and support configuration based on as-procured equipment information. The reconciliation of seismic analysis of NI structures will be complete prior to fuel load.

Conducting the seismic interaction review and the seismic analysis for detail design changes based on as-procured data, as well as the as-constructed condition, does not alter the methods of seismic evaluation required to ensure the as-built design parameters are consistent with the standard design and have been reviewed by the staff as part of VEGP COL 3.7-1, as well as the information incorporated by reference from the AP1000 DCD. In addition, the NRC staff understands and agrees with the need to have as-procured data and the as-constructed condition in order to properly conduct these analyses.

3.7.2.5 *Post Combined License Activities*

The staff notes that Part 10 of the WLS application, Proposed License Conditions (including ITAAC), includes License Condition 14 and ITAAC Table 3.3-10. The staff's review determined that this license condition and ITAAC are not needed because the information sought is adequately addressed in the application. As such, License Condition 14 and the Seismic Category II ITAAC are not addressed here and should be removed from the next revision of the WLS COL FSAR. This issue is being tracked as Confirmatory Item 3.7-1.

<u>Resolution of Confirmatory Item 3.7-1</u>

Confirmatory Item 3.7-1 is an applicant commitment to revise Part 10 of the WLS application to remove License Condition 14 and the Seismic Category II ITAAC. The staff verified that Part 10 of the WLS application was appropriately revised. As a result, Confirmatory Item 3.7-1 is now closed.

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license conditions acceptable:

- License Condition (3-2) – Before initial fuel load, the licensee shall update the seismic interaction analysis in AP1000 DCD, Rev. 19, Section 3.7.5.3 to reflect as-built information, which must be based on as-procured data, as well as the as-constructed condition.

- License Condition (3-3) – Before initial fuel load, the licensee shall reconcile the seismic analyses described in Section 3.7.2 of the AP1000 DCD, Rev. 19, to account for detailed design changes, including, but not limited to, those due to as-procured or as-built changes in component mass, center of gravity, and support configuration based on as-procured equipment information.

3.7.2.6 *Conclusion*

The staff's review confirmed that the applicant addressed the required information relating to the seismic system analysis, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 50, Appendix A, Appendix S, and other relevant staff guidance.

- WLS DEP 2.0-1 is acceptable because the applicant's site-specific analysis demonstrated that the AP1000 DCD design is adequate for use at the WLS site and this analysis addressed the relevant information that meets the guidance in NUREG-0800, Section 3.7.2 and ISG-1. In conclusion, the applicant has provided sufficient information to satisfy the requirements in 10 CFR Part 50, Appendix A, GDC 2; 10 CFR Part 50, Appendix S; and 10 CFR 100.23.

- WLS COL 3.7-1 is acceptable because the applicant addressed the relevant information that meets the guidance in NUREG-0800, Section 3.7.2. In conclusion, the applicant has provided sufficient information to satisfy the requirements in 10 CFR Part 50, Appendix A, GDC 2; 10 CFR Part 50, Appendix S; and 10 CFR 100.23

- WLS SUP 3.7-4 is acceptable because the applicant addressed the relevant information and performed adequate analyses that meet the guidance in NUREG-0800, Section 3.7.2. In conclusion, the applicant has provided sufficient information to satisfy the requirements in 10 CFR Part 50, Appendix A, GDC 2; 10 CFR Part 50, Appendix S; and 10 CFR 100.23.

- WLS SUP 3.7-5 is acceptable because the applicant addressed the relevant information and performed adequate analyses that meet the guidance in NUREG-0800, Section 3.7.2 and ISG-1. In conclusion, the applicant has provided sufficient information to satisfy the requirements in 10 CFR Part 50, Appendix A, GDC 2; 10 CFR Part 50, Appendix S; and 10 CFR 100.23.

- WLS SUP 3.7-6 is acceptable because the applicant addressed the relevant information and performed adequate analyses that meet the guidance in NUREG-0800, Section 3.7.1. In conclusion, the applicant has provided sufficient information to satisfy the requirements in 10 CFR Part 50, Appendix A, GDC 2; 10 CFR Part 50, Appendix S; and 10 CFR 100.23.

3.7.3 Seismic Subsystem Analysis

Seismic input motion, seismic analysis methods, and modeling procedure used for the analysis and design of AP1000 SC-I subsystems are described. In particular, this review focused on such subsystems as the miscellaneous steel platforms, steel frame structures, tanks, cable trays and supports, heating, ventilation, and air conditioning (HVAC) ductwork and supports, and conduit and supports.

Specifically, the criteria and methods for the seismic analysis of safety-related SSCs and equipment include the following:

- Seismic analysis methods
- Determination of number of earthquake cycles
- Procedures used for modeling
- Basis for selection of frequencies
- Equivalent static load method of analysis
- Three components of earthquake motion
- Combination of modal responses
- Analysis procedure for piping
- Vertical static factors
- Torsional effect of eccentric mass
- Seismic Category I buried piping systems and tunnels

- Interaction of other systems with seismic Category I systems
- Seismic analysis of reactor internals
- Analysis procedure for damping
- Analysis of seismic Category I tanks
- Time history analysis of piping systems

Section 3.7 of the WLS COL FSAR, Revision 11, incorporates by reference, Section 3.7.3, "Seismic Subsystem Analysis," of Revision 19 of the AP1000 DCD. In addition, in WLS COL FSAR Section 3.7, the applicant provided the following:

Departures

- WLS DEP 6.4-2

The applicant provided additional information in Table 3.7-207 of the WLS COL FSAR about WLS DEP 6.4-2 related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance. This information, as well as related WLS DEP 6.4-2 information appearing in other chapters of the FSAR, is reviewed in Section 21.3 of this SER.

The NRC staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The NRC staff's review confirmed that there is no outstanding issue related to this section. The results of the NRC staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.7.4 Seismic Instrumentation

3.7.4.1 *Introduction*

Installation of instrumentation that is capable of adequately measuring the effects of an earthquake at the plant site is addressed. The criteria for the seismic instrumentation include a comparison with RG 1.12, "Nuclear Power Plant Instrumentation for Earthquakes," Revision 2, the location and description of instrumentation, control room operator notifications, comparison of measured and predicted responses, and tests and inspections.

3.7.4.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.7 incorporates by reference AP1000 DCD, Section 3.7. The applicant provided the following information in WLS COL FSAR Section 3.7.4:

AP1000 COL Information Item

- STD COL 3.7-2

The applicant provided information for STD COL 3.7-2 in WLS COL FSAR Section 3.7.4.4 to resolve COL Information Item 3.7-2 on post-earthquake procedures to compare measured and predicted ground motions. In STD COL 3.7-2, the applicant stated that post-earthquake operating procedures utilize the guidance of Electric Power Research Institute (EPRI) Reports NP-5930, "A Criterion for Determining Exceedance of the Operating Basis Earthquake";

TR-100082, “Seismic Instrumentation in Nuclear Power Plants for Response to OBE Exceedance: Guideline for Implementation”; and NP-6695, “Guidelines for Nuclear Plant Response to an Earthquake” as modified and endorsed by the NRC in RG 1.166, “Pre-Earthquake Planning and Immediate Nuclear Power Plant Operator Post-earthquake Actions”; and RG 1.167, “Restart of a Nuclear Power Plant Shut Down by a Seismic Event.” A response spectrum check up to 10 Hz will be based on the foundation instrument. The cumulative absolute velocity (CAV) will be calculated based on the recorded motions at the free field instrument. If the OBE ground motion is exceeded or significant plant damage occurs, the plant must be shutdown in an orderly manner. In addition, in WLS COL FSAR Section 3.7.4.4 addresses measurement of post-seismic event gaps between the new fuel rack and walls of the new fuel storage pit, between the individual spent fuel racks, and from the spent fuel racks to the spent fuel pool walls.

- STD COL 3.7-5

The applicant provided information in STD COL 3.7-5 in WLS COL FSAR Section 3.7.4.2.1, “Tri-axial Acceleration Sensors,” to resolve COL Information Item 3.7-5. In STD COL 3.7-5, the applicant stated that a free-field sensor will be located and installed to record the ground surface motion representative of the site. It will be located such that the effects associated with surface features, buildings, and components on the recorded ground motion will be insignificant. The “trigger value” is also described.

Supplemental Information

- STD SUP 3.7-1

The applicant provided supplemental information in WLS COL FSAR Section 3.7.4.1 to address the guidance in RG 1.12 by stating that administrative procedures define the maintenance and repair of the seismic instrumentation to keep the maximum number of instruments in service during plant operation and shutdown.

- STD SUP 3.7-2

The applicant provided supplemental information in WLS COL FSAR Section 3.7.4.4 to address the test and inspection requirements for the acceleration sensors. In this section, the applicant stated that installation and acceptance testing of the tri-axial acceleration sensors described in AP1000 DCD Section 3.7.4.2.1 is completed prior to initial startup. Installation and acceptance testing of the time-history analyzer described in AP1000 DCD Section 3.7.4.2.2 is completed prior to initial startup.

Interface Requirements

AP1000 DCD Table 1.8-1, “Summary of AP1000 Plant Interfaces with Remainder of Plant,” Items 3.3, “Site seismic sensor location and ‘trigger’ value,” and 3.12, “Earthquake response procedures,” refer to interfaces associated with AP1000 DCD Section 3.7.4. The interface requirements for staff review (associated with AP1000 DCD Section 3.7.4.2) include an onsite implementation of the site seismic sensor locations and trigger values, and development of procedures by the COL applicant for earthquake responses from the seismic instrumentation.

3.7.4.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for seismic instrumentation are given in NUREG-0800, Section 3.7.4.

The regulatory requirements and guidance documents for STD COLs 3.7-2 and 3.7-5 and STD SUP 3.7-1 and STD SUP 3.7-2 are 10 CFR Part 50, Appendix S, RG 1.166, RG 1.167, and RG 1.12, which provide for installation of free field tri-axial acceleration sensors and establishment of post-earthquake procedures for comparing measured and predicted responses.

3.7.4.4 *Technical Evaluation*

The staff reviewed this application section and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic. The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the seismic instrumentation. The staff's evaluation of the information incorporated by reference in the WLS application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content for the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (i.e., VEGP) contains evaluation material from the SER for the BLN, Units 3 and 4 COL application. The one notable difference between the VEGP and WLS applications for these COL items is the specification in VEGP COL 3.7-5 that the free-field sensor is located on the ground surface of the engineering backfill. In the WLS COL FSAR, the exact location of the tri-axial ground surface acceleration free-field sensor is not specified, but will be installed using NRC-approved methodology, and will use the same trigger value, and the staff concludes that this minor difference does not negatively affect the conclusion reached previously by the staff. The staff reviewed the following information in the WLS COL FSAR:

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.7.4.4:

<u>AP1000 COL Information Items</u>

- *STD COL 3.7-2*

As a result of the review in Sections 9.1.1.2 and 9.1.2.2 of the AP1000 DCD, STD COL 3.7-2 in Section 3.7.4.4 of the VEGP COL FSAR was identified to clarify the measurement of the post-seismic event gaps between the new fuel rack and walls of the new fuel storage pit, between the individual spent fuel racks, and from the spent fuel racks to the spent fuel pool wall. In a letter dated October 15, 2010, the applicant committed to specify the site-specific procedures, following the guidance of EPRI Reports NP-5930, TR-10082, and NP-6695, for: 1) checking the gaps between the new fuel rack and walls of the new fuel storage pit, between the individual spent fuel racks, and from the spent fuel racks to the spent fuel pool walls following an earthquake; and 2) to take, if needed, appropriate corrective actions in the event of an earthquake such as repositioning the racks or analysis of the as-found condition. The staff considered the applicant response to be acceptable based on the applicant's commitment to use the post-earthquake procedures described in Section 3.7.5.2 of the AP1000 DCD, which comply with the requirements of Appendix S to 10 CFR Part 50. Therefore, the NRC staff considers STD COL 3.7-2 to be resolved. The incorporation of the planned VEGP COL FSAR changes will be tracked as Confirmatory Item 3.7-2.

<u>Resolution of Confirmatory Item 3.7-2</u>

Confirmatory Item 3.7-2 is an applicant commitment to revise its FSAR to adjust the left margin annotations related to STD COL 3.7-2. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.7-2 is now closed.

- *VEGP COL 3.7-2*

The NRC staff reviewed VEGP COL 3.7-2 related to COL Information Item 3.7-2 (COL Action Item 3.7.5-2) included under Section 3.7.4.4 of the VEGP COL FSAR.

The applicant provided additional information in VEGP COL 3.7-2 to resolve COL Information Item 3.7-2. COL Information Item 3.7-2 states:

> *Combined License applicants referencing the AP1000 certified design will prepare site-specific procedures for activities following an earthquake. These procedures will be used to accurately determine both the response spectrum and the cumulative absolute velocity of the recorded earthquake ground motion from the seismic instrumentation system. The procedures and the data from the seismic instrumentation system will provide sufficient information to guide the operator on a timely basis to determine if the level of earthquake ground motion requiring shutdown has*

> *been exceeded. The procedures will follow the guidance of EPRI Reports NP-5930, TR-100082, and NP-6695, as modified by the NRC staff.*

The commitment was also captured as COL Action Item 3.7.5-2 in Appendix F of NUREG-1793, which states:

> *The COL applicant will specify site-specific procedures for activities following an earthquake and those procedures will follow the guidance of Reports NP-5930, TR-100082, and NP-6695 promulgated by the Electric Power Research Institute (EPRI).*

In VEGP COL 3.7-2, the applicant stated the following:

> *Post-earthquake operating procedures utilize the guidance of EPRI Reports NP-5930, TR-100082, and NP-6695, as modified and endorsed by the NRC in Regulatory Guides 1.166 and 1.167. A response spectrum check up to 10Hz will be based on the foundation instrument. The cumulative absolute velocity will be calculated based on the recorded motions at the free field instrument. If the operating basis earthquake ground motion is exceeded or significant plant damage occurs, the plant must be shutdown in an orderly manner.*

The NRC staff reviewed the resolution to VEGP COL 3.7-2 related to comparison of measured and predicted seismic responses included under Section 3.7.4.4 of the VEGP COL FSAR. The applicant committed to specify site-specific procedures, which follow the guidance of EPRI Reports NP-5930, TR-10082, and NP-6695, for activities following an earthquake, which were endorsed by RGs 1.166 and 1.167. In RAI 3.7.4-1, issued to the BLN applicant, the staff asked the applicant to clarify if CAV will be used as one of the criteria to determine if a power plant should be shutdown should the OBE ground motion be exceeded or significant plant damage occurs. The BLN applicant responded by stating "As indicated in FSAR Subsection 3.7.4.4, use of the guidance of Regulatory Guide 1.166 and NP-5930 signifies that CAV is to be used as one of the post-earthquake criteria for determining whether the plant should be shutdown. In addition, BLN COL FSAR Appendix 1AA indicates conformance to the guidance of Regulatory Guide 1.166." The staff considered the applicant's response to be adequate because the BLN applicant confirmed that it will use the recommended criteria from the RG 1.166 to determine a potential plant shutdown, and the staff concludes that this RAI is closed. Furthermore, the BLN response to RAI 3.7.4-4 was endorsed as standard for VEGP by SNC letter dated December 17, 2008.

Based on the VEPG applicant's commitment to use the procedures accepted by NRC for post-earthquake activities and the clarification on the use of CAV in RAI 3.7.4-1, the NRC staff concludes that the applicant provided adequate information regarding the post earthquake activities and procedures to determine if a power plant needs to be shutdown and considers VEGP COL 3.7-2 resolved.

- *VEGP COL 3.7-5*

The applicant provided additional information in VEGP COL 3.7-5 to resolve COL Information Item 3.7-5 (COL Action Item 3.7.5-4) included under Section 3.7.4.2.1 of the VEGP COL FSAR. COL Information Item 3.7-5 states:

> *The Combined License applicant will determine the location for the free-field acceleration sensor as described in [DCD] Subsection 3.7.4.2.1.*

The commitment was also captured as COL Action Item 3.7.5-4 in Appendix F of NUREG-1793, which states:

> *The COL applicant will determine the location for the free-field acceleration sensor.*

In VEGP COL 3.7-5, the applicant stated the following:

> *A free-field sensor will be located and installed to record the ground surface motion representative of the site. To be representative of this site in regards to seismic response of structures, systems, and components, the free-field sensor is located on the ground surface of the engineered backfill. The backfill directly supports the Nuclear Island and the adjacent structures and extends out from these structures a significant distance. The free field sensor is located where the backfill vertically extends from the top of the Blue Bluff Marl to the ground surface, but horizontally at a distance where possible effects on recorded ground motion associated with surface features, buildings, and components would be minimized. The trigger value is initially set at 0.01g.*

The NRC staff reviewed the resolution to VEGP COL 3.7-5 related to triaxial acceleration sensors included under Section 3.7.4.2.1 of the VEGP COL FSAR. The applicant used the guidance in RGs 1.166 and 1.167 and supplemented information in the DCD with appropriate content, as required by Appendix S to 10 CFR Part 50. The applicant also committed to determining the location of the free field acceleration sensor and installing the sensor in a protected area. Based on the applicant's commitment to determine the location of the free-field acceleration sensor and the description of the location provided in STD COL 3.7-5, the staff concludes that the applicant presented sufficient information on the description and locations of field triaxial acceleration sensors and considers VEGP COL 3.7-5 resolved.

<u>*Supplemental information*</u>

- *STD SUP 3.7-1*

The applicant added the following supplemental information at the end of VEGP COL FSAR Section 3.7.4.1 to address RG 1.12:

> *Administrative procedures define the maintenance and repair of the seismic instrumentation to keep the maximum number of instruments inservice during plant operation and shutdown in accordance with Regulatory Guide 1.12.*

The NRC staff reviewed the resolution to STD SUP 3.7-1 using the guidance in RG 1.12 and in Appendix S to 10 CFR Part 50. Because of the equivalence of the applicant's proposed resolution to the administrative procedures, maintenance and repair plans of RG 1.12, the staff concludes the applicant has adequately resolved STD SUP 3.7-1.

- *STD SUP 3.7-2*

The applicant added the following supplemental information at the end of VEGP COL FSAR Section 3.7.4.4 to address comparison of measured and predicted responses:

> *Installation and acceptance testing of the triaxial acceleration sensors described in DCD Subsection 3.7.4.2.1 is completed prior to initial startup. Installation and acceptance testing of the time-history analyzer described in DCD Subsection 3.7.4.2.2 is completed prior to initial startup.*

The NRC staff reviewed the resolution to STD SUP 3.7-2, related to the timing of installation and acceptance testing of the triaxial acceleration sensors described in DCD Section 3.7.4.2.1 for the VEGP site. Because of the equivalence of the proposed resolution of STD SUP 3.7-2 to the general operability guidance for seismic equipment addressed in RG 1.12, RG 1.166 and RG 1.167, the staff concludes the applicant adequately resolved STD SUP 3.7-2.

3.7.4.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.7.4.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the WLS COL applicant addressed the required information relating to seismic instrumentation, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL application is acceptable and meets the requirements of 10 CFR Part 50, Appendix S and complies with the guidance provided in RG 1.166, RG 1.167, and RG 1.12. The staff based its conclusions on the following:

- STD COL 3.7-2 is acceptable because the applicant is committed to use the procedures endorsed by RG 1.166 and RG 1.167 and because the applicant provided sufficient information to satisfy the requirements 10 CFR Part 50, Appendix S by committing to address the measurement of the post-seismic event gaps between the new fuel rack and walls of the fuel storage pit and to take appropriate corrective actions.

- STD COL 3.7-5 is acceptable because the applicant provided sufficient information to satisfy the requirement 10 CFR Part 50, Appendix S by committing to determining the location of the free-field acceleration sensor and installing the sensor in the protected area.

- STD SUP 3.7-1 is acceptable because the applicant is committed to follow RG 1.12, to include developing administrative procedures to define the maintenance and repairing of the seismic instrumentation to keep the maximum number of instruments in service during plant operation and shutdown.

- STD SUP 3.7-2 is acceptable because the applicant provided sufficient information to satisfy the requirement of 10 CFR Part 50, Appendix S by committing to complete installation and acceptance testing of the seismic instrumentation prior to initial startup.

3.8 Design of Category I Structures

3.8.1 Concrete Containment

This section is not applicable to the WLS design, because AP1000 uses a steel containment.

3.8.2 Steel Containment

The steel containment in the AP1000 DCD provides the following information:

- Description of the containment
- Applicable codes, standard, and specifications
- Loads and load combinations
- Design and analysis procedures
- Structural acceptance criteria
- Materials, quality control, and special construction techniques
- In-service testing (IST) and inspection requirements

Section 3.8 of the WLS COL FSAR, Revision 11, incorporates by reference Section 3.8.2, "Steel Containment," of Revision 19 of the AP1000 DCD. In addition, in the WLS COL FSAR, the applicant provided the following:

Departures

- WLS DEP 6.3-1 and WLS DEP 3.2-1

The applicant provided additional information about WLS DEP 6.3-1 and WLS DEP 3.2-1 in Section 3.8.2 of the FSAR related to design modifications to the condensate return portion of the Passive Core Cooling System and quantifying the duration that the passive residual heat removal heat exchanger can maintain safe shutdown conditions, respectively. This information, as well as related WLS DEP 3.2-1 and WLS DEP 6.3-1 information appearing in other chapters of the FSAR, is reviewed in Section 21.1 of this report.

The NRC staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The NRC staff's review confirmed that there is no outstanding issue related to this section. The results of the NRC staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. Section 21.1 of this report evaluates the departures from the DCD provided in WLS DEP 6.3-1 and WLS DEP 3.2-1.

3.8.3 Concrete and Steel Internal Structures of Steel Containment

Structures inside the containment support the reactor coolant system components and related piping systems and equipment inside the containment and provide radiation shielding. These containment internal structures consist of the primary shield wall, reactor cavity, secondary shield walls, in-containment refueling water storage tank (IRWST), refueling cavity walls, operating floor, intermediate floors, and various platforms, and are not part of the containment pressure boundary.

The containment internal structures are constructed of concrete and structural steel. At the lower elevations, conventional concrete and reinforcing steel are used, except that permanent steel forms are used in some areas in lieu of removable forms based on constructability considerations (modular construction). These steel form modules (liners) consist of two steel plates reinforced with steel angle stiffeners and tee sections. The angles and the tee sections are on the concrete side of the plate. Welded studs, or similar embedded steel elements, are attached to the inside of the steel plates where surface attachments to the plate transfer loads into the concrete. Where these surface attachments are Seismic Category I, the portion of the steel module transferring the load into the concrete is classified as Seismic Category I.

WLS COL FSAR, Revision 11, Section 3.8, incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 3.8.3, "Concrete and Steel Internal Structures of Steel Containment." The staff reviewed the application and checked the referenced DCD to ensure that no issues relating to this section remained for review.[1] The staff's review confirmed that there are no outstanding issues related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

AP1000 COL Information Item

- STD COL 3.8-5

In an April 25, 2011, letter, the WLS COL applicant endorsed an October 1, 2010, letter from the VEGP applicant, proposing STD COL 3.8-5 and adding new WLS COL FSAR Sections 3.8.3.7, 3.8.4.7, and 3.8.5.7. The applicant provided information in STD COL 3.8-5 addressing the construction inspection program related to Seismic Category I and II structures. The staff's evaluation of STD COL 3.8-5 is included in Section 3.8.5 of this report.

3.8.4 Other Seismic Category I Structures

3.8.4.1 *Introduction*

The AP1000 DCD defines "other" Seismic Category I structures as the shield building, the auxiliary building, the containment air baffle, Seismic Category I cable tray supports, and Seismic Category I HVAC supports.

The criteria for other Category I structures include the following:

- Description of the structures
- Applicable codes, standards, and specifications
- Loads and load combinations
- Design and analysis procedures
- Structural acceptance criteria
- Materials, quality control, and special construction techniques
- In-service testing (IST) and inspection requirements
- Construction inspection

3.8.4.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.8, incorporates by reference Section 3.8.4, "Other Category I Structures," of the AP1000 DCD, Revision 19. In addition, in WLS COL FSAR Section 3.8.4, the applicant provided the following:

Departures

- WLS DEP 3.8-1

The applicant provided a description summary of the site-specific lateral earth pressure on the nuclear island below-grade wall departure from the AP1000 DCD. This departure affects WLS COL FSAR Section 3.8.4.4.4 and WLS COL FSAR Figures 3.8-201a, -202a, -203, and -204.

AP1000 COL Information Item

- STD COL 3.8-5

The applicant provided information in its application regarding STD COL 3.8-5 addressing the construction inspection program related to Seismic Category I and II structures. In an April 25, 2011, letter, the applicant endorsed the October 1, 2010, letter from the VEGP applicant proposing STD COL 3.8-5 and adding new Sections 3.8.3.7, 3.8.4.7, and 3.8.5.7 to the WLS COL FSAR. The staff's evaluation of STD COL 3.8-5 is included in Section 3.8.5.4 of this report.

Supplemental Information

- STD SUP 3.8-1

The applicant provided a supplement to the existing AP1000 DCD Section 3.8.4.4.4, "Below Grade Exterior Walls," under the sub-heading, "Load Combinations." The supplement provides information supporting the WLS DEP 3.8-1 related to the departure of the WLS site-specific lateral earth pressure from the AP1000 DCD.

3.8.4.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations are given in NUREG-0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition," Section 3.8.4.

3.8.4.4 *Technical Evaluation*

The staff reviewed this application and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to other seismic Category I structures. The staff's evaluation of the information incorporated by reference in the WLS COL application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review evaluate subsequent COL applications. To ensure that the staff's findings on standard content for the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the COL FSAR.
- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double indented formatting.

Departures

- WLS DEP 3.8-1

The staff's evaluation of WLS DEP 3.8-1 is accomplished through the evaluation of the supplemental information section STD SUP 3.8-1. This supplemental information is evaluated below.

Supplemental Information

- STD SUP 3.8-1

STD SUP 3.8-1 addresses WLS DEP 3.8-1 related to the departure of the WLS site-specific lateral earth pressure from the AP1000 DCD. WLS COL FSAR Section 2.5.4.10.3, “Lateral Pressures,” provides a description of the WSL site-specific lateral earth pressures. The departure is the use of a site-specific passive pressure on the below-grade NI walls that is less than the full passive pressure assumed in the analysis of the standard plant. The reason for the departure is that the conservative use of full site-specific passive earth pressure results in an earth pressure exceeding the value used in the standard design. The focus of the staff’s review is the adequacy of the applicant’s justification for the use of partial passive earth pressure and the validity of the approach used to calculate that pressure. WLS COL FSAR Section 2.5.4.10.3, “Lateral Pressures,” provides a description of the WSL site-specific lateral earth pressures. The applicant stated that lateral earth pressures are developed against the below-grade nuclear island walls because of the placement and compaction of granular backfill material and that lateral earth pressures are calculated for active, at-rest, and passive pressure conditions. The applicant further stated that “Westinghouse has evaluated the Lee Nuclear Station site-specific lateral earth pressures and has determined that they are bounded by the standard AP1000 design pressures.”

In RAI 112, Question 02.05.04-20, the staff requested that the applicant provide additional information to confirm that the site-specific lateral earth pressures are bounded by the AP1000 standard design. In an April 10, 2014, response to RAI 112, Question 02.05.04-20, the applicant provided tables that show the comparison of the WLS site-specific lateral earth pressure on the NI’s below grade walls with corresponding pressures that were used in the AP1000 standard design for all the load combinations. The applicant stated that the site-specific lateral pressures on the NI exterior walls below grade are bounded by the AP1000 design pressures for Load Combinations 1 through 6, 8, and 9 in both the east-west (E-W) and north-south (N-S) directions. The applicant noted that the site-specific lateral pressure in Load Combination 7 (LC7), which includes the summation of the full passive lateral earth pressure, the static and dynamic lateral surcharges, and the water pressure for the well-graded gravel (GW) backfill material slightly exceeds the AP1000 LC7 lateral pressure. The applicant stated that the difference in the Load Combination 7 for WLS site compared to the AP1000 generic site is attributed to the site-specific groundwater level, which is 2.4 m (8 ft) below ground surface as compared to the AP1000 groundwater level of 0.6 m (2 ft) below ground surface; a difference of 1.8 m (6 ft) of non-buoyant (heavier) soil resulting in a higher passive earth pressure.

The applicant calculated analytical estimates of the fraction of the full WLS site-specific passive earth pressure that might be mobilized in the GW backfill using a given displacement of the nuclear island assumed as 05 cm (0.2 in.) The applicant included WLS COL FSAR Table 3.8-201 that summarizes the mobilized fraction of the full WLS passive lateral earth pressure for the assumed 0.5 cm (0.2 in) displacement for the range of water-table depths at the WLS site and for the range of values used for the soil modulus and Poisson’s ratio.

AP1000 DCD Section 3.8.5.5.5, “Seismic Stability Analysis,” states that the maximum lateral displacement at the base of the nuclear island when subjected to the CSDRS is expected to be 0.31 cm (0.12 in.) neglecting buoyancy of the nuclear island and 0.48 cm (0.19 in.) considering buoyancy effects. These values are without considering passive resistance from the backfill; therefore, the applicant’s assumed 0.5 cm (0.2 in.) displacement in the analytical estimate is considered conservative. The applicant stated that development of the full passive pressure requires more displacement than the nuclear islands will experience during a seismic event and small lateral displacements such as these are not capable of developing the full passive earth pressure. Therefore, the site-specific nuclear island below-grade wall pressures resulting from the NI FIRS will be less than those used in the standard AP1000 design for this load combination.

The staff reviewed the applicant's April 10, 2014, response to RAI 112, Question 02.05.04-20, and noted that WLS COL FSAR Figures 3.8-203, "William S. Lee Nuclear Station - Mobilized Wall Pressures vs. AP1000 Design Load (E-W)," and 3.8-204, "William S. Lee Nuclear Station - Mobilized Wall Pressures vs. AP1000 Design Load (N-S)," illustrate that the WLS passive pressure in LC7 will not be fully developed and that the pressures on the below-grade walls for the AP1000 standard design continue to bound the pressures that will actually occur at the WLS site. During a May 2014 structural audit, the staff reviewed the, "Lateral Pressure on Nuclear Island Foundation Walls," calculation and found the applicant's approach for estimating the earth pressures to be consistent with the methodology described in its responses to RAI 112, Question RAI 02.05.04-20. For the reasons stated above, the staff finds the applicant's responses to RAI 112, Question RAI 02.05.04-20 acceptable. Therefore, the staff considers STD SUP 3.8-1 and WLS DEP 3.8-1 acceptable because the applicant demonstrated that the passive pressure developed by site-specific conservative maximum displacements is bounded by the AP1000 passive pressure. Accordingly, the staff considers RAI 112, Question 02.05.04-20 resolved.

3.8.4.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.8.4.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to other Seismic Category I structures. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of GDC 1, 2, 4, and 5 in 10 CFR Part 50, Appendix A.

- WLS DEP 3.8-1 is acceptable because the applicant adequately address the relevant information that meets the guidance in NUREG-0800, Section 3.8.4. In conclusion, the applicant has provided sufficient information to satisfy 10 CFR Part 50, Appendix A, GDC 1, GDC 2, GDC 4, and GDC 5.

- STD SUP 3.8-1 is acceptable because the applicant adequately addressed the relevant information that meets the guidance in NUREG-0800, Section 3.8.4. In conclusion, the applicant has provided sufficient information to satisfy the requirements in10 CFR Part 50, Appendix A, GDC 1, GDC 2, GDC 4, and GDC 5.

3.8.5 Foundations

3.8.5.1 *Introduction*

The NI structures consist of the Containment Building, the Shield Building, and the Auxiliary buildings located on a common 1.8 m (6 ft) thick, cast-in-place, reinforced concrete basemat foundation. Adjoining buildings, such as the Radwaste Building, Turbine Building, and Annex Building, are structurally separated from the NI structures by a 5 cm (2 in.) gap at and below grade. A 10 cm (4 in.) minimum gap is provided above grade. This provides space to prevent interaction between the NI structures and the adjacent structures during a seismic event. This space provides the required factor of safety to accommodate lateral movement under the most stringent loading conditions.

The criteria for the design of foundations include the following:

- Description of the foundations
- Applicable codes, standards, and specifications
- Loads and load combinations
- Design and analysis procedures
- Standard acceptance criteria
- Materials, quality control, and special construction techniques
- In-service testing (IST) and inspection requirements
- Construction inspection

3.8.5.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.8 incorporates by reference AP1000 DCD, Revision 19, Section 3.8. AP1000 DCD Section 3.8 includes Section 3.8.5. In addition, in WLS COL FSAR Section 3.8.5, the applicant provided the following:

AP1000 COL Information Items

- WLS COL 2.5-17

The applicant proposed information in WLS COL FSAR Section 3.8.4.7 addressing the type of waterproofing system to be used for the below-grade exterior walls exposed to flood and to groundwater under Seismic Category I structures. In WLS COL FSAR, Section 3.8.4.1, “Description of the Foundations,” the applicant also stated that the site-specific waterproofing approach has not been selected and the applicant will notify the NRC of its selection of system and the qualification testing thereof, on a set schedule.

- STD COL 3.8-5

In an April 25, 2011, letter, the applicant endorsed the August 17, 2010, letter from the VEGP applicant, which proposed STD COL 3.8-5,to replace AP1000 DCD Sections 3.8.3.7, 3.8.4.7, 3.8.5.7, 3.8.6.5. The applicant also provided new WLS COL FSAR sections and revised WLS COL FSAR Section 17.6. The applicant provided information in STD COL 3.8-5 addressing the construction inspection program related to Seismic Category I and II structures.

- STD COL 3.8-6

In an April 25, 2011, letter, the applicant endorsed the October 1, 2010, letter from the VEGP applicant that proposed STD COL 3.8-6 that added a new Section 3.8.6.6 to the WLS COL FSAR. The applicant provided information in STD COL 3.8-6 addressing the construction procedure program related to safety-related Seismic Category I structures. The construction procedures program addresses the pre- and post-concrete placement, and use of construction mock-ups for the steel-concrete composite shield building modules.

Supplemental Information

- STD SUP 3.8-1

The applicant provided supplemental information by adding additional text which states that the depth of overburden and depth of embedment are given in WLS COL FSAR Section 2.5.4.

License Condition

- Part 10, License Condition 6, “Operational Program Readiness,” Item 6.i

The applicant proposed to add “Item 6.i” to proposed License Condition 6 that addresses the availability to of the schedule for the implementation of operational programs, such as construction and inspection procedures, and procedures for concrete placement, use of construction mock-ups, and inspection of module concrete for concrete-filled steel plate modules to the NRC.

ITAAC

The licensee shall satisfy the non-system ITAAC described in WLS COL, Part 10, Appendix B, as new Table 3.3-9, “Waterproof Membrane Inspections, Tests, Analyses, and Acceptance Criteria (Sheet 1 of 1),” requiring a report that documents the as-built waterproofing membrane system beneath the NI basemat has a coefficient of friction to resist sliding of ≥ 0.55, through material qualification testing.

3.8.5.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations (GDC 1, GDC 2, GDC 4, and GDC 5 in 10 CFR Part 50, Appendix A; 10 CFR 50.55(a), and 10 CFR Part 50, Appendix B) for the foundations are given in NUREG-0800, Section 3.8.5.

3.8.5.4 *Technical Evaluation*

The staff reviewed this application section and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic. The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to the foundations. The staff’s evaluation of the information incorporated by reference in the WLS application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content for the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.
- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double indented formatting. The staff reviewed the following information in the WLS COL FSAR.

AP1000 COL Information Items

- *WLS COL 2.5-17*

SRP Section 3.8.5 requires confirmation that the nuclear island remains stable under design-basis demands. AP1000 DCD Section 3.4.1.1.1.1, "Waterproofing," states that (1) the waterproof membrane between the mudmat must provide adequate shear strength to transfer horizontal shear caused by seismic loading and (2) the function of the membrane is Seismic Category I. In this regard, AP1000 DCD Section 3.4.1.1.1 provides a requirement for the COL applicant to identify a waterproofing system and to demonstrate a friction coefficient greater than or equal to 0.55 with all horizontal concrete surfaces.

The staff reviewed the WLS COL FSAR and noticed that although there is a proposed ITAAC in WLS COL Part 10, Appendix B, Table 3.3-9, to address the coefficient of friction, there is no description of the selected waterproofing-membrane design. The staff notes that the regulations in 10 CFR 52.79, "Contents of applications; technical information in final safety analysis report," require the FSAR to contain information relative to materials of construction, arrangement, and dimensions sufficient to provide reasonable assurance that the design will conform to the design bases with adequate margin for safety. Therefore, in RAI 102, Question 03.08.05-6, the staff requested that the applicant describe, in an update to WLS COL FSAR Section 3.8.5.1, the proposed waterproofing approach and demonstrate compliance with the AP1000 DCD provisions. In a January 17, 2012, response to RAI 102, Question 03.08.05-6, the applicant stated that the nuclear island mudmat waterproofing system for the WLS nuclear station has not been chosen. However, the applicant confirmed that the waterproofing system selected will be chosen from one of the acceptable alternatives described in AP1000 DCD Section 3.4.1.1.1.1 and will be demonstrated to produce a friction coefficient of 0.55 or greater with the mudmat's horizontal concrete surface.

The staff reviewed the applicant's January 17, 2012, response to RAI 102, Question 03.08.05-6, and noted that the applicant committed to (1) use one of the three waterproofing membrane systems identified in the standard AP1000 design, and (2) demonstrate that the waterproofing membrane meets the waterproofing and friction requirements of greater than or equal to 0.55 as specified in the AP1000 DCD Section 3.4.1.1.1.1. For the reasons stated above, the staff finds the applicant's response to RAI 102, Question 03.08.05-6 acceptable. Accordingly, the staff considers RAI 102, Question 03.08.05-6 resolved.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.8.5.4:

- *STD COL 3.8-5*

In a letter dated August 17, 2010, the applicant proposed STD COL 3.8-5, adding a new Section 3.8.3.7, 3.8.4.7, and 3.8.5.7 to the VEGP COL FSAR addressing the construction inspection program related to seismic Category I and II structures. The construction inspection program will be consistent with the maintenance rule (10 CFR 50.65) and guidance in RG 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants," in addressing maintenance requirements for the seismic Category I and seismic Category II structures. The staff concludes that the applicant has provided an acceptable construction inspection program that meets the requirement described in Section 3.8.4.8 of the AP1000 DCD. Therefore, the NRC staff considers STD COL 3.8-5 to be resolved. The incorporation of the planned VEGP COL FSAR changes will be tracked as Confirmatory Item 3.8-2.

<u>Resolution of Standard Content Confirmatory Item 3.8-2</u>

Confirmatory Item 3.8-2 is an applicant commitment to revise its FSAR Table 1.8-202, Table 1.9-201, Appendix 1AA, Section 3.8.3.7, Section 3.8.4.7, Section 3.8.5.7, Section 3.8.6.5, and Section 17.6 to address STD COL 3.8-5. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.8-2 is now closed.

- *STD COL 3.8-6*

In a letter dated October 1, 2010, the applicant proposed STD COL 3.8-6, adding a new Section 3.8.6.6 to the VEGP COL FSAR addressing the construction procedure program related to safety-related Category I structures. The construction procedures program addresses the pre- and post-concrete placement, and use of construction mock-ups for the SC modules. The staff concludes that the applicant has provided an acceptable construction procedures program that meets the requirement described in Section 3.8.4.8 of the AP1000 DCD. Therefore, the NRC staff considers STD COL 3.8-6 to be resolved. The incorporation of the planned VEGP COL FSAR changes will be tracked as Confirmatory Item 3.8-3.

<u>Resolution of Standard Content Confirmatory Item 3.8-3</u>

Confirmatory Item 3.8-3 is an applicant commitment to revise its FSAR Table 1.8-202 and Section 3.8.6.6 to address STD COL 3.8-6. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.8-3 is now closed.

Supplemental Information

- STD SUP 3.8-1

In WLS COL FSAR Section 3.8.5.1, “Description of the Foundations,” the applicant cited Section 2.5.4, “Stability of Subsurface Materials and Foundations,” which describes the depth of overburden and embedment of the WLS foundation. A foundation is a structural element that connects the superstructure and the supporting medium, such as soils or rocks. The purpose of the foundation is to hold the superstructure in place and to transmit all the loads from the superstructure to the underlying soils or rocks. The NI foundation basemat will be supported by the existing concrete foundation of Cherokee Nuclear Station Unit 1, which is underlain by continuous rock or by fill concrete supported on continuous rock; rock that is fresh to moderately weathered as determined by visual inspection, and is expected to have a Rock Quality Designation (RQD) of at least 65 percent based on the site exploration boring logs.

Sliding and Overturning

WLS COL FSAR Section 2.5.4.5.3.1, “Nuclear Island Foundation Materials,” provides a description of the overturning and sliding stability evaluation of the Seismic Category I and II structures. The applicant stated that the foundation quality rock and fill concrete provide adequate safety margins against bearing-capacity failure for both static and seismic loading of the NI and that only nominal settlement will occur. In its review of WLS COL FSAR Section 2.5.4.5.3.1, the staff noted that the applicant did not provide sufficient information concerning the factor of safety for sliding and overturning for the Seismic Category I structures.

During the May 2014 structural audit held in Cranberry Township, PA, the staff discussed with the applicant the limited information in the WLS COL FSAR related to the factor of safety for sliding and overturning for the WLS NI structures. The staff requested that the applicant provide the sliding and overturning evaluation of the NI structures subject to dynamic loads. The applicant presented the seismic analysis of the WLS NI, including the resultant shear and moment. The sliding and overturning results were conservative when compared to the AP1000 DCD minimum factor of safety values of 1.1 and 1.5 for sliding and overturning, respectively. However, to better understand as well as document the aspects and the results of the stability analysis, the staff issued post-audit RAI 121, Question 03.08.05-7, requesting that the applicant provide additional information that shows a comparison of the WLS NI maximum basemat forces and moments to the AP1000 CSDRS design-basis forces and moments.

In response to RAI 121, Question 03.08.05-7, the applicant provided WLS COL FSAR Table 2-1, “Comparison of Nuclear Island Maximum Absolute Forces and Moments: Lee vs. CSDRS,” which summarized the seismic analysis results. The table shows the maximum reaction forces and moments at the center of gravity of the WLS NI. The applicant stated that the comparison of the WLS and the AP1000 CSDRS maximum NI basement forces and moments was performed based on time-history seismic analyses using the latest NI20u ANSYS model with contact elements at the basemat interface with the rock. The results of the comparison showed that the site-specific WLS sliding and overturning forces and moments are all less than the AP1000 design-basis forces and moments.

In reviewing the applicant’s response, the staff noted that results of the comparison of the AP1000 CSDRS forces and moments enveloped the WLS forces and moments with significant margin. The comparison of the maximum forces and moments in the table shows that the factors of safety for resultant shear and moments are 2.06 and 3.68, respectively. These factors of safety are greater than the corresponding AP1000 minimum factors of safety of 1.1 for sliding and 1.5 for overturning. Moreover, the sliding and overturning analysis performed by the applicant was carried out by models and using methods acceptable to the staff. Based on the information presented above, the staff considers the applicant's response acceptable because the applicant was able to demonstrate that the WLS NI sliding and overturning factors of safety are adequate. Accordingly, the staff considers RAI 121, Question 03.08.05-7 resolved.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.8.5.4:

> _License Condition_
>
> - *Part 10, License Condition 6*
>
> *In its letter dated October 1, 2010, the applicant proposed to add another line item to proposed License Condition 6 addressing the availability to NRC inspectors of the schedule for the implementation of construction and inspection procedures related to concrete activities. Specifically, the applicant has proposed to add a new standard item to proposed License Condition 6 to read (where # is the next appropriate letter).*
>
> > *#. the implementation of construction and inspection procedures for concrete filled steel plate modules activities before and after concrete placement, use of construction mock-ups, and inspection of modules before and after concrete placement as discussed in DCD Subsection 3.8.4.8.*
>
> *The applicant's proposed new standard item related to concrete construction and inspection procedures will allow the staff sufficient time to inspect the procedures. Therefore, the staff finds the addition of this line item to the proposed License Condition 6 acceptable.*

3.8.5.5 *Post Combined License Activities*

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following ITAAC and license condition acceptable:

- The licensee shall perform and satisfy the non-system ITAAC described in WLS Combined License Application (COLA), Part 10, Appendix B, Table 3.3-9, "Waterproof Membrane Inspections, Tests, Analyses, and Acceptance Criteria (Sheet 1 of 1)."

- License Condition (3-4) – No later than 12 months after issuance of the COL, the licensee shall submit to the Director of NRO, or the Director's designee, a schedule for implementation of the construction and inspection procedures for steel concrete composite (SC) construction activities for seismic Category I nuclear island modules. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until each this license condition has been fully implemented. The schedule shall identify the completion of or implementation of the construction and inspection procedures for steel concrete composite (SC) construction activities for seismic Category I nuclear island modules (including shield building SC modules) described in AP1000 DCD Rev. 19, Section 3.8.4.8.

3.8.5.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to foundations and that no outstanding information is expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of GDC 1, GDC 2, GDC 4, and GDC 5 in 10 CFR Part 50, Appendix A. The staff based its conclusion on the following:

- STD SUP 3.8-1 is acceptable because the applicant adequately provided the relevant information that meets the guidance in NUREG-0800, Section 3.8.5 and specifically addresses WLS COL 2.5-6; WLS COL 2.5-7; WLS COL 2.5-10; WLS COL 2.5-12; and the sliding and overturning evaluation of the Seismic Category I and II structures. In conclusion, the applicant provided sufficient information to satisfy 10 CFR Part 50, Appendix A, GDC 1 GDC 2, GDC 4, and GDC 5.

- WLS COL 2.5-17 is acceptable because the applicant committed to (1) use one of the three waterproofing-membrane systems identified in AP1000 DCD Section 3.4.1.1.1.1 standard design and that were reviewed and accepted by the staff; and (2) demonstrate that the waterproofing membrane meets the waterproofing and friction requirements of greater than or equal to 0.55 as specified in the AP1000 DCD, Section 3.4.1.1.1.1.

3.9 Mechanical Systems and Components

Structural integrity and functional capability of various safety-related mechanical components are described. The design is not limited to ASME Code components and supports, but is extended to other components such as control rod drive mechanisms (CRDMs), certain reactor internals, and any safety-related piping designed to industry standards other than the ASME Code. The design includes issues such as load combinations, allowable stresses, methods of analysis, summary of results, and preoperational testing. The evaluation of this section is focused on determining whether there is adequate assurance of a mechanical component performing its safety-related function under all postulated combinations of normal operating conditions, system operating transients, postulated pipe breaks, and seismic events.

3.9.1 Special Topics for Mechanical Components

In WLS COL FSAR Section 3.9.1, "Special Topics for Mechanical Components," design transients and methods of analysis are described for all Seismic Category I components, component supports, core support (CS) structures, and reactor internals designated as Class 1, 2, 3, and CS under ASME Code, Section III, and those not covered by the ASME Code. Also included are the assumptions and procedures used for the inclusion of transients in the design and fatigue evaluation of ASME Code Class 1 and CS components and the computer programs used in the design and analysis of Seismic Category I components and their supports, as well as experimental and inelastic analytical techniques.

WLS COL FSAR, Revision 11, Section 3.9 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 3.9.1, "Special Topics for Mechanical Components." The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.9.2 Dynamic Testing and Analysis of Systems, Structures and Components

The criteria, testing procedures, and dynamic analyses employed to ensure the structural and functional integrity of piping systems, mechanical equipment, reactor internals, and their supports (including supports for conduit and cable trays, and ventilation ducts) under vibratory loadings, are addressed in this section. The loadings include those due to fluid flow (and especially loading caused by adverse flow conditions, such as flow instabilities over standoff pipes and branch lines in the steam system) and postulated seismic events.

WLS COL FSAR, Revision 11, Section 3.9, incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 3.9.2, "Dynamic Testing and Analysis of Systems, Structures and Components." The staff reviewed the WLS COL application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] Specific to departure WLS DEP 2.0-1, which was not referenced in Section 3.9.2 of the WLS COL FSAR but is addressed further in other sections in this chapter, FSAR Reference 206 shows that the reactor vessel and internals were chosen for evaluation as representative of major equipment. From the analyses performed, the CSDRS was found to have higher loads and stresses than those from the WLS site-specific seismic response. Hence, the WLS site-specific seismic response does not impact the structural integrity of the reactor vessel and internals. The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.9.3 ASME Code Class 1, 2, and 3 Components, Component Supports, and Core Support Structures

3.9.3.1 *Introduction*

The structural integrity and functional capability of pressure-retaining components, their supports, and CS structures are ensured by designing them in accordance with ASME Code, Section III, or other industrial standards. The loading combinations and their respective stress limits, the design and installation of pressure-relief devices, and the design and structural integrity of ASME Code Class 1, 2, and 3 components and component supports are included.

3.9.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.9, incorporates by reference AP1000 DCD, Revision 19, Section 3.9. In addition, in WLS COL FSAR Section 3.9.3, the applicant provided the following:

Departures

- WLS DEP 6.4-2

The applicant provided additional information in Table 3.9-202 of the WLS COL FSAR about WLS DEP 6.4-2 related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance. This information, as well as related WLS DEP 6.4-2 information appearing in other chapters of the FSAR, is reviewed in Section 21.3 of this SER.

AP1000 COL Information Items

- STD COL 3.9-2

The applicant provided information in WLS COL FSAR Section 3.9.8.2, "Design Specifications and Reports," for STD COL 3.9-2 to address COL Information Item 3.9-2, which states that "Reconciliation of the as-built piping (verification of the thermal cycling and stratification loadings considered in the stress analysis discussed in [DCD] Section 3.9.3.1.2) is completed by the COL holder after the construction of the piping systems and prior to fuel load." Evaluation of this particular COL Information Item is provided in Section 3.12 of this report.

- STD COL 3.9-3

The applicant provided information in WLS COL FSAR Sections 3.9.3.4.4, "Inspection, Testing, Repair, and/or Replacement of Snubbers," and 3.9.8.3, "Snubber Operability Testing," for STD COL 3.9-3 to address COL Information Item 3.9-3, which describes snubber design and testing, snubber installation requirements, and snubber preservice and inservice examination and testing.

- STD COL 3.9-5

The applicant provided information in WLS COL FSAR Sections 3.9.3.1.2, "Loads for Class 1 Components, Core Support, and Component Supports," and 3.9.8.5, "Surge Line Thermal Monitoring," for STD COL 3.9-5 to address COL Information Item 3.9-5, that addresses pressurizer surge line monitoring. Evaluation of this particular COL information item is provided in Section 3.12 of this report.

- STD COL 3.9-7

In a June 21, 2011, letter, the applicant endorsed the April 23, 2010, letter from the VEGP applicant that proposed to add STD COL 3.9-7 to the WLS COL FSAR. The applicant provided information in WLS COL FSAR Section 3.9.8.7, "As-Designed Piping Analysis," to address STD COL 3.9-7. This COL item provides additional information on the process to be used to complete the piping design and to complete the ITAAC added to verify the design. Evaluation of this particular COL information item is provided in Section 3.12 of this report.

3.9.3.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the ASME Code Class 1, 2, and 3 components, component supports, and CS structures are given in NUREG-0800, Section 3.9.3.

3.9.3.4 *Technical Evaluation*

The staff reviewed this application section and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic. The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the ASME Code Class 1, 2, and 3 components, component supports, and core support structures. The staff's evaluation of the information incorporated by reference in the WLS application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content for the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews.

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and found the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (VEGP) contains evaluation material from the SER for the BLN, Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from Section 3.9.3.4 of the VEGP SER:

> <u>*AP1000 COL Information Items*</u>
>
> - *STD COL 3.9-3*
>
> *AP1000 DCD, Section 3.9.8.3, "Snubber Operability Testing," states that COL applicants referencing the AP1000 design will develop a program to verify operability of essential snubbers as outlined in Section 3.9.3.4.3, "Snubbers Used as Component and Piping Supports," and Section 3.9.3.4.4, "Inspection,*

Testing, Repair and/or Replacement of Snubbers." In the BLN COL FSAR, the applicant states in Section 3.9.8.3, "Snubber Operability Testing," that STD COL 3.9-3 is addressed in BLN COL FSAR Section 3.9.3.4.4, which incorporates by reference AP1000 DCD Section 3.9.3.4.4, with supplemental snubber information added to the end of the existing Section 3.9.3.4.4.

As indicated in the BLN COL FSAR, STD COL 3.9-3 contains a wide range of supplemental information on snubber design and testing requirements, snubber installation requirements, and snubber preservice and inservice examination and testing. It was not clear to the staff, however, whether STD COL 3.9-3 had provided the required information called for by AP1000 DCD, Section 3.9.8.3. In RAI 3.9.3-1, the staff requested that the applicant address the following: (1) clarify what was meant by "snubber operability testing" when the applicant prepared the COL information; (2) discuss whether the entire STD COL 3.9-3 represents BLN's plant-specific, updated snubber requirements, not already covered in AP1000 DCD, Section 3.9.3; (3) clarify whether all or part of STD COL 3.9-3 is related to snubber operability testing; (4) for the portions of STD COL 3.9-3 which are not related to snubber operability testing, explain why they are included as part of the COL item; (5) discuss all the pertinent codes and standards on which STD COL 3.9-3 is based to assure snubber operability; and (6) discuss the need to modify the content and the physical placement of STD COL 3.9-3 in the BLN COL FSAR.

In its response, the applicant explained that information presented in BLN COL FSAR Section 3.9.3.4.4 regarding snubber testing includes information specific to qualification and installation tests and examinations for snubbers included in the inservice testing (IST) program and preservice examination and testing programs; and information specifically related to snubber inservice examination and testing. The applicant acknowledges, therefore, that not all information added by STD COL 3.9-3 is related specifically to snubber "operability testing." The applicant also noted that BLN COL FSAR Section 3.9.3.4.4 has been subjected to a revision responding to a separate staff RAI on snubber IST programs. Details of the applicant's responses to the RAI are provided in the following:

(1) For the purpose of STD COL 3.9-3, operability testing encompasses the preservice and inservice examinations and testing required by the ASME Code for Operation and Maintenance (OM) for Nuclear Power Plants (ASME OM Code), Subsection ISTD, "Preservice and Inservice Examination and Testing of Dynamic Restraints (Snubbers) in Light-Water Reactor Nuclear Power Plants" as described in BLN COL FSAR Section 3.9.3.4.4.c and Section 3.9.3.4.4.d (as revised in applicant's response to RAI 3.9.6-3).

(2) In order to provide a complete description of the snubber operability testing program, that is, the preservice and IST programs for snubbers, additional information was provided in BLN COL FSAR Section 3.9.3.4.4 as indicated in the applicant's letter to the NRC in response to RAI 3.9.6-3. Previously, only snubber preservice examination and testing had been described in BLN COL FSAR Section 3.9.3.4.4.c.

(3) As noted above, some of the information provided in the original BLN COL FSAR Section 3.9.3.4.4 relates to snubber qualification testing and examinations and snubber installation verification requirements. These activities are considered precursors to the snubber operability testing that will be conducted in accordance with the ASME OM Code, Subsection ISTD.

(4) The information not specifically related to STD COL 3.9-3 operability testing, i.e., Sections 3.9.3.4.4.a and 3.9.3.4.4.b, should have been labeled as standard supplemental information, using the left margin annotation STD SUP 3.9-3.

(5) Snubber operability testing is to be conducted during implementation of the preservice and ISI and testing programs in accordance with the requirements of the ASME OM Code, Subsection ISTD. As indicated in the first paragraph of BLN COL FSAR Section 3.9.3.4.4, the description of the program provided in the BLN COL FSAR is based on the 2001 Edition through the 2003 Addenda of the ASME OM Code. However, the initial IST program for snubbers will incorporate the latest Edition and Addenda of the ASME OM Code approved in 10 CFR 50.55a(f) on the date 12 months before initial fuel load.

(6) BLN COL FSAR Section 3.9.3.4.4 will be revised as indicated in the Application Revision section of this response to segregate the snubber operability testing from the remaining portions of the section (i.e., the snubber design and qualification testing, and the snubber installation requirements) and to include the appropriate left margin annotation. In addition, to maintain consistency, to the extent possible, with other industry COL applications, Section 3.9.3.4.4.a is revised to clarify and expand on snubber qualification examination and testing. Finally, minor editorial changes are made to the Section 3.9.3.4.4.c changes provided in the applicant's letter to the NRC in response to RAI 3.9.6-3. Additionally, changes will be made to the introductory (roadmap) paragraph for BLN COL FSAR Section 3.9.3.4.4 indicating it is a new subsection to follow DCD Section 3.9.3.4.3.

The staff found that above responses provided by the applicant to be adequate in clarifying that the information for snubber operability testing originally provided in STD COL 3.9-3 was primarily intended for preservice and inservice examination and testing. The staff also found that the supplemental information provided under a new STD SUP 3.9-3, for snubber design and qualification testing, and the snubber installation requirements includes a better description for snubber design and qualification testing, and is more consistent with other industry COL applications. The staff confirmed that Revision 1 has incorporated all the changes as required. RAI 3.9.3-1 is closed.

Clarification of BLN SER Standard Content

Based on the staff's review of the standard content, there were two minor changes of an editorial nature that were found not to affect the staff's conclusion.

The first paragraph discussed in Item (5) above was moved in the final VEGP COL FSAR such that it is appropriately included with the write up specific to STD COL 3.9-3. The introductory (roadmap) paragraph was not changed as described following Item (6) above because the AP1000 DCD was modified to include a paragraph numbered "3.9.3.4.4." As a result, the new text was added to an existing section as opposed to being a standalone section.

Resolution of Difference Between FSARs

In Section 3.9.3.4.4 of the BLN COL FSAR, the BLN applicant stated that a list of snubbers on systems which experience sufficient thermal movement to measure cold to hot position, is included as part of the testing program after piping analysis has been completed. In Section 3.9.3 of the VEGP COL FSAR, the VEGP applicant provides Table 3.9-201 with this list of snubbers. The addition of a list of snubbers on systems which experience sufficient thermal movement to measure cold to hot position to the VEGP COL FSAR is acceptable to the staff.

3.9.3.5 *Post Combined License Activities*

There are no post COL activities related to this section.

3.9.3.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to ASME Code Class 1, 2, and 3, components, component supports and CS structures, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 52, "Licenses, certifications, and approvals for nuclear power plants." The staff based its conclusion on the following:

- WLS DEP 6.4-2, related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance, is reviewed and found acceptable by the staff in Section 21.3 of this SER.

- STD COL 3.9-3 is acceptable because the applicant addressed the relevant information that meets the guidance in NUREG-0800, Section 3.9.3. In conclusion, the applicant provided sufficient information to satisfy the requirements in 10 CFR Part 50, Appendix A, GDC 1 and GDC 4.

3.9.4 Control Rod Drive System

The control rod drive system (CRDS) consists of the control rods and the related mechanical components that provide the means for mechanical movement. As discussed in GDC 26, "Reactivity Control System Redundancy and Capability" and GDC 27, "Combined Reactivity Control Systems Capability," the CRDS provides one of the independent reactivity control systems. The rods and the drive mechanism are capable of reliably controlling reactivity changes either under conditions of anticipated operational occurrences, or under postulated accident conditions. A positive means for inserting the rods is always maintained to ensure appropriate margin for malfunction, such as stuck rods. Since the CRDS is a safety-related system and portions of the CRDS are a part of the RCPB, the system is designed, fabricated, and tested to quality standards commensurate with the safety-related functions to be performed. This provides an extremely high probability of accomplishing the safety-related functions either in the event of anticipated operational occurrences or in withstanding the effects of postulated accidents and natural phenomena such as earthquakes, as discussed in GDC 1; GDC 2; GDC 14, “Reactor Coolant Pressure Boundary;” GDC 29 “Protection Against Anticipated Operational Occurrences;” and 10 CFR 50.55a.

WLS COL FSAR, Revision 11, Section 3.9, incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 3.9.4, “Control Rod Drive System (CRDS).” The staff reviewed the WLS COL application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff’s review confirmed that there is no outstanding issue related to this section. The results of the staff’s technical evaluation of the information incorporated by reference are documented in NUREG-1793 and its supplements.

3.9.5 Reactor Pressure Vessel Internals

AP1000 reactor internals consist of two major assemblies - the lower internals and the upper internals. The reactor internals provide protection, alignment and support for the core. Control rods and gray rods provide safe and reliable reactor operation. In addition, the reactor internals help to accomplish the following: direct the main coolant flow to and from the fuel assemblies; absorb control rod dynamic loads, fuel assembly loads, and other loads and transmit these loads to the reactor vessel; support instrumentation within the reactor vessel; provide protection for the reactor vessel against excessive radiation exposure from the core; and position and support reactor vessel radiation surveillance specimens.

WLS COL FSAR, Revision 11, Section 3.9, incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 3.9.5, “Reactor Pressure Vessel Internals.” The staff reviewed the WLS COL application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff’s review confirmed that there is no outstanding issue related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.9.6 Inservice Testing of Pumps and Valves

3.9.6.1 *Introduction*

In this section, the staff describes its review of the functional design, qualification, and inservice testing (IST) programs for pumps, valves, and dynamic restraints as required by the NRC regulations in 10 CFR Part 52 and 10 CFR 50.55a, “Conditions of Construction Permits, Early Site Permits, Combined Licenses, and Manufacturing Licenses,” for WLS. RG 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” discusses the Commission’s position provided in SECY-05-0197, “Review of Operational Programs in a Combined License Application and General Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria,” that operational programs should be fully described in COL applications to avoid the need to specify ITAAC for those programs. The applicant relies on the WLS COL FSAR, with its incorporation by reference of the AP1000 DCD and supplemental information, to fully describe the IST and motor-operated valve (MOV) testing operational programs in support of the COL application for WLS.

3.9.6.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 3.9, incorporates by reference AP1000 DCD, Revision 19, Section 3.9. In addition, in WLS COL FSAR Section 3.9.6, the applicant provided the following

Departures

- WLS DEP 6.4-2

The applicant provided additional information in Table 3.9-203 of the WLS COL FSAR about WLS DEP 6.4-2 related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance. This information, as well as related WLS DEP 6.4-2 information appearing in other chapters of the FSAR, is reviewed in Section 21.3 of this SER.

AP1000 COL Information Item

- STD COL 3.9-4

The applicant provided information in several sections of WLS COL FSAR Section 3.9.6 in response to STD COL 3.9-4 to supplement the AP1000 DCD provisions to fully describe the IST and MOV testing programs for WLS. For example, the WLS COL FSAR supplements the provisions in the AP1000 DCD with respect to the Edition and Addenda of the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) applicable to the description of the IST program for WLS, determination of the MOV testing frequency, operability testing of power-operated valves (POVs) other than MOVs, performance of check valve exercise tests, and plans to apply alternatives to the ASME OM Code.

The AP1000 DCD addresses the functional design and qualification of mechanical equipment to be used at an AP1000 nuclear power plant in several AP1000 DCD sections. For example, AP1000 DCD Section 3.9.3.2, “Pump and Valve Operability Assurance,” states that criteria are developed to assess the functional capability of required components to operate. AP1000 DCD Section 3.9.3.2.2, “Valve Operability,” indicates that operational tests will be performed to verify that valves open and close prior to installation. This section also specifies cold hydro tests, hot functional tests, periodic inservice inspections (ISIs), and periodic inservice operations to be performed in situ to verify the functional capability of the valves. AP1000 DCD Section 5.4.8, “Valves,” includes provisions regarding design and qualification, and preoperational testing of valves within the scope of those systems, and refers to these activities for other safety-related valves. AP1000 DCD Section 5.4.8.3, “Design Evaluations,” specifies that the requirements for qualification testing of power-operated active valves are based on ASME Standard QME-1-2007, “Qualification of Active Mechanical Equipment Used in Nuclear Power Plants.” AP1000 DCD Section 5.4.9, “Reactor Coolant System Pressure Relief Devices,” includes provisions for design, testing, and inspection of relief devices in the reactor coolant system. AP1000 DCD Section 5.4.10, “Component Supports,” includes provisions for design, testing, and inspection of component supports in the reactor coolant system. The WLS COL FSAR incorporates by reference these specific sections in the AP1000 DCD.

With respect to flow-induced vibration (FIV) of plant components, AP1000 DCD Section 3.9.2, "Dynamic Testing and Analysis," describes tests to confirm that piping, components, restraints, and supports have been designed to withstand the dynamic effects of steady-state FIV and anticipated operational transient conditions. AP1000 DCD Section 14.2.9.1.7, "Expansion, Vibration and Dynamic Effects Testing," states that the purpose of the expansion, vibration and dynamic effects testing is to verify that the safety-related, high-energy piping and components are properly installed and supported such that, in addition to other factors, vibrations caused by steady-state or dynamic effects do not result in excessive stress or fatigue to safety-related plant systems. The WLS COL FSAR incorporates by reference these sections in the AP1000 DCD.

AP1000 DCD, Section 3.9.3.4.4, "Inspection, Testing, Repair, and/or Replacement of Snubbers," specifies that a program for inservice examination and testing of dynamic supports (snubbers) will be prepared in accordance with the requirements of the ASME OM Code, Subsection ISTD, "Preservice and Inservice Examination and Testing of Dynamic Restraints (Snubbers) in Light-Water Reactor Nuclear Power Plants." AP1000 DCD Section 3.9.3.4.4 indicates that details of the snubber inservice examination and testing program, including test schedules and frequencies, will be reported in the ISI and testing plan included in the IST program required by AP1000 DCD Section 3.9.8.3, "Snubber Operability Testing." AP1000 DCD Section 3.9.8.3 states that COL applicants referencing the AP1000 design will develop a program to verify operability of essential snubbers. The WLS COL FSAR provides supplemental information for AP1000 DCD Section 3.9.3.4.4 regarding snubbers. For example, WLS COL FSAR Section 3.9.3.4.4, includes provisions for snubber design and testing with specifications that snubber qualification and production testing will satisfy the applicable sections of the ASME Boiler and Pressure Vessel Code (BPV Code); the ASME OM Code; and ASME Standard QME-1-2007. WLS COL FSAR Section 3.9.3.4.4 also describes the inservice examination and testing of safety-related snubbers in accordance with the requirements of the ASME OM Code, Subsection ISTD. The description includes specifications for initial and subsequent examination intervals, visual examination attributes, IST methods and intervals, establishment of snubber test groups, response to examination and test results, snubber repair and replacement, post-maintenance examination and testing, and establishment and monitoring of snubber service life. WLS COL FSAR Table 3.9-201, "Safety Related Snubbers," provides a list of safety-related snubbers to be installed, including the snubber identification number and the associated system or component.

AP1000 DCD Section 3.9.6, "Inservice Testing of Pumps and Valves," provides a general description of the IST Program to be developed for AP1000 reactors. AP1000 DCD Table 3.9-16, "Valve Inservice Test Requirements," lists valves within the scope of the IST program provided in support of the AP1000 DC, and indicates the valve tag number, valve and actuator type, safety-related missions, safety functions, ASME Code class and IST category, and IST type and frequency. WLS COL FSAR Section 3.9.6 incorporates by reference AP1000 DCD Section 3.9.6 with supplemental information in several areas. For example, the applicant states that the description of the IST program for WLS is based on the ASME OM Code, 2001 Edition through 2003 Addenda. The applicant also indicates that the initial IST program will incorporate the latest edition and addenda of the ASME OM Code approved in 10 CFR 50.55a(f) on the date 12 months before initial fuel load. In the WLS COL FSAR, the applicant described the periodic testing program for POVs other than MOVs that incorporates lessons learned based on nuclear power plant operating experience and research programs for MOV performance. The applicant also indicated its plan to apply Revision 1 to ASME OM Code Case OMN-1, "Alternative Rules for the Preservice and Inservice Testing of

Certain Electric Motor-Operated Valve Assemblies in Light Water Reactor Power Plants," as an alternative to the quarterly MOV stroke-time testing provisions in the ASME OM Code, and to satisfy the supplemental requirements specified in 10 CFR 50.55a(b)(3)(ii) to ensure that MOVs continue to be capable of performing their design-basis safety functions. The WLS COL FSAR does not identify any additional plant-specific valves to be included in the IST program beyond those listed in AP1000 DCD Table 3.9-16.

License Conditions

- Part 10, License Condition 3, "Operational Program Implementation," Items G.2 and G.5

The applicant proposed a license condition providing the implementation milestones for the Preservice Testing Program and MOV Testing Program.

- Part 10, License Condition 6, "Operational Program Readiness," Item 6.d

The applicant proposed a license condition to provide a schedule to support the NRC inspection of operational programs, including the Preservice Testing Program and MOV Testing Program.

3.9.6.3 *Regulatory Basis*

The regulatory basis of the design related information incorporated by reference is addressed in NUREG-1793 and its supplements. The regulatory basis for the staff's review of the WLS COL FSAR is provided by 10 CFR Parts 50 and 52. Specifically, the NRC regulations in 10 CFR 52.79(a) require that the COL application include information at a level sufficient to enable the Commission to reach a final conclusion on all safety matters that must be resolved by the Commission before COL issuance. For example, paragraph (4) in 10 CFR 52.79(a) requires that a COL application include the design of the facility with specific reference to the GDC in 10 CFR Part 50, Appendix A which establish the necessary design, fabrication, construction, testing, and performance requirements for SSCs that provide reasonable assurance that the facility can be operated without undue risk to the health and safety of the public. 10 CFR 52.79(a), Paragraph (11) requires that a COL application provide a description of the programs and their implementation necessary to ensure that the systems and components meet the requirements of the ASME BPV Code and the ASME OM Code in accordance with 10 CFR 50.55a. 10 CFR 52.79(a), Paragraph (29)(i) requires that a COL application provide plans for conduct of normal operations, including maintenance, surveillance, and periodic testing of SSCs. 10 CFR 52.79(a), Paragraph (37) requires that a COL application provide the information necessary to demonstrate how operating experience insights have been incorporated into the plant design.

RG 1.206 provides guidance for a COL applicant in preparing and submitting its COL application in accordance with NRC regulations. For example, RG 1.206, Section C.IV.4 discusses the requirement in 10 CFR 52.79(a) for descriptions of operational programs that need to be included in the FSAR for a COL application to allow a reasonable assurance finding of acceptability. In particular, a COL applicant should fully describe the IST, MOV testing, and other operational programs as defined in Commission Paper SECY-05-0197 to avoid the need for ITAAC for the implementation of those programs. The term "fully described" for an operational program should be understood to mean that the program is clearly and sufficiently described in terms for scope and level of detail to allow a reasonable assurance finding of acceptability. Further, operational programs should be described at a functional level and an increasing level of detail where implementation choices could materially and negatively affect the program effectiveness and acceptability. The Commission approved the use of a license condition for operational program implementation milestones that are fully described or referenced in the FSAR as discussed in the SRM for SECY-05-0197, February 22, 2006.

The staff followed NUREG-0800, Section 3.9.6, “Functional Design, Qualification, and Inservice Testing Programs for Pumps, Valves, and Dynamic Restraints,” in its review of the WLS COL application. The staff also evaluated the WLS COL FSAR information against the guidance provided in RG 1.206. Appendix 1AA, “Conformance with Regulatory Guides,” and confirms that the COL application conforms to RG 1.206 without exceptions related to the IST program. In addition, WLS COL FSAR Table 1.9-202, “Conformance with SRP Acceptance Criteria,” conforms to NUREG-0800, Section 3.9.6.

3.9.6.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 3.9.6 and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to functional design, qualification and IST programs for pumps, valves, and dynamic restraints. The results of the staff’s evaluation of the design-related information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The results of the staff’s review of the material in the AP1000 DCD related to the IST operational program for pumps, valves, and dynamic restraints are in this section of the report.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each “standard issue” and use this review to evaluate subsequent COL applications. To ensure that the staff’s findings on standard content that were documented in the SER for the reference COL application (i.e., VEGP Units 3 and 4) were equally applicable to the WLS COL application, the staff undertook the following reviews.

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were included in the WLS COL FSAR.

- The staff verified that site-specific differences did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (i.e., VEGP) contains evaluation material from the SER for the BLN, Units 3 and 4 COL application. The staff reviewed the following information in the WLS COL FSAR:

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.9.6.4:

> *In its letter dated December 17, 2008, Southern Nuclear Operating Company (SNC) listed the RAIs prepared by the NRC staff on the BLN Units 3 and 4 COL application. In that letter, SNC endorsed the responses, including proposed changes to the FSAR, submitted by the Tennessee Valley Authority (TVA) on 16 RAIs related to the functional design, qualification, and IST programs for pumps, valves, and dynamic restraints as applicable to the VEGP COL application. In letters dated December 14, 2009, and January 12, March 1, and May 14, 2010, SNC described its plans to resolve open items identified in the "SER with open items on the standard content information" prepared by the NRC staff on the description of the functional design, qualification, and IST programs for pumps, valves, and dynamic restraints in the BLN Units 3 and 4 COL application. The NRC staff has reviewed the SNC letters and Revision 2 to the VEGP COL FSAR to determine whether the description of the functional design, qualification, and IST programs for pumps, valves, and dynamic restraints in the VEGP COL application with its incorporation by reference of the AP1000 DCD meets the regulatory requirements to provide reasonable assurance that those components at VEGP will be capable of performing their safety functions if these programs are developed and implemented consistent with the description in the VEGP COL FSAR and AP1000 DCD.*

> - *STD COL 3.9-4*
>
> *The NRC staff reviewed STD COL 3.9-4 related to COL Information Item 3.9-4 included in AP1000 DCD Tier 2, Section 3.9.8.4. COL Information Item 3.9-4 states:*
>
>> *Combined License applicants referencing the AP1000 design will develop an inservice test program in conformance with the valve inservice test requirements outlined in subsection 3.9.6 and Table 3.9-16. For power-actuated valves, the requirements for operability testing shall be based on subsection 3.9.6.2.2. This program will include provisions for nonintrusive check valve testing methods and the program for valve disassembly and inspection outlined in subsection 3.9.6.2.3. The Combined License applicant will complete an evaluation as identified in subsection 3.9.6.2.2 to determine the frequency of power-operated valve operability testing.*
>
> *The information item for COL applicants to develop an IST Program was specified as COL Action Item 3.9.6.4-1 in Appendix F of NUREG-1793, which states:*

> *The COL applicant will provide an inservice test (IST) program that complies with the inservice testing requirements for valves.*

In STD COL 3.9-4, the applicant states that this COL item is addressed in Sections 3.9.6, 3.9.6.2.2, 3.9.6.2.3, 3.9.6.2.4, 3.9.6.2.5, and 3.9.6.3 for the VEGP COL application.

In this section of the SER, the NRC staff describes its review of the VEGP COL FSAR with the incorporation by reference of the AP1000 DCD for an acceptable description of the functional design, qualification, and IST programs, including the MOV Testing Program, for VEGP Units 3 and 4 to provide reasonable assurance that the safety-related components within the scope of the VEGP IST Program will be capable of performing their safety functions in accordance with the NRC regulations and the ASME Code requirements.

AP1000 DCD Tier 2, Section 3.9.6.1, "Inservice Testing of Pumps," specifies that the AP1000 reactor design does not include pumps with safety functions with the exception of the coastdown of the reactor coolant pumps. As determined in NUREG-1793, the NRC staff considers the IST Program scope for the AP1000 design with respect to pumps to be acceptable. Therefore, the NRC staff did not include pumps in the review of the IST Program for safety-related components at VEGP Units 3 and 4.

VEGP COL FSAR Section 3.9.6 states that the description of the IST Program for VEGP Units 3 and 4 is based on the ASME OM Code, 2001 Edition through 2003 Addenda, and that the limitations and modifications set forth in 10 CFR 50.55a will be incorporated. The NRC regulations in 10 CFR 50.55a incorporate by reference the ASME OM Code, 2001 Edition through 2003 Addenda, with certain limitations and modifications. Therefore, the NRC staff considers the application of the ASME OM Code, 2001 Edition through 2003 Addenda, as incorporated by reference in the NRC regulations with applicable limitations and modifications, to be acceptable for the VEGP IST Program description in support of the VEGP COL application. As specified in 10 CFR 50.55a, a COL licensee is required to incorporate in its IST Program the latest Edition and Addenda of the ASME OM Code approved in 10 CFR 50.55a(f) on the date 12 months before initial fuel load.

The VEGP COL FSAR incorporates by reference AP1000 DCD Tier 2, Table 3.9-16, "Valve Inservice Test Requirements," that includes the valve type, safety-related missions, safety functions, the ASME Code IST category, and IST type and frequency. The NRC staff considers this table to be sufficient in describing the IST Program in support of the VEGP COL application. Following the issuance of the VEGP COL, the guidance in NUREG-1482, "Guidelines for Inservice Testing at Nuclear Power Plants," can be used to develop the VEGP IST Program, including the specific information to be included in the IST Program documentation and tables for NRC inspection.

On March 26 and 27, 2008, the NRC staff held a public meeting to discuss the NRC's review of the description of the functional design, qualification, and IST programs for pumps, valves, and dynamic restraints in COL applications *referencing the AP1000 certified design and the AP1000 DC amendment application. At the public meeting, Westinghouse stated that it would make information available on the functional design and qualification of safety-related valves and dynamic restraints within the scope of the AP1000 DCD in design and procurement specifications that will be applicable to AP1000 COL applications. On October 14 and 15, 2008, the NRC staff conducted an audit of design and procurement specifications for pumps, valves, and dynamic restraints to be used for the AP1000 reactor at the Westinghouse office in Monroeville, Pennsylvania. In a memorandum dated November 6, 2008, the NRC staff documented the results of the onsite review with specific open items. For example, the staff found that Westinghouse had included ASME Standard QME-1-2007 in its design and procurement specifications for AP1000 components. ASME QME-1-2007 incorporates lessons learned from valve testing and research programs performed by the nuclear industry and the NRC Office of Nuclear Regulatory Research. Also, AP1000 DCD Tier 2 has been revised in Section 5.4.8.3 to specify that the provisions for qualification testing of power-operated active valves will be based on ASME QME-1-2007. In September 2009, the NRC issued RG 1.100, "Seismic Qualification of Electric and Active Mechanical Equipment and Functional Qualification of Active Mechanical Equipment for Nuclear Power Plants," Revision 3, which accepts the use of ASME QME-1-2007, with certain staff positions, for the functional design and qualification of safety-related pumps, valves, and dynamic restraints. In a letter dated January 26, 2010, Westinghouse provided its planned response to the audit follow-up items. In a letter dated December 14, 2009, SNC stated, in response to Standard Content Open Item 3.9-1 in the "SER with open items" on the BLN COL application, that it had not identified any specific actions for the VEGP COL application based on the audit open items. The NRC staff discussion of the audit of the design and procurement specifications for pumps, valves, and dynamic restraints to be used for the AP1000 reactor is in the SER on the AP1000 DC amendment application. Therefore, the staff considers Standard Content Open Item 3.9-1 resolved.*

The VEGP COL FSAR incorporates by reference AP1000 DCD Tier 2, Section 3.9.3.4, "Component and Piping Supports," and adds a new Section 3.9.3.4.4, "Inspection, Testing, Repair and/or Replacement of Snubbers." VEGP COL FSAR Section 3.9.3.4.4 specifies that snubber design and testing will satisfy the applicable sections of the ASME BPV Code, ASME OM Code, and ASME QME-1-2007. Further, VEGP COL FSAR Section 3.9.3.4.4 describes the snubber inservice examination and testing program for VEGP Units 3 and 4. For example, the FSAR specifies that the inservice examination and testing of safety-related snubbers will be conducted in accordance with the requirements of the ASME OM Code, Subsection ISTD. The inservice visual examination will be performed to identify physical damage, leakage, corrosion, degradation, indication of binding, misalignment or deformation, and potential defects generic to a particular design. Snubbers will be tested in service to determine operational readiness during each fuel cycle, beginning no sooner than 60 days before the start of the refueling outage. Defined test plan groups will be established and snubbers in each group will be tested each fuel cycle according to an established sampling plan. Unacceptable snubbers will be adjusted, modified, or replaced. Service life for snubbers will be established, monitored, *and adjusted in accordance with ASME OM Code, ISTD-6000, "Service Life Monitoring," and ASME OM Code, Appendix F, "Dynamic Restraints (Snubbers) Service Life Monitoring Methods." In addition, VEGP COL FSAR Table 3.9-201 provides a list of safety-related snubbers to be installed at VEGP, including the snubber identification number and the associated system or component. Revision 3 to RG 1.100 accepts with certain conditions the use of ASME QME-1-2007 for the functional design and qualification of dynamic restraints. The NRC staff finds that the provisions in the VEGP COL FSAR, together with the AP1000 DCD, provide an acceptable description of the inservice examination and testing program for dynamic restraints that support a finding that the program, when developed and implemented, will satisfy the 10 CFR 50.55a regulatory requirements.*

The VEGP COL FSAR incorporates by reference AP1000 DCD Tier 2, Section 3.9.6.2.2, "Valve Testing," with supplemental information. Table 3.9-16 in AP1000 DCD lists the valves in the IST Program for the AP1000 design. VEGP COL FSAR Section 3.9.6.2.2 includes provisions for (a) the establishment of reference values; (b) the prohibition of preconditioning that undermines the purpose of IST activities; (c) comparison of stroke time to the reference value except for fast-acting valves for which a stroke-time limit of 2 seconds is assigned; (d) determination of valve obturator movement during valve exercise tests; (e) testing of solenoid-operated valves; (f) preoperational testing of check valves; (g) acceptance criteria for check valve tests; (h) use of nonintrusive techniques for check valve tests; (i) test conditions for check valve tests; (j) post-maintenance testing for check valves; (k) check valve disassembly and testing; and (l) re-establishment of reference values following maintenance. The VEGP COL FSAR also includes provisions for valve disassembly and inspection; valve preservice tests; and valve replacement, repair, and maintenance in Sections 3.9.6.2.3 to 3.9.6.2.5. The NRC staff finds that these provisions in the VEGP COL FSAR are consistent with Subsection ISTC of the ASME OM Code incorporated by reference in 10 CFR 50.55a, and therefore, are acceptable.

In its letter dated March 1, 2010, SNC provided its planned response for VEGP to Standard Content Open Item 3.9-2 on POV operability tests discussed in the "SER with open items" on the BLN COL application. The NRC staff review of the response by SNC to the three issues in this open item is discussed below.

First, SNC states in its letter dated March 1, 2010, that TVA had indicated in its response to BLN RAI 3.9.6-8 that the BLN COL FSAR would be revised to indicate that MOV testing will apply the provisions of ASME OM Code Case OMN-1 (Revision 1) and the guidance in the Joint Owners Group (JOG) MOV Periodic Verification Program including the applicable NRC safety evaluation (and its supplement) for periodic verification of the design-basis capability of safety-related MOVs. SNC did not consider additional changes to the VEGP COL FSAR to be necessary. The NRC staff finds that the VEGP COL FSAR with its incorporation by reference of the AP1000 DCD (including the planned DCD changes) will address the use of JOG MOV Periodic Verification Program. As the AP1000 IST Program applies the JOG MOV Periodic Verification Program, SNC will need to confirm that MOVs provided by the valve supplier and their application at VEGP Units 3 and 4 are within the scope of the JOG program. The *planned use of ASME OM Code Case OMN-1 (Revision 1) is addressed below in this SER section.*

Second, SNC provides in its letter dated March 1, 2010, a planned revision to the VEGP COL FSAR that specifies the use of Revision 1 to ASME OM Code Case OMN-1 as an alternative to the quarterly MOV stroke-time testing provisions in the ASME OM Code. In the letter, SNC notes that RG 1.192, "Operation and Maintenance Code Case Acceptability, ASME OM Code," accepts the use of Revision 0 to ASME OM Code Case OMN-1 with three conditions. SNC considers Revision 1 to ASME OM Code Case OMN-1 to represent a superior alternative to Revision 0 to ASME OM Code Case OMN-1 by addressing the conditions on the use of the Code case specified in RG 1.192. In a telephone discussion on April 13, 2010, the NRC staff requested that SNC address the specific provisions in RG 1.192 in justifying the use of Revision 1 to ASME OM Code Case OMN-1 as an alternative to the MOV stroke-time provisions in the ASME OM Code pursuant to 10 CFR 50.55a(a)(3)(i).

In a letter dated May 14, 2010, SNC modified its response to Standard Content Open Item 3.9-2 to provide a planned revision to the VEGP COL FSAR in Section 3.9.6.3 in support of the request to apply Revision 1 to Code Case OMN-1 as an alternative to the quarterly IST stroke-time provisions in the ASME OM Code. The NRC staff has accepted the application of ASME OM Code Case OMN-1 (Revision 0) in RG 1.192 with certain conditions. In the planned VEGP COL FSAR revision, SNC has addressed those conditions as they apply to the requested use of ASME OM Code Case OMN-1 (Revision 1) at VEGP Units 3 and 4. In particular, the VEGP COL FSAR revision specifies that the IST Program will incorporate the provisions in RG 1.192 by providing that the adequacy of the diagnostic test interval for each MOV will be evaluated and adjusted as necessary, but not later than 5 years or three refueling outages (whichever is longer) from the initial implementation of the Code case. The planned VEGP COL FSAR revision also states that the potential increase in core damage frequency (CDF) and risk associated with extending high-risk MOV test intervals beyond quarterly will be determined to be small and consistent with the intent of the Commission's Safety Goal Policy Statement. The VEGP COL FSAR also specifies this provision as consistent with the conditions specified in RG 1.192 for application of ASME OM Code Case OMN-11, "Risk-Informed Testing of Motor-Operated Valves," which has been incorporated into Revision 1 to ASME OM Code Case OMN-1. The planned VEGP COL FSAR revision specifies that risk insights will be applied using MOV risk ranking methodologies accepted by the NRC on a plant-specific or industry-wide basis, consistent with the conditions in the applicable safety evaluations. The planned VEGP COL FSAR revision also indicates that the benefits for performing any particular test will be balanced against the potential adverse effects placed on the valve or system caused by this testing. The VEGP COL FSAR indicates that use of Revision 1 to ASME OM Code Case OMN-1 will be appropriate for the ASME OM Code 2001 Edition with the 2003 Addenda that is the basis for the description of the VEGP Units 3 and 4 IST Program in support of the COL application. The NRC staff finds that the provisions to be specified in the VEGP COL FSAR for the use of Revision 1 to ASME OM Code Case OMN-1 satisfy the conditions specified in RG 1.192 for the use of Revision 0 to ASME OM Code

Case OMN-1. The staff considers Revision 1 in ASME OM Code Case OMN-1 to continue to provide an acceptable technical approach for MOV diagnostic testing as an alternative to quarterly MOV stroke-time testing, and that the changes from Revision 0 to Revision 1 reflect improvements for user application and incorporation of ASME OM Code Case OMN-11. Pursuant to 10 CFR 50.55a(a)(3)(i), the staff authorizes the use of ASME OM Code Case OMN-1 (Revision 1) requested by SNC as an alternative to the quarterly MOV stroke-time testing provisions in the ASME OM Code for VEGP Units 3 and 4 on the basis that the proposed alternative provides an acceptable level of quality and safety and therefore, Standard Content Open Item 3.9-2 is resolved. The incorporation of the planned VEGP COL FSAR changes will be tracked as Confirmatory Item 3.9-1.

<u>Resolution of Standard Content Confirmatory Item 3.9-1</u>

Confirmatory Item 3.9-1 is an applicant commitment to revise its FSAR Table 1.9-201, Section 3.9.6.3, Section 3.9.6.2.2, and Section 3.9.9, to address IST of valves. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.9-1 is now closed.

Third, SNC in its March 1, 2010, submittal provides several planned changes to the VEGP COL FSAR to clarify the provisions that would be redundant when combined with the valve testing provisions in the AP1000 DCD. The NRC staff considers the proposed changes to the VEGP COL FSAR to be acceptable because these provisions are incorporated by reference as part of the AP1000 DCD. The incorporation of the planned VEGP COL FSAR changes will be tracked as part of Confirmatory Item 3.9-2.

<u>Resolution of Standard Content Confirmatory Item 3.9-2</u>

Confirmatory Item 3.9-2 is an applicant commitment to revise its FSAR. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.9-2 is now closed.

In light of the weaknesses in the IST provisions in the ASME OM Code for quarterly MOV stroke-time testing, the NRC issued Generic Letter (GL) 96-05, "Periodic Verification of Design-Basis Capability of Safety-Related Motor-Operated Valves," to request that nuclear power plant licensees establish programs to assure the capability of safety-related MOVs to perform their design-basis functions on a periodic basis. Further, the NRC revised 10 CFR 50.55a to require that nuclear power plant licensees supplement the quarterly MOV stroke-time testing provisions specified in the ASME OM Code with a program to ensure that MOVs continue to be capable of performing their design-basis safety functions. In its letter dated March 1, 2010, SNC provided its response to Standard Content Open Item 3.9-3 related to MOV testing in the "SER with open items" on the BLN COL application. The NRC staff review of the response by SNC to the six issues in this open item is discussed below:

First, SNC notes the planned use of Revision 1 to ASME OM Code Case OMN-1 as part of the IST Program to be developed for VEGP. As discussed above in *this SER section, the NRC staff authorized the use of Revision 1 to ASME OM Code Case OMN-1 at VEGP Units 3 and 4.*

Second, SNC states that the MOV Testing Program at VEGP will implement the JOG MOV Periodic Verification Program as described in the VEGP COL FSAR and AP1000 DCD. As indicated above, the NRC staff finds that the VEGP COL FSAR with its incorporation by reference of the AP1000 DCD (including the planned DCD changes) will address the use of the JOG MOV Periodic Verification Program. Other necessary changes to the VEGP COL FSAR regarding MOV testing are discussed in this SER section.

Third, SNC indicates that MOV output capability will be determined using the provisions of ASME OM Code Case OMN-1. The NRC staff has reviewed ASME OM Code Case OMN-1 as part of its acceptance in RG 1.192, and has determined that the Code case provides acceptable provisions for diagnostic testing to determine the output capability of MOVs.

Fourth, SNC describes MOV testing using the guidance in the JOG MOV Periodic Verification Program and Revision 1 to ASME OM Code Case OMN-1 to periodically determine the capability of MOVs to perform under design-basis conditions. The NRC staff has reviewed the JOG MOV Periodic Verification Program as part of its acceptance in an NRC safety evaluation dated September 25, 2006 with a supplement dated September 18, 2008, and has reviewed ASME OM Code Case OMN-1 as part of its acceptance in RG 1.192. From those evaluations, the staff has determined that the JOG MOV Periodic Verification Program and ASME OM Code Case OMN-1 will demonstrate continued MOV capability to open and close under design-basis conditions. As discussed above in this SER section, the NRC staff authorized the use of Revision 1 to ASME OM Code Case OMN-1 at VEGP Units 3 and 4.

Fifth, SNC notes that the initial test frequency of POVs will be based on the ASME OM Code or applicable ASME OM Code cases. For example, the VEGP COL FSAR specifies that the IST frequency will be determined as specified by ASME OM Code Case OMN-1. Further, the JOG MOV Periodic Verification Program with the NRC safety evaluation and its supplement includes provisions for MOV test frequencies based on risk ranking and functional margin with a maximum diagnostic test interval of 10 years. The staff considers these provisions in the VEGP COL FSAR and the AP1000 DCD for POV test frequency to incorporate lessons learned from MOV testing and research programs, and therefore, to be acceptable.

Sixth, SNC describes provisions for successful completion of MOV testing at VEGP in its March 1, 2010, letter, and provides several planned changes to the VEGP COL FSAR. For example, SNC provides a planned FSAR change to specify the use of ASME OM Code Case OMN-1, Revision 1. SNC also plans to revise the FSAR to specify that the design-basis capability testing of MOVs will apply guidance from GL 96-05 and the JOG MOV Periodic Verification Program. SNC will revise the FSAR to note the need to consider degraded voltage, control switch repeatability, and load-sensitive MOV behavior in ensuring that MOVs have adequate capability margin, in addition to the consideration of age-related *degradation. SNC provides a proposed addition to the description of the MOV test frequency determination in the FSAR that will specify that maximum torque and/or thrust (as applicable) achieved by the MOV (allowing sufficient margin for diagnostic equipment inaccuracies and control switch repeatability) must not exceed the allowable structural and undervoltage motor capability limits for the individual parts of the MOV. SNC provides a proposed addition to the description of POV operability testing that specifies that successful completion of the preservice testing and IST of MOVs, in addition to MOV testing as required by 10 CFR 50.55a, will demonstrate that the following criteria are met for each valve tested: (i) valve fully opens and/or closes as required by its safety function; (ii) adequate margin exists and includes consideration of diagnostic equipment inaccuracies, degraded voltage, control switch repeatability, load-sensitive MOV behavior, and margin for degradation; and (iii) maximum torque and/or thrust (as applicable) achieved by the MOV (allowing sufficient margin for diagnostic equipment inaccuracies and control switch repeatability) does not exceed the allowable structural and undervoltage motor capability limits for the individual parts of the MOV. In its letter dated May 14, 2010, SNC provided an additional planned revision to the VEGP COL FSAR that clarifies the application of the JOG MOV Periodic Verification Program (including the applicable NRC safety evaluation and its supplement on the JOG program) in response to NRC staff comments provided during the telephone discussion on April 13, 2010. The NRC staff considers the planned changes to the VEGP COL FSAR to resolve Standard Content Open Item 3.9-3. The incorporation of the planned changes to the VEGP COL FSAR will be tracked as Confirmatory Item 3.9-3.*

<u>Resolution of Standard Content Confirmatory Item 3.9-3</u>

Confirmatory Item 3.9-3 is an applicant commitment to revise its FSAR Section 3.9.6.2.2 to address MOV testing. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.9-3 is now closed.

In addition to incorporating by reference AP1000 DCD Tier 2 Section 3.9.6.2.2, the VEGP COL FSAR includes a paragraph titled "Other Power-Operated Valve Operability Tests," that states that POVs other than active MOVs are exercised quarterly in accordance with ASME OM Code, Subsection ISTC, unless justification is provided in the IST Program for testing these valves at other Code-mandated frequencies. Lessons learned from the resolution of weaknesses in the design, qualification, and testing of MOVs are also applicable to other POVs used at nuclear power plants. In discussing the MOV lessons learned applicable to other POVs in Regulatory Issue Summary (RIS) 2000-03, "Resolution of Generic Safety Issue 158: Performance of Safety-Related Power-Operated Valves Under Design Basis Conditions," the NRC staff determined that the current regulations provide adequate requirements to ensure design-basis capability of safety-related POVs. For example, the staff noted that licensees are required by 10 CFR 50.65 (Maintenance Rule) to monitor the performance of SSCs in a manner sufficient to provide reasonable assurance that the SSCs are capable of fulfilling their intended functions. VEGP COL FSAR Section 3.9.6.2.2 provides a description of operability testing for POVs other than MOVs to be implemented at VEGP. For example, the FSAR states that *subsequent to verification of the design-basis capability of POVs as part of the design and qualification program, POVs that perform an active safety function will be tested after installation to ensure valve setup is acceptable to perform their required functions consistent with valve qualification. This testing will document the baseline performance of the valves and will include measurement of critical parameters with consideration of uncertainties associated with the performance of these tests and use of the test results. Additional periodic testing will be performed as part of the air-operated valve (AOV) program based on the JOG AOV program discussed in RIS 2000-03 with specific reference to NRC staff comments on that program. The AOV program will also include the attributes for a successful POV periodic verification program described in RIS 2000-03 by incorporating lessons learned from nuclear power plant operations and research programs as they apply to the periodic testing of AOVs and other POVs in the IST Program. The FSAR specifies AOV program attributes including valve categorization based on safety significance and risk ranking, AOV setpoints based on current vendor information or valve qualification diagnostic testing, periodic static testing to identify potential degradation, use of sufficient diagnostics to collect relevant data to verify that the valve meets functional requirements, specification of test frequency and evaluation based on data trends, post-maintenance procedures to ensure baseline testing will be re-performed as necessary when high-risk valve performance could be affected, inclusion of lessons learned from other valve programs, and retention and periodic evaluation of AOV test documentation.*

The NRC staff has reviewed the VEGP COL FSAR, including the incorporation by reference of the AP1000 DCD, to determine whether it addresses the lessons learned from MOV operating experience and research programs in describing the program for the periodic verification of the design-basis capability of POVs other than MOVs. In its letters dated December 14, 2009, and March 1, 2010, SNC provided a response to Standard Content Open Item 3.9-4 related to other POV operability testing in the "SER with open items" on the BLN COL application. In particular, SNC provided planned changes to the VEGP COL FSAR to clarify the potential need for periodic dynamic testing of POVs other than MOVs based on the design qualification results or valve operating experience. The planned FSAR change will also clarify that post-maintenance procedures will be implemented for all safety-related POVs consistent with the QA requirements in 10 CFR Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants," regardless of their specific risk ranking. SNC also provided a proposed change to the VEGP COL FSAR specifying that the attributes of the AOV testing program, to the extent that they apply to and can be implemented on other safety-related POVs (such as electro-hydraulic valves) will be applied to those other POVs. The NRC staff considers that the planned revision to the VEGP COL FSAR, when combined with the AP1000 DCD provisions incorporated by reference, will adequately describe the periodic testing program for POVs other than MOVs to be used at VEGP and resolves Standard Content Open Item 3.9-4. The incorporation of the planned changes to the VEGP COL FSAR will be tracked as Confirmatory Item 3.9-4.

<u>Resolution of Standard Content Confirmatory Item 3.9-4</u>

Confirmatory Item 3.9-4 is an applicant commitment to revise its FSAR Section 3.9.6.2.2, to address POV testing. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.9-4 is now closed.

The VEGP COL FSAR incorporates by reference AP1000 DCD Tier 2, Section 3.9.6.3, "Relief Requests," with a discussion of the planned use of ASME OM Code Case OMN-1, Revision 1. The applicant stated that use of Revision 1 to ASME OM Code Case OMN-1 will require request for relief, unless it is approved by the NRC in RG 1.192 or incorporated into the ASME OM Code on which the IST Program is based and that Code Edition is incorporated by reference in 10 CFR 50.55a. As discussed above in this SER section, the NRC staff authorized the use of Revision 1 to the ASME OM Code Case OMN-1 at VEGP Units 3 and 4.

AP1000 DCD Tier 2, Section 3.9.2, "Dynamic Testing and Analysis," describes tests to confirm that piping, components, restraints, and supports have been designed to withstand the dynamic effects of steady-state FIV and anticipated operational transient conditions. Section 14.2.9.1.7, "Expansion, Vibration and Dynamic Effects Testing," in AP1000 DCD Tier 2, Chapter 14, "Initial Test Program," states that the purpose of the expansion, vibration and dynamic effects testing is to verify that safety-related, high energy piping and components are properly installed and supported such that, in addition to other factors, vibrations caused by steady-state or dynamic effects do not result in excessive stress or fatigue to safety-related plant systems. Nuclear power plant operating experience has revealed the potential for adverse flow effects from vibration caused by hydrodynamic loads and acoustic resonance on reactor coolant, steam, and feedwater systems. In its letter dated January 12, 2010, SNC provided its response for VEGP to Standard Content Open Item 3.9-5 related to FIV in the "SER with open items" on the BLN COL application. In its response, SNC stated that it intended to use the overall Initial Test Program to demonstrate that the plant has been constructed as designed and the systems perform consistent with design requirements. SNC referenced the provisions in the AP1000 DCD for vibration monitoring and testing to be implemented at VEGP. For example, the applicant notes that AP1000 DCD Tier 2, Section 3.9.2.1, "Piping Vibration, Thermal Expansion and Dynamic Effects," specifies that the preoperational test program for ASME BPV Code, Section III, Class 1, 2, and 3 piping systems simulates actual operating modes to demonstrate that components comprising these systems meet functional design requirements and that piping vibrations are within acceptable levels. SNC indicates that the planned vibration testing program described in AP1000 DCD Tier 2, Sections 14.2.9 and 14.2.10, with the preservice and IST programs described in AP1000 DCD Tier 2, Sections 3.9.3.4.4 and 3.9.6, will confirm component installation in accordance with design requirements, and address the effects of steady-state (flow-induced) and transient vibration to ensure the operability of valves and dynamic restraints in the IST Program. The NRC staff considers the response by SNC clarifies its application of the provisions in the AP1000 DCD to ensure that potential adverse flow effects will be addressed at VEGP. Therefore, *the staff considers Standard Content Open Item 3.9-5 to be resolved for the VEGP COL application.*

Subsection ISTC-5260, "Explosively Actuated Valves," in the ASME OM Code specifies that at least 20 percent of the charges in explosively actuated valves shall be fired and replaced at least once every 2 years. If a charge fails to fire, the ASME OM Code states that all charges with the same batch number shall be removed, discarded, and replaced with charges from a different batch. In light of the updated design and safety significance of squib valves in new reactors, the need for improved surveillance activities for squib valves is being considered by the nuclear industry, ASME, and U.S. and international nuclear regulators. In RAI 3.9.6-1, the NRC staff requested that SNC describe its plans for addressing the surveillance of squib valves that will provide reasonable assurance of the operational readiness of those valves to perform their safety functions in support of the VEGP COL application. In a letter dated May 27, 2010, SNC submitted a planned revision to VEGP COL FSAR Section 3.9.6 to specify that industry and regulatory guidance will be considered in the development of the IST Program for squib valves. The FSAR will also state that the IST Program for squib valves will incorporate lessons learned from the design and qualification process for these valves such that surveillance activities provide reasonable assurance of the operational readiness of squib valves to perform their safety functions. The NRC staff finds that the planned changes to the VEGP COL FSAR are sufficient to describe the IST Program for squib valves for incorporating the lessons learned from the design and qualification process in developing surveillance activities that will provide reasonable assurance of the operational readiness for squib valves to perform their safety functions. Therefore, the NRC staff considers the planned changes to the VEGP COL FSAR to resolve this RAI acceptable. The incorporation of the planned changes to the VEGP COL FSAR will be tracked as Confirmatory Item 3.9-5.

<u>Resolution of Standard Content Confirmatory Item 3.9-5</u>

Confirmatory Item 3.9-5 is an applicant commitment to revise its FSAR Section 3.9.6.2.2 to address squib valve testing. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.9-5 is now closed.

<u>Technical Specifications</u>

In its letter dated December 14, 2009, SNC provided a response to an open item related to Part 4, "Technical Specifications," (Standard Content Open Item 3.9-6) in the "SER with open items" on the BLN COL application. In its response, SNC stated that Part 4 of the VEGP COL application will be revised to ensure that Technical Specifications and Technical Specification Bases are consistent with the ASME OM Code, 2001 Edition through the 2003 Addenda. Therefore, the NRC staff considers the planned changes to the VEGP COL application in Part 4 to resolve Standard Content Open Item 3.9-6. The incorporation of the planned changes to the VEGP COL FSAR will be tracked as Confirmatory Item 3.9-6.

<u>Resolution of Standard Content Confirmatory Item 3.9-6</u>

Confirmatory Item 3.9-6 is an applicant commitment to revise its FSAR Section 3.9.6.2.2 to address the ASME OM Code. The staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.9-6 is now closed.

<u>License Conditions</u>

- *Part 10, License Condition 3, Items G.2 and G.5*

The applicant proposed a license condition providing the implementation milestones for the Preservice Testing Program and MOV Testing Program.

- *Part 10, License Condition 6*

The applicant proposed a license condition to provide a schedule to support the NRC's inspection of operational programs including the Preservice Testing Program and MOV Testing Program. These license conditions are consistent with the policy established in SECY-05-0197 and are, thus, acceptable.

<u>Squib Valves</u>

During the uncontested hearing for the VEGP Units 3 and 4 COL application, the Commission discussed issues associated with the inservice testing and inspection program for squib valves to be used to perform safety functions at VEGP Units 3 and 4. Tier 1 of the AP1000 DCD requires squib valves to undergo tests or type tests to demonstrate their operational capability under design conditions. Additionally, the Commission asked the staff questions on this topic after the VEGP and V.C. Summer Nuclear Station (VCSNS) COL uncontested hearings. For these COL applications, the Commission concluded that, although it found that the staff's review of the squib valve issues was rigorous, it had a concern similar to that initially raised by the Advisory Committee on Reactor Safeguards (ACRS) regarding the status of the inservice testing and inspection program for this component. As such, the Commission imposed a license condition for each COL that directs the implementation of a surveillance program for squib valves at VEGP Units 3 and 4 and VCSNS Units 2 and 3, with the specific requirements described in the Commission orders authorizing issuance of the VEGP and VCSNS COLs.

The squib valves subject to the surveillance program license condition under the VEGP and VCSNS COLs are part of the AP1000 certified design, and the same squib valves are specified in the Levy COL application. Therefore, the staff determined that it was appropriate to apply the same surveillance program license condition to the WLS Units 1 and 2 squib valves.

The surveillance program is established to provide reasonable assurance that the WLS squib valves are operational and ready to perform their safety function. The staff-proposed license condition follows the precedent set in the VEGP and VCSNS COLs (ADAMS Accession Nos. ML113540620 and ML113420105) to require such a surveillance program.

3.9.6.5 *Post Combined License Activities*

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license conditions acceptable:

- License Condition (3-5) – Before initial fuel load, the licensee shall implement (1) the Preservice Testing Program and (2) the Motor-Operated Valve Testing Program.

- License Condition (3-6) – No later than 12 months after issuance of the COL, the licensee shall submit to the Director of NRO a schedule that supports planning for and conduct of NRC inspections of the IST program (including preservice and MOV testing). The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the inservice testing program (including preservice testing and the MOV testing) has been fully implemented or the plant has been placed in commercial service, whichever comes first.

- License Condition (3-7) – Before initial fuel load, the licensee shall implement a surveillance program for explosively actuated valves (squib valves) that includes the following provisions in addition to the requirements specified in the edition of the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) as incorporated by reference in 10 CFR 50.55a.

    a. Preservice Testing

    All explosively actuated valves shall be preservice tested by verifying the operational readiness of the actuation logic and associated electrical circuits for each explosively actuated valve with its pyrotechnic charge removed from the valve. This must include confirmation that sufficient electrical parameters (voltage, current, resistance) are available at the explosively actuated valve from each circuit that is relied upon to actuate the valve. In addition, a sample of at least 20% of the pyrotechnic charges in all explosively actuated valves shall be tested in the valve or a qualified test fixture to confirm the capability of each sampled pyrotechnic charge to provide the necessary motive force to operate the valve to perform its intended function without damage to the valve body or connected piping. The sampling must select at least one explosively actuated valve from each redundant safety train. Corrective action shall be taken to resolve any deficiencies identified in the operational readiness of the actuation logic or associated electrical circuits, or the capability of a pyrotechnic charge. If a charge fails to fire or its capability is not confirmed, all charges with the same batch number shall be removed, discarded, and replaced with charges from a different batch number that has demonstrated successful 20% sampling of the charges.

    b. Operational Surveillance

    Explosively actuated valves shall be subject to the following surveillance activities after commencing plant operation:

    (1) At least once every 2 years, each explosively actuated valve shall undergo visual external examination and remote internal examination (including evaluation and removal of fluids or contaminants that may interfere with operation of the valve)

to verify the operational readiness of the valve and its actuator. This examination shall also verify the appropriate position of the internal actuating mechanism and proper operation of remote position indicators. Corrective action shall be taken to resolve any deficiencies identified during the examination with post-maintenance testing conducted that satisfies the preservice testing requirements.

(2) At least once every 10 years, each explosively actuated valve shall be disassembled for internal examination of the valve and actuator to verify the operational readiness of the valve assembly and the integrity of individual components and to remove any foreign material, fluid, or corrosion. The examination schedule shall provide for both of the two valve designs used for explosively actuated valves at the facility to be included among the explosively actuated valves to be disassembled and examined every 2 years. Corrective action shall be taken to resolve any deficiencies identified during the examination with post-maintenance testing conducted that satisfies the preservice testing requirements.

(3) For explosively actuated valves selected for test sampling every 2 years in accordance with the ASME OM Code, the operational readiness of the actuation logic and associated electrical circuits shall be verified for each sampled explosively actuated valve following removal of its charge. This must include confirmation that sufficient electrical parameters (voltage, current, resistance) are available for each valve actuation circuit. Corrective action shall be taken to resolve any deficiencies identified in the actuation logic or associated electrical circuits.

(4) For explosively actuated valves selected for test sampling every 2 years in accordance with the ASME OM Code, the sampling must select at least one explosively actuated valve from each redundant safety train. Each sampled pyrotechnic charge shall be tested in the valve or a qualified test fixture to confirm the capability of the charge to provide the necessary motive force to operate the valve to perform its intended function without damage to the valve body or connected piping. Corrective action shall be taken to resolve any deficiencies identified in the capability of a pyrotechnic charge in accordance with the preservice testing requirements.

This license condition shall expire upon (1) incorporation of the above surveillance provisions for explosively actuated valves into the facility's inservice testing program, or (2) incorporation of inservice testing requirements for explosively actuated valves in new reactors (i.e., plants receiving a construction permit, or combined license for construction and operation, after January 1, 2000) to be specified in a future edition of the ASME OM Code as incorporated by reference in 10 CFR 50.55a, including any conditions imposed by the NRC, into the facility's inservice testing program.

3.9.6.6 *Conclusion*

The staff reviewed the WLS COL application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the IST Program, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the design-related information incorporated by reference in the COL application are documented in NUREG-1793 and its supplements. The results of the staff's review of the material in the AP1000 DCD related to the IST operational program for pumps, valves, and dynamic restraints are in this section of the report. In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the guidance in NUREG-0800, Section 3.9.6 and in RG 1.206. The staff based its conclusion on the following:

- WLS DEP 6.4-2, related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance, is reviewed and found acceptable by the staff in Section 21.3 of this SER.

- STD COL 3.9-4, regarding the operational program for pumps, valves, and dynamic restraints is acceptable because the requirements of 10 CFR 52.79(a) are satisfied.

3.9.7 Integrated Head Package

AP1000 DCD Section 3.9.7 describes the integrated head package (IHP). The IHP combines several components in one assembly to simplify refueling the reactor. The IHP includes a lifting rig, seismic restraints for CRDM, support for reactor head vent piping, cable bridge, power cables, cables for in-core instrumentation, cable supports, and shroud assembly. The IHP provides the ability to rapidly disconnect cables, including the CRDM power cables, digital rod position indication cables, and in-core instrument cables from the components.

WLS COL FSAR, Revision 11, Section 3.9, incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19 Section 3.9.7, "Integrated Head Package." The staff reviewed the WLS COL application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

3.10 Seismic and Dynamic Qualification of Mechanical and Electrical Equipment

3.10.1 Introduction

Seismic Category I equipment includes the following types (1) safety-related active mechanical equipment that performs a mechanical motion while accomplishing a system safety-related function. Examples include pumps, valves, and valve operators, (2) safety-related, nonactive mechanical equipment whose mechanical motion is not required while accomplishing a system safety-related function, but whose structural integrity must be maintained to fulfill its design safety-related function (3) safety-related instrumentation and electrical equipment and certain monitoring equipment.

Mechanical and electrical equipment (including instrumentation and controls), and where applicable, their supports classified as Seismic Category I must demonstrate that they are capable of performing their intended safety-related functions under the full range of normal and accident (including seismic) loadings. The equipment includes devices associated with systems essential to safe shutdown, containment isolation, reactor core cooling, containment and reactor heat removal, or equipment otherwise essential to prevent significant release of radioactive material to the environment or in mitigating the consequences of accidents.

3.10.2 Summary of Application

WLS COL FSAR, Revision 11, Section 3.10, incorporates by reference AP1000 DCD, Revision 19, Section 3.10. This section of the WLS COL FSAR does not include any COL information items or supplemental information related to AP1000 DCD Section 3.10.

3.10.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the seismic and dynamic qualification of mechanical and electrical equipment are given in NUREG-0800, Section 3.10.

3.10.4 Technical Evaluation

The staff reviewed this application and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the seismic and dynamic qualification program. The staff's evaluation of the information incorporated by reference in the WLS COL application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the Reference COL application (i.e., VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from responses to RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.
- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion,

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.10.4:

<u>Implementation Program</u>

In RAI 3.10-1, dated August 7, 2008, the applicant was requested to provide an implementation program, including milestones and completion dates with appropriate information submitted with sufficient time for staff review and approval prior to installation of the equipment, not prior to fuel loading, in accordance with Section C.I.3.10.4 of RG 1.206.

In its response, the applicant stated that details of the implementation milestones for the seismic and dynamic qualification program are not currently available, and are not expected to be available until after a detailed construction schedule of the plant has been developed. Appropriate scheduling information will be provided, when available, to the NRC as necessary to support timely completion of their inspection and audit functions. Additionally, seismic and dynamic qualification is the subject of ITAAC, and 10 CFR 52.99(a) does not require that a schedule for implementing ITAAC be provided to the NRC until one year after issuance of the COL.

*The NRC staff determined that the applicant's response to RAI 3.10-1 is not adequate because, in accordance with Section C.I.3.10.4 of RG 1.206, if the results of seismic and dynamic qualification is not available at the time of the COL application, the applicant is expected to submit the following before the issuance of the combined license: (1) descriptions of the implementation program such as identification of seismic qualification methods (Testing or Analysis) for each type of equipment; and (2) milestones for when the different aspects of the seismic qualification program will be complete - dates or condition should be such that the NRC staff will be able to audit the qualification results prior to the installation of the equipment (not before fuel loading as part of the ITAAC program). This is **Open Item 3.10-1.***

<u>Resolution of Open Item 3.10-1</u>

In its responses dated February 5, 2010 and April 2, 2010, the VEGP applicant submitted a table providing the planned methods of seismic qualification for safety-related, seismic Category I equipment types listed in AP1000 DCD, Chapter 3, Table 3.2-3. Furthermore, the applicant stated that the seismic qualification packages will be available to the NRC as necessary to support timely completion of its inspection and audit functions. Because not all packages are expected to be completed within a year of the issuance of the COL (or at the start of construction as defined in 10 CFR 50.10(a), whichever is later), a schedule for the availability of the seismic qualification packages will be included with the schedule information for closure of ITAAC (as required by 10 CFR 52.99(a)). The staff finds the applicant's response acceptable, and Open Item 3.10-1 is closed. The incorporation of the planned changes to the VEGP COL FSAR is complete.

On April 25, 2012, the staff issued RAI 105, Questions 01.05-1 through 01.05-4 on the NRC Fukushima NTTF Recommendation 2.1, Recommendation 9.3, spent fuel instrumentation, and mitigation strategies for beyond-design-basis events. The staff completed the review of the Duke Energy's January 30, 2014, response as supplemented by the February 28, 2014, response to the questions in RAI 105. In the Duke Energy's January 30, 2014, response as supplemented by the February 28, 2014, the applicant stated that the only equipment potentially affected by the identified high frequency (HF) exceedance is tested to levels higher than those imposed by those equipment ISRS. In RAI 114, Question 03.10-1, the staff questioned how the exceedances for those affected equipment were resolved if the seismic qualification by analysis was used. In a June 5, 2014, response to RAI 114, Question 03.10-1, Duke Energy stated that AP1000 DCD Chapter 3, Appendix 3I identifies equipment that is potentially sensitive to HF excitation. No such HF sensitive equipment is qualified by analysis, and all such HF sensitive equipment is qualified by testing, thereby confirming that equipment is adequate for the site-specific demands. The staff finds the applicant's response acceptable and, therefore, considers RAI 114, Question 03.10-1 resolved.

In RAI 114, Question 03.10-2, the staff requested that the applicant provide technical explanation for the fact that the AP1000 combined CSDRS & HRHF equipment Required Response Spectra (RRS) exceed the WLS RRS, even though both the horizontal and vertical design ground motion response spectra for WLS-CEUS spectra exceed the AP1000 CSDRS and AP1000 HRHF ground spectra (RRS) for some equipment. In a June 5, 2014, response to RAI 114, Question 03.10-2, the applicant stated that the differences in determining ISRS are discussed in WLG-GW-GLR-815, Section 5.3 and the ISRS differences are predominately attributed to (1) model refinements and (2) rock profile differences between the AP1000 generic hard rock profile and the site-specific WLS concrete/rock profiles (i.e., lower shear wave velocity (Vs) in the 15 m (50 ft) directly below basemat. The staff finds the applicant's response acceptable and, therefore, considers RAI 114, Question 3.10-2 resolved.

In RAI 114, Question 03.10-3, the staff requested that the applicant provide the source of test data for protection and monitoring systems, nuclear instrumentation source- and intermediate-range systems, and main control room/remote shutdown panels, shown on the Duke Energy January 20, 2014, submittal (WLG-GW-GLR-815, Letter WLG 2014.01-02) Enclosure 4, Figures 6.4-1 through 6.4-8. In a June 5, 2014, response to RAI 114, Question 03.10-3, the applicant stated that Westinghouse calculation WLG-1000-SC2-702 documents the source of AP1000 TRS/RRS testing references and the site-specific Lee RRS plots in WLG-GW-GLR-815, Figures 6.4-1 through 6.4-8 for some equipment cited in WLG-GW-GLR-815, specifically, Westinghouse calculations, APP-PMS-VPR-006, APP-PMS-VPR-004, and APP-JW03-VBR-001. The staff reviewed those calculations and verified the source of the TRS shown in WLG-GW-GLR-815, Figures 6.4-1 through 6.4-8. The staff finds the applicant's response acceptable and, therefore, considers RAI 114, Question 03.10-3 resolved.

3.10.5 Post Combined License Activities

There are no post COL activities related to this section.

3.10.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the seismic and dynamic qualification program, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff compared the information in the application to relevant NRC regulations, the acceptance criteria in NUREG-0800, Section 3.10. The staff's review confirmed that the applicant has adequately addressed the COL information relating to the seismic qualification of equipment in accordance with the requirements of GDC 2, GDC 4, and GDC 14.

3.11 Environmental Qualification of Mechanical and Electrical Equipment

3.11.1 Introduction

The objective of environmental qualification (EQ) is to reduce the potential for common failure due to specified environmental and seismic events and to demonstrate that equipment within the scope of the EQ program is capable of performing its intended design safety function under all conditions including environmental stresses resulting from design bases events. The information presented includes identification of the equipment required to be environmentally qualified and, for each item of equipment, the designated functional requirements, definition of the applicable environmental parameters, and documentation of the qualification process employed to demonstrate the required environmental capability. During plant operation, the licensee implements the EQ program. This specifies the replacement frequencies of affected safety-related equipment in harsh environments, and non-safety-related equipment whose failure under the postulated environmental conditions could prevent satisfactory performance of the safety functions of the safety-related equipment, and certain post-accident monitoring equipment. The seismic qualification of mechanical and electrical equipment is presented in Section 3.10 of this report. The portions of post-accident monitoring equipment required to be environmentally qualified are identified in AP1000 DCD Table 7.5-1.

RG 1.206 discusses the Commission's position provided in SECY-05-0197 stating that operational programs should be fully described in COL applications to avoid the need to specify ITAAC for those programs. The applicant relies on the WLS COL application with its incorporation by reference of the AP1000 DCD and supplemental information to fully describe the EQ program and other related operational programs.

3.11.2 Summary of Application

WLS COL FSAR, Revision 11, Section 3.11 incorporates by reference AP1000 DCD, Revision 19, Section 3.11. AP1000 DCD Section 3.11 describes the EQ Program for electrical and mechanical equipment to be used in the AP1000 certified design.

Departures

- WLS DEP 3.11-1

In WLS COL FSAR Table 3.11-201 (Sheet 14 of 51), "Environmentally Qualified Electrical and Mechanical Equipment," the applicant added three spent fuel pool level instruments related to the Fukushima Lessons Learned report. The staff addressed the departure in the technical evaluation section below.

- WLS DEP 6.4-2

The applicant provided additional information in Tables 3.11-202, 3I-201, and 3I-202 and in Figure 3D-201 of the WLS COL FSAR about WLS DEP 6.4-2 related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance. This information, as well as related WLS DEP 6.4-2 information appearing in other chapters of the FSAR, is reviewed in Section 21.3 of this SER.

AP1000 COL Information Item

- STD COL 3.11-1

In WLS COL FSAR Section 3.11.5, "Combined License Information Item For Equipment Qualification File," the applicant provided information to address COL Information Item 3.11-1 regarding administrative control and milestones for implementation of the EQ Program for WLS.

License Conditions

- Part 10, License Condition 3, "Operational Program Implementation," Item G.1

The applicant proposed a license condition requiring the submittal of a schedule to the NRC to aid in the planning for and conduct NRC inspections of operational programs including the EQ program.

- Part 10, License Condition 6

The applicant proposed a license condition to provide a schedule to support the NRC's inspection of operational programs including the EQ Program.

3.11.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the environmental qualification of mechanical and electrical equipment are given in NUREG-0800, Section 3.11.

The applicable regulatory requirements for the Operational EQ program are as follows:
10 CFR 52.79(a)(10) requires that a COL application provide a description of the program, and its implementation, required by 10 CFR 50.49(a) for the EQ of electric equipment important to safety and the list of electric equipment important to safety that is required by 10 CFR 50.49(d).
10 CFR 52.79(a)(29)(I) requires that a COL application provide plans for conduct of normal operations, including maintenance, surveillance, and periodic testing of SSCs. RG 1.206 provides guidance for a COL applicant in preparing and submitting its COL application in accordance with the NRC regulations. For example, RG 1.206, Section C.IV.4 discusses the requirement in 10 CFR 52.79(a) for descriptions of operational programs that need to be included in the FSAR for a COL application to allow a reasonable assurance finding of acceptability. In particular, a COL applicant should fully describe EQ and other operational programs as defined in Commission Paper SECY-05-0197 to avoid the need for ITAAC for the implementation of those programs. The term "fully described" for an operational program should be understood to mean that the program is clearly and sufficiently described in terms of

scope and level of detail to allow a reasonable assurance finding of acceptability. Further, operational programs should be described at a functional level and an increasing level of detail where implementation choices could materially and negatively affect the program effectiveness and acceptability. The Commission approved the use of a license condition for operational program implementation milestones that are fully described or referenced in the FSAR as discussed in the February 22, 2006, SRM for SECY-05-0197.

3.11.4 Technical Evaluation

Mechanical and electrical equipment (including instrumentation and controls), its supports (classified as Seismic Category I) must demonstrate that it is capable of performing its intended safety-related functions under the full range of normal and accident (including seismic) loadings. This equipment includes devices associated with systems essential to safe shutdown, containment isolation, reactor core cooling, and containment and reactor heat removal, or equipment otherwise essential in preventing significant release of radioactive material to the environment or in mitigating the consequences of accidents.

The staff reviewed this application section and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic. The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the environmental qualification of mechanical and electrical equipment. The staff's evaluation of the information incorporated by reference in the WLS application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content for the Reference COL application FSAR (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews.

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the COL FSAR.

- The staff verified that site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the Reference COL application (i.e., VEGP) contains evaluation material from the SER for the BLN, Units 3 and 4 COL application.

Departures

- WLS DEP 3.11-1

In WLS COL FSAR Table 3.11-201, the applicant included a departure of "Environmental Zone" for three spent fuel pool level instruments (SFS-JE-LT 019A, SFS-JE-LT 019B, and SFS-JE-LT 019C) from AP1000 DCD Table 3.11-1, "Environmentally Qualified Electrical and Mechanical Equipment," (Sheet 14 of 51) to correct the location of those instruments. This change updates DCD Table 3.11-1 and addresses the spent fuel pool level instruments concern related to the Fukushima Lessons Learned report. All the aforementioned instruments currently shown in an Environmental Zone (number) 11 will change (i.e., SFS-JE-LT 019A to Environmental Zone 6, SFS-JE-LT 019B to Environmental Zone 7, and SFS-JE-LT 019C to Environmental Zone 6) in the proposed DCD Table 3.11-1.

The staff reviewed the departure that corrects the location of three spent fuel pool level instruments (i.e., Environmental Zone from 11 to 6 and 7). The staff finds that the above corrections do not result in any changes in the environmental qualification requirements (i.e., environment, "Function," "Operating Time Required," and "Qualification Program." Thus, the staff concludes the departure is acceptable.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.11.4:

> *<u>AP1000 COL Information Item</u>*
>
> - *STD COL 3.11-1*
>
> *The COL information item for the EQ file in Section 3.11.5 of the AP1000 DCD, states:*
>
> > *Westinghouse Electric Company LLC will act as the agent for the COL holder during the equipment design phase, equipment selection and procurement phase, equipment qualification phase, plant construction phase, and ITAAC inspection phases.*
> >
> > *The COL holder will define the process and procedures for which the equipment qualification files will be accepted from Westinghouse and how the files will be retained and maintained in an auditable format for the period that the equipment is installed and/or stored for future use in the nuclear power plant.*
>
> *This commitment was also captured as COL Action Item 3.11.2-1 in the NRC staff's FSER for the AP1000 DCD (NUREG-1793), which states:*
>
> > *Pursuant to 10 CFR 50.49(j), the COL applicant shall keep the list and information in the file current and retain the file in auditable form for the entire period during which the covered item is installed in the nuclear power plant or is stored for the future use to permit verification that each item of electrical equipment important to safety (1) is qualified for its application, and (2) meets its specified performance requirements. To conform with 10 CFR 50.49, electrical equipment for PWRs referencing the AP1000 design should be qualified according to the criteria in Category I of NUREG-0588 and Revision 1 of RG 1.89.*

This commitment was also listed as COL Action Item 3.11.2-1 in Appendix F of the NRC staff's FSER for the AP1000 DCD (NUREG-1793), which states:

> *The COL applicant is responsible for maintaining the equipment qualification file during the equipment selection and procurement phase.*

In STD COL 3.11-1, the applicant describes under "Combined License Information Item for Equipment Qualification File," that the COL holder is responsible for the maintenance of the equipment qualification file. The NRC staff reviewed STD COL 3.11-1 related to equipment qualification file included under Section 3.11.5 of the BLN COL. The NRC staff's evaluation is as follows.

Section 3.11.5 of the BLN COL FSAR states that the COL holder is responsible for the maintenance of the equipment qualification file upon receipt from the reactor vendor. EQ files developed by the reactor vendor are maintained as applicable for equipment and certain post-accident monitoring devices that are subject to a harsh environment. The files are maintained for the operational life of the plant.

The Environmental Qualification Master Equipment List (EQMEL) identifies the electrical and mechanical equipment or components that must be environmentally qualified for use in a harsh environment. The BLN COL FSAR states that the EQMEL and a summary of equipment qualification results are maintained as part of the equipment qualification file for the operational life of the plant. Administrative programs are in place to control revision to the EQ files and the EQMEL. When adding or modifying components in the EQ Program, EQ files are generated or revised to support qualification. The EQMEL is revised to reflect these new components. Plant modifications and design basis changes are subject to change process reviews, e.g., reviews in accordance with 10 CFR 50.59 or Section VIII of Appendix D to 10 CFR Part 52, in accordance with appropriate plant procedures. Any changes to the EQMEL that are not the result of a modification or design basis change are subject to a separate review that is accomplished and documented in accordance with plant procedures.

Based on the above, the NRC staff concludes that the COL applicant would keep the equipment qualification file and information in the file current and retain the file in an auditable form for the entire period during which the covered item is installed in the nuclear power plant or is stored for the future use to permit verification that each item of electrical equipment important to safety: (1) is qualified for its application; and (2) meets its specified performance requirements. This is consistent with 10 CFR 50.49(j) and acceptable.

In addition, the staff requested additional information related to specific implementation of this program, which is discussed below.

BLN COL FSAR Section 3.11 incorporates by reference AP1000 DCD Tier 2, Section 3.11.2.2, "Environmental Qualification of Mechanical Equipment," in the AP1000 DCD, which references Appendix 3D, "Methodology for Qualifying AP1000 Safety-Related Electrical and Mechanical Equipment." In RAI 3.11-1, the NRC staff requested that the applicant describe in more detail the EQ

Program for safety-related mechanical equipment to be used at BLN Units 3 and 4. In its response, the applicant stated that the EQ Program will be performed as described in Section 3.11 and Appendix 3D of the AP1000 DCD, by reference as stated in the BLN COL FSAR. The EQ Program will be implemented through design specifications, equipment procurement documents, and equipment qualification procedures. Equipment qualification specifications and equipment design specifications will be developed based on the AP1000 EQ requirements. The incorporation of the AP1000 DCD, Section 3.11 and Appendix 3D into the BLN COL FSAR also includes future maintenance, surveillance, and replacement activities to maintain EQ over the life of the BLN plant through operational programs and procedures. AP1000 DCD, Table 3.11-1 provides a listing of the safety-related mechanical equipment, its location, and the environment to be considered in the EQ Program. AP1000 DCD, Appendix 3D, describes: (1) qualification methodology for the critical safety-related nonmetallic sub-components; (2) thermal and radiation information for the nonmetallic components used in safety-related mechanical equipment; (3) plant normal, abnormal, and accident environmental parameters; and (4) documentation requirements. On October 14 and 15, 2008, the NRC staff conducted an onsite review of design and procurement specifications, including EQ, for pumps, valves, and dynamic restraints to be used for the AP1000 reactor at the Westinghouse offices in Monroeville, PA. The staff found that Westinghouse had included ASME Standard QME-1-2007, "Qualification of Active Mechanical Equipment Used in Nuclear Power Plants," in its design and procurement specifications for AP1000 components, including ASME QME-1, Appendix QR-B, "Guide for Qualification of Nonmetallic Parts." At the conclusion of the onsite review, the staff provided comments on the AP1000 design procurement specifications, and Westinghouse indicated that those comments would be addressed in a future revision to the specifications. The staff also identified several items that remain open from the onsite review that are specified in Section 3.9.6 of the SER on the AP1000 DCD revision. As noted in Section 3.9.6 of the BLN COL FSAR, the NRC staff documented the results of the on-site review with follow-up items in a memorandum dated November 6, 2008, (ML083110154). This is Open Item 3.11-1.

Section 3D.6.2.3, "Analysis of Safety-Related Mechanical Equipment," in the AP1000 DCD, Appendix 3D, summarizes the EQ of safety-related mechanical equipment by analysis methods, but does not discuss implementation of the EQ approach. In RAI 3.11-2, the NRC staff requested that the applicant discuss the implementation of the EQ approach, including the application of industry standards, prescribed in Section 3D.6.2.3 in Appendix 3D to Chapter 3 in the AP1000 DCD. In its response to this RAI, the applicant stated that equipment qualification specifications and equipment design specifications have been developed based on the AP1000 DCD EQ requirements. The applicant stated that these procurement documents reference ASME QME-1 and Institute of Electrical and Electronic Engineers (IEEE) Standard 323 for the EQ of active safety-related mechanical equipment. As noted above, the NRC staff conducted an onsite review of the Westinghouse design and procurement specifications for the AP1000 components on October 14 and 15, 2008. The issues in this RAI are being addressed under Open Item 3.11-1. Therefore, RAI 3.11-2 is closed.

AP1000 DCD, Appendix 3D, Section 3D.6.3, "Operating Experience in the Equipment Qualification Program," states that the COL applicant will provide documentation of the EQ methodology where seismic experience data are used. In RAI 3.11-3, the NRC staff requested that the applicant discuss the documentation of the EQ methodology where seismic experience data are used. In its response to this RAI, the applicant stated that Westinghouse would revise the AP1000 DCD to resolve this issue. Revision 17 to the AP1000 DCD, Appendix 3D, Section 3D.6.3 specifies that qualification by experience is not employed in the AP1000 equipment qualification program as a method of qualification. The applicant revised the BLN COL FSAR to reflect the revision to the AP1000 DCD. Therefore, RAI 3.11-3 is resolved.

The section titled "In-Service Vibration" in Section B.4.5, "External Stresses," in Attachment B, "Aging Evaluation Program," to Appendix 3D to Chapter 3 in the AP1000 DCD, states that inservice pipe and FIV may be significant for line-mounted equipment. As a consequence, the section states that an additional vibration aging step is included in the aging sequence. Operating experience has revealed that FIV from acoustic resonance and hydraulic loading can adversely impact safety-related mechanical equipment at nuclear power plants. The COL applicant will demonstrate the performance of this additional vibration aging step specified in the AP1000 DCD in the EQ of safety-related mechanical equipment to be used at BLN Units 3 and 4. This technical issue is addressed in Section 3.9.6 of this SER.

License Conditions

Section 3, "Operational Program Implementation," in Part 10 of the BLN COL application provides proposed license conditions for operational program implementation. One specified license condition is that the EQ Program will be implemented prior to initial fuel loading. In addition, Section 6 in Part 10 provides a proposed license condition for operational program readiness that requires the licensee to submit a schedule no later than 12 months after COL issuance that supports planning and conducting NRC inspections of operational programs with periodic updating. These license conditions are consistent with the policy established in SECY-05-0197 and are, thus, acceptable.

Resolution of Standard Content Open Item 3.11-1

Standard Content Open Item 3.11-1 resulted from the identification of items that remained open from the October 14 and 15, 2008, onsite review at Westinghouse offices of design and procurement specifications, including EQ, for pumps, valves, and dynamic restraints to be used for the AP1000 reactor. As noted in Section 3.9.6.4 of the BLN COL FSAR, the NRC staff documented the results of the onsite review with follow-up items in a memorandum dated November 6, 2008. In a letter dated December 14, 2009, the VEGP applicant stated that it had not identified any specific actions for the VEGP COL application based on the audit open items. The NRC staff's discussion of the audit of the EQ specifications, which includes the issues in RAI 3.11-2 addressed to the BLN applicant, is in NUREG-1793 and its supplements. Therefore, Standard Content Open Item 3.11-1 is resolved for the VEGP COL application.

<u>*Supplemental Review of Operational Aspects of the EQ Program*</u>

As discussed in RG 1.206 and Commission Paper SECY-05-0197, COL applicants must fully describe their operational programs to avoid the need for ITAAC regarding those programs. In addition to the initial EQ of electrical and mechanical equipment, the NRC staff reviewed the VEGP COL FSAR Section 3.11 with its incorporation by reference of the AP1000 DCD and supplemental information for operational aspects of the EQ Program. For example, AP1000 DCD Tier 2, Appendix 3D, Section 3D.7, "Documentation," states that information regarding maintenance, refurbishment, or replacement of the equipment will be included in the equipment qualification package if necessary to provide confidence in the equipment's capability to perform its safety function. Further, Section 3D.7.1, "Equipment Qualification Data Package," states that equipment qualification data packages will specify preventive maintenance that is required to support qualification or the qualified life, including maintenance or periodic activities assumed as part of the qualification program or necessary to support qualification. With respect to safety-related mechanical equipment, AP1000 DCD Tier 2, Section 3D.6.2.3.8, "Equipment Qualification Maintenance Requirements," specifies that maintenance requirements resulting from EQ activities will be based on: (1) qualification evaluation results (for example, periodic replacement of age-susceptible parts before the end of their qualified life); (2) equipment qualification-related maintenance activities derived from the qualification report; and (3) vendor recommended equipment qualification maintenance, if required, in order to maintain qualification. The staff finds that the VEGP COL applicant provides an acceptable description of the transition from the initial to the operational aspects of the EQ Program in support of the VEGP COL application through the VEGP COL FSAR with its incorporation by reference of the AP1000 DCD Tier 2, Section 3.11. The NRC staff will evaluate the implementation of the EQ Program through inspections conducted during plant construction and operation. The NRC inspection activities will include consideration of: (1) evaluation of EQ results for design life to establish activities to support continued EQ; (2) determination of surveillance and preventive maintenance activities based on EQ results; (3) consideration of EQ maintenance recommendations from equipment vendors; (4) evaluation of operating experience in developing surveillance and preventive maintenance activities for specific equipment; (5) development of plant procedures that specify individual equipment identification, appropriate references, installation requirements, surveillance and maintenance requirements, post-maintenance testing requirements, condition monitoring requirements, replacement part identification, and applicable design changes and modifications; (6) development of plant procedures for reviewing equipment performance and EQ operational activities, and for trending the results to incorporate lessons learned through appropriate modifications to the EQ Program; and (7) development of plant procedures for the control and maintenance of EQ records.

Based on the above discussion, the NRC staff finds the information added to the VEGP COL application as part of STD COL 3.11-1 to be acceptable.

<u>License Conditions</u>

- *Part 10, License Condition 3, Item G.1*

The applicant proposed a license condition providing the implementation milestone for the EQ Program.

- *Part 10, License Condition 6*

The applicant proposed a license condition to provide a schedule to support the NRC's inspection of operational programs including the EQ Program.

These license conditions are consistent with the policy established in SECY-05-0197 and are, thus, acceptable.

3.11.5 Post Combined License Activities

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license conditions acceptable:

- License Condition (3-8) – Before initial fuel load, the licensee shall implement the Environmental Qualification Program.

- License Condition (3-9) – No later than 12 months after issuance of the COL, the licensee shall submit to the Director of NRO a schedule that supports planning for and conduct of NRC inspections of the Environmental Qualification Program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the Environmental Qualification Program has been fully implemented.

3.11.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the environmental qualification program, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff compared the information in the application to relevant NRC regulations, the acceptance criteria in NUREG-0800, Section 3.11. The staff's review confirmed that the applicant has adequately addressed the COL information relating to the environmental qualification of equipment in accordance with the requirements of GDC 1, GDC 2, GDC 4, and GDC 23.

- WLS DEP 3.11-1, regarding a correction to the Environmental Zone designation for three level instruments for the spent fuel pool, is acceptable because the correction does not result in any changes in the environmental qualification requirements applicable to the instruments.

- WLS DEP 6.4-2, related to design changes affecting how the temperature and humidity in the main control room are maintained within the limits for reliable human performance, is reviewed and found acceptable by the staff in Section 21.3 of this SER.

- STD COL 3.11-1, regarding the administrative control of the EQ program for WLS, is acceptable because the requirements of 10 CFR 52.79(a)(10) and 10 CFR 52.79(a)(29)(I) are satisfied.

3.12 Piping Design

3.12.1 Introduction

This section covers the design of piping systems and supports for Seismic Category I and non-seismic systems. It also discusses the adequacy of the structural integrity, as well as the functional capability, of the safety-related piping systems, piping components, and their associated supports. The design of piping systems should ensure that they perform their safety-related functions under all postulated combinations of normal operating conditions, system operating transients, postulated pipe breaks, and seismic events. This includes pressure-retaining piping components and their supports, buried piping, instrumentation lines, and the interaction of Non-seismic Category I piping and associated supports with Seismic Category I piping and associated supports. This section covers the design transients and resulting loads and load combinations with appropriate specified design and service limits for Seismic Category I piping and piping support, including those designated as ASME Code Class 1, 2, and 3.

3.12.2 Summary of Application

WLS COL FSAR, Revision 11, Chapter 3, incorporates by reference AP1000 DCD, Revision 19, Chapter 3. NUREG-0800, Sections 3.7 and 3.9 address Section 3.12, “ASME Code Class 1, 2, and 3 Piping Systems, Piping Components and their Associated Supports.” In addition, in WLS COL FSAR Sections 3.7 and 3.9, the applicant provided the following:

Departures

- WLS DEP 2.0-1

WLS DEP 2.0-1 provides updated seismic hazards and updated site-specific foundation response spectra (i.e., GMRS, FIRS, and NI FIRS (envelope of GMRS and FIRS)) for WLS that exceed the AP1000 CSDRS. These spectra consider the newly released model described in NUREG-2115, “Central and Eastern United States Seismic Source Characterization for Nuclear Facilities,” as well as local and regional refinements. This updated information affects the seismic inputs to the piping analysis, the methodology for which is described in the AP1000 DCD.

AP1000 COL Information Items

- STD COL 3.9-2

The applicant provided information in STD COL 3.9-2 to address COL Information Item 3.9-2, which states that design specifications and design reports for the ASME Code, Section III piping will be available for the staff review and that reconciliation of these documents is completed after construction and prior to fuel load.

- STD COL 3.9-5

The applicant provided information in STD COL 3.9-5 to address COL Information Item 3.9-5, which provides a description for pressurizer surge line monitoring.

- STD COL 3.9-7

In a November 4, 2010, letter, the applicant endorsed the April 23, 2013, letter from the VEGP applicant, which proposed to add STD COL 3.9-7 to the FSAR. This COL item provides additional information on the process to be used to complete the piping design and ITAAC added to verify the design.

License Condition

- Part 10, License Condition 2, "COL Holder Items" Item 3.9-7

In a November 4, 2010, letter, the applicant endorsed an April 23, 2010, letter from the VEGP applicant, which proposed a license condition addressing the as-designed piping analysis reconciliation schedule.

ITAAC

In a November 4, 2010, letter, the applicant endorsed the April 23, 2010, letter from the VEGP applicant, proposing ITAAC requiring the completion of a design report referencing the as-designed piping calculation packages, including the ASME Code, Section III piping analysis, support evaluations and piping component fatigue analysis for Class 1 piping using the methods and criteria outlined in AP1000 DCD Table 3.9-19.

3.12.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the pipe and support analysis are given in NUREG-0800, Section 3.12.

3.12.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 3.9 and checked the referenced DCD to ensure that the combination of the DCD and the WLS COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the piping design review. The staff's evaluation of the information incorporated by reference in the WLS application is documented in NUREG-1793 and its supplements. Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform a technical review for each "standard issue" and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the Reference

COL application (i.e., VEGP Units 3 and 4) were equally applicable to the WLS application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In the comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the application, as applicable) resulting from responses to RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the COL FSAR.
- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting.

Departures

- WLS DEP 2.0-1

The WLS COL Part 7, "Departures and Exemptions Requests," Revision 9, identifies in departure WLS DEP 2.0-1 that the WLS FIRS exceeds the AP1000 DCD CSDRS and HRHF spectra. The applicant's June 11, 2014, response to RAI 115, Question 03.12-1, shows that safety-related piping (ASME Class 1, Class 2, and Class 3) is designed for both CSDRS and HRHF spectra, as described in AP1000 DCD Appendix 3I. 10 CFR Part 50, Appendix A, GDC 2 and 10 CFR Part 50, Appendix S, "Earthquake Engineering Criteria for Nuclear Power Plants," state that SSCs important to safety shall be designed to withstand the effects of earthquakes. In the applicant's June 11, 2014, response to RAI 115, Question 03.12-1, Westinghouse, as documented in its report WLG-GW-GLR-815, which is cited as WLS COL FSAR Section 3.7, Reference 206, performed a detailed review of all WLS site-specific in-structure floor response spectra (FRS) X-, Y-, and Z-direction exceedances of both the AP1000 CSDRS design spectra and the HRHF design spectra. The applicant's response also stated that selected piping packages in Reference 206 showed that resulting pipe stresses due to WLS FRS are bounded by the CSDRS or HRHF design basis analysis results.

The staff reviewed Reference 206 for the effects of the WLS FIRS exceedances on piping. Forty ASME Class 1, 2 and 3 piping layout packages were reviewed. Reference 206, Figures 5.4-15 and 5.4-16, state that the horizontal WLS FRS for the hot legs and pressurizer bottom has exceedances at lower frequencies. On this basis, two piping packages inside containment were selected for analysis. These two packages are the automatic depressurization system (ADS) 4th stage east compartment and passive residual heat removal (RHR) supply and the pressurizer surge line. A third package, the spent fuel cooling system (SFS) from the auxiliary building steel containment vessel (SCV) to the auxiliary building SFS pumps was also selected for review because it is potentially sensitive to high frequency response. These three piping systems were analyzed using the PIPESTRESS computer program with seismic FRS input loadings from CSDRS, HRHF and WLS FIRS. The staff reviewed a comparison of moment stresses from the seismic analyses due to these seismic input loadings was performed. For all three piping systems, the WLS spectrum resulting stresses were bounded either by the AP1000 DCD CSDRS or the AP1000 DCD HRHF spectra. The Reference 206 report also determined that piping support loads due to WLS FRS are enveloped by CSDRS loads. Furthermore, the applicant, in a revised January 13, 2015, response to RAI 116, Question 03.12-2, the applicant stated that when piping reanalysis is required to reconcile as-built piping, in addition to the AP1000 DCD CSDRS and HRHF spectra, the as-built piping system will also be qualified using the Lee site-specific spectra to confirm that configuration changes during construction have not affected the piping system qualification for site-specific demands. The staff also notes that the applicant revised the WLS COLA, Part 2, and WLS COL FSAR, Chapter 3, Appendix 3I to identify WLS DEP 2.0-1 and provide additional information to the end of AP1000 DCD Sections 3I.1, 3I.2, 3I.3, 3I.6, 3I.6.1, 3I.6.2, 3I.6.3, 3I.6.4, and 3I.7. Specifically, the revised Appendix 3I, Section 3I.6.3 describes the applicant's site-specific analyses for piping, supporting WLS DEP 2.0-1. The staff's concluded that the additional information in AP1000 Appendix 3I.6.3 regarding piping systems is consistent with the information provided in Reference 206.

Based on its review above, the staff finds that the applicant adequately evaluated the effects of the exceedances of the WLS site-specific spectra to the AP1000 DCD CSDRS and HRHF spectra on piping and has provided reasonable assurance that the WLS site-specific seismic exceedances will not adversely affect the structural integrity of the WLS AP1000 safety related piping.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 3.12.4:

> *Due to the significant amount of new information provided by both the VEGP applicant and Westinghouse on the piping design issues since the development of the BLN SER for Section 3.12, the NRC staff decided not to use the BLN SER material as a starting point for the evaluation of these issues.*
>
> *<u>AP1000 COL Information Items</u>*
>
> - *STD COL 3.9-2*
>
> *COL Information Item 3.9-2 states that design specifications and design reports for the ASME Code, Section III piping will be available for the NRC's review and that reconciliation of the piping is completed prior to fuel load in accordance with an ITAAC in AP1000 DCD Tier 1, Section 2. The discussion on STD COL 3.9-7 below addresses design specifications and design reports.*
>
> *The staff acknowledged that an ITAAC in the AP1000 DCD Tier 1 addresses verification of this aspect of the design and that COL Information Item 3.9-2 has been addressed.*
>
> - *STD COL 3.9-5*
>
> *The staff reviewed STD COL 3.9-5 (surge line thermal monitoring) and determined that the proposed program did not provide sufficient information for the staff to determine reasonable assurance for safety. The staff issued RAI 3.12-2 to ask the applicant to provide additional information including a test abstract including stating the standard operating conditions in Chapter 14 that identifies the objective, prerequisites, test method, data required, and acceptance*

criteria for surge line thermal monitoring that complies with NRC Bulletin 88-11. In this RAI, the staff also noted that

> *For subsequent SCOLs, the design is such that assumptions are made that the layout will be the same such that monitoring of the follow-on plants is not required. However, all plants are required to comply with NRC Bulletin 88-11. Given that the heatup and cooldown procedures have not been developed and the affect on the plant, even with similar layout, will be different depending on the procedures used, subsequent plants will need to verify that they will be using the same heatup and cooldown procedures as the monitored plant to comply with NRC Bulletin 88-11.*

In a letter dated July 2, 2010, the applicant provided its response to address the staff's concern. In the response, the applicant stated that VEGP COL FSAR Section 3.9.3.1.2 would be revised to add the following paragraph:

> *Subsequent AP1000 plants (after the first AP1000 plant) confirm that the heatup and cooldown procedures are consistent with the pertinent attributes of the first AP1000 plant surge line monitoring. In addition, changes to the heatup and cooldown procedures consider the potential impact on stress and fatigue analyses consistent with the concerns of NRC Bulletin 88-11.*

In this letter, the applicant also added a new Section 14.2.9.2.22 to provide a test abstract. The test abstract included the purpose, prerequisites, general test methods, and acceptance criteria.

In a subsequent letter dated August 6, 2010, the applicant provided additional information for the location of test instruments. In the response, the applicant stated that VEGP COL FSAR Section 3.9.3.1.2 would be revised to add the following paragraph:

> *In addition to the existing permanent plant temperature instrumentation, temperature and displacement monitoring will be included at critical locations on the surge line. The additional locations utilized for monitoring during the hot functional testing and the first fuel cycle (see Subsection 14.2.9.2.22) are selected based on the capability to provide effective monitoring.*

The staff reviewed the RAI responses and concluded the position is acceptable to comply with NRC Bulletin 88-11. On this basis, the proposed program for surge line thermal monitoring is acceptable. The incorporation of the planned changes to the VEGP COL FSAR detailed in the applicant's July 2, 2010, letter will be tracked as Confirmatory Item 3.12-1.

Resolution of Standard Content Confirmatory Item 3.12-1

Confirmatory Item 3.12-1 is an applicant commitment to revise its FSAR Table 1.9-204 and Sections 3.9.3.1.2 and 3.9.8.5 for surge line monitoring testing. The *staff verified that the VEGP COL FSAR was appropriately updated. As a result, Confirmatory Item 3.12-1 is now closed.*

- *STD COL 3.9-7*

In letter dated April 23, 2010, the applicant proposes that the as-designed piping analysis is made available for NRC review. Additionally in this letter, License Condition 2, Item 3.9-7, proposed by the applicant, calls for the design to be made available for review prior to installation of the piping and adding a site-specific ITAAC in Table 3.8-# [where # is the next sequential number] of Part 10 of the VEGP COL application for verification of the ASME Code design reports. In this letter, the applicant also proposed adding Section 14.3.3 to the VEGP COL FSAR, describing the process to be followed to address closure of the piping DAC during the construction period, to complete the review of the piping design including an ITAAC to review the design, and an ITAAC to review reconciliation of the design after it is built.

The staff reviewed the applicant's proposed approach of including ITAAC for verification of the design and reconciliation of the design, and a license condition to address timing of when the initial design verification would occur. The approach, including the ITAAC and the license condition, is acceptable to the staff as it allows verification that the methodology described in the AP1000 DCD and VEGP COL FSAR and the general requirements of the ASME Code, as specified in 10 CFR 50.55a, were met.

Proposed VEGP COL FSAR Section 14.3.3.# [where # is the next sequential number] also states that "The piping design completed for the first standard AP1000 plant will be available to subsequent standard AP1000 plants under the "one issue, one review, one position" approach for closure." Westinghouse letter dated August 17, 2010, as supplemented by letter dated August 23, 2010, stated that the ASME Code Class 1, 2 and 3 piping systems will be evaluated as part of the piping DAC for hard rock site to address hard rock site seismic issue. The standard AP1000 plant will have analysis that addresses both CSDRS and HRHF GMRS effect. Therefore, the one issue, one review, one position approach applies and the staff finds this acceptable for piping analysis.

*The incorporation of the planned changes to the VEGP COL application detailed in the applicant's April 23, 2010, letter and in response to hard rock seismic issues will be tracked as **Confirmatory Item 3.12-2**.*

<u>*Resolution of Standard Content Confirmatory Item 3.12-2*</u>

Confirmatory Item 3.12-2 is an applicant commitment to revise its FSAR Table 1.8-202, Section 3.9.8.2, Section 3.9.8.7, and Section 14.3.3.3 for pipe analysis and add an ITAAC (Table 3.8-2) for verification of the ASME Code design reports. The staff verified that the VEGP COL FSAR and Part 10 of the application (ITAAC Table 3.8-2) were appropriately updated. As a result, Confirmatory Item 3.12-2 is now closed.

3.12.5 Post Combined License Activities

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following ITAAC and license condition acceptable:

- The licensee shall perform and satisfy the piping design analysis ITAAC in requiring the completion of a design report referencing the as-designed piping calculation packages, including the ASME Code, Section III piping analysis, support evaluations and piping component fatigue analysis for Class 1 piping using the methods and criteria outlined in AP1000 DCD Table 3.9-19.

- License Condition (3-10) – Before commencing installation of individual piping segments identified in AP1000 DCD, Rev. 19, Section 3.9.8.7, and connected components in their final locations in the facility, the licensee shall complete the analysis of the as-designed individual piping segments and shall inform the Director of NRO, or the Director's designee, in writing, upon the completion of these analyses and the availability of the design reports for the selected piping packages.

3.12.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to piping design, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL application is acceptable and meets NRC regulations.

- WLS DEP 2.0-1 is acceptable because the applicant provided sufficient information to satisfy the requirements of 10 CFR Part 50, Appendix A, GDC 2 of Appendix A and 10 CFR Part 50, Appendix S, "Earthquake engineering criteria for nuclear power plants."

- STD COL 3.9-2 is acceptable because it meets the general requirements of the ASME Code, as specified in 10 CFR 50.55a.

- STD COL 3.9-5 is acceptable because it is consistent with pressurizer surge line monitoring discussed in 10 CFR Part 52, Appendix D, "Design Certification Rule for the AP1000 Design."

- STD COL 3.9-7 is acceptable because it meets the general requirements of the ASME Code, as specified in 10 CFR 50.55a.

- WLS DEP 2.0-1 is acceptable because the applicant provided sufficient information to satisfy the requirements of 10 CFR Part 50, Appendix A, GDC 2 and 10 CFR Part 50, Appendix S, "Earthquake engineering criteria for nuclear power plants."

5 REACTOR COOLANT SYSTEM AND CONNECTED SYSTEMS

5.1 Introduction

The reactor coolant system (RCS) consists of two heat transfer circuits, each with a steam generator (SG), two reactor coolant pumps (RCPs) and a single hot leg and two cold legs for circulating reactor coolant. In addition, the system includes the pressurizer, interconnecting piping/valves and instrumentation for operational control and safeguards actuation. All RCS equipment is located in the reactor containment. The RCS is designed to transfer heat generated by the reactor core, located in the reactor vessel (RV), to the secondary side of the steam generators for plant power generation.

Section 5.1 of the William States Lee III Nuclear Station (WLS) combined license (COL) Final Safety Analysis Report (FSAR), Revision 11, incorporates by reference, with no departures or supplements, Section 5.1 of Revision 19 of the AP1000 Design Control Document (DCD). The U.S. Nuclear Regulatory Commission (NRC) staff (the staff) reviewed the COL application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," and its supplements.

5.2 Integrity of Reactor Coolant Pressure Boundary

5.2.1.1 *Compliance with 10 CFR 50.55a*

5.2.1.1.1 Introduction

Title 10 of the *Code of Federal Regulations* (10 CFR) 50.55a incorporates by reference the American Society of Mechanical Engineers (ASME) *Boiler & Pressure Vessel Code* (B&PV Code) and the ASME Code for Operation and Maintenance for Nuclear Power Plants (OM Code), including Editions and Addenda for ASME Class 1, 2, and 3 components, required for component design, construction, inservice inspection (ISI), and inservice testing (IST).

AP1000 DCD Tier 2, Table 3.2-1 classifies the pressure-retaining components of the reactor coolant pressure boundary (RCPB) as ASME BPV Code, Section III, Class 1 components. These Class 1 components are designated quality group (QG) A in conformance with Regulatory Guide (RG) 1.26, "Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants," Revision 4.

---

[1] See Section 1.2.2 of this safety evaluation report (SER) for a discussion of the staff's review related to verification of the scope of information to be included in a COL application that references a design certification (DC).

5.2.1.1.2 Summary of Application

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference AP1000 DCD, Revision 19, Section 5.2 with departures and/or supplements. AP1000 DCD Section 5.2 includes Section 5.2.1.1.

To address the departures and/or supplements in WLS COL FSAR Section 5.2.1.1, the applicant provided the following additional information:

AP1000 COL Information Item

- Standard (STD) COL 5.2-1

The applicant provided additional information in STD COL 5.2-1 to address COL Action Item 5.2.1.1-1 identified in NUREG-1793, Appendix F, “Combined License Action Items,” and COL Information Item 5.2-1 discussed in AP1000 DCD Section 5.2.6.1, “ASME Code and Addenda.” The portion of STD COL 5.2-1 evaluated here applies to ASME B&PV Code reconciliation. The portion applicable to Code cases is reviewed in Section 5.2.1.2 of this SER.

Specifically, WLS COL FSAR Section 5.2.1.1 states:

> If a later Code edition/addenda than the Design Certification Code edition/addenda is used by the material and/or component supplier, then a code reconciliation to determine acceptability is performed as required by the ASME Code, Section III, NCA-1140. The later Code edition/addenda must be authorized in 10 CFR 50.55a or in a specific authorization as provided in 50.55a(a)(3). Code Cases to be used in design and construction are identified in the DCD; additional Code Cases for design and construction beyond those for the design certification are not required.
>
> Inservice inspection of the reactor coolant pressure boundary is conducted in accordance with the applicable edition and addenda of the ASME Boiler and Pressure Vessel Code Section XI, as described in Subsection 5.2.4. Inservice testing of the reactor coolant pressure boundary components is in accordance with the edition and addenda of the ASME OM Code as discussed in Subsection 3.9.6 for pumps and valves, and as discussed in Subsection 3.9.3.4.4 for dynamic restraints.

5.2.1.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference in the COLA is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the ASME B&PV Code reconciliation are given in NUREG-0800, Section 5.2.1, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition.”

The applicable regulatory requirements for the staff’s review of STD COL 5.2-1 are provided in 10 CFR 50.55a, as it relates to the establishment of the minimum quality standards for the design, fabrication, erection, construction, testing, and inspection of RCPB components and other safety-related fluid systems of pressurized-water reactor (PWR) nuclear power plants by compliance with appropriate editions of published industry codes and standards. The regulatory basis is also provided in 10 CFR Part 50, Appendix A, General Design Criterion (GDC) 1, “Quality Standards and Records,” as it relates to requirements that nuclear power plant structures, systems, and components (SSCs) important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

5.2.1.1.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 5.2.1.1 and the referenced DCD to ensure that the combination of the DCD information incorporated by reference and the information in the COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and that incorporated by reference addressed the required information relating to integrity of the RCPB. The results of the staff’s evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff’s findings on standard content that were documented in the SER for the reference COL application (Vogtle Electric Generating Plant (VEGP), Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from requests for additional information (RAIs).

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff’s review determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the Bellefonte Nuclear Plant (BLN), Units 3 and 4 COL application. There was a change to the AP1000 DCD and NUREG-1793 referenced in the standard content material. This change is discussed in this SER.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.2.1.1.4:

AP1000 COL Information Item

- *STD COL 5.2-1*

The NRC staff reviewed STD COL 5.2-1 related to ASME BPV Code reconciliation included under Section 5.2.1.1 of the BLN COL FSAR.

The regulations in 10 CFR 50.55a(a)(3) provide requirements to authorize alternatives to the regulations in 10 CFR 50.55a, while 10 CFR 50.55a(f)(6)(i) and 10 CFR 50.55(g)(6)(i) provide requirements to grant requests for relief from impractical ASME Code requirements. In addition, NUREG-1793, Section 5.2.1.1 provides a discussion on the need for allowing changes to the ASME Code Edition and Addenda during plant construction to ensure consistency between design and construction requirements.

Section 5.2.1.1 of the NRC staff's NUREG-1793 states:

> *DCD Tier 2, Section 5.2.1.1, states that the baseline code used to support the AP1000 DCD is ASME Code, Section III, 1998 Edition, up to and including the 2000 Addenda. However, the ASME Code, Section III, 1989 Edition, 1989 Addenda will be used for Articles NB-3200, NB-3600, NC-3600, and ND-3600 in lieu of the later edition and addenda. The use of these editions and addenda meets the requirements of 10 CFR 50.55a(b) and the associated modifications in 10 CFR 50.55a(b)(1)(iii) and is, thus, acceptable. Any proposed change to the use of the ASME Code editions or addenda by a Combined License (COL) applicant will require NRC approval prior to implementation.*

The issue was also captured as COL Action Item 5.2.1.1-1 in Appendix F of NUREG-1793. The NRC staff states in Section 5.2.1.1 of NUREG-1793.

> *The COL applicant should ensure that the design is consistent with the construction practices (including inspection and examination methods) of the ASME Code edition and addenda, as endorsed in 10 CFR 50.55a. DCD Tier 2, Section 5.2.6.1, "ASME Code and Addenda," contains a commitment that the COL applicant will address consistency of the design with the construction practices (including inspection and examination methods) of the later ASME Code edition and addenda. The staff finds this to be an acceptable commitment. This is COL Action Item 5.2.1.1-1.*

Specifically, the AP1000 DCD in Section 5.2.6.1 identified a COL information item stating:

> *The Combined License applicant will address in its application the portions of later Code editions and addenda to be used to construct components that will require NRC staff review and approval. The Combined License applicant will address consistency of the design with the construction practices*

> *(including inspection and examination methods) of the later ASME Code edition and addenda added as part of the Combined License application. The Combined License applicant will address the addition of ASME Code cases approved subsequent to design certification.*

The staff reviewed conformance of BLN's resolution to COL Action Item 5.2.1.1-1 to the guidance in NUREG-0800, Section 5.2.1.1, "Compliance with the Codes and Standards Rule, 10 CFR 50.55a." ASME Code, Section III, NCA-1140, "Use of Code Editions, Addenda, and Cases," states that specific provisions within an Edition or Addenda later than those established in the design specifications may be used, provided that all the related requirements are met. NCA-1140(a)(1) also states:

> *Under the rules of this Section [Section III], the Owner or his designee shall establish the Code Edition and Addenda to be included in the Design Specifications. All items of a nuclear power plant may be constructed to a single Code Edition and Addenda, or each item may be constructed to individually specified Code Editions and Addenda.*

Accordingly, a COL applicant should establish whether it plans to use a single Code Edition and Addenda consistent with the certified design or to use individually specified Code Editions and Addenda. If individually specified Code Editions and Addenda are used, then differences between those Editions and Addenda are required to be reconciled consistent with requirements in the ASME BPV Code, Section III, NCA-1140.

The NRC staff found that Revision 0 to the BLN COL FSAR did not address NCA-1140 in describing the use of later Code Editions and Addenda. Therefore, in request for additional information (RAI) 5.2.1.1-1, the staff requested that the applicant explain the methodology for the ASME BPV Code reconciliation consistent with NCA-1140.

In its response to RAI 5.2.1.1-1 (this also applies to RAI 5.2.1.2-1 and RAI 5.2.1.1-3), the COL applicant described a revision to the FSAR to address this issue. Revision 1 to BLN COL FSAR Section 5.2.1.1, specifies that the methodology used to ensure consistency of design and construction practices when using later Section III Code Editions and Addenda would conform to the provisions of NCA-1140, and that all related requirements of the Code case(s) would be met. The use of NCA-1140 addresses the provisions to be followed for reconciliation of later Editions/Addenda of the ASME BPV Code. As a result, RAI 5.2.1.1-1 and RAI 5.2.1.2-1 are closed.

Revision 0 of the BLN COL FSAR referred to the use of ASME BPV Code, Section XI, as part of the reconciliation process if a later-Code year/Addenda than the DC Code year/Addenda is used by the material and/or component supplier. In RAI 5.2.1.1-3, the staff requested that the applicant provide justification for the use of ASME BPV Code, Section XI, which addresses ISI at *operating nuclear power plants, in the reconciliation process for new reactor designs.*

In its response to RAI 5.2.1.1-3 (referring to the response to RAI 5.2.1.1-1), the applicant noted that ASME BPV Code, Section III components are being designed using the baseline ASME BPV Code defined in DCD Section 5.2.1.1. Design specifications for component and material procurement will specify the ASME BPV Code to be used for design and construction to be that identified in the DCD. The applicant also noted that the reference in FSAR Section 5.2.1.1 to the ASME BPV Code, Section XI reconciliation process for repair and replacement was inappropriate for the original design and construction. Therefore, the applicant stated that this reference would be corrected. Revision 1 to the BLN COL FSAR in Section 5.2.1.1 removes the reference to ASME BPV Code, Section XI, and states, if a later Code Edition/Addenda than the DC Code Edition/Addenda is used by the material and/or component supplier, then a Code reconciliation to determine acceptability is performed as required by the ASME Code, Section III, NCA-1140. The staff finds that Revision 1 to the BLN COL FSAR meets the requirements of 10 CFR 50.55a. As a result, RAI 5.2.1.1-3 is closed.

Revision 0 of the BLN COL FSAR referenced Revision 16 of the AP1000 DCD. AP1000 DCD, Revision 16 required the use of the 1989 Edition, 1989 Addenda for NB-3200, NB-3600, NC-3600 and ND-3600 for construction of components and piping. In RAI 5.2.1.1-5, the NRC staff requested that the applicant identify components that are designed and constructed using the 1989 ASME BPV Code and discuss whether these components will meet the requirements of the 1998 Edition through and including the 2000 Addenda ASME BPV Code, which is the Code of record for the AP1000 DCD. In its response to RAI 5.2.1.1-5, the applicant indicated that in a letter dated May 16, 2008, Westinghouse submitted a document (APP-GW-GLE-005) to address the limitation on the use of ASME Section III Code for seismic design in accordance with 10 CFR 50.55a(b)(1)(iii) as related to the use of the above four articles. The AP1000 DCD was accordingly changed in Revision 17 to limit the use of the 1989 Edition, 1989 Addenda to piping design only. Since BLN COL FSAR, Revision 1 incorporated by reference Revision 17 of AP1000 DCD, no components will be constructed using the 1989 Edition, 1989 Addenda Code and they will be used for piping design only. As a result, RAI 5.2.1.1-5 is closed.

AP1000 DCD, Section 5.2.1.1 discusses the application of ASME BPV Code, Section III, for the design and fabrication of RCPB components. In RAI 5.2.1.1-2, the NRC staff requested that the applicant discuss the application of other sections of the ASME BPV Code and the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) not specified in the AP1000 DCD, Section 5.2.1.1. In its response to RAI 5.2.1.1-2, provided in a letter dated July 25, 2008, the applicant discussed other sections in the AP1000 DCD and the BLN COL FSAR that reference the ASME BPV Code and the ASME OM Code. In response to RAI 5.2.1.1-2, the applicant stated that BLN COL FSAR Section 5.2.1.1 would be revised to address this issue. Revision 1 to the BLN COL FSAR in Section 5.2.1.1, specifies that ISI of the RCPB will be conducted in accordance with the applicable Edition and Addenda of the ASME

BPV Code, Section XI, as described in BLN COL FSAR Section 5.2.4, "Inservice Inspection and Testing of Class 1 Components." The BLN COL FSAR, Revision 1 also specifies that IST of the RCPB components will be performed in accordance with the applicable Edition and Addenda of the ASME OM Code as discussed in BLN COL FSAR Section 3.9.6, "Inservice Testing of Pumps and Valves," and as discussed in BLN COL FSAR Section 3.9.3.4.4, "Inspection, Testing, Repair and/or Replacement of Snubbers." Revision 1 to the BLN COL FSAR clarified the application of other sections of the ASME BPV Code and the ASME OM Code in the design, construction, and operation of BLN Units 3 and 4. As a result, RAI 5.2.1.1-2 is closed.

As discussed in NUREG-1793, use of the ASME BPV Code for the AP1000 reactor is Tier 1 information while the specific Edition and Addenda are designated Tier 2 because of the continually evolving design and construction practices (including inspection and examination techniques) of the ASME BPV Code. The NRC staff finds that the design and construction of ASME BPV Code Class 1, 2, and 3 components and their supports will conform to the appropriate ASME BPV Code Editions and Addenda and, thus, meet the relevant NRC regulations governing the use of codes and standards. The use of Editions and Addenda of the ASME BPV Code, Section III issued subsequent to the AP1000 design code of record may be used provided the Edition and Addenda are incorporated by reference in the regulations, and NRC staff approval is obtained as required for Tier 2* changes to the AP1000 DC information. Generic NRC approval of the Tier 2* changes related to use of later Editions and Addenda during construction may be obtained by a COL applicant through NCA-1140(a)(1) for components other than piping. Further, the staff finds that quality standards used will be commensurate with the importance of the safety function of all safety-related components because the ASME BPV Code, Section III that is incorporated by reference into the NRC regulations will be used by the COL licensee to ensure consistency with design, construction, and inspection requirements. The staff finds this to be an acceptable basis for satisfying the requirements of GDC 1. Finally, STD COL 5.2-1 states that any proposed alternatives to the ASME BPV Code must be authorized by the NRC pursuant to 10 CFR 50.55a(a)(3). This meets the regulations and is, therefore, acceptable.*

<u>Correction to the Standard Content Evaluation Text</u>

The section of the technical evaluation above, which discusses the Tier 2 information is no longer valid. Westinghouse, in a proposed revision of its DCD, changed the Edition and Addenda of the ASME BPV Code from a Tier 2* designation to Tier 2. This change is evaluated in a supplement to NUREG-1793.*

This change does not impact the conclusions of the BLN or VEGP evaluations.

In a February 5, 2009, letter, Duke Energy endorsed BLN standard content RAIs 05.02.01.01-01 through 05.02.01.01-05, and 05.02.01.02-01. Therefore, the above discussion related to the BLN standard content RAIs is equally applicable to WLS COL application.

5.2.1.1.5 Post Combined License Activities

There are no post COL activities related to this section.

5.2.1.1.6 Conclusion

The staff reviewed the COL application and the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to codes and standards, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR 50.55a and GDC 1. The staff based its conclusion on the following:

- STD COL 5.2-1, as related to ASME Code reconciliation, is acceptable because the design and construction of ASME BPV Code Class 1, 2, and 3 components and their supports will conform to the appropriate ASME B&PV Code Editions and Addenda and, thus, meet the relevant NRC regulations in 10 CFR 50.55a governing the use of codes and standards. Further, the staff finds that quality standards used will be commensurate with the importance of the safety function of all safety-related components that is an acceptable basis for satisfying the requirements of GDC 1. Also, STD COL 5.2-1 states that any proposed alternatives to the ASME B&PV Code must be authorized by the NRC pursuant to 10 CFR 50.55a(a)(3).

5.2.1.2 *Applicable Code Cases (Related to RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.1.2, "Compliance with Applicable ASME Code Cases")*

5.2.1.2.1 Introduction

This section addresses the ASME Code cases to be used at WLS. In general, a Code case is developed by ASME based on inquiries from the nuclear industry associated with Code clarification, modification or alternative to the Code. All Code cases will remain valid and available for use until annulled by the ASME B&PV Standards Committee. ASME Code cases acceptable to the staff are published in RG 1.84, "Design and Fabrication Code Case Acceptability, ASME Section III, Division 1"; RG 1.147, "Inservice Inspection Code Case Acceptability, ASME Section XI, Division 1"; and RG 1.192, "Operation and Maintenance Code Case Acceptability, ASME OM Code"; in accordance with the requirements of 10 CFR 50.55a(b)(4), 10 CFR 50.55a(b)(5) and 10 CFR 50.55a(b)(6).

5.2.1.2.2 Summary of Application

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference AP1000 DCD, Revision 19, Section 5.2 with departures and/or supplements. AP1000 DCD Section 5.2 includes Section 5.2.1.2.

WLS COL FSAR Section 5.2 does not include supplemental information in the incorporation by reference of AP1000 DCD Section 5.2.1.2. However, WLS COL FSAR Section 5.2 specifies supplementary information in STD COL 5.2-1 that relates to applicable Code cases.

To address the departure and/or supplements in WLS COL FSAR Section 5.2.1.1, the applicant provided the following additional information:

AP1000 COL Information Item

- STD COL 5.2-1

The applicant provided additional information in STD COL 5.2-1 to address COL Action Item 5.2.1.1-1 identified in NUREG-1793 and COL Information Item 5.2-1 discussed in AP1000 DCD Section 5.2.6.1, “ASME Code and Addenda.” The portion of STD COL 5.2-1 evaluated in this section applies to the applicable Code cases.

5.2.1.2.3 Regulatory Basis

The regulatory basis of the AP1000 DCD information incorporated by reference in the WLS COL application is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the applicable Code cases are given in NUREG-0800, Section 5.2.1.2.

The applicable regulatory requirements for the staff’s review of the WLS COL application are as follows.

GDC 1 in 10 CFR Part 50, Appendix A and 10 CFR 50.55a, as it relates to the establishment of the minimum quality standards for the design, fabrication, erection, construction, testing, and inspection of nuclear power plant components, requires conformance to appropriate editions of published industry codes and standards.

As one means of meeting the applicable NRC regulations, RG 1.84 lists ASME B&PV Code, Section III Code cases oriented to design, fabrication, materials, and testing, which are acceptable with applicable conditions for implementation at nuclear power plants. RG 1.147 lists ASME B&PV Code, Section XI Code cases, which are acceptable with applicable conditions for use in the ISI of nuclear power plant components and their supports. RG 1.192 lists Code cases related to the ASME OM Code oriented to operation and maintenance of nuclear power plant components, which are acceptable with applicable conditions for implementation at nuclear power plants.

5.2.1.2.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 5.2 and the referenced DCD to ensure that the combination of the DCD information incorporated by reference in COL application and the information in the COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the COL application and that incorporated by reference from the DCD addressed the required information relating to applicable Code cases. The results of the staff’s evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In NUREG-1793, Section 5.2.1.2, the NRC staff states that the COL applicant may submit, with its COL application, future Code cases that are endorsed in RG 1.84 at the time of the application, provided that they do not alter the staff's safety findings on the AP1000 certified design. The staff also states that the COL applicant should submit those Code cases that are in effect at the time of the COL application and apply to operational programs involving ISI and IST. The supplement to NUREG-1793 describes the staff's technical evaluation of modifications to the list of ASME Code cases in AP1000 DCD, Revision 19, Table 5.2-3.

The staff followed the guidance provided in NUREG-0800, Section 5.2.1.2, "Applicable Code Cases," and RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.1.2, in evaluating WLS COL FSAR Section 5.2.1.2 for compliance with NRC regulations.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and to use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.
- The staff verified that the site-specific differences were not relevant.

The staff's review determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.2.1.2.4:

> *<u>AP1000 COL Information Item</u>*
>
> - *STD COL 5.2-1*
>
> *Revision 0 to the BLN COL FSAR in Section 5.2.1.1 had referenced ASME BPV Code, Section XI, as part of the reconciliation process for the use of ASME Code cases other than those included in AP1000 DCD Table 5.2-3. In RAI 5.2.1.1-4, the staff requested that the applicant explain how this met 10 CFR 50.55a(a)(3), 10 CFR 50.55a(b)(4), 10 CFR 50.55a(b)(5), and10 CFR 50.55a(b)(6).*
>
> *In its response to RAI 5.2.1.1-4, the applicant noted that no Code cases other than those included in the DCD have been identified as necessary at this time. Code cases approved by the NRC in RG 1.147 may be used, and if so, they will*

be identified in a revision to the FSAR. The applicant also indicated that the FSAR statement regarding reconciliation of Code cases was incorrect and would be revised. Revision 1 to the BLN COL FSAR in Section 5.2.1.1 specifies that Code cases to be used in design and construction are identified in the DCD and that additional Code cases for design and construction beyond those for the DC are not required. The staff considers Revision 1 to the BLN COL FSAR Section 5.2.1.1 to be acceptable. As a result, RAI 5.2.1.1-4 is closed.

AP1000 DCD, Revision 17, Section 5.2.1.2 indicated that use of Code cases approved in revisions of the RGs issued subsequent to the DC may be used as discussed in Section 5.2.6.1 by using the process outlined for updating the ASME Code Edition and Addenda. Section 5.2.6.1 stated that the COL applicant will address in its application, the addition of ASME Code cases approved subsequent to DC. Similar to the Section III Code cases listed in DCD Table 5.2-3, in RAI 5.2.1.2-2, the staff requested that the applicant identify the ASME BPV Code, Section XI ISI and the ASME OM Code cases that are used for BLN design and construction. The applicant was also requested to confirm whether these Code cases are approved by the NRC as documented in RGs 1.147 and 1.192. If not, these Code cases must be submitted to the NRC for authorization pursuant to 10 CFR 50.55a(a)(3).

In its response to RAI 5.2.1.2-2, the applicant referred to its response to RAI 5.2.1.1-4 and noted that there are no additional Code cases used for design and construction beyond those identified in the DCD. In its RAI response, the applicant stated that the IST Program described in BLN COL FSAR Section 3.9.6 will utilize Code Case OMN- 1, Revision 1, "Alternative Rules for the Preservice and In-service Testing of Certain Electric Motor-Operated Valve Assemblies in Light Water Reactor Power Plants," which establishes alternate rules and requirements for preservice and IST to assess the operational readiness of certain motor operated valves. The staff notes that the current revision to RG 1.192 at the time of this COL review conditionally accepts the use of Code Case OMN-1, Revision 0, and does not address Revision 1 to Code Case OMN-1. The applicant will need to submit a request under 10 CFR 50.55a for authorization to apply Revision 1 to Code Case OMN-1, if RG 1.192 is not updated to accept this revision to the Code case prior to development of the IST Program for BLN. The NRC staff's review of the use of OMN-1, Revision 1, for BLN is discussed in Section 3.9.6 of this SER. In its response to RAI 5.2.1.2-2, the applicant stated that no code cases other than those included in the DCD are used for BLN and the FSAR would be revised as indicated in response to RAI 5.2.1.1-4. As noted above, Revision 1 to the BLN COL FSAR resolved RAI 5.2.1.1-4. Therefore, RAI 5.2.1.2-2 is also closed.

Based on its review, the NRC staff has determined that BLN COL FSAR Section 5.2 appropriately incorporates by reference AP1000 DCD, Section 5.2.1.2, in satisfying the NRC regulations for the design, fabrication, erection, testing, and inspection of plant SSCs commensurate with the importance of the safety function to be performed by referencing the use of accepted ASME Code cases. As a result, the staff concludes that compliance by the applicant with the provisions of the ASME Code cases accepted in RGs 1.84, 1.147, and 1.192, or individually reviewed and accepted in NUREG-1793 or its

> *supplements, will result in component quality that is commensurate with the importance of the safety functions of the components at BLN Units 3 and 4. This satisfies the requirements of GDC 1, and, therefore, is acceptable.*
>
> *AP1000 DCD, Section 5.2.6.1 states, in part, that the COL applicant will address the addition of ASME Code cases approved subsequent to the DC. As noted above, the applicant has not identified any Code cases other than those included in the AP1000 DCD as necessary at this time for the design and construction of BLN Units 3 and 4. If the applicant determines the need to apply other ASME Code cases in the future, it may apply those ASME Code cases in accordance with their acceptance in RG 1.84, RG 1.147, or RG 1.192, including any applicable conditions, or must request NRC authorization to use those Code cases.*

In a February 5, 2009, letter, Duke Energy endorsed BLN standard content RAIs 05.02.01.01-04 and 05.02.01.02-02. Therefore, the above discussion related to the BLN standard content RAIs is equally applicable to WLS COL application. In addition, the staff also verified that the equivalent changes are incorporated in the WLS COL FSAR.

5.2.1.2.5 Post Combined License Activities

There are no post-COL activities related to this section.

5.2.1.2.6 Conclusion

The staff reviewed the COL application and the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to ASME Code cases, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR 50.55a and GDC 1, and complies with the provisions of the ASME Code cases accepted in RGs 1.84, 1.147, and 1.192. The staff based its conclusion on the following:

- STD COL 5.2-1, as related to applicable ASME Code cases, is acceptable because the staff concluded that WLS COL FSAR Section 5.2.1.2 appropriately incorporated by reference AP1000 DCD Section 5.2.1.2, to satisfy NRC regulations for the design, fabrication, erection, testing, and inspection of plant SSCs commensurate with the importance of the safety function to be performed by referencing the use of accepted ASME Code cases. As a result, the staff concludes that compliance by the applicant with the provisions of the ASME Code cases accepted in RG 1.84, RG 1.147, and RG 1.192, or individually reviewed and accepted in NUREG-1793 or its supplements, will result in component quality that is commensurate with the importance of the safety functions of the components at WLS Units 1 and 2. This satisfies the requirements of GDC 1 and, therefore, is acceptable.

5.2.1.3 *Alternate Classification*

In the standard plant design, Westinghouse applies an alternate classification for the chemical and volume control system (CVCS).

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 5.2.1.3, “Alternate Classification.” The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff’s review confirmed that there is no outstanding issue related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

5.2.2 Overpressure Protection

RCS and steam system overpressure protection during power operation is provided by the pressurizer safety valves and the steam generator safety valves, in conjunction with the action of the reactor protection system. In addition, a relief valve in the suction line of the normal residual heat removal system (RNS) provides low-temperature overpressure protection (LTOP) for the RCPB during low-temperature operation of the plant (startup, shutdown).

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 5.2.2, “Overpressure Protection.” The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff’s review confirmed that there is no outstanding issue related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

5.2.3 Reactor Coolant Pressure Boundary Materials

5.2.3.1 *Introduction*

Materials selected for RCS components must be compatible with reactor coolant water chemistry, thermal insulation materials, and the atmosphere. The specific processes (including heat treatment and welding practices) used to fabricate RCS components must maximize the corrosion resistance and fracture toughness of the components.

5.2.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference AP1000 DCD, Revision 19, Section 5.2 of the with departures and supplements. AP1000 DCD Section 5.2 includes Section 5.2.3.

To address the departures and/or supplements in WLS COL FSAR Section 5.2.3.2.1, the applicant provided the following additional information:

<u>*Supplemental Information*</u>

- STD SUP 5.2-1

The applicant provided supplemental information to describe the monitoring program for primary water chemistry to be implemented at the plant during plant operation.

5.2.3.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the RCPB materials are identified in NUREG-0800, Section 5.2.3.

The applicable regulatory requirements for acceptance of the supplementary information on water chemistry monitoring is established in GDC 14, "Reactor Coolant Pressure Boundary," which requires that the RCPB shall be designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture.

5.2.3.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 5.2 and checked the referenced DCD to ensure that the combination of the DCD information incorporated in the COL application and that included in the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to RCPB materials. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff completed its review and concluded that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference

COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.2.3.4:

Supplemental Information

- *STD SUP 5.2-1*

The NRC staff reviewed the standard supplementary information on water chemistry as discussed in Section 5.2.3.2.1 of the BLN COL FSAR. In its review of the supplemental information the staff used the applicable sections of NUREG-0800 and RG 1.206 as guidance. However, Section 5.2.3 of NUREG-0800 does not directly address PWR reactor coolant chemistry, but, rather, refers the reviewer to NUREG-0800, Section 9.3.4, "Chemical and Volume Control System (PWR) Including Boron Recovery." Section 9.3.4 of NUREG-0800 recommends that the Chemical and Volume Control System (CVCS) ensure that RCS chemistry meets GDC 14, by maintaining acceptable purity levels in the reactor coolant through the removal of insoluble corrosion products and dissolved ionic material by filtration and ion exchange. In addition, Section 9.3.4 of NUREG-0800 recommends that the CVCS maintain proper RCS chemistry by controlling total dissolved solids, pH, oxygen concentration, and halide concentrations within the acceptable ranges. RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.3.2 recommends that COL applications referencing PWR standard designs describe the chemistry of the reactor coolant and the additives (such as inhibitors), the water chemistry, including maximum allowable content of chloride, fluoride, sulfate, and oxygen and permissible content of hydrogen and soluble poisons, the methods to control water chemistry, including pH, the industry-recommended methodologies to be used to monitor water chemistry, and provide appropriate references. Additionally, RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.3.2 also states that "this section may reference the Electric Power Research Institute (EPRI) water chemistry guidelines to support the plant-specific program. However, this section should fully describe and discuss the plant-specific water coolant chemistry control program and its compatibility with the RCPB materials."

The supplementary information in the BLN COL FSAR states that monitoring of water chemistry is implemented using the guidance of EPRI TR-1002884, "Pressurized Water Reactor Primary Water Chemistry Guidelines: Volume 1," Appendix F (Revision 5, dated October 2003). The cited appendix pertains specifically to sampling of soluble and insoluble corrosion products from the RCS. Use of this appendix is consistent with the recommendation in NUREG-0800 that the CVCS system maintains acceptable purity levels in the reactor coolant through the removal of insoluble corrosion products and dissolved ionic material by filtration and ion exchange, and must maintain proper RCS chemistry by controlling total dissolved solids, pH, oxygen concentration, and halide concentrations within the acceptable ranges. Accurate sampling of corrosion products supports this recommendation.

Appendix F of the Primary Water Chemistry Guidelines only provides a recommended methodology for sampling RCS corrosion products, and does not provide acceptance criteria or methods for reducing/controlling RCS corrosion products. Further, other primary water chemistry parameters that NUREG-0800 and RG 1.206 recommend be addressed in the FSAR are not addressed by Appendix F, such as pH, oxygen, and halide concentrations. These parameters are addressed in DCD Section 5.2.3 and DCD Table 5.2.2, which provides maximum values of primary water chemistry parameters including oxygen, pH and halide concentration for the various plant operating modes. Referencing Appendix F only of the Primary Water Chemistry Guidelines does not add any more detail or specificity for these other parameters. Therefore, in a letter dated April 10, 2008, the staff requested additional information (RAI 5.2.3-1) from the applicant to address these items.

Specifically, the NRC staff requested that the applicant explain the rationale for referencing only Appendix F to the "Pressurized Water Reactor Primary Water Chemistry Guidelines" rather than referencing the entire guidelines document.

The applicant responded to RAI 5.2.3-1, in a letter dated May 23, 2008, stating that "the AP1000 Design Control Document (DCD) describes, in Section 5.2.3.2.1, the RCS chemistry specifications and the methods to control water chemistry. In addition, DCD Table 5.2-2 summarizes these specifications for conductivity, pH, oxygen, chloride, hydrogen, suspended solids (corrosion product particulates), pH control agent, boric acid, silica, aluminum, calcium, magnesium, and zinc."

The applicant's response further stated that FSAR Section 5.2 incorporates the aforementioned DCD section by reference and refers to Appendix F of EPRI TR-1002884 as the industry recommended methodology to be used to monitor water chemistry. As noted by the question, Appendix F of the EPRI document is limited to corrosion products and as such, is insufficient to address the remaining details of the program. As such, the text of FSAR Section 5.2.3.2.1 will be revised to reference the complete EPRI document which does address the requested program attributes not covered by the DCD.

The applicant also proposed changes to the BLN COL FSAR Chapter 5, Section 5.2.3.2.1. The following information is to replace the previous supplemental information:

> *The water chemistry program is based on industry guidelines as described In EPRI TR-1002884, "Pressurized Water Reactor Primary Water Chemistry." The program includes periodic monitoring and control of chemical additives and reactor coolant impurities listed in DCD Table 5.2-2. Detailed procedures implement the program requirements for sampling and analysis frequencies, and corrective actions for control of reactor water chemistry. The frequency of sampling water chemistry varies (e.g., continuous, daily, weekly, or as needed) based on plant operating conditions and the EPRI water chemistry guidelines. Whenever corrective actions are taken to address an abnormal*

> *chemistry condition, increased sampling is utilized to verify the effectiveness of these actions. When measured water chemistry parameters are outside the specified range, corrective actions are taken to bring the parameter back within the acceptable range and within the time period specified in the EPRI water chemistry guidelines. Following corrective actions, additional samples are taken and analyzed to verify that the corrective actions were effective in returning the concentrations of contaminants.*

The staff finds the applicant's response, and the proposed COL application changes, acceptable because it meets the acceptance criteria in Section 9.3.4 of NUREG-0800 related to the evaluation of the proposed chemistry program using the latest version in the EPRI report series, "PWR Primary Water Guidelines." The staff verified that Revision 1 of the FSAR (STD SUP 5.2-1) adequately incorporates the above. As a result, RAI 5.2.3-1 is closed.

Additionally, the staff finds that the BLN FSAR meets the recommendation in RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.3.2 to fully describe the primary water chemistry control program in the FSAR by referencing the most recent version of the "EPRI PWR Primary Water Guidelines" in its entirety. Although Section 5.2 of the AP1000 DCD, Revision 17, provides maximum values (and in some cases, normal ranges) for the key primary water chemistry parameters, referencing the EPRI PWR Primary Water Guidelines provides a more detailed description of the chemistry control program because various action levels (at which varying levels of corrective action are required) are specified for the key parameters for different reactor operating modes, as well as the required periodicity for sampling the various parameters.

Although the staff does not formally review or issue a safety evaluation of the revisions to the EPRI water chemistry guidelines (including the PWR Primary Water Chemistry Guidelines), the guidelines are recognized as representing industry best practices in water chemistry control. Extensive experience in operating reactors has demonstrated that following the EPRI guidelines minimizes the occurrence of corrosion related failures. Further, the EPRI guidelines are periodically revised to reflect evolving knowledge with respect to best practices in chemistry control. Therefore, the staff accepts the use of the EPRI PWR Primary Water Chemistry Guidelines as a basis for a primary water chemistry program for a COL referencing a standard reactor design.

In a February 5, 2009, letter, Duke Energy endorsed BLN standard content RAI 05.02.03-01. Therefore, the above discussion related to the BLN standard content RAIs is equally applicable to WLS COL application. In addition, the staff also verified that WLS COL FSAR, Section 5.2.3.2.1, has been adequately updated to include similar changes.

5.2.3.5 *Post Combined License Activities*

There are no post COL activities related to this section.

5.2.3.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to RCPB materials, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of GDC 14. The staff based its conclusion on the following:

- STD SUP 5.2-1 meets the relevant guidance in NUREG-0800, Section 9.3.4 with respect to developing a water chemistry program consistent with the latest EPRI guidelines and is acceptable. Conformance to these guidelines provides an acceptable basis to satisfy, in part, the requirements of GDC 14.

5.2.4 Inservice Inspection and Testing of Class 1 Components (Related to RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.4, "Inservice Inspection and Testing of Reactor Coolant Pressure Boundary")

5.2.4.1 *Introduction*

Components that are part of the RCPB must be designed to permit periodic inspection and testing of important areas and features to assess their structural and leaktight integrity. ISI programs are based on the requirements of 10 CFR 50.55a, "Codes and Standards," in that Code Class 1 components, as defined in Section III of the ASME B&PV Code, meet the applicable inspection requirements set forth in the ASME Code, Section XI, "Rules for Inservice Inspection of Nuclear Power Plant Components,"

5.2.4.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference AP1000 DCD, Revision 19, Section 5.2 with departure and/or supplements. AP1000 DCD Section 5.2 includes Section 5.2.4.

To address departure and/or supplements in WLS COL FSAR Section 5.2.4, the applicant provided the following additional information:

AP1000 COL Information Item

- STD COL 5.2-2

The applicant provided additional information in STD COL 5.2-2 to address COL Information Item 5.2-2. The information relates to plant-specific preservice inspection (PSI) and ISI programs.

- STD COL 5.3-7

The applicant provided additional information in STD COL 5.3-7 to address COL Information Item 5.3-7. The information relates to the ISI program for the Quickloc weld buildup on the reactor vessel head.

Supplemental Information

- STD SUP 5.2-2

The applicant provided supplemental information regarding guidance for inspecting the integrity of bolting and threaded fasteners.

License Condition

- Proposed License Condition 6, regarding PSI/ISI program readiness

5.2.4.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for ISI are given in NUREG-0800, Section 5.2.4.

The applicable regulatory requirements for acceptance of the resolution to COL Information Items 5.2-2 and 5.3-7 and supplementary information on ISI and testing of Class 1 components are established in GDC 32, "Inspection of Reactor Coolant Pressure Boundary," found in 10 CFR Part 50, Appendix A, as it relates to periodic inspection and testing of the RCPB, and 10 CFR 50.55a, as it relates to the requirements for inspecting and testing ASME Code Class 1 components of the RCPB.

The applicable policy for acceptance of COL Information Item 5.2-2, as it relates to fully describing an operational program, is found in SECY-05-0197, "Review of Operational Programs in a Combined License Application and Generic Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria," October 28, 2005.

5.2.4.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 5.2.4 and the referenced DCD to ensure that the combination of the DCD information incorporated by reference and the COL application information represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and that incorporated by reference from the DCD addressed the required information relating to the RCPB ISI and testing. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In NUREG-1793, Section 5.2.4, the staff concluded that the AP1000 ISI program for Code Class 1 components is acceptable and meets the requirements of 10 CFR 50.55a with regard to the preservice and inservice inspectability of these components. The specific version of the ASME Code, Section XI used as the baseline Code in the AP1000 certified design is the

1998 Edition up to and including the 2000 Addenda. It should be noted that the staff did not identify any portions of the AP1000 ISI program for Class 1, 2, and 3 components that were excluded from the scope of the staff's review of the AP1000 DC (as the staff did for IST of valves in AP1000 Final Safety Evaluation Report (FSER) Section 3.9.6.4). Therefore, the staff's conclusions regarding the acceptability of the AP1000 ISI program based on the 1998 Edition up to and including the 2000 Addenda of the ASME Code, Section XI with regard to preservice and inservice inspectability of Class 1 components remain unchanged with Revision 19 of the AP1000 DCD. Accordingly, the staff's evaluation of this section focused on the acceptability of the COL applicant's supplemental information and responses to AP1000 COL information items and action items. The staff's evaluation in this section also addresses the operational program aspects of the ASME Code Class 1, 2, and 3 PSI and ISI programs.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff completed its review and determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.2.4.4:

> *<u>AP1000 COL Information Item</u>*
>
> - *STD COL 5.2-2*
>
> *The COL applicant added the following after the first paragraph in DCD Section 5.2.4:*
>
> > *The initial inservice inspection program incorporates the latest edition and addenda of the ASME Boiler and Pressure Vessel Code approved in 10 CFR 50.55a(b) on the date 12 months before the initial fuel load. Inservice examination of components and system pressure tests conducted during successive 120-month inspection intervals must comply with the requirements*

of the latest edition and addenda of the Code incorporated by reference in 10 CFR 50.55a(b) 12 months before the start of the 120-month inspection interval (or the optional ASEM [sic] *Code cases listed in NRC Regulatory Guide 1.147, that are incorporated by reference in 10 CFR 50.55a(b), subject to the limitations and modifications listed in 10 CFR 50.55a(b).*

10 CFR 50.55a(g) requires that inservice examinations of components and system pressure tests conducted during the initial 120-month inspection interval must comply with the requirements in the latest edition and addenda of the Code incorporated by reference in paragraph (b) of 10 CFR 50.55a on the date 12 months before the date scheduled for initial loading of fuel under a combined license under 10 CFR Part 52. The staff concludes that the supplemental information provided by the COL applicant meets the NRC's regulations and is, therefore, acceptable.

The COL applicant added the following at the end of DCD Section 5.2.4.1:

The Class 1 system boundary for both preservice and inservice inspection programs and the system pressure test program include those items within the Class 1 and Quality Group A (Equipment Class A [in accordance with] DCD Section 3.2.2 and DCD Table 3.2-3 boundary). Based on 10 CFR Part 50 and Regulatory Guide 1.26, the Class 1 boundary includes the following:

- *reactor pressure vessel;*
- *portions of the reactor system(RXS);*
- *portions of the chemical and volume control system (CVS);*
- *portion of the in core instrumentation system (IIS);*
- *portions of the passive core cooling system (PXS);*
- *portions of the reactor coolant system;*
- *portions of the normal residual heat removal system.*

Those portions of the above systems within the Class 1 boundary are those items that are part of the RCPB as defined in Section 5.2 of the Bellefonte COL FSAR.

Exclusions

Portions of the systems within the reactor coolant pressure boundary [RCPB], as defined above, that are excluded from the Class 1 boundary in accordance with 10 CFR Part 50, Section 50.55a, are as follows:

- *Those components where, in the event of postulated failure of the component during normal operation, the reactor can be shut down and cooled down in an orderly manner, assuming makeup is provided by the reactor coolant makeup system only; or*

- *Components that are or can be isolated from the reactor coolant system by two valves (both closed, both open, or one closed and other open). Each open valve is capable of automatic actuation and, assuming the other valve is open, its closure time is such that, in the event of postulated failure of the component during normal reactor operation each valve remains operable and the reactor can be shut down and cooled down in an orderly manner, assuming makeup is provided by the reactor coolant makeup system only.*

The NRC staff compared the proposed description of the system boundary subject to inspection and the exclusions with ASME Section XI and 10 CFR 50.55a. The staff found that the proposed system boundary and exclusions were in agreement with the ASME guidelines and regulations, and are therefore, acceptable. This portion of STD COL 5.2-2 is acceptable.

In Revision 0 of the BLN COL FSAR, the COL applicant states that NRC First Revised Order, EA-03-009, "Interim Inspection Requirements for Reactor Pressure Vessel Heads at Pressurized Water Reactors," will be used to establish the required inspections of RPV heads and associated penetration nozzles to detect primary stress corrosion cracking. In addition, the COL applicant states that ASME Code Case N-729-1 (N-729-1), "Alternative Examination Requirements for Pressurized-Water Reactor (PWR) Vessel Upper Heads With Nozzles Having Pressure-Retaining Partial-Penetration Welds," will be used. N-729-1, as modified by the NRC staff may be used to perform the inspection of the AP1000 RPV head. Finally, a visual inspection to identify potential boric acid leaks from pressure-retaining components above the RPV head is performed by each refueling outage.

COL Information Item 5.2-2 includes a commitment that the COL applicant's PSI program will include specific preservice examinations of the RV closure head equivalent to those outlined in AP1000 DCD Tier 2, Section 5.3.4.7. The BLN COL FSAR added supplemental information to the end of Section 5.2.4.3.1, describing the design of the RV closure head as it pertains to meeting the PSI requirements. The staff could not determine from the information provided, the extent of PSI examinations. Based on the information provided by the applicant, the staff requested additional information in RAI 5.2.4-1.

In response to RAI 5.2.4-1, the COL applicant stated that the PSI related to the RV closure head and penetrations as discussed in DCD Section 5.3.4.7 includes the regions identified in the first revised order, EA-03-009. The design specification includes a requirement for PSIs consistent with the first revised order EA-03-009. As part of the RPV and integrated head package design *finalization, the RV closure head design and the design of components connected to, and in the region of, the RV closure head was reviewed.*

The COL applicant determined that the required PSI/ISI examinations can be performed as required by ASME Section III and Section XI. Based on the information provided by the COL applicant, the staff concludes that the PSI and ISI examinations will be accomplished in accordance with the first revised order, EA-03-009, ASME Sections III and XI, and are, thus, acceptable. As a result, RAI 5.2.4-1 is closed.

In Revision 1 to the BLN COL FSAR, the COL applicant states that its augmented inspection for the reactor vessel top head uses N-729-1 as modified by the NRC in the proposed rulemaking dated April 5, 2007 (72 FR 16740). The COL applicant further noted in response to RAI 5.2.4-5, that the wording in the final rule will be adopted when the final rule is issued. The final rule to amend 10 CFR 50.55a was issued on September 10, 2008 (73 FR 52730) and includes a requirement to inspect the RPV head in accordance with N-729-1 as amended by 10 CFR 50.55a(g)(6)(ii)(D). The COL applicant's methodology to inspect the RPV head in accordance with N-729-1, as amended by 10 CFR 50.55a(g)(6)(ii)(D) meets the regulations, and is therefore acceptable. The staff will verify that the next update of the BLN COL FSAR (Section 5.2.4.1) adequately incorporates reference to the final rule. This is ***Confirmatory Item 5.2-1.***

The COL applicant added the following after the second sentence of the first paragraph of DCD Section 5.2.4.4:

> *Because 10 CFR 50.55a(g)(4) requires 120-month inspection intervals, inspection Program B of IWB-2400 must be chosen. The inspection interval is divided into three periods. Each period can be extended up to one year to enable an inspection to coincide with a plant outage. The adjustment of period end dates shall not alter the rules and requirements for scheduling inspection intervals.*

RG 1.206 recommends that inspection intervals be described in comparison with the ASME Code. The information provided by the COL applicant indicated that Inspection Program B of IWB-2400 would be used over a 10-year interval. The three periods would be three, four, and three years to comprise the interval and extensions of a period may be performed up to a year to coincide with a plant outage. The staff finds that the supplemental information provided by the COL applicant meets the requirements of the ASME Code, Section XI and the guidelines of RG 1.206, and is, thus, acceptable.

The COL applicant proposed adding the following section after the last paragraph of DCD Section 5.2.4.7:

> *5.2.4.8 Relief Requests*
>
> *The specific areas where the applicable ASME Code requirements cannot be met are identified after the initial*

> *examinations are performed. Should relief requests be required, they will be developed through the regulatory process and submitted to the NRC for approval in accordance with 10 CFR 50.55a(a)(3) or 10 CFR 50.55a(g)(5). The relief requests include appropriate justifications and proposed alternative inspection methods.*

In addition to the above, the COL applicant stated at the end of Section 5.2.4.3:

> *The RPV nozzle-to-shell welds are 100 percent accessible for preservice inspection but might have limited areas that may not be accessible from the outer surface for inservice examination techniques. If accessibility is limited, an inservice inspection program relief request is prepared and submitted for review approval by the NRC.*

The information lead [sic] *the staff to believe that areas where preservice and inservice examination requirements cannot be met or where compliance with the ASME Code is impractical will result in a need for the licensee to submit a request for relief from impractical Code requirements pursuant to 10 CFR 50.55a(g)(5)(iii). This is not consistent with the regulations in 10 CFR 50.55a(g)(3)(i) which state that Class 1 components must be designed and provided with access to enable the performance of preservice and inservice examinations in accordance with the requirements of the ASME Code, Section XI. Furthermore, the information is not consistent with AP1000 DCD Section 5.2.4.2, which states that the components will be designed to eliminate any hindrances to performing preservice or inservice examinations. The only time a relief request for a newly designed system or component should occur is when the updated edition and addenda to the ASME Code, Section XI is selected 1 year before the initial fuel load date for the first 120-month ISI interval and during subsequent ISI intervals when later edition and addenda of the ASME Code, Section XI that are incorporated by reference in 10 CFR 50.55a(b) change the examination requirements or coverage.*

The staff considers accessibility to perform ISI on both sides of austenitic and dissimilar metal welds critical to making its safety determination in order to monitor structural integrity of these welds due to their history of cracking. Cracking of these welds due to primary water stress corrosion cracking (PWSCC) or intergranular stress corrosion cracking (IGSCC) is a well-known occurrence and a safety significant issue. Consequently, the NRC staff is not expecting to grant requests for relief from ISIs of these susceptible welds on the basis of design, geometry or materials of construction, since these factors can be rectified at the design stage before the plant is constructed. Based on the above discussion, the staff requested additional information from the COL applicant in RAIs 5.2.4-2 and 5.2.4-3 on accessibility for nondestructive examinations of the RV head and austenitic/dissimilar metal welds.

The COL applicant stated in its response to RAI 5.2.4-2 that as part of the design-for-inspectability process, the capability of examining the RV welds was assessed. The result was that with ISI tooling design and consideration of the

AP1000 RV design, examinations from the inside of the AP1000 pressure vessel, including examinations of the reactor nozzle-to-shell welds, can be completed without a need for the applicant to request relief from the ASME Code, Section XI examination requirements. Based on the response provided by the applicant, the staff concludes that the reactor nozzle-to-shell welds are adequately designed to enable the performance of inservice examinations in accordance with 10 CFR 50.55a(g)(3)(ii), and is, thus, acceptable. As a result, RAI 5.2.4-2 is closed.

The COL applicant stated in its response to RAI 5.2.4-3 that as part of the design-for-inspectability process, the ASME Class 1 portion of welds are designed for two-sided access for austenitic stainless steel piping welds wherever possible. Where two-sided access is not feasible, such as branch connection examination for circumferential degradation, the weld crowns are ground flush for one-sided examinations. The COL applicant stated that the examination procedures, equipment and personnel for one-sided examinations of austenitic/dissimilar metal welds would be qualified in accordance with Appendix VIII, as modified by 10 CFR 50.55a(b)(2)(xv)(A)(2) and 10 CFR 50.55a(b)(2)(xvi)(B). Based on the response provided by the applicant, in instances where one-sided examinations have to be performed for austenitic/dissimilar metal welds, the examinations will be conducted with ultrasonic systems that have demonstrated the capability to detect flaws, and is, thus, acceptable. As a result, RAI 5.2.4-3 is closed.

The COL applicant proposed adding the following section after the last paragraph of DCD Section 5.2.4.7:

> *<u>5.2.4.9 Preservice Inspection of Class 1 Components</u>*
>
> *Preservice examinations required by design specification and preservice documentation are in accordance with ASME Section III, NB-5281. Volumetric and surface examinations are performed as specified in ASME Section III, NB-5282. Components described in ASME Section III, NB-5283 are exempt from preservice examination.*

RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.4 recommends that a preservice examination program that meets the standards of NB-5280 of ASME Code, Section III, Division 1, be described because it is an operational program and that the program implementation milestones should be fully described. The information indicated that preservice examinations and documentation are in accordance with ASME Code, Section III, NB-5281, and that volumetric and surface examinations are performed as specified in ASME Code, Section III, NB-5282. The information stated that components described in ASME Code, Section III, NB-5283 are exempt from preservice examination. The staff found that the information did not fully describe the preservice examination program, in scope and a level of detail, necessary for the staff to reach a reasonable assurance finding. Therefore, the staff requested additional information in RAI 5.2.4-4.

In its response to RAI 5.2.4-4, the applicant noted that AP1000 DCD Section 5.2.4.5, which is incorporated by reference in the COL FSAR, indicates PSI will meet the requirements in the ASME Code, Section XI, paragraph IWB-2200 consistent with NUREG-0800 acceptance criteria. FSAR Section 5.2.4.1 provides a discussion of the scope of the PSI and ISI programs by system. FSAR Section 5.2.4.3.1 describes the methods for examination for both PSI and ISI. FSAR Section 5.2.4.3.1 [sic] [5.2.4.3.2] *describes the qualification requirements of personnel performing ultrasonic examinations. In addition, DCD Section 5.2.4.5, incorporated by reference in the COL FSAR, indicates that PSIs of Class 1 components will meet the requirements of IWB-2200, and as indicated in the response to RAI 5.2.4-1, RV head preservice examinations are described in DCD Section 5.3.4.7, and are also incorporated by reference in the COL FSAR. These FSAR sections, combined with the DCD sections, provide a full description of the PSI program consistent with by* [sic] *SECY-05-0197. The response provided by the applicant addressed PSI program areas involving qualification requirements, scope, exemptions and methods of examination. The areas addressed meet the guidelines of Section 5.2.4 of NUREG-0800, and are therefore acceptable. Based on the information provided by the applicant, the staff concludes that the PSI program is fully described. As a result, RAI 5.2.4-4 is closed.*

The COL applicant proposed adding the following section after the last paragraph of DCD Section 5.2.4.7:

> *<u>5.2.4.10 Program Implementation</u>*
>
> *The milestones for preservice and inservice inspection program implementation are identified in Table 13.4-201.*

RG 1.206 states that the detailed procedures for performing the examinations may not be available at the time of the COL application, and the COL applicant should make a commitment to provide sufficient information to demonstrate that the procedures meet ASME Code standards. This information should be provided at a predetermined time agreed upon by both parties. In the BLN COL FSAR, Part 10, "License Conditions and ITAAC," proposed License Condition 6, "Operational Program Readiness," the COL applicant states:

> *The licensee shall submit to the appropriate Director of the NRC, a schedule, no later than 12 months after issuance of the COL, that supports planning for and conduct of the NRC inspection of the operational programs listed in the operation program FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until either the operation programs in the FSAR table have been fully implemented or the plant has been placed in commercial service.*

The staff reviewed the BLN COL FSAR Table 13.4-201, and notes that both the PSI and ISI programs are listed as operational programs required by NRC regulations. The staff concludes that the commitment under proposed License

Condition 6 meets the guidelines in RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.4.1, and is, thus, acceptable.

The COL applicant proposed to add the following paragraphs at the end of Section 5.2.4.3 of the AP1000 DCD.

> ***Ultrasonic Examination of the Reactor Vessel***
>
> *Ultrasonic (UT) examination for the RPV is conducted in accordance with the ASME Code, Section XI. The RPV shell welds are designed for 100 percent accessibility for both preservice and inservice examinations. The RPV nozzle-to-shell welds are 100 percent accessible for preservice examinations but might have limited areas that may not be accessible from the outer surface for inservice examination techniques. If accessibility is limited, an inservice inspection program relief request is prepared and submitted for review approval by the NRC.*
>
> *Inner radius examinations are performed from the outside of the nozzle using several compound angle transducer wedges to obtain complete coverage of the required examination volume. Alternatively, nozzle inner radius examinations may be performed using enhanced visual techniques as allowed by 10 CFR 50.55a(b)(2)(xxi).*

The staff finds that the information provided by the COL applicant meets ASME Section XI and is in compliance with 10 CFR 50.55a. With respect to relief requests and accessibility, see the staff evaluation of BLN COL FSAR Section 5.4.2.8.

The COL applicant added the following after the first sentence of DCD Section 5.2.4.5:

> *Class 1 piping supports will be examined in accordance with ASME Section XI, IWF-2500.*
>
> *Preservice examinations required by design specifications and preservice documentation are in accordance with ASME Section III, NB-5280. Components exempt from preservice examination are described in ASME Section III, NB-5283.*

The staff finds that the information provided by the COL applicant meets ASME Section XI and is in compliance with 10 CFR 50.55a. With respect to preservice inspection, see the staff evaluation of BLN COL FSAR Section 5.4.2.9.

The COL applicant proposed adding the following after the last sentence of DCD Section 5.2.4.5:

> *The preservice examination is performed once in accordance with ASME Section XI, IWB-2200, on all of the items selected for inservice examination, with the exception of the examinations*

> *specifically excluded by ASME Section XI from preservice requirements, such ASME Section XI VT-3 examination of valve body and pump casing internal surfaces (B-L-2 and B-M-2 examination categories, respectively) and the visual VT-2 examinations for category B-P.*

The staff finds that the information provided by the COL applicant meets ASME Section XI and is in compliance with 10 CFR 50.55a. With respect to preservice inspection, see the staff evaluation of BLN COL FSAR Section 5.4.2.9.

The COL applicant proposed adding the following after the last sentence of DCD Section 5.2.4.3:

> ***Visual Examination***
>
> *Visual examination methods VT-1, VT-2, and VT-3 are conducted in accordance with ASME Section XI, IWA-2210. In addition, VT-2 examinations will meet the requirements of IWA-5240.*
>
> *Where direct VT-1 examinations are conducted without the use of mirrors or with other viewing aids, clearance is provided where feasible for the head and shoulders of a man within a working arm's length of the surface to be examined.*
>
> ***Surface Examination***
>
> *Magnetic particle (MT) and liquid penetrant (PT) examination techniques are performed in accordance with ASME Section XI, IWA-2221 and IWA-2222, respectively. Direct examination access for magnetic particle [MT] and liquid penetrant [PT] examination is the same as that required for direct visual (VT-1) examination (See Visual Examination), except that the additional access is provided as necessary to enable physical contact with the item in order to perform the examination. Remote MT and PT generally are not appropriate as a standard examination process; however, boroscopes and mirrors can be used at close range to improve the angle of vision.*
>
> ***Alternative Examination Techniques***
>
> *As provided by ASME Section XI, IWA-2240, alternative examination methods, a combination of methods, or newly developed techniques may be substituted for the methods specified for a given item in this section, provided that they are demonstrated to be equivalent or superior to the specified methods, techniques, etc., which may result in improvements in examination reliability and reductions in personnel exposure. In accordance with 10 CFR 50.55a(b)(2)(xix), IWA-2240 as written in the 1997 Addenda of ASME Section XI must be used when applying these provisions.*

> *5.2.4.3.2 Qualification of Personnel and Examination Systems for Ultrasonic Examination*
>
> *Personnel performing examinations shall be qualified in accordance with ASME Section XI, Appendix VII. Ultrasonic examination systems shall be qualified in accordance with industry accepted programs for implementation of ASME Section XI, Appendix VIII. Qualification to ASME Section XI, Appendix VIII, in compliance with the provisions of 10 CFR 50.55a is considered as a satisfactory alternative to Regulatory Guide 1.150.*

The COL applicant also proposed adding the following at the end of AP1000 DCD Section 5.2.4.6:

> *Components containing flaws or relevant conditions and accepted for continued service in accordance with the requirements of IWB-3132.4 or IWB-3142.4 are subjected to successive period examinations in accordance with the requirements of IWB-2420. Examinations that reveal flaws or relevant conditions exceeding Table IWB-3410-1 acceptance standards are extended to include additional examinations in accordance with the requirements of IWB-2430.*

10 CFR 50.55a requires that nondestructive testing procedures, methods, and techniques meet ASME Code standards, including ASME Section XI, Appendix VIII requirements for ultrasonic examinations and methodology for evaluation of flaws. The COL applicant indicated that the qualification of ultrasonic testing personnel and procedures would be in accordance with ASME Section XI, Appendices VII and VIII, respectively. Based on the information provided by the COL applicant, the staff concludes that the COL applicant referenced the appropriate sections of the ASME Code to describe visual, surface volumetric and alternative examinations.

The staff concludes that the PSI and ISI programs will conform to the guidelines and requirements provided under NUREG-0800, Order EA-03-009, and the ASME Code. Therefore, the staff finds that the COL applicant's proposed resolution to the COL information items and its supplementary information are acceptable on the basis that it meets GDC 32 of Appendix A to 10 CFR Part 50, as it relates to periodic inspection and testing of the RCPB and 10 CFR 50.55a.

Resolution of Standard Content Confirmatory Item 5.2-1

Confirmatory Item 5.2-1 required the applicant to update its FSAR to incorporate reference to the final rule. The NRC staff verified that the VEGP COL FSAR was appropriately updated to incorporate reference to 10 CFR 50.55a(g)(6)(ii)(D). As a result, Confirmatory Item 5.2-1 is now resolved.

<u>Correction of Error in the Standard Content Evaluation Text</u>

The NRC staff identified an error in the text reproduced above from the BLN SER, Section 5.2.4.4, that requires correction. The BLN SER quotes an applicant-proposed addition to its FSAR stating, in part:

> *Qualification to ASME Section XI, Appendix VIII, in compliance with the provisions of 10 CFR 50.55a is considered as a satisfactory alternative to Regulatory Guide 1.150.*

That quote is from Revision 0 of the BLN FSAR. The correct quote from Revision 1 of the BLN FSAR is:

> *Qualification to ASME Section XI, Appendix VIII, is in compliance with the provisions of 10 CFR 50.55a.*

This error does not impact the conclusions of the BLN or VEGP evaluations.

- *STD COL 5.3-7*

The NRC reviewed the applicant's proposal submitted in a letter dated August 27, 2010, to include additional information which addresses newly identified COL Information Item 5.3-7 in the AP1000 DCD. The applicant proposes to add the following item, STD COL 5.3-7, to the end of Section 5.2.4.1 of the VEGP COL FSAR:

> *The in-service inspection program is augmented to include the performance of a 100 percent volumetric examination of the weld build-up on the reactor vessel head for the instrumentation penetrations (Quickloc) conducted once during each 120-month inspection interval in accordance with the ASME Code, Section XI. The weld build-up acceptance standards are those provided in ASME Code, Section XI, IWB-3514. Personnel performing examinations and the ultrasonic examination systems are qualified in accordance with ASME Code, Section XI, Appendix VIII. Alternatively, an alternative inspection may be developed in conjunction with the voluntary consensus standards bodies (i.e., ASME) and submitted to the NRC for approval.*

The proposed information, which will augment the plant-specific ISI program to include a 100 percent volumetric examination of the weld build-up on the reactor vessel head for the instrumentation penetrations (Quickloc) conducted once during each 120-month inspection interval in accordance with the ASME Code, Section XI, is acceptable to the NRC staff because a volumetric examination ensures that potential degradation of the inside surface of the weld build-up during plant operation will be detected before it progresses through-wall. In addition, the NRC staff finds it acceptable that any alternative inspection will be submitted to the NRC for approval because it will ensure that (1) the NRC staff is informed of changes to inservice inspection requirements established in the reference design certification and (2) licensee submittals for NRC authorization to use alternatives to the regulations in 10 CFR 50.55a will be reviewed by the NRC *staff pursuant to 10 CFR 50.55a(a)(3). The NRC staff finds that this adequately addresses COL Information Item 5.3-7 and will ensure the integrity of the reactor coolant pressure boundary weld during service. The staff notes that since this information augments the ISI program, this augmentation is part of License Condition (5-1) described in SER Section 5.2.4.5. The incorporation of the changes associated with proposed STD COL 5.3-7 into a future revision of the VEGP COL FSAR is* ***Confirmatory Item 5.2-2****.*

Resolution of Standard Content Confirmatory Item 5.2-2

Confirmatory Item 5.2-2 is an applicant commitment to revise its FSAR Table 1.8-202 and Section 5.2.4.1 to address COL Information Item STD COL 5.3-7. The staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 5.2-2 is now closed.

The following portion of this technical evaluation section is reproduced from Section 5.2.4.4 of the BLN SER:

License Condition

- *License Condition 6, regarding PSI/ISI program details*

The BLN COL FSAR addresses implementation milestones for the PSI/ISI programs in Part 10, or [sic] *the application "Proposed License Conditions (Including ITAAC)." As discussed in Part 10, Section 6, the applicant proposes a license condition for BLN for all operational programs requiring that the licensee shall submit to the appropriate Director of the NRC, a schedule, no later than 12 months after issuance of the COL, that supports planning for and conduct of NRC inspections of operational programs. This proposed license condition is consistent with the policy established in SECY-05-0197, and is therefore acceptable.*

For PSI/ISI programs, the ASME Code, Section XI provides requirements for program implementation in Paragraph IWB-2200(a) for PSI programs and Paragraph IWA-2430(b) for ISI programs. As such, a license condition for program implementation requirements is not necessary in the BLN COL FSAR. However, submittal of the schedule for the program development is necessary to plan for and conduct NRC inspections during construction. The staff finds that the license condition complies with RG 1.206, and is therefore acceptable.

Operational programs are specific programs required by regulations. The COL application should fully describe operational programs as defined in SECY-05-0197. In addition, COL applicants should provide schedules for implementation milestones of these operational programs. The PSI and ISI programs are identified as operational programs in RG 1.206. This section of the SER addresses the PSI and ISI operational programs for ASME Code Class 1, 2, and 3 components.

As discussed in RG 1.206, a fully described PSI and ISI program should address: (1) system boundary subject to inspection; (2) accessibility; (3) examination categories and methods; (4) inspection intervals; (5) evaluation of examination *results; (6) system pressure tests; (7) Code exemptions; (8) relief requests; and (9) ASME Code cases. For BLN, the applicant incorporated by reference the PSI and ISI programs descriptions from AP1000 DCD Sections 5.2.4 and 6.6. The DCD descriptions as supplemented by the BLN COL FSAR address these nine items and therefore fully describe the PSI/ISI operational programs.*

Supplemental Information

- *STD SUP 5.2-2*

The COL applicant added the following text at the end of DCD Section 5.2.4.1:

> *The inservice inspection program, along with the boric acid corrosion control procedures, provides guidance for inspecting the integrity of bolting and threaded fasteners.*

NUREG-0800, Section 3.13, "Threaded Fasteners – ASME Code Class 1, 2, and 3," acceptance criteria states that the inspection provisions are acceptable if they conform to ASME Section XI. In addition, the staff position in Generic Letter 88-05, "Staff Position on Boric Acid Corrosion of Carbon Steel Reactor Pressure Boundary Components in PWR Plants," specifically recommends inspection in accordance with a boric acid corrosion control program. GL 88-05 also recommends that a boric acid control program contain four elements consisting of inspections, discovery of leak path, assessment, and follow-up inspections. In its proposed changes to Section 5.2.4.1, the COL applicant described the boric acid corrosion control procedures. The staff noted that the program description was in compliance with the four elements described under GL 88-05. Based on compliance with both ASME Section XI and staff guidance, the staff concludes that the proposed change under STD SUP 5.2-2 is acceptable.

Exception to RG 1.65

The Bellefonte FSAR Appendix 1AA provides conformance discussions for Regulatory Guides (RGs) applicable to the Bellefonte COLA. RG 1.65, "Materials and Inspections for Reactor Vessel Closure Studs," was not addressed in Revision 0 of the FSAR. In a response to the staff's RAI-1-5, the COL applicant added a conformance discussion for RG 1.65 which takes an exception to RG position C.4. The exception states:

> *ASME XI ISI criteria for reactor vessel closure stud examinations are applied in lieu of the ASME Section III, NB-2545 and NB-2546 surface examinations. The volumetric examination currently required by ASME Section XI provides improved (since 1973) detection of bolting degradation.*

The staff reviewed ASME Section XI, Table IWB-2500-1 examination requirements for the reactor vessel closure studs, Examination Category B-G-1, Item No. B 6.20. The subject table lists volumetric examination of the studs when in place. The staff finds that the COL applicant's proposed exception to

RG 1.65 is in compliance with the 1998 Edition of the ASME Code with the 2000 Addenda, and is therefore, acceptable. This portion of RAI 1-5 is closed.

In a February 5, 2009, letter, Duke Energy endorsed BLN RAIs 01-05 and 05.02.04-01 through 05.02.04-05. Therefore, the above discussion related to the BLN RAIs is equally applicable to WLS COL application. In addition, the staff also verified that the WLS COL FSAR, Section 5.2.4, has been adequately updated to include the applicable changes that were committed to in the RAI responses.

5.2.4.5 *Post Combined License Activities*

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license condition acceptable:

- License Condition (5-1) – No later than 12 months after issuance of the COL, the licensee shall submit to the Director of NRO, or the Director's designee, a schedule for implementation of the operational programs listed in FSAR Table 13.4-201, including the associated estimated date for initial loading of fuel. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until all the operational programs listed in FSAR Table 13.4-201 have been fully implemented.

5.2.4.6 *Conclusion*

The staff reviewed the application and the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to the RCPB ISI and testing, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff concludes that the information presented in the WLS COL FSAR meets the relevant acceptance criteria provided in NUREG-0800, Section 5.2.4, the policy established in SECY-05-0197, the guidelines addressed in RG 1.206, and the requirements of GDC 32, staff positions, and 10 CFR 50.55a. The staff based its conclusion on the following:

- STD COL 5.2-2, as it relates to the PSI and ISI programs, conforms to the guidelines provided under NUREG-0800, Order EA-03-009, and the ASME Code. Therefore, the staff finds that the COL applicant's resolution to the COL information items is acceptable on the basis that it meets GDC 32 in10 CFR Part 50, Appendix A, as it relates to periodic inspection and testing of the RCPB and 10 CFR 50.55a.

- STD SUP 5.2-2, as it relates to guidance for inspecting the integrity of bolting and threaded fasteners, is acceptable because it meets the relevant guidelines in the ASME Code, Section XI; NUREG-0800, Section 3.13; and GL 88-05.

- STD COL 5.3-7, as it relates to the ISI program augmentation to include 100 percent volumetric examination of the weld build-up on the reactor vessel head for the Quickloc penetrations ensures that the integrity of the RCPB weld will be maintained. Therefore, the staff finds that the applicant's information in STD COL 5.3-7 addressing COL Information Item 5.3-7 is acceptable on the basis that it meets GDC 32 in 10 CFR Part 50, Appendix A, as it relates to periodic inspection to ensure the integrity of the RCPB is maintained.

5.2.5 Detection of Leakage through Reactor Coolant Pressure Boundary (Related to RG 1.206, Section C.III.1, Chapter 5, C.I.5.2.5, "Reactor Coolant Pressure Boundary Leakage Detection")

5.2.5.1 *Introduction*

The RCPB leakage detection systems are designed to detect and, to the extent practical, identify the source of reactor coolant leakage.

5.2.5.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 5.2.5.

In addition, the applicant provided the following additional information to address STD COL 5.2-3 in new WLS COL FSAR Section 5.2.5.3.5:

AP1000 COL Information Item

- STD COL 5.2-3

The applicant provided additional information in STD COL 5.2-3 to address COL Information Item 5.2-3. The information relates to prolonged low level unidentified reactor coolant leakage inside containment.

5.2.5.3 *Regulatory Basis*

The regulatory basis of the AP1000 DCD information incorporated by reference in the COL application is addressed in NUREG-1793 and its supplements.

The regulatory basis for raising the issue of prolonged low-level RCS leakage is in 10 CFR 52.79(a)(37), as it relates to "information necessary to demonstrate how operating experience insights have been incorporated into the plant design." The applicable regulatory requirements for acceptance of the resolution to COL Information Item 5.2-3 are established in GDC 30, "Quality of Reactor Coolant Pressure Boundary," as it relates to detecting RCPB leakage. The guidance for the staff's review is in RG 1.45, Revision 1, "Guidance on Monitoring and Responding to Reactor Coolant System Leakage."

5.2.5.4 *Technical Evaluation*

WLS COL FSAR, Revision 11, Section 5.2 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 5.2.5. The staff reviewed the application and checked the applicable sections of the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section, with one exception. That exception is discussed in the standard content material below. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.
- The staff verified that the site-specific differences were not relevant.

The staff completed its review and determined that the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.2.5.4:

> *The exception, which the NRC staff identified in its review, pertains to the operating experiences at Davis Besse concerning prolonged low-level RCS leakage. The operating experiences at Davis Besse (NRC Bulletin 2002-01) indicated that prolonged low-level unidentified reactor coolant leakage inside containment could cause corrosion and material degradation such that it could compromise the integrity of a system leading to the gross rupture of the RCPB. Therefore, pursuant to 10 CFR 52.79,(a) 37, "information necessary to demonstrate how operating experience insights have been incorporated into the plant design," the NRC staff requested additional information from both the DCD applicant (Westinghouse) and the COL applicant (Southern Nuclear Operating Company [SNC]) to address the issue of prolonged low-level RCS leakage. The NRC staff requested the COL applicant in VEGP RAI 5.2.5-1 and RAI 5.2.5-2 to address this issue as it relates to operating procedures. The NRC staff also asked Westinghouse in RAI-DCP-CN45-SBP-01 to address this issue as it related to Design Change Package (DCP) Change Number 45 for AP1000 DCD. The procedures should specify operator actions in response to prolonged low-level unidentified reactor coolant leakage conditions that exist above normal leakage rates and below the Technical Specification (TS) limits to provide*

operators sufficient time to take action before the TS limit is reached. The procedures would include identifying, monitoring, trending, and managing prolonged low-level leakage.

In a letter, dated July 29, 2010, Westinghouse responded to RAI-DCP-CN45-SBP-01 by stating that Revision 18 of the AP1000 DCD would add new COL Information Item 5.2-3, and described the COL item in Section 5.2.6.3 of the AP1000 DCD to address the prolonged low-level RCS leakage. The staff's review of DCP 45 is in Chapter 23 of a supplement to NUREG-1793.

AP1000 COL Information Item

- *STD COL 5.2-3*

In a letter, dated August 5, 2010, SNC responded to VEGP RAI 5.2.5-1 and RAI 5.2.5-2 and provided additional information in the markups of VEGP COL FSAR Table 1.8-202, Section 5.2.6.3 and Section 5.2.5.3.5 to add STD COL 5.2-3 to address the COL information item. VEGP COL FSAR Section 5.2.6.3 states that the COL item is addressed in Section 5.2.5.3.5. The proposed Section 5.2.5.3.5 reads as follows:

> *5.2.5.3.5 Response to Reactor Coolant System Leakage*
>
> *Operating procedures specify operator actions in response to prolonged low level unidentified reactor coolant leakage conditions that exist above normal leakage rates and below the Technical Specification (TS) limits to provide operators sufficient time to take action before the TS limit is reached. The procedures include identifying, monitoring, trending, and addressing prolonged low level leakage. The procedures for effective management of leakage, including low level leakage, are developed including the following operations related activities:*
>
> - *Trends in the unidentified leakage rates are periodically analyzed. When the leakage rate increases noticeably from the baseline leakage rate, the safety significance of the leak is evaluated. The rate of increase in the leakage is determined to verify that plant actions can be taken before the plant exceeds TS limits.*
>
> - *Procedures are established for responding to leakage. These procedures address the following considerations to prevent adverse safety consequence from the leakage:*
>
>   - *Plant procedures specify operator actions in response to leakage rates less than the limits set forth in the Technical Specifications. The procedures include actions for confirming the existence of a leak, identifying its source, increasing the frequency of monitoring, verifying the*

leakage rate (through a water inventory balance), responding to trends in the leakage rate, performing a walkdown outside containment, planning a containment entry, adjusting alarm setpoints, limiting the amount of time that operation is permitted when the sources of the leakage are unknown, and determining the safety significance of the leakage.

– *Plant procedures specify the amount of time the leakage detection and monitoring instruments (other than those required by Technical Specifications) may be out of service to effectively monitor the leakage rate during plant operation (i.e., hot shutdown, hot standby, startup, transients, and power operation).*

- *The output and alarms from leakage monitoring systems are provided in the main control room. Procedures are readily available to the operators for converting the instrument output to a common leakage rate. (Alternatively, these procedures may be part of a computer program so that the operators have a real-time indication of the leakage rate as determined from the output of these monitors.) Periodic calibration and testing of leakage monitoring systems are conducted. The alarm(s), and associated setpoint(s), provide operators an early warning signal so that they can take corrective actions, as discussed above, i.e., before the plant exceeds TS limits.*

- *During maintenance and refueling outages, actions are taken to identify the source of any unidentified leakage that was detected during plant operation. In addition, corrective action is taken to eliminate the condition resulting in the leakage.*

The procedures described above will be available prior to fuel load.

The staff found in the RAI response that the COL applicant committed to develop operating procedures prior to fuel load, and the procedures include identifying, monitoring, trending, and managing the prolonged low-level RCS leakage. Further, the procedures include converting the instrument output to a common leakage rate and the alarm setpoints for early warning for the operators. Therefore, the staff determined that the RAI response addressed all the questions being asked in VEGP RAI 5.2.5-1 and RAI 5.2.5-2 regarding the procedures for the prolonged low-level RCS leakage. Further, the staff reviewed the description of the procedures in the proposed VEGP COL FSAR Section 5.2.5.3.5 and determined that it is consistent with the guidance in RG 1.45, Revision 1, pertaining to managing the prolonged low-level RCS *leakage. Therefore, the staff finds that the RAI response is acceptable and concludes that GDC 30 is met based on the applicant's conformance to RG 1.45. The incorporation of the changes associated with proposed STD COL 5.2-3 into a future revision of the VEGP COL FSAR is* ***Confirmatory Item 5.2-3.***

<u>Resolution of Standard Content Confirmatory Item 5.2-3</u>

Confirmatory Item 5.2-3 is an applicant commitment to revise its FSAR Table 1.8-202 and Section 5.2.5.3.5 to address COL Information Item STD COL 5.2-3. The staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 5.2-3 is now closed.

In an April 25, 2011, letter, Duke Energy endorsed RAIs 05-02.05-01 and 05-02.05-02. Therefore, the above discussion related to the VEGP RAIs is equally applicable to WLS COL application. In addition, the staff also verified that the WLS COL FSAR has been adequately updated to include the applicable changes resulting from these RAIs.

5.2.5.5 *Post Combined License Activities*

For the reasons discussed in the technical evaluation above, the following FSAR commitment is identified as the responsibility of the licensee:

- Prior to initial fuel load, the operating procedures, that include identifying, monitoring, trending, and managing the prolonged low-level RCS leakage, will be developed.

5.2.5.6 *Conclusion*

The staff reviewed the application and checked the applicable sections of the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to RCPB leakage detection, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the DCD information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of GDC 30. The staff based its conclusion on the following:

- STD COL 5.2-3 meets the relevant guidance in RG 1.45, Revision 1 with respect to operating procedures for the prolonged low-level RCS leakage detection. Conformance to these guidelines provides an acceptable basis to satisfy the requirements of GDC 30.

5.3 Reactor Vessel

5.3.1 Reactor Vessel Design

The RV, as an integral part of the RCPB, will be designed, fabricated, erected and tested to quality standards commensurate with the requirements set forth in 10 CFR Part 50, 10 CFR 50.55a, and GDC 1.

WLS COL FSAR, Revision 11, Section 5.3 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 5.3.1. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

5.3.2 Reactor Vessel Materials

5.3.2.1 *Introduction*

This section of this report addresses material specifications, special processes used for manufacture and fabrication of components, special methods for nondestructive examination, special controls and special processes used for ferritic steels and austenitic stainless steels, fracture toughness, material surveillance (which will be referred to as the reactor vessel surveillance capsule program (RVSP) to avoid confusion with material surveillance programs that exist in other parts of a nuclear power plant), and RV fasteners. RCS components are addressed separately in Section 5.2.3 of this SER.

5.3.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 5.3 incorporates by reference AP1000 DCD, Revision 19, Section 5.3 with departures and/or supplements. AP1000 DCD Section 5.3 includes Section 5.3.2.

To address the departures and/or supplements in WLS COL FSAR Section 5.3.2.6, the applicant provided the following additional information:

AP1000 COL Information Item

- STD COL 5.3-2

The applicant provided additional information in STD COL 5.3-2 to address COL Information Item 5.3-2 and COL Action Item 5.3.2.4-1 identified in NUREG-1793, Appendix F. The additional information discusses the RV material surveillance program.

License Conditions

- Part 10, License Condition 3.J.1, Reactor Vessel Material Surveillance

The COL Holder shall implement this operational program prior to initial criticality.

- Part 10, License Condition 6

The COL applicant shall provide an operational program schedule to support NRC inspections.

5.3.2.3 *Regulatory Basis*

The regulatory basis of the AP1000 DCD information incorporated by reference In the COL application is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the RV materials are given in NUREG-0800, Section 5.3.1.

The applicable regulatory requirements and guidance for acceptance of the COL information item are as follows:

- GDC 32 found in 10 CFR Part 50, Appendix A, as it relates to the RVSP
- 10 CFR 50.60, as it relates to compliance with the requirements of 10 CFR Part 50, Appendix G
- 10 CFR Part 50, Appendix G, as it relates to materials testing and acceptance criteria for fracture toughness
- 10 CFR 50.55a, as it relates to the requirements for testing and inspecting Code Class 1 components of the RCPB as specified in ASME Code, Section XI
- SECY-05-0197, as it relates to fully describing an operational program
- 10 CFR Part 50, Appendix H, as it relates to the RVSP

5.3.2.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 5.3.2 and the referenced DCD to ensure that the combination of the DCD information and the COL application information represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and that incorporated by reference addresses the relevant information related to RV materials. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.
- The staff verified that the site-specific differences were not relevant.

The staff's review determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.3.2.4:

> *The NRC staff reviewed conformance of Section 5.3 of the BLN COL FSAR to the guidance in RG 1.206, Section C.III.1, Chapter 5, C.I.5.3.1, "Reactor Vessel Materials." The RG 1.206 sections related to Material Specifications, Special Processes Used for Manufacturing and Fabrication, Special Methods for Nondestructive Examination, Special Controls for Ferritic and Austenitic Stainless Steels, Fracture Toughness and Reactor Vessel Fasteners all state that the COL applicants that reference a certified design do not need to include additional information. These topic areas were previously addressed in the AP1000 DCD and evaluated in NUREG-1793, Section 5.3.2. No COL action items were identified in these topic areas. The remaining topic area, RVSP, has a COL action item that must be addressed by a COL applicant.*
>
> *Appendix G to 10 CFR Part 50 specifies the fracture toughness requirements for ferritic materials of the pressure-retaining components of the RCPB. The RV beltline materials must have a Charpy Upper Shelf Energy (USE) in the transverse direction for base material and along the weld for weld material, of no less than 75 ft-lbs initially, and must maintain Charpy USE throughout the life of the vessel of no less than 50 ft-lbs. The fracture toughness tests required by ASME Code and by Appendix G to 10 CFR Part 50 provide reasonable assurance that adequate safety margins against the possibility of non-ductile behavior or rapidly propagating fracture can be established for all pressure-retaining components of the reactor coolant boundary. Appendix H to 10 CFR Part 50 presents the requirements for an RVSP to monitor the changes in the fracture toughness properties of the materials in the RV beltline region resulting from exposure to neutron irradiation and the thermal environment.*
>
> *Operational programs are specific programs required by regulations. The COL application should fully describe operational programs as defined in SECY-05-0197. In addition, COL applicants should provide schedules for implementation milestones for these operational programs. The RVSP is identified as an operational program in RG 1.206. This section of the SER addresses the adequacy of the RVSP description as it relates to meeting the requirements of Appendix H to 10 CFR Part 50.*
>
> *RG 1.206, Section C.III.1, Chapter 5, C.I.5.3.1.6, "Material Surveillance," provides guidelines for fully describing a material surveillance program. Specifically, this section states that the RVSP and its implementation must be described in sufficient detail to ensure that the program meets the requirements of Appendix H to 10 CFR Part 50.*
>
> *In addition, the application should describe the method for calculating neutron fluence for the RV beltline and the surveillance capsules. RG 1.206 lists some of the topics that should be addressed in the description of the RVSP:*
>
> - *Basis for the selection of material in the program.*

- *Number and type of specimens in each capsule.*
- *Number of capsules and proposed withdrawal schedule in compliance with the edition of American Society for Testing Materials (ASTM) E-185 Annual Book of ASTM Standards, Part 30, referenced in Appendix H to 10 CFR Part 50.*
- *Neutron flux and fluence calculations for vessel wall and surveillance specimens.*
- *Projected radiation embrittlement on vessel wall.*
- *Location of capsules, method of attachment, and provisions to ensure that capsules are retained in position throughout the vessel lifetime.*

Section 5.3.2.6 of the AP1000 DCD addresses the description of the RVSP. The DCD states that the base metal specimens are oriented both parallel and normal to the principal rolling direction of the limiting base material located in the core region of the RV. In accordance with the current DCD, there are no welds in the beltline region. Therefore, the applicant has addressed the entire beltline region in their RVSP. The DCD also addresses the number and type of specimens by meeting the ASTM E-185 requirements and describing 8 capsules, along with their proposed withdrawal schedule, that contain 72 tensile specimens, 480 Charpy V-notch specimens, and 48 compact tension specimens.

The DCD states that the neutron fluence assessments of the AP1000 RV are conducted in accordance with the guidelines that are specified in RG 1.190. The vessel fracture toughness data are given in Table 5.3-3 of the AP1000 DCD, Revision 17. The end-of-life nil-ductility reference transition temperature (RT_{NDT}) and upper shelf energy projections were estimated using RG 1.99, Revision 2, “Radiation Embrittlement of Reactor Vessel Materials,” for the end-of-life neutron fluence at the ¼-thickness and inner-diameter RV locations.

Finally, BLN has addressed the location of the capsules, their method of attachment, and the provisions to ensure that capsules are retained in position throughout the vessel lifetime by referencing AP1000 DCD, Section 5.3.2.6, which states that the capsules are located in guide baskets welded to the outside of the core barrel and positioned directly opposite the center portion of the core. DCD Figure 5.3-4 shows the azimuthal locations of the capsules around the RV.

Information about the implementation of the BLN RVSP is provided in Part 10 of the BLN COL. Section 3 proposes the following license condition:

> *J. Initial Criticality – The licensee shall implement each operational program identified below prior to initial criticality.*
>
> *J.1 – Reactor Vessel Material Surveillance*

In addition, Section 6, “Operational Program Readiness,” states that the licensee will submit to the NRC a schedule, no later than 12 months after issuance of the

COL, that supports the planning for and conduct of NRC inspections of operational programs, including RVSP.

<u>AP1000 COL Information Item</u>

- *STD COL 5.3-2*

The NRC staff reviewed STD COL 5.3-2 related to the COL information item included under Section 5.3.6.2 of the BLN COL FSAR, which states:

> *The Combined License applicant will address a Reactor Vessel Reactor Material Surveillance program based on Section 5.3.2.6.*

The commitment was also captured as COL Action Item 5.3.2.4-1 in Appendix F of the NRC staff's FSER for the AP1000 DCD (NUREG-1793), which states:

> *The COL applicant will provide its Reactor Vessel Material Surveillance program.*

RG 1.206 clarifies the intent of the COL information item. RG 1.206 Section C.III.1, Chapter 5, C.I.5.3.1.6, provides guidelines for addressing an RVSP. The applicant should fully describe the program and identify the implementation milestones. As previously discussed, the applicant references Section 5.3.2 of the AP1000 DCD, which addresses the topics listed in RG 1.206 that should be included in the description of the RVSP. The applicant provided License Condition 3.J.1 to implement the RVSP and License Condition 6 to support scheduling of NRC staff inspections, consistent with SECY-05-0197.

In addition, the applicant provided supplemental information in its FSAR to address COL Information Item 5.3-2 regarding the RVSP. The applicant added text between the first and second paragraphs of Section 5.3.2.6 to the AP1000 DCD, Revision 17 to reference the milestone of initial criticality for RVSP implementation. The applicant also added a new Section 5.3.2.6.3, "Report of Test Results," to the AP1000 DCD, Revision 17 to outline the reporting criteria associated with the RVSP. When each capsule is withdrawn, a summary technical report of the data required by ASTM E-185-82 and the results of the fracture toughness tests conducted on the beltline materials in the irradiated and unirradiated conditions will be submitted to the NRC within one year of the date of capsule withdrawal.

In its review of the FSAR, the staff noted that the information provided in Section 5.3.2 of the DCD, in addition to the RVSP program implementation information provided in Part 10 of the BLN COL application, meets the minimum guidelines in RG 1.206 for a description of the RVSP and its implementation. However, the staff determined that more information was needed to fully describe the RVSP in accordance with SECY-05-0197 to reach a resolution of the COL information item. A description of the process for preparing the capsule specimens must confirm that the materials selected for the capsules are samples of the same materials used in the fabrication of the RV. Therefore, the staff must receive this information before the vessel is fabricated. Other information, such as the capsule environment and the material types of the capsule specimens, *can be provided after the RV has been procured. Thus, the staff requested additional information in RAI 5.3.1-1 to complete its review.*

First, the staff requested additional information about the RVSP description. The purpose of the RVSP, as described in ASTM E-185, is to monitor radiation effects on RV materials under operating conditions. Section C.III.1, Chapter 5, C.I.5.3.1.6 of RG 1.206 states, "because the material surveillance program is an operational program, as discussed in SECY-05-0197, the applicant must describe the program and its implementation in sufficient scope and level of detail for the staff to make a reasonable assurance finding on its acceptability." The NRC staff recognizes that certain information about the program, such as actual material properties of the RV, is not currently known, but in order to complete its review of the adequacy of the RVSP, the staff requested that the applicant describe its process for preparing the capsule specimens. This description should confirm that the materials selected for the capsules are samples of those materials most likely to limit the operation of the RV.

Secondly, the staff requested additional information about the RVSP. The COL applicant must fully describe its RVSP to ensure that it meets ASTM E-185 and other requirements listed in 10 CFR Part 50, Appendix H. Specifically, the NRC staff requested detailed information on the RVSP associated with the AP1000 design, including, but not limited to, the capsule environment and the material types of the capsule specimens.

In RAI 5.3.1-1, the staff requested that the applicant describe the process for preparing the capsule specimens and to include detailed information on the capsule environment and material types of the capsule specimens. The applicant responded with a detailed description of the capsule specimen preparation process to be incorporated into the next revision of the BLN COL FSAR. The applicant also stated that the capsule environment and the material types of the capsule specimens are addressed in AP1000 DCD, Section 5.3.2.6 which is incorporated by reference.

The staff finds that the response to RAI 5.3.1-1 is acceptable, provided that the BLN COL FSAR is revised as stated by the applicant, and that the applicant confirms the staff's understanding that the surveillance capsules are backfilled with inert gas. Therefore, the staff identifies ***Confirmatory Item 5.3-1*** *to confirm that the BLN COL FSAR is revised as stated, and to confirm the staff's understanding that the surveillance capsules are backfilled with inert gas.*

Generic Letter 92-01

Generic Letter (GL) 92-01, "Reactor Vessel Structural Integrity," addressed NRC concerns regarding compliance with the requirements of Appendices G and H to 10 CFR Part 50, which address fracture toughness requirements and RVSP requirements, respectively. Specifically, NRC had concerns about Charpy USE predictions for end-of-life for the limiting beltline weld and the plate or forging, RVs constructed to an ASME Code earlier than the Summer 1972 Addenda of the 1971 Edition, and use of RG 1.99, Revision 2, to estimate the embrittlement of the materials in the RV beltline. These topics have been addressed in the

AP1000 DCD, Revision 17, which is incorporated by reference in the BLN COL FSAR.

The AP1000 DCD, Revision 17, also states that end-of-life RT_{NDT} and USE projections were estimated using RG 1.99. The construction of the RV to an ASME Code earlier than the Summer 1972 Addenda of the 1971 Edition is not a concern for new reactors, including BLN. In the BLN COL FSAR Section 5.3.2.6.3, the applicant provides additional information, which states that when each capsule is withdrawn, a summary technical report of the data required by ASTM E-185-82 and the results of the fracture toughness tests conducted on the beltline materials in the irradiated and unirradiated conditions will be submitted to the NRC within one year of the date of capsule withdrawal.

On the basis of the information discussed above, the NRC staff concludes that the applicant has adequately addressed the issues in GL 92-01.

<u>*Resolution of Standard Content Confirmatory Item 5.3-1*</u>

The NRC staff verified that the VEGP FSAR was updated to include a detailed description of the capsule specimen preparation process and to document that the surveillance capsules are backfilled with inert gas. As a result, Confirmatory Item 5.3-1 is resolved.

In an April 25, 2011, letter, Duke Energy endorsed VEGP RAI 05-03.01-01. Therefore, the above discussion related to the VEGP RAI is equally applicable to WLS COL application. In addition, the staff also verified that the WLS COL FSAR has been adequately updated to include the applicable changes resulting from this RAI.

5.3.2.5 *Post Combined License Activities*

For the reasons discussed in the technical evaluation section above, the staff finds the following license conditions related to the RV Material Surveillance program acceptable:

- License Condition (5-2) – The licensee shall implement the RV Material Surveillance program prior to initial criticality.

- License Condition (5-3) – No later than 12 months after issuance of the COL, the licensee shall submit to the Director of NRO a schedule that supports planning for and conduct of NRC inspections of the RV Material Surveillance program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the RV Material Surveillance program has been fully implemented.

5.3.2.6 *Conclusion*

The staff reviewed the application and the applicable sections of the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to RV materials, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the

information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff concludes that the information presented in the WLS COL FSAR is acceptable and meets the relevant regulatory guidance provided in NUREG-0800, Section 5.3.1 and RG 1.206, the policy established in SECY-05-0197, and the requirements of 10 CFR Part 50, Appendices G and H. The staff based its conclusion on the following:

- STD COL 5.3-2, relating to the RV material surveillance program, is acceptable because the program is consistent with the relevant guidelines addressed in NUREG-0800, Section 5.3.1 and in RG 1.206, Section C.III.1, Chapter 5, C.I.5.3.1. Conformance to these guidelines provides an acceptable basis to satisfy, in part, the requirements of to 10 CFR Part 50, Appendices G and H.

5.3.3 Pressure Temperature Limits (Related to RG 1.206, Section C.III.1, Chapter 5, C.I.5.3.2, "Pressure-Temperature Limits, Pressurized Thermal Shock, and Charpy Upper-Shelf Energy Data and Analyses")

5.3.3.1 *Introduction*

Pressure Temperature (P-T) limits are required as a means of protecting the RV during startup and shut down to minimize the possibility of fast fracture. The methods outlined in ASME Code, Section XI, Appendix G are employed in the analysis of protection against nonductile failure. Beltline material properties degrade with radiation exposure and this degradation is measured in terms of the adjusted reference temperature, which includes a reference nil-ductility temperature shift, initial RT_{NDT}, and margin.

5.3.3.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 5.3 incorporates by reference AP1000 DCD, Revision 19, Section 5.3 with departures and/or supplements. AP1000 DCD Section 5.3 includes Section 5.3.3.

To address departures and/or supplements in WLS COL FSAR Section 5.3.6.1, the applicant provided the following additional information:

AP1000 COL Information Item

- STD COL 5.3-1

The applicant provided additional information in STD COL 5.3-1 to address COL Information Item 5.3-1 of the AP1000 DCD and COL Action Item 5.2.2.2-1 in NUREG-1793. The information relates to plant-specific P-T curves.

Supplemental Information

- STD SUP 5.3-1

The applicant provided supplemental information related to development of operating procedures as required by Technical Specification (TS) 5.6.6.

<u>*License Condition*</u>

- Part 10, License Condition 2, Item 5.3-1

The license condition related to COL Information Item 5.3-1 sets the implementation milestone for development of plant-specific P-T curves.

5.3.3.3 *Regulatory Basis*

The regulatory basis of the AP1000 DCD information incorporated by reference in the COL application is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for P-T limits are given in NUREG-0800, Section 5.3.2.

5.3.3.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 5.3.3 and the referenced DCD to ensure that the combination of the DCD information incorporated by reference and the information in the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the COL application and that incorporated by reference addresses the required information relating to P-T limits. The results of the staff's evaluation of the DCD information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff's review determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.3.3.4:

AP1000 COL Information Item

- *STD COL 5.3-1*

The NRC staff reviewed STD COL 5.3-1 related to COL Information Item 5.3-1 included under Section 5.3.6.1 of the COL FSAR. The applicant proposes to replace the text in AP1000 DCD Section 5.3.6.1 with the following:

> *The pressure-temperature curves shown in DCD Figures 5.3-2 and 5.3-3 are generic curves for AP1000 reactor vessel design, and they are limiting curves based on copper and nickel material composition. Plant-specific curves will be developed based on material composition of copper and nickel. Use of plant-specific curves will be addressed during procurement and fabrication of the reactor vessel. As noted in the bases to Technical Specification 3.4.14, use of plant-specific curves requires evaluation of the LTOP system. This includes an evaluation of the setpoint pressure for the RNS relief valve to determine if the setpoint pressure needs to be changed based on plant-specific pressure-temperature curves. The development of the plant-specific curves and evaluation of the setpoint pressure are required prior to fuel load.*

In addition, in Section 5.3.3.2 of NUREG-1793, the staff identified related COL Action Item 5.2.2.2-1 in which the COL applicant will address the use of plant-specific curves during procurement of the RV.

The COL applicant stated that the P-T limits shown in DCD Figures 5.3-2 and 5.3-3 are generic curves for AP1000 RV design, and they are limiting curves based on copper and nickel material composition. The applicant committed to provide P-T limits using the plant-specific material composition after the combined license is issued and when the RV is procured. The applicant also stated that the development of the plant-specific P-T limits is required prior to fuel load. The staff found that a more specific implementation milestone for completing the plant-specific P-T limits was needed. Thus, the following additional information was requested.

In RAI 5.3.2-1, the staff noted Westinghouse's plan to: a) submit a generic PTLR [pressure temperature limits report] for the AP1000 RV using the bounding properties for NRC staff review and approval; and b) update the AP1000 DCD to include the use of the generic AP1000 PTLR by all COL applicants. The NRC staff requested that Part 10 of the BLN COL, proposed license conditions, Section 2, COL holder items, and COL Information Item 5.3-1 be revised by adding the following statement:

> *The COL Holder shall update the P/T limits using the PTLR methodologies approved in the AP1000 DCD, and using the plant-specific material properties. The COL Holder will inform the NRC of the updated P/T limits.*

The approach described above is consistent with that used for all operating reactors where licensees using PTLRs (reference: GL 96-03) inform the NRC staff of any subsequent change in P-T limits with no NRC approval necessary when there are no changes to the approved PTLR methodology. Subsequently, in a letter dated May 30, 2008, Westinghouse submitted a generic PTLR for AP1000 plants. The NRC staff reviewed the PTLR and approved its use for AP1000 RVs in a safety evaluation (ML083470258) dated December 30, 2008.

In response to RAI 5.3.2-1, the applicant proposed to modify the COL application Part 10, Proposed Combined License Conditions, Section 2, COL Holder Item 5.3-1. Accordingly, the modified license condition states, "The COL Holder shall update the P/T limits using the PTLR methodologies approved in the AP1000 DCD using plant-specific material properties or confirm that the reactor vessel material properties meet the specifications and use the Westinghouse generic PTLR curves."

The staff finds that the applicant's modification to the proposed license condition is adequate and the staff verified that the revision to Part 10 of the application incorporates the above. As a result, RAI 5.3.2-1 is closed.

Supplemental Information

- *STD SUP 5.3-1*

Development of plant operating procedures as required by TS 5.6.6 ensures that P-T limits are adhered to during normal and abnormal operating conditions and system tests and is therefore, acceptable.

In a February 5, 2009, letter, Duke Energy endorsed BLN RAI 05.03.02-01. Therefore, the above discussion related to the BLN RAI is equally applicable to WLS COL application. In addition, the staff also verified that the WLS COL FSAR, Section 5.3 and WLS COL Part 10, have been adequately updated to include the applicable changes resulting from this RAI.

5.3.3.5 *Post Combined License Activities*

For the reasons discussed in the technical evaluation section above, the staff finds the following license condition related to P-T limits acceptable:

- License Condition (5-4) – Before initial fuel load, the licensee shall update the P-T limits using the pressure-temperature limits report (PTLR) methodologies approved in the AP1000 DCD using the plant-specific material properties or confirm that the RV material properties meet the specifications and use the Westinghouse generic PTLR curves.

5.3.3.6 *Conclusion*

The staff reviewed the application and the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to P-T limits, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the regulatory basis addressed in NUREG-1793. Specifically, the relevant regulatory basis includes NUREG-0800, Section 5.3.2, GL 96-03, and 10 CFR Part 50, Appendix G. The staff based its conclusion on the following:

- STD COL 5.3-1, relating to plant-specific P-T curves, is acceptable because the program is consistent with the guidelines addressed in NUREG-0800, Section 5.3.2 . Conformance to these guidelines provides an acceptable basis to satisfy in part, the requirements of 10 CFR Part 50, Appendix G.

- STD SUP 5.3-1, relating to development of operating procedures, is acceptable because it ensures that P-T limits are adhered to during normal and abnormal operating conditions and system tests.

5.3.4 Reactor Vessel Integrity (Related to RG 1.206, Section C.III.1, Chapter 5, C.I.5.3.3 “Reactor Vessel Integrity”)

5.3.4.1 *Introduction*

AP1000 DCD Section 5.3.4 describes the RV integrity. The RV is the RCPB used to support and enclose the reactor core. The RV provides flow direction with the reactor internals through the core and maintains a volume of coolant around the core. The vessel is fabricated by welding together the lower head, the transition ring, the lower shell, and the upper shell. The upper shell contains the penetrations from the inlet and outlet nozzles and direct vessel injection nozzles.

As part of the RV integrity, AP1000 DCD Section 5.3.4 also addresses the pressurized thermal shock (PTS) for the PWR RV. PTS events are potential transients in a PWR RV that can cause severe overcooling of the vessel wall, followed by immediate repressurization. The thermal stresses, caused when the inside surface of the RV cools rapidly, combined with high-pressure stresses, will increase the potential for fracture if a flaw is present in a low-toughness material. The materials most susceptible to PTS are the materials in the RV beltline where neutron radiation gradually embrittles the material over time.

5.3.4.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 5.3 incorporates by reference AP1000 DCD, Revision 19, Section 5.3 with departures and/or supplements. AP1000 DCD Section 5.3 includes Section 5.3.4.

To address departures and/or supplements in WLS COL FSAR Section 5.3.6, the applicant provided the following additional information:

<u>*AP1000 COL Information Item*</u>

- STD COL 5.3-4

The applicant provided additional information in STD COL 5.3-4 to address COL Information Item 5.3-4 and related COL Action Item 5.3.4.3-1. The applicant proposed to verify the plant-specific beltline material properties consistent with the requirements in AP1000 DCD

Section 5.3.3.1 and AP1000 DCD Tables 5.3-1 and 5.3-3 prior to fuel load. The applicant also proposed in STD COL 5.3-4 to perform a PTS evaluation based on as procured RV material data and the projected neutron fluences for the plant design objective of 60 years.

License Condition

- Part 10, License Condition 2, Item 5.3-4

The milestone for the implementation of the proposed actions related to RV material properties will be prior to initial fuel load.

5.3.4.3 *Regulatory Basis*

The regulatory basis of the DCD information incorporated by reference in the COL application is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the relevant requirements of NRC regulations for the RV integrity are given in NUREG-0800, Section 5.3.3.

In addressing the COL information item, PWRs are required, in part, to have the pressurized thermal shock reference temperature (RT_{PTS}), evaluated for the end-of-life fluence for each of the RV beltline materials in accordance with requirements of 10 CFR 50.61.

5.3.4.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 5.3.4 and checked the applicable sections of the referenced DCD to ensure that the combination of the DCD information and that in the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and that incorporated by reference from the DCD addresses the required information relating to RV integrity. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff's review determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.3.4.3:

AP1000 COL Information Item

- *STD COL 5.3-4*

The NRC staff reviewed STD COL 5.3-4 related to COL Information Item 5.3-4 and related COL Action Item 5.3.4.3-1. The applicant proposed to verify the plant-specific beltline material properties consistent with the requirements in DCD Section 5.3.3.1 and DCD Tables 5.3-1 and 5.3-3 prior to fuel load. The applicant also proposed in STD COL 5.3-4 to perform a PTS evaluation based on as procured RV material data and the projected neutron fluences for the plant design objective of 60 years.

License Condition

- *Part 10, License Condition 2, Item 5.3-4*

In response to the COL information item, the applicant proposed a license condition (Part 10, Item 2, COL Information Item 5.3-4) that a plant-specific PTS evaluation would be performed by the COL holder using as-procured RV material data and submitted for NRC review prior to initial fuel loading.

The as-procured RV material properties will be available to the COL holder after the acceptance of the RV. In order to provide sufficient time for NRC review of the PTS evaluation using the as-procured RV material properties as required by 10 CFR 50.61, the staff requested a more specific and timely milestone for submitting the PTS evaluation to the NRC be established. Therefore, the staff requested that the proposed license condition for COL Information Item 5.3-4 be revised to state that, within a reasonable period of time following acceptance of the RV, the COL holder submit to the NRC staff the plant-specific PTS evaluation, for example, one year after the acceptance of the RV. This was identified in RAI 5.3.3-1. In response to RAI 5.3.3-1, the applicant proposed that the licensee shall submit to the appropriate Director of the NRC, a schedule, no later than 12 months after the issuance of the COL, that supports planning for and conduct of NRC inspections of operational programs listed in the operational program FSAR Table 13.4-201. This schedule shall include a submittal schedule for the RV pressurized thermal shock evaluation at least 18 months prior to initial fuel load. Accordingly, the applicant will revise the COL application, Part 10, proposed License Condition 6.

The staff finds that Revision 1 of the application incorporates the proposed change to the proposed License Condition 6, and therefore the applicant's response to COL Information Item 5.3-4 meets the implementation requirements of 10 CFR 50.61, and is therefore acceptable. As a result, RAI 5.3.3-1 is closed.

In a February 5, 2009, letter, Duke Energy endorsed BLN RAI 05.03.03-01. Therefore, the above discussion related to RAI 05.03.03-01 is equally applicable to the WLS COL application. In addition, the staff also verified that the WLS COL FSAR, Section 5.3 and WLS COL Part 10 have been adequately updated to include the applicable changes resulting from this RAI response.

5.3.4.5 *Post Combined License Activities*

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license condition acceptable:

- License Condition (5-5) – Before initial fuel load, the licensee shall verify that plant-specific belt line material properties are consistent with the properties given in AP1000 DCD Rev. 19, Section 5.3.3.1 and Tables 5.3-1 and 5.3-3. The verification must include a pressurized thermal shock (PTS) evaluation based on as-procured reactor vessel material data and the projected neutron fluence for the plant design objective. Submit this PTS evaluation report to the Director of NRO, or the Director's designee, in writing, at least 18 months before the latest date set forth in the schedule for completing the inspections, tests, and analyses in the ITAAC submitted in accordance with 10 CFR 52.99(a).

5.3.4.6 *Conclusion*

The staff reviewed the COL application and checked the applicable sections of the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to RV integrity, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

In addition, the staff concludes that the information presented in the WLS COL FSAR meets the relevant acceptance criteria provided in NUREG-0800, Section 5.3.3, and the requirements of 10 CFR Part 50, Appendix B, and 10 CFR 50.61. The staff based its conclusion on the following:

- STD COL 5.3-4, relating to plant-specific beltline material properties, is acceptable because the applicant's proposed resolution meets the relevant acceptance criteria addressed in NUREG-0800, Section 5.3.3 and thus provides an acceptable basis to satisfy, in part, the requirements of 10 CFR Part 50, Appendix B, and 10 CFR 50.61.

5.3.5 Reactor Vessel Insulation

RV insulation is provided to minimize heat losses from the primary system. Non-safety-related reflective insulation similar to that in use in current PWRs is utilized.

WLS COL FSAR, Revision 11, Section 5.3 incorporates by reference, with no departures or supplements, AP1000 DCD, Revision 19, Section 5.3.5. The staff reviewed the COL application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff's review confirmed that there is no outstanding issue related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

5.4 Component and Subsystem Design (Related to RG 1.206, Section C.III.1, Chapter 5, C.I.5.4, "Reactor Coolant System Component and Subsystem Design")

5.4.1 Introduction

This section pertains to the design of various components and subsystems within, or associated with, the RCS. Principal components or subsystems include the following:

- Reactor coolant pumps
- Steam generators (SG), including materials and ISI
- RCS piping and valves
- Main steam line flow restriction
- Pressurizer and pressurizer relief discharge
- Automatic depressurization system valves
- Normal residual heat removal system
- RCS pressure relief devices
- Component supports
- RCS high point vents
- Core makeup tank
- Passive residual heat removal heat exchanger

The majority of the design-related information in the AP1000 DCD is incorporated by reference in the WLS COL application. Regarding the SGs, a program is developed by the COL applicant to ensure tube structural and leakage integrity will be maintained at a level comparable to that of the original design requirements. An effective program depends on both the program and the design features of the SGs.

The RNS is a non-safety-related system. Since the RNS is not required to operate to mitigate design-basis events, it is not credited in the Chapter 15, "Transient and Accident Analysis," safety analysis. However, the RNS is considered an important system because the RNS provides residual heat removal capability to several reactor systems. These major RNS non-safety-related functions include the RCS shutdown heat removal, RCS LTOP, RCS and refueling cavity purification during refueling operations, in-containment refueling water storage tank (IRWST) cooling, low pressure makeup to the RCS, and post-accident heat removal recovery. In addition, the RNS provides safety-related functions that include containment isolation of the RNS lines penetrating the containment, preservation of the RCS pressure boundary, and long term post-accident makeup to the containment inventory.

5.4.2 Summary of Application

WLS COL FSAR, Revision 11, Section 5.4 incorporates by reference AP1000 DCD, Revision 19, Section 5.4 with departures and/or supplements.

To address these departures and/or supplements in WLS COL FSAR Section 5.4.2.5, the applicant provided the following additional information:

Departures

- WLS DEP 3.2-1 and WLS 6.3-1

The applicant provided additional information in WLS COL FSAR Section 5.4 about WLS DEP 3.2-1 and WLS DEP 6.3-1 related to design modifications to the condensate return portion of the Passive Core Cooling System and quantifying the duration that the passive residual heat removal heat exchanger (PRHR-HX) can maintain safe shutdown conditions, respectively. This information, as well as related WLS DEP 3.2-1 and WLS DEP 6.3-1 information appearing in other chapters of the FSAR, is reviewed in Section 21.1 of this SER.

AP1000 COL Information Item

- STD COL 5.4-1

The applicant provided additional information in STD COL 5.4-1 to address COL Information Item 5.4-1 as described in AP1000 DCD Section 5.4.15. The information in STD COL 5.4-1 provides the SG program description, references the applicable ASME B&PV Code, Section XI requirements and industry guidelines, and refers to the TS for the program requirements.

The detailed inspection and reporting requirements are provided in WLS COL FSAR, Part 4, “Technical Specifications,” Sections 1.1 (“Definitions”), 3.4.7 (“RCS Operational Leakage”), 3.4.18 (“Steam Generator (SG) Tube Integrity”), 5.5.4 (“Steam Generator (SG) Program”), 5.6.8 (“Steam Generator Tube Inspection Report”), and in the associated bases sections of the TS.

5.4.3 Regulatory Basis

The regulatory basis of the AP1000 DCD information incorporated by reference in the COL application is addressed in NUREG-1793 and its supplements.

In addition, the acceptance criteria associated with the applicable requirements of NRC regulations for the component and subsystem design are given in NUREG-0800, Section 5.4.2.

The applicable regulatory requirements for acceptance of the COL information item are 10 CFR 50.55a, “Codes and Standards,” as it relates to periodic inspection and testing of the

RCPB as detailed in ASME Code, Section XI, and 10 CFR Part 50, Appendix A, GDC 32, "Inspection of Reactor Coolant Pressure Boundary," as it relates to the accessibility of SG tubes for periodic testing. In addition, 10 CFR 50.55a(b)(2)(iii) states that if the TS include SG surveillance requirements that are different than those in ASME Code, Section XI, Article IWB-2000, then the SG tube inspection requirements are governed by the TS.

The regulatory basis for evaluating the RNS is documented in NUREG-1793, Section 5.4.7 and its supplements. While the RNS is a non-safety-related system, it is considered to be important to safety because it provides the first line of defense during an accident to prevent unnecessary actuation of the passive core cooling systems. Regulatory oversight of the active non-safety systems in passive plant designs is subject to a staff evaluation of the regulatory treatment of non-safety systems (RTNSS). NUREG-1793, Chapter 22, "Regulatory Treatment of Non-safety Systems," provides a detailed evaluation of the RTNSS issue in accordance with NRC policy for passive reactor plant designs. Non-safety-related systems that provide defense-in-depth capabilities for the AP1000 design includes the RNS. For this defense-in-depth system to operate, the associated systems and structures to support these functions must also be operable, including non-safety-related component cooling water system and the service water system. The staff's evaluation of the changes that are proposed focused primarily on confirming that the changes will not adversely affect safety-related SSCs or those that satisfy the criteria for RTNSS. Therefore, the proposed changes were evaluated using the guidance provided by NUREG-0800, Section 5.4.7, as it pertains to these considerations. Acceptability was determined based on conformance to the existing AP1000 licensing basis, the guidance specified by NUREG-0800, Section 5.4.7 (10 CFR Part 50, Appendix A, GDC 34, "Residual heat removal," as it relates to requirements for a RNS system), and NRC policy with respect to RTNSS as discussed in SECY-94-084 and SECY-95-132.

5.4.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 5.4 and the referenced DCD to ensure that the combination of the DCD information incorporated by reference and the COL application information represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the DCD information incorporated by reference addressed the required information relating to RCS component and subsystem design. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this SER provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review in evaluating subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the reference COL application (VEGP Units 3 and 4) were equally applicable to the WLS Units 1 and 2 COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed.

- The staff verified that the site-specific differences were not relevant.

The staff's review determined the evaluation performed for the standard content to be directly applicable to the WLS COL application. This standard content material is identified in this SER by use of italicized, double-indented formatting. Section 1.2.3 of this SER provides an explanation of why the standard content material from the SER for the reference COL application (VEGP) contains evaluation material from the SER for the BLN Units 3 and 4 COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 5.4.4:

> *AP1000 COL Information Item*
>
> - *STD COL 5.4-1*
>
> *In AP1000 DCD Section 5.4.15, Westinghouse identified COL Information Item 5.4-1 for the COL applicant to address the SG tube integrity with an SG Tube Surveillance Program and address the need to develop a program for periodic monitoring of degradation of steam generator internals. Similarly, in NUREG-1793, Section 5.4.2.2.2, the staff identified COL Action Item 5.4.2.2.3-1 and noted that an SG tube surveillance program is necessary to address the concerns raised in GL 97-06, "Degradation of Steam Generator Internals."*
>
> *In Revision 17 of the AP1000 DCD, Westinghouse proposed changes to the AP1000 generic TS related to adopting TS Task Force Traveler (TSTF) 449, Revision 4, "Steam Generator Tube Integrity." TSTF 449 is incorporated in the current Westinghouse Owners Group Standard Technical Specifications (STS), NUREG-1431, Revision 3.1, December 1, 2005. The TS and bases sections listed above for SG tube integrity in the BLN SER are identical to those in Revision 17 of the AP1000 DCD.*
>
> *With respect to the information provided in STD COL 5.4-1, the staff reviewed the description in Chapter 5 of the FSAR using the guidelines in RG 1.206, Section C.III.1, Chapter 5, C.I.5.4.2.2; Section 5.4.2.2 of NUREG-0800; and the TS proposed in the AP1000 DCD (which are based on NUREG-1431, Revision 3.1 and are the STS for Westinghouse operating plants). The staff confirmed tube inspection will meet the requirements of Section XI of the ASME Code, and that the applicant referenced an acceptable method (RG 1.121) for determining the tube repair criteria for maintaining structural integrity. The staff determined the TS proposed for BLN Nuclear Plant, Units 3 and 4 are consistent with the approved STS and the leakage limits and SG tube integrity requirements are appropriate as they apply to BLN, and are therefore acceptable. In addition, the applicant took exception to the guidance contained in Regulatory Guide 1.83, Revision 1 and stated that the applicant's program will be implemented according to Nuclear Energy Institute (NEI) 97-06 ("Steam Generator Program Guidelines") and EPRI SG guidelines, which are referenced in the STS and, thus, provide acceptable methods for implementing ASME Code requirements. With respect to tube integrity considerations, the Model Delta-125 SG planned for the BLN*

> *units closely resembles the Model Delta-75 installed as replacement SGs at some operating plants*
>
> *According to Section 5.4.2.2 of NUREG-0800, because the SG program is part of the ISI requirements, it is an operational program that should be fully described, with implementation milestones listed in the appropriate table in Chapter 13 of the FSAR. In response to RAI 5.4.2.2-1 from the staff, in a letter dated June 5, 2008, the applicant proposed revising FSAR Chapter 13, Table 13.4-201 to add Section 5.4.2.5 ("Steam Generator Inservice Inspection") as one of the FSAR sections addressed by the operational program titled "Inservice Inspection Program." Similarly, in response to RAI 5.4.2.2-2, the applicant proposed revising Table 13.4-201 to add Section 5.4.2.5 as one of the FSAR sections addressed by the operational program titled "Preservice Inspection Program." These proposed revisions are acceptable because they make the SG tube ISI part of the operational programs and ensure PSIs will be performed, consistent with the acceptance criteria in Section 5.4.2.2 of NUREG-0800 and RG 1.206. The staff verified that Revision 1 of Table 13.4-201 adequately incorporates the above. As a result, RAI 5.4.2.2-1 and RAI 5.4.2.2-2 are closed.*

In a February 5, 2009, letter, Duke Energy endorsed BLN RAIs 05.04.02.02-01 and 05.04.02.02-02. Therefore, the above discussion related to these RAIs is equally applicable to the WLS COL application. In addition, the staff also verified that the WLS COL FSAR, Section 5.3 and WLS COL Part 10 have been adequately updated to include the applicable changes resulting from these RAI responses.

5.4.5 Post Combined License Activities

The license condition language in this section has been clarified from previously considered language. In a letter dated March 22, 2016 (ADAMS Accession No. ML16084A099), the applicant did not identify any concerns with the clarified license condition language. The changes do not affect the staff's above analysis of the conditions, and therefore, for the reasons discussed in the technical evaluation section above, the staff finds the following license condition acceptable:

- License Condition (5-6) – No later than 12 months after the issuance of the COL, the licensee shall submit to the Director of NRO a schedule that supports planning for and conduct of NRC inspections of the PSI/ISI program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until either the PSI/ISI program has been fully implemented.

5.4.6 Conclusion

The staff reviewed the WLS COL application and the applicable sections of the referenced DCD. The staff's review confirmed that the applicant adequately addressed the required information relating to RCS component and subsystem design, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the relevant regulatory requirements provided in 10 CFR Part 50, Appendix A, GDC 32 and 10 CFR 50.55a, and the regulatory guidance addressed in RG 1.206 and RG 1.121. The staff based its conclusion on the following:

- WLS DEP 3.2-1 and WLS DEP 6.3-1, related to design modifications to the condensate return portion of the Passive Core Cooling System and quantifying the duration that the passive residual heat removal heat exchanger can maintain safe shutdown conditions, respectively, are reviewed and found acceptable by the staff in Section 21.1 of this SER.

- STD COL 5.4-1 relating to the SG Program, is acceptable because it meets the relevant guidelines of RG 1.206, Section C.III.1, Chapter 5, C.I.5.4.2.2 and RG 1.121. Conformance with these guidelines provides an acceptable basis for satisfying, in part, the requirements of 10 CFR Part 50, Appendix A, GDC 32, and 10 CFR 50.55a including the specific modification provided in 10 CFR 50.55a(b)(2)(iii).

6 ENGINEERED SAFETY FEATURES

6.0 Engineered Safety Features

Engineered safety features (ESF) are design features designed to preclude an accidental release of reactor fission products or to protect the public in the event of an accidental release from the reactor coolant system (RCS). The function of the ESF is to localize, control, mitigate, and terminate such accidents, and to maintain radiation exposure levels to the public below applicable limits and guidelines. William States Lee III Nuclear Station, Units 1 and 2, (WLS), combined license (COL) Final Safety Analysis Report (FSAR), Revision 11, Section 6.0, incorporates by reference with no departures or supplements, AP1000 Design Control Document (DCD), Revision 19, Section 6.0, “Engineered Safety Features.” . The U.S. Nuclear Regulatory Commission (NRC) staff (the staff) reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remained for review.[1] The staff confirmed that there are no outstanding issues related to this section. The results of the staff’s technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793, “Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design,” and its supplements.

6.1 Engineered Safety Features Materials

This section of the report provides the evaluation of the materials used in the fabrication of ESF components and of the provisions to avoid material interactions that could impair the operation of the ESF. The design information in WLS COL FSAR Section 6.1, is divided into two sections, Section 6.1.1, “Metallic Materials”; and Section 6.1.2, “Organic Materials.” The staff’s evaluation of these sections is provided below.

6.1.1 Metallic Materials

6.1.1.1 *Introduction*

In this section of the report, the staff reviewed metallic materials used in ESF components to ensure that they are compatible with one another and with ESF fluids. The compatibility of ESF component materials with fluids in ESF systems should ensure that there is a low probability of causing abnormal leakage, of rapidly propagating failure, and of gross rupture of reactor coolant pressure boundary components. Metallic materials and fluids should also be compatible with the auxiliary systems that directly support ESF systems.

---

[1] See Section 1.2.2 of this report for a discussion of the staff’s review related to verification of the scope of information to be included in a COL application that references a design certification (DC).

6.1.1.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 6.1, incorporates by reference AP1000 DCD, Revision 19, Section 6.1. In addition, in WLS COL FSAR Section 6.1.1, the applicant provided the following:

<u>*AP1000 COL Information Item*</u>

- STD COL 6.1-1

The applicant provided information in Standard (STD) COL 6.1-1 to resolve AP1000 COL Information Item 6.1-1. STD COL 6.1-1 describes quality assurance measures for special processes in fabricating austenitic stainless steels. STD COL 6.1-1 is discussed in WLS COL FSAR Sections 6.1.1.2, Fabrication Requirements," and 6.1.3.1, "Procedure Review."

6.1.1.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for the metallic materials are given in NUREG-0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants," Section 6.1.1. This reference will be referred to in this report as the SRP.

The regulatory basis for the AP1000 COL information item is Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, "Domestic Licensing of Production and Utilization Facilities," Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants," as it relates to the quality assurance requirements for the design, fabrication, and construction of safety-related structures, systems, and components (SSCs). Guidance used in the review of this COL information item is described in Regulatory Guide (RG) 1.31, "Control of Ferrite Content in Stainless Steel Weld Metal," Revision 3, and RG 1.44, "Control of the Use of Sensitized Stainless Steel."

6.1.1.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 6.1.1, and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to metallic materials. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the safety evaluation report (SER) for the Vogtle (VEGP) reference COL (RCOL) application were equally applicable to the WLS COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from responses to requests for additional information (RAIs).

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the VEGP reference COL application includes evaluation material from the SER for the Bellefonte Nuclear Plant, Units 3 and 4 (BLN), COL application.

The following portion of this technical evaluation section is reproduced from the VEGP SER Section 6.1.1.4:

> <u>*COL Information Item*</u>
>
> - *STD COL 6.1-1*
>
> *The NRC staff reviewed STD COL 6.1-1 related to COL Information Item 6.1-1 included under Section 6.1.1.2 of the BLN COL FSAR, which addresses the COL information item identified in AP1000 DCD Section 6.1.3.1 related to the fabrication requirements for austenitic stainless steel.*
>
> *The COL information item identified in AP1000 DCD Section 6.1.3.1 states:*
>
>> *The Combined License applicants referencing the AP1000 will address review of vendor fabrication and welding procedures or other quality assurance methods to judge conformance of austenitic stainless steels with Regulatory Guides 1.31 and 1.44.*
>
> *This commitment was also documented as COL Action Item 6.1.1-1 in the NRC staff's FSER for the AP1000 DCD (NUREG-1793), which states:*
>
>> *The COL applicant will review vendor fabrication and welding procedures or other quality assurance methods to ensure that austenitic stainless steels meet the guidelines of RGs 1.31 and 1.44.*
>
> *The COL information in the FSAR that is to be added to AP1000 DCD Section 6.1.1.2 states:*

> *In accordance with Appendix B to 10 CFR Part 50, the quality assurance program establishes measures to provide control of special processes. One element of control is the review and acceptance of vendor procedures that pertain to the fabrication, welding, and other quality assurance methods for safety related component [sic] to determine both code and regulatory conformance. Included in this review and acceptance process are those vendor procedures necessary to provide conformance with the requirements of Regulatory Guides 1.31 and 1.44 for engineered safety features components as discussed in DCD Section 6.1 and reactor coolant system components as discussed in DCD Section 5.2.3.*

The staff finds the COL information provided by the applicant meets the quality assurance guidelines for austenitic stainless steels specified in RG 1.31 (weld metal ferrite content) and RG 1.44 (the use of sensitized stainless steel). The staff's conclusion is based on the applicant's statement affirming that its Appendix B quality assurance program will address the concerns of these RGs. It is also based on Appendix 1A of the AP1000 DCD, as modified by a letter dated April 7, 2010, from the AP1000 applicant. The modified DCD appendix will be incorporated by reference in a future version of the BLN COL FSAR and will indicate full conformance with these RGs. In addition, the discussions in AP1000 DCD Sections 6.1.1.2 and 5.2.3.4 provide details about how conformance will be accomplished.

6.1.1.5 *Post Combined License Activities*

There are no post COL activities related to this section.

6.1.1.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to metallic materials used in ESF and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable because it meets the requirements of 10 CFR Part 50, Appendix B, and the guidance provided in RG 1.31 and RG 1.44. STD COL 6.1-1 is acceptable because the Appendix B quality assurance program proposed by the applicant provides adequate controls over vendor fabrication and welding procedures to ensure that austenitic stainless steels meet the guidelines of RG 1.31 and RG 1.44.

6.1.2 Organic Materials

6.1.2.1 *Introduction*

Protective coatings are applied for corrosion prevention to the interior and exterior surfaces of the containment vessel, radiologically controlled areas outside containment, and the remainder of the plant. The coatings selection process accounts for these differing coating needs for these four areas. The AP1000 design considers the function of the coatings, their potential failure modes, and their requirements for maintenance. Other organic materials that may be present in the containment are associated with the specific type of equipment and the supplier selected to provide it. Materials are evaluated for potential interaction with the ESF to provide confidence that the performance of the ESF is not unacceptably affected.

6.1.2.2 *Summary of Application*

WLS COL FSAR, Revision 11, Section 6.1, incorporates by reference the AP1000 DCD, Revision 19, Section 6.1. AP1000 DCD Section 6.1 includes Section 6.1.2. In addition, in WLS COL FSAR, Section 6.1.2, the applicant provided the following:

AP1000 COL Information Item

- STD COL 6.1-2

The applicant provided information in STD COL 6.1-2 to resolve AP1000 COL Information Item 6.1-2. STD COL 6.1-2 discusses a program to control procurement, application, inspection, and monitoring of Service Level I and Service Level III coatings. This COL information item is discussed in WLS COL FSAR Sections 6.1.2.1.6, “Quality Assurance Features,” and 6.1.3.2, “Coating Program.” In a March 31, 2010, letter, the AP1000 DCD applicant (Westinghouse) proposed revisions to AP1000 COL Information Item 6.1-2 in AP1000 DCD Section 6.1.3.2, to address Service Level II coatings. In a March 24, 2011, letter the WLS COL applicant endorsed the VEGP August 13, 2010 letter, respectively, that proposed revising the FSAR to address the updated AP1000 COL Information Item 6.1-2.

6.1.2.3 *Regulatory Basis*

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for protective coatings are given in NUREG-0800, Section 6.1.2. The applicable regulatory basis for the resolution of the COL information item is 10 CFR Part 50, Appendix B, as it relates to the quality assurance requirements for the design, fabrication, and construction of safety-related SSCs. Guidance for the resolution of the COL information item is described in RG 1.54, “Service Level I, II, and III Protective Coatings Applied to Nuclear Power Plants,” Revision 1.

6.1.2.4 *Technical Evaluation*

The staff reviewed WLS COL FSAR Section 6.1.2, and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and incorporated by reference addresses the required information relating to protective coatings and other organic materials inside containment. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the VEGP reference COL application includes evaluation material from the SER for the BLN COL application. Although the staff concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application, there is a difference in how the VEGP applicant addressed STD COL 6.1-2 and how the BLN applicant addressed this review item. This difference, which is based on a change proposed in the AP1000 DCD, is evaluated by the staff below, following the standard content material for STD COL 6.1-2. The two confirmatory items in the standard content material retain the number assigned in the VEGP SER, and are also addressed in the standard content material.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 6.1.2.4:

> *<u>AP1000 COL Information Item</u>*
>
> - *STD COL 6.1-2*
>
> *The NRC staff reviewed STD COL 6.1-2 included under Section 6.1.2.1.6 of the BLN COL FSAR related to COL Information Item 6.1-2. COL Information Item 6.1-2 states:*
>
> > *The Combined License applicants referencing the AP1000 will provide a program to control procurement, application, and monitoring of Service Level I and Service Level III coatings. The program for the control of the use of these coatings will be consistent with [DCD] subsection 6.1.2.1.6.*
>
> *This commitment was also captured as COL Action Item 6.1.2-1 in Appendix F of the NRC staff's FSER for the AP1000 DCD (NUREG-1793), which states:*
>
> > *The COL applicant will prepare a program to control procurement, application, and monitoring of Service Level I and Service Level III coatings.*
>
> *The added information in the BLN COL FSAR replaces the third paragraph under the section titled, "Service Level I and Service Level III Coatings," in AP1000 DCD Section 6.1.2.1.6 with the following:*
>
> > *During the design and construction phase the coatings program associated with selection, procurement and application of safety related coatings is performed to applicable quality standards. Regulatory Guide 1.54 and [American Society for Testing and*

> *Materials] ASTM D5144 form the basis for the coating program. During the operations phase, the coatings program is administratively controlled in accordance with the quality assurance program implemented to satisfy 10 CFR Part 50, Appendix B, and 10 CFR Part 52 requirements. The coatings program provides direction for the procurement, application, and monitoring of safety related coating systems. Coating system monitoring requirements for the containment coating systems are based on ASTM D5163, "Establishing Procedures to Monitor the Performance of Coating Service Level I Coating Systems in an Operating Nuclear Power Plant," and ASTM D7167, "Establishing Procedures to Monitor the Performance of Safety-Related Coating Service Level III Lining Systems in an Operating Nuclear Power Plant." Any anomalies identified during coating monitoring are resolved in accordance with applicable quality assurance requirements.*

The AP1000 DCD, which the applicant incorporates by reference, includes the following description of the quality assurance program:

> *The quality assurance program for Service Level I and Service Level III coatings conforms to the requirements of [American Society of Mechanical Engineers] ASME NQA-1-1983 as endorsed in Regulatory Guide 1.28 ["Quality Assurance Program Criteria (Design and Construction)"]. Safety related coatings meet the pertinent provisions of 10 CFR Part 50 Appendix B to 10 CFR Part 50. The service level classification of coatings is consistent with the positions given in Revision 1 of Regulatory Guide 1.54, "Service Level I, II, and III Protective Coatings Applied to Nuclear Power Plants." Service Level I and Service Level III coatings used in the AP1000 are tested for radiation tolerance and for performance under design basis accident conditions. Where decontaminability is desired, the coatings are evaluated for decontaminability. The coating applicator submits and follows acceptable procedures to control surface preparation, application of coatings and inspection of coatings. The painters are qualified and certified, and the inspectors are qualified and certified.*
>
> *The inorganic zinc coating used on the inside surface (Service Level I coatings) and outside surface (Service Level III coatings) of the containment shell is inspected using a non-destructive dry film thickness test and a MEK rub test. These inspections are performed after the initial application and after recoating. Long term surveillance of the coating is provided by visual inspections performed during refueling outages. Other inspections are not required.*

Section 6.1.2 of NUREG-0800 references RG 1.54 as providing an acceptable method of complying with the quality assurance requirements in regard to protective coatings applied to ferritic steels, aluminum, stainless steel, *zinc-coated (galvanized) steel, concrete, or masonry surfaces of nuclear facilities. RG 1.54 lists a number of ASTM standards that provide guidance on practices and programs that are acceptable to the NRC staff for the selection, application, qualification, inspection, and maintenance of protective coatings applied in nuclear power plants. Section 6.1.2 of NUREG-0800 also states that a coating system to be applied inside the containment vessel is acceptable if it meets the regulatory positions of RG 1.54 and the standards of ASTM D5144-00 and ASTM D3911-03. By contrast, the AP1000 DCD references RG 1.54, but only with respect to classification of coating service level as I, II, or III.*

The AP1000 DCD text to be replaced with the COL information item stated that the procurement, application, and monitoring of Service Level I and Service Level III coatings are controlled by a program prepared by the COL applicant The information provided clarified that the applicant's coatings program, with respect to procurement, application, inspection, and monitoring, will be consistent with the recommendations of RG 1.54, which is endorsed in Section 6.1.2 of NUREG-0800 as an acceptable method of meeting the quality assurance requirements of 10 CFR Part 50, Appendix B for safety-related and nonsafety-related coatings. However, the information provided by the applicant to resolve the COL information item merely states that the protective coatings program complies with RG 1.54, when, in fact, the program was not yet developed. Therefore, the COL applicant had not provided a coatings program as committed in COL Information Item 6.1-2.

To resolve this issue, in request for additional information (RAI) 6.1.2-1, the staff requested the following information:

1. *The applicant should describe the standards to be applied to maintenance of the protective coatings in the program description. The description of the proposed coatings program should also describe the standards to be applied to selection and qualification of coatings, if the applicant intends to use coatings systems different than those described in the AP1000 DCD, either during construction or after plant operation commences.*

2. *The program description should describe the administrative controls that will be applied to the coatings program.*

3. *Provide the schedule for full implementation of the coatings program with respect to major milestones in the construction of the plant; for example, prior to application of coatings, prior to preparation of surfaces to be coated, or prior to procurement of coatings materials.*

In a letter dated May 23, 2008, the applicant provided the following response:

Item 1) The coating program will be based on Revision 1 of RG 1.54 and the referenced ASTM standards in ASTM D5144. Also, the guidance provided in ASTM D5163, "Establishing Procedures to Monitor the Performance of Coating Service Level I Coating Systems in an Operating

Nuclear Power Plant," and in ASTM D7167, "Establishing Procedures to Monitor the Performance of Coating Service Level III Coating Systems in an Operating Nuclear Power Plant," will be used to specify monitoring (maintenance) requirements for the safety-related coating systems pertaining to containment. While a change in coating systems (from those described in the AP1000 DCD) is not anticipated, if a different safety-related coating system is needed, it will be evaluated in accordance with the appropriate change process, i.e., 10 CFR 50.59 or 10 CFR Part 52, Appendix D, Section VIII.

Item 2) FSAR Section 6.1.3.2, Coating Program, will be revised to indicate compliance with 10 CFR Part 50, Appendix B, and 10 CFR Part 52 requirements implemented by the quality assurance program for the plant (see FSAR Chapter 17 and Part 11 of the COL application) for design, construction, and operation of the units.

Item 3) During the design and construction phase, the requirements for the coating program will be contained in certified drawings and/or standards and specifications controlling the coating processes of the designer (Westinghouse); these design documents will be available prior to the procurement and application of the coating material by the constructor of the plant. Prior to initial fuel loading, a consolidated plant coating program will be in place to address procurement, application, and monitoring (maintenance) of those coating system(s) for the life of the plant.

The staff finds the applicant's response to Item 1 acceptable because, pursuant to RG 1.54, ASTM D5163 provides guidelines that are acceptable to the NRC staff for establishing an in-service coatings monitoring program for Service Level I coating systems in operating nuclear power plants and for Service Level II and other areas outside containment (as applicable). The applicant also specified ASTM D7167 for monitoring (maintenance) requirements for the safety-related coating systems pertaining to containment. Although ASTM D7167 is not listed in RG 1.54 or ASTM D5144, the staff finds it an appropriate standard because it addresses maintenance of Service Level III coatings. Additionally, ASTM D7167 references ASTM D4541 and ASTM D3359, which are listed in RG 1.54 as acceptable standards for maintenance of protective coatings in nuclear power plants. Further, if a change in any of the originally specified coatings systems is necessary, the applicant will use an appropriate process, either the 10 CFR 50.59 or 10 CFR Part 52, Appendix D, Section VIII process, to evaluate the change. The staff finds the application of these regulations an appropriate alternative to control of the selection of coatings by the consolidated coatings program.

The BLN application references later versions of ASTM D5144 and ASTM D5163 than those referenced in RG 1.54, Revision 1. The use of the 2008 revision of ASTM D5144 is acceptable because it provides detailed requirements through reference to other coatings standards applicable to BLN. In this regard, it is not changed with respect to the 2000 revision referenced in the RG 1.54, Revision 1.

Similarly, the 2005 revision of ASTM D5163 is referenced in the BLN COL application rather than the 1996 revision referenced in RG 1.54, Revision 1. The staff finds this acceptable because the NRC staff has accepted the 2005 revision of ASTM D5163 as the basis for the Aging Management Program XI.S8 in NUREG-1801, "Generic Aging Lessons Learned (GALL) Report," Volume 2, Revision 2 (license renewal). With respect to simulated design-basis accident qualification testing for coatings, the staff notes that the applicable version of ASTM D3911 is the 1995 revision, as indicated in Appendix 1A of the AP1000 DCD.

In response to Item 2, the applicant stated that the administrative controls spelled out in its Quality Assurance Program Document (QAPD) will be applied to the coatings program. The staff finds that this will ensure compliance with the requirements of 10 CFR Part 50, Appendix B, which is a regulatory acceptance criterion of Section 6.1.2 of NUREG-0800. However, the staff notes that the QAPD references ASME NQA-1-1994 as an acceptable means to implement the requirements of 10 CFR Part 50, Appendix B, rather than ASME NQA-1-1983 as referenced by AP1000 DCD Section 6.1.2.1.6. ASME NQA-1-1994 is used as the basis for NUREG-0800 Section 17.5, "Quality Assurance Program Description - Design Certification, Early Site Permit and New License Applicants," which is applicable to the quality assurance program for a COL. Therefore, the staff finds the use of ASME NQA-1-1994 acceptable with respect to quality assurance requirements for coatings.

The staff finds the response to Item 3 acceptable because the applicant indicated the consolidated plant coating program will be in place to address procurement, application, and monitoring (maintenance) of those coating system(s) for the life of the plant, prior to initial fuel loading. During the construction phase, the requirements for the coating program will be contained in certified drawings and/or standards and specifications controlling the coating processes, which meets the requirements of 10 CFR Part 50, Appendix B, Criterion III with respect to design control and instructions, Criterion IV with respect to procurement document control, and Criterion V with respect to procedures and drawings.

The applicant also provided proposed changes to BLN COL FSAR Section 6.1.2.1.6 to incorporate the information included in the response to RAI 6.1.2-1. The staff confirmed that FSAR Section 6.1.2.1.6 has been revised to include information on the quality assurance program. However, since the information proposed to be added does not include the detailed information on control of coatings during the design and construction phase, the staff identified Open Item 6.1.2-1 to ensure that BLN COL FSAR Section 6.1.2.1.6 is revised to include the information from the response to RAI 6.1.2-1, Item 3, related to control of the coating program during the design and construction phase and the schedule for full implementation of the consolidated coatings program.

<u>*Resolution of Standard Content Open Item 6.1.2-1*</u>

Standard Content Open Item 6.1.2-1 was identified by the staff because the information the BLN applicant provided about the control of coatings during the *design and construction phase, although acceptable, was not included in the BLN COL FSAR. In the July 2, 2010, letter, the VEGP applicant proposed inserting the three paragraphs below in Section 6.1.2.1.6 of the VEGP FSAR. These paragraphs would replace the third paragraph under "Service Level I and Service Level III Coatings" in DCD Section 6.1.2.1.6.*

> *During the design and construction phase, the coatings program associated with selection, procurement and application of safety related coatings is performed to applicable quality standards. The requirements for the coatings program are contained in certified drawings and/or standards and specifications controlling the coating processes of the designer (Westinghouse) (these design documents will be available prior to the procurement and application of the coating material by the constructor of the plant). Regulatory Guide 1.54 and ASTM D5144 ([FSAR] Reference 201) form the basis for the coatings program.*
>
> *During the operations phase, the coatings program is administratively controlled in accordance with the quality assurance program implemented to satisfy 10 CFR Part 50, Appendix B, and 10 CFR Part 52 requirements. The coatings program provides direction for the procurement, application, inspection, and monitoring of safety related coating systems. Prior to initial fuel loading, a consolidated plant coatings program will be in place to address procurement, application, and monitoring (maintenance) of those coating system(s) for the life of the plant.*
>
> *Coating system monitoring requirements for the containment coating systems are based on ASTM D5163 ([FSAR] Reference 202), "Standard Guide for Establishing Procedures to Monitor the Performance of Coating Service Level I Coating Systems in an Operating Nuclear Power Plant," and ASTM D7167 ([FSAR] Reference 203), "Standard Guide for Establishing Procedures to Monitor the Performance of Safety-Related Coating Service Level III Lining Systems in an Operating Nuclear Power Plant." Any anomalies identified during coating inspection or monitoring are resolved in accordance with applicable quality assurance requirements.*

As discussed above in the portion of the staff's evaluation reproduced from Section 6.1.2.4 of the BLN SER, the staff found the COL information related to control of coatings during the design and construction phase acceptable. The staff finds that the FSAR revisions proposed above are consistent with the information reviewed for the BLN SER and applicable to VEGP. Therefore, the staff finds the FSAR revisions proposed in the July 2, 2010, letter, acceptable for closing Open Item 6.1.2-1. The incorporation of these proposed revisions is being tracked as Confirmatory Item 6.1-1.

<u>Resolution of Standard Content Confirmatory Item 6.1-1</u>

Confirmatory Item 6.1-1 is an applicant commitment to revise its FSAR Section 6.1.2.1.6 to provide information regarding Service Level I and Service Level III coatings. The Staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 6.1-1 is now closed.

<u>Evaluation of Additional Design Information</u>

As discussed above, AP1000 DCD Section 6.1.3.2 requires the COL applicants to provide a program for procurement, application, and monitoring of Service Level I and Service Level III coatings consistent with DCD Section 6.1.2.1.6. However, DCD Section 6.1.2.1.6 also states that COL applicants will also address the program for Service Level II coatings, and that coatings programs for Service Level I, II, and III will include inspection. Therefore, in a letter dated March 31, 2010, the AP1000 DCD applicant proposed the following revision to DCD Section 6.1.3.2:

> *The Combined License applicants referencing the AP1000 will provide programs to control procurement, application, inspection, and monitoring of Service Level I, Service Level II, and Service Level III coatings. The programs for the control of the use of these coatings will be consistent with subsection 6.1.2.1.6.*

In letters dated July 2 and August 13, 2010, the VEGP applicant addressed the addition of Service Level II to the COL information item by proposing the following additions to Section 6.1.2.1.6 of the VEGP COL FSAR. The first is a new second paragraph under "Service Level II Coatings" in DCD Section 6.1.2.1.6.

> *Such safety-related Service Level II coatings used inside containment are procured to the same standards as Service Level I coatings with regard to radiation tolerance and performance under design basis accident conditions as discussed below.*

The second addition replaces the second sentence of the third paragraph under "Service Level II Coatings" in DCD Section 6.1.2.1.6.

> *Coating system application, inspection, and monitoring requirements for the Service Level II coatings used inside containment will be performed in accordance with a program based on ASTM D5144 ([FSAR] Reference 201), "Standard Guide for Use of Protective Coating Standards in Nuclear Power Plants," and the guidance of ASTM D5163 ([FSAR] Reference 202), "Standard Guide for Establishing Procedures to Monitor the Performance of Coating Service Level I Coating Systems in an Operating Nuclear Power Plant." Any anomalies identified during coating inspection or monitoring are resolved in accordance with applicable quality requirements.*

The NRC staff finds it acceptable to procure Service Level II coatings in containment to the same standards as Service Level I coatings because the staff, through RG 1.54, has endorsed the use of these standards to procure safety-related coatings inside containment. The staff also finds it acceptable to use ASTM D5144 and D5163 as a basis for application, inspection, and monitoring requirements for Service Level II coatings. As discussed in RG 1.54, ASTM D5144 is a top-level standard that provides general guidance on coating programs and detailed guidance by reference to other ASTM standards. Since it contains a single set of application requirements for all coatings, the staff finds it an acceptable basis for Service Level II coatings application and inspection. The staff finds ASTM D5163 acceptable for monitoring Service Level II coatings in containment because the use of ASTM D5163 conforms to the guidance in RG 1.54 for monitoring the performance of safety-related (Service Level I) coatings in containment, and there is no separate standard for Service Level II coatings. The incorporation of the proposed revisions to address Service Level II coatings into a future revision of the VEGP COL FSAR is being tracked as Confirmatory Item 6.1-2

Resolution of Standard Content Confirmatory Item 6.1-2

Confirmatory Item 6.1-2 is an applicant commitment to revise its FSAR Section 6.1.2.1.6 to provide information regarding the procurement of Service Level II coatings. The staff verified that the VEGP COL FSAR was appropriately revised. As a result, Confirmatory Item 6.1-2 is now closed.

6.1.2.5 *Post Combined License Activities*

There are no post COL activities related to this section.

6.1.2.6 *Conclusion*

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to protective coatings and other organic materials inside containment, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. The staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and meets the requirements of 10 CFR Part 50, Appendix B, and the guidance provided in RG 1.54, Revision 1. STD COL 6.1-2 is acceptable because the coating program meets a 10 CFR Part 50, Appendix B, quality assurance program, with the additional guidance provided in RG 1.54, Revision 1, and provides adequate controls over the programs to control procurement, application, inspection, and monitoring of Service Level I, Service Level II, and Service Level III coatings.

6.2 Containment Systems

6.2.1 Introduction

The containment systems (CSs), which include the primary containment, passive cooling system (heat removal system), isolation system, hydrogen control system, and leak rate test system, are discussed in this section. The containment encloses the reactor system and is the final barrier against the release of significant amounts of radioactive fission products in the event of an accident. The containment structure must be capable of withstanding, without loss of function, the pressure and temperature conditions resulting from postulated loss-of-coolant, steam line break, or feed water line break accidents. The containment structure must also maintain functional integrity in the long term following a postulated accident (i.e., it must remain a low leakage barrier against the release of fission products for as long as postulated accident conditions require).

6.2.2 Summary of Application

WLS COL FSAR, Revision 11, Section 6.1.2.4, incorporates by reference AP1000 DCD, Revision 19, Section 6.2. AP1000 DCD Section 6.2 includes Sections 6.2.1, “Containment Functional Design”; 6.2.2, “Passive Containment Cooling System”; 6.2.3, “Containment Isolation System”; 6.2.4, “Containment Hydrogen Control System”; and 6.2.5, “Containment Leak Rate Test System.” AP1000 DCD Section 6.2.5, is evaluated by the staff in NUREG-1793, Section 6.2.6. NUREG-1793 also includes the staff’s evaluation of fracture prevention of the containment pressure boundary in accordance with NUREG-0800, Section 6.2.7, and in-containment refueling water storage tank (IRWST) hydrodynamic loads. The staff’s evaluation of fracture prevention of the containment pressure boundary is found in Section 3.8 of this report. With respect to the hydrodynamic loads, the staff’s evaluation is discussed in NUREG-1793, Section 6.2.8. The staff’s evaluation of the containment cleanliness program associated with Generic Safety Issue (GSI)-191, “Assessment of Debris Accumulation on PWR [Pressurized-Water Reactor] Sump Performance,” is evaluated in Section 6.3 of this report.

WLS COL FSAR Table 1.9-203, “Listing of Unresolved Safety Issues and Generic Safety Issues,” includes a line item for Task Action Plan Item A-23, “Containment Leak Testing.” This item is addressed in WLS COL FSAR Section 6.2.5.1. In addition, in WLS COL FSAR Section 6.2, and in WLS COLA Part 10, the applicant provided information to address the following:

Departures

- WLS DEP 6.2-1

The applicant provided additional information in Section 6.2.4.5.1 of the WLS COL FSAR about WLS DEP 6.2-1 related to changes to the acceptance criteria applied to a specific ITAAC design commitment and associated inspection, test, or analysis in Tier 1 Table 2.3.9-3, Item 3 (for control of containment hydrogen concentration for beyond-design-basis accidents) to establish consistency with the current detailed design of the plant. This information, as well as related

WLS DEP 6.2-1 information appearing in other chapters of the FSAR, is reviewed in Section 21.4 of this SER.

AP1000 COL Information Item

- STD COL 6.2-1

The applicant provided information in STD COL 6.2-1 to address AP1000 COL Information Item 6.2-1, which addresses the containment leak rate test program.

In addition to addressing the AP1000 COL information item, STD COL 6.2-1 also addresses, WLS COL FSAR Table 1.9-203, “Listing of Unresolved Safety Issues and Generic Safety Issues,” Task Action Plan Item A-23, “Containment Leak Testing.” This item is discussed in WLS COL FSAR Sections 6.2.5.1, ”Design Basis”; 6.2.5.2.2, “System Operation”; and 6.2.6, “Combined License Information for Containment Leak Rate Testing.”

License Conditions

- WLS COLA Part 10, “Proposed License Conditions (Including ITAAC),” License Condition 3, “Operational Program Implementation,” Section G “Fuel Loading,” Item G.8 –“Containment Leakage Rate Testing”

This proposed license condition states that the COL holder shall implement the containment leakage rate testing program prior to initial fuel load, as stated in WLS COL FSAR Table 13.4-201, “Operational Programs Required by NRC Regulations.”

- WLS COLA Part 10, “Proposed License Conditions (Including ITAAC),” License Condition 6, “Operational Program Readiness.”

This proposed license condition states that the COL holder shall provide an operational program implementation schedule to support NRC inspections. Specifically, the operational program relevant to this evaluation in Section 6.2 is WLS COL FSAR, Table 13.4-201, Item #7, “Containment Leakage Rate Testing Program.”

6.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. The acceptance criteria associated with the relevant requirements of NRC regulations for containment functional design are given in NUREG-0800, Section 6.2.1.1A. The regulatory requirements related to this section are 10 CFR Part 50, Appendix A, “General Design Criteria for Nuclear Power Plants”; General Design Criterion (GDC) 16, “Containment Design”; GDC 38, “Containment Heat Removal”; and GDC 50, “Containment Design Basis.” The acceptance criteria associated with the relevant requirements of NRC regulations for containment leak rate testing are given in NUREG-0800, Section 6.2.6. The regulatory requirements related to this section are GDC 52, “Capability for Containment Leakage Rate Testing”; GDC 53, “Provisions for Containment Testing and Inspection”; GDC 54, “Piping System Penetrating Containment”; and 10 CFR Part 50, Appendix J, “Primary Reactor Containment Leakage Testing for Water-Cooled Power Reactors.” Compliance with the requirements of 10 CFR Part 50, Appendix J, Option A, or the requirements of 10 CFR Part 50,

Appendix J, Option B, and the provisions of RG 1.163, "Performance-Based Containment Leak-Test Program," constitutes an acceptable basis for satisfying the requirements of the GDC applicable to containment leakage rate testing. In addition, the staff used guidance in Nuclear Energy Institute (NEI) 94-01, as endorsed and modified by RG 1.163, "Performance-Based Containment Leak-Test Program." The staff used the guidelines of NuStart Technical Report, AP-TR-NS01-A, Revision 2, "Containment Leak Rate Test Program," to review the containment leakage rate testing operational program.

6.2.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 6.2, and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the containment systems. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the VEGP reference COL application were equally applicable to the WLS COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR, Revision 5, to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from responses to RAIs.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.

- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the VEGP reference COL application includes evaluation material from the SER for the BLN COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 6.2.4:

<u>AP1000 COL Information Item</u>

- *STD COL 6.2-1*

The NRC staff reviewed STD COL 6.2-1 related to COL Information Item 6.2-1 included under Section 6.2.5 of the BLN COL FSAR regarding the text added to Section 6.2.6 of the COL application. The added text references the program, which was reviewed and approved by the NRC in a letter from Stephanie Coffin, NRC, to Marilyn Kray, NuStart, "Final Safety Evaluation for AP1000 Technical Report No. AP-TR-NS01, Containment Leak Rate Test Program (TAC No. MD5136)," dated October 25, 2007.

<u>License Conditions</u>

- *Part 10, License Condition 3, Item G.<u>8</u>*

- *Part 10, License Condition 6*

The portion of License Conditions 3 and 6 relevant to this SER section is the containment leakage rate testing program listed in BLN COL FSAR Table 13.4-201. As noted in Section 13.4 of this SER, the containment leakage rate testing program meets the criteria for an operational program as specified in SECY-05-0197, "Review of Operational Programs in a Combined License Application and Generic Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria." Therefore, the NRC staff finds License Conditions 3 and 6 acceptable, with respect to the inclusion of the containment leakage rate testing program in Table 13.4-201.

Due to discrepancies in the implementation milestones provided in various locations in the BLN COL application, RAI 6.2.6-1 was forwarded to the applicant. The applicant's response was that the milestones were meant to reflect the implementation of an approved testing program and when the tests were actually to be performed. However, the applicant agreed that this was not consistently reflected. The discrepancies have been addressed in BLN COL FSAR, Table 13.4-201, Sheet 2 of 7, and Part 10, License Conditions and ITAAC. The changes indicate that the containment leak rate testing program will be implemented prior to initial fuel load. This RAI is closed.

6.2.5 Post Combined License Activities

For the reasons discussed in the technical evaluation section above, the staff finds the following license conditions related to the containment leakage rate testing program acceptable:

- License Condition (6-1) – The licensee shall implement the containment leakage rate testing program before initial fuel load.

- License Condition (6-2) – No later than 12 months after issuance of the COL, the licensee shall submit to the appropriate Director of the Office of New Reactors (NRO) a schedule that supports planning for and conduct of NRC inspections of the containment leakage rate testing program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the containment leakage rate testing program has been fully implemented.

6.2.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant addressed the required information relating to the containment systems, and there is no outstanding information expected to be addressed in the WLS COL FSAR related to this section. The results of the staff's technical evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements. In addition, the staff concludes that the relevant information presented in the WLS COL FSAR is acceptable and conforms to the guidance in NUREG-0800, Sections 6.2.1 and 6.2.6. The staff based its conclusion on the following:

- WLS DEP 6.2-1, related to changes to the acceptance criteria applied to a specific ITAAC design commitment and associated inspection, test, or analysis in Tier 1 Table 2.3.9-3, Item 3 (for control of containment hydrogen concentration for beyond-design-basis accidents) to establish consistency with the current detailed design of the plant, is reviewed and found acceptable by the staff in Section 21.4 of this SER.

- STD COL 6.2-1, as related to the containment leak rate testing program, is acceptable because the staff has determined that the requirements of 10 CFR Part 50, Appendix J, have been met.

6.3 Passive Core Cooling System

6.3.1 Introduction

The passive core cooling system is designed to provide emergency core cooling to mitigate design-basis events that involve a decrease in the reactor coolant system (RCS) inventory, such as a loss-of-coolant accident (LOCA), a decrease in heat removal by the secondary system, such as a feedwater system piping failure, or an increase in heat removal by the secondary system, such as a steam system piping failure. It also provides core cooling for shutdown events, such as a loss of the normal residual heat removal system during a shutdown operation. The passive core cooling system is designed to perform the following safety-related functions:

- emergency core decay heat removal
- RCS emergency makeup and boration
- safety injection
- containment sump pH control

During long-term operation, the AP1000 passive core cooling system must withstand the effects of debris loading on the containment recirculation screens IRWST screens and the fuel assemblies. The concern that debris may lead to unacceptable head loss for the recirculating flow was raised in GSI-191 and it is the topic of BL 2003-01, "Potential Impact of Debris Blockage on Emergency Sump Recirculation at Pressurized-Water Reactors," and Generic Letter (GL) 2004-02, "Potential Impact of Debris Blockage on Emergency Recirculation during

Design Basis Accidents at Pressurized-Water Reactors." Section 6.3 of the AP1000 DCD includes an evaluation of this issue and Section 6.2.1.8 of NUREG-1793, "Final Safety Evaluation Report Related to Certification of the AP1000 Standard Design," includes the staff's review, which was performed in accordance with the NRC-approved evaluation methodology.

In order to support long term operation in a closed loop configuration, the AP1000 passive core cooling system must also achieve a sufficient condensate return rate such that inventory in the IRWST is maintained in order to retain the heat transfer capability of the passive residual heat removal (PRHR) heat exchanger (HX) (and return condensate to the sump during recirculation). Water is steamed from the IRWST during transients that require the PRHR-HX to remove decay heat from the RCS. The steam that reaches the containment shell condenses and returns to the IRWST through a gutter system. WLS DEP 3.2-1, a departure from the AP1000 DCD requested by the applicant reviewed in Section 21.1 of this report, proposes design changes to improve condensate return to the IRWST and quantifies the condensate losses associated with the pressurizing of the containment atmosphere, condensation on heat sinks within the containment, and from dripping or splashing from structures and components attached to the containment.

6.3.2 Summary of Application

WLS COL FSAR, Revision 11, Section 6.3, incorporates by reference AP1000 DCD, Revision 19, Section 6.3. In addition, in WLS COL FSAR Section 6.3.8.1, the applicant provided the following:

Departures

- WLS DEP 3.2-1 and WLS DEP 6.3-1

The applicant provided additional information in Section 6.3 of the WLS COL FSAR about WLS DEP 3.2-1 and WLS DEP 6.3-1 related to design modifications to the condensate return portion of the Passive Core Cooling System and quantifying the duration that the PRHR-HX can maintain safe shutdown conditions, respectively. This information, as well as related WLS DEP 3.2-1 and WLS DEP 6.3-1 information appearing in other chapters of the FSAR, is reviewed in Section 21.1 of this SER.

AP1000 COL Information Items

- STD COL 6.3-1

The applicant provided information in STD COL 6.3-1 to address AP1000 COL Information Item 6.3-1 identified in AP1000 DCD Table 1.8-2, "Summary of AP1000 Standard Plant Combined License Information Items." STD COL 6.3-1 describes the features of the administrative procedures implementing a containment cleanliness program to limit the amount of debris that might be left in the containment following refueling and maintenance outages. STD COL 6.3-1 is discussed in WLS COL FSAR Section 6.3.8.1, "Containment Cleanliness Program." WLS COL FSAR Section 1.9, incorporates by reference AP1000 DCD Section 1.9, "Compliance with Regulatory Criteria." In addition, in WLS COL FSAR Section 1.9, the applicant provided the following information related to the effect of debris accumulation on long-term cooling:

- STD COL 1.9-2

The applicant provided information in STD COL 1.9-2 to address BL 03-01 and GL 04-02, both relating to the potential impact of containment debris on emergency recirculation during design basis accidents, identified in the AP1000 DCD Section 1.9.4.2.3, Table 1.9-2 and actualized in WLS COL FSAR Section 1.9.5.5, "Operational Experience," and Table 1.9-204, "Generic Communications Assessment."

- STD COL 1.9-3

The applicant provided information in STD COL 1.9-3 to address GSI-191, relating to the performance of a PWR sump during ECCS operation, identified in the AP1000 DCD Section 1.9.4.2.3, Table 1.9-2 and actualized in WLS COL FSAR Section 1.9.4.1, "Review of NRC List of Unresolved Safety Issues and Generic Safety Issues," and related Table 1.9-203.

6.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1793 and its supplements. In conducting its review of STD COL 6.3-1, the staff used the guidance and staff positions of RG 1.82, Revision 3, "Potential Impact of Debris Blockage on Emergency Recirculation during Design Basis Accidents at Pressurized-Water Reactors," and the "Safety Evaluation by the Office of Nuclear Reactor Regulation Related to NRC Generic Letter 2004-02," for NEI 04-07, "Pressurized Water Reactor Sump Performance Evaluation Methodology."

The changes proposed in WLS DEP 3.2-1 and WLS DEP 6.3-1 are also required to meet NRC general design criteria, which also apply to the AP1000 DCD, 10 CFR Part 50, Appendix A, GDC 34, "Residual heat removal," as it applies to the capability of the PRHR-HX to perform safety related safe shutdown cooling of the RCS. Additionally, WLS DEP 3.2-1 and WLS DEP 6.3-1 are required to meet GDC 44, "Cooling Water," as it applies to the ability of the containment systems to transfer heat from the PRHR-HX to the ultimate heat sink via the passive containment cooling system.

6.3.4 Technical Evaluation

The staff reviewed WLS COL FSAR Section 6.3, and checked the referenced DCD to ensure that the combination of the DCD and the COL application represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference addresses the required information relating to the passive core cooling system. The results of the staff's evaluation of the information incorporated by reference in the WLS COL application are documented in NUREG-1793 and its supplements.

Section 1.2.3 of this report provides a discussion of the strategy used by the staff to perform one technical review for each standard issue outside the scope of the DC and use this review to evaluate subsequent COL applications. To ensure that the staff's findings on standard content that were documented in the SER for the VEGP reference COL application were equally applicable to the WLS COL application, the staff undertook the following reviews:

- The staff compared the VEGP COL FSAR to the WLS COL FSAR. In performing this comparison, the staff considered changes made to the WLS COL FSAR (and other parts of the COL application, as applicable) resulting from responses to RAIs.
- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation were endorsed and that those changes were actualized in the WLS COL FSAR.
- The staff verified that the site-specific differences, if any, did not adversely affect any previous relevant evaluation or conclusion.

The staff completed its review and concluded that the evaluation performed for the standard content is directly applicable to the WLS COL application. This standard content material is identified in this report by use of italicized, double-indented formatting. Section 1.2.3 of this report provides an explanation of why the standard content material from the SER for the VEGP reference COL application includes evaluation material from the SER for the BLN COL application.

The following portion of this technical evaluation section is reproduced from VEGP SER Section 6.3.4:

> *<u>AP1000 COL Information Items</u>*
>
> - *STD COL 6.3-1*
>
> *The applicant provided additional information in STD COL 6.3-1 to address COL Action Item 6.2.1.8.1-1 identified in NUREG-1793 and COL Information Item 6.3-1 identified in Table 1.8-2 of the AP1000 DCD. The applicant added information to BLN COL FSAR Section 6.3.8.1, "Containment Cleanliness Program," providing details of the program and procedures to minimize the amount of debris that might be left in containment following refueling and maintenance outages, including requirements for cleanliness inspections and limits on materials introduced into containment. TVA states that the cleanliness program will be consistent with the evaluation discussed in the AP1000 DCD.*
>
> *In its June 9, 2009, response to [RAI 30, Question 06.02.02-1], the applicant addressed the changes made to Revision 17 of the AP1000 DCD in APP-GW-GLE-002 and staff questions on cleanliness measurements with a modification to STD COL 6.3-1. This included adding that the cleanliness program will meet the DCD limits on latent debris, that housekeeping procedures will be implemented to return work areas to original conditions upon completion of work, and that a sampling program will be used to quantify the amount of latent debris. The sampling program is stated to be consistent with NEI 04-07 Volumes 1 (guidance report) and 2 (NRC safety evaluation). The sampling will be done after containment exit cleanliness inspections, prior to start up, and the results will be evaluated post-start up. Any non-conforming results will be addressed in the Corrective Action Program.*

The resulting cleanliness program is consistent with the RG 1.82 recommendation that procedures be in place to regularly clean the containment and to control and remove foreign materials from containment. The sampling program included in STD COL 6.3-1 is required to demonstrate that the latent debris found in containment is within the AP1000 DCD specified limits of 130 pounds, of which, up to 6.6 pounds may be fibrous material. The DCD specified limits were demonstrated to be acceptable through scale testing and analysis. Thus, STD COL 6.3-1 is consistent with the RG 1.82 recommendation that the cleanliness program be correlated to the amount of debris used in the long term cooling analysis. It is appropriate that the sampling program be in accordance with NEI 04-07, Volumes 1 and 2, because these documents contain the most recent NRC-approved evaluation methodology for cleanliness programs. The response to [RAI 30, Question 06.02.02-1] is acceptable and incorporation of the changes to STD COL 6.3-1 in the BLN FSAR will be tracked as Confirmatory Item 6.3-1.

The staff reviewed the following information in the BLN COL FSAR as it relates to the effect of debris accumulation on long term cooling:

- *STD COL 1.9-3*

The applicant added information to Section 1.9.4.2.3, "New Generic Issues," regarding Issue 191. The applicant states that the design aspects are addressed by the AP1000 DCD and the COL applicant portions are the protective coatings program discussed in BLN COL FSAR Section 6.1.2.1.6 and the containment cleanliness program discussed in BLN COL FSAR Section 6.3.8.1. The staff agrees that these are the only two COL items identified in the staff's review of GSI-191 from Section 6.2.1.8 of NUREG-1793.

- *STD COL 1.9-2*

The applicant added line items for Bulletin 03-01 and GL 04-02 in Table 1.9-204, "Generic Communications Assessment." The new information states that the design aspects are addressed in the AP1000 DCD and that the COL applicant aspects are addressed in BLN COL FSAR Section 6.3 for Bulletin 03-01 and BLN COL FSAR Section 6.3.8.1 for GL 04-02. The staff agrees that the design aspects of these generic communications are addressed in the staff's review of GSI-191 from Section 6.2.1.8 of NUREG-1793. The COL applicant aspects are addressed in the staff's review of BLN COL FSAR Section 6.1.2.1.6 and BLN COL FSAR Section 6.3.8.1.

<u>Resolution of Standard Content Confirmatory Item 6.3-1</u>

Confirmatory Item 6.3-1 required the applicant to update its FSAR to include the information related to the cleanliness program provided in the BLN applicant's above-mentioned June 9, 2009, response to [RAI 30, Question 60.02.02-1] (which was endorsed by the VEGP applicant). The NRC staff verified that the VEGP COL FSAR was appropriately updated with this information. As a result, Confirmatory Item 6.3-1 is resolved.

6.3.5 Post Combined License Activities
