Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Methodology for Cross-Reference Tables
(Continued)

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).
Note:	The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

**Methodology for Cross-Reference Tables
(Continued)**

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is used to cover all sub-paragraphs (e.g., "A.1" is used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

MARK-UP OF CURRENT TS

Mark-up

<u>SPECIFICATION</u>	<u>PAGE</u>
1.1 - Definitions	1-1
1.2 - Logical Connectors.	1-9a
1.3 - Completion Times	1-9a
1.4 - Frequency	1-9a
Methodology	(2 Pages)

1.0 USE AND APPLICATION

1.01 DEFINITIONS

The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases.

01-01-A

ACTIONS

- 1.1 ACTIONS shall be that part of a Specification which ~~that~~ prescribes remedial ~~measures~~ required actions to be taken under designated conditions within ~~specified completion times~~.

01-01-A

ACTUATION LOGIC TEST

- 1.2 An ACTUATION LOGIC TEST shall be the application of various simulated or ~~actual~~ input combinations in conjunction with each possible interlock logic state and the verification of the required logic output. The ACTUATION LOGIC TEST as a ~~minimum~~ shall include a continuity check as a ~~minimum~~ of output devices.

01-01-A

CHANNEL OPERATIONAL TEST (COT)

- 1.3 A CHANNEL OPERATIONAL TEST (COT) shall be the injection of a simulated or ~~actual~~ signal into the channel as close to the sensor as practicable to verify the OPERABILITY of the required alarm, interlock, including all components in the channel such as alarms, interlocks, displays, and/or trip functions required to perform the specified safety function(s). The COT may be performed by means of any series of sequential, overlapping, or total channel steps so that the entire channel is tested. The CHANNEL OPERATIONAL TEST (COT) shall include adjustments, as necessary, of the required alarm, interlock and/or trip setpoints such so that the setpoints are within the required range and accuracy.

01-01-A

01-32-A

01-30-A

AXIAL FLUX DIFFERENCE (AFD)

- 1.4 AXIAL FLUX DIFFERENCE (AFD) shall be the difference in normalized flux signals between the top and bottom halves of an ~~two-section~~ excore neutron detector.

01-01-A

CHANNEL CALIBRATION

- 1.5 A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel such so that it responds within the required range and accuracy to known values of input. The CHANNEL CALIBRATION shall encompass the entire channel including the required sensor, s and alarm, interlock and/or trip functions, those components such as sensors, alarms, displays, and trip functions required to perform the specified safety function(s), and may be performed by any series of sequential, overlapping calibrations or total channel steps such that the entire channel is

01-32-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

calibrated. Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an in-place qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel. Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION shall include an in-place cross calibration that compares the other sensing elements with the recently installed sensing element.

01-03-M

CHANNEL CHECK

- 1.6 A CHANNEL CHECK shall be the qualitative assessment ~~by observation~~ of channel behavior during operation ~~by observation~~. This determination shall include, where possible, comparison of the channel indication and/or status with ~~to~~ other indications and/or status derived from independent instrument channels measuring the same parameter.

01-01-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

CHANNEL FUNCTIONAL TEST

1.7 A CHANNEL FUNCTIONAL TEST shall be:

- a. Analog channels - the injection of a simulated or actual signal into the channel as close to the sensor as practicable to verify OPERABILITY including required alarm and/or trip functions, or 01:01-A
- b. Bistable channels - the injection of a simulated or actual signal into the sensor to verify OPERABILITY including required alarm and/or trip functions, or 01:01-A
- c. Digital channels - the injection of a simulated or actual signal into the channel as close to the sensor input to the process racks as practical to verify OPERABILITY including required alarm and/or trip functions. 01:01-A

The Channel Functional Test may be performed by means of any series of sequential overlapping, or total channel steps so that the entire channel is tested. 01:30-A

CONTAINMENT INTEGRITY

01:04-A

~~1.8 CONTAINMENT INTEGRITY shall exist when:~~

- ~~a. All penetrations required to be closed during accident conditions are either:
 - ~~1. Capable of being closed by an OPERABLE containment automatic isolation valve system, or~~
 - ~~2. Closed by manual valves, blind flanges, or deactivated automatic valves secured in their closed positions, except for valves that are open under administrative control as permitted by Specification 3.6.3.~~~~
- ~~b. All equipment hatches are closed and sealed,~~
- ~~c. Each air lock is in compliance with the requirements of Specification 3.6.1.3,~~
- ~~d. The containment leakage rates are within the limits of specification 3.6.1.2, and~~
- ~~e. The sealing mechanism associated with each penetration (e.g., welds, bellows or O rings) is OPERABLE.~~

CONTROLLED LEAKAGE

01:05-A

~~1.9 CONTROLLED LEAKAGE shall be that seal water flow supplied to the reactor coolant pump seals.~~

1.0 USE AND APPLICATION

1.01 DEFINITIONS

CORE ALTERATIONS

- 1.10 CORE ALTERATIONS shall be the movement or manipulation of any fuel, sources, or reactivity control components within the reactor vessel with the vessel head removed and fuel in the vessel. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe conservative position.

01-33A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

DOSE EQUIVALENT I-131

- 1.11 DOSE EQUIVALENT I-131 shall be that concentration of I-131 (microcuries/gram) which that alone would produce the same thyroid dose as the quantity and isotopic mixture of I-131, I-132, I-133, I-134, and I-135 actually present.

The thyroid dose conversion factors used for this calculation shall be those listed in Table III of TID-14844, AEC, 1962, "Calculation of Dose Factors for Power and Test Reactor Sites" or those listed in Table E-7 of NRC Regulatory Guide 1.109, Revision 1, October 1977.

01-07-A

E - AVERAGE DISINTEGRATION ENERGY

- 1.12 \bar{E} shall be the average (weighted in proportion to the concentration of each radionuclide in the sample reactor coolant at the time of sampling) of the sum of the average beta and gamma energies per disintegration (in MeV/d) for the radionuclides in the sample isotopes, other than iodines, with half-lives greater than 10 minutes making up at least 95% of the total non-iodine activity in the coolant.

01-01-A

ENGINEERED SAFETY FEATURES (ESF) RESPONSE TIME

- 1.13 The ENGINEERED SAFETY FEATURES (ESF) RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays where applicable. The response time may be verified by means of any series of sequential overlapping or total steps so that the entire response time is verified.

01-08-A

ENVIRONMENTAL RADIOLOGICAL MONITORING PROCEDURE

- 1.14 The ENVIRONMENTAL RADIOLOGICAL MONITORING PROCEDURE (ERMP) shall contain a description of sample locations, types of sample locations, methods and frequency of analysis, and reporting requirements.

01-13-A

FREQUENCY NOTATION

- 1.15 The FREQUENCY NOTATION specified for the performance of Surveillance Requirements shall correspond to the intervals defined in Table 1.1.

01-09-A

GASEOUS RADWASTE SYSTEM

- 1.16 A GASEOUS RADWASTE SYSTEM shall be any system designed and installed to

01-31-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

~~reduce radioactive gaseous effluents by collecting Reactor Coolant System off-gases from the Reactor Coolant System and providing for delay or holdup for the purpose of reducing the total radioactivity prior to release to the environment.~~

(new) L_1 The maximum allowable primary containment leakage rate, L_1 , shall be 0.10 % of primary containment air weight per day at the calculated peak containment pressure (P_1)

1-10-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

IDENTIFIED LEAKAGE shall be:

1.17 a. ~~IDENTIFIED~~ ~~Identified~~ LEAKAGE shall be:

- 1 a. ~~Leakage, except CONTROLLED LEAKAGE, into closed systems, LEAKAGE such as that from pump seals or valve packing leaks (except reactor coolant pump (RCP) seal water injection or leakoff) that are captured and conducted to a collection systems or a sump or collecting tank; or~~ 01-11-A
- 2 b. ~~Leakage~~ LEAKAGE into the containment atmosphere from sources that are both specifically located and known either not to interfere with the operation of leakage detection systems or not to be ~~PRESSURE BOUNDARY~~ ~~pressure boundary~~ LEAKAGE; or
- 3 e. ~~Reactor Coolant System leakage (RCS) LEAKAGE through a steam generator (SG) to the Secondary Coolant System.~~

b. Unidentified LEAKAGE

~~All LEAKAGE (except RCP seal water injection or leakoff) that is not identified LEAKAGE.~~ 01-11-A

c. Pressure Boundary LEAKAGE

~~LEAKAGE (except SG LEAKAGE) through a nonisolable fault in an RCS component body, pipe wall, or vessel wall.~~

MASTER RELAY TEST

1.18 A MASTER RELAY TEST shall be ~~the energization of~~ ~~consist of energizing~~ each master relay and ~~verification of~~ ~~verifying the~~ OPERABILITY of each relay. The MASTER RELAY TEST shall include a continuity check of each associated slave relay. 01-01-A

MEMBER(S) OF THE PUBLIC

1.19 ~~MEMBER(S) OF THE PUBLIC shall include all persons who are not occupationally associated with the plant. This category does not include employees of the licensee, its contractors, or vendors. Also excluded from this category are persons who enter the site to service equipment or to make deliveries. This category does include persons who use portions of the site for recreational, occupational, or other purposes not associated with the plant.~~ 01-12-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

OFFSITE DOSE CALCULATION PROCEDURE

01-13-A

~~1.20 The OFFSITE DOSE CALCULATION PROCEDURE (ODCP) shall contain the methodology and parameters used in the calculation of offsite doses due to radioactive gaseous and liquid effluents and in the calculation of gaseous and liquid effluent monitoring Alarm/Trip Setpoints.~~

OPERABLE - OPERABILITY

1.21 A system, subsystem, train, component or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified safety function(s) and when all necessary attendant instrumentation, controls, normal or emergency electric power, cooling or seal water, lubrication or other auxiliary equipment that are required for the system, subsystem, train, component or device to perform its specified safety function(s) are also capable of performing their related support function(s).

01-01-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

OPERATIONAL MODE — MODE

1.22 An OPERATIONAL MODE (i.e., MODE) shall correspond to any one inclusive combination of core reactivity condition, power level and average reactor coolant temperature and reactor vessel head closure bolt tensioning specified in Table 1-2 1 1-1 with fuel in the reactor vessel

01-14-A

PHYSICS TESTS

1.23 PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation and (1) described in Chapter 14.0 of the FSAR, (2) authorized under the provisions of 10 CFR 50.59, or (3) otherwise approved by the Nuclear Regulatory Commission.

01-25-LS2

01-01-A

PRESSURE BOUNDARY LEAKAGE

~~1.24 PRESSURE BOUNDARY LEAKAGE shall be leakage, except steam generator tube leakage, through a non isolable fault in a Reactor Coolant System component body, pipe wall or vessel wall.~~

01-11-A

PROCESS CONTROL PROGRAM

~~1.25 The PROCESS CONTROL PROGRAM (PCP) shall contain the current formulas, sampling, analyses, tests, and determinations to be made to ensure that processing and packaging of solid radioactive wastes based on demonstrated processing of actual or simulated wet solid wastes will be accomplished in such a way as to assure compliance with 10 CFR Parts 20, 61, and 71 and Federal and State regulations, burial ground requirements, and other requirements governing the disposal of solid radioactive waste.~~

01-16-LG

PURGE — PURGING

~~1.26 PURGE or PURGING shall be the controlled process of discharging air or gas from a confinement to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air or gas is required to purify the confinement.~~

01-15-A

(new)

PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR)

The PTLR is the unit specific document that provides the reactor vessel pressure and temperature limits, including heatup and cooldown rates, and the power operated relief valve (PORV) lift settings and enable temperature associated with the Low Temperature Over pressurization Protection (LTOP) System, for the current reactor vessel fluence period. These pressure and temperature limits shall be determined for each fluence period in accordance with ITS Specification 5.6.6. Plant operation within these operating limits is addressed in individual specifications.

01-17-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

QUADRANT POWER TILT RATIO (QPTR)

- 1.27 ~~QUADRANT POWER TILT RATIO QPTR~~ shall be the ratio of the maximum upper excore detector calibrated output to the average of the upper excore detector calibrated outputs, or the ratio of the maximum lower excore detector calibrated output to the average of the lower excore detector calibrated outputs, whichever is greater. ~~With one excore detector inoperable, the remaining three detectors shall be used for computing the average.~~
- 01-01-A
- 01-18-A

RATED THERMAL POWER (RTP)

- 1.28 ~~RATED THERMAL POWER RTP~~ shall be a total reactor core heat transfer rate to the reactor coolant of 3338 Mwt for Unit 1 and 3411 Mwt for Unit 2.
- 01-01-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

REACTOR TRIP SYSTEM (RTS) RESPONSE TIME

1.29 The REACTOR TRIP SYSTEM RTS RESPONSE TIME shall be the time interval from when the monitored parameter exceeds its RTS trip setpoint at the channel sensor until loss of stationary gripper coil voltage. The response time may be verified by means of any series of sequential, overlapping, or total steps so that the entire response time is verified.

01-08-A

REPORTABLE EVENT

~~1.30 A REPORTABLE EVENT shall be any of those conditions specified in Section 50.73 of 10 CFR Part 50.~~

01-19-A

SHUTDOWN MARGIN (SDM)

1.31 SHUTDOWN MARGIN SDM shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming:

- a) All full-length rod cluster control assemblies (RCCAs) (shutdown and control) are fully inserted except for the single rod cluster assembly (RCCA) of highest reactivity worth which is assumed to be fully withdrawn. With any RCCA not capable of being fully inserted, the reactivity worth of the RCCA must be accounted for in the determination of SDM; and
- b) In MODES 1 and 2, the fuel and moderator temperatures are changed to the hotzero power temperatures.

01-20-M

01-20-M

SITE BOUNDARY

~~1.32 SITE BOUNDARY shall be that line as shown in Figure 5.1-3.~~

01-24-A

SLAVE RELAY TEST

1.33 A SLAVE RELAY TEST shall be the energization of consist of energizing each slave relay and verification of verifying the OPERABILITY of each slave relay. The SLAVE RELAY TEST shall include, as a minimum, a continuity check, as a minimum, of associated testable actuation devices.

01-01-A

1.34 Deleted

1.0 USE AND APPLICATION

1.01 DEFINITIONS

SOURCE CHECK

~~1.35 A SOURCE CHECK shall be the qualitative assessment of channel response when the channel sensor is exposed to a source of increased radioactivity.~~

01-22-A

STAGGERED TEST BASIS

1.36 A STAGGERED TEST BASIS shall consist of ~~the testing of one of the~~

- a. ~~A test schedule for n systems, subsystems, trains channels or other designated components obtained by dividing the specified test interval into n equal sub-intervals, and during the interval specified by the surveillance frequency, so that all systems, subsystems, channels, or other designated components are tested during n surveillance frequency intervals, where n is the total number of systems, subsystems, channels, or other designated components in the associated function.~~
- b. ~~The testing of one system, subsystem, train or other designated component at the beginning of each sub-interval.~~

01-23-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

THERMAL POWER

1.37 THERMAL POWER shall be the total reactor core heat transfer rate to the reactor coolant.

TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT)

1.38 A ~~TRIP ACTUATING DEVICE OPERATIONAL TEST TADOT~~ shall consist of operating the ~~7~~ trip A actuating ~~0~~ device and verifying OPERABILITY, including all components in the channel, such as alarms, interlocks, displays and/or trip functions required to perform the specified safety function(s). ~~The TADOT may be performed by means of any series of sequential, overlapping, or total channel steps so that the entire channel is tested. The TRIP ACTUATING DEVICE OPERATIONAL TEST TADOT shall include adjustment, as necessary, of the 7 trip A actuating 0 device such so that it actuates at the required setpoint within the required accuracy.~~

01-01-A

01-32-A

01-30-A

UNIDENTIFIED LEAKAGE

~~1.39 UNIDENTIFIED LEAKAGE shall be all leakage which is not IDENTIFIED LEAKAGE or CONTROLLED LEAKAGE.~~

01-11-A

UNRESTRICTED AREA

~~1.40 An UNRESTRICTED AREA shall be any area at or beyond the SITE BOUNDARY access to which is not controlled by the licensee for purposes of protection of individuals from exposure to radiation and radioactive materials, or any area within the SITE BOUNDARY used for residential quarters or for industrial, commercial, institutional, and/or recreational purposes.~~

01-24-A

VENTILATION EXHAUST TREATMENT SYSTEM

~~1.41 A VENTILATION EXHAUST TREATMENT SYSTEM shall be any system designed and installed to reduce gaseous radioiodine or radioactive material in particulate form in effluents by passing ventilation or vent exhaust gases through charcoal adsorbers and/or HEPA filters for the purpose of removing iodines or particulates from the gaseous exhaust stream prior to the release to the environment. Such a system is not considered to have any effect on noble gas effluents. Engineered Safety Features Atmospheric Cleanup Systems are not normally considered to be VENTILATION EXHAUST TREATMENT SYSTEM components.~~

01-15-A

1.0 USE AND APPLICATION

1.01 DEFINITIONS

VENTING

~~1.42 VENTING shall be the controlled process of discharging air or gas from a confinement to maintain temperature, pressure, humidity, concentration, or other operating condition, in such a manner that replacement air or gas is not provided or required during VENTING. Vent, used in system names, does not imply a VENTING process.~~

01-15-A

CORE OPERATING LIMITS REPORT (COLR)

~~1.43 The CORE OPERATING LIMITS REPORT COLR is the unit specific document that provides core operating cycle specific parameter limits for the current operating reload cycle. These cycle specific core operating parameter limits shall be determined for each reload cycle in accordance with Specification 6.9.1.8 5.6.5. Unit Plant operation within these operating limits is addressed in individual specifications.~~

01-01-A

RADIOLOGICAL MONITORING AND CONTROLS PROGRAM

~~1.44 The RADIOLOGICAL MONITORING AND CONTROLS PROGRAM (RMCP) shall contain (1) the Radioactive Effluent Controls and Radiological Environmental Monitoring Programs required by Section 6.8.4 and (2) descriptions of the information that should be included in the Annual Radiological Environmental Operating and Annual Radioactive Effluent Release Reports required by Specifications 6.9.1.5 and 6.9.1.6.~~

1.3. Completion Times and

1.4. Frequency

are new sections which will be incorporated in the IIS in their entirety. See the corresponding sections in Enclosure 5A.

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. Deletions - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. Additions - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. Modifications - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. Administrative - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

**Methodology For Mark-Up of Current TS
(Continued)**

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

ENCLOSURE 3A

DESCRIPTION OF CHANGES TO CURRENT TS

Technical Specification Conversion Change Numbers

None

Description of Changes

(5 Pages)

DESCRIPTION OF CHANGES TO TS SECTION 1.0

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	These definitions would be reworded to be consistent with NUREG-1431. The proposed rewording included in this category does not involve any changes of a technical nature.
01-02	A	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-03	M	The definition of CHANNEL CALIBRATION is reworded to be consistent with NUREG-1431. The revised wording provides additional detail concerning calibration of instrument channels with resistance temperature detector (RTDs) or thermocouples.
01-04	A	The definition of CONTAINMENT INTEGRITY would no longer be used and the specifications in ITS Section 3.6 and the Administrative Controls Section would be revised accordingly. The CTS definition for CONTAINMENT INTEGRITY would be deleted to be consistent with NUREG-1431. This definition is effectively incorporated into the NUREG-1431 Bases for the new Containment Limiting Condition for Operation (LCO) (ITS 3.6.1) and the Administrative Controls Section for the Containment Leakage Testing Program [].
01-05	A	The current definition for CONTROLLED LEAKAGE would be in accordance with NUREG-1431. This definition will no longer be required for the ITS because LCO 3.5.5 ensures that reactor coolant pump (RCP) seal injection flow remains within limits. Therefore, this change is not technical and has been categorized as administrative.
01-06	LS1	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B)
01-07	A	The location of the thyroid dose conversion factors used for the calculation of DOSE EQUIVALENT I-131 have been added in accordance with NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 1.0

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-08	A	The CTS definitions for ENGINEERED SAFETY FEATURES (ESF) RESPONSE TIME and REACTOR TRIP SYSTEM (RTS) RESPONSE TIME would be modified to be consistent with NUREG-1431. In addition, the term "measured" would be replaced by "verified" to be consistent with the requirements of ITS Surveillance Requirement (SR) 3.3.1.16 and SR 3.3.2.10 to verify response time is within limits. The addition of the statement that response time may be verified by means of any series of sequential, overlapping, or total steps so that the entire response time is verified, is administrative in nature. This is consistent with the methodology presently described in the CTS Bases for demonstrating total channel response time.
01-09	A	The CTS definition for FREQUENCY NOTATION (and Table 1.1, FREQUENCY NOTATION) would be deleted to be consistent with NUREG-1431. The acronyms defined in Table 1.1, FREQUENCY NOTATION, are no longer used in NUREG-1431. Surveillance frequencies are specified in NUREG-1431; thereby, obviating the definition. This is a nontechnical change made to conform to NUREG-1431.
01-10	A	The definition for maximum allowable primary containment leakage rate (L_p) would be added in the ITS to be consistent with NUREG-1431. This addition has been determined to be an administrative change on the basis that this definition has simply been [copied] from the [CTS Administrative Controls 6.8.4.j] to the definitions.
01-11	A	The CTS definitions for IDENTIFIED LEAKAGE, UNIDENTIFIED LEAKAGE, and PRESSURE BOUNDARY LEAKAGE have been merged into one definition for LEAKAGE and reworded to be consistent with NUREG-1431. This is a nontechnical change since it will not alter the manner in which LEAKAGE is accounted for and treated from present practice. The definition of UNIDENTIFIED LEAKAGE has been expanded to include "except RCP seal water [injection or leakoff,]" to be consistent with NUREG-1431.
01-12	A	The CTS definition for MEMBER OF THE PUBLIC, would be deleted to be consistent with NUREG-1431. This definition would be deleted on the basis that it is defined in 10 CFR 20.1003 and 40 CFR 190.
01-13	A	The CTS definition of the Offsite Dose Calculation Manual (ODCM) [OFFSITE DOSE CALCULATION PROCEDURE (ODCP), ENVIRONMENTAL RADIOLOGICAL MONITORING PROCEDURE (ERMP), and RADIOLOGICAL MONITORING AND CONTROLS PROGRAM (RMCP)] would be [merged where duplications occur and would be] incorporated into the Administrative Controls Section 5.5.1 of the ITS. [These] changes [are] nontechnical because the definitions of the ODCM [ODCP, ERMP, AND RMCP] will be [combined and] moved to another section of the ITS.

DESCRIPTION OF CHANGES TO TS SECTION 1.0

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-14	A	The CTS definition for OPERATIONAL MODE would be revised to "MODE" and the wording would be revised to be consistent with NUREG-1431. The changes are nontechnical since they will not affect current practice.
01-15	A	The CTS definitions of heating, ventilation, and air conditioning (HVAC) systems and functions would be deleted to be consistent with NUREG-1431. "[Ventilation Exhaust Treatment System,]" "PURGE -SPARE PURGING," and "VENTING," where used, do not require special definitions.
01-16	LG	The CTS definition of the PROCESS CONTROLS PROGRAM (PCP) would be moved outside of the TS along with the Administrative Controls description (CTS 6.8.1.e) of this program to be consistent with NUREG-1431. The PCP definition and program description from Administrative Controls are moved into the Final Safety Analysis Report (FSAR). The PCP implements regulatory requirements and need not be restated in the TS. The requirement to comply with applicable Federal and State regulations for the processing of radioactive waste provides sufficient control of future changes to the PCP.
01-17	A	The definition of a PRESSURE TEMPERATURE LIMITS REPORT (PTLR) would be added to be consistent with NUREG-1431 and Westinghouse Owners Group (WOG) 67, Rev. 1. The definition will support the use of a PTLR. Adding the definition is administrative in nature.
01-18	A	The portion of the QUADRANT POWER TILT RATIO (QPTR) definition dealing with an inoperable excore detector is addressed in the Conditions and SRs of ITS 3.2.4.
01-19	A	The CTS definition of REPORTABLE EVENT is not used in the ITS and would be deleted to be consistent with NUREG-1431. This definition would be deleted on the basis that a REPORTABLE EVENT is defined by 10 CFR 50.72 and 50.73. This change is administrative in nature because it will have no effect on current reporting practices.
01-20	M	The CTS definition of SHUTDOWN MARGIN (SDM) would be revised to be consistent with NUREG-1431. The requirement to account for any rod control cluster assemblies (RCCAs) not capable of being fully inserted was moved from CTS ACTION and SRs. The only substantive technical change to this definition is the addition of the requirement that in MODES 1 and 2, the fuel and moderator temperatures be changed to the hot zero power temperatures. This ensures that the power defect due to shutting the reactor down from MODES 1 or 2 is accounted for in the SDM. While this requirement is consistent with current practice, it has not been specified in the existing definition. Consequently, it has been categorized as a more restrictive change.

DESCRIPTION OF CHANGES TO TS SECTION 1.0

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-21		Not used.
01-22	A	The definition of SOURCE CHECK is deleted from the CTS in accordance with NUREG-1431. No surveillances in the ITS require SOURCE CHECKS; therefore, this is an administrative change. It will be defined where used in licensee controlled documents; however, it has not been used in the CTS since the implementation of NRC Generic Letter 89-01.
01-23	A	The CTS definition for STAGGERED TEST BASIS (STB) would be revised to be consistent with NUREG-1431. The test intervals for throughout the ITS that are to be performed on a STB will be revised to be consistent with the new definition so that there will be no net change in the CTS implementation of staggered test intervals. For example, under the CTS, if a parameter is monitored by 3 channels of instrumentation, and the test interval is quarterly, 1 channel would be tested each month during any given quarter by dividing the test interval into 3 equal sub-intervals. Under the new definition, the test interval for that same instrumentation in the ITS would be specified as monthly so that the net effect is the same. One channel would be tested each month during any given quarter.
01-24	A	The CTS definitions of SITE BOUNDARY and UNRESTRICTED AREA ARE deleted to be consistent with NUREG-1431. These definitions are deleted on the basis that they are defined in 10 CFR 20.1003.
01-25	LS2	Table 1.2 of the CTS would become Table 1.1-1 in the ITS. The following changes would be made to conform to NUREG-1431. In ITS Table 1.1-1, the notation "NA" would replace "0" under % RATED THERMAL POWER for MODES 3, 4, 5, and 6. This is a nontechnical change since with K_{eff} less than 0.99, THERMAL POWER would be zero anyway. For MODE 6, the temperature has been replaced with NA since there is no safety analysis basis for the value of 140°F specified in the CTS. Also for MODE 6, the reactivity Condition has been designated NA since the value of 0.95 is specified in the Bases of ITS 3.9.1. The temperatures for MODES 1 and 2 are designated as NA on the basis that temperature for these MODES is less restrictive than the minimum temperature for criticality and the operating program for reactor coolant system Tavg. A new Note b has been added to MODES 4 and 5 stating that the required number of reactor vessel head closure bolts are fully tensioned, and a new Note c replaces the Note applied to MODE 6. The new Note c states that the required reactor vessel head closure bolts are less than fully tensioned. The new Note c no longer specifies that fuel is in the vessel because the condition of fuel in the vessel is addressed by the definition of the term MODE. This definition stipulates that fuel be in the vessel in order to be in a "MODE." These changes are administrative, except for the new Notes b and c per Traveler TSTF-88 and addressed in NSHC LS2.

DESCRIPTION OF CHANGES TO TS SECTION 1.0

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-26	A	New Sections 1.2, 1.3, and 1.4 would be incorporated into the ITS to be consistent with NUREG-1431. Section 1.2 provides specific examples of the use of the logical connectors <u>AND</u> and <u>OR</u> and the numbering sequence associated with their use in the ITS. Section 1.3 deals with the proper use and interpretation of Completion Times, and specific examples are given that will aid the user in understanding Completion Times. Section 1.4 deals with the proper use and interpretation of surveillance Frequencies. Specific examples are given that will aid the user in understanding surveillance Frequencies as they will appear in the ITS. The proposed changes are administrative in nature and by themselves are not technical changes, incorporating Travelers WOG-74, Rev. 1, and WOG-90, Rev. 1.
01-27	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-28	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-29	LS3	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-30	A	Consistent with TSTF-39, Rev. 1, the definitions of COT, [CHANNEL FUNCTIONAL TEST (CFT)], and TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT) are expanded to include the details of acceptable performance methodology. Performance of these tests in a series of sequential, overlapping, or total channel steps provides the necessary assurance of appropriate operation of the entire channel. This change also makes the COT, [CFT], and TADOT definitions consistent with the CTS and the NUREG-1431 definition of CHANNEL CALIBRATION which already contains similar wording.
01-31	A	Definitions of specific plant systems which are defined by the plant design are deleted consistent with NUREG-1431. The definitions contained in ITS 1.0 are intended for definitions that are necessary for the understanding of the specifications and can be generically defined for most plants. Definitions of systems that are not used in the specifications, or are specific to a particular plant (or only a few plants) are no longer defined in this section. Where necessary, such items are defined in the Bases for the applicable specifications.
1-32	A	The definitions of CHANNEL CALIBRATION, COT, [CFT], and TADOT are reworded to be consistent with Industry Traveler TSTF-64 to clarify the phrase "entire channel," thus reducing the potential for inconsistent interpretation of the phrase as experienced by a number of plants.
1-33	A	This change revises the CTS definition of CORE ALTERATIONS to delete "or manipulation" and "conservative" in accordance with NUREG-1431. The words as used in the definition were redundant and deleting the words does not alter the meaning of the definition.

ENCLOSURE 3B

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3..." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92© as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92© as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92© as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92© as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2

10CFR50.92 EVALUATION
FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS Table 1.2 (ITS Table 1.1-1) is revised such that the required vessel head closure bolt requirements for MODES 4, 5, and 6 are clarified. Currently a footnote applicable only to MODE 6 defines that MODE, in part, by reference to "vessel head closure bolts less than fully tensioned." That footnote does not specify the transition point between MODES 5 and 6 with regard to the number of vessel head closure bolts that must be fully tensioned, leaving the issue open to interpretation. The proposed change provides the necessary clarification by adding a footnote to MODES 4 and 5, consistent with the approach used in NUREG-1431 to define those MODES as having the required number of reactor head closure bolts fully tensioned. The transition point between MODES 5 and 6 would also be clarified as occurring when the reactor vessel head closure bolts are less than fully tensioned. The required number of closure bolts, which may be less than the total number, is established by analysis that demonstrates adequate O-ring compression to prevent leakage and ensures that ASME Section III stress limits for affected components are not exceeded. This revision is consistent with TSTF-88.

The proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92© as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change clarifies the requirement for one or more required reactor vessel head closure bolts not fully tensioned as a condition to define MODE 6. The proposed change would not result in any hardware changes, would not affect the initiators of any analyzed events, and would not alter assumptions relative to mitigation of accident or transient events. Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (continued)

The proposed change does not involve any changes in the method by which any safety-related system performs its function. Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. There is no effect on systems necessary to assure the accomplishment of accident mitigation. Therefore, the proposed change will not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS2" resulting from the conversion to the ITS format are seen to satisfy the NSHC of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

1.0 USE AND APPLICATION

1.1 Definitions

NOTE

The defined terms of this section appear in capitalized type and are applicable throughout these Technical Specifications and Bases.

<u>Term</u>	<u>Definition</u>
ACTIONS	ACTIONS shall be that part of a Specification that prescribes Required Actions to be taken under designated Conditions within specified Completion Times.
ACTUATION LOGIC TEST	An ACTUATION LOGIC TEST shall be the application of various simulated or actual input combinations in conjunction with each possible interlock logic state and the verification of the required logic output. The ACTUATION LOGIC TEST, as a minimum, shall include a continuity check of output devices.
AXIAL FLUX DIFFERENCE (AFD)	AFD shall be the difference in normalized flux signals between <u>B-PS</u> the top and bottom halves of a two-section an excore neutron detector.
CHANNEL CALIBRATION	A CHANNEL CALIBRATION shall be the adjustment, as necessary, of the channel so that it responds within the required range and accuracy to known input. The CHANNEL CALIBRATION shall encompass those components the entire channel, including the required such as sensors, alarms, interlock, displays, and trip functions required to perform the specified safety function(s). Calibration of instrument channels with resistance temperature detector (RTD) or thermocouple sensors may consist of an in-place qualitative assessment of sensor behavior and normal calibration of the remaining adjustable devices in the channel. Whenever a sensing element is replaced, the next required CHANNEL CALIBRATION shall include an in-place cross calibration that compares the other sensing elements with the recently installed sensing element. The CHANNEL CALIBRATION may be performed by means of any series of sequential, overlapping calibrations or total channel steps so that the entire channel is calibrated. <u>1.1-1</u>

(Continued)

1.1 Definitions (continued)

CHANNEL CHECK

A CHANNEL CHECK shall be the qualitative assessment, by observation, of channel behavior during operation. This determination shall include, where possible, comparison of the channel indication and status to other indications or status derived from independent instrument channels measuring the same parameter.

CHANNEL FUNCTIONAL TEST (CFT)

A CFT shall be:

- a. Analog channels - the injection of a simulated or actual signal into the channel as close to the sensor as practical to verify OPERABILITY including required alarm and trip functions. 1.1-7
- b. Bistable channels - the injection of a simulated or actual signal into the sensor to verify OPERABILITY including required alarm and trip functions. 1.1-7
- c. Digital channels - the injection of a simulated or actual signal into the channel as close to the sensor input to the process racks as practical to verify OPERABILITY including required alarm and trip functions. 1.1-7

The Channel Functional Test may be performed by means of any series of sequential, overlapping, or total channel steps so that the entire channel is tested. 1.1-9

CHANNEL OPERATIONAL

A COT shall be the injection of a simulated or actual signal TEST (COT) into the channel as close to the sensor as practicable to verify the OPERABILITY of required including all components in the channel such as alarms, interlocks, displays, and trip functions required to perform the specified safety function(s). The COT may be performed by means of any series of sequential, overlapping or total channel steps so that the entire channel is tested. The COT shall include adjustments, as necessary, of the required alarm, interlock, and trip setpoints so that the setpoints are within the required range and accuracy. 1.1-1
1.1-9

CORE ALTERATION

CORE ALTERATION shall be the movement of any fuel, sources, or reactivity control components, within the reactor vessel with the vessel head removed and fuel in the vessel. Suspension of CORE ALTERATIONS shall not preclude completion of movement of a component to a safe position.

(Continued)

1.1 Definitions (continued)

CORE OPERATING LIMITS REPORT (COLR)

The COLR is the unit specific document that provides cycle specific parameter limits for the current reload cycle. These cycle specific parameter limits shall be determined for each reload cycle in accordance with Specification 5.6.5. Plant operation within these limits is addressed in individual Specifications.

DOSE EQUIVALENT I-131

DOSE EQUIVALENT I-131 shall be that concentration of I-131 (microcuries/gram) that alone would produce the same thyroid dose as the quantity and isotopic mixture of I-131, I-132, I-133, I-134, and I-135 actually present. The thyroid dose conversion factors used for this calculation shall be those listed in ~~Table III of TID-14844, AEC, 1962, "Calculation of Distance Factors for Power and Test Reactor Sites," or those listed in Table E-7 of NRC Regulatory Guide 1.109, Rev. 1, October, 1977, or ICRP 30, Supplement to Part 1, page 192-212, Table titled, "Committed Dose Equivalent in Target Organs or Tissues per Intake of Unit Activity" .]~~

B

\bar{E} -AVERAGE DISINTEGRATION ENERGY

\bar{E} shall be the average (weighted in proportion to the concentration of each radionuclide in the reactor coolant at the time of sampling) of the sum of the average beta and gamma energies per disintegration (in MeV) for isotopes, other than iodines, with half lives > ~~[15]~~ minutes, making up at least 95% of the total non-iodine activity in the coolant.

B-PS

ENGINEERED SAFETY FEATURE (ESF) RESPONSE TIME

The ESF RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays, where applicable. The response time may be measured ~~verified~~ by means of any series of sequential, overlapping, or total steps so that the entire response time is measured ~~verified~~.

1.1-5

L_p

The maximum allowable primary containment leakage rate, L_p , shall be ~~[0.10]~~ % of primary containment air weight per day at the calculated peak containment pressure (P_p).

B-PS

(Continued)

1.1 Definitions (continued)

LEAKAGE

LEAKAGE shall be:

a. Identified LEAKAGE

1. LEAKAGE, such as that from pump seals or valve packing (except reactor coolant pump (RCP) seal water injection or leakoff), that is captured and conducted to collection systems or a sump or collecting tank;
2. LEAKAGE into the containment atmosphere from sources that are both specifically located and known either not to interfere with the operation of leakage detection systems or not to be pressure boundary LEAKAGE; or
3. Reactor Coolant System (RCS) LEAKAGE through a steam generator (SG) to the Secondary System.

b. Unidentified LEAKAGE

All LEAKAGE (except RCP seal water injection or leakoff) that is not identified LEAKAGE.

c. Pressure Boundary LEAKAGE

LEAKAGE (except SG LEAKAGE) through a nonisolable fault in an RCS component body, pipe wall, or vessel wall.

MASTER RELAY TEST

A MASTER RELAY TEST shall consist of energizing each master relay and verifying the OPERABILITY of each relay. The MASTER RELAY TEST shall include a continuity check of each associated slave relay.

MODE

A MODE shall correspond to any one inclusive combination of core reactivity condition, power level, average reactor coolant temperature, and reactor vessel head closure bolt tensioning specified in Table 1.1-1 with fuel in the reactor vessel.

OPERABLE-OPERABILITY

A system, subsystem, train, component, or device shall be OPERABLE or have OPERABILITY when it is capable of performing its specified safety function(s) and when all necessary attendant instrumentation, controls, normal or emergency electrical power, cooling and seal water, lubrication, and other auxiliary equipment that are required

(Continued)

1.1 Definitions (continued)

for the system, subsystem, train, component, or device to perform its specified safety function(s) are also capable of performing their related support function(s).

PHYSICS TESTS

PHYSICS TESTS shall be those tests performed to measure the fundamental nuclear characteristics of the reactor core and related instrumentation. These tests are:

- a. Described in Chapter ~~[14 Initial Test Program]~~ of the FSAR;
- b. Authorized under the provisions of 10 CFR 50.59; or
- c. Otherwise approved by the Nuclear Regulatory Commission.

B-PS

PRESSURE AND TEMPERATURE LIMITS REPORT (PTLR)

The PTLR is the unit specific document that provides the reactor vessel pressure and temperature limits, including heatup and cooldown rates, and the power operated relief valve (PORV) lift settings and arming temperature associated with the Low Temperature Overpressurization Protection (LTOP) System, for the current reactor vessel fluence period. These pressure and temperature limits shall be determined for each fluence period in accordance with Specification 5.6.6. Plant operation within these operating limits is addressed in individual specifications, LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," and LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System."

1.1-6

QUADRANT POWER TILT RATIO (QPTR)

QPTR shall be the ratio of the maximum upper excore detector calibrated output to the average of the upper excore detector calibrated outputs, or the ratio of the maximum lower excore detector calibrated output to the average of the lower excore detector calibrated outputs, whichever is greater.

RATED THERMAL POWER (RTP)

RTP shall be a total reactor core heat transfer rate to the reactor coolant of ~~[2893 Mwt]~~ [3338 MWT for Unit 1 and 3411 MWT for Unit 2]

B-PS

REACTOR TRIP SYSTEM (RTS) RESPONSE TIME

The RTS RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its RTS trip setpoint at the channel sensor until loss of stationary gripper coil voltage. The response time may be measured verified by means of any series of sequential, overlapping, or total steps so that the entire response time is measured verified.

1.1-5

(Continued)

1.1 Definitions (continued)

SHUTDOWN MARGIN (SDM)	<p>SDM shall be the instantaneous amount of reactivity by which the reactor is subcritical or would be subcritical from its present condition assuming:</p> <p>a. All rod cluster control assemblies (RCCAs) are fully inserted except for the single RCCA of highest reactivity worth, which is assumed to be fully withdrawn. With any RCCA not capable of being fully inserted, the reactivity worth of the RCCA must be accounted for in the determination of SDM; and</p> <p>b. In MODES 1 and 2, the fuel and moderator temperatures are changed to the nominal hot zero power design level temperatures]</p>	<hr/> <p>B-PS</p>
SLAVE RELAY TEST	<p>A SLAVE RELAY TEST shall consist of energizing each slave relay and verifying the OPERABILITY of each slave relay. The SLAVE RELAY TEST shall include, as a minimum, a continuity check of associated testable actuation devices.</p>	
STAGGERED TEST BASIS	<p>A STAGGERED TEST BASIS shall consist of the testing of one of the systems, subsystems, channels, or other designated components during the interval specified by the Surveillance Frequency, so that all systems, subsystems, channels, or other designated components are tested during n Surveillance Frequency intervals, where n is the total number of systems, subsystems, channels, or other designated components in the associated function.</p>	
THERMAL POWER	<p>THERMAL POWER shall be the total reactor core heat transfer rate to the reactor coolant.</p>	
TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT)	<p>A TADOT shall consist of operating the trip actuating device and verifying the OPERABILITY of required including all components, such as alarms, interlocks, displays, and trip functions required to perform the specified safety function(s). The TADOT may be performed by means of any series of sequential overlapping or total channel steps so that the entire channel is tested. The TADOT shall include adjustment, as necessary, of the trip actuating device so that it actuates at the required setpoint within the required accuracy.</p>	<hr/> <p>1.1-1</p> <hr/> <p>1.1-9</p> <hr/>

1.0 USE AND APPLICATION

1.2 Logical Connectors

PURPOSE The purpose of this section is to explain the meaning of logical connectors. Logical connectors are used in Technical Specifications (TS) to discriminate between, and yet connect, discrete Conditions, Required Actions, Completion Times, Surveillances, and Frequencies. The only logical connectors that appear in TS are AND and OR. The physical arrangement of these connectors constitutes logical conventions with specific meanings.

BACKGROUND

Several levels of logic may be used to state Required Actions. These levels are identified by the placement (or nesting) of the logical connectors and by the number assigned to each Required Action. The first level of logic is identified by the first digit of the number assigned to a Required Action and the placement of the logical connector in the first level of nesting (i.e., left justified with the number of the Required Action). The successive levels of logic are identified by additional digits of the Required Action number and by successive indentations of the logical connectors.

When logical connectors are used to state a Condition, Completion Time, Surveillance, or Frequency, only the first level of logic is used, and the logical connector is left justified with the statement of the Condition, Completion Time, Surveillance, or Frequency.

EXAMPLES The following examples illustrate the use of logical connectors.

(Continued)

1.2 Logical Connectors

EXAMPLES
(continued)

EXAMPLE 1.2-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Verify... <u>AND</u> A.2 Restore...	

In this example the logical connector AND is used to indicate that when in Condition A, both Required Actions A.1 and A.2 must be completed.

(Continued)

1.2 Logical Connectors

EXAMPLES
(continued)

EXAMPLE 1.2-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. LCO not met.	A.1 Trip... <u>OR</u> A.2.1 Verify... <u>AND</u> A.2.2.1 Reduce... <u>OR</u> A.2.2.2 Perform... <u>OR</u> A.3 Align...	

This example represents a more complicated use of logical connectors. Required Actions A.1, A.2, and A.3 are alternative choices, only one of which must be performed as indicated by the use of the logical connector OR and the left justified placement. Any one of these three Actions may be chosen. If A.2 is chosen, then both A.2.1 and A.2.2 must be performed as indicated by the logical connector AND. Required Action A.2.2 is met by performing A.2.2.1 or A.2.2.2. The indented position of the logical connector OR indicates that A.2.2.1 and A.2.2.2 are alternative choices, only one of which must be performed.

1.0 USE AND APPLICATION

1.3 Completion Times

PURPOSE The purpose of this section is to establish the Completion Time convention and to provide guidance for its use.

BACKGROUND Limiting Conditions for Operation (LCOs) specify minimum requirements for ensuring safe operation of the unit. The ACTIONS associated with an LCO state Conditions that typically describe the ways in which the requirements of the LCO can fail to be met. Specified with each stated Condition are Required Action(s) and Completion Time(s).

DESCRIPTION The Completion Time is the amount of time allowed for completing a Required Action. It is referenced to the time of discovery of a situation (e.g., inoperable equipment or variable not within limits) that requires entering an ACTIONS Condition unless otherwise specified, providing the unit is in a MODE or specified condition stated in the Applicability of the LCO. Required Actions must be completed prior to the expiration of the specified Completion Time. An ACTIONS Condition remains in effect and the Required Actions apply until the Condition no longer exists or the unit is not within the LCO Applicability.

If situations are discovered that require entry into more than one Condition at a time within a single LCO (multiple Conditions), the Required Actions for each Condition must be performed within the associated Completion Time. When in multiple Conditions, separate Completion Times are tracked for each Condition starting from the time of discovery of the situation that required entry into the Condition.

Once a Condition has been entered, subsequent trains, subsystems, components, or variables expressed in the Condition, discovered to be inoperable or not within limits, will not result in separate entry into the Condition, unless specifically stated. The Required Actions of the Condition continue to apply to each additional failure, with Completion Times based on initial entry into the Condition.

1.3 Completion Times

DESCRIPTION
(continued)

However, when a subsequent train, subsystem, component, or variable expressed in the Condition is discovered to be inoperable or not within limits, the Completion Time(s) may be extended. To apply this Completion Time extension, two criteria must first be met. The subsequent inoperability:

- a. Must exist concurrent with the first inoperability; and
- b. Must remain inoperable or not within limits after the first inoperability is resolved.

The total Completion Time allowed for completing a Required Action to address the subsequent inoperability shall be limited to the more restrictive of either:

- a. The stated Completion Time, as measured from the initial entry into the Condition, plus an additional 24 hours; or
- b. The stated Completion Time as measured from discovery of the subsequent inoperability.

The above Completion Time extensions do not apply to those Specifications that have exceptions that allow completely separate re-entry into the Condition (for each train, subsystem, component, or variable expressed in the Condition) and separate tracking of Completion Times based on this re-entry. These exceptions are stated in individual Specifications.

The above Completion Time extension does not apply to a Completion Time with a modified "time zero." This modified "time zero" may be expressed as a repetitive time (i.e., "once per 8 hours," where the Completion Time is referenced from a previous completion of the Required Action versus the time of Condition entry) or as a time modified by the phrase "from discovery..." Example 1.3-3 illustrates one use of this type of Completion Time. The 10 day Completion Time specified for Conditions A and B in Example 1.3-3 may not be extended.

(Continued)

1.3 Completion Times

EXAMPLES

The following examples illustrate the use of Completion Times with different types of Conditions and changing Conditions.

EXAMPLE 1.3-1

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	<u>AND</u> B.2 Be in MODE 5.	36 hours

Condition B has two Required Actions. Each Required Action has its own separate Completion Time. Each Completion Time is referenced to the time that Condition B is entered.

The Required Actions of Condition B are to be in MODE 3 within 6 hours AND in MODE 5 within 36 hours. A total of 6 hours is allowed for reaching MODE 3 and a total of 36 hours (not 42 hours) is allowed for reaching MODE 5 from the time that Condition B was entered. If MODE 3 is reached within 3 hours, the time allowed for reaching MODE 5 is the next 33 hours because the total time allowed for reaching MODE 5 is 36 hours.

If Condition B is entered while in MODE 3, the time allowed for reaching MODE 5 is the next 36 hours.

(Continued)

1.3 Completion Times

EXAMPLES
(continued)

EXAMPLE 1.3-2

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One pump inoperable.	A.1 Restore pump to OPERABLE status.	7 days
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	<u>AND</u> B.2 Be in MODE 5.	36 hours

When a pump is declared inoperable, Condition A is entered. If the pump is not restored to OPERABLE status within 7 days, Condition B is also entered and the Completion Time clocks for Required Actions B.1 and B.2 start. If the inoperable pump is restored to OPERABLE status after Condition B is entered, Condition A and B are exited, and therefore, the Required Actions of Condition B may be terminated.

When a second pump is declared inoperable while the first pump is still inoperable, Condition A is not re-entered for the second pump. LCO 3.0.3 is entered, since the ACTIONS do not include a Condition for more than one inoperable pump. The Completion Time clock for Condition A does not stop after LCO 3.0.3 is entered, but continues to be tracked from the time Condition A was initially entered.

While in LCO 3.0.3, if one of the inoperable pumps is restored to OPERABLE status and the Completion Time for Condition A has not expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition A.

While in LCO 3.0.3, if one of the inoperable pumps is restored to OPERABLE status and the Completion Time for Condition A has expired, LCO 3.0.3 may be exited and operation continued in accordance with Condition B. The Completion Time for Condition B is tracked from the time the Condition A Completion Time expired.

(Continued)

1.3 Completion Times

EXAMPLES

EXAMPLE 1.3-2 (continued)

On restoring one of the pumps to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first pump was declared inoperable. This Completion Time may be extended if the pump restored to OPERABLE status was the first inoperable pump. A 24 hour extension to the stated 7 days is allowed, provided this does not result in the second pump being inoperable for > 7 days.

(Continued)

1.3 Completion Times

EXAMPLES
(continued)

EXAMPLE 1.3-3

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One Function X train inoperable.	A.1 Restore Function X train to OPERABLE status.	7 days <u>AND</u> 10 days from discovery of failure to meet the LCO
B. One Function Y train inoperable.	B.1 Restore Function Y train to OPERABLE status.	72 hours <u>AND</u> 10 days from discovery of failure to meet the LCO
C. One Function X train inoperable. <u>AND</u> One Function Y train inoperable.	C.1 Restore Function X train to OPERABLE status. <u>OR</u> C.2 Restore Function Y train to OPERABLE status.	72 hours 72 hours

(Continued)

1.3 Completion Times

EXAMPLES

EXAMPLE 1.3-3 (continued)

When one Function X train and one Function Y train are inoperable, Condition A and Condition B are concurrently applicable. The Completion Times for Condition A and Condition B are tracked separately for each train starting from the time each train was declared inoperable and the Condition was entered. A separate Completion Time is established for Condition C and tracked from the time the second train was declared inoperable (i.e., the time the situation described in Condition C was discovered).

If Required Action C.2 is completed within the specified Completion Time, Conditions B and C are exited. If the Completion Time for Required Action A.1 has not expired, operation may continue in accordance with Condition A. The remaining Completion Time in Condition A is measured from the time the affected train was declared inoperable (i.e., initial entry into Condition A).

The Completion Times of Conditions A and B are modified by a logical connector with a separate 10 day Completion Time measured from the time it was discovered the LCO was not met. In this example, without the separate Completion Time, it would be possible to alternate between Conditions A, B, and C in such a manner that operation could continue indefinitely without ever restoring systems to meet the LCO. The separate Completion Time modified by the phrase "from discovery of failure to meet the LCO" is designed to prevent indefinite continued operation while not meeting the LCO. This Completion Time allows for an exception to the normal "time zero" for beginning the Completion Time "clock". In this instance, the Completion Time "time zero" is specified as commencing at the time the LCO was initially not met, instead of at the time the associated Condition was entered.

(Continued)

1.3 Completion Times

EXAMPLES
(continued)

EXAMPLE 1.3-4

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve(s) to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	<u>AND</u> B.2 Be in MODE 4.	12 hours

A single Completion Time is used for any number of valves inoperable at the same time. The Completion Time associated with Condition A is based on the initial entry into Condition A and is not tracked on a per valve basis. Declaring subsequent valves inoperable, while Condition A is still in effect, does not trigger the tracking of separate Completion Times.

Once one of the valves has been restored to OPERABLE status, the Condition A Completion Time is not reset, but continues from the time the first valve was declared inoperable. The Completion Time may be extended if the valve restored to OPERABLE status was the first inoperable valve. The Condition A Completion Time may be extended for up to 4 hours provided this does not result in any subsequent valve being inoperable for > 4 hours.

If the Completion Time of 4 hours (including the extension) expires while one or more valves are still inoperable, Condition B is entered.

(Continued)

1.3 Completion Times

EXAMPLES
(continued)

EXAMPLE 1.3-5

ACTIONS

NOTE

Separate Condition entry is allowed for each inoperable valve.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more valves inoperable.	A.1 Restore valve to OPERABLE status.	4 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	<u>AND</u> B.2 Be in MODE 4.	12 hours

The Note above the ACTIONS Table is a method of modifying how the Completion Time is tracked. If this method of modifying how the Completion Time is tracked was applicable only to a specific Condition, the Note would appear in that Condition rather than at the top of the ACTIONS Table.

The Note allows Condition A to be entered separately for each inoperable valve, and Completion Times tracked on a per valve basis. When a valve is declared inoperable, Condition A is entered and its Completion Time starts. If subsequent valves are declared inoperable, Condition A is entered for each valve and separate Completion Times start and are tracked for each valve.

(Continued)

1.3 Completion Times

EXAMPLES

EXAMPLE 1.3-5 (continued)

If the Completion Time associated with a valve in Condition A expires, Condition B is entered for that valve. If the Completion Times associated with subsequent valves in Condition A expire, Condition B is entered separately for each valve and separate Completion Times start and are tracked for each valve. If a valve that caused entry into Condition B is restored to OPERABLE status, Condition B is exited for that valve.

Since the Note in this example allows multiple Condition entry and tracking of separate Completion Times, Completion Time extensions do not apply.

(Continued)

1.3 Completion Times

EXAMPLES
(continued)

EXAMPLE 1.3-6

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One channel inoperable.	A.1 Perform SR 3.x.x.x.	Once per 8 hours
	<u>OR</u> A.2 Reduce THERMAL POWER to \leq 50% RTP.	8 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours

Entry into Condition A offers a choice between Required Action A.1 or A.2. Required Action A.1 has a "once per" Completion Time, which qualifies for the 25% extension, per SR 3.0.2, to each performance after the initial performance. The initial 8 hour interval of Required Action A.1 begins when Condition A is entered and the initial performance of

Required Action A.1 must be complete within the first 8 hour interval. If Required Action A.1 is followed, and the Required Action is not met within the Completion Time (plus the extension allowed by SR 3.0.2), Condition B is entered. If Required Action A.2 is followed and the Completion Time of 8 hours is not met, Condition B is entered.

If after entry into Condition B, Required Action A.1 or A.2 is met, Condition B is exited and operation may then continue in Condition A.

(Continued)

1.3 Completion Times

EXAMPLES
(continued)

EXAMPLE 1.3-7

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One subsystem inoperable.	A.1 Verify affected subsystem isolated.	1 hour <u>AND</u> Once per 8 hours thereafter
	<u>AND</u> A.2 Restore subsystem to OPERABLE status.	72 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	<u>AND</u> B.2 Be in MODE 5.	36 hours

Required Action A.1 has two Completion Times. The 1 hour Completion Time begins at the time the Condition is entered and each "Once per 8 hours thereafter" interval begins upon performance of Required Action A.1.

If after Condition A is entered, Required Action A.1 is not met within either the initial 1 hour or any subsequent 8 hour interval from the previous performance (plus the extension allowed by SR 3.0.2), Condition B is entered. The Completion Time clock for Condition A does not stop after Condition B is entered, but continues from the time

(Continued)

1.3 Completion Times

EXAMPLES

EXAMPLE 1.3-7 (continued)

Condition A was initially entered. If Required Action A.1 is met after Condition B is entered, Condition B is exited and operation may continue in accordance with Condition A, provided the Completion Time for Required Action A.2 has not expired.

IMMEDIATE
COMPLETION TIME

When "Immediately" is used as a Completion Time, the Required Action should be pursued without delay and in a controlled manner.

1.0 USE AND APPLICATION

1.4 Frequency

PURPOSE The purpose of this section is to define the proper use and application of Frequency requirements.

DESCRIPTION Each Surveillance Requirement (SR) has a specified Frequency in which the Surveillance must be met in order to meet the associated LCO. An understanding of the correct application of the specified Frequency is necessary for compliance with the SR.

The "specified Frequency" is referred to throughout this section and each of the Specifications of Section 3.0, Surveillance Requirement (SR) Applicability. The "specified Frequency" consists of the requirements of the Frequency column of each SR as well as certain Notes in the Surveillance column that modify performance requirements.

Situations where a Surveillance could be required (i.e., its Frequency could expire), but where it is not possible or not desired that it be performed until sometime after the associated LCO is within its Applicability, represent potential SR 3.0.4 conflicts. To avoid these conflicts, the SR (i.e., the Surveillance or the Frequency) is stated such that it is only "required" when it can be and should be performed. With an SR satisfied, SR 3.0.4 imposes no restriction.

EXAMPLES The following examples illustrate the various ways that Frequencies are specified. In these examples 1 through 4, the Applicability of the LCO (LCO not shown) is MODES 1, 2, and 3. In example 5, the Applicability of the LCO is MODES 1, 2, 3, and 4.

(Continued)

1.4 . Frequency

EXAMPLES
(continued)

EXAMPLE 1.4-1

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Perform CHANNEL CHECK.	12 hours

Example 1.4-1 contains the type of SR most often encountered in the Technical Specifications (TS). The Frequency specifies an interval (12 hours) during which the associated Surveillance must be performed at least one time. Performance of the Surveillance initiates the subsequent interval. Although the Frequency is stated as 12 hours, an extension of the time interval to 1.25 times the stated Frequency is allowed by SR 3.0.2 for operational flexibility. The measurement of this interval continues at all times, even when the SR is not required to be met per SR 3.0.1 (such as when the equipment is inoperable, a variable is outside specified limits, or the unit is outside the Applicability of the LCO). If the interval specified by SR 3.0.2 is exceeded while the unit is in a MODE or other specified condition in the Applicability of the LCO, and the performance of the Surveillance is not otherwise modified (refer to Example 1.4-3), then SR 3.0.3 becomes applicable.

If the interval as specified by SR 3.0.2 is exceeded while the unit is not in a MODE or other specified condition in the Applicability of the LCO for which performance of the SR is required, the Surveillance must be performed within the Frequency requirements of SR 3.0.2 prior to entry into the MODE or other specified condition. Failure to do so would result in a violation of SR 3.0.4.

(Continued)

1.4 Frequency

EXAMPLES
(continued)

EXAMPLE 1.4-2

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
Verify flow is within limits.	Once within 12 hours after ≥ 25% RTP <u>AND</u> 24 hours thereafter

Example 1.4-2 has two Frequencies. The first is a one time performance Frequency, and the second is of the type shown in Example 1.4-1. The logical connector "AND" indicates that both Frequency requirements must be met. Each time reactor power is increased from a power level < 25% RTP to ≥ 25% RTP, the Surveillance must be performed within 12 hours.

The use of "once" indicates a single performance will satisfy the specified Frequency (assuming no other Frequencies are connected by "AND"). This type of Frequency does not qualify for the 25% extension allowed by SR 3.0.2. "Thereafter" indicates future performances must be established per SR 3.0.2, but only after a specified condition is first met (i.e., the "once" performance in this example). If reactor power decreases to < 25% RTP, the measurement of both intervals stops. New intervals start upon reactor power reaching 25% RTP.

(Continued)

1.4 Frequency

EXAMPLES
(continued)

EXAMPLE 1.4-3

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>NOTE</p> <p>Not required to be performed until 12 hours after \geq 25% RTP.</p> <hr style="border-top: 1px dashed black;"/> <p>Perform channel adjustment.</p>	<p>7 days</p>

The interval continues, whether or not the unit operation is $<$ 25% RTP between performances.

As the Note modifies the required performance of the Surveillance, it is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is $<$ 25% RTP, this Note allows 12 hours after power reaches \geq 25% RTP to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency." Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was $<$ 25% RTP, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not exceed 12 hours with power \geq 25% RTP.

Once the unit reaches 25% RTP, 12 hours would be allowed for completing the Surveillance. If the Surveillance were not performed within this 12 hour interval, there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply.

(Continued)

1.4 Frequency

EXAMPLES (continued) EXAMPLE 1.4-4

1.1-3

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
NOTE	
Only required to be performed in MODE 1	
Perform complete cycle of the valve	7 days

The interval continues, whether or not the unit operation is in MODE 1, 2, or 3 (the assumed Applicability of the associated LCO) between performances.

As the Note modifies the required performance of the Surveillance, the Note is construed to be part of the "specified Frequency." Should the 7 day interval be exceeded while operation is not in MODE 1, this note allows entry into and operation in MODES 2 and 3 to perform the Surveillance. The Surveillance is still considered to be performed within the "specified Frequency" if completed prior to entering MODE 1. Therefore, if the Surveillance were not performed within the 7 day (plus the extension allowed by SR 3.0.2) interval, but operation was not in MODE 1, it would not constitute a failure of the SR or failure to meet the LCO. Also, no violation of SR 3.0.4 occurs when changing MODES, even with the 7 day Frequency not met, provided operation does not result in entry into MODE 1.

Once the unit reaches MODE 1, the requirement for the Surveillance to be performed within its specified Frequency applies and would require that the Surveillance have been performed. If the Surveillance were not performed upon prior to entering MODE 1, there would then be a failure to perform a Surveillance within the specified Frequency, and the provisions of SR 3.0.3 would apply (as well as having had a violation of SR 3.0.4).

(Continued)

1.4 Frequency

EXAMPLES (continued) EXAMPLE 1.4-5

1.1-11

SURVEILLANCE REQUIREMENTS

1.1-3

SURVEILLANCE	FREQUENCY
Verify each containment isolation manual valve is closed	Prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days

In Example 1.4-5, the "specified Frequency" begins when the Surveillance is performed, but when the interval expires the Surveillance is not required to be performed until certain conditions are met. The Surveillance must be performed prior to entering MODE 4 from MODE 5, but only if the 92 day "specified Frequency" has passed. Although the period prior to the specified conditions is given as 92 days, the time interval may be extended to 1.25 times the stated period as allowed by SR 3.0.2 for operational flexibility.

The measurement of this interval continues at all times, even when the SR is not required to be met per SR 3.0.1 (such as when the equipment is inoperable, a variable is outside specified limits, or the unit is outside the Applicability of the LCO). If the conditions in the Frequency are met and the interval specified by SR 3.0.2 is exceeded without the Surveillance having been performed and the performance of the Surveillance is not otherwise modified (refer to Example 1.4-3), then SR 3.0.3 becomes applicable.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 1.0

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE NUMBER

JUSTIFICATION

- 1.1-1 The NUREG-1431 definition of CHANNEL CALIBRATION states, "The CHANNEL CALIBRATION shall encompass the entire channel, including the required sensor, alarm, display, and trip functions." This change clarifies what encompasses the entire channel by rewording the definition to state, "The CHANNEL CALIBRATION shall encompass those components, such as sensors, alarms, displays, and trip functions required to perform the specified safety function(s)." The COT and TADOT definitions are also similarly revised. This change is consistent with TSTF-64.
- 1.1-2 Not Used.
- 1.1-3 Adds new example 1.4-4 to ITS 1.4 to clarify meaning of SR notes of the type, "Only required to be performed in MODE..." This change is consistent with WOG- 74, Rev. 1.
- 1.1-4 Not Used.
- 1.1-5 The definitions for ESF RESPONSE TIME and RTS RESPONSE TIME would be revised to substitute the word "verified" in lieu of "measured," consistent with the terminology of NUREG-1431, SR 3.3.1.16, and SR 3.3.2.10. This change would ensure consistency between the definitions for time and the requirements to periodically verify response time is within limits. This change is consistent with Industry Traveler TSTF-111, Rev. 1.
- 1.1-6 The definition of the PTLR would be revised to include the maximum allowable PORV lift settings and arming temperature associated with the [low temperature Over pressurization protection (LTOP)] system, and to be consistent with the CORE OPERATING LIMITS REPORT (COLR) definition. ITS 3.4.12 states that the PORV lift settings are specified in the PTLR. The current definition for PTLR does not identify these lift settings as being contained in the PTLR.
- The [LTOP] arming temperature was added to the PTLR since changes in the heatup/cooldown figures could change the arming temperature. This change corrects the PTLR definition to be consistent with all of the requirements contained in the PTLR. Referenced methodologies for the PTLR would contain the methodology used to develop the heatup and cooldown figures, as well as the methodology for developing the [LTOP] setpoints. This change is consistent with Industry Traveler WOG 67, Rev. 1.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 1.0

CHANGE

NUMBER

JUSTIFICATION

- 1.1-7 The definition for CFT in the current DCPD TS will be retained in the ITS. CFT is in active use in numerous procedures in the plant. The CFT is used in applications for which the COT is not fully suitable. Although CFT and COT definitions appear similar, there is one important difference. Strict adherence to COT requirements includes quantitative adjustments as appropriate to bring setpoints into the desired range. This requirement for quantitative adjustment cannot be satisfied in a reasonable manner on some components/sensors/channels due to their design. However, CFT is a qualitative test to determine functionality. A loss of function indicated by the CFT results in a notification to restore the functional performance, following existing procedures. The CFT definition is in the DCPD CTS. The words "or actual," "required," and the "CHANNEL FUNCTIONAL TEST may be performed by means of any series of sequential, overlapping, or total channel steps so that the entire channel is tested" are added to the definition of CFT consistent with NUREG-1431 definition for COT.
- 1.1-8 The reactor vessel head closure bolt requirements for MODES 4, 5, and 6 are clarified. Footnote b, is revised for MODES 4 and 5 to refer to "the required reactor vessel head closure bolts fully tensioned" and Note c for MODE 6 is revised to read "the required reactor head closure bolts less than fully tensioned." The transition point between MODES 5 and 6 would also be clarified as occurring when the required reactor vessel head closure bolts are less than fully tensioned. The required number of closure bolts, which may be less than the total number, is established by analysis that demonstrates adequate O-ring compression to prevent leakage and ensures the ASME Section III stress limits for affected components are not exceeded. This change is consistent with Industry Traveler TSTF-88.
- 1.1-9 The definitions of COT, [CFT], and TADOT are expanded to include the details of acceptable performance methodology. Performance of these tests in a series of sequential, overlapping, or total channel steps provides the necessary assurance of appropriate operation of the entire channel. This change also makes the COT and TADOT definitions consistent with the NUREG-1431 definition of CHANNEL CALIBRATION which already contains similar wording. This change is consistent with Industry Traveler TSTF-39, Rev. 1.
- 1.1-10 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 1.1-11 This change adds a new example (1.4-5) to ITS Section 1.4 to clarify surveillance Frequencies that are contingent on both a "specified frequency" and plant conditions. The ITS contains many surveillance Frequencies that are contingent on both a "specified frequency" and plant conditions. For example, "Within 7 days prior to the initiation of PHYSICS TESTS," and "Prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days." These Frequencies do not fall clearly under any of the existing Section 1.4 examples. The proposed example is needed to make clear that: (1) the SR 3.0.2 extension of 1.25 times the specified Frequency applies to the specified Frequency, and (2) that the interval allowed to perform a missed surveillance by SR 3.0.3 applies.
- SR 3.0.2 is clear that the 1.25 extension may be applied to "the interval specified in the Frequency," so the proposed change does not change the intent of the specifications. SR 3.0.2 applies if a surveillance is not performed within the "specified Frequency."

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 1.0

CHANGE

NUMBER

JUSTIFICATION

1.1-11
(continued)

Again, the example does not change the intent of the specifications but only makes clear the application of SR 3.0.2 and 3.0.3 to surveillances with Frequencies tied to plant conditions. This change will eliminate confusion and misapplication of the ITS and will ensure consistent application of SR 3.0.2 and 3.0.3 to these types of surveillance Frequencies. This change is consistent with Industry Traveler WOG-90.

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

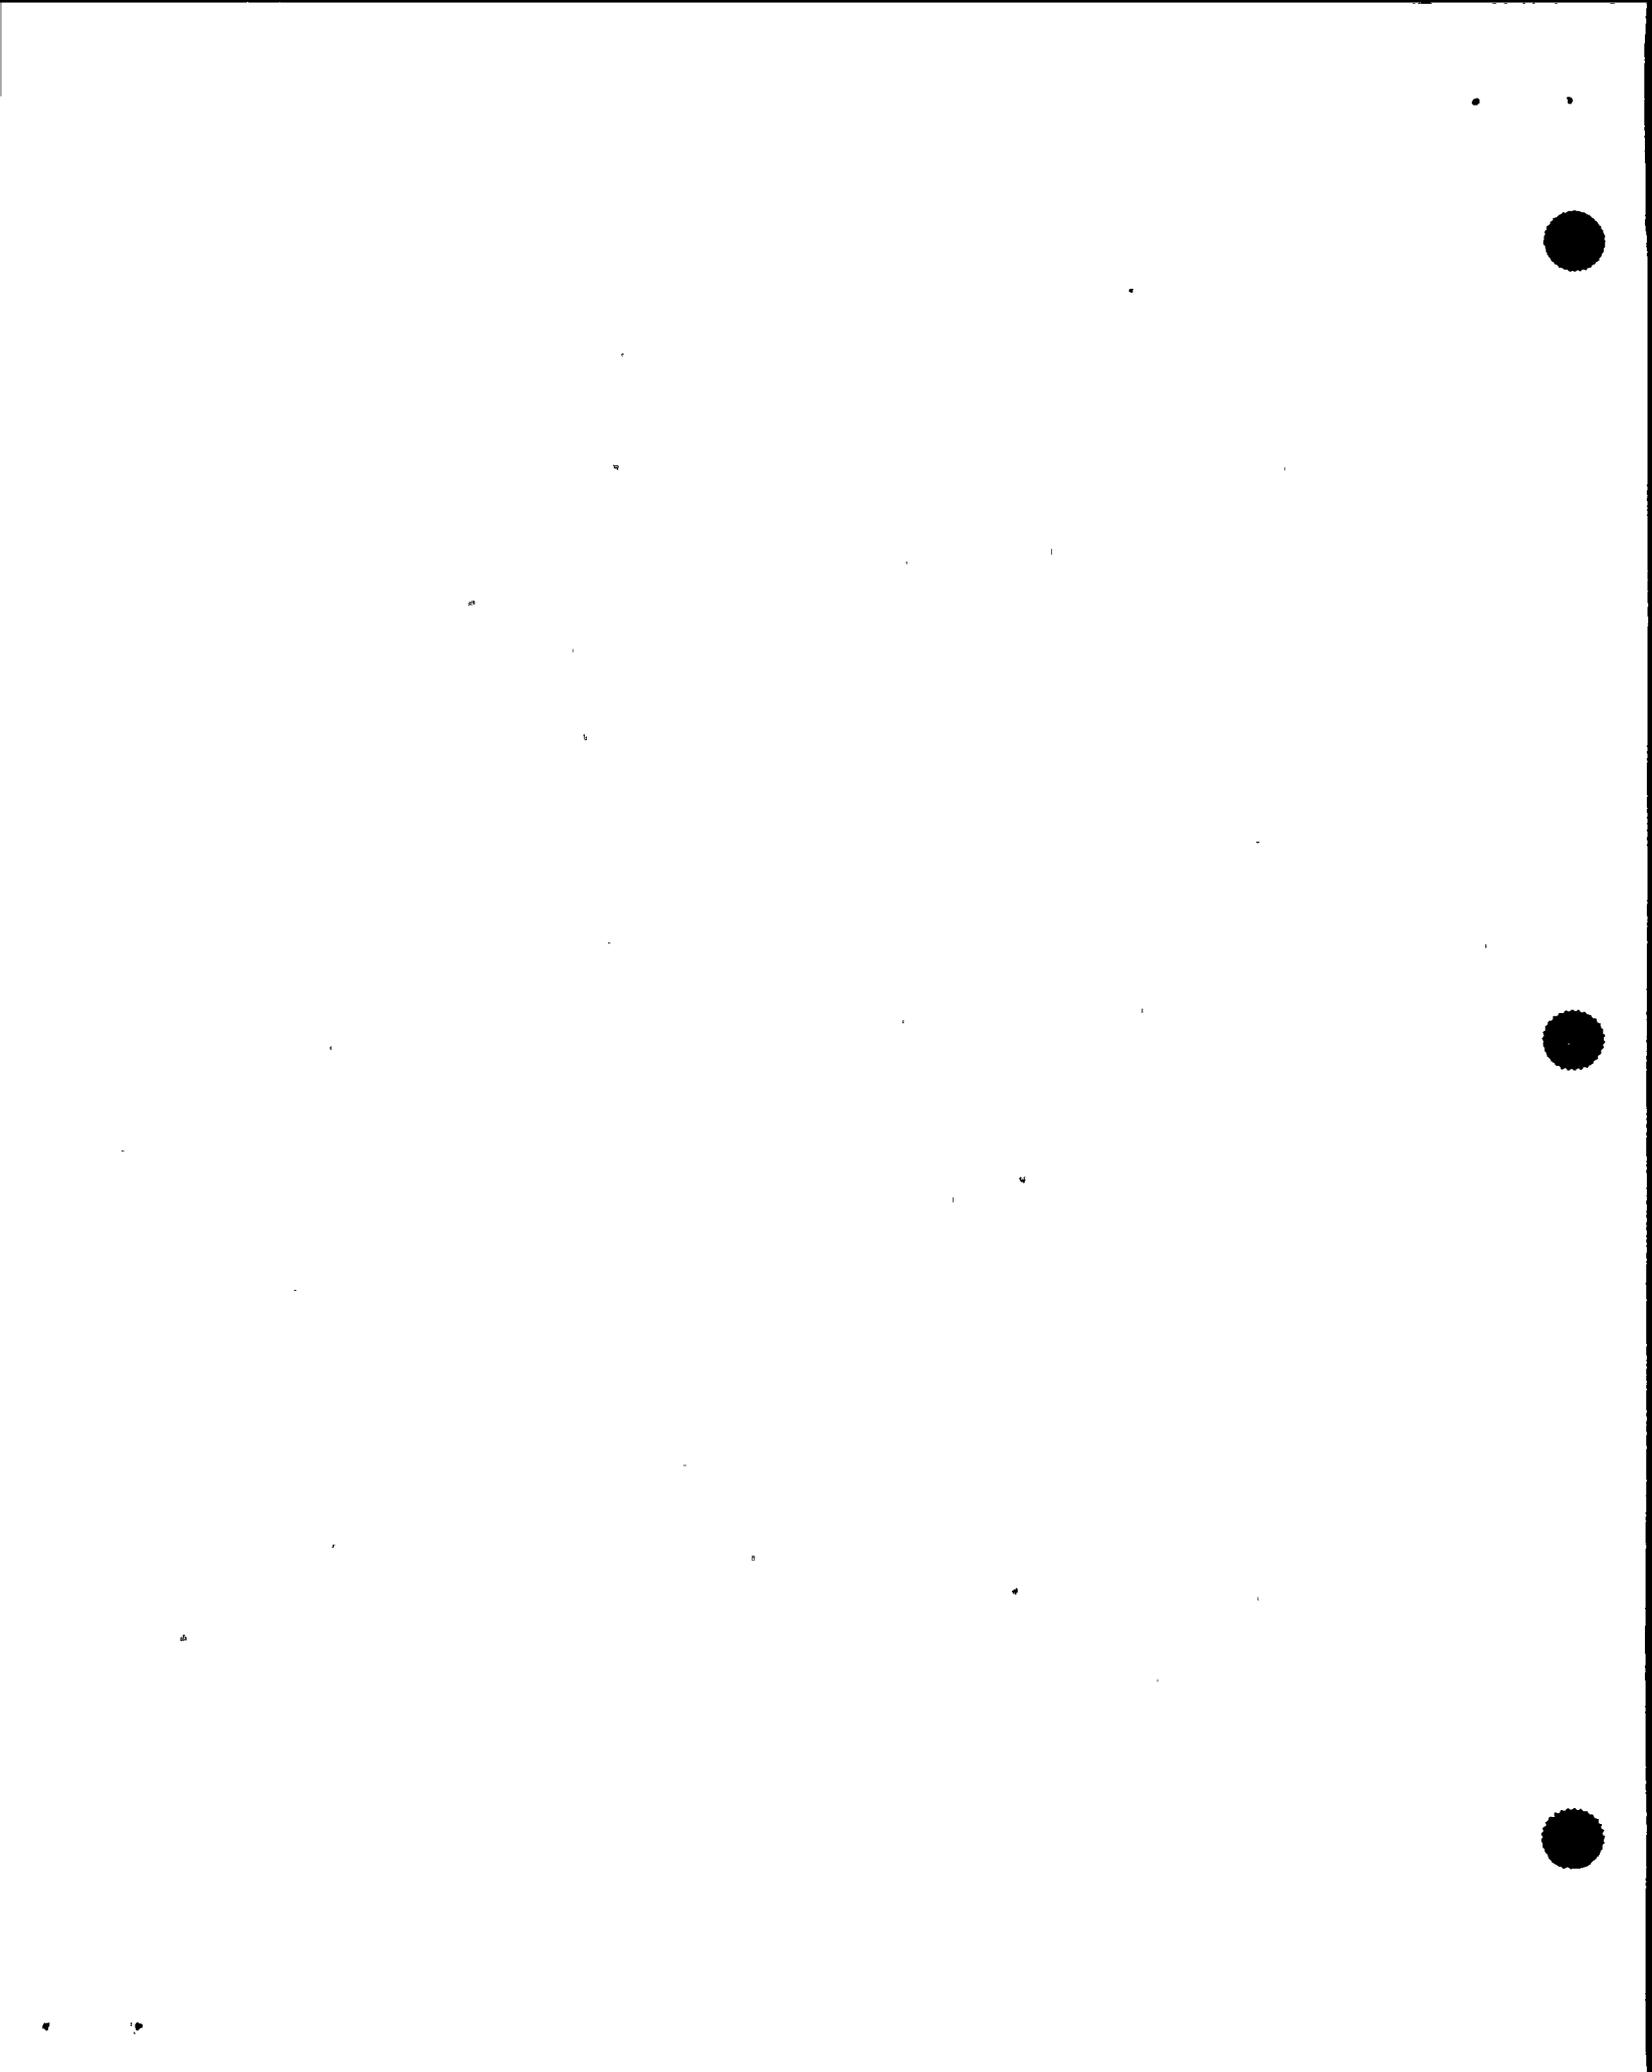

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Methodology for Cross-Reference Tables
(Continued)

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated This item is relocated to another licensee control document outside the TS (see Code for specific reference location).

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

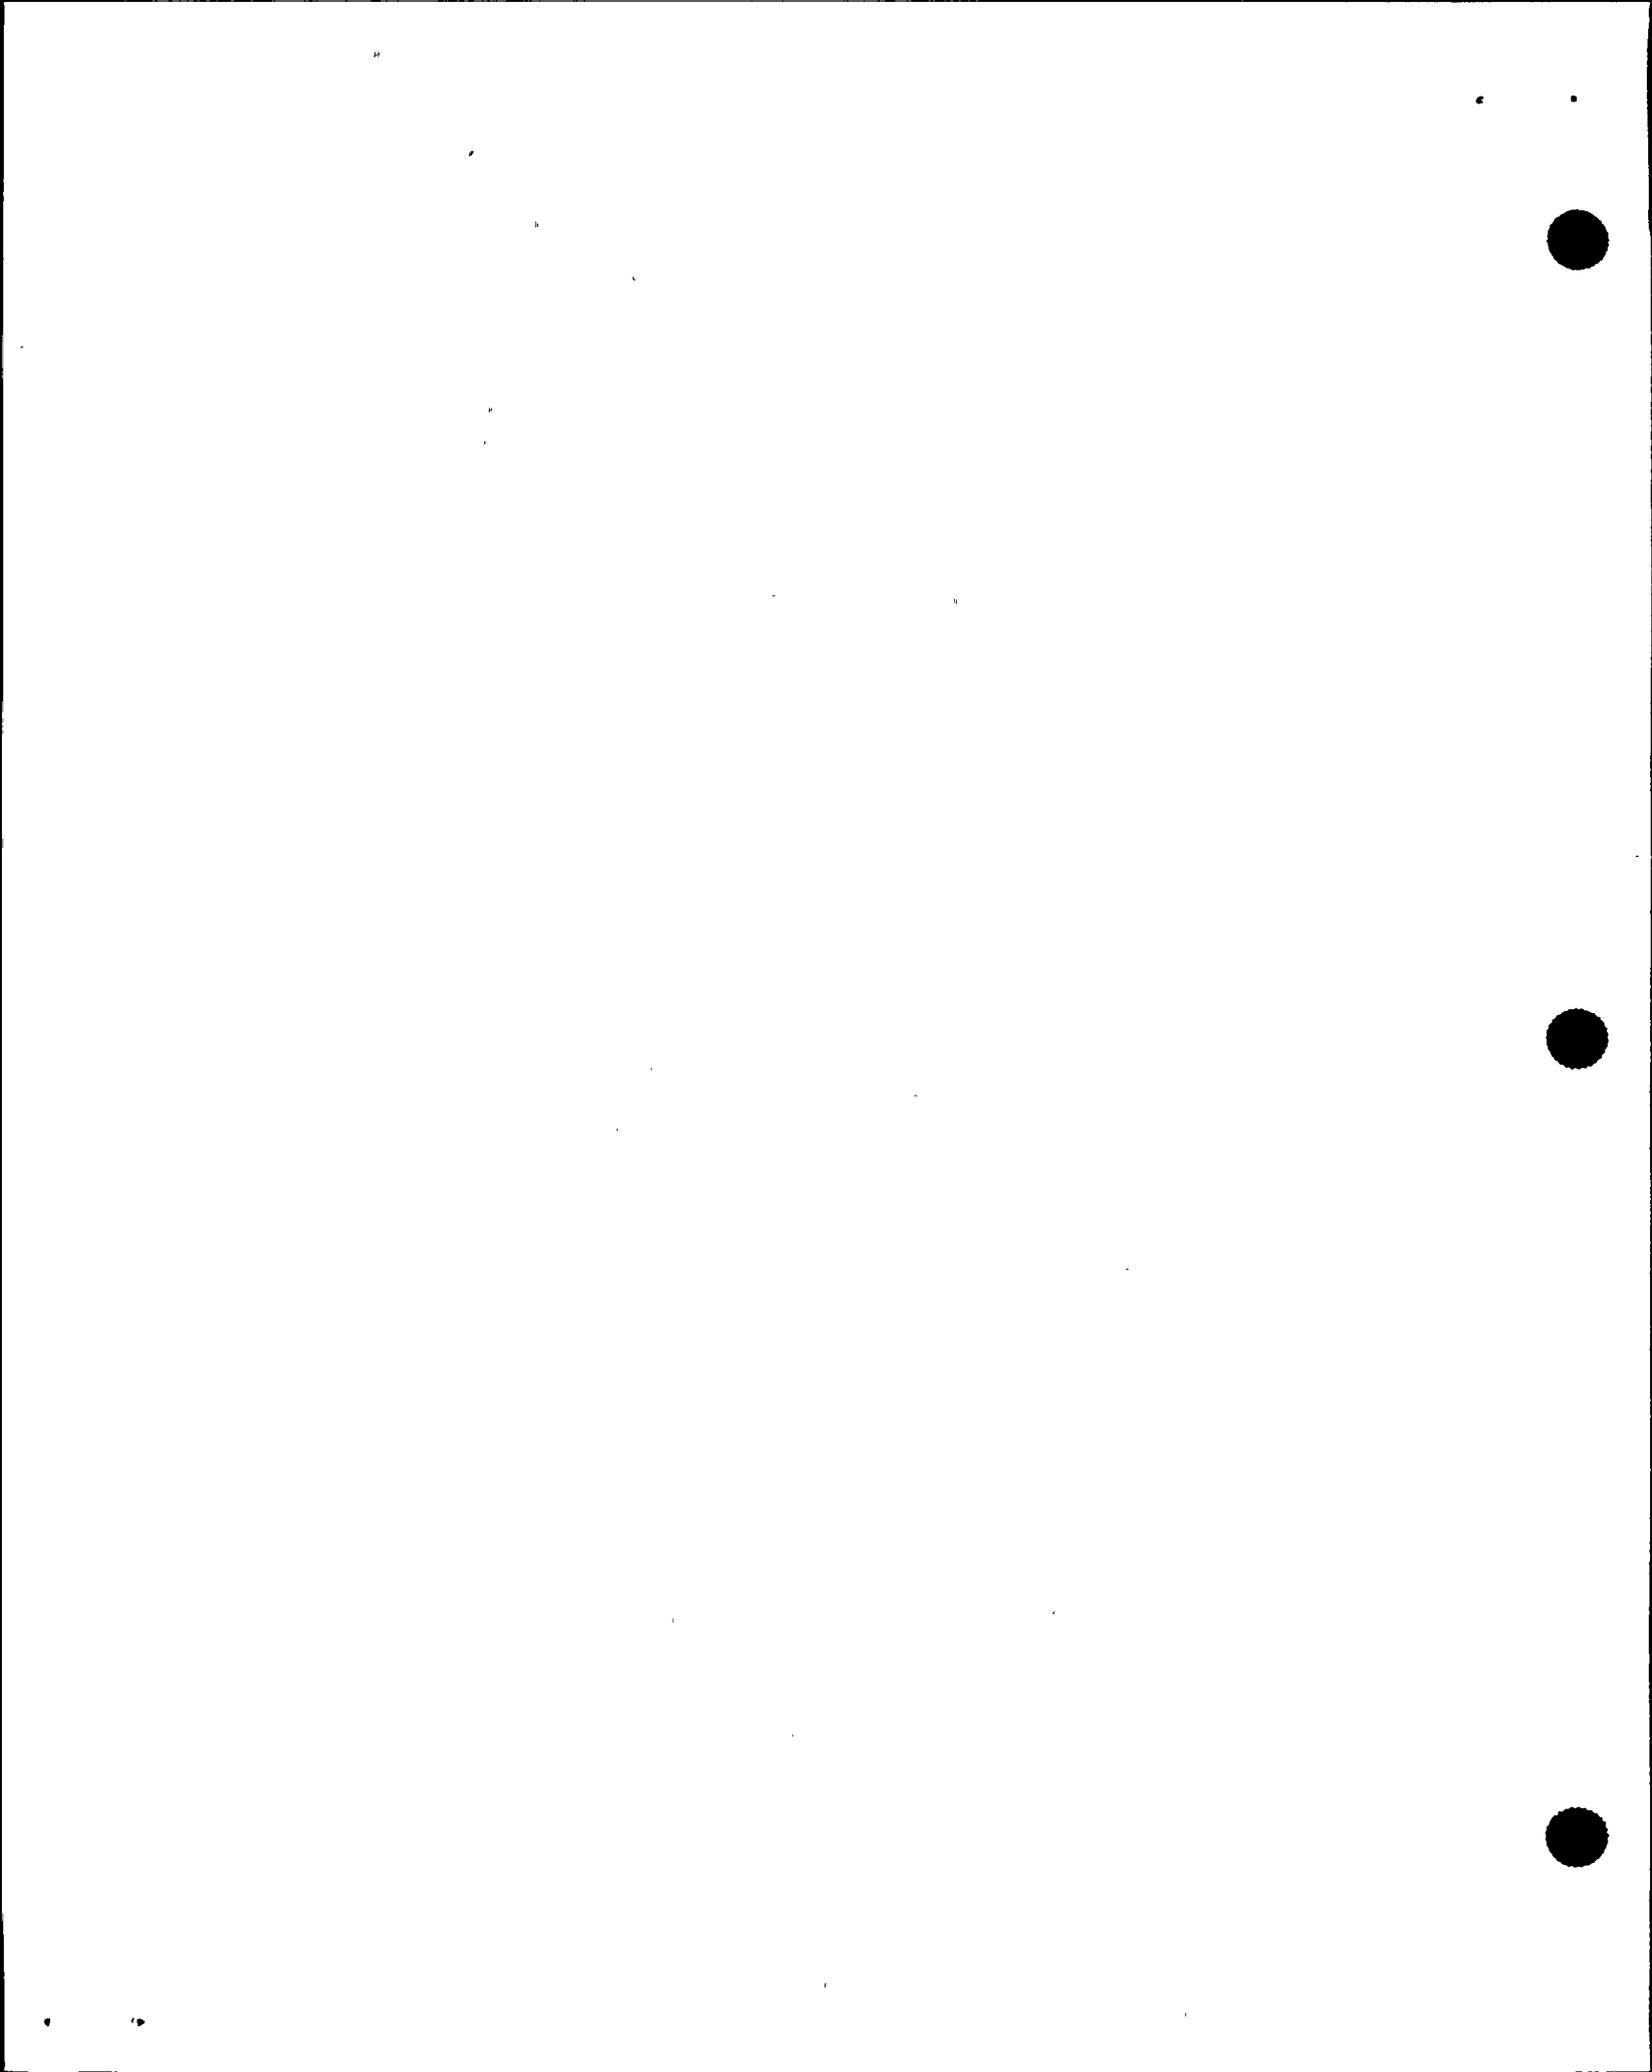

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

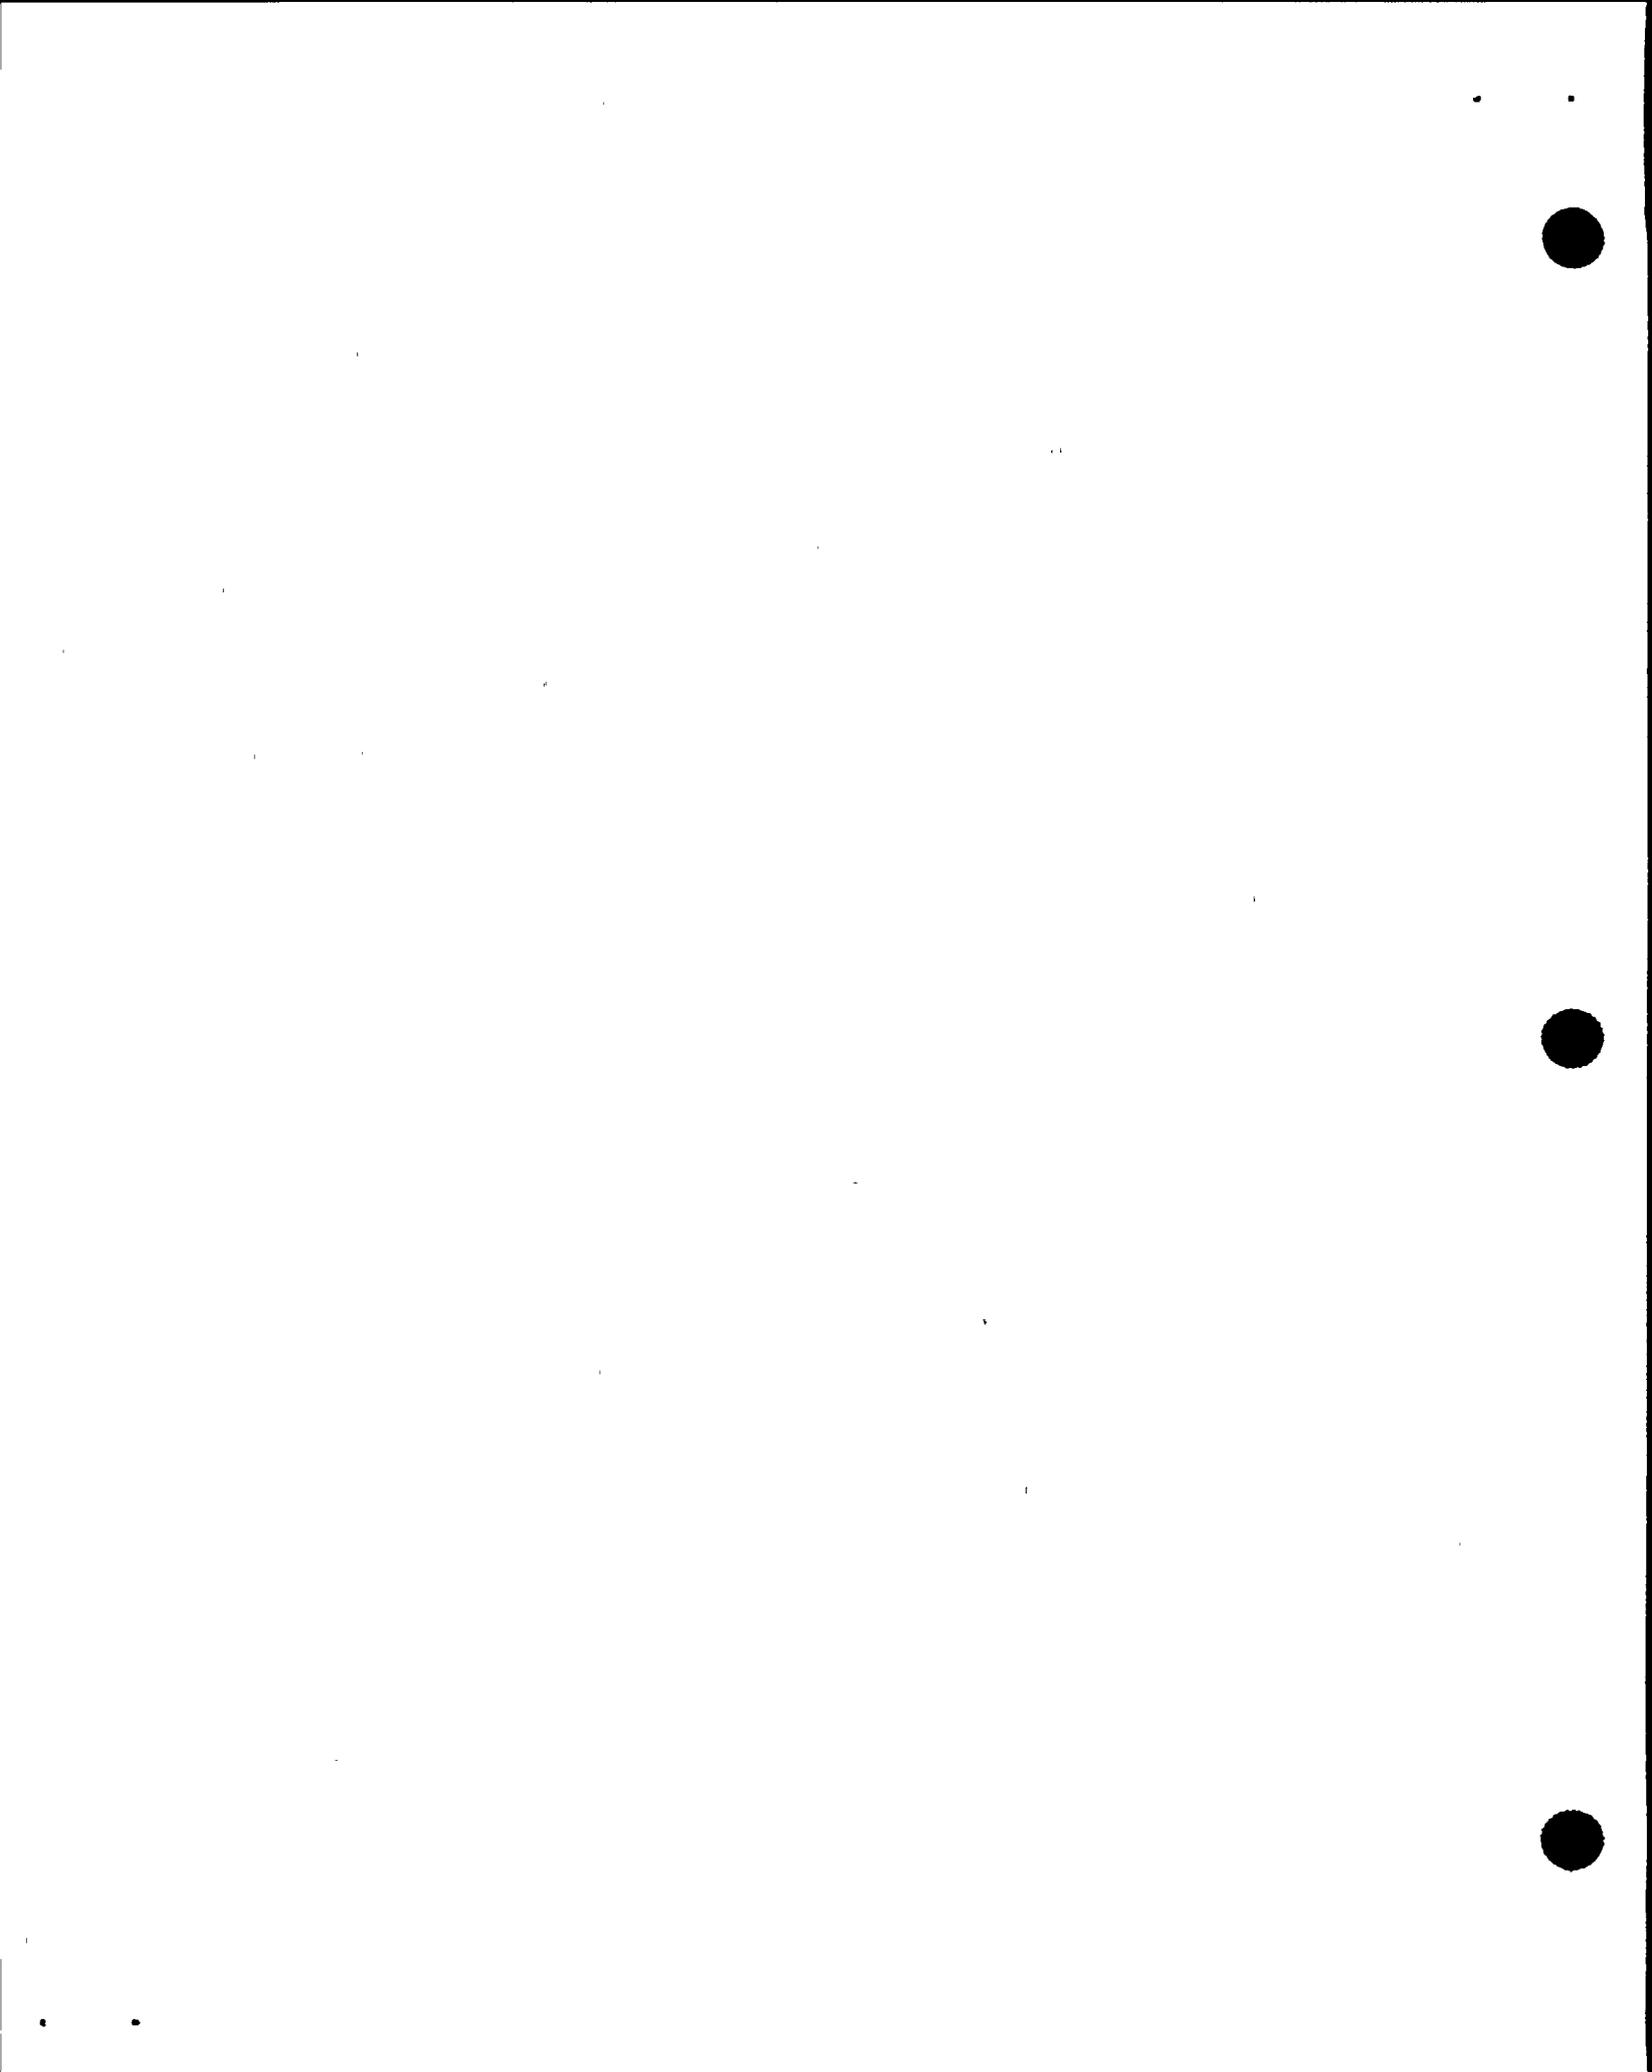

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).
Note:	The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

2.0 SAFETY LIMITS AND LIMITING SAFETY SYSTEM SETTINGS

2.1 SAFETY LIMITS

REACTOR CORE

2.1.1 The combination of THERMAL POWER, pressurizer pressure, and the highest operating loop coolant temperature (T_{avg}) shall not exceed the limits shown in Figure 2.1-1.

APPLICABILITY: MODES 1 and 2.

ACTION:

Whenever the point defined by the combination of the highest operating loop average temperature and THERMAL POWER has exceeded the appropriate pressurizer pressure line, be in HOT STANDBY within 1 hour ~~and comply with the requirements of Specification 6.7.~~

01-02-A

REACTOR COOLANT SYSTEM PRESSURE

2.1.2 The Reactor Coolant System pressure shall not exceed 2735 psig.

APPLICABILITY: MODES 1, 2, 3, 4 and 5.

ACTION:

MODES 1 and 2:

Whenever the Reactor Coolant System pressure has exceeded 2735 psig, be in HOT STANDBY with the Reactor Coolant System pressure within its limit within 1 hour, ~~and comply with the requirements of Specification 6.7.~~

01-02-A

MODES 3, 4 and 5:

Whenever the Reactor Coolant System pressure has exceeded 2735 psig, reduce the Reactor Coolant System pressure to within its limit within 5 minutes, ~~and comply with the requirements of Specification 6.7.~~

01-02-A

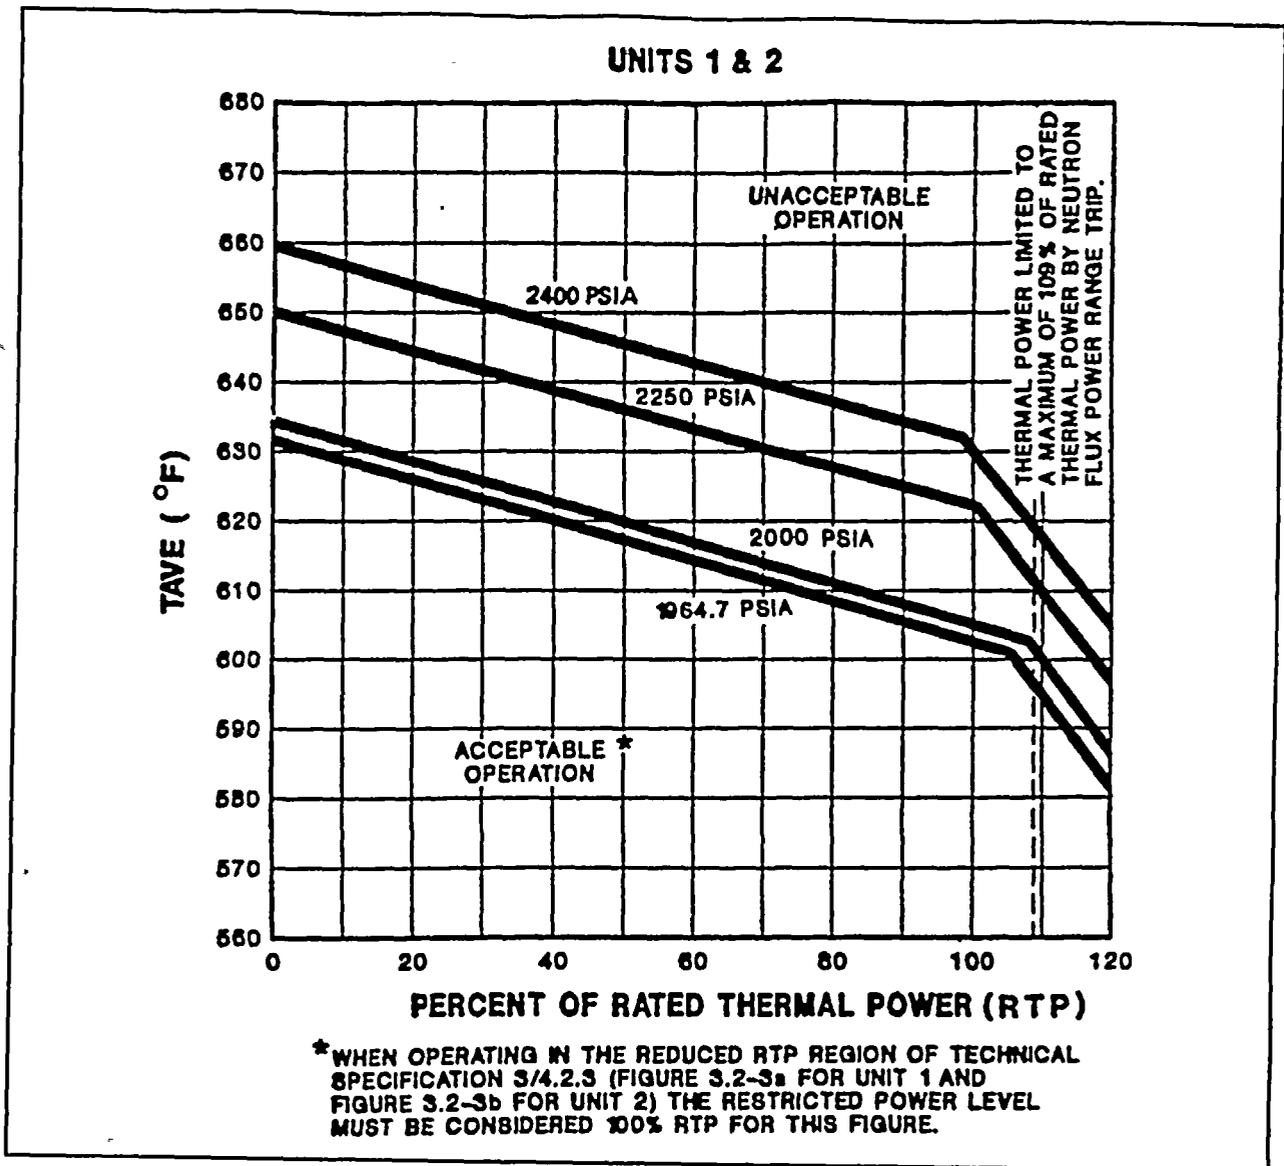

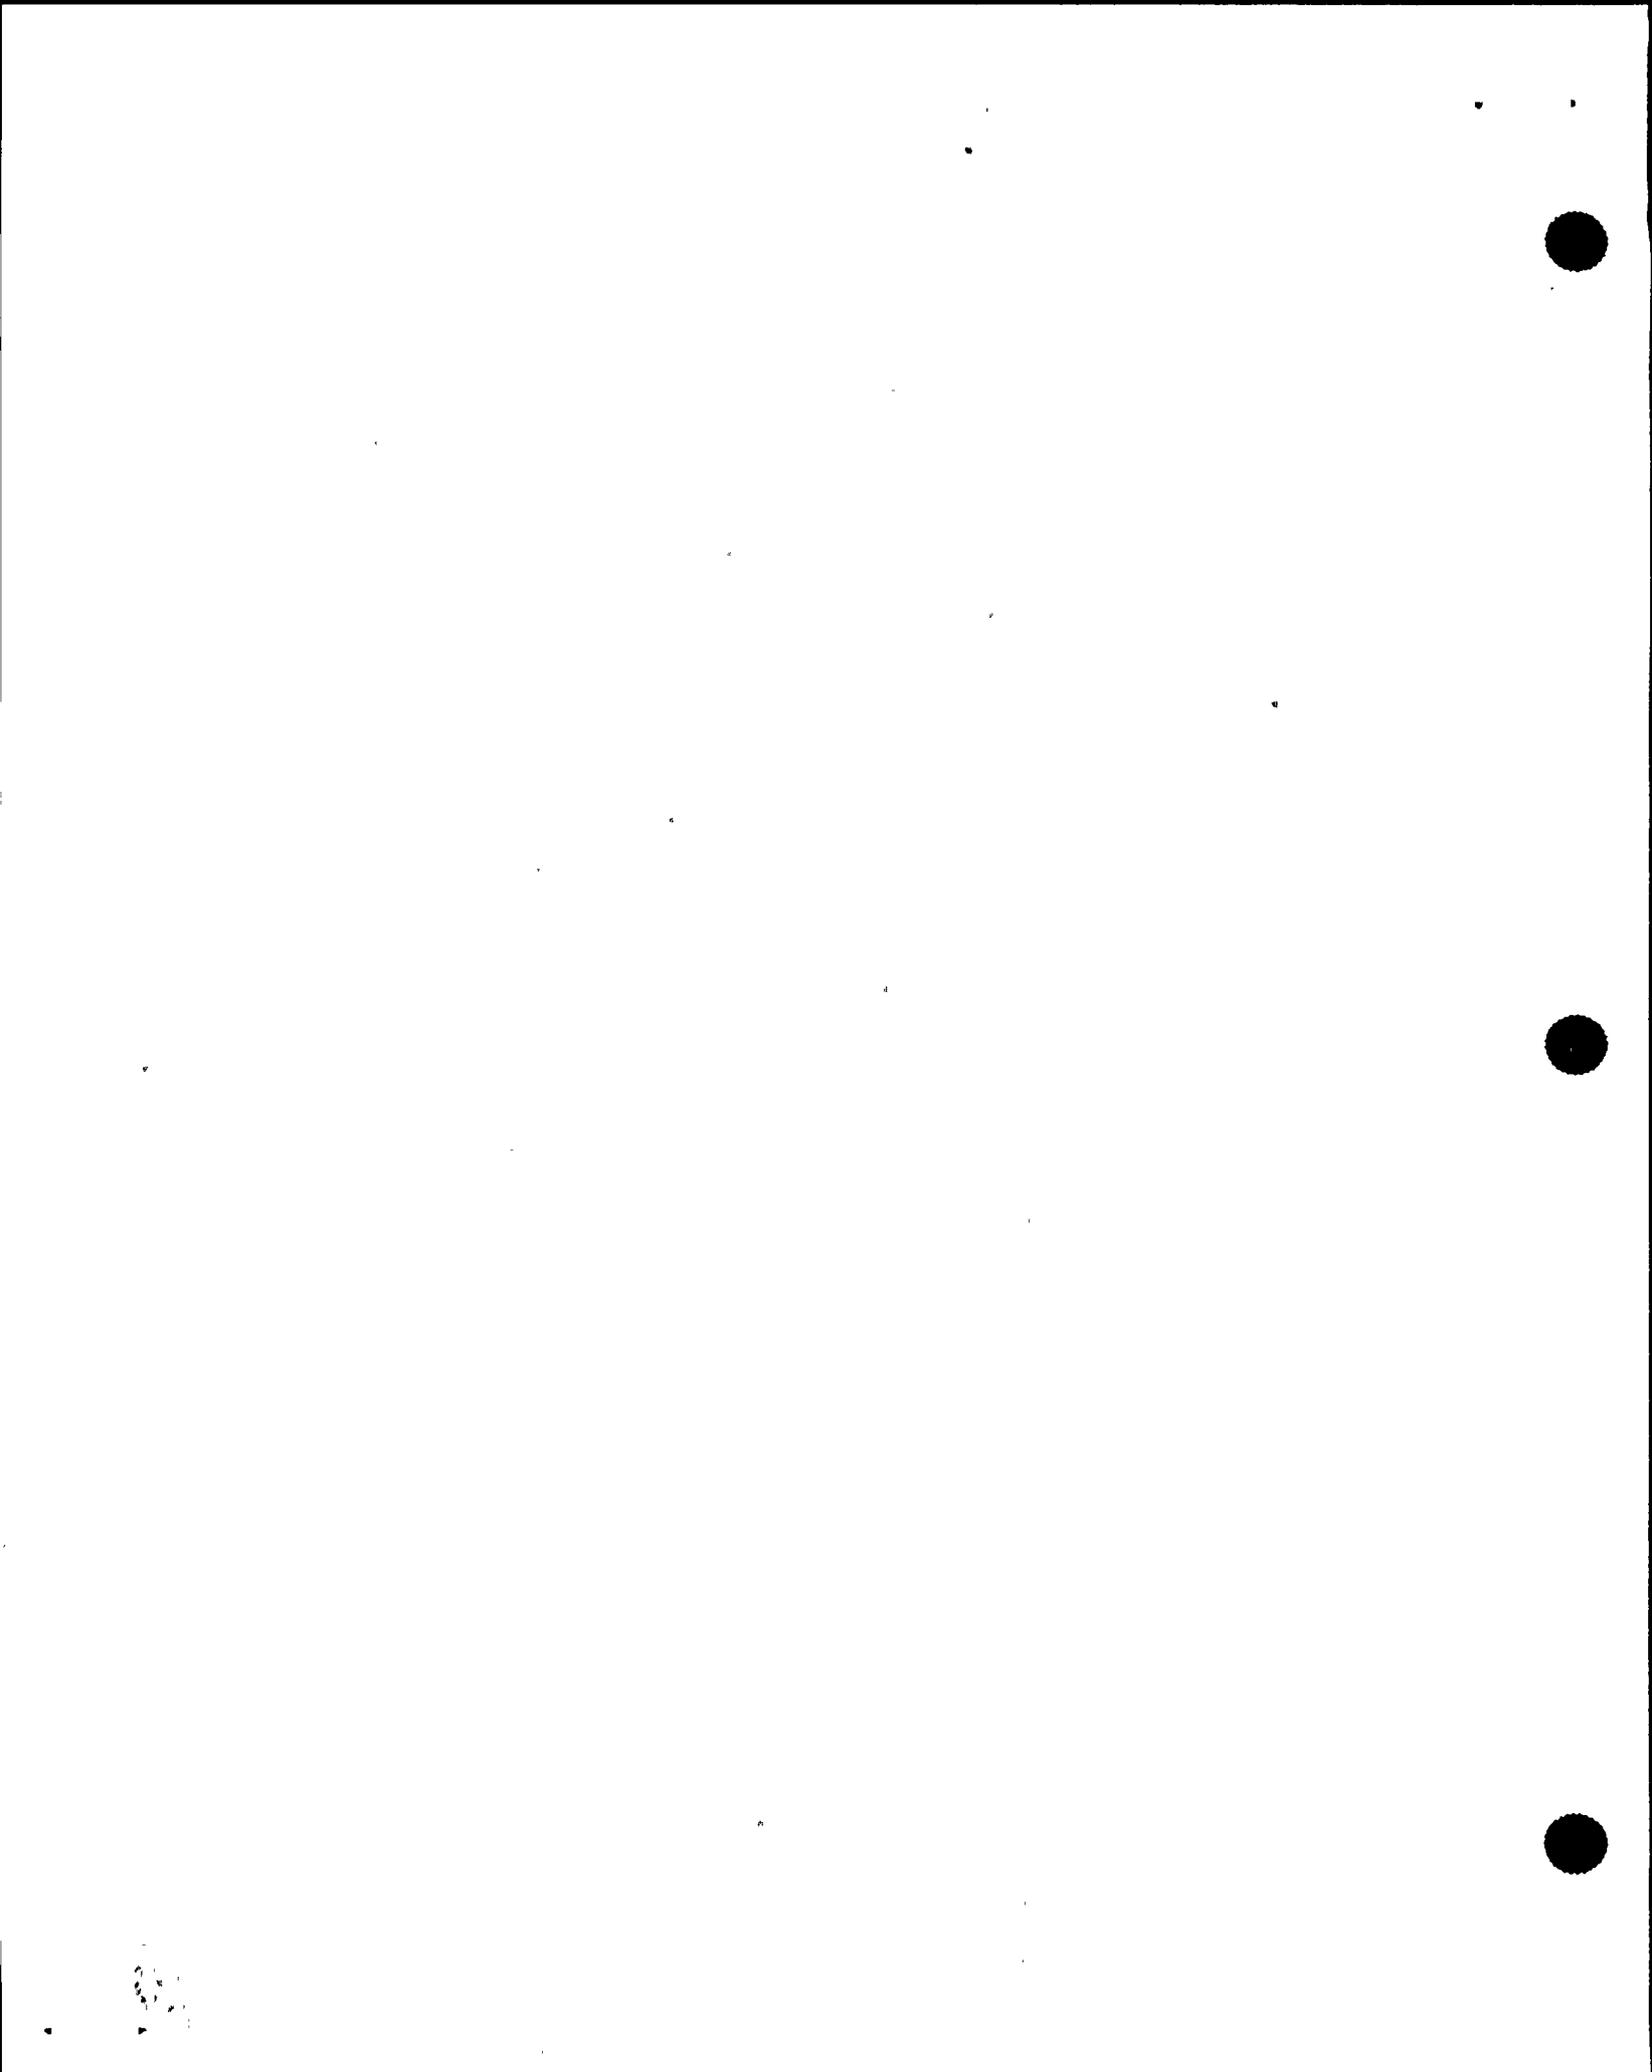

FIGURE 2.1-1

REACTOR TRIP SYSTEM INSTRUMENTATION SETPOINTS

~~2.2.1 The Reactor Trip System Instrumentation and Interlock Setpoints shall be set consistent with the Trip Setpoint values shown in Table 2.2-1.~~

APPLICABILITY: As shown for each channel in Table 3.3-1.

ACTION:

a. ~~With a Reactor Trip System Instrumentation or Interlock Setpoint less conservative than the value shown in the Trip Setpoint column but more conservative than the value shown in the Allowable Values column of Table 2.2-1, adjust the Setpoint consistent with the Trip Setpoint value.~~

02-06-LG

b. ~~With a Reactor Trip System Instrumentation or Interlock Setpoint less conservative than the value shown in the Allowable Values column of Table 2.2-1, declare the channel inoperable and apply the applicable ACTION statement requirements of Specification 3.3.1 until the channel is restored to OPERABLE status with its Setpoint adjusted consistent with the Trip Setpoint value.~~

02-06-LG

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. **Deletions** - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. **Additions** - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. **Modifications** - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. **Administrative** - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions** - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions** - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications** - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative** - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

Methodology For Mark-Up of Current TS
(Continued)

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 2.0

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-02	A	The requirements embodied in separate administrative controls dealing with Safety Limits (SL) violations are deleted. Specifications 6.7 is deleted per CN 02-02-LS in Enclosure 3A of the Administrative Controls package.
02-01	A	The requirements of this LCO are moved to ITS LCO 3.3.1.
02-02	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-03	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-04	M	Addition of the inequality signs, consistent with NUREG-1431, indicates the conservative direction for these K values.
02-05	A	This change corrects the $OT_{\Delta T}$ equation by relocating the bracket to the correct position, as described in CN 3.3-10 of the CTS 3/4.3 attachment.
02-06	LG	The requirements stipulated in ACTIONS [a and b] are moved to ITS Table 3.3.1-1, with explicit direction contained in [the ITS Background (Trip Setpoints and Allowable Values) Bases, ACTIONS Bases, and SR 3.3.1.10 and SR 3.3.1.11 Bases]. This change removes details more appropriately controlled outside of the TS while retaining those aspects necessary to assure the protection functions are performed if necessary.
02-07	A	This change incorporates the values for T' (Nominal T_{avg} at RATED THERMAL POWER), that were inadvertently deleted during a previous License Amendment.

I.	Organization	2
II.	Description of NSHC Evaluations.	3
III.	Generic NSHCs	
	"A" - Administrative Changes	5
	"R" - Relocated Technical Specifications	7
	"LG" - Less Restrictive (moving information out of the TS)	10
	"M" - More Restrictive	12
IV.	Specific NSHCs - "LS"	
	None	
V.	Recurring NSHCs	
	None	

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

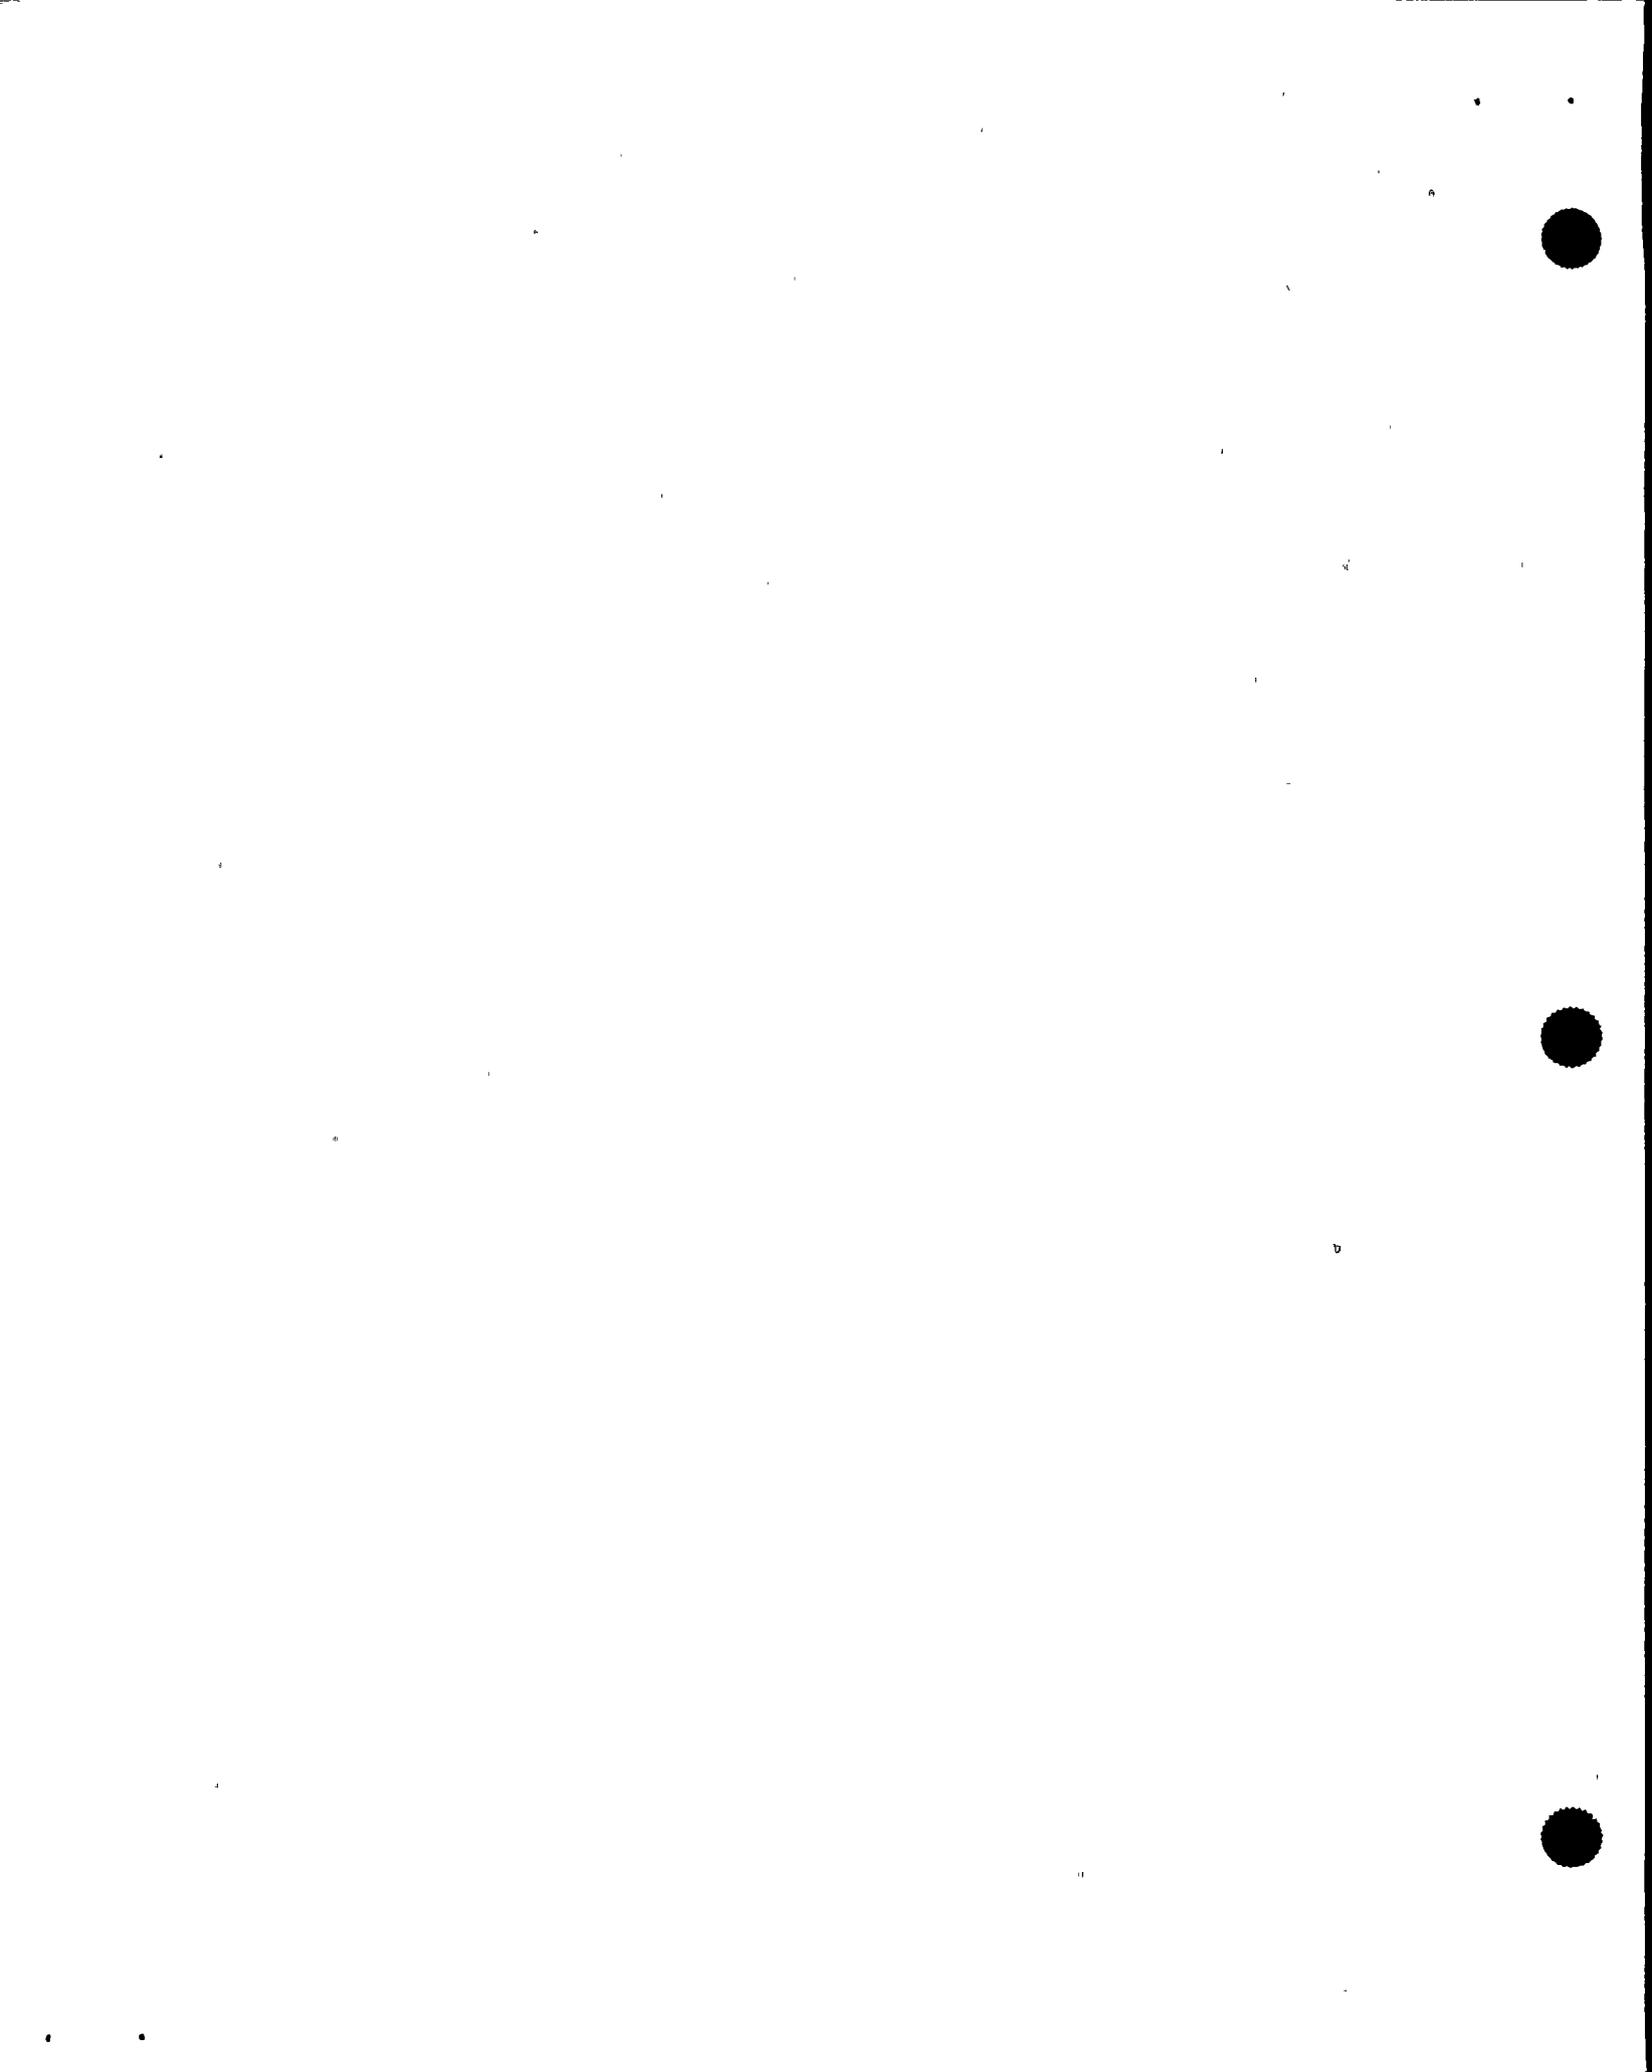

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3..." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

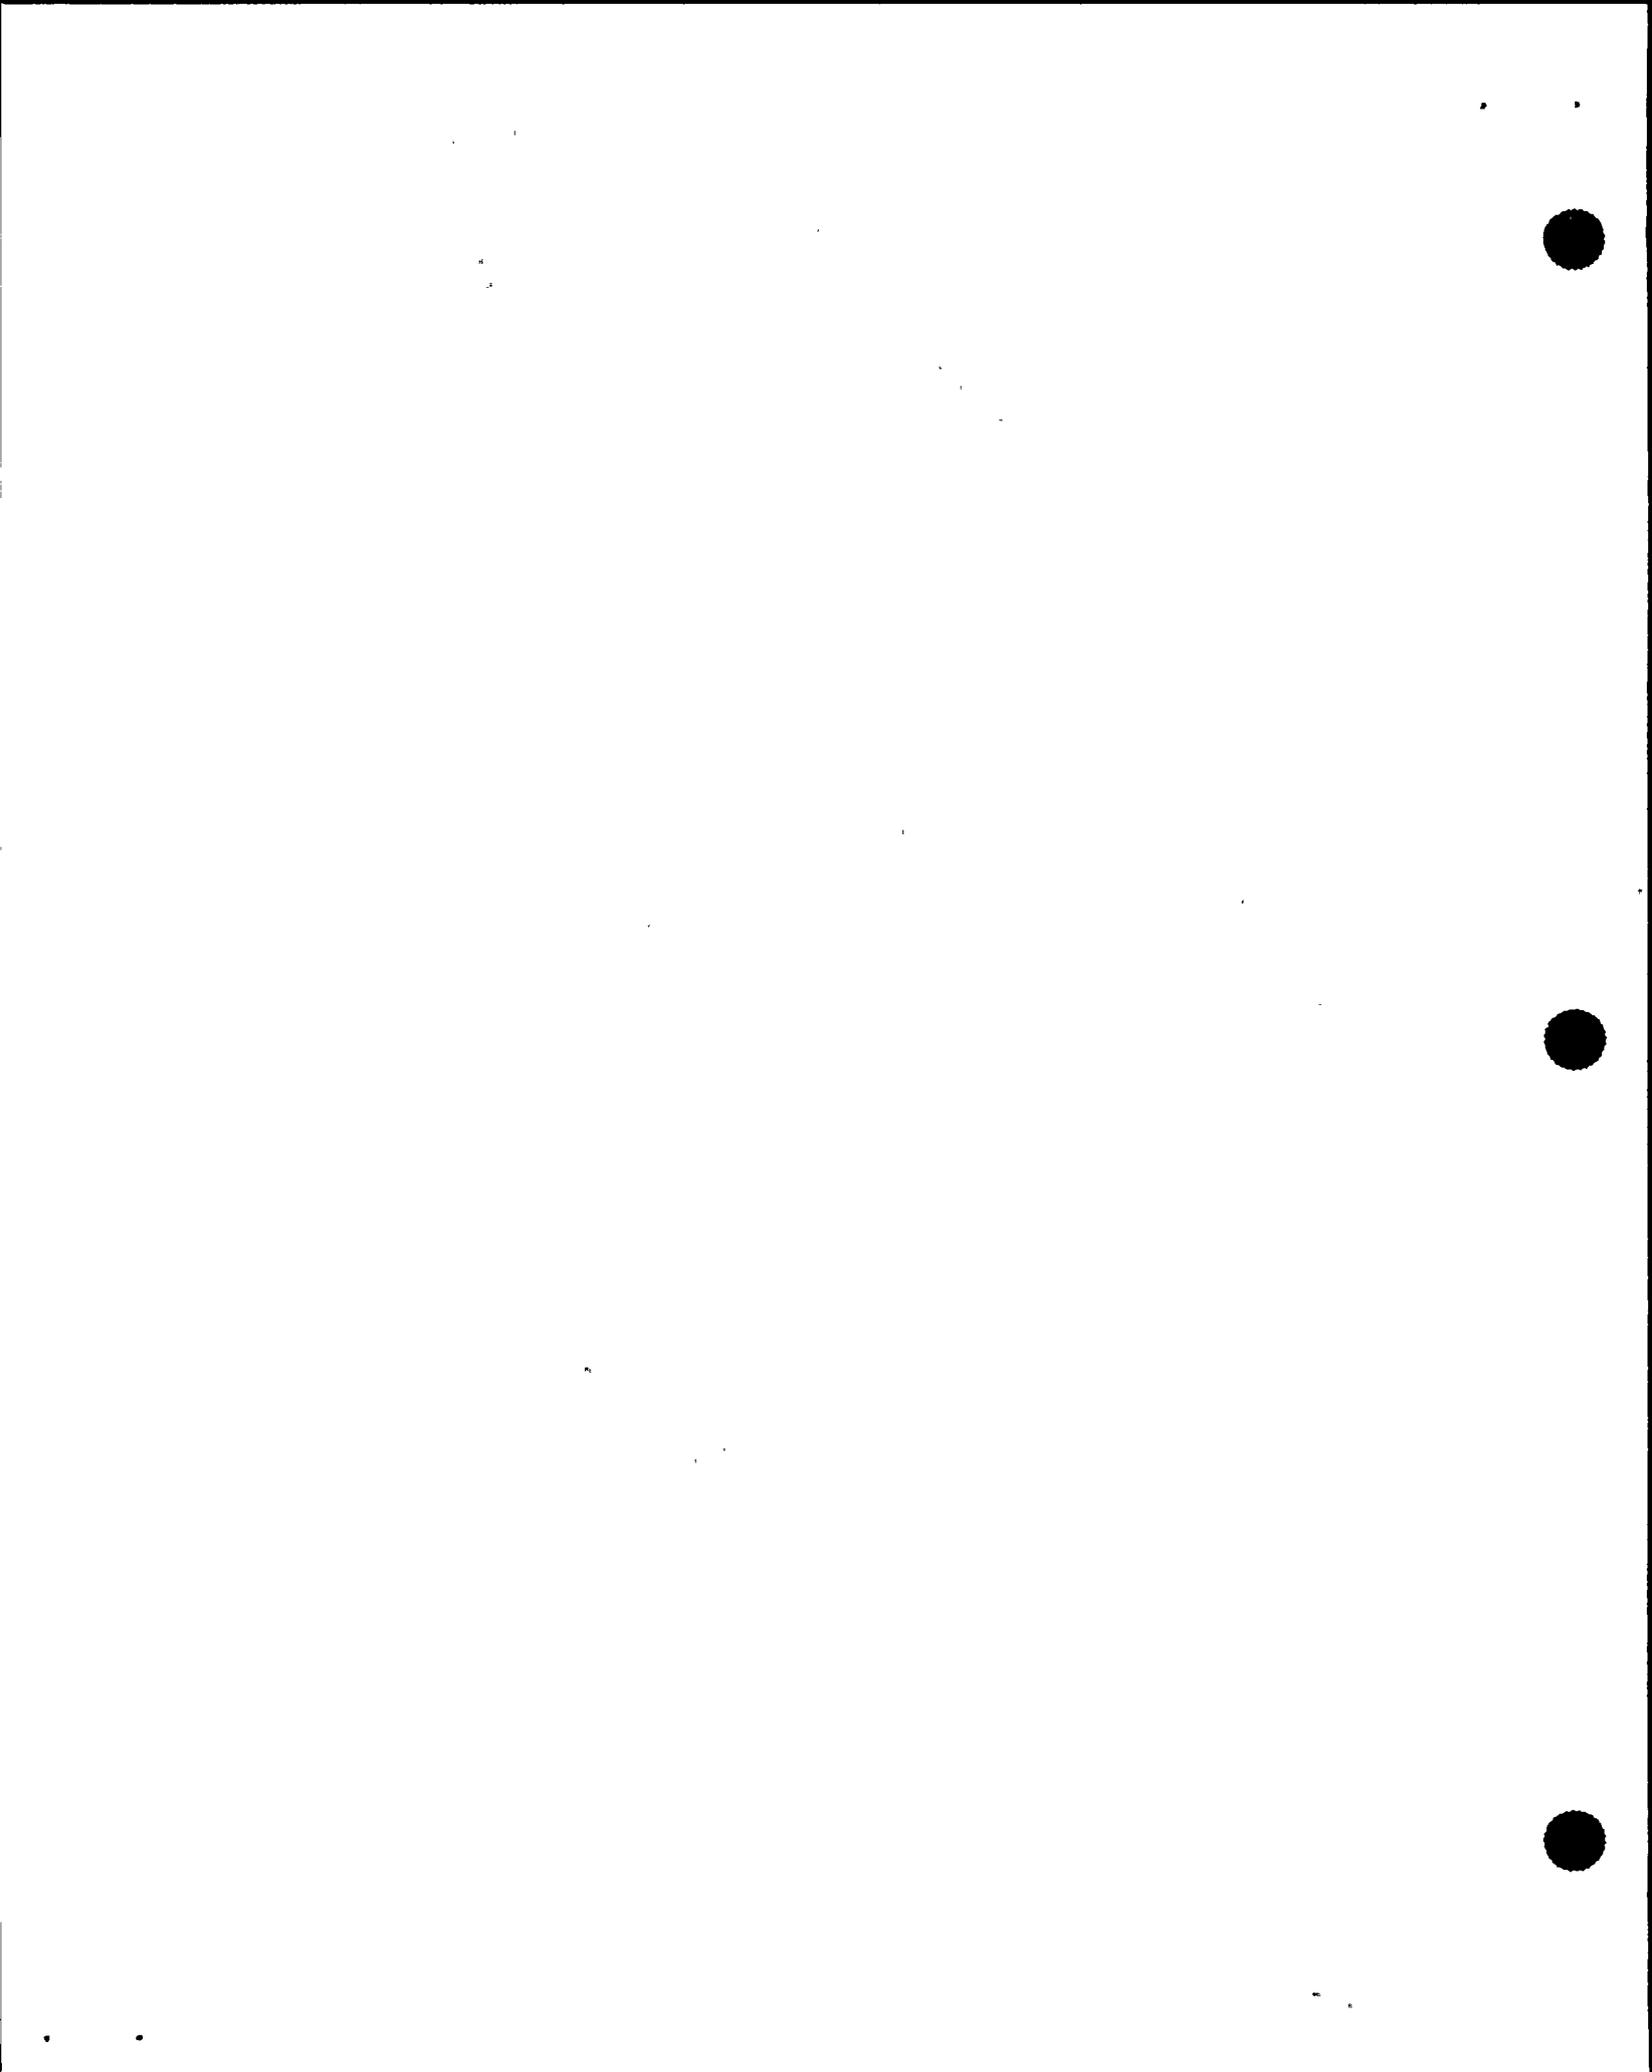

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

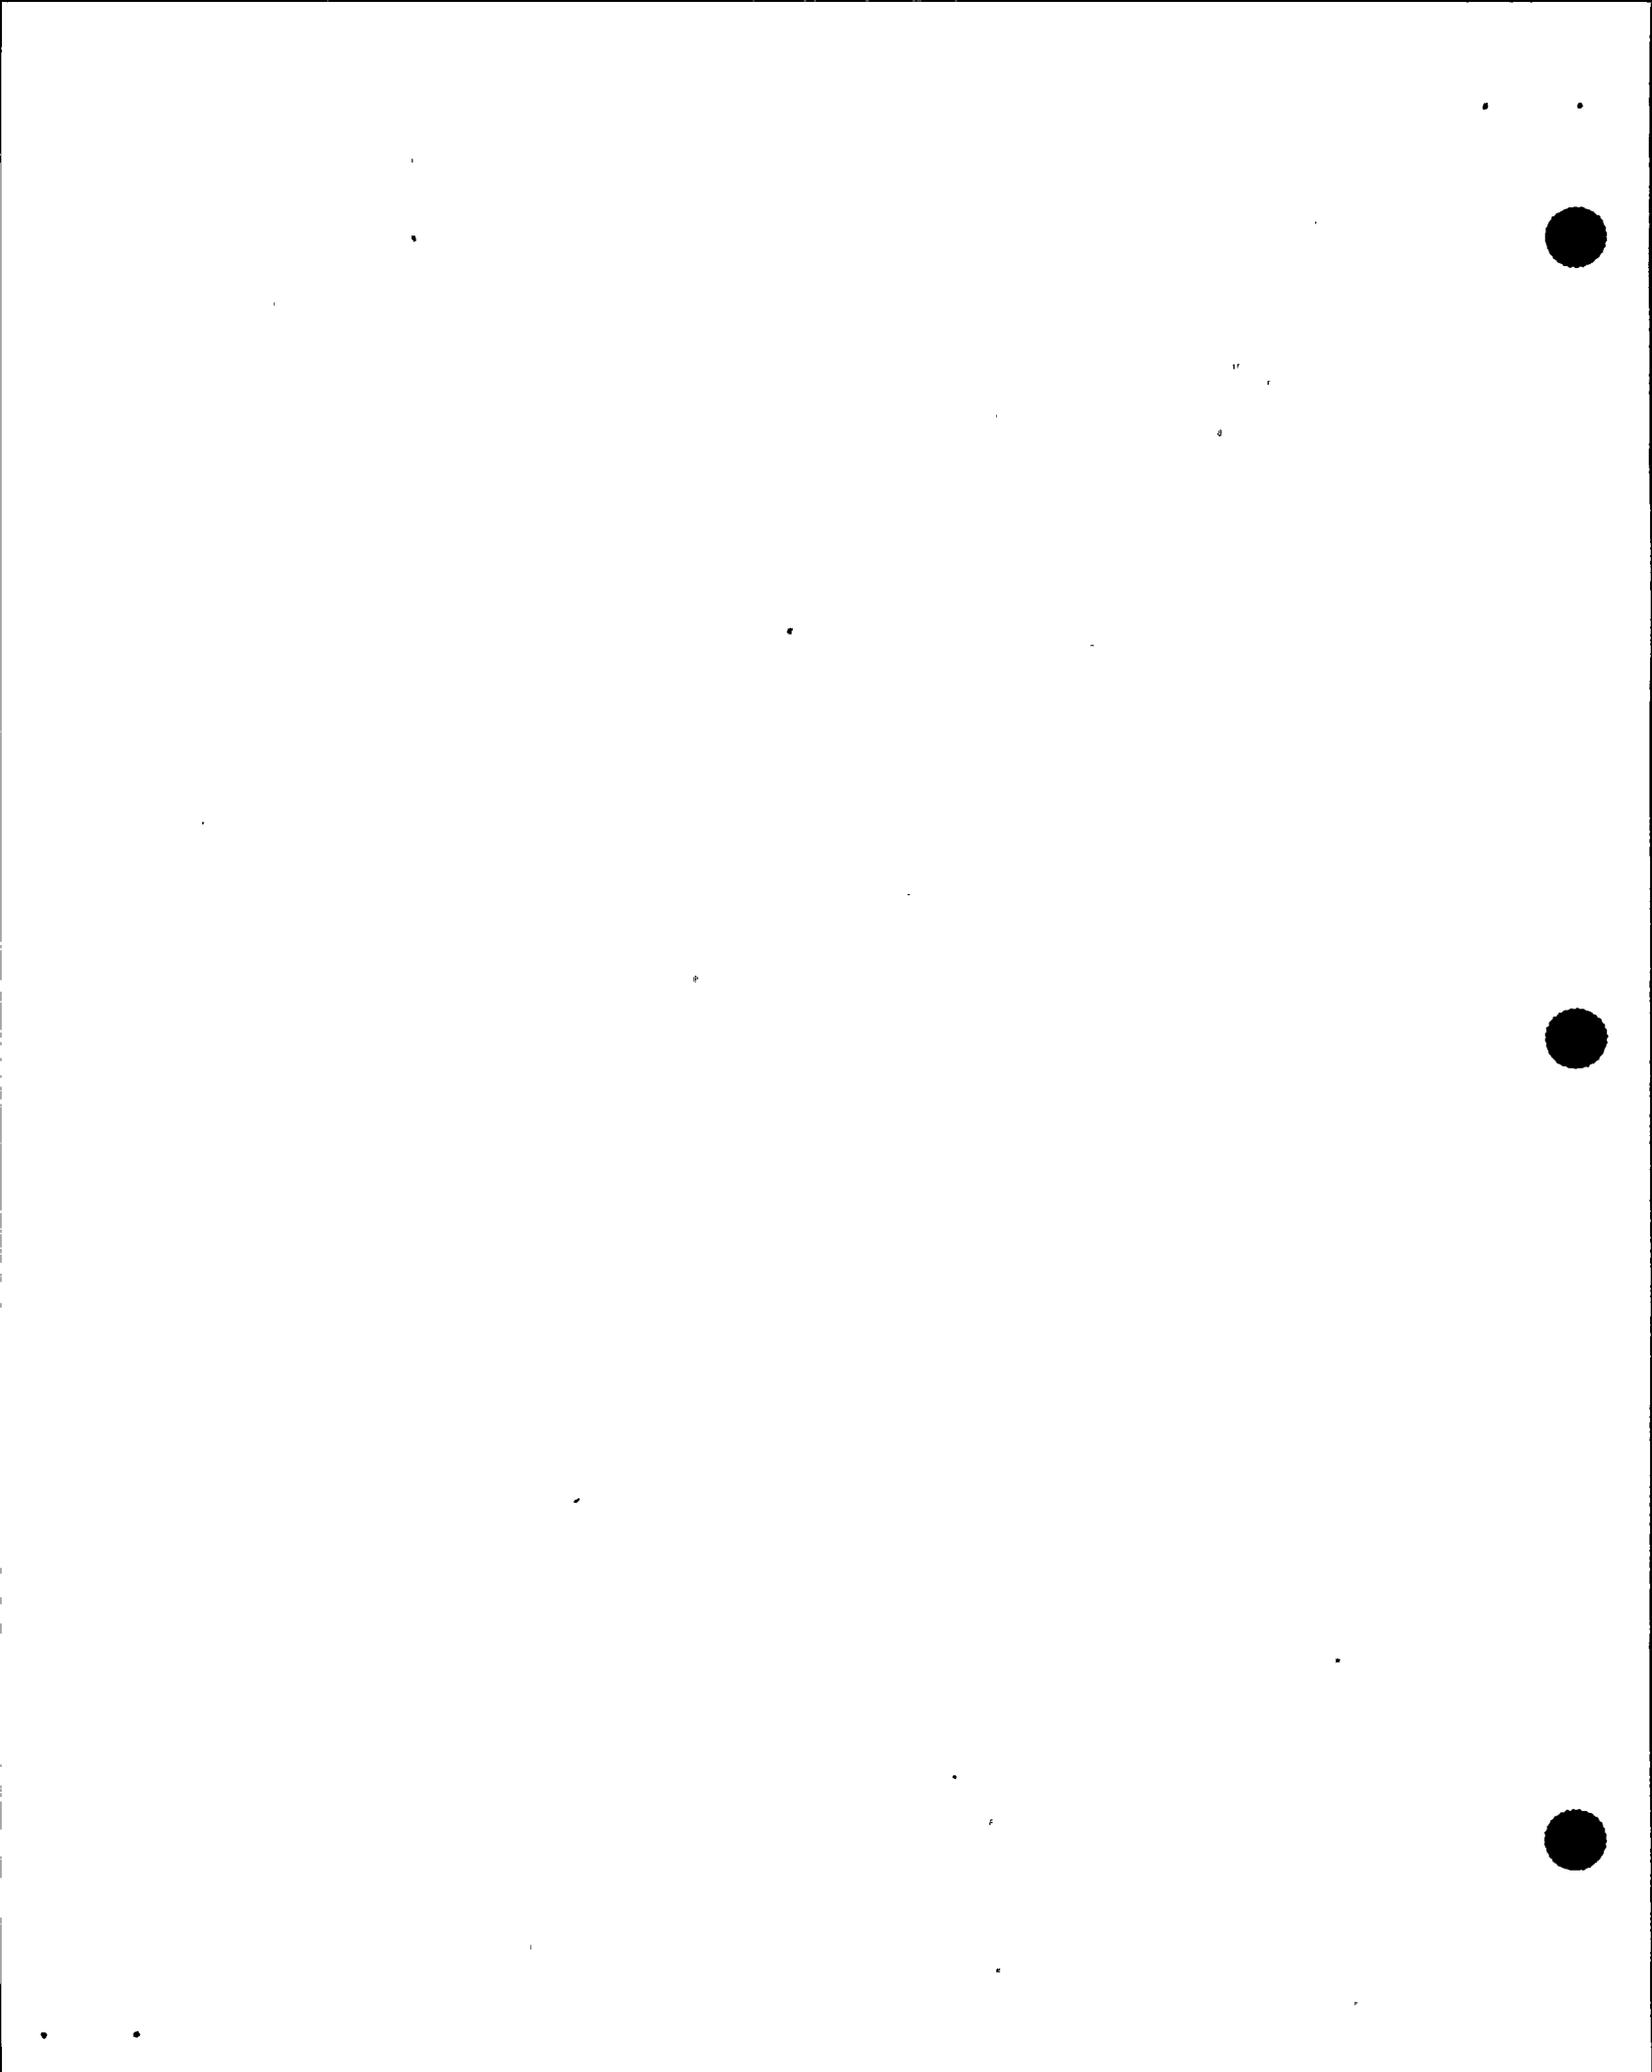

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

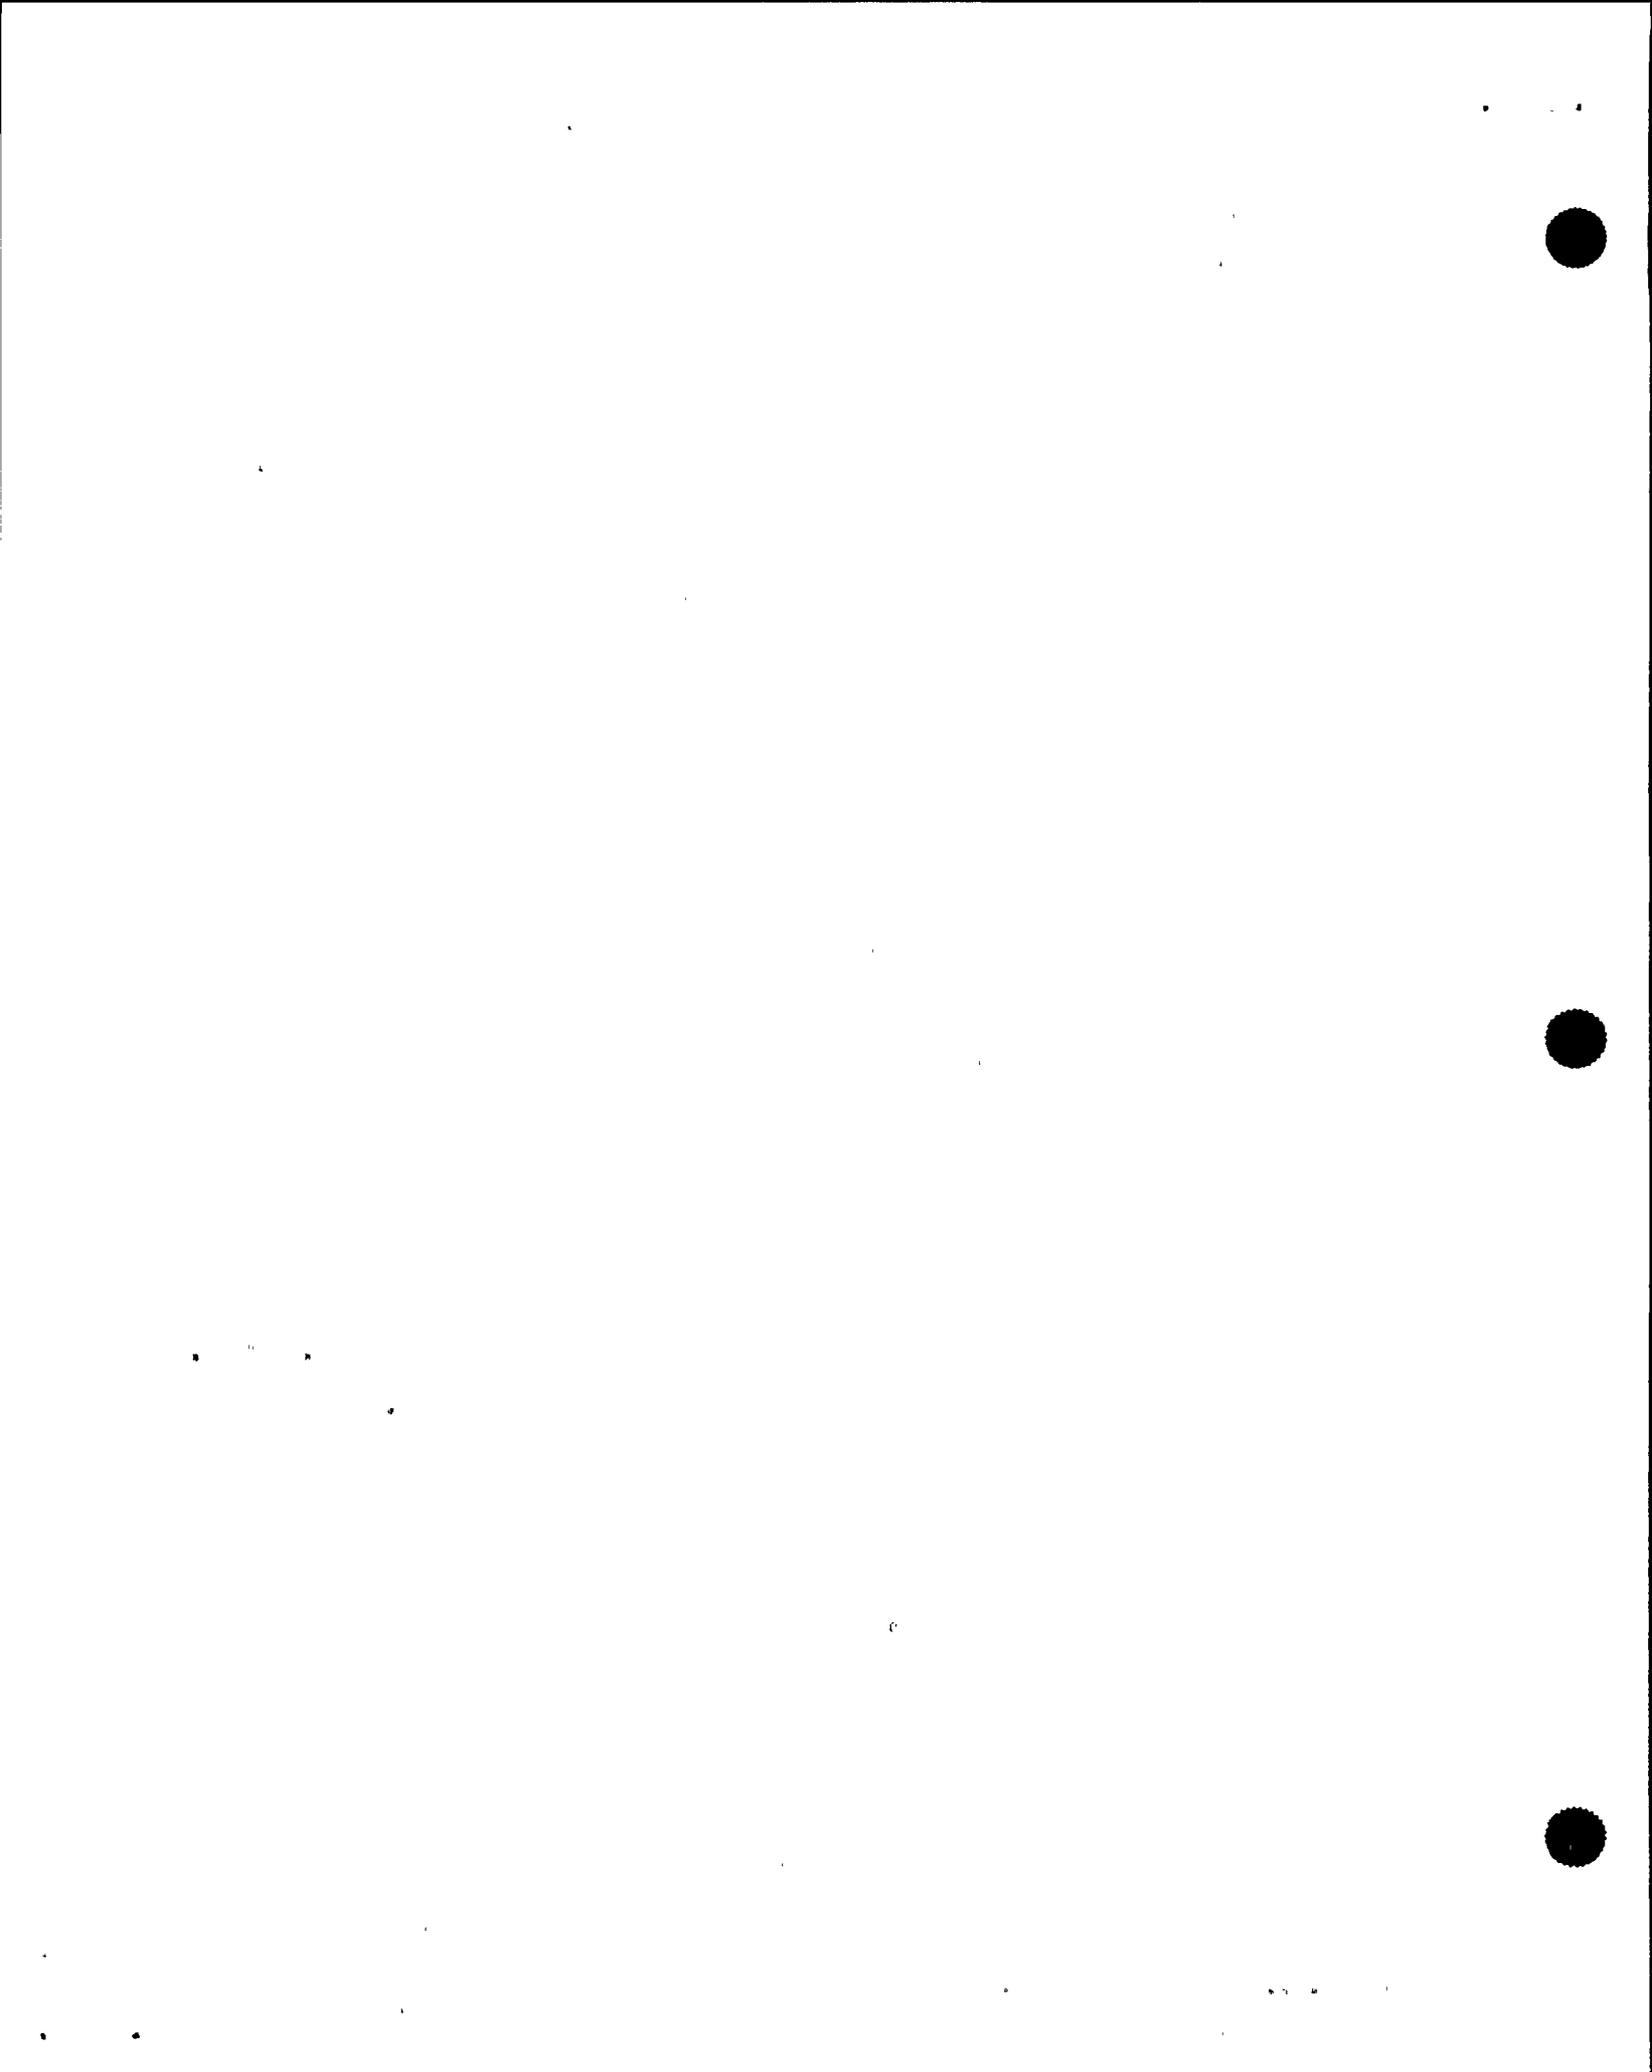

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

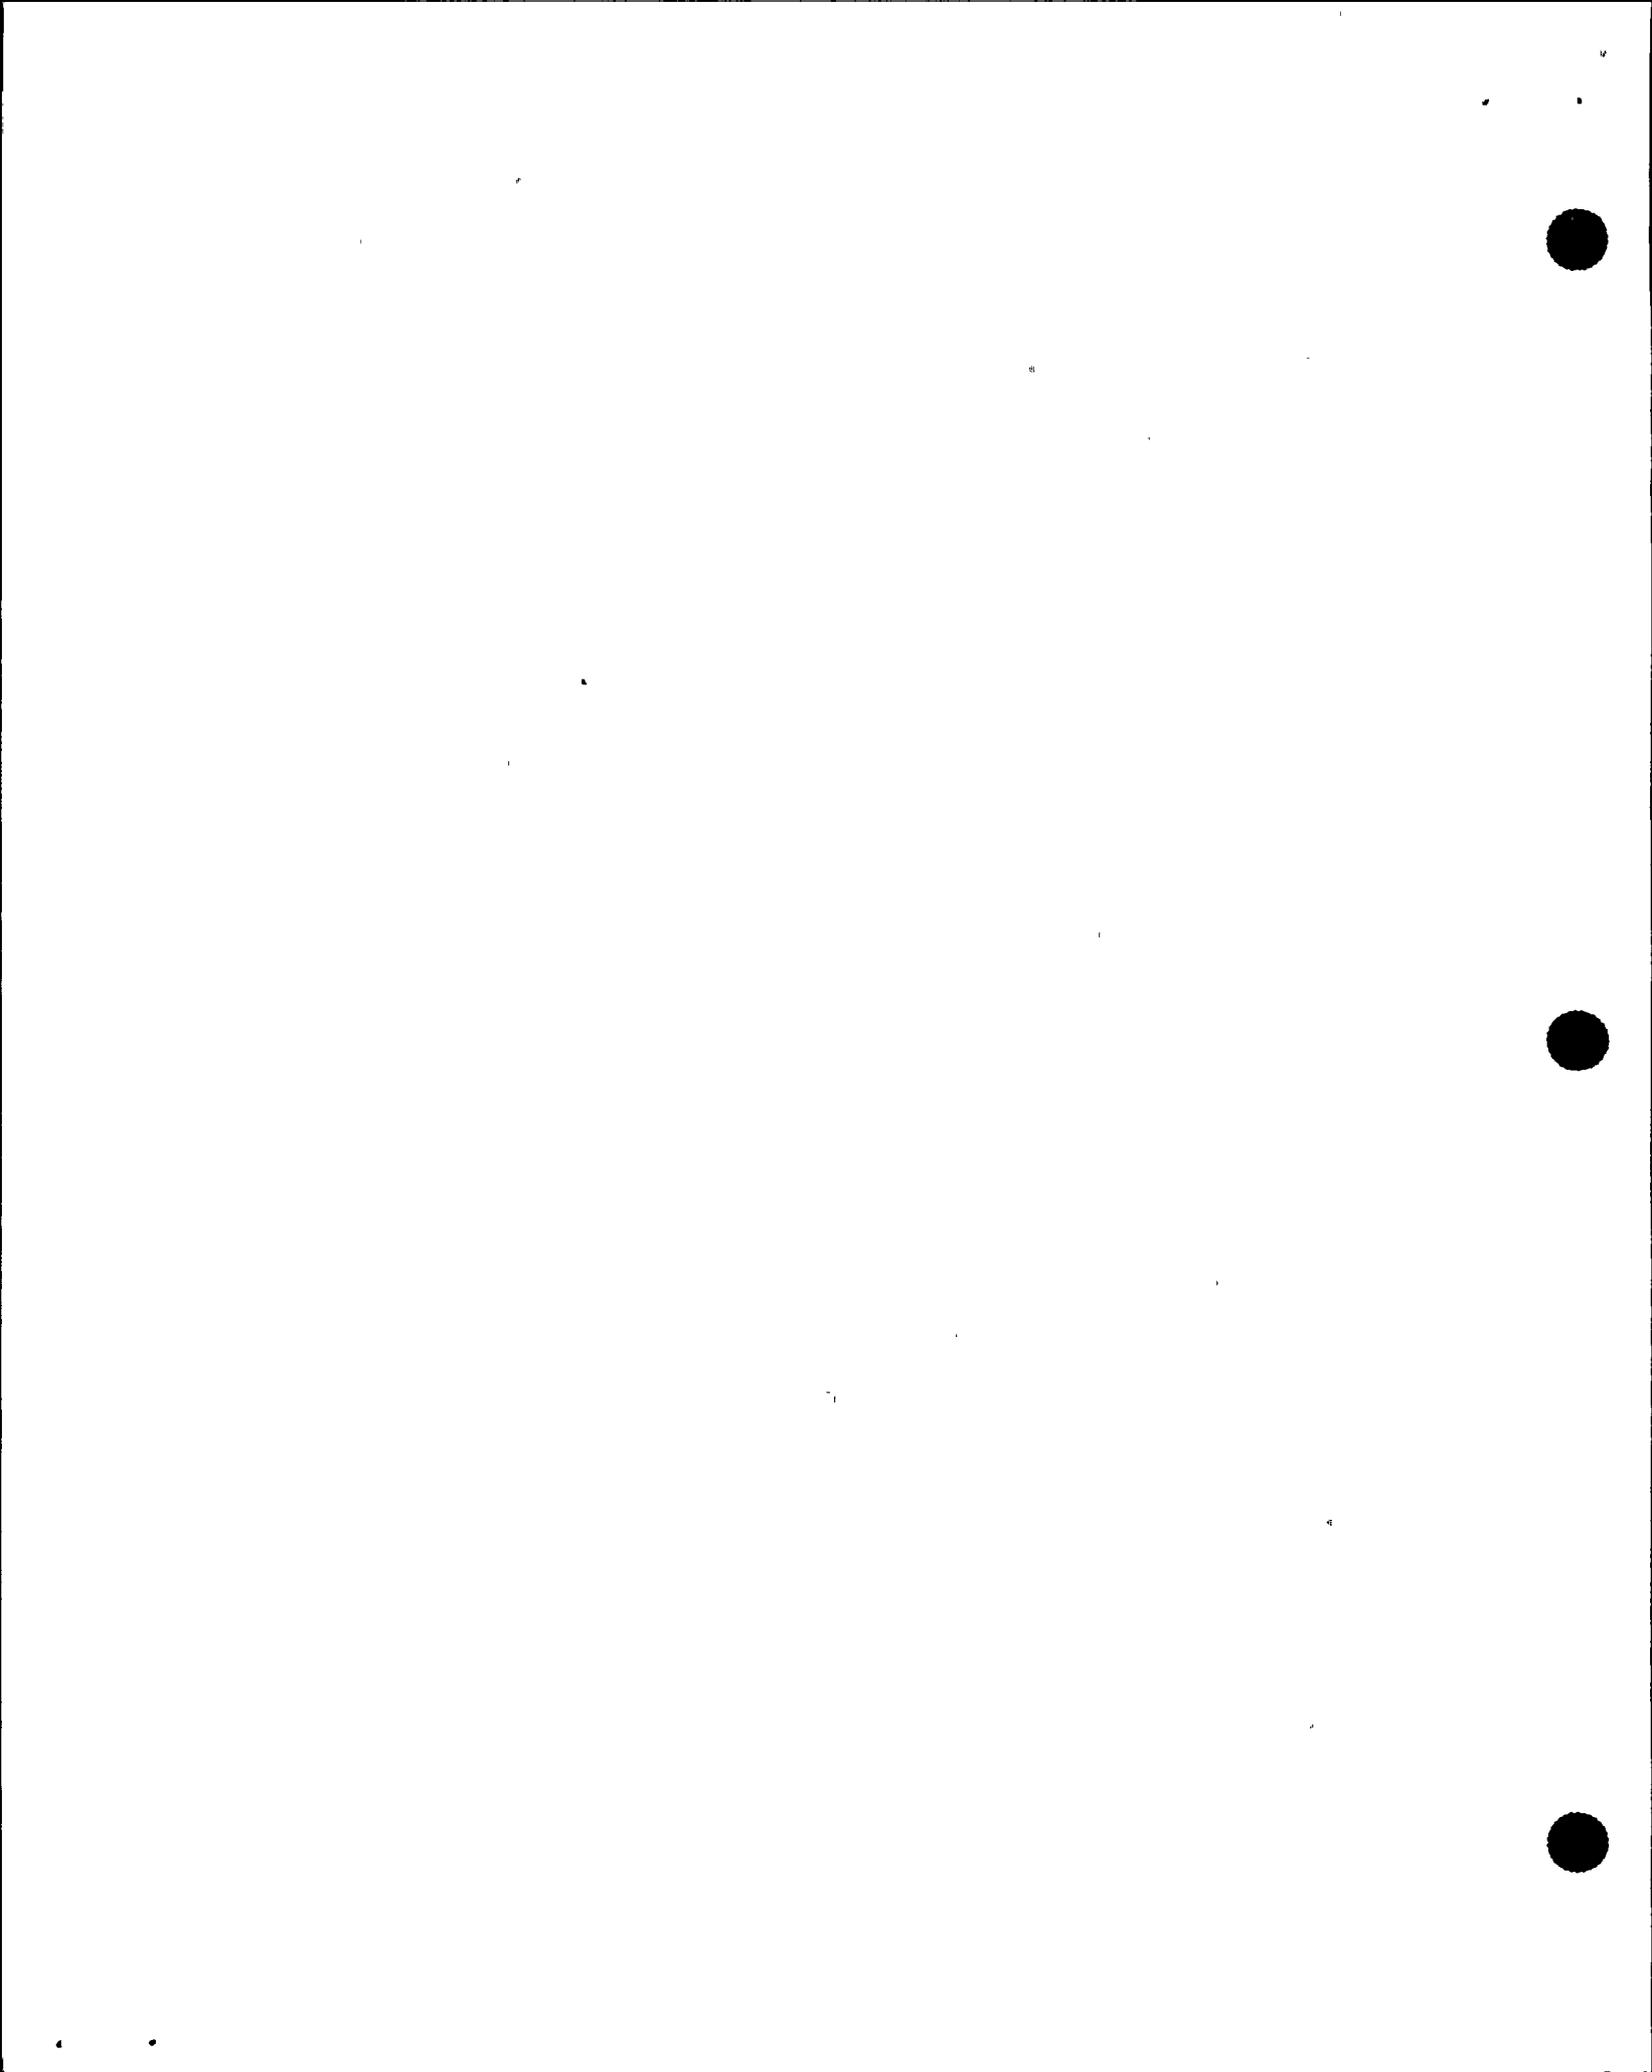

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

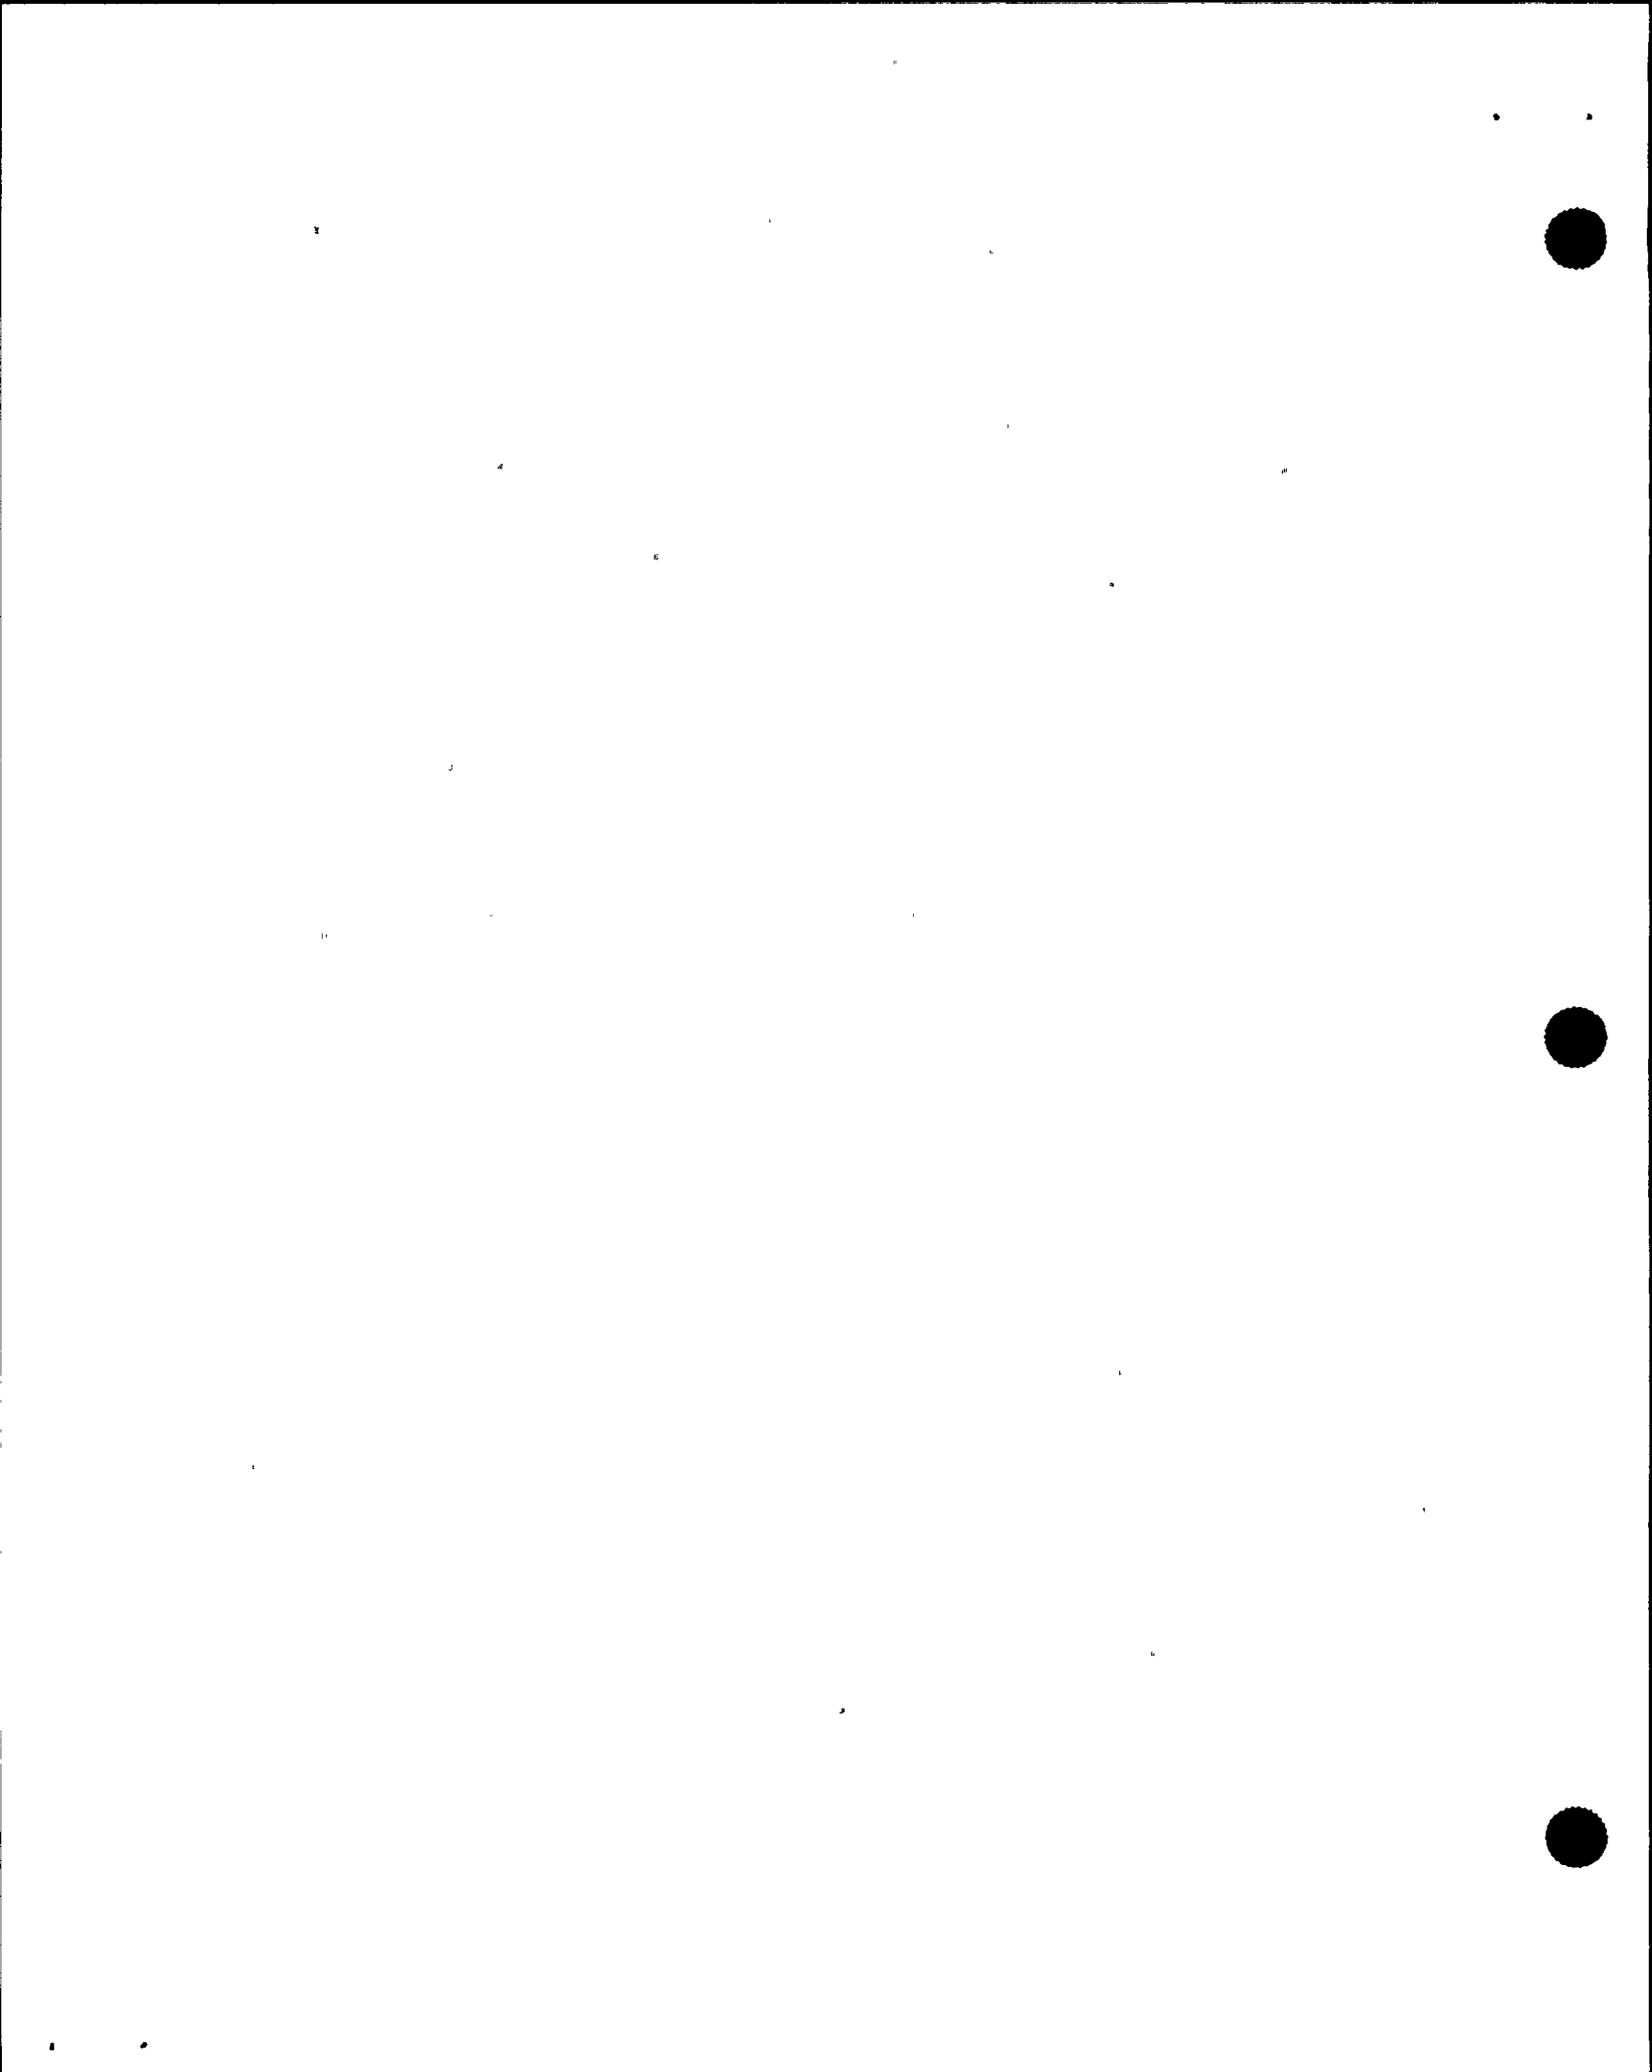

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

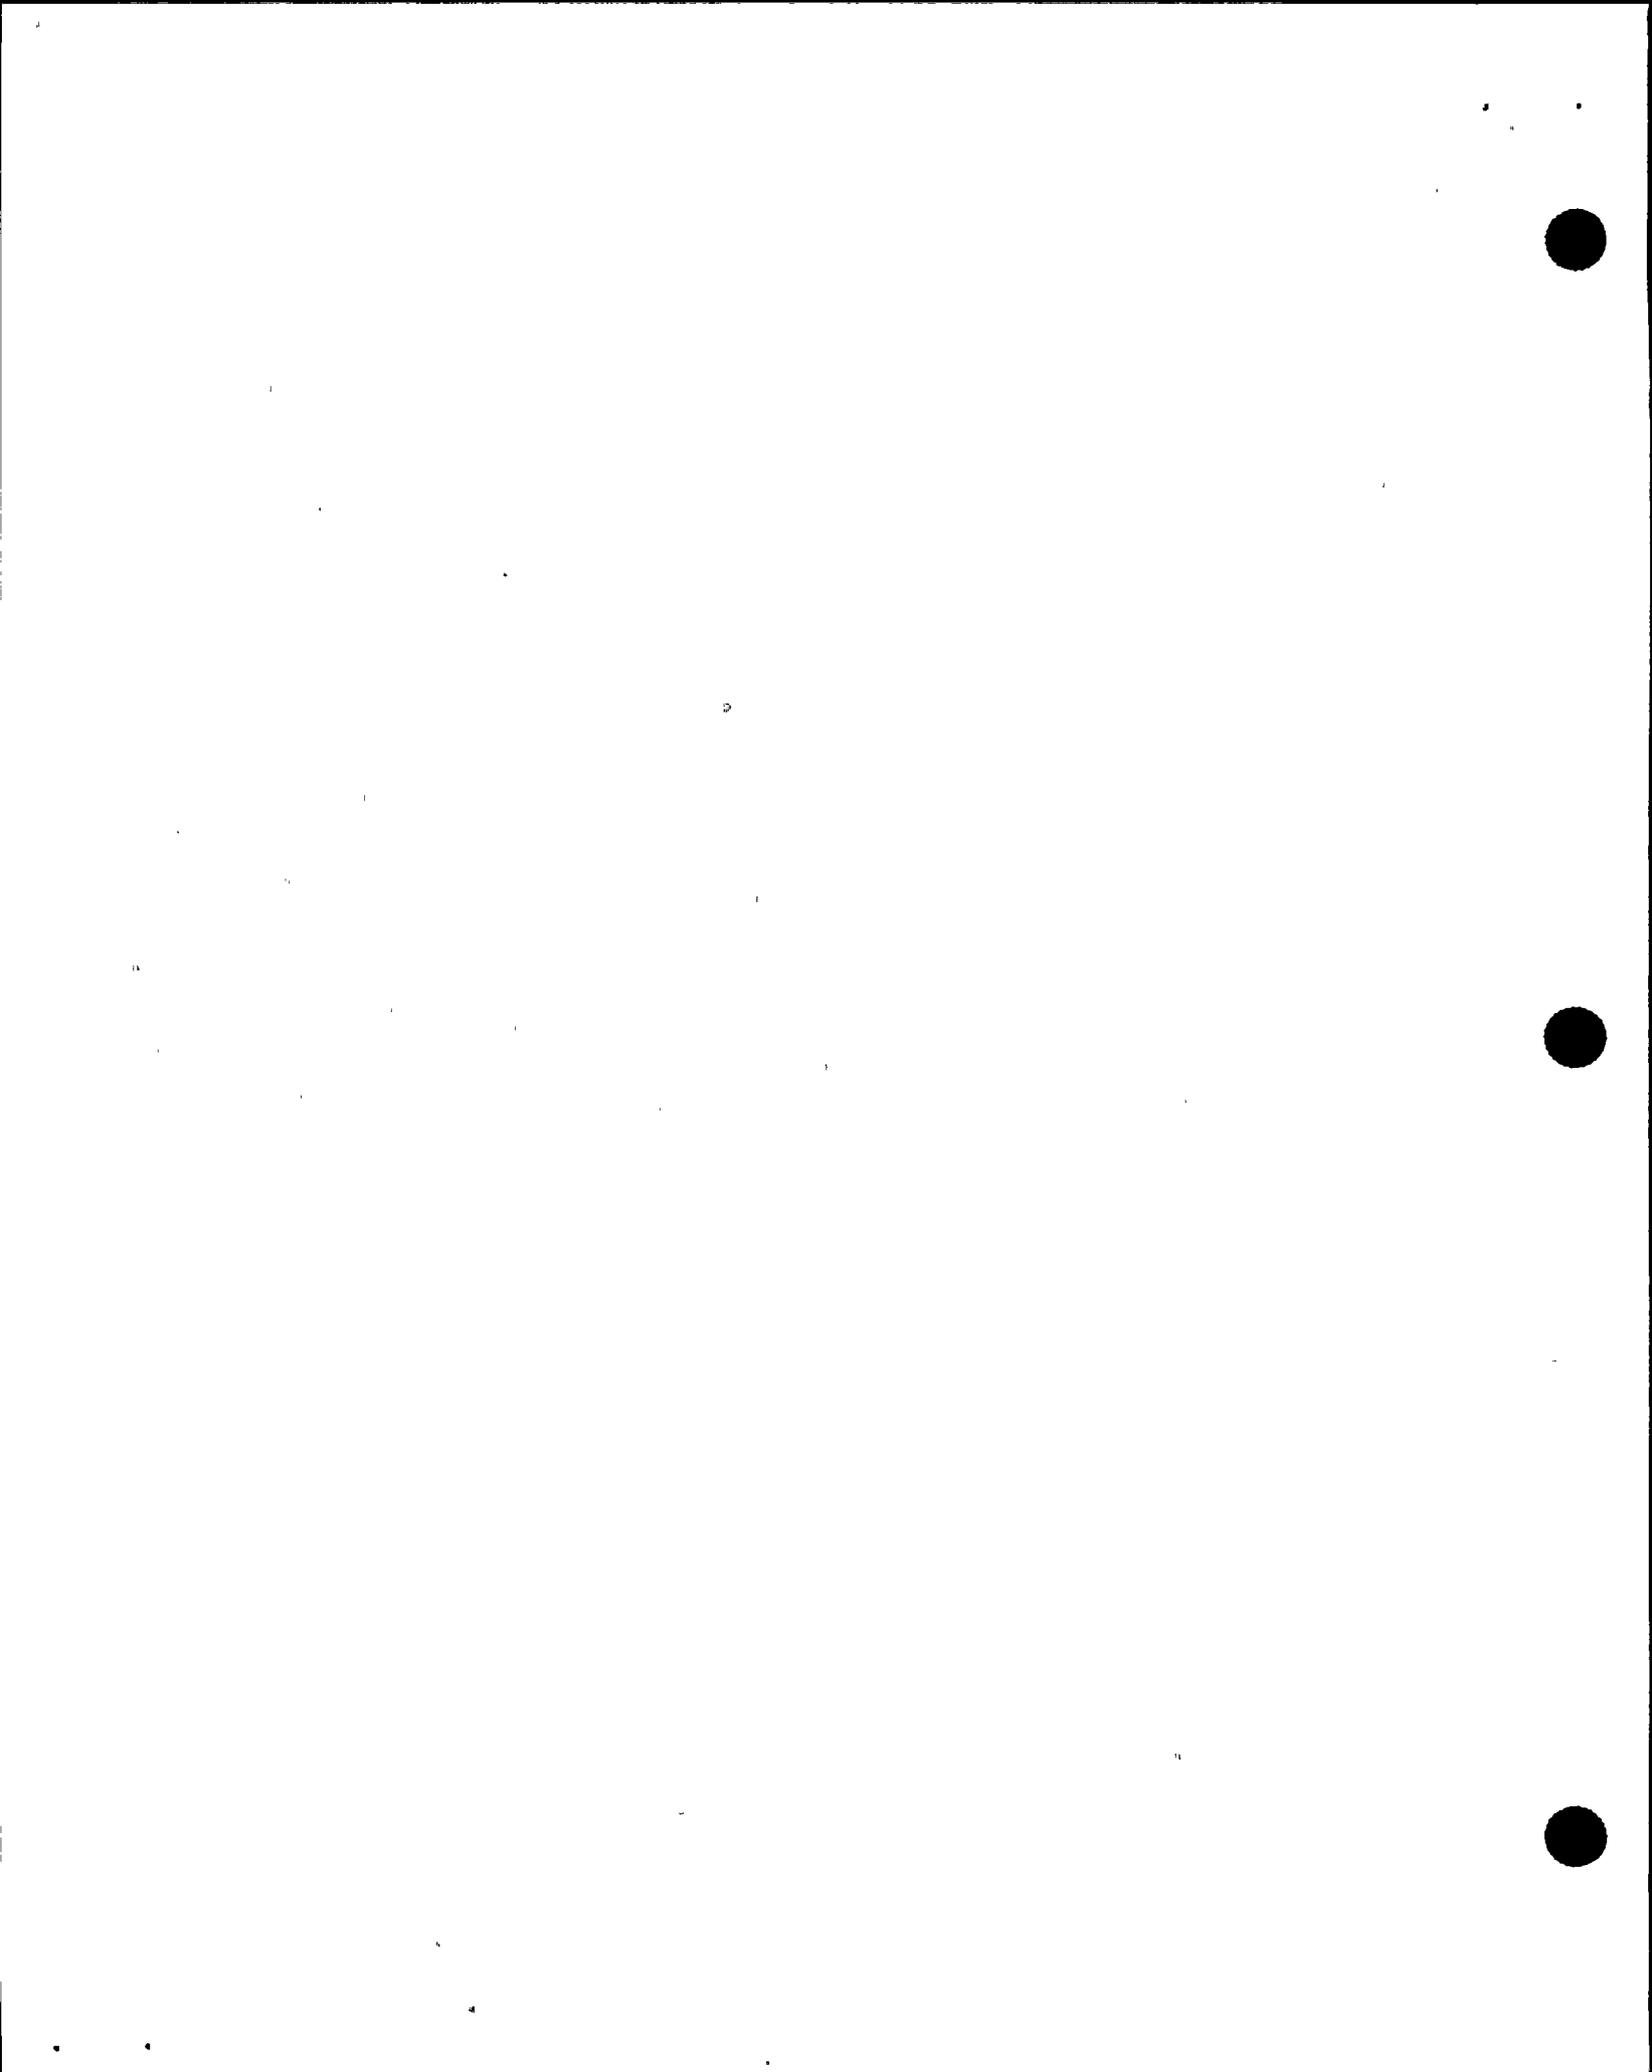

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

Mark-up:

<u>BASES</u>	<u>PAGE</u>
2.1.1	B 2.0-1
2.1.2	B 2.0-6
Methodology	(1 Page)

B 2.0 SAFETY LIMITS (SLs)

B 2.1.1 Reactor Core SLs

BASES

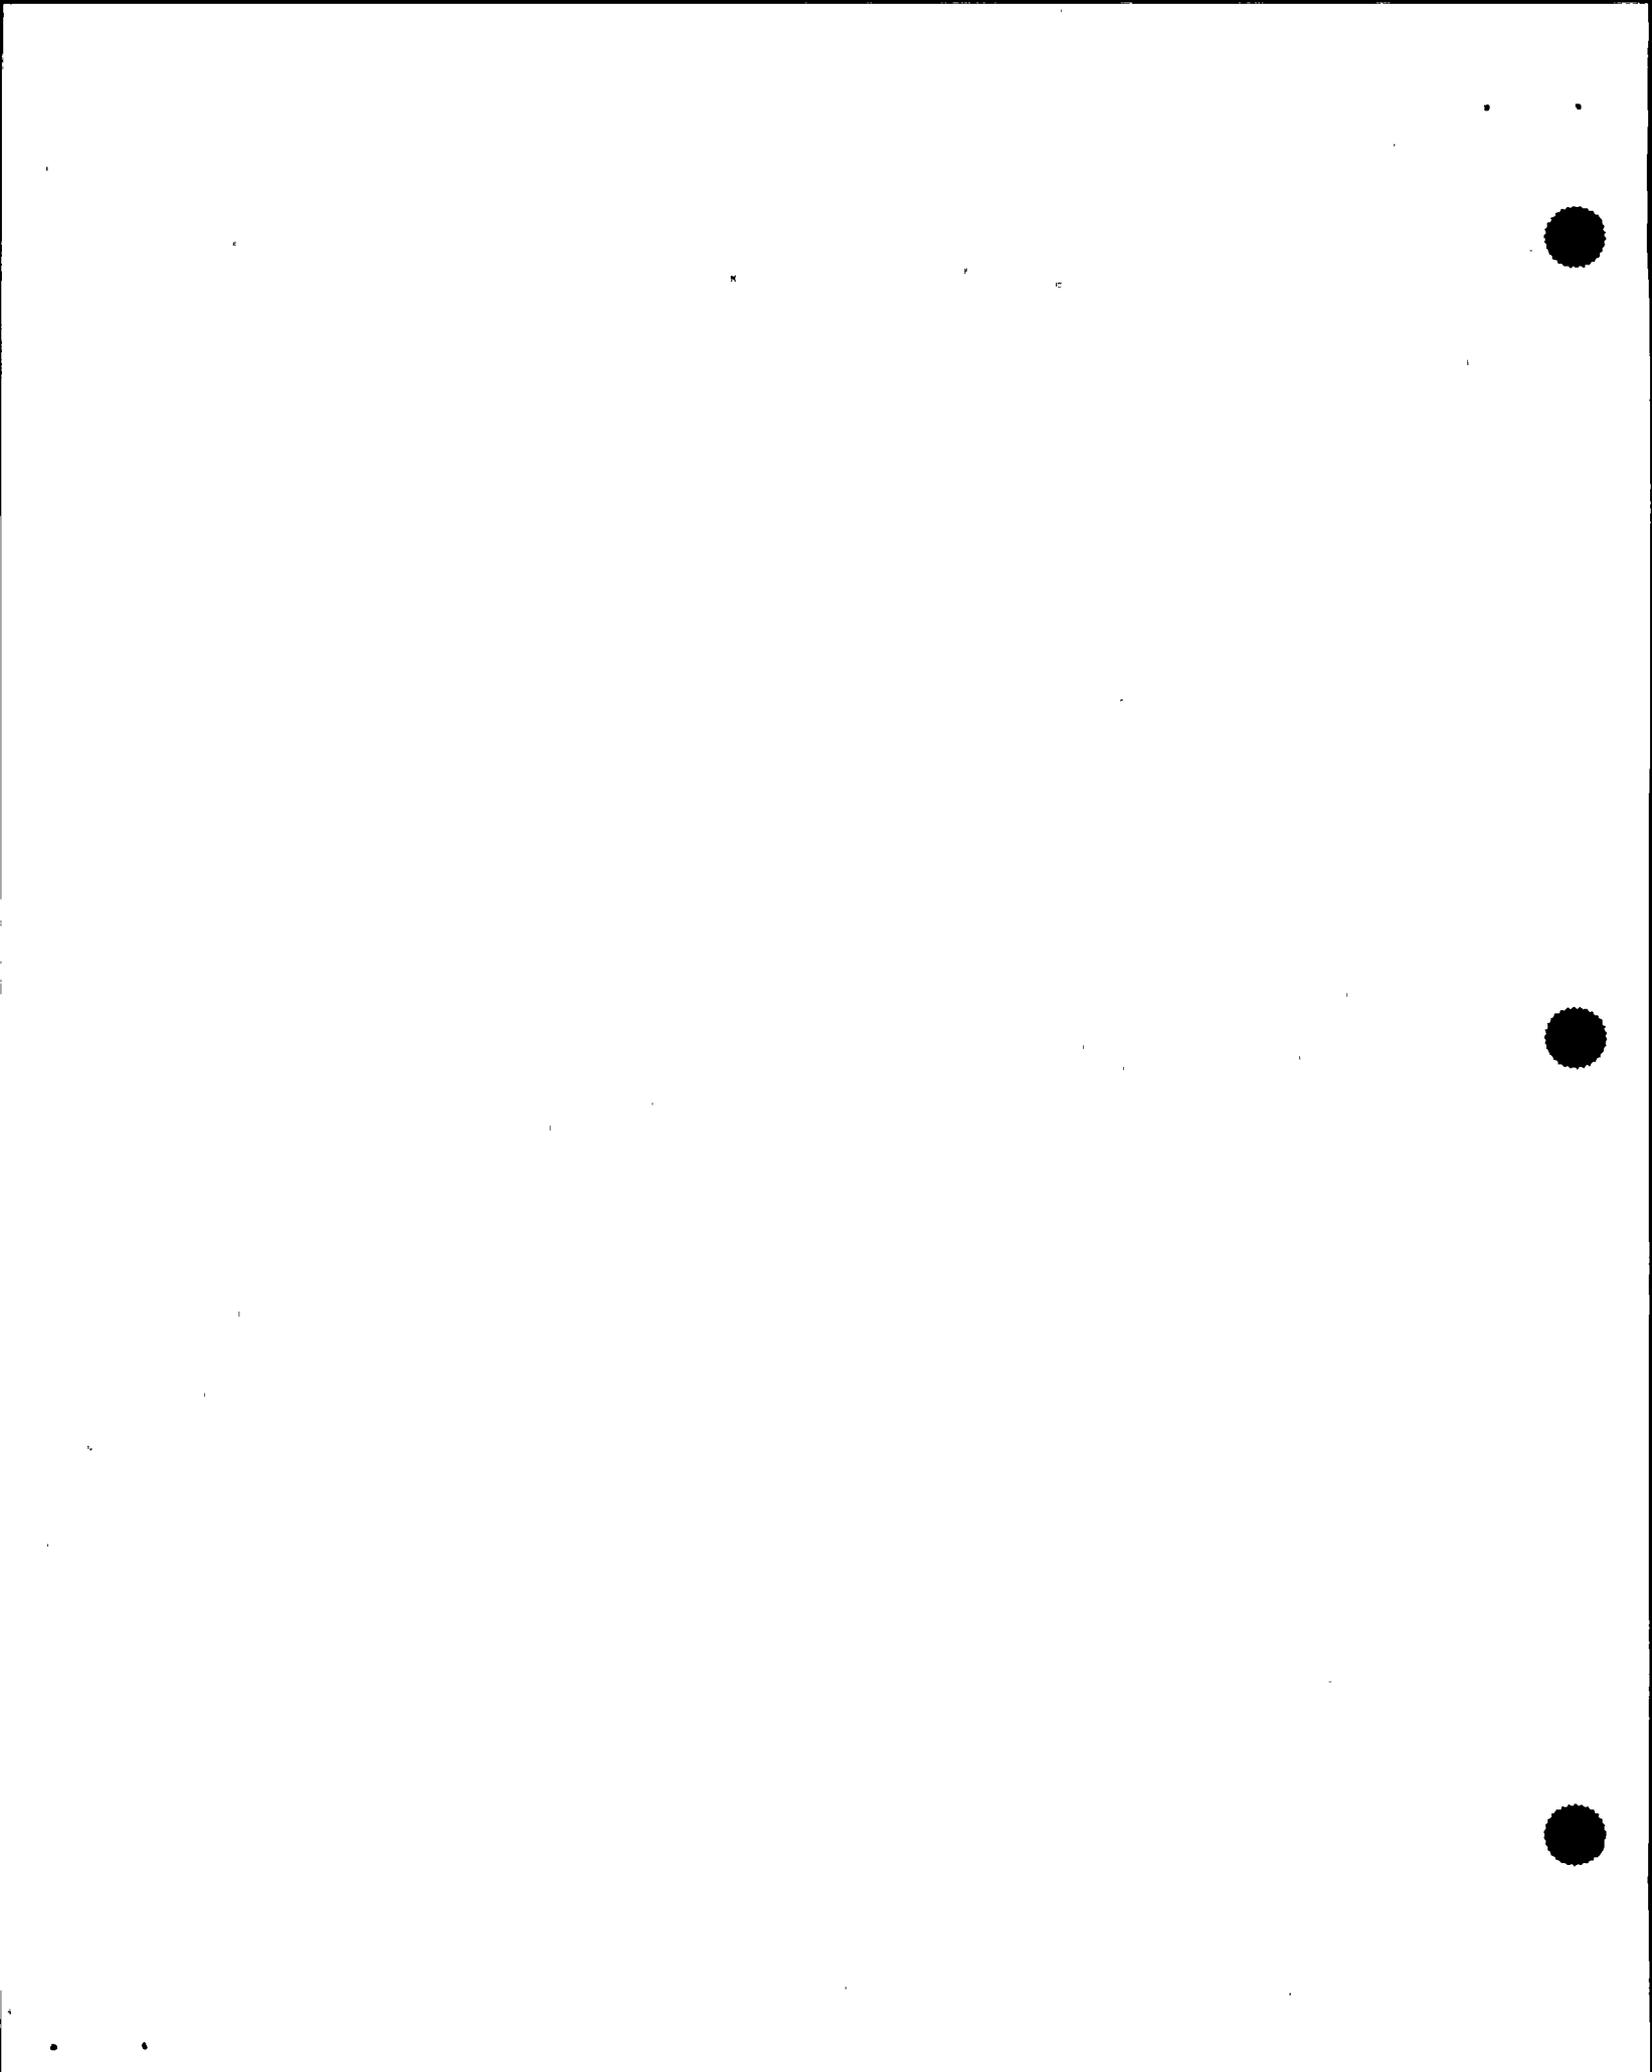

BACKGROUND GDC 10 (Ref. 1) requires that specified acceptable fuel design limits are not exceeded during steady state operation, normal operational transients, and anticipated operational occurrences (AOOs). This is accomplished by having a departure from nucleate boiling (DNB) design basis, which corresponds to a 95% probability at a 95% confidence level (the 95/95 DNB criterion) that DNB will not occur and by requiring that fuel centerline temperature stays below the melting temperature.

The restrictions of this SL prevent overheating of the fuel and cladding, as well as possible cladding perforation, that would result in the release of fission products to the reactor coolant. Overheating of the fuel is prevented by maintaining the steady state peak linear heat rate (LHR) below the level at which fuel centerline melting occurs. Overheating of the fuel cladding is prevented by restricting fuel operation to within the nucleate boiling regime, where the heat transfer coefficient is large and the cladding surface temperature is slightly above the coolant saturation temperature.

Fuel centerline melting occurs when the local LHR, or power peaking, in a region of the fuel is high enough to cause the fuel centerline temperature to reach the melting point of the fuel. Expansion of the pellet upon centerline melting may cause the pellet to stress the cladding to the point of failure, allowing an uncontrolled release of activity to the reactor coolant.

Operation above the boundary of the nucleate boiling regime could result in excessive cladding temperature because of the onset of DNB and the resultant sharp reduction in heat transfer coefficient. Inside the steam film, high cladding temperatures are reached, and a cladding water (zirconium water) reaction may take place. This chemical reaction results in oxidation of the fuel cladding to a structurally weaker form. This weaker form may lose its integrity, resulting in an uncontrolled release of activity to the reactor coolant. The proper functioning of the Reactor Protection System (RPS) and steam generator safety valves prevents violation of the reactor core SLs.

(Continued)

BASES (Continued)

APPLICABLE SAFETY ANALYSES The fuel cladding must not sustain damage as a result of normal operation and AOOs. The reactor core SLs are established to preclude violation of the following fuel design criteria:

- a. There must be at least 95% probability at a 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience DNB; and
- b. The hot fuel pellet in the core must not experience centerline fuel melting.

The Reactor Trip System setpoints (Ref. 2), in combination with all the LCOs, are designed to prevent any anticipated combination of transient conditions for Reactor Coolant System (RCS) temperature, pressure, and THERMAL POWER level that would result in a departure from nucleate boiling ratio (DNBR) of less than the DNBR limit and preclude the existence of flow instabilities.

~~Automatic enforcement of Protection for these reactor core SLs is provided by the steam generator safety valves and the following automatic reactor trip functions:~~ following functions:

- a. High pressurizer pressure trip;
- b. Low pressurizer pressure trip;
- c. Overtemperature ΔT trip;
- d. Overpower ΔT trip;
- e. Power Range Neutron Flux High trip; and
- f. ~~Steam generator safety valves.~~

The limitation that the average enthalpy in the hot leg be less than or equal to the enthalpy of saturated liquid also ensures that the ΔT measured by instrumentation, used in the RPS design as a measure of core power, is proportional to core power.

The SLs represent a design requirement for establishing the RPS trip setpoints identified previously. LCO 3.4.1, "RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits," or the assumed initial conditions of the safety analyses (as indicated in the FSAR, Ref. 2 5) provide more restrictive limits to ensure that the SLs are not exceeded.

(Continued)

BASES (Continued)

SAFETY LIMITS

The curves provided in Figure B 2.1.1-1 show the loci of points of THERMAL POWER, RCS pressure, and average temperature for below which the minimum calculated DNBR is not less than the safety analyses limit, the design DNBR value, that fuel centerline temperature remains below melting, that the average enthalpy in the hot leg is less than or equal to the enthalpy of saturated liquid, or that the exit quality is within the limits defined by the DNBR correlation.

The curves are based on enthalpy rise hot channel factor limits provided in the COLR. The dashed line of Figure B 2.1.1-1 shows an example of a limit curve at 2235 psig. In addition, it illustrates the various RPS functions that are designed to prevent the unit from reaching the limit.

The SL is higher than the limit calculated when the AFD is within the limits of the $F_1(\Delta I)$ function of the overtemperature ΔT reactor trip. When the AFD is not within the tolerance, the AFD effect on the overtemperature ΔT reactor trips will reduce the setpoints to provide protection consistent with the reactor core SLs (Refs. 3 and 4).

APPLICABILITY

SL 2.1.1 only applies in MODES 1 and 2 because these are the only MODES in which the reactor is critical. Automatic protection functions are required to be OPERABLE during MODES 1 and 2 to ensure operation within the reactor core SLs. The steam generator safety valves or automatic protection actions serve to prevent RCS heatup to the reactor core SL conditions or to initiate a reactor trip function, which forces the unit into MODE 3. Setpoints for the reactor trip functions are specified in LCO 3.3.1, "Reactor Trip System (RTS) Instrumentation." In MODES 3, 4, 5, and 6, Applicability is not required since the reactor is not generating significant THERMAL POWER.

SAFETY LIMIT VIOLATIONS

~~The following SL violation responses are applicable to the reactor core SLs.~~

2.2.1

~~The following SL violation responses are applicable to the reactor core SLs. If SL 2.1.1 is violated, the requirement to go to MODE 3 places the unit in a MODE in which this SL is not applicable.~~

The allowed Completion Time of 1 hour recognizes the importance of bringing the unit to a MODE of operation where this SL is not applicable, and reduces the probability of fuel damage.

~~Per 10CFR50.36, if a safety limit is violated, operations must not be resumed until authorized by the Commission.~~

2.2.3

~~If SL 2.1.1 is violated, the NRC Operations Center must be notified within 1 hour, in accordance with 10 CFR 50.72 (Ref. 5).~~

(Continued)

BASES (Continued)

SAFETY LIMIT
VIOLATIONS
(continued)

2.2.4

~~If SL 2.1.1 is violated, the Plant Superintendent and the Vice President Nuclear Operations shall be notified within 24 hours. This 24 hour period provides time for the plant operators and staff to take the appropriate immediate action and assess the condition of the unit before reporting to senior management.~~

2.2.5

~~If SL 2.1.1 is violated, a Licensee Event Report shall be prepared and submitted within 30 days to the NRC in accordance with 10 CFR 50.73 (Ref. 6). A copy of the report shall also be provided to the Plant Superintendent and the Vice President Nuclear Operations.~~

2.2.6

~~If SL 2.1.1 is violated, restart of the unit shall not commence until authorized by the NRC. This requirement ensures the NRC that all necessary reviews, analyses, and actions are completed before the unit begins its restart to normal operation.~~

Figure B 2.1.1-1 (page 1 of 1)
Reactor Core Safety Limits vs. Boundary of Protection

B 2.0 SAFETY LIMITS (SLs)

B 2.1.2 Reactor Coolant System (RCS) Pressure SL

BASES

BACKGROUND

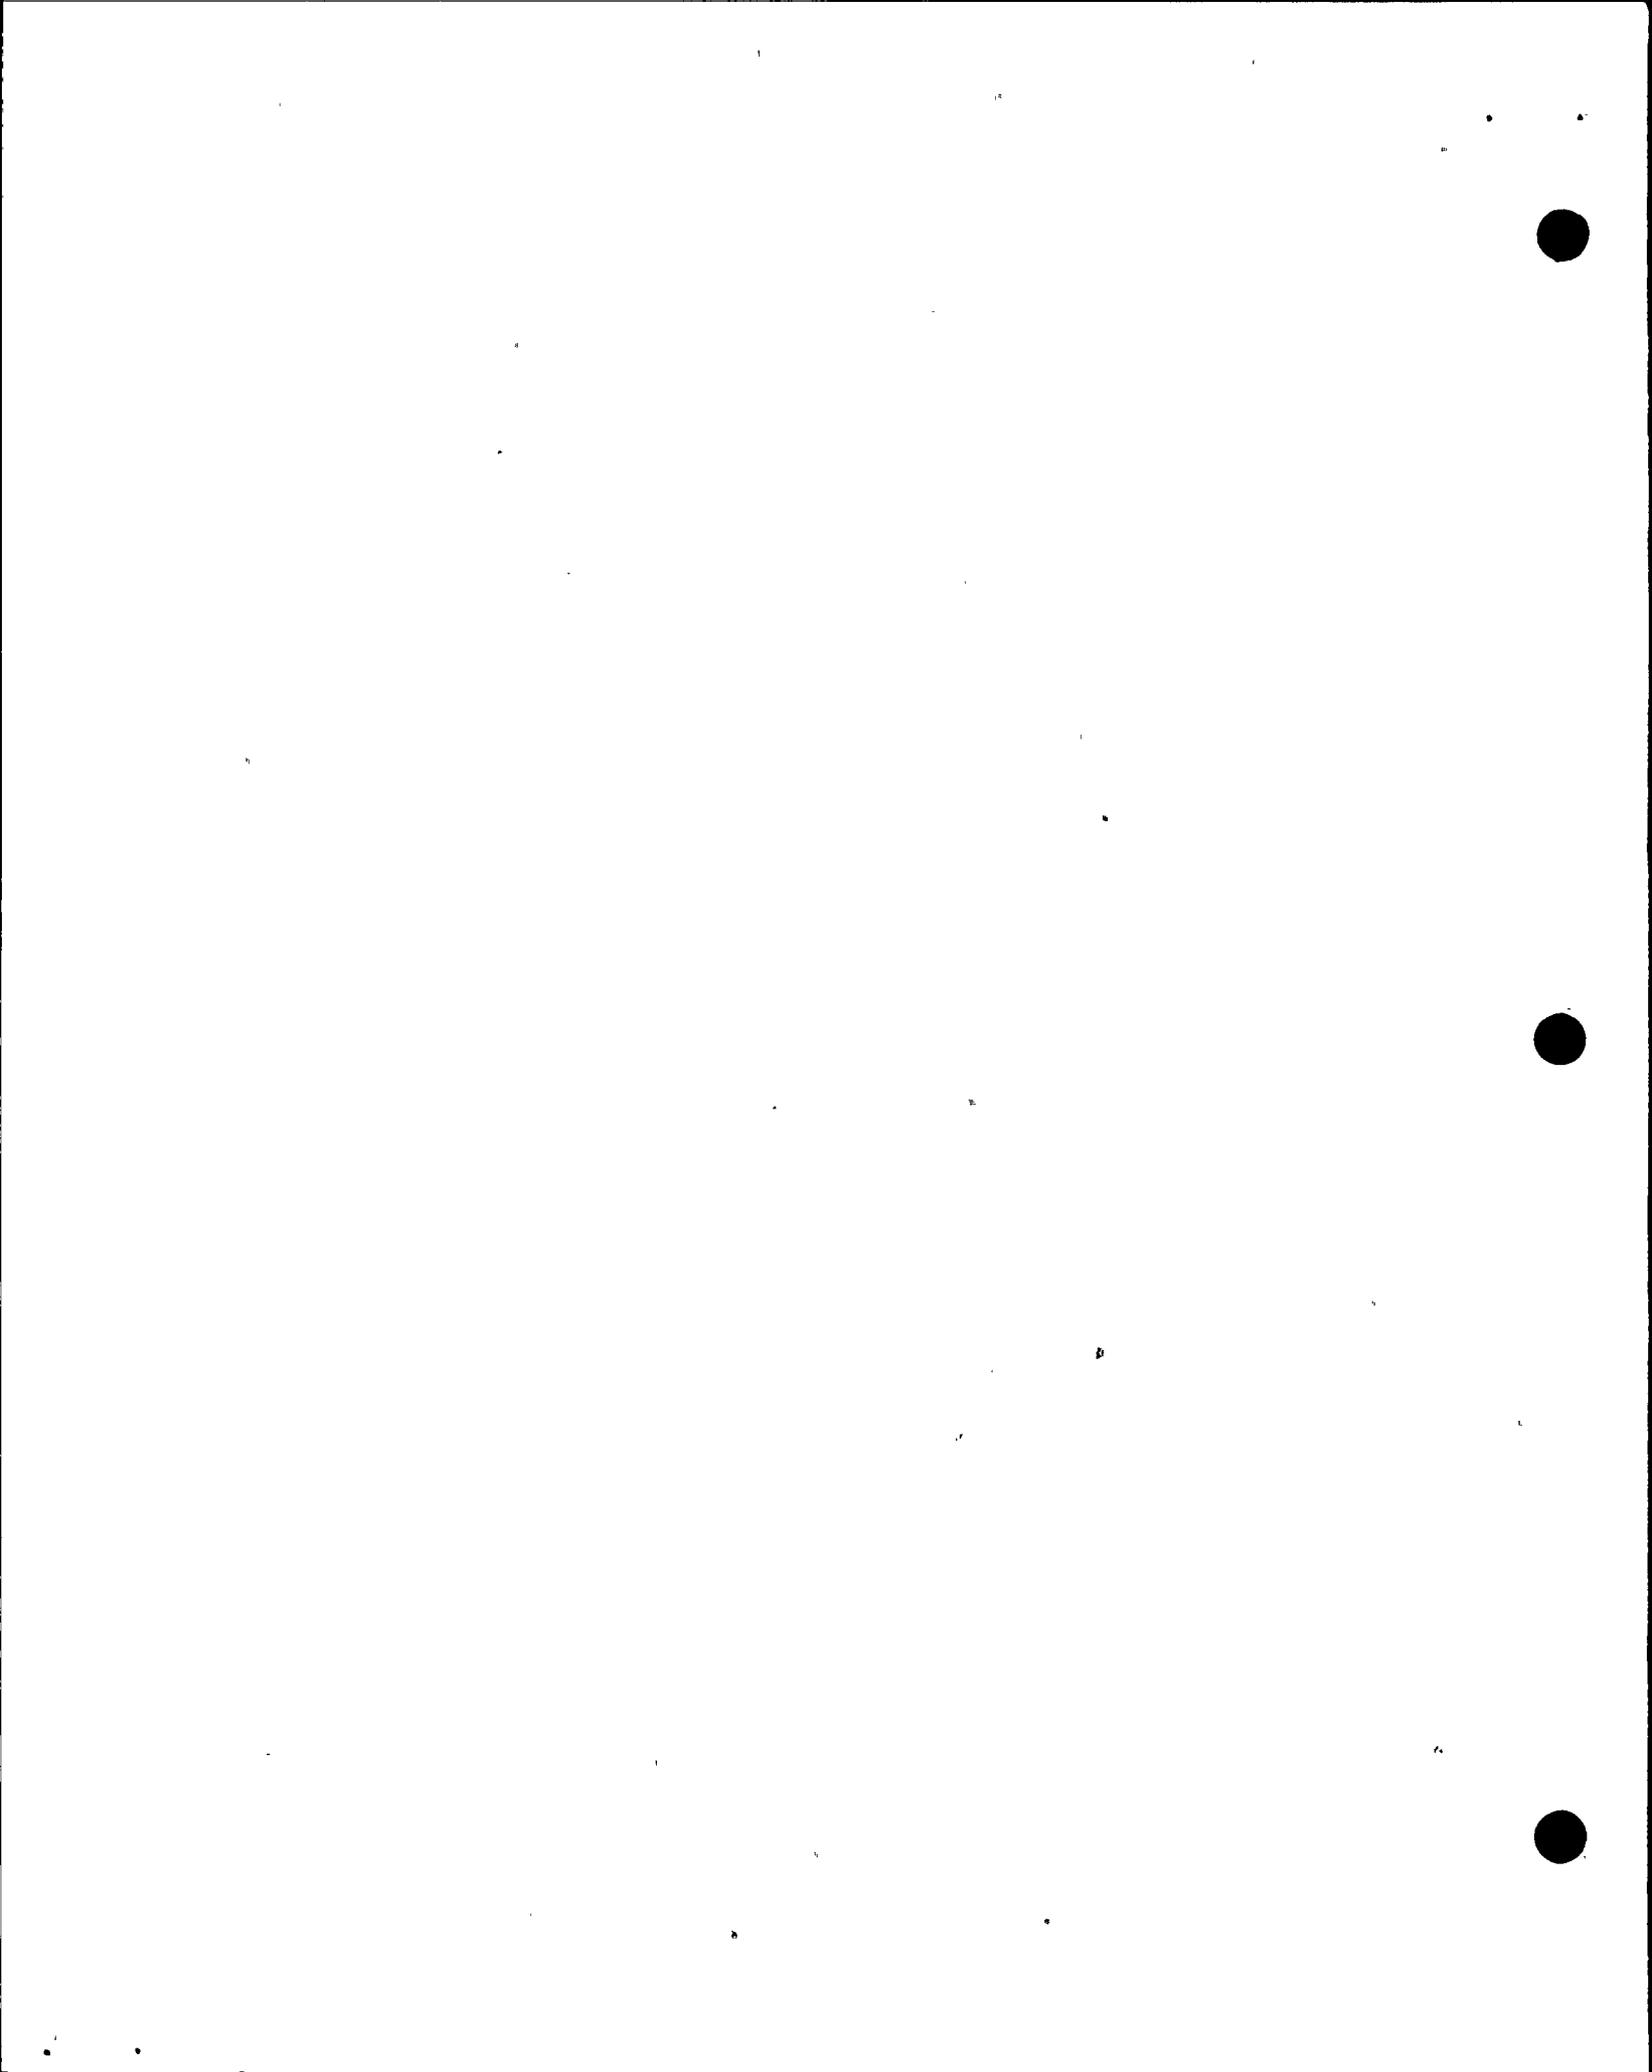

The SL on RCS pressure protects the integrity of the RCS against overpressurization. In the event of fuel cladding failure, fission products are released into the reactor coolant. The RCS then serves as the primary barrier in preventing the release of fission products into the atmosphere. By establishing an upper limit on RCS pressure, the continued integrity of the RCS is ensured. According to 10 CFR 50, Appendix A, GDC 14, "Reactor Coolant Pressure Boundary," and GDC 15, "Reactor Coolant System Design" (Ref. 1), the reactor pressure coolant boundary (RCPB) design conditions are not to be exceeded during normal operation and anticipated operational occurrences (AOOs). Also, in accordance with GDC 28, "Reactivity Limits" (Ref. 1), reactivity accidents, including rod ejection, do not result in damage to the RCPB greater than limited local yielding.

The design pressure of the RCS is 2485 psig ~~2500 psia~~. During normal operation and AOOs, RCS pressure is limited from exceeding the design pressure by more than 10%, in accordance with Section III of the ASME Code (Ref. 2). To ensure system integrity, all RCS components ~~are~~ were hydrostatically tested at ~~125% 150% (3750)~~ (Ref. 9) of design pressure, according to the ASME Code requirements prior to initial operation when there is no fuel in the core. Following inception of unit operation, RCS components shall be pressure tested, in accordance with the requirements of ASME Code, Section XI (Ref. 3).

Overpressurization of the RCS could result in a breach of the RCPB. If such a breach occurs in conjunction with a fuel cladding failure, fission products could enter the containment atmosphere, raising concerns relative to limits on radioactive releases specified in 10 CFR 100, "Reactor Site Criteria" (Ref. 4).

APPLICABLE
SAFETY ANALYSES

The RCS pressurizer safety valves, the main steam safety valves (MSSVs), and the reactor high pressure trip have settings established to ensure that the RCS pressure SL will not be exceeded.

BASES (Continued)

APPLICABLE
SAFETY ANALYSES
(continued)

The RCS pressurizer safety valves are sized to prevent system pressure from exceeding the design pressure by more than 10%, as specified in Section III of the ASME Code for Nuclear Power Plant Components (Ref. 2). The transient that establishes the required relief capacity, and hence valve size requirements and lift settings, is a complete loss of external load turbine trip without a direct reactor trip. During the transient, no control actions are assumed, except that the Safety valves on the secondary plant side are assumed to open when the steam pressure reaches the secondary plant safety valve settings, and nominal lost at the time of turbine trip main feedwater supply is maintained.

The Reactor Trip System setpoints (Ref. 5) allowable values, together with the settings of the MSSVs, provide pressure protection for normal operation and AOOs. The reactor high pressure trip setpoint is specifically set to provide protection against overpressurization (Ref. 5). The safety analyses for both the high pressure trip and the RCS pressurizer safety valves are performed using conservative assumptions relative to pressure control devices.

More specifically, no credit is taken for operation of the following:

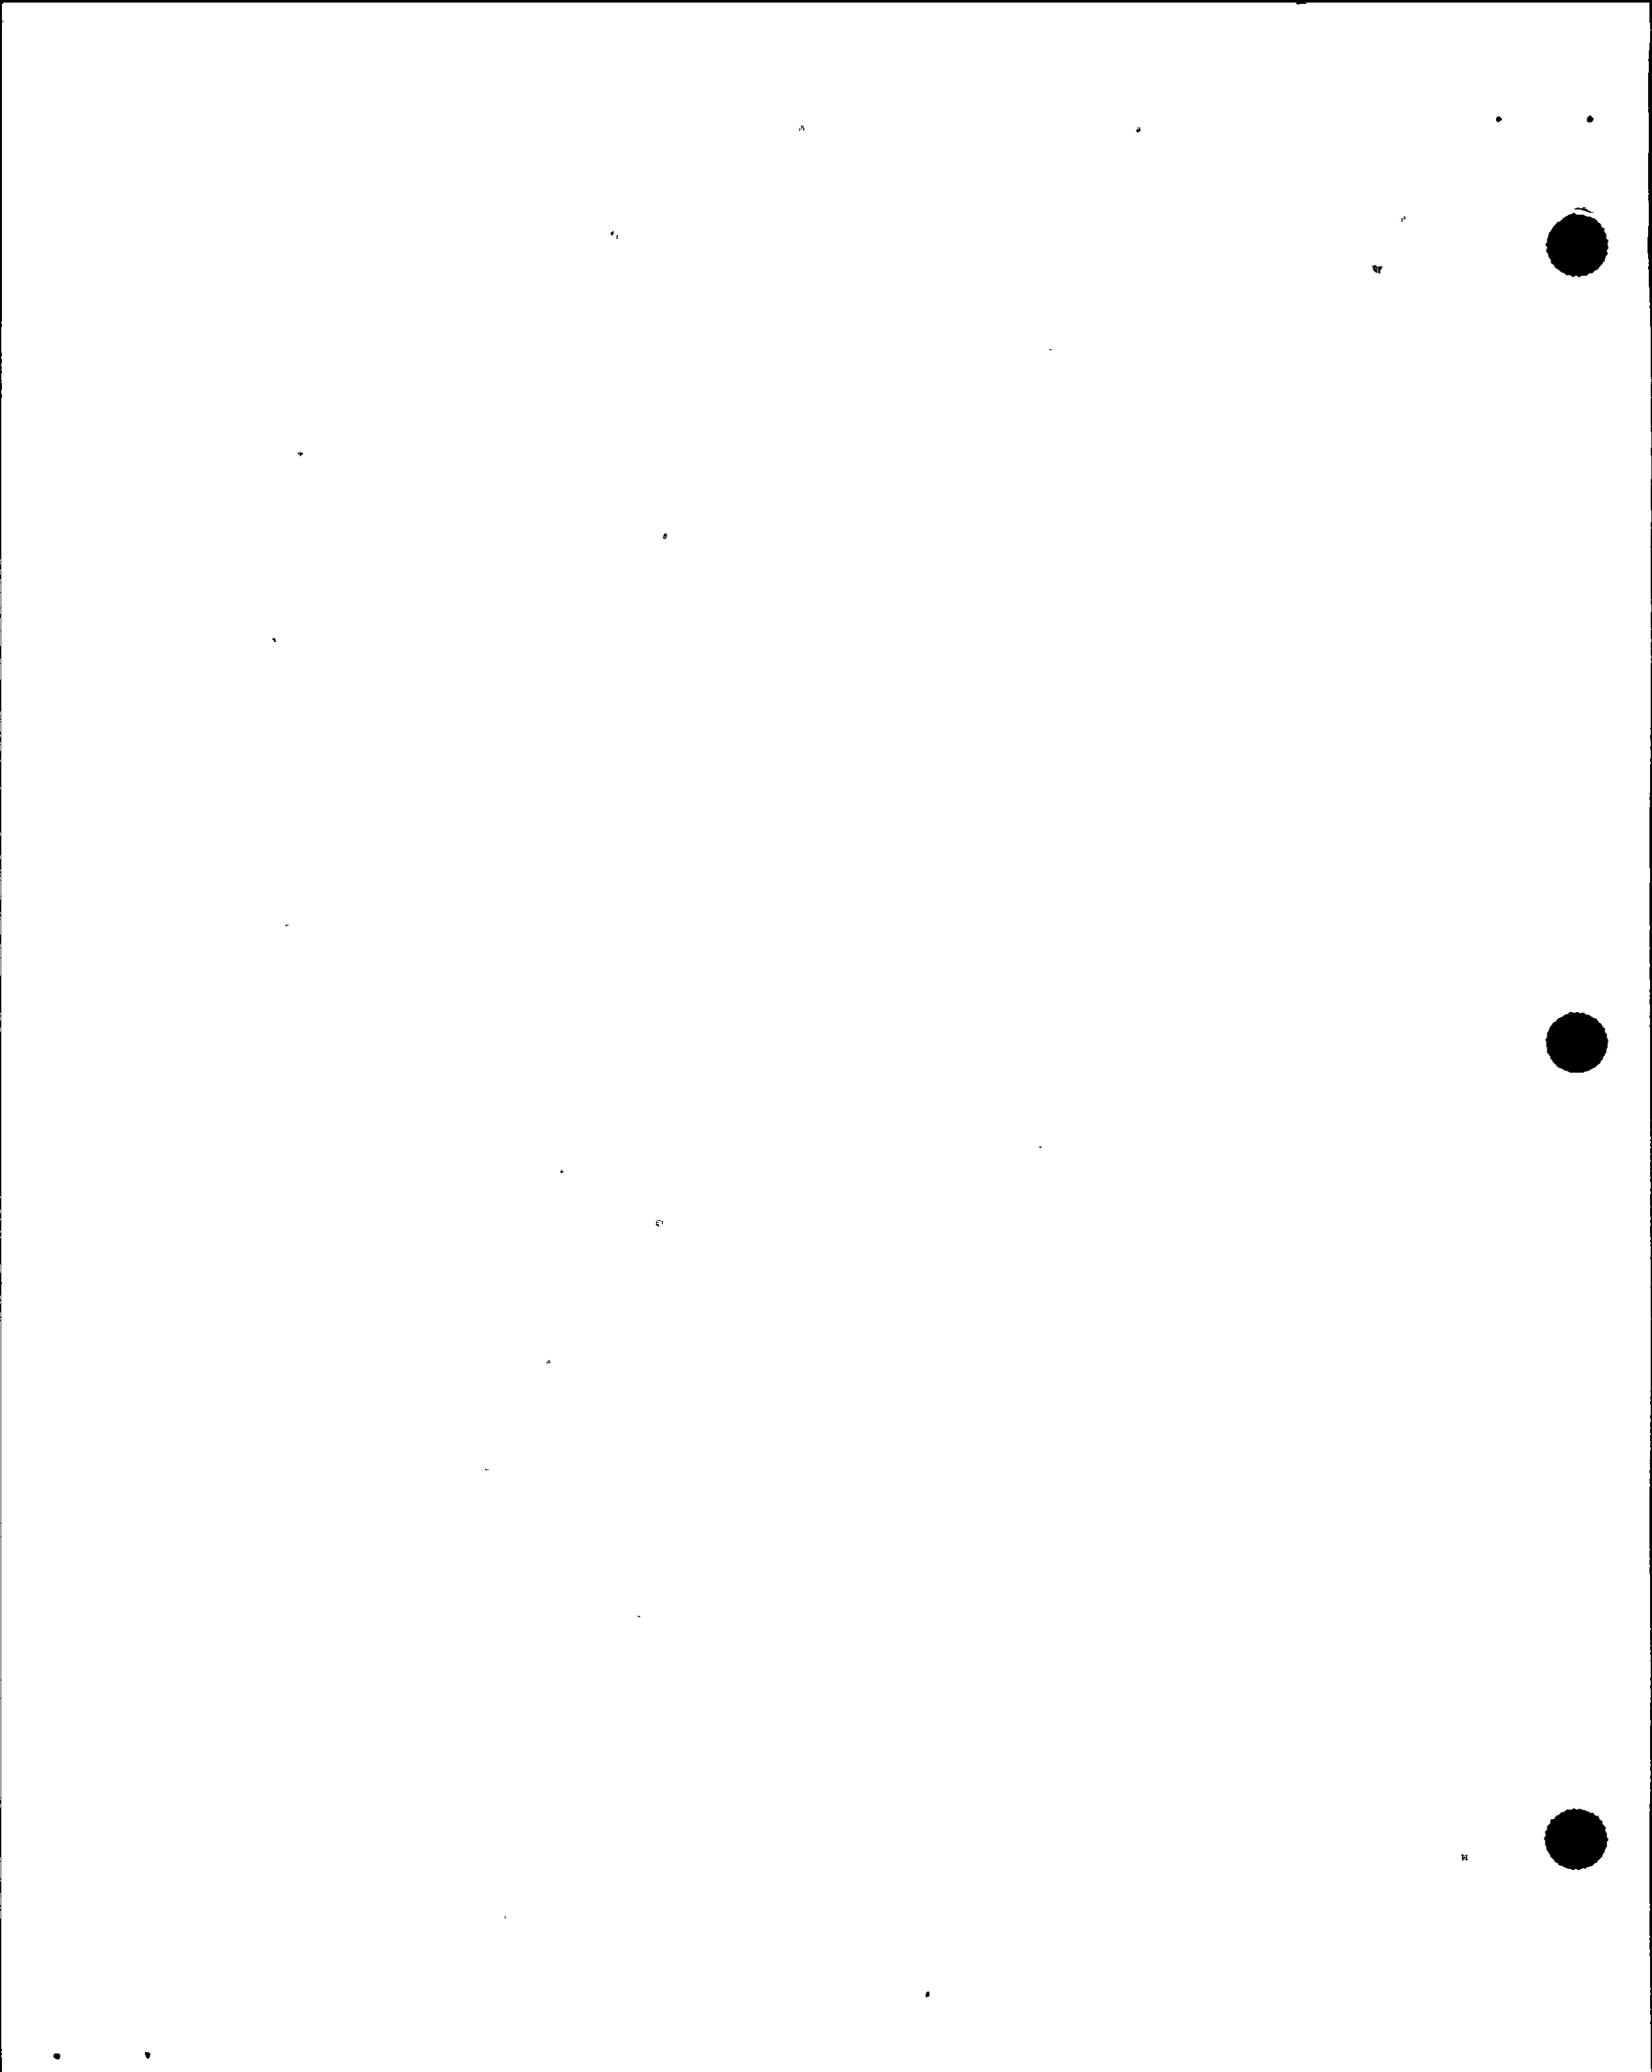

- a. Pressurizer power operated relief valves (PORVs);
- b. Steam line relief valve Generator Atmospheric Dump valves;
- c. Steam Dump System;
- d. Reactor Control System;
- e. Pressurizer Level Control System; or
- f. Pressurizer spray valve.

SAFETY LIMITS

The maximum transient pressure allowed in the RCS pressure vessel under the ASME Code, Section III, is 110% of design pressure. The maximum transient pressure allowed in the RCS piping, valves, and fittings under [USAS, Section B31.1 (Ref. 6)] is 120% of design pressure. The most limiting of these two allowances is the 110% of design pressure; therefore, The SL on maximum allowable RCS pressure is 2735 psig.

APPLICABILITY

SL 2.1.2 applies in MODES 1, 2, 3, 4, and 5 because this SL could be approached or exceeded in these MODES due to overpressurization events. The SL is not applicable in MODE 6 because the reactor vessel head closure bolts are not fully tightened, or the reactor vessel is sufficiently vented making it unlikely that the RCS can be pressurized.

BASES (Continued)

SAFETY LIMIT
VIOLATIONS

~~The following SL violations are applicable to the RCS pressure SL.~~

2.2.2.1

If the RCS pressure SL is violated when the reactor is in MODE 1 or 2, the requirement is to restore compliance and be in MODE 3 within 1 hour.

Exceeding the RCS pressure SL may cause immediate RCS failure and create a potential for radioactive releases in excess of 10 CFR 100, "Reactor Site Criteria," limits (Ref. 4).

The allowable Completion Time of 1 hour recognizes the importance of reducing power level to a MODE of operation where the potential for challenges to safety systems is minimized.

2.2.2.2

If the RCS pressure SL is exceeded in MODE 3, 4, or 5, RCS pressure must be restored to within the SL value within 5 minutes. Exceeding the RCS pressure SL in MODE 3, 4, or 5 is more severe than exceeding this SL in MODE 1 or 2, since the reactor vessel temperature may be lower and the vessel material, consequently, less ductile. As such, pressure must be reduced to less than the SL within 5 minutes. The action does not require reducing MODES, since this would require reducing temperature, which would compound the problem by adding thermal gradient stresses to the existing pressure stress.

2.2.3

~~If the RCS pressure SL is violated, the NRC Operations Center must be notified within 1 hour, in accordance with 10 CFR 50.72 (Ref. 7).~~

2.2.4

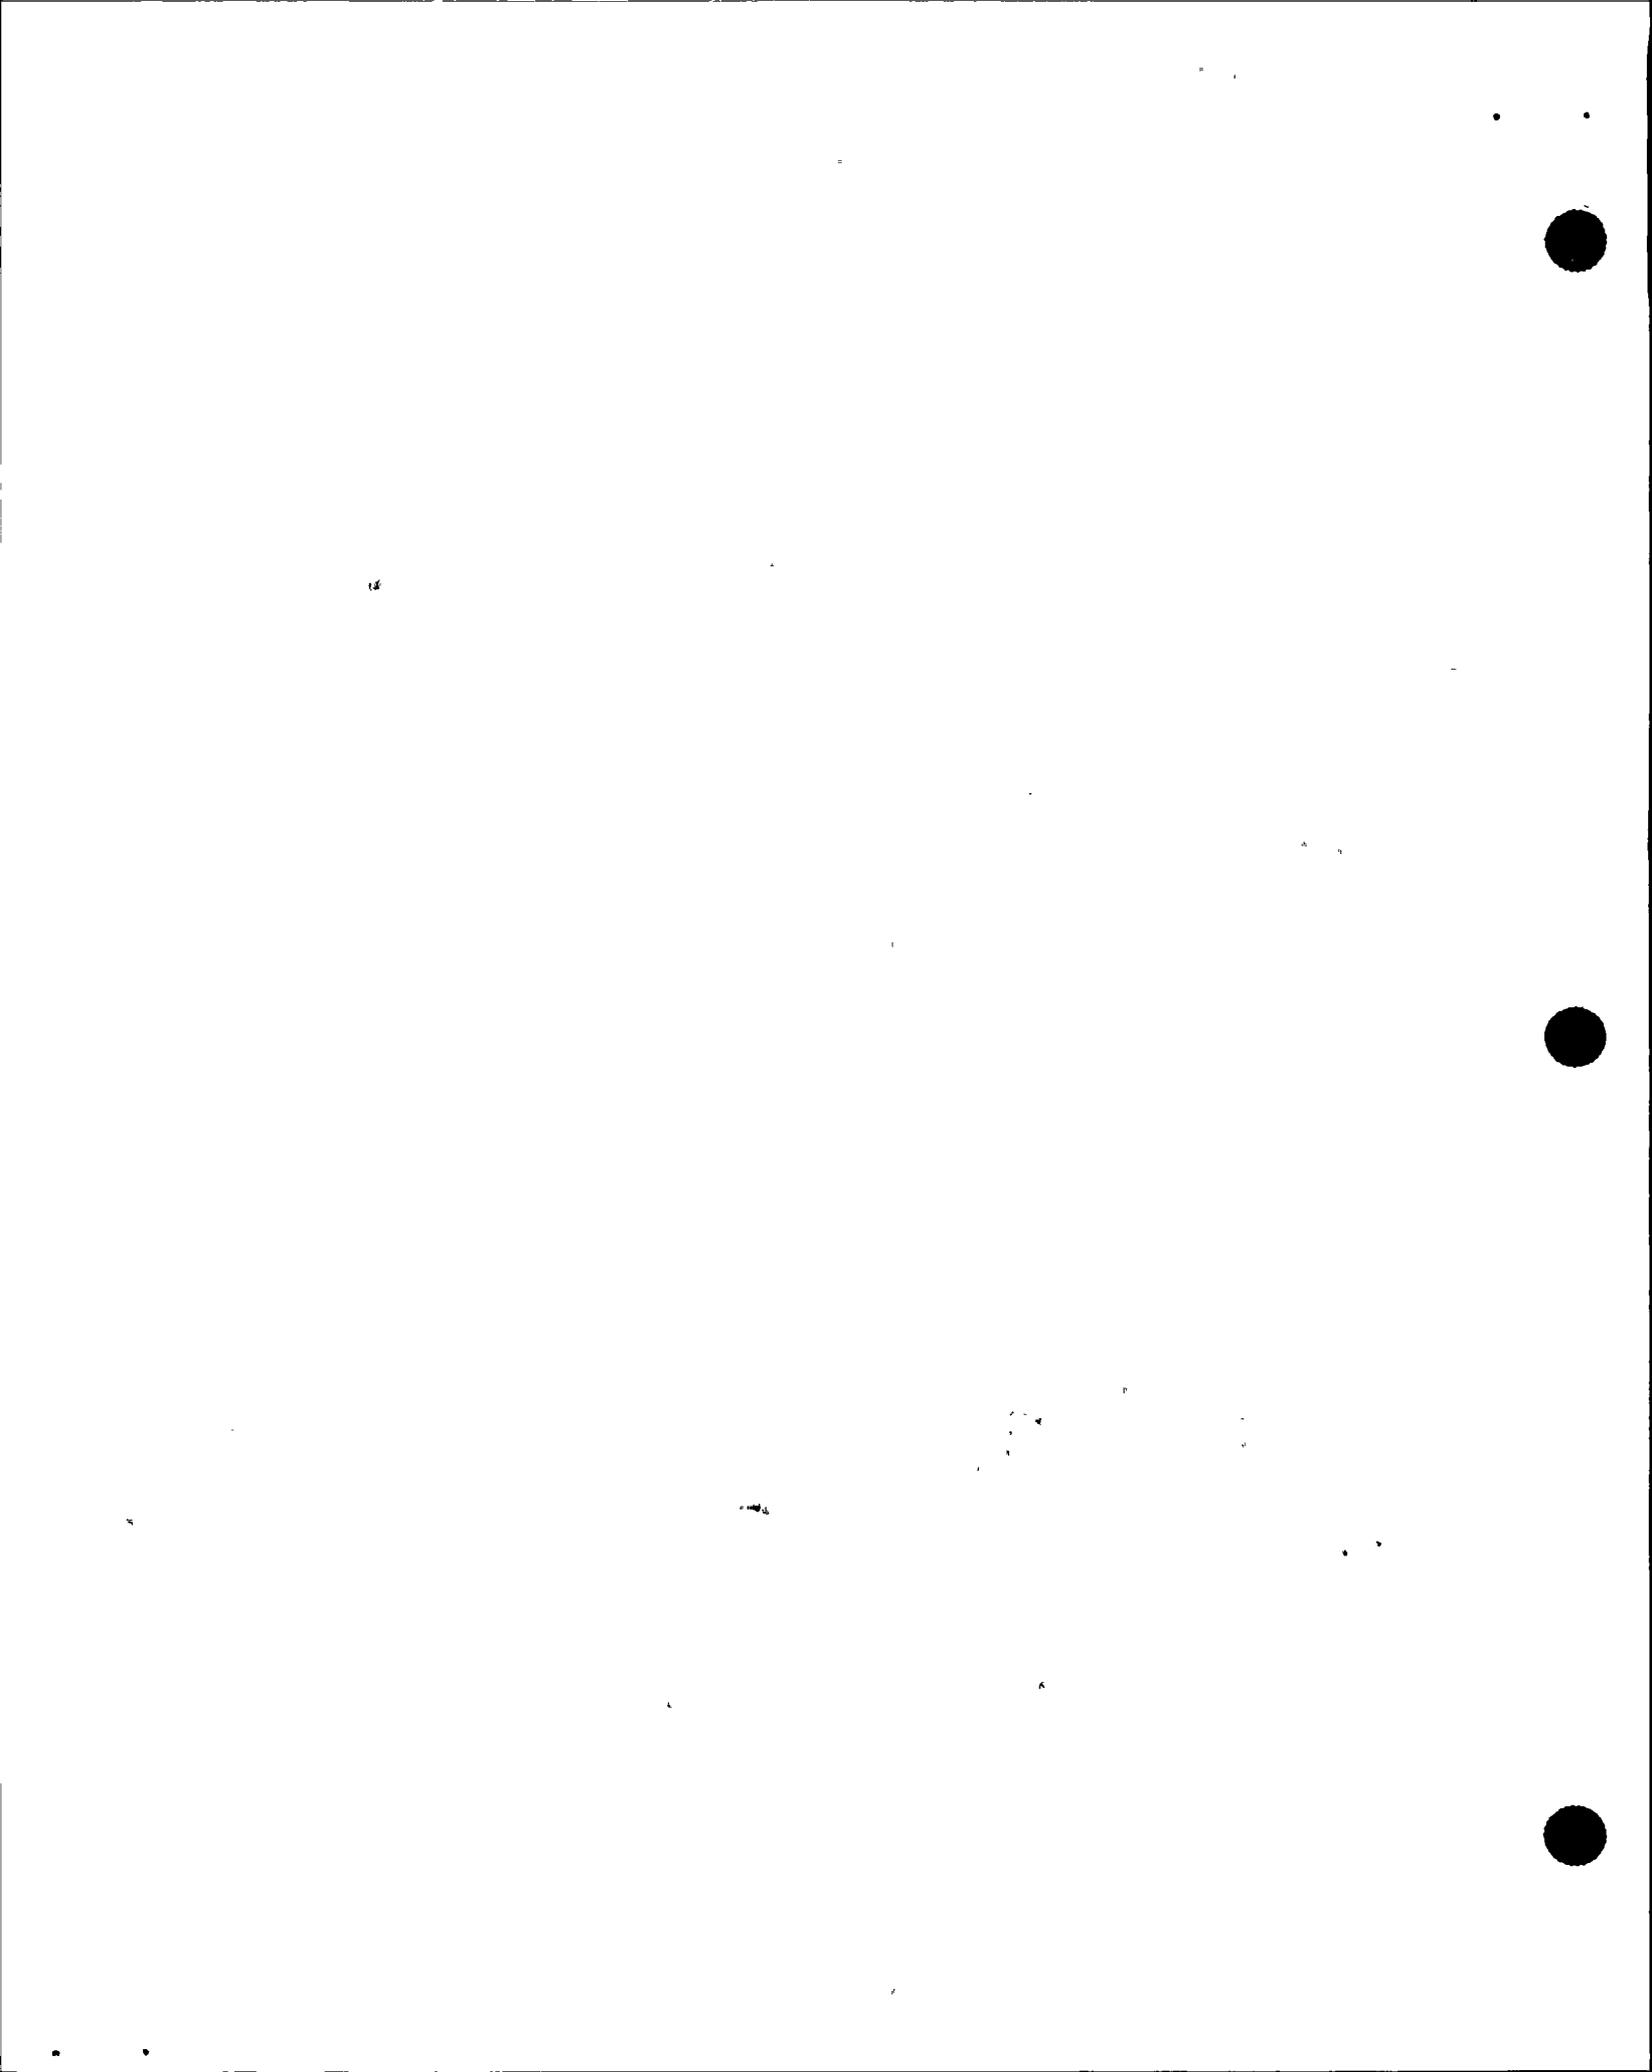

~~If the RCS pressure SL is violated, the Plant Superintendent and the Vice President Nuclear Operations shall be notified within 24 hours. The 24 hour period provides time for the plant operators and staff to take the appropriate immediate action and assess the condition of the unit before reporting to senior management.~~

2.2.5

~~If the RCS pressure SL is violated, a Licensee Event Report shall be prepared and submitted within 30 days to the NRC in accordance with 10 CFR 50.73 (Ref. 8). A copy of the report shall also be provided to the Plant Superintendent and the Vice President Nuclear Operations.~~

2.2.6

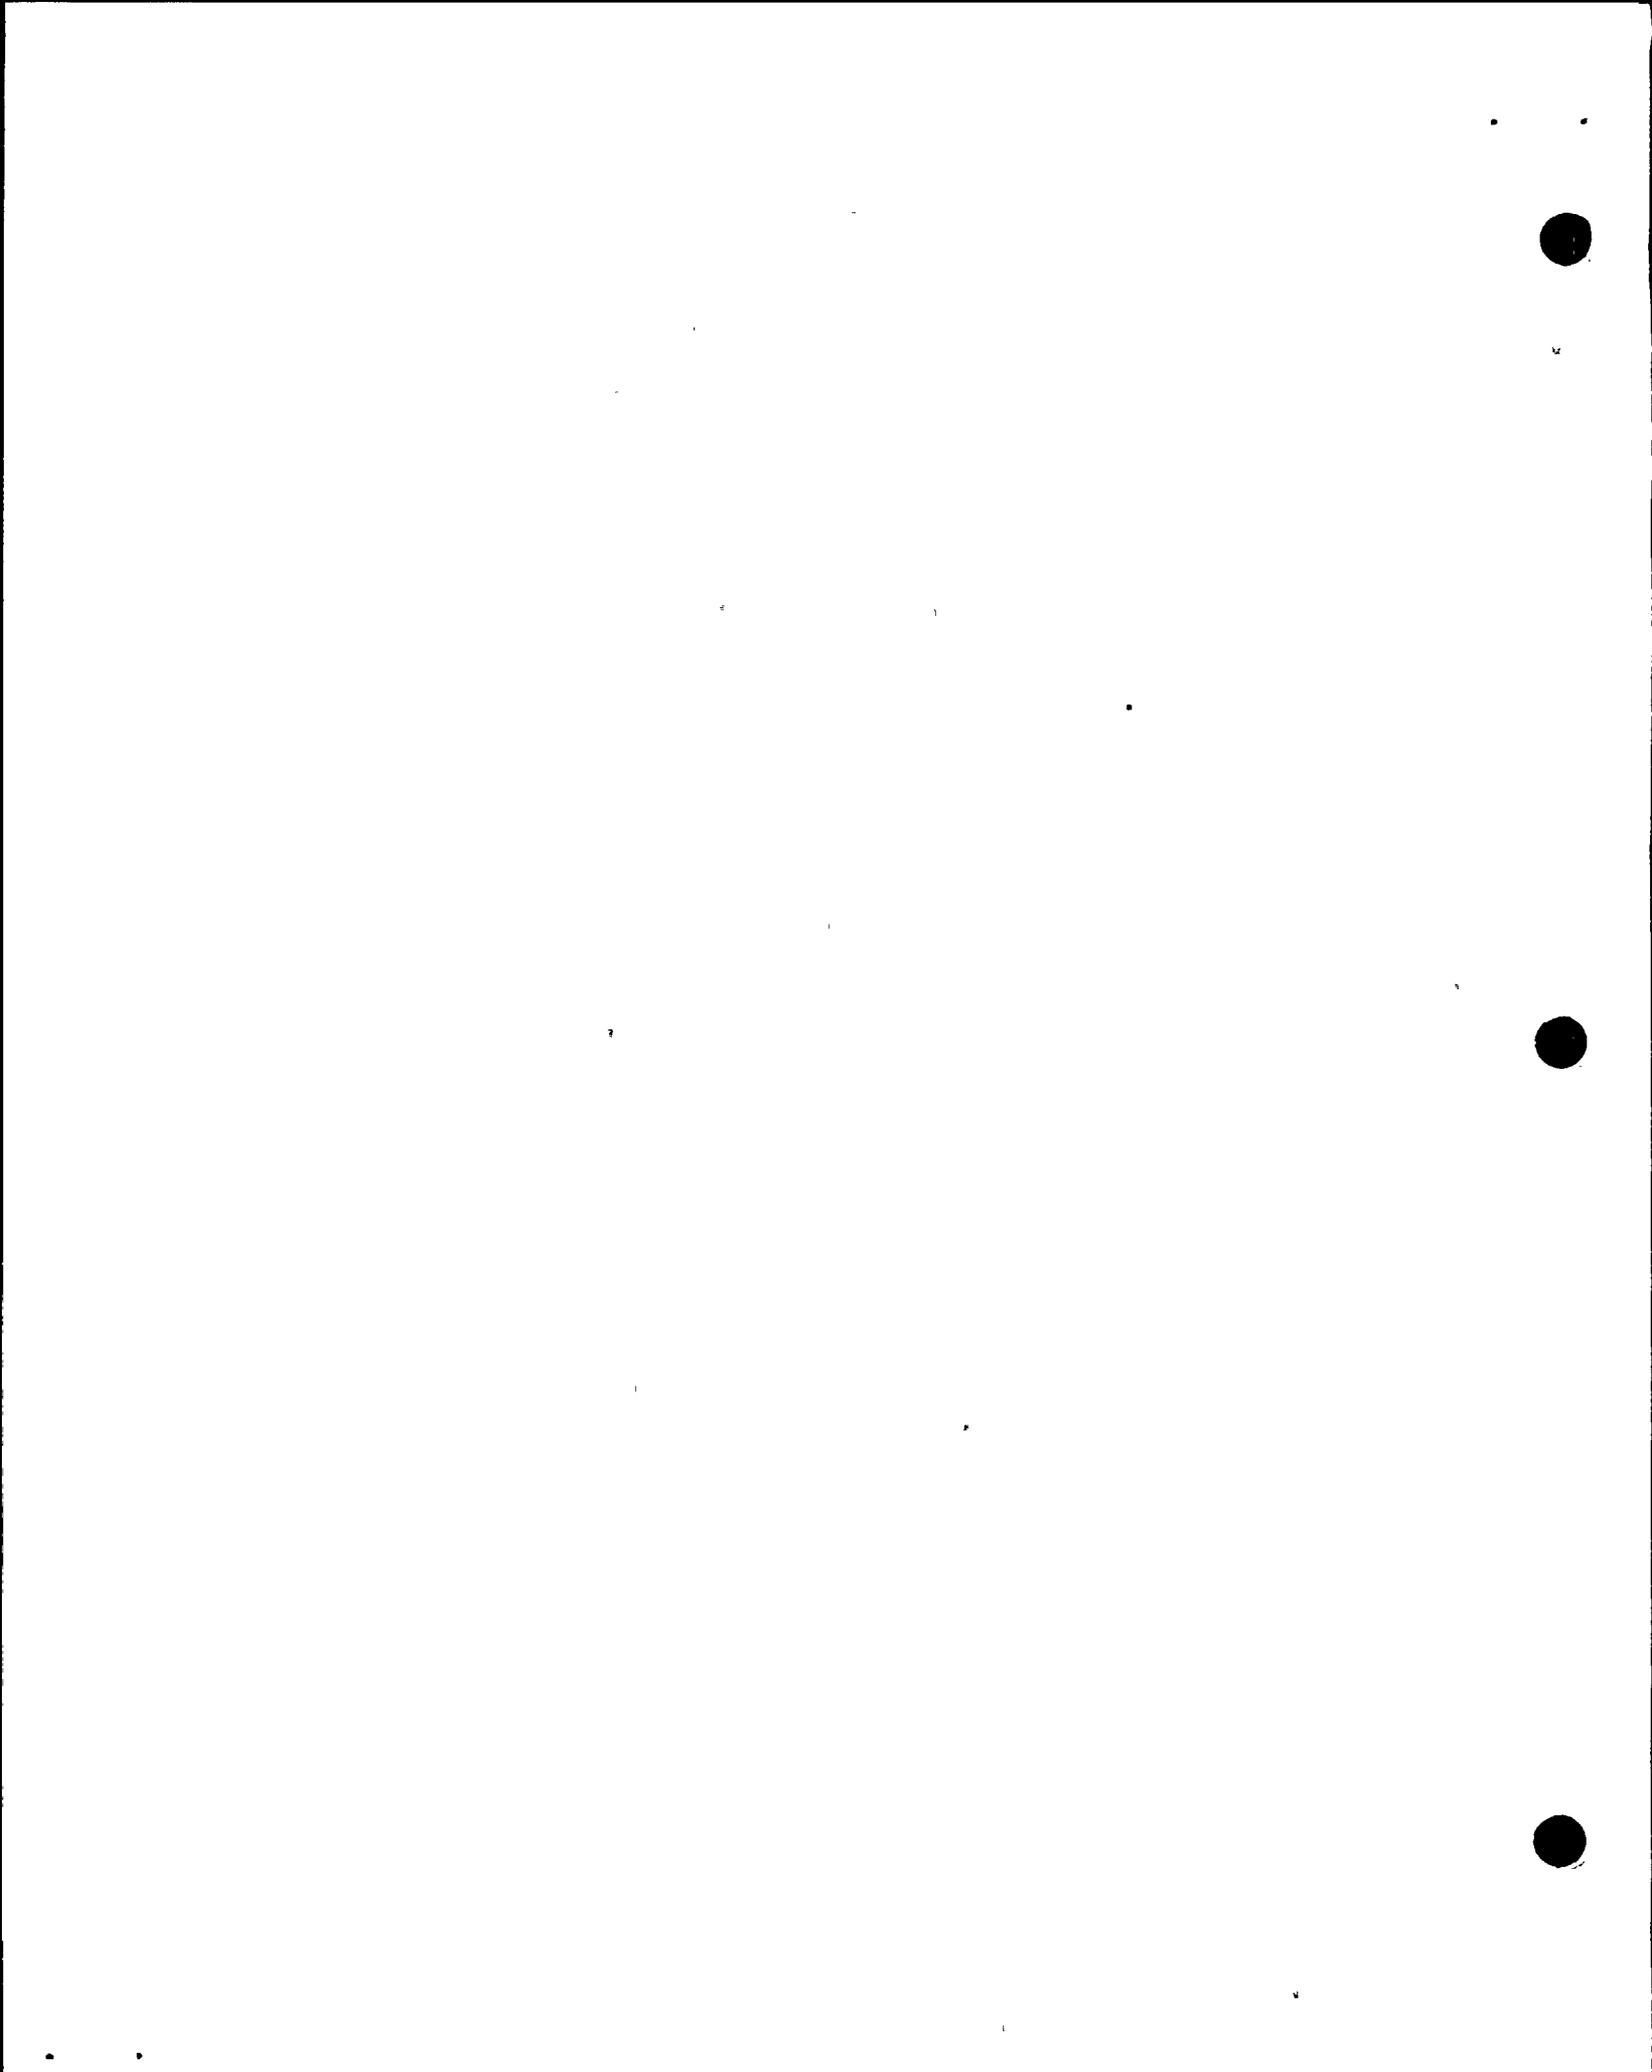

~~If the RCS pressure SL is violated, restart of the unit shall not commence until authorized by the NRC. This requirement ensures the NRC that all necessary reviews, analyses, and actions are completed before the unit begins its restart to normal operation.~~

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific. To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

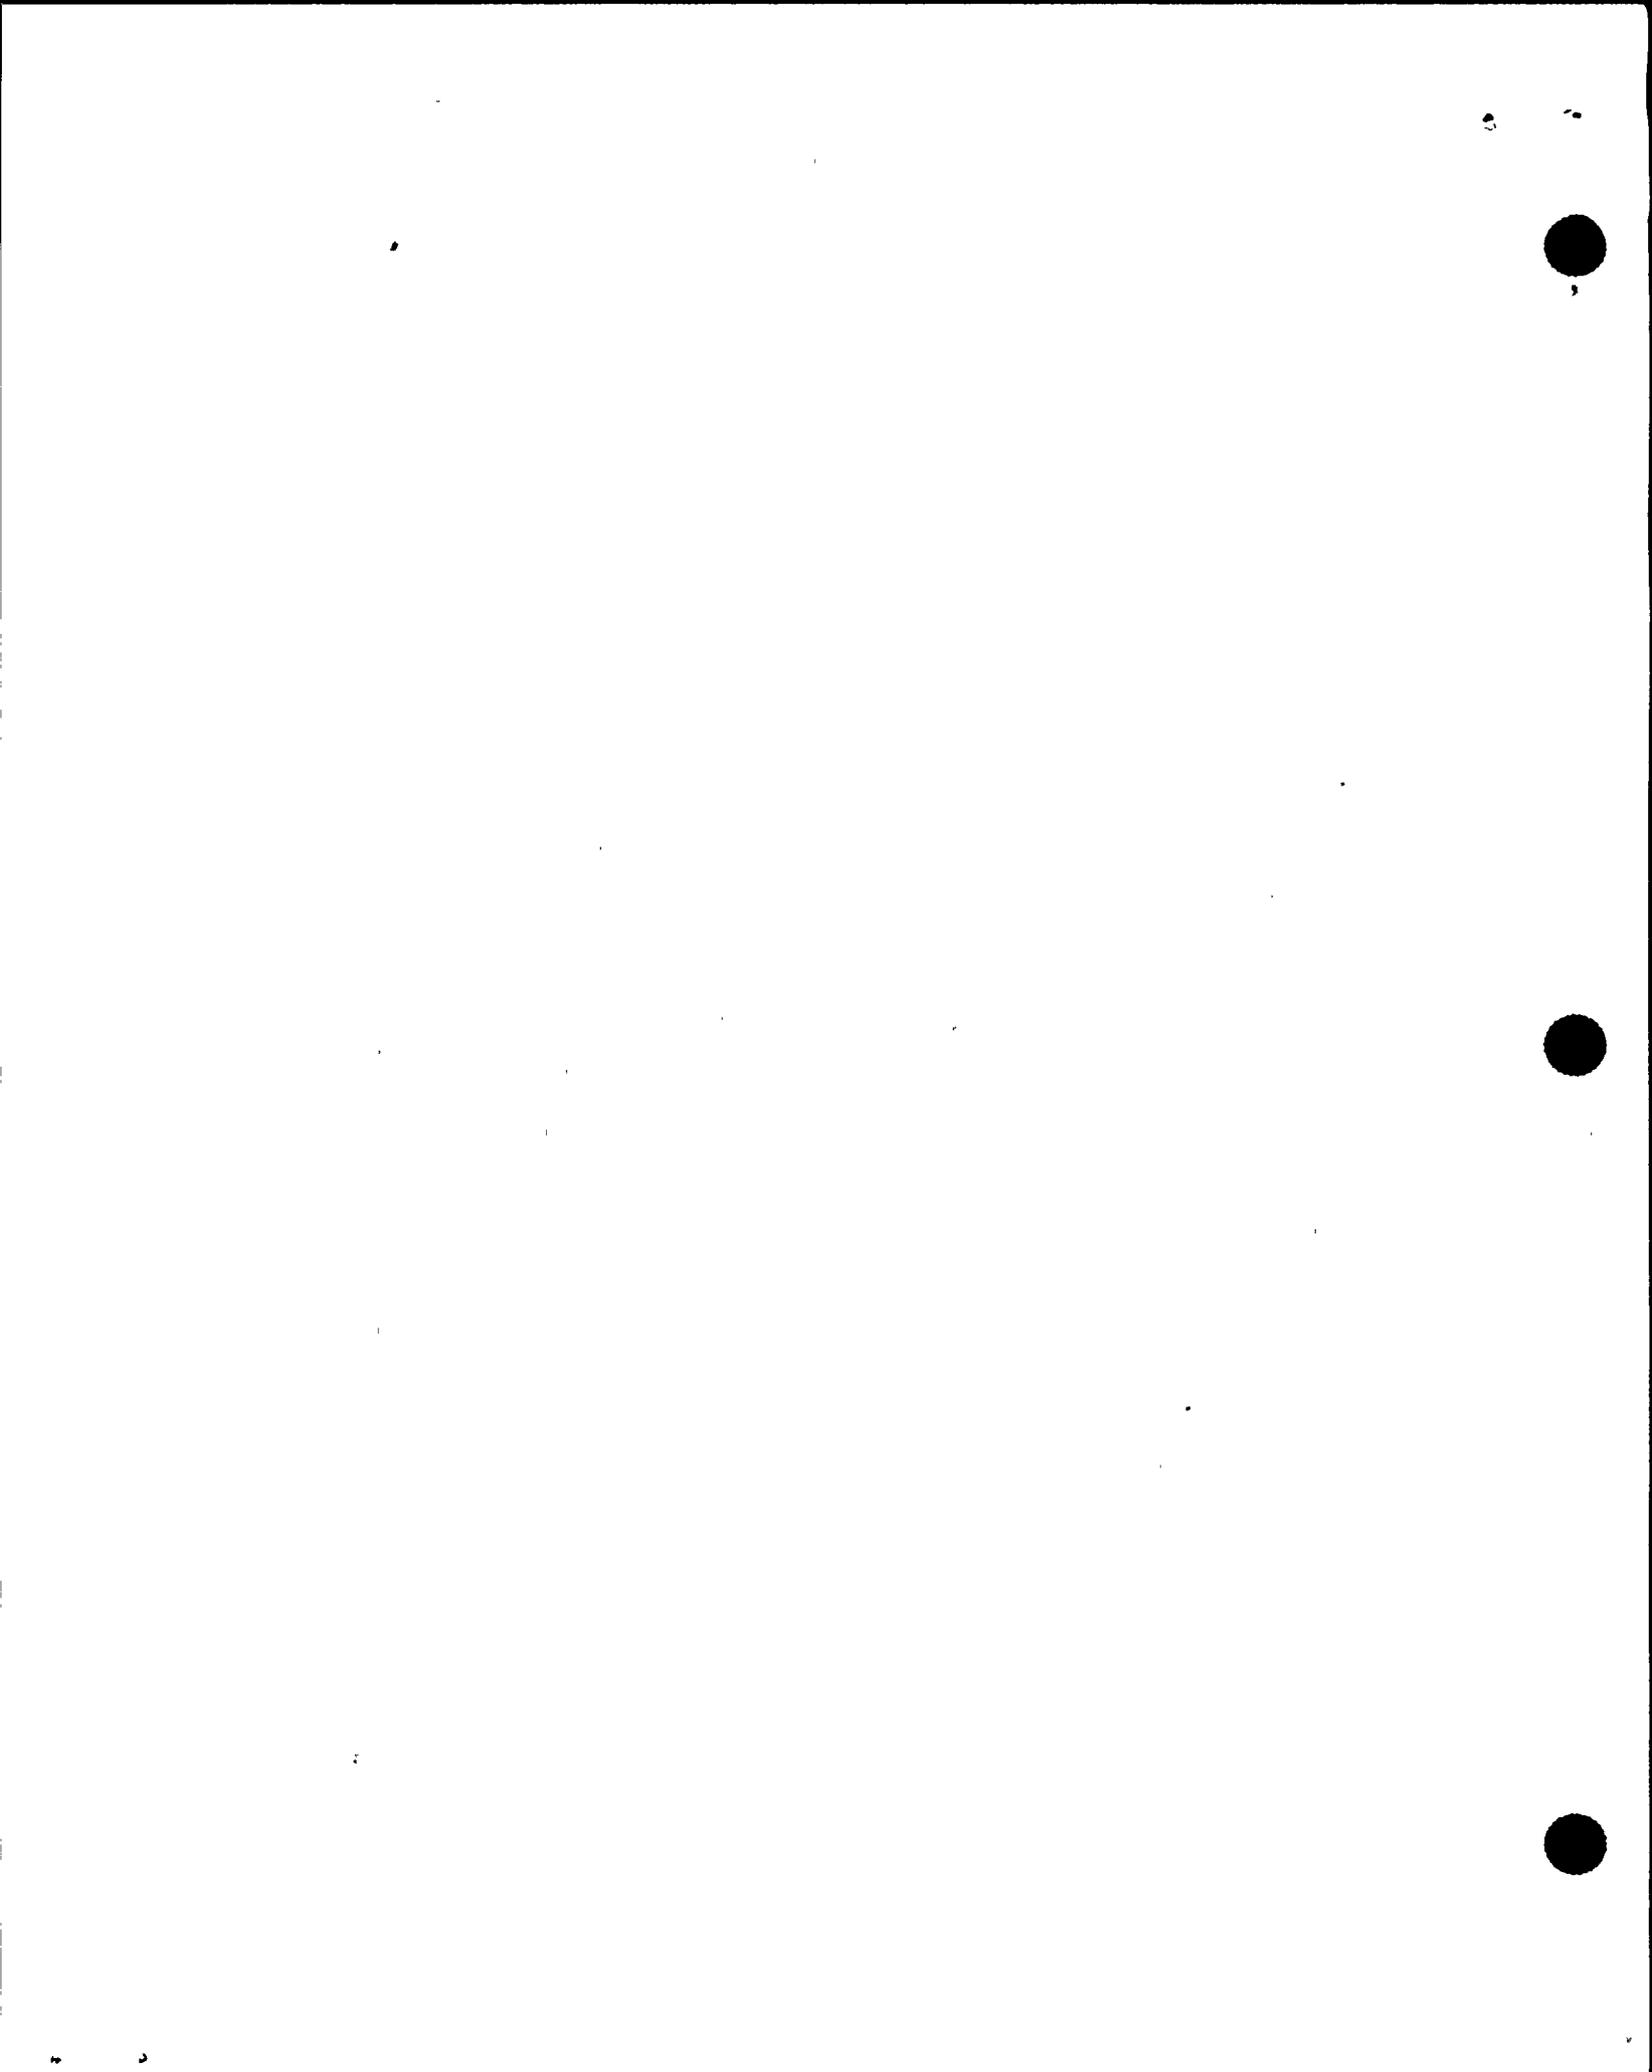

ENCLOSURE 6A

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(1 Page)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 2.0

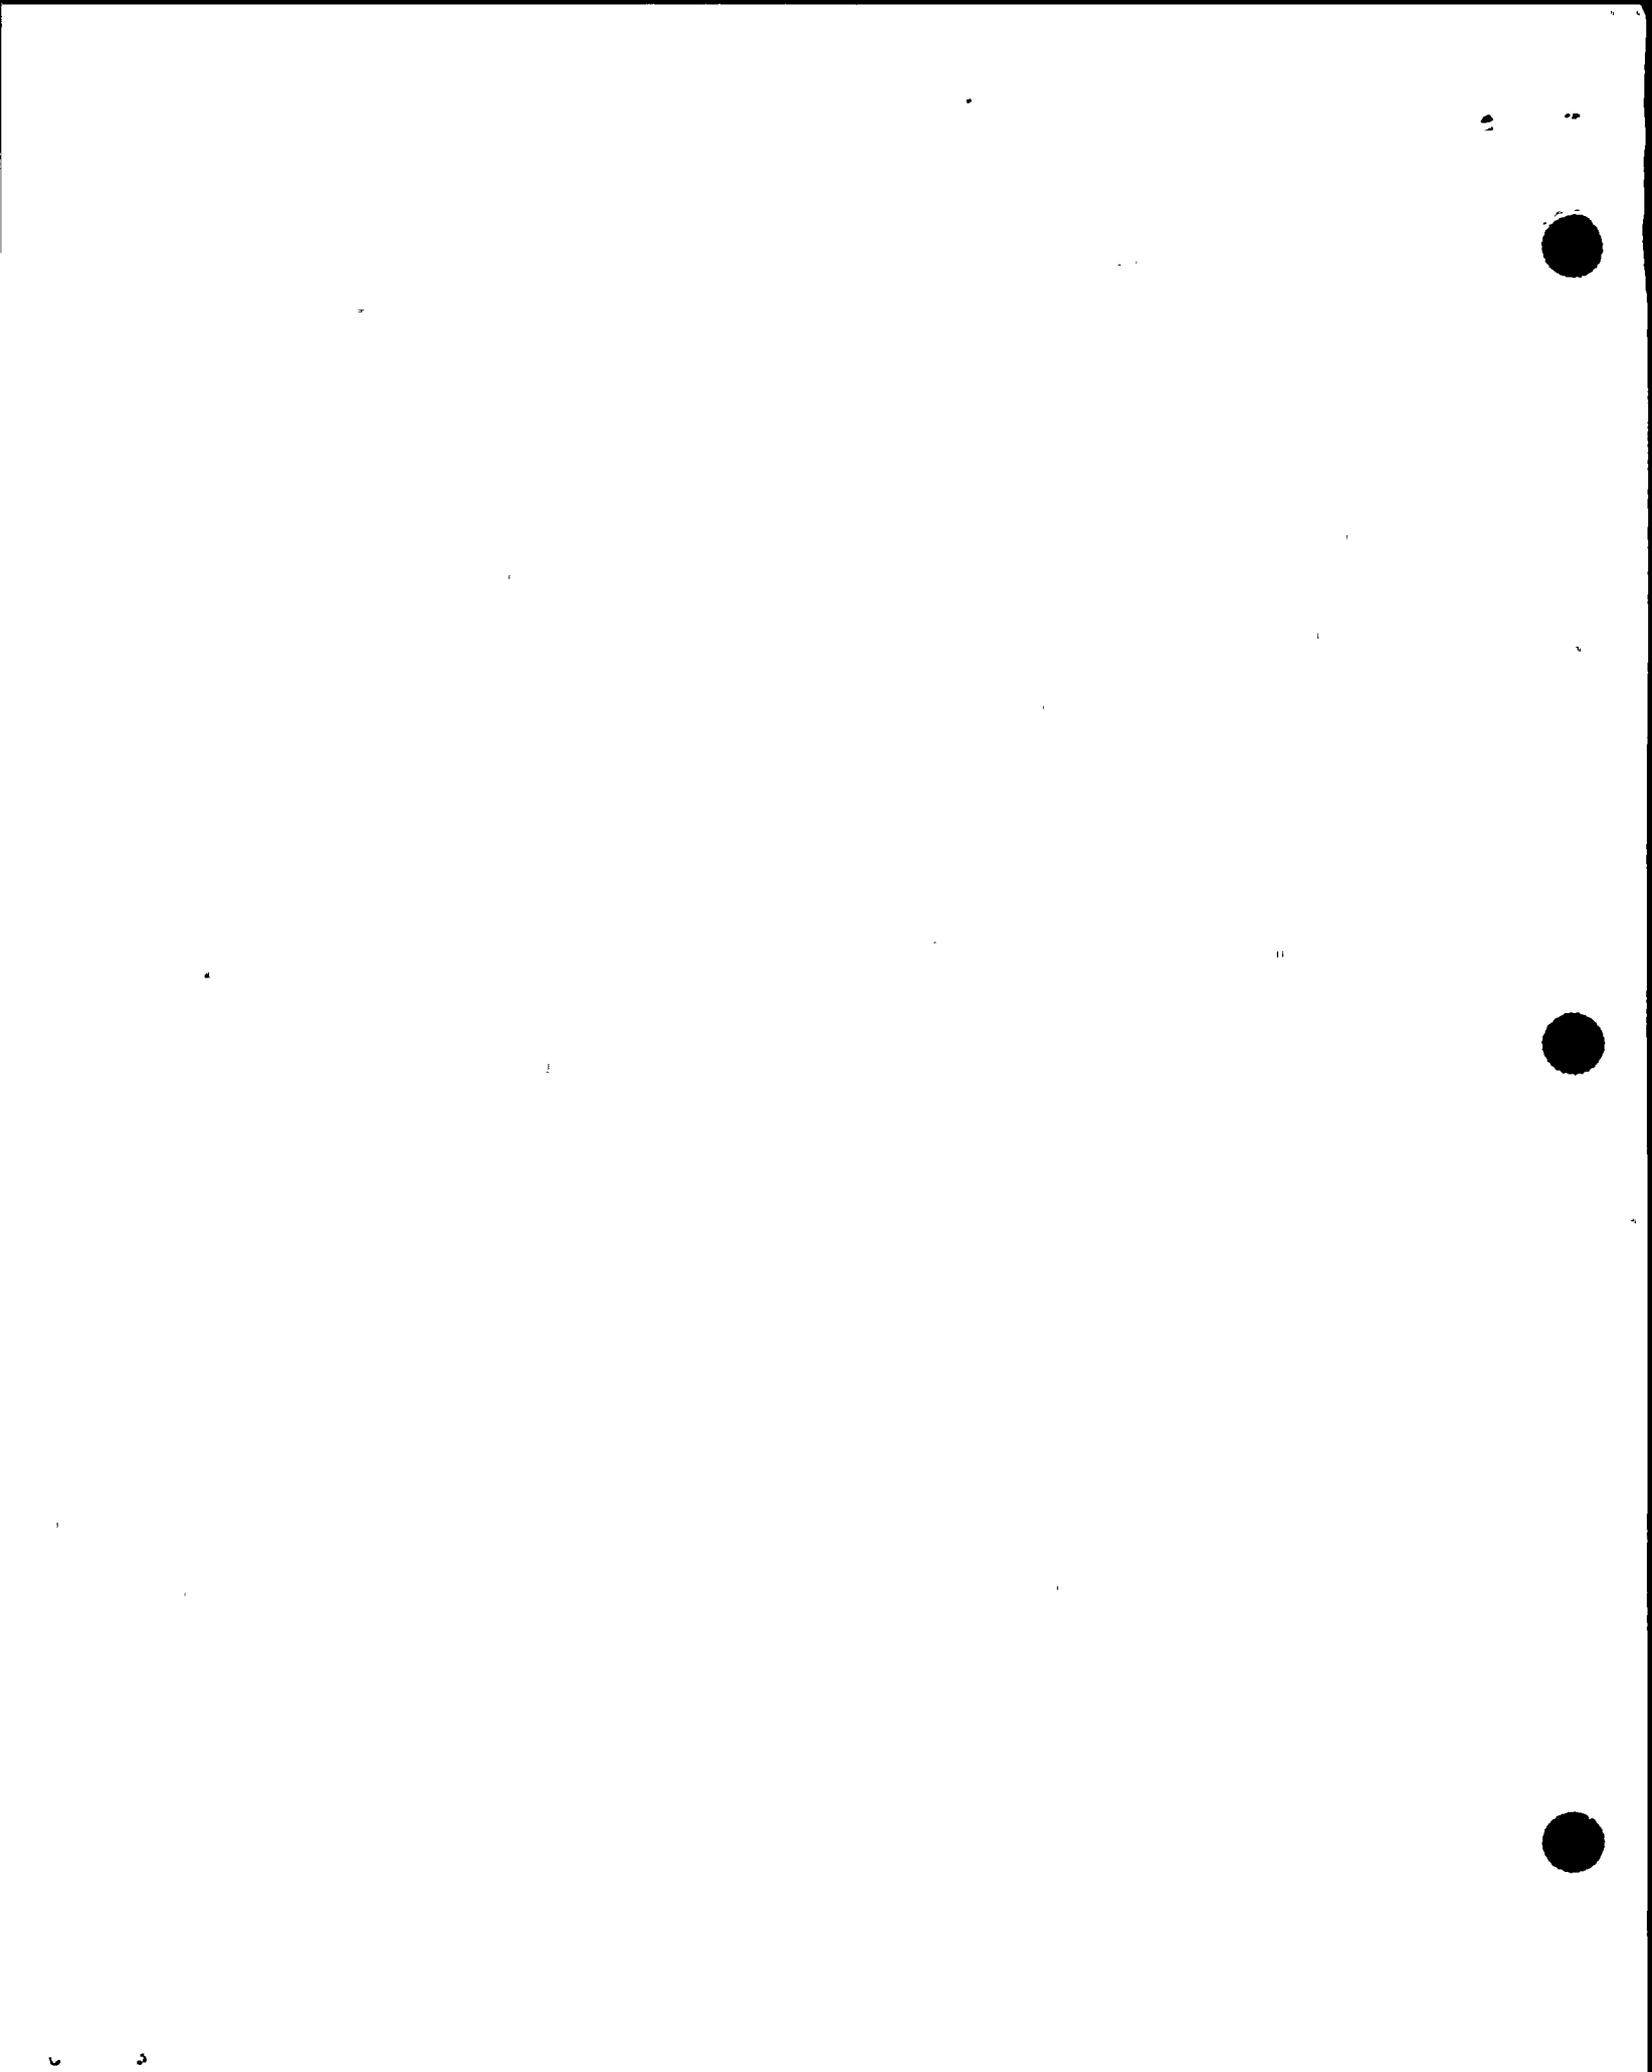

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

|--------|--|
| 2.0-01 | SL violation requirements that duplicate regulations would be eliminated. The applicable regulations are 50.36, 50.72, and 50.73 for reporting an SL violation and 50.36 for obtaining NRC authorization to operate the reactor following an SL violation. These changes are in accordance with TSTF-5, Rev. 1 which has been approved by the NRC. |
| 2.0-02 | The requirements regarding notification of licensee management following SL violations and obtaining reviews of LERs by management and the offsite review committee would be deleted. These requirements would be contained in licensee controlled documents. These changes are also in accordance with TSTF-5, Rev. 1. |

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

**Methodology for Cross-Reference Tables
(Continued)**

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).
Note:	The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

MARK-UP OF CURRENT TS

Mark-up

<u>SPECIFICATION</u>	<u>PAGE</u>
3/4.0 Applicability	
Limiting Condition For Operation	3/4 0-1
Surveillance Requirements	3/4 0-2
Methodology	(2 Pages)

3/4 LIMITING CONDITIONS FOR OPERATION AND SURVEILLANCE REQUIREMENTS

3/4.0 APPLICABILITY

LIMITING CONDITION FOR OPERATION

3.0.1 Compliance with the Limiting Conditions for Operation contained in the succeeding specifications is required during the OPERATIONAL MODES or other conditions specified therein; except that upon failure to meet the Limiting Conditions for Operation, the associated ACTION requirements shall be met, except as provided in LCO 3.0.2 and LCO 3.0.7. 01-01-A

3.0.2 Noncompliance with a specification shall exist when the requirements of the Limiting Condition for Operation and associated ACTION requirements are not met within the specified time intervals, except as provided in LCO 3.0.5 and LCO 3.0.6. If the Limiting Condition for Operation is restored or is no longer applicable prior to expiration of the specified time intervals, completion of the ACTION requirements is not required unless otherwise stated. 01-01-A

3.0.3 When a Limiting Condition for Operation is not met, except as provided in the associated ACTION requirements, within 1 hour action shall be initiated to place the unit in a MODE in which the specification does not apply by placing it, as applicable, in:

- a. At least HOT STANDBY within the next 6 hours,
- b. At least HOT SHUTDOWN within the following 6 hours, and
- c. At least COLD SHUTDOWN within the subsequent 24 hours.

Where corrective measures are completed that permit operation under the ACTION requirements, the action may be taken in accordance with the specified time limits as measured from the time of failure to meet the Limiting Condition for Operation. Exceptions of these requirements are stated in the individual specifications.

This specification is not applicable in MODE 5 or 6.

3.0.4 Entry into an OPERATIONAL MODE or other specified condition shall not be made when the conditions for the Limiting Conditions for Operation are not met and the associated ACTION requires a shutdown if they are not met within a specified time interval. Entry into an OPERATIONAL MODE or specified condition may be made in accordance with ACTION requirements when conformance to them permits continued operation of the facility for an unlimited period of time. This provision shall not prevent passage through or to OPERATIONAL MODES as required to comply with ACTION statements or that are part of a shutdown of the unit. Exceptions to these requirements are stated in the individual specifications. 01-02-ESI

LCO 3.0.4 is only applicable for entry into a MODE or other specified condition in the Applicability in MODE 1, 2, 3, and 4. 01-02-ESI

3/4.0 APPLICABILITY

LIMITING CONDITION FOR OPERATION

~~3.0.5 Limiting Conditions for Operation including the associated ACTION requirements shall apply to each unit individually unless otherwise indicated as follows:~~

- ~~a- Whenever the Limiting Conditions for Operation refers to systems or components which are shared by both units, the ACTION requirements will apply to both units simultaneously. This will be indicated in the ACTION section;~~ 01-03-A
- ~~b- Whenever the Limiting Conditions for Operation applies to only one unit, this will be identified in the APPLICABILITY section of the specification; and~~
- ~~c- Whenever certain portions of a specification contain operating parameters, Setpoints, etc., which are different for each unit, this will be identified in parentheses, footnotes or body of the requirement.~~

~~(new) Equipment removed from service or declared inoperable to comply with ACTIONS may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the testing required to demonstrate OPERABILITY.~~ 01-04-ES2

~~(new) When a supported system LCO is not met solely due to a support system LCO not being met, the Conditions and Required Actions associated with this supported system are not required to be entered. Only the support system LCO ACTIONS are required to be entered. This is an exception to LCO 3.0.2 for supported system. In this event, an evaluation shall be performed in accordance with Specification 5.5.15, Safety Function Determination Program (SFDP). If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.~~ 01-05-M

~~When a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.~~

~~(new) ITS Test Exception LCO 3.1.8 allows specified Technical Specification (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with Test Exception LCOs is optional. When a Test Exception LCO is desired to be met but is not met, the ACTIONS of the Test Exception LCO shall be met. When a Test Exception LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall be made in accordance with the other applicable Specifications.~~ 01-06-A

APPLICABILITY

SURVEILLANCE REQUIREMENTS

4.0.1 Surveillance Requirements shall be met during the OPERATIONAL MODES or other conditions specified for individual Limiting Conditions for Operation unless otherwise stated in an individual Surveillance Requirement. Failure to meet a Surveillance, whether such failure is experienced during the performance of the Surveillance or between performances of the Surveillance, shall be failure to meet the LCO.

4.0.2 Each Surveillance Requirement shall be performed within the specified surveillance interval with a maximum allowable extension not to exceed 25 percent of the specified surveillance interval.

For Frequencies specified as "once," the above interval extension does not apply.

01-07-LS3

If a Completion Time requires periodic performance on a "once per" basis, the above Frequency extension applies to each performance after the initial performance.

Exceptions to this requirement are stated in the individual specifications.

01-19-A

4.0.3 Failure to perform a Surveillance Requirement within the allowed surveillance interval defined by Specification 4.0.2 shall constitute noncompliance with the OPERABILITY requirements for a Limiting Condition for Operation. The time limits of the ACTION requirements are applicable at the time it is identified that a Surveillance Requirement has not been performed. The ACTION requirements may be delayed for up to 24 hours to permit the completion of the surveillance when the allowable outage time limits of the ACTION requirements are less than 24 hours. If it is discovered that a Surveillance was not performed within its specified Frequency, then compliance with the requirement to declare the LCO not met may be delayed from the time of discovery, for up to 24 hours or up to the limit of the specified Frequency, whichever is less. This delay period is permitted to allow performance of the Surveillance. Exceptions to these requirements are stated in the individual specifications. If the Surveillance is not performed within the delay period, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered. When the Surveillance is performed within the delay period and the Surveillance is not met, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

01-08-LS4

Surveillances Requirements do not have to be performed on inoperable equipment or variables outside specified limits.

01-20-A

4.0.4 Entry into an OPERATIONAL MODE or other specified condition shall not be made unless the Surveillance Requirement(s) associated with the Limiting Condition for Operation has been performed within the stated surveillance interval or as otherwise specified. This provision shall not prevent passage through or to OPERATIONAL MODES as required to comply with ACTION requirements or that are part of a shutdown of the unit.

01-09-LS1

SR 4.0.4 is only applicable for entry into a MODE or other specified Condition in the APPLICABILITY in MODES 1, 2, 3, and 4.

01-09-LS1

4.0.5 Surveillance Requirements for inservice inspection and testing of ASME Code Class 1, 2 and 3 components shall be applicable as follows:

- a. ~~Inservice inspection of ASME Code Class 1, 2 and 3 components and inservice testing of ASME Code Class 1, 2 and 3 pumps, valves.~~

01-11-EG

01-10-A

APPLICABILITY

SURVEILLANCE REQUIREMENTS (Continued)

~~and snubbers shall be performed in accordance with Section XI of the ASME Boiler and Pressure Vessel Code and applicable Addenda as required by 10CFR50, Section 50.55a(g), except where specific written relief has been granted by the Commission pursuant to 10 CFR 50, Section 50.55a(g)(6)(I);~~

b. Surveillance intervals specified in Section XI of the ASME Boiler and Pressure Vessel Code and applicable Addenda for the inservice ~~inspection and testing activities required by the ASME Boiler and Pressure Vessel Code and applicable Addenda shall be applicable as follows in these Technical Specifications:~~

SURVEILLANCE REQUIREMENTS (Continued)

4.0.5 (Continued)

- c. The provisions of Specification 4.0.2 are applicable to the above required frequencies for performing inservice inspection and testing activities; 01-10-A
- d. Performance of the above inservice inspection and testing activities shall be in addition to other specified Surveillance Requirements; and 01-17-A
- e. Nothing in the ASME Boiler and Pressure Vessel Code shall be construed to supersede the requirements of any Technical Specification.

~~The provisions of 4.0.3 are applicable to IST activities~~

01-13-A

~~4.0.6 Surveillance Requirements shall apply to each unit individually unless otherwise indicated as stated in Specification 3.0.5 for individual specifications or whenever certain portions of a specification contain surveillance parameters different for each unit, which will be identified in parentheses, footnotes or body of the requirement.~~

01-03-A

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. Deletions - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. Additions - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. Modifications - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. Administrative - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

**Methodology For Mark-Up of Current TS
(Continued)**

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

ENCLOSURE 3A

DESCRIPTION OF CHANGES TO CURRENT TS

Description of Changes (5 Pages)

DESCRIPTION OF CHANGES TO TS SECTION 3/4.0

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	Adds exceptions to CTS Limiting Condition for Operation (LCO) 3.0.1 and LCO 3.0.2 as provided in improved Technical Specifications (ITS) LCOs 3.0.5, 3.0.6, and 3.0.7. The effects of this change will be discussed later under the discussion of the addition of these LCOs. The exception to CTS LCO 3.0.1 regarding ITS LCO 3.0.7 is in accordance with industry Traveler TSTF-06, Rev. 1 included clarification that completion of an ACTION is not required when the LCO is no longer applicable [].
01-02	LS1	CTS LCO 3.0.4 was previously applicable for entry into all MODES. The specification has been revised to not prevent unit shutdowns and will apply only to entry into MODES 1, 2, 3, and 4 from lower MODES. This change is less restrictive in that it will allow MODE changes from either direction into MODES 5 and 6 while operating within an ACTION with a limited time window. This change is also less restrictive in that MODE changes which are part of a unit shutdown are not prevented. As required in the "Reviewer's Note" of NUREG-1431, LCO 3.0.4, a matrix is provided (see LS1) which documents the plant-specific review of all specifications for determination of where specific restrictions on MODE changes or Required Actions should be included in individual LCOs. The change is acceptable for those specific ACTIONS for which specific restrictions were not deemed warranted.
01-03	A	CTS LCO 3.0.5 [and associated Surveillance Requirement (SR) 4.0.6 are] being deleted. The conventions established by this LCO [and SR] are not needed and are no longer used. Through experience gained at two unit operation and the improved guidance of Specification 1.3, Completion Times, and the Bases discussion of Section 3.0, further clarification in the form of an additional LCO [and SR] is not warranted. This deletion is consistent with NUREG-1431, which does not include the current LCO 3.0.5 or SR 4.0.6.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.0
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-04	LS2	ITS LCO 3.0.5 would be added to the CTS in conformance with NUREG-1431. LCO 3.0.5 provides for returning to service under administrative control, equipment previously declared inoperable or removed from service, for the purpose of demonstrating its OPERABILITY or the OPERABILITY of other equipment. This is acceptable since the equipment remains under appropriate administrative control while it is in service prior to its OPERABILITY being formally established. The administrative controls will limit the time the equipment is in service to that which is necessary for performing the required testing. Furthermore, after corrective maintenance has been performed on the affected equipment, there is reasonable assurance that the required OPERABILITY testing will indeed demonstrate the equipment is capable of performing its safety function.
01-05	M	ITS LCO 3.0.6 as modified by TSTF-166 would be added to the CTS in conformance with NUREG-1431. ITS LCO 3.0.6 provides for an exception to LCO 3.0.2 for the case of an inoperable support system that has its own LCO specified in the Technical Specifications (TS.) When a support system is inoperable and there is an LCO specified for it in the TS, the supported system(s) are required to be declared inoperable if they are determined to be inoperable as a result of the support system inoperability. However, it is not necessary to enter into the supported system's ACTIONS unless directed to do so by the support system's Required ACTIONS. This exception is justified because the ACTIONS that are required to ensure the unit is maintained in a safe Condition are specified in the support system's LCO Required ACTIONS. Furthermore, the Safety Function Determination Program (SFDP) will ensure that there is no resulting loss of safety function. Finally, the potential confusion and inconsistency of requirements related to the entry into multiple support and supported system's LCO's ACTIONS are eliminated by providing all the actions that are necessary to ensure the unit is operated in an acceptably safe manner in the support system's Required Actions. While the proposed change clarifies CTS requirements regarding support system OPERABILITY, it also imposes the SFDP where no such program previously existed. Therefore, the proposed change is considered more restrictive.
01-06	A	New ITS LCO 3.0.7, as modified by Industry Travelers TSTF-12, Rev. 1 and TSTF-136, would be added to the CTS in conformance with NUREG-1431. This LCO provides for the optional application of test exception LCOs for the purpose of performing physics testing. The proposed change does not change the technical manner in which special test exceptions are administered; however, the addition of the LCO for this purpose is considered a change.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.0
(Continued)

CHANGE
NUMBER

NSHC

DESCRIPTION

01-07

LS3

CTS SR 4.0.2 is being changed in conformance with NUREG-1431 to apply the 25 percent extension to the Completion Times of repetitive Required Actions. This is a relaxation because it has been previously interpreted that the extension of SR 4.0.2 did not apply within ACTION statements. This change is considered acceptable as the current practice of performing the initial Required Action does not allow extension. Therefore, no loss of safety function is demonstrated within the required Completion Time. Following the initial performance, repetitive Required Actions are specifically delineated as SRs and as such it is appropriate for reasons of scheduling and plant Conditions that the 25 percent extension be allowable. As is the case with SRs, the extension is not intended to be used repeatedly merely as an operational convenience to extend periodic Completion Times beyond those specified.

01-08

LS4

CTS SR 4.0.3 is being changed with respect to the allowance for performing a missed surveillance upon discovery. This change is in conformance to NUREG-1431. The CTS allows the ACTION requirements to be delayed for up to 24 hours for completion of the surveillance when the allowed outage time (AOT) limits of the ACTION requirements are less than 24 hours after declaring the equipment inoperable, from the point of discovery. The proposed NUREG-1431 specification does not require the equipment to be declared inoperable and allows the lesser of 24 hours or the specified frequency for performance of the surveillance.

The allowance to not declare the equipment inoperable upon discovery of a missed surveillance is a relaxation in that ACTIONS for inoperable equipment are not entered solely due to a missed surveillance. The change in time to perform the surveillance could either be a relaxation or restriction based on whether the surveillance frequency or the AOT was more restrictive. The new requirement is based on time to perform a surveillance, and is therefore more consistent. The change still restricts performance of the surveillance to within 24 hours of discovery and is seen as acceptable, from the perspective of safety, as equipment is normally demonstrated OPERABLE, not inoperable via surveillance performance.

01-09

LS1

CTS SR 4.0.4 was previously applicable for entry into all MODES. The specification has been revised to not prevent unit shutdown and will apply only to entry into MODES 1, 2, 3, and 4 from lower MODES. This change is less restrictive in that it will allow MODE changes in either direction into MODES 5 and 6 prior to the performance of SRs. As required in the "Reviewer's Note" of NUREG-1431, SR 3.0.4, a matrix is provided (see LS1) which documents the plant-specific review of all specifications for determination of where specific restrictions on MODE changes or Required Actions should be included in individual LCOs. The change is acceptable for those specifications for which specific restrictions were not deemed warranted.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.0
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-10	A	TS 4.0.5, the SR for inservice testing, is moved to the ITS Administrative Controls Section 5.5.8 consistent with NUREG-1431. The reference to 10CFR50.55a is unnecessary and has been deleted.
01-11	LG	The portions of CTS 4.0.5 concerning inservice inspection (ISI) are moved to the ISI Program Plan. The requirements of 10CFR50.55a are adequate and TS are not necessary.
01-12	A	Consistent with NUREG-1431 Inservice Testing Program, ITS 5.5.8, the CTS is clarified to address the Inservice Testing (IST) Frequency (in days) for biennial requirements which was previously inferred but not explicitly stated in the CTS.
01-13	A	This change adds Applicability of CTS SR 4.0.3 (SR 3.0.3 in the ITS) for inservice testing for consistency with the wording in NUREG-1431. In NUREG-1431, inservice testing is moved to the Programs and Manuals Section (ITS 5.5.8) and is no longer a SR. Thus, an explicit statement that ITS SR 3.0.3 (CTS SR 4.0.3) was applicable to inservice testing was necessary to provide for the performance of missed IST requirements. CTS SR 4.0.5 (IST) is already an SR, and thus by definition, CTS SR 4.0.3 applies.
01-14	A	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-15	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-16	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-17	A	Consistent with the wording used in NUREG-1431, Section 5.5.8, CTS SR [4.0.5d] concerning performance of IST being performed in addition to other specified SRs, is deleted. The statement is redundant to the usage rules and is not necessary.
01-18	LS5	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-19	A	The phrase "Exceptions to this Specification are stated in the individual specifications" was added to CTS 4.0.2 to provide exceptions in individual frequencies where the allowances provided in CTS 4.0.2 are not allowed. This additional wording will have no impact on current practice regarding compliance with SRs. [The statement in CTS 4.0.3, "Exceptions to these requirements are stated in the individual specifications" is deleted in accordance with NUREG-1431.]
01-20	A	Consistent with NUREG-1431, the phrase "or variables outside specified limits" is added to the statement that surveillances do not have to be performed on inoperable equipment. This is not a technical change in that "variables outside specified limits" is now explicitly stated in the ITS; whereas, in the CTS, it was implicit in the definition of inoperable equipment.

ENCLOSURE 3B

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information may be moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3...." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

LCO 3.0.4 and SR 4.0.4 in the CTS are applicable for entry into all MODES. The proposed change revises the applicability of these specifications to not prevent unit shutdowns and will apply to entry into MODES 1, 2, 3, and 4 only. This change is less restrictive in that it will allow MODE changes from either direction into MODES 5 and 6 while operating within an ACTION with a finite time period or prior to performance of a SR. This change is also less restrictive in that MODE changes that are part of a unit shutdown are not prevented.

All specifications were evaluated for individual acceptability of this application. Based on this evaluation, (see attached LCO 3.0.4 evaluation and matrix), where MODE change restrictions were determined to be required in MODES 5 and 6, or in MODES 1, 2, 3, and 4 during unit shutdown, notes containing the appropriate MODE change restrictions were added to the individual specifications.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change has impact on what equipment is required to be OPERABLE or demonstrated OPERABLE via surveillance prior to unit shutdowns or entry into MODES 5 and 6. This change could increase the probability or consequences of an accident previously evaluated if applied without consideration to all applicable transitions. However, as part of the change, an evaluation is attached in the form of a matrix, that identifies those specifications which must continue to apply LCO 3.0.4 and SR 3.0.4. Therefore, only those specifications that do not impact safety for these plant conditions, are afforded this relaxation.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change administratively changes when equipment is required to be OPERABLE or demonstrated OPERABLE via surveillance prior to entry into MODES 5 and 6. However, the proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change administratively changes what equipment is required to be OPERABLE or demonstrated OPERABLE via surveillance prior to unit shutdown or entry into MODES 5 and 6. However, the proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 1" resulting from the conversion to the ITS format, satisfy the NSHC standards of 10CFR50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2

10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS
WITHIN THE TECHNICAL SPECIFICATIONS

ITS LCO 3.0.5 provides for an allowance to return equipment which had previously been declared inoperable back to service to either demonstrate the equipment's OPERABILITY or the OPERABILITY of other equipment.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

ITS LCO 3.0.5 provides for an allowance to return equipment which had previously been declared inoperable back to service to either demonstrate the equipment's OPERABILITY or the OPERABILITY of other equipment. Returning inoperable equipment to service under administrative control for testing will be to demonstrate equipment OPERABILITY. The equipment remains under appropriate administrative control while it is in service prior to its OPERABILITY being formally established. The expected result is that the equipment will be restored to OPERABLE status. In any case, however, the situation of inoperable safety-related equipment is controlled within the limits provided in the Applicability and ACTION statements to ensure there are no significant changes to risks or consequences as a result of the process of returning equipment to service.

Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change administratively changes the allowance to return equipment to service when inoperable for demonstrating that the equipment is OPERABLE or other equipment is OPERABLE. However, the proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS 2" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10CFR50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS SR 4.0.2 is being revised to allow application of the 25 percent extension for surveillance performance to the Completion Times of repetitive Required ACTIONS, following the initial performance. The extension is not allowed on initial performance as the first performance is demonstrating a necessary OPERABILITY. The subsequent performances are confirming that OPERABILITY is being maintained.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The extension is not applied to the initial performance which is required to demonstrate a component or system is OPERABLE, and therefore continued operation within the confines of the Condition are acceptable. The subsequent performances of the requirement are not time critical as the expectation is that the performance will confirm OPERABILITY. Therefore, there is no reduction in requirements for the initial performance and only up to a maximum of 25 percent extension (the same as for routine surveillances) on subsequent performance. Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change relaxes the Completion Times for performing repetitive ACTIONS designed to confirm OPERABILITY within a Required Action. This change is consistent with the allowances for performing routine surveillances which are anticipated to confirm OPERABILITY. However, the proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS 3" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10CFR50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed change revises the time allowed to perform a missed surveillance upon discovery from up to 24 hours. When the AOT limits of the ACTION requirements are less than 24 hours, the AOT may be the lesser of 24 hours or the surveillance frequency interval. Additionally, the equipment is not required to be declared inoperable at the time of discovery of a missed surveillance. This prevents unnecessary entry into Conditions based solely on equipment inoperabilities when the equipment is anticipated to be demonstrated OPERABLE by surveillance performance. The change is acceptable because it still restricts performance of the surveillance to within 24 hours of discovery and the equipment is normally demonstrated to be OPERABLE, not inoperable, by performance of the surveillance.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Surveillance performance is nominally considered to demonstrate equipment OPERABILITY. Therefore, identifying that a surveillance has been missed usually does not result in any true inoperabilities existing as the equipment is normally demonstrated OPERABLE upon performance of the missed surveillance. This change potentially allows a longer time in some instances for performance of the surveillance from time of discovery that the surveillance was missed. In these cases, if the equipment were truly inoperable, there would be an extended duration in which the appropriate Required ACTIONS were not taken. Not taking the Required ACTIONS could have a negative effect on the probability or consequences of an accident. However, at no time will this period exceed 24 hours. Based on the short duration, a minimal impact if any, would be expected to overall plant safety. Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change potentially relaxes the allowed times for performing a surveillance once identified as missed. However, the proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS4" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10CFR50.92(c), and accordingly a NSHC finding is justified.

3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

LCO 3.0.1 LCOs shall be met during the MODES or other specified conditions in the Applicability, except as provided in LCO 3.0.2 and ~~LCO 3.0.7~~.

3.0.01

LCO 3.0.2 Upon discovery of a failure to meet an LCO, the Required Actions of the associated Conditions shall be met, except as provided in LCO 3.0.5 and LCO 3.0.6.

If the LCO is met or is no longer applicable prior to expiration of the specified Completion Time(s), completion of the Required Action(s) is not required unless otherwise stated.

LCO 3.0.3 When an LCO is not met and the associated ACTIONS are not met, an associated ACTION is not provided, or if directed by the associated ACTIONS, the unit shall be placed in a MODE or other specified condition in which the LCO is not applicable. Action shall be initiated within 1 hour to place the unit, as applicable, in:

- a. MODE 3 within 7 hours;
- b. MODE 4 within 13 hours; and
- c. MODE 5 within 37 hours.

Exceptions to this Specification are stated in the individual Specifications.

Where corrective measures are completed that permit operation in accordance with the LCO or ACTIONS, completion of the actions required by LCO 3.0.3 is not required.

LCO 3.0.3 is only applicable in MODES 1, 2, 3, and 4.

(Continued)

3.0 LCO APPLICABILITY (Continued)

LCO 3.0.4 When an LCO is not met, entry into a MODE or other specified condition in the Applicability shall not be made except when the associated ACTIONS to be entered permit continued operation in the MODE or other specified condition in the Applicability for an unlimited period of time. This ~~LCO 3.0.4~~ Specification shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit. ED

Exceptions to this Specification are stated in the individual Specifications. ~~These exceptions allow entry into MODES or other specified conditions in the Applicability when the associated ACTIONS to be entered allow unit operation in the MODE or other specified condition in the Applicability only for a limited period of time.~~ 3:0:03

LCO 3.0.4 is only applicable for entry into a MODE or other specified condition in the Applicability in MODES 1, 2, 3, and 4.

~~Reviewers's Note: LCO 3.0.4 has been revised so that changes in MODES or other specified conditions in the Applicability that are part of a shutdown of the unit shall not be prevented. In addition, LCO 3.0.4 has been revised so that it is only applicable for entry into a MODE or other specified condition in the Applicability in MODES 1, 2, and 3. The MODE change restrictions in LCO 3.0.4 were previously applicable in all MODES. Before this version of LCO 3.0.4 can be implemented on a plant specific basis, the licensee must review the existing technical specifications to determine where specific restrictions on MODE changes or Required Actions should be included in individual LCOs to justify this change; such an evaluation should be summarized in a matrix of all existing LCOs to facilitate NRC staff review of a conversion to the STS.~~

LCO 3.0.5 Equipment removed from service or declared inoperable to comply with ACTIONS may be returned to service under administrative control solely to perform testing required to demonstrate its OPERABILITY or the OPERABILITY of other equipment. This is an exception to LCO 3.0.2 for the system returned to service under administrative control to perform the testing required to demonstrate OPERABILITY.

(Continued)

3.0 LCO APPLICABILITY (Continued)

LCO 3.0.6 When a supported system LCO is not met solely due to a support system LCO not being met, the Conditions and Required Actions associated with this supported system are not required to be entered. Only the support system LCO ACTIONS are required to be entered. This is an exception to LCO 3.0.2 for the supported system. In this event, ~~additional evaluations and limitations may be required shall be performed~~ in accordance with Specification 5.5.15, "Safety Function Determination Program (SFDP)." If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

3.0-04

When a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2.

LCO 3.0.7 Test Exception LCOs ~~[3.1.8, 3.1.10, 3.1.11, and 3.4.19]~~ allows specified Technical Specification (TS) requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other TS requirements remain unchanged. Compliance with Test Exception LCOs is optional. When a Test Exception LCO is desired to be met but is not met, the ACTIONS of the Test Exception LCO shall be met. When a Test Exception LCO is not desired to be met, entry into a MODE or other specified condition in the Applicability shall be made in accordance with the other applicable Specifications.

3.0-02

B-PS

3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

SR 3.0.1 SRs shall be met during the MODES or other specified conditions in the Applicability for individual LCOs, unless otherwise stated in the SR. Failure to meet a Surveillance, whether such failure is experienced during the performance of the Surveillance or between performances of the Surveillance, shall be failure to meet the LCO. Failure to perform a Surveillance within the specified Frequency shall be failure to meet the LCO except as provided in SR 3.0.3. Surveillances do not have to be performed on inoperable equipment or variables outside specified limits

SR 3.0.2 The specified Frequency for each SR is met if the Surveillance is performed within 1.25 times the interval specified in the Frequency, as measured from the previous performance or as measured from the time a specified condition of the Frequency is met.

For Frequencies specified as "once," the above interval extension does not apply.

If a Completion Time requires periodic performance on a "once per . . ." basis, the above Frequency extension applies to each performance after the initial performance

Exceptions to this Specification are stated in the individual Specifications.

SR 3.0.3 If it is discovered that a Surveillance was not performed within its specified Frequency, then compliance with the requirement to declare the LCO not met may be delayed, from the time of discovery, up to 24 hours or up to the limit of the specified Frequency, whichever is less. This delay period is permitted to allow performance of the Surveillance.

If the Surveillance is not performed within the delay period, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered

When the Surveillance is performed within the delay period and the Surveillance is not met, the LCO must immediately be declared not met, and the applicable Condition(s) must be entered.

(Continued)

3.0 SR APPLICABILITY (Continued)

SR 3.0.4 Entry into a MODE or other specified condition in the Applicability of an LCO shall not be made unless the LCO's Surveillances have been met within their specified Frequency. This provision shall not prevent entry into MODES or other specified conditions in the Applicability that are required to comply with ACTIONS or that are part of a shutdown of the unit.

SR 3.0.4 is only applicable for entry into a MODE or other specified condition in the Applicability in MODES 1, 2, 3, and 4.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions -** The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions -** The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications -** The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes-** Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts -** The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

Methodology For Mark-up of NUREG-1431 Specifications
(Continued)

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

B 3.0 LIMITING CONDITION FOR OPERATION (LCO) APPLICABILITY

BASES

LCOs LCO 3.0.1 through LCO 3.0.6 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated.

LCO 3.0.1 LCO 3.0.1 establishes the Applicability statement within each individual Specification as the requirement for when the LCO is required to be met (i.e., when the unit is in the MODES or other specified conditions of the Applicability statement of each Specification).

LCO 3.0.2 LCO 3.0.2 establishes that upon discovery of a failure to meet an LCO, the associated ACTIONS shall be met. The Completion Time of each Required Action for an ACTIONS Condition is applicable from the point in time that an ACTIONS Condition is entered. The Required Actions establish those remedial measures that must be taken within specified Completion Times when the requirements of an LCO are not met. This Specification establishes that:

- a. Completion of the Required Actions within the specified Completion Times constitutes compliance with a Specification; and
- b. Completion of the Required Actions is not required when an LCO is met within the specified Completion Time, unless otherwise specified.

There are two basic types of Required Actions. The first type of Required Action specifies a time limit in which the LCO must be met. This time limit is the Completion Time to restore an inoperable system or component to OPERABLE status or to restore variables to within specified limits. If this type of Required Action is not completed within the specified Completion Time, a shutdown may be required to place the unit in a MODE or condition in which the Specification is not applicable. (Whether stated as a Required Action or not, correction of the entered Condition is an action that may always be considered upon entering ACTIONS.) The second type of Required Action specifies the remedial measures that permit continued operation of the unit that is not further restricted by the Completion Time. In this case, compliance with the Required Actions provides an acceptable level of safety for continued operation

(Continued)

BASES

LCO 3.0.2 (Continued) Completing the Required Actions is not required when an LCO is met or is no longer applicable, unless otherwise stated in the individual Specifications.

The nature of some Required Actions of some Conditions necessitates that, once the Condition is entered, the Required Actions must be completed even though the associated Conditions no longer exist. The individual LCO's ACTIONS specify the Required Actions where this is the case. An example of this is in LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits."

The Completion Times of the Required Actions are also applicable when a system or component is removed from service intentionally. The reasons for intentionally relying on the ACTIONS include, but are not limited to, performance of Surveillances, preventive maintenance, corrective maintenance, or investigation of operational problems. Entering ACTIONS for these reasons must be done in a manner that does not compromise safety. Intentional entry into ACTIONS should not be made for operational convenience. Alternatives that would not result in redundant equipment being inoperable should be used instead. Doing so limits the time both subsystems/trains of a safety function are inoperable and limits the time other conditions exist which result in LCO 3.0.3 being entered. Individual Specifications may specify a time limit for performing an SR when equipment is removed from service or bypassed for testing. In this case, the Completion Times of the Required Actions are applicable when this time limit expires, if the equipment remains removed from service or bypassed.

When a change in MODE or other specified condition is required to comply with Required Actions, the unit may enter a MODE or other specified condition in which another Specification becomes applicable. In this case, the Completion Times of the associated Required Actions would apply from the point in time that the new Specification becomes applicable, and the ACTIONS Condition(s) are entered.

LCO 3.0.3 LCO 3.0.3 establishes the actions that must be implemented when an LCO is not met an

- a. An associated Required Action and Completion Time is not met and no other Condition applies; or

(Continued)

BASES

LCO 3.0.3
(Continued)

- b. The condition of the unit is not specifically addressed by the associated ACTIONS. This means that no combination of Conditions stated in the ACTIONS can be made that exactly corresponds to the actual condition of the unit. Sometimes, possible combinations of Conditions are such that entering LCO 3.0.3 is warranted; in such cases, the ACTIONS specifically state a Condition corresponding to such combinations and also that LCO 3.0.3 be entered immediately.

This Specification delineates the time limits for placing the unit in a safe MODE or other specified condition when operation cannot be maintained within the limits for safe operation as defined by the LCO and its ACTIONS. It is not intended to be used as an operational convenience that PERMITS routine voluntary removal of redundant systems or components from service in lieu of other alternatives that would not result in redundant systems or components being inoperable.

Upon entering LCO 3.0.3, 1 hour is allowed to prepare for an orderly shutdown before initiating a change in unit operation. This includes time to permit the operator to coordinate the reduction in electrical generation with the load dispatcher to ensure the stability and availability of the electrical grid. The time limits specified to reach lower MODES of operation permit the shutdown to proceed in a controlled and orderly manner that is well within the specified maximum cooldown rate and within the capabilities of the unit, assuming that only the minimum required equipment is OPERABLE. This reduces thermal stresses on components of the Reactor Coolant System and the potential for a plant upset that could challenge safety systems under conditions to which this Specification applies. The use and interpretation of specified times to complete the actions of LCO 3.0.3 are consistent with the discussion of Section 1.3, Completion Times.

A unit shutdown required in accordance with LCO 3.0.3 may be terminated and LCO 3.0.3 exited if any of the following occurs:

- a. The LCO is now met.
- b. A Condition exists for which the Required Actions have now been performed.
- c. ACTIONS exist that do not have expired Completion Times. These Completion Times are applicable from the point in time that the Condition is initially entered and not from the time LCO 3.0.3 is exited

(Continued)

BASES

LCO 3.0.3 (Continued) The time limits of Specification 3.0.3 allow 37 hours for the unit to be in MODE 5 when a shutdown is required during MODE 1 operation. If the unit is in a lower MODE of operation when a shutdown is required, the time limit for reaching the next lower MODE applies. If a lower MODE is reached in less time than allowed, however, the total allowable time to reach MODE 5, or other applicable MODE, is not reduced. For example, if MODE 3 is reached in 2 hours, then the time allowed for reaching MODE 4 is the next 11 hours, because the total time for reaching MODE 4 is not reduced from the allowable limit of 13 hours. Therefore, if remedial measures are completed that would permit a return to MODE 1, a penalty is not incurred by having to reach a lower MODE of operation in less than the total time allowed.

In MODES 1, 2, 3, and 4, LCO 3.0.3 provides ACTIONS for Conditions not covered in other Specifications. The requirements of LCO 3.0.3 do not apply in MODES 5 and 6 because the unit is already in the most restrictive Condition required by LCO 3.0.3. The requirements of LCO 3.0.3 do not apply in other specified conditions of the Applicability (unless in MODE 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken.

Exceptions to LCO 3.0.3 are provided in instances where requiring a unit shutdown, in accordance with LCO 3.0.3, would not provide appropriate remedial measures for the associated condition of the unit. An example of this is in LCO 3.7.15, "Spent Fuel Storage Pool Water Level." LCO 3.7.15 has an Applicability of "During movement of irradiated fuel assemblies in the spent fuel storage pool." Therefore, this LCO can be applicable in any or all MODES. If the LCO and the Required Actions of LCO 3.7.15 are not met while in MODE 1, 2, or 3, or 4, there is no safety benefit to be gained by placing the unit in a shutdown condition. The Required Action of LCO 3.7.15 of "Suspend movement of irradiated fuel assemblies in the spent fuel storage pool" is the appropriate Required Action to complete in lieu of the ACTIONS of LCO 3.0.3. These exceptions are addressed in the individual Specifications.

LCO 3.0.4 LCO 3.0.4 establishes limitations on changes in MODES or other specified conditions in the Applicability when an LCO is not met. It precludes placing the unit in a MODE or other specified condition stated in that Applicability (e.g., Applicability desired to be entered) when the following exist

(Continued)

BASES

LCO 3.0.4
(Continued)

- a. Unit conditions are such that the requirements of the LCO would not be met in the Applicability desired to be entered; and
- b. Continued noncompliance with the LCO requirements, if the Applicability were entered, would result in the unit being required to exit the Applicability desired to be entered to comply with the Required Actions.

Compliance with Required Actions that permit continued operation of the unit for an unlimited period of time in a MODE or other specified condition provides an acceptable level of safety for continued operation. This is without regard to the status of the unit before or after the MODE change. Therefore, in such cases, entry into a MODE or other specified condition in the Applicability may be made in accordance with the provisions of the Required Actions. The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or components to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

The provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown.

Exceptions to LCO 3.0.4 are stated in the individual Specifications. ~~These exceptions allow entry into MODES or other specified conditions in the Applicability when the associated ACTIONS to be entered do not provide for continued operation for an unlimited period of time.~~ Exceptions may apply to all the ACTIONS or to a specific Required Action of a Specification.

LCO 3.0.4 is only applicable when entering MODE 4 from MODE 5, MODE 3 from MODE 4, MODE 2 from MODE 3, or MODE 1 from LCO 3.0.4 MODE 2. Furthermore, LCO 3.0.4 is applicable when entering any other specified condition in the Applicability only while operating in MODES 1, 2, 3, or 4. The requirements of LCO 3.0.4 do not apply in MODES 5 and 6, or in other specified conditions of the Applicability (unless in MODES 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken. In some cases (e.g., where a review has concluded that specific restriction on MODE changes should be included) these ACTIONS provide a Note that states "While this LCO is not met, entry into a MODE or other specified condition

(Continued)

BASES

LCO 3.0.4
(Continued)

in the Applicability is not permitted, unless required to comply with ACTIONS." This Note is a requirement explicitly precluding entry into a MODE or other specified condition of the Applicability. Surveillances do not have to be performed on the associated inoperable equipment (or on variables outside the specified limits), as permitted by SR 3.0.1. Therefore, changing MODES or other specified conditions while in an ACTIONS Condition, in compliance with LCO 3.0.4 or where an exception to LCO 3.0.4 is stated, is not a violation of SR 3.0.1 or SR 3.0.4 for those Surveillances that do not have to be performed due to the associated inoperable equipment. However, SRs must be met to ensure OPERABILITY prior to declaring the associated equipment OPERABLE (or variable within limits) and restoring compliance with the affected LCO.

LCO 3.0.5

LCO 3.0.5 establishes the allowance for restoring equipment to service under administrative controls when it has been removed from service or declared inoperable to comply with ACTIONS. The sole purpose of this Specification is to provide an exception to LCO 3.0.2 (e.g., to not comply with the applicable Required Action(s) to allow the performance of SRs required testing to demonstrate:

- a. The OPERABILITY of the equipment being returned to service; or
- b. The OPERABILITY of other equipment.

The administrative controls ensure the time the equipment is returned to service in conflict with the requirements of the ACTIONS is limited to the time absolutely necessary to perform the allowed SRs - required testing to demonstrate OPERABILITY. This Specification does not provide time to perform any other preventive or corrective maintenance.

An example of demonstrating the OPERABILITY of the equipment being returned to service is reopening a containment isolation valve that has been closed to comply with Required Actions and must be reopened to perform the SRs - required testing.

An example of demonstrating the OPERABILITY of other equipment is taking an inoperable channel or trip system out of the tripped condition to prevent the trip function from occurring during the performance of an SR required testing on another channel in the other trip system. A similar example of demonstrating the OPERABILITY of other equipment is taking

(Continued)

BASES

LCO 3.0.5 (Continued) an inoperable channel or trip system out of the tripped condition to permit the logic to function and indicate the appropriate response during the performance of an SR ~~required testing~~ on another channel in the same trip system.

LCO 3.0.6 LCO 3.0.6 establishes an exception to LCO 3.0.2 for support systems that have an LCO specified in the Technical Specifications (TS). This exception is provided because LCO 3.0.2 would require that the Conditions and Required Actions of the associated inoperable supported system LCO be entered solely due to the inoperability of the support system. This exception is justified because the actions that are required to ensure the unit is maintained in a safe condition are specified in the support system LCO's Required Actions. These Required Actions may include entering the supported system's Conditions and Required Actions or may specify other Required Actions.

When a support system is inoperable and there is an LCO specified for it in the TS, the supported system(s) are required to be declared inoperable if determined to be inoperable as a result of the support system inoperability. However, it is not necessary to enter into the supported systems' Conditions and Required Actions unless directed to do so by the support system's Required Actions. The potential confusion and inconsistency of requirements related to the entry into multiple support and supported systems' LCOs' Conditions and Required Actions are eliminated by providing all the actions that are necessary to ensure the unit is maintained in a safe condition in the support system's Required Actions.

However, there are instances where a support system's Required Action may either direct a supported system to be declared inoperable or direct entry into Conditions and Required Actions for the supported system. This may occur immediately or after some specified delay to perform some other Required Action. Regardless of whether it is immediate or after some delay, when a support system's Required Action directs a supported system to be declared inoperable or directs entry into Conditions and Required Actions for a supported system, the applicable Conditions and Required Actions shall be entered in accordance with LCO 3.0.2

(Continued)

BASES

LCO 3.0.6 (Continued) Specification 5.5.15, "Safety Function Determination Program (SFDP)," ensures loss of safety function is detected and appropriate actions are taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other limitations, remedial actions, or compensatory actions may be identified as a result of the support system inoperability and corresponding exception to entering supported system Conditions and Required Actions. The SFDP implements the requirements of LCO 3.0.6.

Cross train checks to identify a loss of safety function for those support systems that support multiple and redundant safety systems are required. The cross train check verifies that the supported systems of the redundant OPERABLE support system are OPERABLE, thereby ensuring safety function is retained. If this evaluation determines that a loss of safety function exists, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

LCO 3.0.7 There are certain special tests and operations required to be performed at various times over the life of the unit. These special tests and operations are necessary to demonstrate select unit performance characteristics, to perform special maintenance activities, and to perform special evolutions. Test Exception LCOs ~~3.1.8, 3.1.10, and 3.1.11~~ and ~~3.4.19~~ allows specified Technical Specification (TS) requirements to be changed to permit performances of these special tests and operations, which otherwise could not be performed if required to comply with the requirements of these TS. Unless otherwise specified, all the other TS requirements remain unchanged. This will ensure all appropriate requirements of the MODE or other specified condition not directly associated with or required to be changed to perform the special test or operation will remain in effect.

The Applicability of a Test Exception LCO represents a condition not necessarily in compliance with the normal requirements of the TS. Compliance with Test Exception LCOs is optional. A special operation may be performed either under the provisions of the appropriate Test Exception LCO or under the other applicable TS requirements. If it is desired to perform the special operation under the provisions of the Test Exception LCO, the requirements of the Test Exception LCO shall be followed.

B 3.0 SURVEILLANCE REQUIREMENT (SR) APPLICABILITY

BASES

SRs SR 3.0.1 through SR 3.0.4 establish the general requirements applicable to all Specifications and apply at all times, unless otherwise stated.

SR 3.0.1 SR 3.0.1 establishes the requirement that SRs must be met during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply, unless otherwise specified in the individual SRs. This Specification is to ensure that Surveillances are performed to verify the OPERABILITY of systems and components, and that variables are within specified limits. Failure to meet a Surveillance within the specified Frequency, in accordance with SR 3.0.2, constitutes a failure to meet an LCO.

Systems and components are assumed to be OPERABLE when the associated SRs have been met. Nothing in this Specification, however, is to be construed as implying that systems or components are OPERABLE when:

- a. The systems or components are known to be inoperable, although still meeting the SRs; or
- b. The requirements of the Surveillance(s) are known not to be met between required Surveillance performances.

Surveillances do not have to be performed when the unit is in a MODE or other specified condition for which the requirements of the associated LCO are not applicable, unless otherwise specified. The SRs associated with a test exception are only applicable when the test exception is used as an allowable exception to the requirements of a Specification.

Unplanned events may satisfy the requirements for a given SR. In this case, the unplanned event may be credited as fulfilling the performance of the SR. This allowance includes those SRs whose performance is normally precluded in a given MODE or other specified condition.

Surveillances, including Surveillances invoked by Required Actions, do not have to be performed on inoperable equipment because the ACTIONS define the remedial measures that apply. Surveillances have to be met and performed in accordance with SR 3.0.2, prior to returning equipment to OPERABLE status

(Continued)

BASES

SR 3.0.1 (Continued) Upon completion of maintenance, appropriate post maintenance testing is required to declare equipment OPERABLE. This includes ensuring applicable Surveillances are not failed and their most recent performance is in accordance with SR 3.0.2. Post maintenance testing may not be possible in the current MODE or other specified conditions in the Applicability due to the necessary unit parameters not having been established. In these situations, the equipment may be considered OPERABLE provided testing has been satisfactorily completed to the extent possible and the equipment is not otherwise believed to be incapable of performing its function. This will allow operation to proceed to a MODE or other specified condition where other necessary post maintenance tests can be completed.

SR 3.0.2 SR 3.0.2 establishes the requirements for meeting the specified Frequency for Surveillances and any Required Action with a Completion Time that requires the periodic performance of the Required Action on a "once per . . ." interval.

SR 3.0.2 permits a 25% extension of the interval specified in the Frequency. This extension facilitates Surveillance scheduling and considers plant operating conditions that may not be suitable for conducting the Surveillance (e.g., transient conditions or other ongoing Surveillance or maintenance activities).

The 25% extension does not significantly degrade the reliability that results from performing the Surveillance at its specified Frequency. This is based on the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the SRs. The exceptions to SR 3.0.2 are those Surveillances for which the 25% extension of the interval specified in the Frequency does not apply. These exceptions are stated in the individual Specifications. An example of where SR 3.0.2 does not apply is ~~the Containment Leakage Rate Testing Program~~ a Surveillance with a Frequency of ~~"in accordance with 10 CFR 50, Appendix J, as modified by approved exemptions."~~ The requirements of regulations take precedence over the TS. ~~The TS cannot in and of themselves extend a test interval specified in the regulations.~~

(Continued)

BASES

SR 3.0.2 ~~Therefore, there is a Note in the Frequency stating, "SR 3.0.2 is not~~
(Continued) ~~applicable."~~

As stated in SR 3.0.2, the 25% extension also does not apply to the initial portion of a periodic Completion Time that requires performance on a "once per ..." basis. The 25% extension applies to each performance after the initial performance. The initial performance of the Required Action, whether it is a particular Surveillance or some other remedial action, is considered a single action with a single Completion Time. One reason for not allowing the 25% extension to this Completion Time is that such an action usually verifies that no loss of function has occurred by checking the status of redundant or diverse components or accomplishes the function of the inoperable equipment in an alternative manner.

The provisions of SR 3.0.2 are not intended to be used repeatedly merely as an operational convenience to extend Surveillance intervals (other than those consistent with refueling intervals) or periodic Completion Time intervals beyond those specified.

SR 3.0.3 SR 3.0.3 establishes the flexibility to defer declaring affected equipment inoperable or an affected variable outside the specified limits when a Surveillance has not been completed within the specified Frequency. A delay period of up to 24 hours or up to the limit of the specified Frequency, whichever is less, applies from the point in time that it is discovered that the Surveillance has not been performed in accordance with SR 3.0.2, and not at the time that the specified Frequency was not met.

This delay period provides adequate time to complete Surveillances that have been missed. This delay period permits the completion of a Surveillance before complying with Required Actions or other remedial measures that might preclude completion of the Surveillance.

The basis for this delay period includes consideration of unit conditions, adequate planning, availability of personnel, the time required to perform the Surveillance, the safety significance of the delay in completing

(Continued)

BASES

SR 3.0.3
(Continued)

the required Surveillance, and the recognition that the most probable result of any particular Surveillance being performed is the verification of conformance with the requirements. When a Surveillance with a Frequency based not on time intervals, but upon specified unit conditions or operational situations, is discovered not to have been performed when specified, SR 3.0.3 allows the full delay period of 24 hours to perform the Surveillance.

SR 3.0.3 also provides a time limit for completion of Surveillances that become applicable as a consequence of MODE changes imposed by Required Actions.

Failure to comply with specified Frequencies for SRs is expected to be an infrequent occurrence. Use of the delay period established by SR 3.0.3 is a flexibility which is not intended to be used as an operational convenience to extend Surveillance intervals.

If a Surveillance is not completed within the allowed delay period, then the equipment is considered inoperable or the variable is considered outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon expiration of the delay period. If a Surveillance is failed within the delay period, then the equipment is inoperable, or the variable is outside the specified limits and the Completion Times of the Required Actions for the applicable LCO Conditions begin immediately upon the failure of the Surveillance.

Completion of the Surveillance within the delay period allowed by this Specification, or within the Completion Time of the ACTIONS, restores compliance with SR 3.0.1.

SR 3.0.4

SR 3.0.4 establishes the requirement that all applicable SRs must be met before entry into a MODE or other specified condition in the Applicability.

This Specification ensures that system and component OPERABILITY requirements and variable limits are met before entry into MODES or other specified conditions in the Applicability for which these systems and components ensure safe operation of the unit.

The provisions of this Specification should not be interpreted as endorsing the failure to exercise the good practice of restoring systems or component to OPERABLE status before entering an associated MODE or other specified condition in the Applicability.

(Continued)

BASES

SR 3.0.4
(Continued)

However, in certain circumstances, failing to meet an SR will not result in SR 3.0.4 restricting a MODE change or other specified condition change. When a system, subsystem, division, component, device, or variable is inoperable or outside its specified limits, the associated SR(s) are not required to be performed, per SR 3.0.1, which states that surveillances do not have to be performed on inoperable equipment. When equipment is inoperable, SR 3.0.4 does not apply to the associated SR(s) since the requirement for the SR(s) to be performed is removed. Therefore, failing to perform the Surveillance(s) within the specified Frequency does not result in an SR 3.0.4 restriction to changing MODES or other specified conditions of the Applicability. However, since the LCO is not met in this instance, LCO 3.0.4 will govern any restrictions that may (or may not) apply to MODE or other specified condition changes.

The provisions of SR 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that are required to comply with ACTIONS. In addition, the provisions of LCO ~~SR~~ 3.0.4 shall not prevent changes in MODES or other specified conditions in the Applicability that result from any unit shutdown.

The precise requirements for performance of SRs are specified such that exceptions to SR 3.0.4 are not necessary. The specific time frames and conditions necessary for meeting the SRs are specified in the Frequency, in the Surveillance, or both. This allows performance of Surveillances when the prerequisite condition(s) specified in a Surveillance procedure require entry into the MODE or other specified condition in the Applicability of the associated LCO prior to the performance or completion of a Surveillance. A Surveillance that could not be performed until after entering the LCO Applicability, would have its Frequency specified such that it is not "due" until the specific conditions needed are met. Alternately, the Surveillance may be stated in the form of a Note as not required (to be met or performed) until a particular event, condition, or time has been reached. Further discussion of the specific formats of SRs' annotation is found in Section 1.4, Frequency.

SR 3.0.4 is only applicable when entering MODE 4 from MODE 5, MODE 3 from MODE 4, MODE 2 from MODE 3, or MODE 1 from MODE 2. Furthermore, SR 3.0.4 is applicable when entering any other specified condition in the Applicability only while operating in MODES 1, 2, 3, or 4

(Continued)

BASES

SR 3.0.4 (Continued) The requirements of SR 3.0.4 do not apply in MODES 5 and 6, or in other specified conditions of the Applicability (unless in MODES 1, 2, 3, or 4) because the ACTIONS of individual Specifications sufficiently define the remedial measures to be taken.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

Methodology For Mark-up of NUREG-1431 Bases

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

Descriptions of NUREG-1431 Differences

(1 Page)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.0

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE
NUMBER

JUSTIFICATION

- | | |
|--------|--|
| 3.0-01 | Industry Traveler TSTF-06, Rev.1, requests a PWR Generic (except CEOG) change to include LCO 3.0.7 as a specified exclusion to the Applicability of LCO 3.0.1. This exclusion is inherent in the discussion of LCO 3.0.7 and is added for consistency in TS interpretation. This change does not result in a technical change to application of the specifications. |
| 3.0-02 | Consistent with Traveler TSTF-12, Rev. 1, and TSTF-136, LCOs 3.1.9 and 3.1.11 are deleted and LCO 3.1.10 is relabeled to be LCO 3.1.8. The PHYSICS TESTS contained in LCO 3.1.9. were only contained in some initial plant startup testing programs. The PHYSICS TESTS can be deleted since these PHYSICS TESTS were never performed during past refueling outages. The PHYSIC TEST that LCO 3.1.11 required was the rod worth measurement in the N-1 Condition. The use of other Rod Worth Measurement techniques will maintain the SHUTDOWN MARGIN during the entire measurement process and still provide the necessary physics data verification. Since the N-1 measurement technique is no longer used, the SDM test exception can be deleted. ITS LCO 3.4.19 is not applicable because this test exception [is not in the DCPD CTS]. |
| 3.0-03 | This change provides consistency between LCO 3.0.4 and LCO 3.0.3 by moving the discussion of exceptions to LCO 3.0.4 to the Bases. This change is consistent with Industry Traveler TSTF-104. |
| 3.0-04 | This change provides consistency between LCO 3.0.6 and TS 5.5.15 and the Bases for LCO 3.0.6 to explicitly require SFDP evaluations. This change is consistent with Industry Traveler TSTF-166. |

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Methodology for Cross-Reference Tables
(Continued)

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).
Note:	The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note: . When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

3/4.1 REACTIVITY CONTROL SYSTEMS

3/4.1.1 BORATION CONTROL

SHUTDOWN MARGIN — ~~T_{avg}~~ GREATER THAN 200°F

02-01-A

LIMITING CONDITION FOR OPERATION

3.1.1.1 The SHUTDOWN MARGIN shall be greater than or equal to 1.6% $\Delta k/k$ within the limits provided in the COER.

01-01-LG

APPLICABILITY: MODES 1, 2*, 3, and 4, and 5

02-01-A

ACTION:

01-06-A

With the SHUTDOWN MARGIN less than 1.6% $\Delta k/k$, immediately not within limit within 15 minutes initiate and continue boration at greater than or equal to 30 gpm of a solution containing greater than or equal to 7,000 ppm boron or equivalent until the required to restore SHUTDOWN MARGIN is restored to within limit.

01-01-LG

01-07-LS16

01-03-LS1

SURVEILLANCE REQUIREMENTS

4.1.1.1.1 The SHUTDOWN MARGIN shall be determined to be greater than or equal to 1.6% $\Delta k/k$ within limits at least once per 24 hour:

01-01-LG

- a. Within 1 hour after detection of an inoperable control rod(s) and at least once per 12 hours thereafter while the rod(s) is inoperable. If the inoperable control rod is immovable or untrippable, the above required SHUTDOWN MARGIN shall be verified acceptable with an increased allowance for the withdrawn worth of the immovable or untrippable control rod(s);
- b. When in MODES 1 or 2 with K_{eff} greater than or equal to 1, at least once per 12 hours by verifying that control bank withdrawal is within the limits of Specification 3.1.3.6;
- c. When in MODE 2 with K_{eff} less than 1, within 4 hours prior to achieving reactor criticality by verifying that the predicted critical control rod position is within the limits of Specification 3.1.3.6;
- d. Prior to initial operation above 5% RATED THERMAL POWER after each fuel loading, by consideration of the factors of Specification 4.1.1.1.e., below, with the control banks at the maximum insertion limit of Specification 3.1.3.6; and

01-04-LS2

12-03-A

01-08-A

01-09-A

05-04-A

03-01-A

*See Special Test Exceptions Specification 3.10.1. With $K_{eff} \geq 1.0$

01-06-A

REACTIVITY CONTROL SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

e. When in MODES 2, 3 or 4, at least once per 24 hours by consideration of the following factors: 01-10-M

1) ~~Reactor Coolant System boron concentration.~~ 01-05-LG

2) ~~Control rod position.~~

3) ~~Reactor Coolant System average temperature.~~

4) ~~Fuel burnup based on gross thermal energy generation.~~

5) ~~Xenon concentration, and~~

6) ~~Samarium concentration.~~

4.1.1.1.2 The overall core reactivity balance shall be compared to predicted values to demonstrate agreement within $\pm 1\% \Delta k/k$ once prior to entering MODE 1 after each refueling and at least once per 31 Effective Full Power Days (EFPD) after burnup > 60 EFPD. This comparison shall consider at least those factors stated in Specification 4.1.1.1.1.e., above. The predicted reactivity values shall be adjusted (normalized) to correspond to the actual core conditions prior to exceeding a fuel burnup of 60 EFPD after each fuel loading. If the reactivity balance is not within limits within 72 hours, evaluate the Safety Analyses and establish appropriate operating restrictions and/or surveillance requirements or be in at least MODE 3 within the next 6 hours. 05-01-M
05-03-LG
05-02-LS7
05-05-LS17

~~_____~~ 01-10-M

~~With $k_{eff} > 1.0$~~

REACTIVITY CONTROL SYSTEMS

SHUTDOWN MARGIN — T_{avg} LESS THAN OR EQUAL TO 200°F

02-01-A

LIMITING CONDITION FOR OPERATION

3.1.1.2 The SHUTDOWN MARGIN shall be greater than or equal to 1% $\Delta k/k$ within the limits provided in the COLR.

01-01-LG

APPLICABILITY: MODE 5.

02-01-A

ACTION:

With the SHUTDOWN MARGIN less than 1% $\Delta k/k$, immediately not within limit, within 15 minutes initiate and continue boration at greater than or equal to 30 gpm of a solution containing greater than or equal to 7,000 ppm boron or equivalent until the required SHUTDOWN MARGIN is restored to within limit.

01-01-LG

01-07-LS16

01-03-LS1

SURVEILLANCE REQUIREMENTS

4.1.1.2 The SHUTDOWN MARGIN shall be determined to be greater than or equal to 1% $\Delta k/k$ within limits at least once per 24 hours:

01-01-LG

- a. Within 1 hour after detection of an inoperable control rod(s) and at least once per 12 hours thereafter while the rod(s) is inoperable. If the inoperable control rod is immovable or untrippable, the SHUTDOWN MARGIN shall be verified acceptable with an increased allowance for the withdrawn worth of the immovable or untrippable control rod(s); and

01-04-LS2

12-03-A

- b. At least once per 24 hours by consideration of the following factors:

- 1) Reactor Coolant System boron concentration,
- 2) Control rod position,
- 3) Reactor Coolant System average temperature,
- 4) Fuel burnup based on gross thermal energy generation,
- 5) Xenon concentration, and
- 6) Samarium concentration.

01-05-LG

REACTIVITY CONTROL SYSTEMS

MODERATOR TEMPERATURE COEFFICIENT

LIMITING CONDITION FOR OPERATION

3.1.1.3 The moderator temperature coefficient (MTC) shall be ~~within the limits specified in the COLR:~~ 03-07-LG

- a. ~~The maximum upper limit shall be less positive than $+5 \times 10^{-5} \Delta k/k/^\circ F$ for 0% to 70% RATED THERMAL POWER, and for $\geq 70\%$ to 100% RATED THERMAL POWER the MTC decreases linearly to $0 \Delta k/k/^\circ F$ for the all rods withdrawn condition, beginning of cycle life (BOL); or~~
- b. ~~Less negative than $-3.9 \times 10^{-4} \Delta k/k/^\circ F$ specified in the COLR for all rods withdrawn, end of cycle life (EOL), RATED THERMAL POWER condition.~~ 03-07-LG

APPLICABILITY: Specification 3.1.1.3a. - MODES 1 and 2* only#. 03-01-A
Specification 3.1.1.3b. - MODES 1, 2, and 3 only#.

ACTION:

- a. With the MTC more positive than the limit of Specification 3.1.1.3a. above, operation in MODES 1 and 2 may proceed provided:
 - 1. Control rod withdrawal limits are established and maintained sufficient to restore the MTC to less positive than the limit of Specification 3.1.1.3a within 24 hours or be in ~~HOT STANDBY MODE 2 with $K_{eff} < 1.0$~~ in the next 6 hours. These withdrawal limits shall be in addition to the insertion limits of Specification 3.1.3.6; 03-02-LS3
03-03-A
 - 2. ~~The control rods are maintained within the withdrawal limits established above until a subsequent calculation verifies that the MTC has been restored to within its limit for the all rods withdrawn condition; and~~ 03-04-LG
 - 3. ~~A Special Report is prepared and submitted to the Commission pursuant to Specification 6.9.2 within 10 days describing the value of the measured MTC, the interim control rod withdrawal limits and the predicted average core burnup necessary for restoring the positive MTC to within its limit for the all rods withdrawn condition.~~ 03-05-TR2
- b. With the MTC more negative than the limit of Specification 3.1.1.3b. above, be in HOT SHUTDOWN within 12 hours.
- c. The provisions of Specification 3.0.4 are not applicable.

*With K_{eff} greater than or equal to 1.
#See ~~Special Test Exceptions Specification 3.10.3.~~

03-01-A

REACTIVITY CONTROL SYSTEMS

SURVEILLANCE REQUIREMENTS

4.1.1.3 The MTC shall be determined to be within its limits during each fuel cycle as follows:

- a. The MTC shall be measured and compared to the BOL limit of Specification 3.1.1.3a., above, prior to initial operation above 5% of RATED THERMAL POWER, after each fuel loading; and
- b. The MTC shall be measured at any THERMAL POWER and compared to $-3 \times 10^{-4} \Delta k/k/^\circ F$ (all rods withdrawn, RATED THERMAL POWER condition) within 7 EFPD after reaching an equilibrium boron concentration of 300 ppm. In the event this comparison indicates the MTC is more negative than $-3 \times 10^{-4} \Delta k/k/^\circ F$, the MTC shall be remeasured, and compared to the EOL MTC limit of Specification 3.1.1.3b., at least once per 14 EFPD during the remainder of the fuel cycle.

(new) SR 4.1.1.3b need not be repeated if the MTC measured at the equivalent of equilibrium RTP-ARO boron concentration of 60 ppm is less negative than the 60 ppm surveillance limit specified of the COLR

03-06-LS4

REACTIVITY CONTROL SYSTEMS

MINIMUM TEMPERATURE FOR CRITICALITY

04-03-A

LIMITING CONDITION FOR OPERATION

3.1.1.4 The Reactor Coolant System lowest operating loop temperature (T_{avg}) shall be greater than or equal to 541°F.

APPLICABILITY: MODES 1 and 2#*.

03-01-A

ACTION:

With a Reactor Coolant System operating loop temperature (T_{avg}) less than 541°F, restore T_{avg} to within its limit within 15 minutes or be in HOT STANDBY within the next 15 minutes ~~be in MODE 2 with $k_{eff} < 1.0$ within 30 minutes.~~

04-01-LS5

SURVEILLANCE REQUIREMENTS

4.1.1.4 The Reactor Coolant System temperature (T_{avg}) shall be determined to be greater than or equal to 541°F: ~~every 12 hours~~

- a. ~~Within 15 minutes prior to achieving reactor criticality, and~~
- b. ~~At least once per 30 minutes when the reactor is critical and the Reactor Coolant System T_{avg} is less than 551°F, with the $T_{avg} - T_{set}$ Deviation Alarm not reset.~~

04-02-LS6

#With K_{eff} greater than or equal to 1.

*See ~~Special Test Exceptions Specification 3.10.3.~~

03-01-A

LIMITING CONDITION FOR OPERATION

3.1.1.5 The measured core reactivity shall be within $\pm 1\%$ $\Delta k/k$ of predicted values.

APPLICABILITY: MODES 1 and 2.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. Measured core reactivity not within limit.	A.1 Re-evaluate core design and safety analysis, and determine that the reactor core is acceptable for continued operation.	72 hours <u>05-05-LS17</u>
	<u>AND</u> A.2 Establish appropriate operating restrictions and SRs.	72 hours
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>(new) -----NOTE----- The predicted reactivity values shall be adjusted (normalized) to correspond to the measured core reactivity prior to exceeding a fuel burnup of 60 effective full power days (EFPD) after each fuel loading. ----- Verify measured core reactivity is within $\pm 1\% \Delta k/k$ of predicted values.</p>	<p><u>01-06-A</u></p> <p><u>05-03-LG</u></p> <p><u>05-04-A</u></p> <p><u>05-01-M</u></p> <p><u>05-02-LS7</u></p> <p>Once prior to entering MODE 1 after each refueling</p> <p><u>AND</u></p> <p>-----NOTE----- Only required after 60 EFPD ----- 31 EFPD thereafter</p>

REACTIVITY CONTROL SYSTEMS

3/4.1.2 BORATION SYSTEMS

FLOW PATH SHUTDOWN

06-01-R

LIMITING CONDITION FOR OPERATION

~~3.1.2.1 As a minimum, one of the following boron injection flow paths shall be OPERABLE with motor operated valves required to change position and pumps required to operate for boron injection capable of being powered from an OPERABLE emergency power source:~~

- ~~a. A flow path from the boric acid tanks via a boric acid transfer pump and charging pump to the Reactor Coolant System if the boric acid storage tank in Specification 3.1.2.5a. is OPERABLE, or~~
- ~~b. The flow path from the refueling water storage tank via a charging pump to the Reactor Coolant System if the refueling water storage tank in Specification 3.1.2.5b. is OPERABLE.~~

~~APPLICABILITY: MODES 5 and 6.~~

ACTION:

~~With none of the above flow paths OPERABLE or capable of being powered from an OPERABLE emergency power source, suspend all operations involving CORE ALTERATIONS or positive reactivity changes.~~

SURVEILLANCE REQUIREMENTS

~~4.1.2.1 At least one of the above required flow paths shall be demonstrated OPERABLE:~~

- ~~a. At least once per 7 days by verifying that the temperature of the flow path is greater than or equal to 65°F when a flow path from the boric acid tanks is used, and~~
- ~~b. At least once per 31 days by verifying that each valve (manual, power operated or automatic) in the flow path that is not locked, sealed or otherwise secured in position, is in its correct position.~~

REACTIVITY CONTROL SYSTEMS

FLOW PATHS OPERATING

07-01-R

LIMITING CONDITION FOR OPERATION

~~3.1.2.2 Each of the following boron injection flow paths shall be OPERABLE:-~~

- ~~a. The flow path from the boric acid tanks via a boric acid transfer pump and a charging pump to the Reactor Coolant System (RCS), and~~
- ~~b. The flow path from the refueling water storage tank via a charging pump to the RCS.~~

~~APPLICABILITY: MODES 1, 2, 3 and 4#.~~

ACTION:-

- ~~a. With the flow path from the boric acid tanks inoperable, restore the inoperable flow path to OPERABLE status within 72 hours or be in at least HOT STANDBY and borated to a SHUTDOWN MARGIN equivalent to at least 1% $\Delta k/k$ at 200°F within the next 6 hours; restore the flow path to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.~~
- ~~b. With the flow path from the refueling water storage tank inoperable, restore the flow path to OPERABLE status within 1 hour or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.~~

SURVEILLANCE REQUIREMENTS

~~4.1.2.2 Each of the above required flow paths shall be demonstrated OPERABLE:-~~

- ~~a. At least once per 7 days by verifying that the temperature of the flow path from the boric acid tanks is greater than or equal to 65°F.~~
- ~~b. At least once per 31 days by verifying that each valve (manual, power operated or automatic) in the flow path that is not locked, sealed or otherwise secured in position, is in its correct position.~~
- ~~c. At least once per 18 months by verifying that each automatic valve in the flow path actuates to its correct position on a safety injection test signal, and~~
- ~~d. At least once per 18 months by verifying that the flow path required by Specification 3.1.2.2a delivers at least 30 gpm to the RCS.~~

~~#Only one boron injection flow path is required to be OPERABLE whenever the temperature of one or more of the RCS cold legs is less than or equal to 270°F.~~

~~THIS PAGE WAS INTENTIONALLY LEFT BLANK~~

REACTIVITY CONTROL SYSTEMS

CHARGING PUMP SHUTDOWN

08-01-R

LIMITING CONDITION FOR OPERATION

~~3.1.2.3 At least one charging pump in the boron injection flow path required by Specification 3.1.2.1 shall be OPERABLE and capable of being powered from an OPERABLE emergency power source.~~

~~APPLICABILITY: MODES 5 and 6.~~

ACTION:

~~With no charging pump OPERABLE or capable of being powered from an OPERABLE emergency power source, suspend all operations involving CORE ALTERATIONS or positive reactivity changes.~~

SURVEILLANCE REQUIREMENTS

~~4.1.2.3.1 At least the above required charging pump shall be demonstrated OPERABLE when tested pursuant to Specification 4.0.5. In addition, when the above required charging pump is a centrifugal charging pump, verify that, on recirculation flow, the centrifugal charging pump develops a differential pressure of greater than or equal to 2400 psid.~~

~~4.1.2.3.2 All centrifugal charging pumps, excluding the above required OPERABLE pump, shall be demonstrated inoperable* at least once per 12 hours, except when the reactor vessel head is removed, by verifying that the motor breaker D.C. control power is de-energized.~~

~~*An inoperable pump may be made OPERABLE for testing per Specification 4.0.5 provided the discharge of the pump has been isolated from the Reactor Coolant System by an isolation valve with power removed from the valve operator, or by a sealed closed manual isolation valve.~~

REACTIVITY CONTROL SYSTEMS

CHARGING PUMPS OPERATING

09-01-R

LIMITING CONDITION FOR OPERATION

~~3.1.2.4 At least two charging pumps shall be OPERABLE.~~

~~APPLICABILITY: MODES 1, 2, 3 and 4#.~~

ACTION:

~~With only one charging pump OPERABLE, restore at least two charging pumps to OPERABLE status within 72 hours or be in at least HOT STANDBY and borated to a SHUTDOWN MARGIN equivalent to at least 1% $\Delta k/k$ at 200°F within the next 6 hours; restore at least two charging pumps to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.~~

SURVEILLANCE REQUIREMENTS

~~4.1.2.4.1 At least two charging pumps shall be demonstrated OPERABLE when tested pursuant to Specification 4.0.5. In addition, when the above required charging pumps include a centrifugal charging pump(s), verify that, on recirculation flow, each required centrifugal charging pump(s) develops a differential pressure of greater than or equal to 2400 psid.~~

~~4.1.2.4.2 All centrifugal charging pumps, except the above required OPERABLE pump, shall be demonstrated inoperable* at least once per 12 hours whenever the temperature of one or more of the Reactor Coolant System (RCS) cold legs is less than or equal to 270°F by verifying that the motor breaker D.C. control power is de-energized.~~

~~#A maximum of one centrifugal charging pump shall be OPERABLE whenever the temperature of one or more of the RCS cold legs is less than or equal to 270°F.~~

~~*An inoperable pump may be made OPERABLE for testing per Specification 4.0.5 provided the discharge of the pump has been isolated from the Reactor Coolant System by an isolation valve with power removed from the valve operator, or by a sealed closed manual isolation valve.~~

REACTIVITY CONTROL SYSTEMS

BORATED WATER SOURCE SHUTDOWN

10-01-R

LIMITING CONDITION FOR OPERATION

~~3.1.2.5 As a minimum, one of the following borated water sources shall be OPERABLE:~~

- ~~a. A Boric Acid Storage System with:
 - ~~1) A minimum contained borated water volume of 2,499 gallons,~~
 - ~~2) A boron concentration between 7,000 and 7,700 ppm, and~~
 - ~~3) A minimum solution temperature of 65°F.~~~~
- ~~b. The Refueling Water Storage Tank (RWST) with:
 - ~~1) A minimum contained borated water volume of 50,000 gallons,~~
 - ~~2) A minimum boron concentration of 2300 ppm, and~~
 - ~~3) A minimum solution temperature of 35°F.~~~~

~~APPLICABILITY: MODES 5 and 6.~~

ACTION:

~~With no borated water source OPERABLE, suspend all operations involving CORE ALTERATIONS or positive reactivity changes.~~

SURVEILLANCE REQUIREMENTS

~~4.1.2.5 The above required borated water source shall be demonstrated OPERABLE:~~

- ~~a. At least once per 7 days by:
 - ~~1) Verifying the boron concentration of the water,~~
 - ~~2) Verifying the contained borated water volume, and~~
 - ~~3) Verifying the boric acid storage tank solution temperature when it is the source of borated water.~~~~
- ~~b. At least once per 24 hours by verifying the RWST temperature when it is the source of borated water and the outside ambient air temperature is less than 35°F.~~

LIMITING CONDITION FOR OPERATION

~~3.1.2.6 The following borated water source shall be OPERABLE:~~

- ~~a. A Boric Acid Storage System with:~~
 - ~~1) A minimum contained borated water volume of 14,042 gallons,~~
 - ~~2) A boron concentration between 7,000 and 7,700 ppm, and~~
 - ~~3) A minimum solution temperature of 65°F.~~

~~APPLICABILITY: MODES 1, 2, 3 and 4.~~

ACTION:

- ~~a. With the Boric Acid Storage System inoperable, restore the system to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and borated to a SHUTDOWN MARGIN equivalent to at least 1% Δk/k at 200°F; restore the Boric Acid Storage System to OPERABLE status within the next 7 days or be in COLD SHUTDOWN within the next 30 hours.~~

SURVEILLANCE REQUIREMENTS

~~4.1.2.6 The borated water source shall be demonstrated OPERABLE:~~

~~a. At least once per 7 days by:~~

~~1) Verifying the boron concentration in the water,~~

~~2) Verifying the contained borated water volume of the water source,
and~~

~~3) Verifying the Boric Acid Storage System solution temperature.~~

REACTIVITY CONTROL SYSTEMS

3/4.1.3 MOVABLE CONTROL ASSEMBLIES

GROUP HEIGHT

LIMITING CONDITION FOR OPERATION

3.1.3.1 All full length shutdown and control rods shall be OPERABLE and positioned within ± 12 steps (indicated position) of their group demand position.

12-01-A

APPLICABILITY: MODES 1* and 2*.

03-01-A

ACTION:

a. With one or more full length rods inoperable due to being immovable as a result of excessive friction or mechanical interference or known to be untrippable inoperable, determine that the SHUTDOWN MARGIN requirement of Specification 3.1.1.1 is satisfied is within the limits in the COLR or initiate boration to restore the SHUTDOWN MARGIN within limits within 1 hour and be in HOT STANDBY within 6 hours.

12-01-A

12-14-M

01-01-LG

12-06-A

b. With one full length rod trippable but inoperable due to causes other than addressed by ACTION a. above, or misaligned from its group demand height by more than ± 12 steps (indicated position), POWER OPERATION may continue provided that within 1 hour:

12-01-A

12-17-A

1. The rod is restored to OPERABLE status within the above alignment requirements, or

12-04-A

2. The rod is declared inoperable and the remainder of the rods in the group with the inoperable misaligned rod are aligned to within ± 12 steps of the inoperable misaligned rod or while maintaining the rod sequence and insertion limits of Specification 3.1.3.6. The THERMAL POWER level shall be restricted pursuant to Specification 3.1.3.6 during subsequent operation, or

12-18-LG

3. The rod is declared inoperable and the SHUTDOWN MARGIN requirement of Specification 3.1.1.1 is satisfied is verified to be within the limits provided in the COLR or initiate boration to restore the SHUTDOWN MARGIN within limits. POWER OPERATION may then continue provided that:

12-04-A

01-01-LG

12-06-A

a) A reevaluation of each accident analysis of Table 3.1.1 is performed within 5 days; this reevaluation shall confirm that the previously analyzed results of these accidents remain valid for the duration of operation under these conditions; and

12-07-A

b) THE SHUTDOWN MARGIN requirement of Specification 3.1.1.1 is determined is verified to be within limits at least once per 12 hours;

01-01-LG

*See Special Test Exceptions Specifications 3.10.2 and 3.10.3.

REACTIVITY CONTROL SYSTEMS

LIMITING CONDITION FOR OPERATION

ACTION (Continued)

- c) A power distribution map is obtained from the movable incore detectors and $F_0(Z)$ and F_{th} are verified to be within their limits within 72 hours; and
- d) The THERMAL POWER level is reduced to less than or equal to 75% of RATED THERMAL POWER within the next hour and within the following 4 hours the High Neutron Flux Trip Setpoint is reduced to less than or equal to 85% of RATED THERMAL POWER or be in HOT STANDBY within 6 hours 12-08-LS9
12-22-M
- c. With more than one rod trippable but inoperable due to causes other than addressed by ACTION a above, POWER OPERATION may continue provided that: 12-12-LS13
 - 1. Within 1 hour, the remainder of the rods in the bank(s) with the inoperable rods are aligned to within ± 12 steps of the inoperable rods while maintaining the rod sequence and insertion limits of Specification 3.1.3.6. The THERMAL POWER level shall be restricted pursuant to Specification 3.1.3.6 during subsequent operation, and
 - 2. The inoperable rods are restored to OPERABLE status within 72 hours.
- d. With more than one rod misaligned from its group demand position by more than $+ 12$ steps (indicated position), determine that the SHUTDOWN MARGIN is within the COLR or initiate boration to restore the SHUTDOWN MARGIN within limits within one hour, and be in HOT STANDBY within 6 hours. 01-01-LG
12-02-M

SURVEILLANCE REQUIREMENTS

- 4.1.3.1.1 The position of each full length rod shall be determined to be within the group demand limit by verifying the individual rod positions at least once per 12 hours except during time intervals when the Rod Position Deviation Monitor is inoperable, then verify the group positions at least once per 4 hours. 12-01-A
12-16-LG
- 4.1.3.1.2 Each full length rod not fully inserted in the core shall be determined to be OPERABLE by movement of at least 10 steps in any one direction at least once per 92 days. 12-01-A
- 4.1.3.1.3 The rod drop time of rods shall be demonstrated less than or equal to 2.7 seconds from beginning of decay of the stationary gripper coil voltage to dash pot entry with t_{rod} greater than or equal to 500 °F and all reactor coolant pumps operating, prior to criticality after each reactor head removal. 12-10-LS10

REACTIVITY CONTROL SYSTEMS

POSITION INDICATION SYSTEMS - OPERATING

LIMITING CONDITION FOR OPERATION

3.1.3.2 The Digital Rod Position Indication System and the Demand Position Indication System shall be OPERABLE and capable of determining the control rod positions within ± 12 steps.

13-01-LG

APPLICABILITY: MODES 1* and 2*.

13-08-LS20

ACTION:

- a. With a maximum of one digital rod position indicator per bank group inoperable for one or more groups either:
- 13-02-LS15
- Determine the position of the nonindicating rod(s) indirectly by the movable incore detectors at least once per 8 hours and immediately within 4 hours after any motion of the nonindicating rod which exceeds 24 steps in one direction since the last determination of the rod's position, or

13-03-LS12

 - Reduce THERMAL POWER to less than 50% of RATED THERMAL POWER within 8 hours or be in Hot Standby within the next 6 hours.

13-04-M
- b. With more than one digital rod position indicator per group inoperable either:
- a) Determine the position of the nonindicating rods indirectly by the movable incore detectors at least once per 8 hours and within 4 hours after any motion of the nonindicating rod which exceeds 24 steps in one direction since the last determination of the rod's position, and

13-08-LS20

 - b) Restore the digital rod position indicators to OPERABLE status within 24 hours such that a maximum of one digital rod position indicator per group is inoperable, or

13-08-LS20

 - Be in HOT STANDBY within the next 6 hours.

13-08-LS20
- b c. With a maximum of one demand position indicator per bank inoperable either:
- Verify that all digital rod position indicators for the affected bank are OPERABLE and that the most withdrawn rod and the least withdrawn rod of the bank are within a maximum of 12 steps of each other at least once per 8 hours, or
 - Reduce THERMAL POWER to less than 50% of RATED THERMAL POWER within 8 hours or be in Hot Standby within the next 6 hours.

13-04-M

SURVEILLANCE REQUIREMENTS

4.1.3.2 Each digital rod position indicator shall be determined to be OPERABLE by verifying that the Demand Position Indication System and the Digital Rod Position Indication System agree within 12 steps at least once per 12 hours except during time intervals when the rod position deviation monitor is inoperable, then compare the Demand Position Indication System and the Digital Rod Position Indication System at least once per 4 hours when exercised over the full range of rod travel once prior to criticality after each removal of the reactor head.

13-07-M

12-16-LG

* Separate condition entry is allowed for each inoperable rod position indicator and each demand position indicator per bank.

13-08-LS20

14-01-R

LIMITING CONDITION FOR OPERATION

~~3.1.3.3 One digital rod position indicator (excluding demand position indication) shall be OPERABLE and capable of determining the control rod position within \pm 12 steps for each shutdown or control rod not fully inserted.~~

~~APPLICABILITY: MODES 3*#, 4*# and 5*#.~~

ACTION:

~~With less than the above required position indicator(s) OPERABLE, immediately open the Reactor Trip System breakers.~~

SURVEILLANCE REQUIREMENTS

~~4.1.3.3 Each of the above required digital rod position indicator(s) shall be determined to be OPERABLE by verifying that the digital rod position indicators agree with the demand position indicators within 12 steps when exercised over the full range of rod travel at least once per 18 months prior to criticality after each removal of the reactor head.~~

13-07-M

~~*With the Reactor Trip System breakers in the closed position.
#See Special Test Exceptions Specification 3.10.4~~

14-01-R
03-01-A

REACTIVITY CONTROL SYSTEMS

ROD DROP TIME

15-01-R

LIMITING CONDITION FOR OPERATION

3.1.3.4 The individual full-length shutdown and control rod drop time from the fully withdrawn position shall be less than or equal to 2.7 seconds from beginning of decay of stationary gripper coil voltage to dashpot entry with:

- a. Tavg greater than or equal to 541 ~~500~~°F, and
- b. All reactor coolant pumps operating.

12-10-LS10

APPLICABILITY: ~~MODES 1 and 2.~~

ACTION:

12-01-A

With the drop time of any full-length rod determined to exceed the above limit, restore the rod drop time to within the above limit prior to proceeding to ~~MODE 1 or 2 reactor criticality.~~

12-20-A

SURVEILLANCE REQUIREMENTS

12-01-A

4.1.3.4 The rod drop time of ~~full-length rods~~ shall be demonstrated through measurement prior to reactor criticality:

- a. For all rods following each removal of the reactor vessel head. 15-02-A
- b. ~~For specifically affected individual rods following any maintenance on or modification to the Control Rod Drive System which could affect the drop time of those specific rods, and~~ 12-11-TR3
- c. ~~At least once per 18 months.~~

REACTIVITY CONTROL SYSTEMS

SHUTDOWN ROD INSERTION LIMIT

LIMITING CONDITION FOR OPERATION

3.1.3.5 All ~~Each~~ shutdown rods bank shall be limited in physical insertion as specified in the CORE OPERATING LIMITS REPORT (COLR).

16-01-LS14

APPLICABILITY: MODES 1* and 2*#.

ACTION:

With a ~~maximum of one or more~~ shutdown rod banks inserted beyond the insertion limit specified in the COLR, ~~except for surveillance testing pursuant to Specification 4.1.3.1.2, within 1 hour either:~~

16-01-LS14

a. ~~Within 2 hours Restore the rod to Shutdown Banks within the insertion limits specified in the COLR, or and~~

16-02-M

b. ~~Declare the rod to be inoperable and apply Specification 3.1.3.1. Within 1 hour verify SHUTDOWN MARGIN to be within the limits provided in the COLR, or initiate boration to restore SHUTDOWN MARGIN to within limits, or~~

16-06-A

01-01-LG

c. ~~Be in Hot Standby within 6 hours~~

16-05-M

SURVEILLANCE REQUIREMENTS

4.1.3.5 Each shutdown rod bank shall be determined to be within the insertion limits specified in the COLR ~~at least once per 12 hours~~

16-01-LS14

a. ~~Within 15 minutes prior to withdrawal of any rods in Control Banks A, B, C or D during an approach to reactor criticality, and~~

16-03-LS22

b. ~~At least once per 12 hours thereafter.~~

* ~~See Special Test Exceptions Specifications 3.10.2 and 3.10.3 Not applicable while performing SR 4.1.3.1.2.~~

03-01-A

~~With Keff greater than or equal to 1 With any Control Bank not fully inserted.~~

16-04-M

REACTIVITY CONTROL SYSTEMS

CONTROL ROD INSERTION LIMITS

LIMITING CONDITION FOR OPERATION

3.1.3.6 The control banks shall be limited in physical insertion sequence and over lap limits as specified in the CORE OPERATING LIMITS REPORT (COLR).

17-01-M

APPLICABILITY: MODES 1* and 2*# except for surveillance testing pursuant to Specification 4.1.3.1.2.

03-01-A

ACTION:

With the control banks inserted beyond the insertion limits, except for surveillance testing pursuant to Specification 4.1.3.1.2 or not within sequence and over lap:

17-01-M

- a. Within 1 hour, verify that the SHUTDOWN MARGIN is within the limits provided in the COLR or initiate boration until the SHUTDOWN MARGIN is restored to within limits.
- b. Restore the control banks to within the limits within 2 hours, or
- c. Reduce THERMAL POWER within 2 hours to less than or equal to that fraction of RATED THERMAL POWER which is allowed by the group position using the insertion limits specified in the COLR, or
- d. Be in at least HOT STANDBY within next 6 hours.

17-02-M

17-03-LS21

SURVEILLANCE REQUIREMENTS

4.1.3.6.1 The position of each control bank shall be determined to be within the insertion limits at least once per 12 hours except during time intervals when the rod insertion limit monitor is inoperable, then verify the individual rod positions at least once per 4 hours.

12-16-LG

4.1.3.6.2 When in MODE 2, with K_{eff} less than 1, verify that the predicted critical Control Rod position is within insertion limits within 4 hours prior to achieving reactor criticality.

01-09-A

4.1.3.6.3 Verify sequence and over lap limits specified in the COLR are met for Control Banks not fully withdrawn from the core at least once per 12 hours.

17-01-M

*See Special Test Exceptions Specifications 3.10.2 and 3.10.3.
#With K_{eff} greater than or equal to 1.

03-01-A

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. Deletions - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. Additions - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. Modifications - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. Administrative - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

Methodology For Mark-Up of Current TS
(Continued)

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	LG	In accordance with TSTF-9, Rev. 1, this change would move the specified limit for SHUTDOWN MARGIN (SDM) from Technical Specification (TS) to the CORE OPERATING LIMITS REPORT (COLR). This change occurs in several specifications including the specifications for SDM and those specifications with ACTIONS that require verifying SDM within limits. SDM is a cycle-specific parameter that is calculated based on an NRC approved methodology. Moving the SDM to the COLR will provide core design and operational flexibility that can be used for improved fuel management.
01-02	M	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-03	LS1	The ACTION statement would be modified to reflect that the requirement to initiate boration at a specified rate with fluid at a specified boron concentration is generalized to simply require boration. As described in the ITS Bases, the required flow rate and boron concentration should be selected depending on plant conditions and available equipment. The ITS Bases allow the operator to use the "best source available for the plant conditions." This is an example of maintaining the overall safety requirement in the TS, but removing procedural details from the TS allowing the plant operator the ability to select the appropriate procedure and equipment for the existing plant condition.
01-04	LS2	<p>The existing Surveillance Requirements (SRs) require SDM to be verified within 1 hour in the event of detecting inoperable control rods. Since the SRs apply to inoperable (untripable) rods, they should only be applicable in MODES 1 and 2 []. The control rods are used to maintain SDM in MODES 1 and 2 by maintaining the rods within insertion limits. The requirements for rod alignment limits in CTS specify ACTIONS to be taken upon detecting an inoperable rod(s). The ACTIONS include verifying SDM within 1 hour. Deletion of the CTS surveillance(s) to verify SDM when a rod(s) is inoperable in the shutdown in MODES [3 through 5] accomplishes the following:</p> <ol style="list-style-type: none">1) Deletes an inappropriate Applicability (i.e., the surveillance(s) should not apply in those MODES when the rods are not required to be OPERABLE); and,2) Deletes redundant requirements (i.e., the requirements are properly and fully addressed in the specifications related to rod alignment/OPERABILITY and insertion limits).

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-05	LG	The list of specific items to be considered in the performance of an SDM verification would be deleted. These items are listed in the ITS Bases. This change is of the type that removes unnecessary procedural details from the specifications while leaving the overall safety requirement intact.
01-06	A	This change revises the SDM limiting condition of operation (LCO) Applicability to MODE 2 with $k_{eff} < 1.0$, MODE 3, and MODE 4. This change also creates a new core reactivity LCO based on ITS 3.1.3. This is consistent with NUREG-1431.
01-07	LS16	The term "immediately" is changed to "15 minutes" which is more specific. The term "immediately" simply specifies a prompt ACTION. The term "completion time of 15 minutes" is meant to clearly state a completed ACTION. The requirements of this ACTION are met only if boron is already being injected at 15 minutes. This time period provides adequate time for the operator to align and start the required systems. This is consistent with NUREG-1431.
01-08	A	The technical contents of this SR (verification of SDM through compliance with rod insertion limits) in MODE 1 and MODE 2 with $k_{eff} \geq 1.0$ have been incorporated into LCO 3.1.6 of the ITS.
01-09	A	The SR for verification of the estimated critical Condition during the approach to criticality is moved to ITS SR 3.1.6.1.
01-10	M	CTS SR 4.1.1.1.1.e is modified by this change to be applicable to MODE 2 with $k_{eff} < 1.0$ as well as current MODES 3 and 4. This is consistent with NUREG-1431.
02-01	A	In the conversion process, this LCO will be combined with the SDM LCO applicable for $T_{avg} > 200^\circ\text{F}$, in accordance with Traveler TSTF-136. Traveler TSTF-9, Rev. 1, relocated values for SDM to the COLR which removed the only difference between ITS LCO 3.1.1 and ITS LCO 3.1.2. Differences above and below 200°F will be addressed in the COLR.
03-01	A	The footnote referring to CTS special test exceptions would be deleted. This is acceptable because the requirements for special test exceptions are provided in separate LCOs. Therefore, a separate reference in the footnote is redundant.
03-02	LS3	ACTION Statement A.1 would be revised to require achieving MODE 2 with $k_{eff} < 1.0$ instead of achieving HOT STANDBY if the beginning of life (BOL) moderator temperature coefficient (MTC) limit is exceeded and revised rod withdrawal limits cannot be established. This change corrects a discrepancy between the BOL Applicability and the ACTION, while ensuring that the plant is taken to a Condition in which the LCO is not applicable. Revising the CTS, even to correct an inconsistency, represents a relaxation in ACTION Statement A.1.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
03-03	A	The statement that administrative withdrawal limits required to meet ACTION Statement a.1 are in addition to insertion limits of another specification would be removed. This change is an administrative change because the statement is redundant to the requirements of CTS 3.1.3.6 and, therefore, can be deleted.
03-04	LG	The requirement of CTS ACTION Statement a.2, which provides the details of how to verify that MTC has been restored to within limits (i.e., calculation) for the all rods withdrawn Condition prior to exiting ACTION Statement a.1, is addressed in the ITS 3.1.3 Bases.
03-05	TR2	The requirement to submit a special report to the NRC would be deleted. This deletion is consistent with NUREG-1431.
03-06	LS4	This change would incorporate a note from ITS 3.1.3, allowing suspension of MTC testing near the end of the cycle when further significant changes to the MTC would not occur and result in exceeding the end of life (EOL) limit. This represents a relaxation in performing the SR.
03-07	LG	This change will relocate the negative EOL moderator temperature limit to the COLR. This is consistent with NUREG-1431.
04-01	LS5	This proposed change would make two changes to the ACTION statement. First, it would alter the ACTION statement shutdown requirement time limit from a combination of 15 minutes to restore T_{avg} to within limits followed by 15 minutes to be in MODE 3, if T_{avg} could not be restored to a single 30 minute limit to exit the Applicability if T_{avg} were not within its limit. Second, the ACTION statement would be revised to require achieving MODE 2 with $k_{eff} < 1.0$ instead of achieving HOT STANDBY if the LCO were not met (refer to TSTF-26). Regarding the first change, both the CTS requirement and the ITS requirement are essentially equivalent in that the plant is now required to shutdown and exit the Applicability of the specification within 30 minutes after discovering that a parameter is not within its limits if the parameter is not restored to within its limits in that 30 minute time period. If the LCO can be satisfied at any time during the 30 minute time frame, the plant shutdown can be terminated. Regarding the second change, it represents a relaxation in current ACTION statement requirements for plant shutdown, consistent with exiting the LCO's Applicability.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1

(Continued)

CHANGE NUMBER

NSHC

DESCRIPTION

04-02

LS6

The proposed change would revise the conditional SR for verifying that reactor coolant system (RCS) temperature (T_{avg}) is within limits by changing the frequency to once per 12 hours in accordance with TSTF-27, Rev. 2. The original frequency requirements were within 15 minutes prior to achieving reactor criticality and at least once per 30 minutes when the reactor is critical and the ($T_{avg} - T_{ret}$) deviation alarm is not reset. The RCS temperature is maintained within limit: (1) to assure that the MTC is within the limits assured in the accident analysis, (2) to assure that the neutron detectors are not adversely affected by attenuation caused by low RCS temperature, (3) to assure that the RCS and pressurizer response to thermal hydraulic transients is as predicted, and (4) to assure that the reactor vessel temperature is above the nil-ductility transition reference temperature.

The plant design incorporates monitoring of T_{avg} and provides an alarm, the ($T_{avg} - T_{ret}$) deviation alarm, as T_{avg} approaches its limit. This alarm Condition requires a response by the operating staff. Therefore, at any time that T_{avg} is approaching its limiting value, the plant operators would receive an alarm and initiate corrective ACTION.

04-03

A

The LCO for Minimum Temperature For Criticality, CTS 3/4.1.1.4, is moved to ITS 3.4.2 in the RCS section. This is consistent with NUREG-1431.

05-01

M

The CTS SR that requires a comparison of measured reactivity with predicted would be modified to add the requirement for performance prior to entry into MODE 1 after refueling outages. This is a new requirement from the ITS that is not in CTS. The CTS Bases indicate that the comparison should be made at RATED THERMAL POWER (RTP) after startup from a refueling outage.

05-02

LS7

This proposed change would specify that the overall core reactivity balance comparison shall be done every 31 effective full power days (EFPD) after burnup exceeds 60 EFPD. This clarifies when the 31 EFPD surveillance should start. The current SR specifies a frequency of 31 EFPD. The delay in initiating the monthly surveillance is acceptable because of the slow rate of changes in the core due to fuel depletion and the presence of other indicators for prompt determination of an anomaly. As noted in the Bases for Specification 3.1.2, the reactivity balance comparison must be done within the first 60 EFPDs after each fuel loading. This allows sufficient time for core conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations.

05-03

LG

The list of specific items to be considered in the performance of a reactivity balance verification is moved to the Bases for ITS 3.1.2. This change is of the type that moves unnecessary details from the specifications while leaving the overall safety requirement intact. See also CN 01-05-LG.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1

(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
05-04	A	CTS SR requires a SDM verification prior to operation above 5 percent power after each refueling with the control rod banks at maximum insertion limits. SDM in MODES 1 and 2 is determined by shutdown and control rods maintained at their insertion limits. The relevant requirements regarding the adequacy of the SDM with rods at their insertion limits is determined through compliance with ITS 3.1.2, which requires a reactivity balance prior to entering MODE 1 after each refueling; and ITS SR 3.1.6.1, which requires a verification of control bank position within insertion limits within 4 hours prior to criticality. Therefore, the requirements of this SR would be performed by other specifications in the ITS. []
05-05	LS17	ACTIONS to be taken should the reactivity balance not be within limits are provided, in lieu of a TS 3.0.3 shutdown. This is consistent with NUREG-1431.
05-06	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
06-01	R	The CTS 3.1.2.1, "Boration Flow Path Shutdown," and associated SR 4.1.2.1 are relocated outside of the TS. This is consistent with NUREG-1431.
07-01	R	The CTS 3.1.2.2, "Boration Flow Path Operating," and associated SR 4.1.2.2 are relocated outside of the TS. This is consistent with NUREG-1431.
07-02	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
08-01	R	The CTS 3.1.2.3, "Charging Pump Shutdown," and associated SRs 4.1.2.3.1 and 4.1.2.3.2 are relocated outside of the TS. This is consistent with NUREG-1431.
08-02	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
08-03	LS19	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
09-01	R	The CTS 3.1.2.4, "Charging Pump Operating," and associated SRs 4.1.2.4.1 and 4.1.2.4.2 are relocated outside of the TS. This is consistent with NUREG-1431.
10-01	R	The CTS 3.1.2.5, "Borated Water Source Shutdown," and associated CTS SR 4.1.2.5 are relocated outside of the TS. This is consistent with NUREG-1431.
11-01	R	The CTS 3.1.2.6, "Borated Water Source Operating," and associated CTS SR 4.1.2.6 are relocated outside of the TS. This is consistent with NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
12-01	A	The term "full-length" has been deleted. The plant design does not include full- and part-length control rods. Also, the LCO defines the indicated position limits that must be maintained.
12-02	M	Consistent with NUREG-1431, the ACTIONS required for more than one misaligned, but operable rod would be changed to be identical to those for inoperable rod(s). The current ACTION b. requires achieving HOT STANDBY within 6 hours. The ITS ACTIONS would require SDM verification and restoration as well as achieving HOT STANDBY within 6 hours. Therefore, adopting the ITS requirement would add additional restrictions to assure safe plant operation.
12-03	A	The requirement to include an increased allowance in the SDM calculation for the untrippable rod is addressed by the definition of SDM. The ITS 3.1.4 Bases for ACTION A.1.1 and A.1.2 note that the effect of this rod must be considered as well as the worth of the most reactive rod that is neglected as a safety analysis assumption.
12-04	A	Consistent with NUREG-1431, rods must be OPERABLE and properly positioned. A misaligned rod is not necessarily inoperable. Modifying the ACTION for a misaligned rod to remove the notion that it is also, by definition, inoperable is consistent with the ITS approach.
12-05		Not Used.
12-06	A	The proposed deletion of the requirement to declare the misaligned rod "inoperable" and the addition of requirements to either verify SDM or initiate boration for a misaligned [or inoperable] rod are consistent with NUREG-1431. In practice, if compliance with the SDM were not verified, boration would be immediately initiated. Because the time typically required to recover the SDM is short, the SDM would typically be determined to be within its limit within the required time frame. Therefore, the additional note to either verify SDM or initiate boration is an administrative change.
12-07	A	Table 3.1-1, "Accident Analyses Reevaluation in the Event of an Inoperable [Full-Length] Rod," would be deleted and replaced with a more general requirement to evaluate accidents to assure the results remain valid. This is acceptable because the general requirement is sufficient to assure that the affected accident analyses will be considered and the ITS Bases discuss the accident analyses affected by rod misalignment.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
12-08	LS9	Consistent with NUREG-1431, the requirement to reduce the high neutron flux set point to ≤ 85 percent of RTP would be deleted. This is acceptable because the underlying safety limits are not of a nature that requires immediate shutdown of the plant if they are exceeded. This is evidenced by the allowance of 72 hours to verify peaking factors. It is assumed that during this 72-hour period an event will not occur which will raise the power level and cause a high neutron flux trip at 100 percent RTP. If a power excursion would occur from the 75 percent RTP ACTION statement limit, the initial peaking factors would not be critical to the analysis, since the analysis is based on the peaking factors at 100 percent RTP. Therefore, the risk of a reactor trip caused by adjusting the power range trip set points is not justified by the potential consequences of failing to reduce the trip set points.
12-09	M	Not applicable to DCCP. See Conversion Comparison Table. (Enclosure 3B)
12-10	LS10	The requirement to maintain RCS $T_{avg} \geq 541^{\circ}\text{F}$ during rod drop testing would be revised to maintain $T_{avg} \geq 500^{\circ}\text{F}$. NUREG-1431, allows the tests to be performed at temperatures as low as 500°F . Because the RCS coolant is more dense at lower temperatures, the rod drop time would be greater at the lower temperatures than at the higher temperatures. In addition, the RCS is borated such that the SDM remains within its limits at the Conditions existing during these tests. Nevertheless, this change, which allows more flexibility of plant conditions for conducting rod drop testing, is a relaxation in plant operations in the CTS.
12-11	TR3	It is proposed to move the requirement to perform rod drop testing on individual rods following maintenance that could affect the drop time to licensee controlled documents [and to delete the 18 month requirement]. The requirement to perform drop time testing following each removal of the reactor vessel head would not be modified. The proposed change is justified, because in addition to being consistent with NUREG-1431, Rev. 1, good maintenance practices would require a retest following any maintenance on a rod or its drive system that could affect drop time. Furthermore, it is difficult to postulate any maintenance on a rod that could affect its drop time without requiring the reactor vessel head to be removed in the process. The components of the rod and rod drive system that affect drop time (as defined in TS) are all inside the reactor coolant pressure boundary. Therefore, moving this requirement outside the TS would have essentially no impact on rod OPERABILITY. [Measuring rod drop time following each removal of the reactor vessel head is considered equivalent if not more restrictive than an 18 month frequency requirement; therefore, deleting the 18 month requirement where it exists (not all plants have it in the CTS) is an administrative change.]

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
12-12	LS13	CTS [3.1.3.1] ACTIONS are revised to delete reference to causes of control rod inoperability due to rod control urgent failure or other electrical problems in the rod control system.
12-13		Not used.
12-14	M	This wording is broadened from "untrippable" to "inoperable" to ensure all causes of inoperability are covered. The previous wording covered inoperable rods if they were untrippable (e.g., "immovable as a result of excessive friction or mechanical interference...") but did not cover trippable rods with drop times that exceed the surveillance limit. These slow rods are inoperable. This more restrictive change clarifies the appropriate ACTIONS to be taken for all causes of inoperability, consistent with Traveler TSTF-107.
12-15	A	Not applicable to DCPD. See Comparison Table (Enclosure 3B).
12-16	LG	Several surveillances (e.g., rod position deviation monitor and rod insertion limit monitor in this section) contain ACTIONS in the form of increased surveillance frequency to be performed in the event of inoperable alarms. These ACTIONS are moved from the CTS to license controlled documents since the alarm does not, in itself, directly relate to the limits. This detail is not required to be in the TS. Therefore, moving this detail is acceptable and is consistent with Traveler TSTF-110, Rev. 1.
12-17	A	Editorial changes are made for clarity. Untrippable rods are addressed through ACTION A; hence, there is no additional need to exclude those rods from these required ACTIONS.
12-18	LG	The technical contents of the ACTION statement which allow continued power operation with a misaligned rod are incorporated into LCO 3.1.4, ACTION B.1 Bases, of the ITS.
12-19	LS18	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
12-20	A	The ACTION statement in the CTS to restore the rod drop time to within limits as a Condition for MODE 2 is captured in the frequency for the performance of ITS SR 3.1.4.3.
12-21		Not used.
12-22	M	This change, in accordance with NUREG-1431, provides a new ACTION in the event the allowed outage times are not met for the rod misalignment action. Prior to this change, LCO 3.0.3 would have been entered allowing for 1 hour prior to placing the plant in HOT STANDBY within the next 6 hours. This change is more restrictive in that the 1 hour time frame is eliminated.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1

(Continued)

**CHANGE
NUMBER**

NSHC

DESCRIPTION

13-01	LG	Consistent with NUREG-1431, the OPERABILITY attributes of equipment and components are described in the Bases. The proposed elimination of the accuracy attributes of the DRPI system and demand position indication system from the specification on position indicating systems would have no impact on OPERABILITY of these systems because the design of these systems is fixed. Furthermore, ITS LCO 3.1.4 requires that all individual indicated rod positions be within 12 steps of their group step counter demand position. Therefore, the LCO effectively establishes the accuracy requirements for the rod position indicating system, and eliminating it from the specification for indicating systems would have no effect on the OPERABILITY of the indicating systems.
13-02	LS15	The requirement for inoperable DRPI is changed from "with a maximum of one per bank" to "one per group for one or more groups." This change is consistent with NUREG-1431. However, the change from "bank" to "group" could potentially result in additional rods with inoperable DRPI because the plant has more groups of rods than banks. Entry into this condition for more than one rod per bank is acceptable because the required ACTIONS, if applied to each non indicating rod, provide appropriate compensatory actions. Position verification of the nonindicating rod within each group within 8 hours is adequate to allow continued full power operation since this frequent monitoring ensures that the probability of having a rod significantly out of position and the simultaneous occurrence of an event sensitive to rod position is small.
13-03	LS12	Consistent with NUREG-1431, a 4 hour completion time is specified to verify rod position after movement of a rod with inoperable indicators more than 24 steps in one direction. This is justified in the ITS Bases as an acceptable Completion Time to perform the verification of rod position using the movable incore detectors. The CTS requirement to perform the verification "immediately" is intended to reflect a quick starting time. A completion time of 4 hours also would assure a prompt start time as stated in the ITS Bases; however, since a flux map can be obtained in less than 4 hours, the change could represent a relaxation in start time.
13-04	M	The ITS specify that the plant be brought to MODE 3 within 6 hours if the Required ACTION and Completion Times are not met. The current specifications do not specify an ACTION if the ACTIONS are not met within the required completion time. The ITS Bases state that 6 hours is a reasonable time, based on operating experience, for reaching MODE 3 from full power conditions without challenging plant systems. The CTS would require entry into TS 3.0.3 which would require achieving MODE 3 within 7 hours. Therefore, the plant shutdown to MODE 3 requirement would be required in 1 less hour.
13-05	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
13-06	A	Not applicable to DCPP. See Conversion Comparison Table. (Enclosure 3B)
13-07	M	The proposed modifications to the SR would require a verification of agreement between digital and demand indicator systems prior to criticality after each removal of the reactor vessel head, instead of every 12 hours. This reflects a reorganization of SRs in the ITS. The requirement for a 12 hour comparison would be moved to SR 3.1.4.1 in the ITS. The post-vessel head removal requirement would be a new specification that demonstrates rod position system OPERABILITY based on a comparison of indicating systems throughout the full range of rod travel. The Frequency requirement of prior to criticality after each removal of the reactor vessel head would permit this comparison to be performed only during plant outages that involve plant evolutions (vessel head removal) that could affect the OPERABILITY of the rod position indication systems. The Frequency change is based on Traveler TSTF-89.
13-08	LS20	Adds provision from Callaway's current specifications which would, under certain conditions, allow continued operation with more than one inoperable DRPI per group. A separate Condition entry allowance is permitted for each inoperable rod position indicator per group and each demand position indicator per bank. A proposed Traveler Westinghouse Owners Group (WOG) - 73, Rev. 1 is in processing to cover this issue.
13-09	LS23	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
14-01	R	The Shutdown Position Indication System Specification 3.1.3.3 is relocated outside of the TS. This is consistent with NUREG-1431.
15-01	R	The Rod Drop Time Specification 3.1.3.4 is relocated outside of the TS. The RCS temperature limit and reactor coolant pumps operating requirement for rod drop testing are combined with CTS Surveillance 4.1.3.4, then incorporated into ITS SR 3.1.4.3. This is consistent with NUREG-1431.
15-02	A	The Rod Drop Time SR 4.1.3.4.a is moved to the Control Rod ITS LCO 3.1.4 as SR 3.1.4.3. This change is consistent with NUREG-1431.
16-01	LS14	This TS would be revised to apply to shutdown "banks" instead of shutdown "rods;" this is consistent with NUREG-1431. The current ACTION statement permits one rod to be inserted beyond the limits; the proposed ITS Condition A would allow one or more banks to be inserted beyond the limit.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
16-02	M	The proposed changes to the ACTION statement would require that the shutdown banks be aligned within limits and that SDM be verified or restored. The new ACTION statement would extend the time to achieve alignment from 1 to 2 hours as justified in the Bases for ITS 3.1.5. The new ACTION statement would establish a Completion Time of 1 hour for verifying and restoring SDM. In the proposed ACTION statement, both the realignment and the SDM verification would be required. The current ACTION statement provides a 1 hour limit to achieve realignment and effectively applies a 2 hour Completion Time to SDM verification and restoration (which would be performed under the TS for rod group alignment limits). In the CTS, either the realignment or the SDM verification are required. The CTS could, in some circumstance, allow continued POWER OPERATION with a shutdown rod out of alignment because it was written to apply to individual rods and refers to the rod group alignment specification. The new ACTION statement, which applies to shutdown banks, would not permit operation with a shutdown bank outside its insertion limits. Overall, the proposed requirements are more restrictive.
16-03	LS22	The CTS SR requiring shutdown rod insertion limits to be verified within 15 minutes prior to withdrawing control rods during approaches to criticality would be deleted. This requirement essentially has been incorporated into LCO 3.1.5 Applicability, which would require that the shutdown banks meet the LCO when in MODE 2 with any control bank not fully inserted. The requirement to perform this check prior to entering the LCO Applicability is covered in plant procedures for startups which require the operator to closely monitor rod position.
16-04	M	Consistent with NUREG-1431, the Applicability would be modified to include MODE 2 with any control bank not fully inserted rather than MODE 2 with $k_{eff} \geq 1.0$. This is more restrictive than the current Applicability.
16-05	M	This change, in accordance with NUREG-1431, provides a new ACTION in the event the AOT are not met for the restoration of the shutdown banks to their insertion limit and the verification that the SDM is within its COLR limit or restored to its limit. Prior to this change, LCO 3.0.3 would have been entered allowing 1 hour prior to placing the plant in HOT STANDBY within the next 6 hours. This change is more restrictive in that the 1 hour time frame is eliminated.
16-06	A	Consistent with NUREG-1431, this change eliminates an unnecessary reference to a separate LCO (see also CN 16-02-M). This change adds the ACTIONS contained in another specification. Rather than reference the other specification, the relevant requirements would simply be inserted into this specification. Therefore, there are no technical differences introduced by this change.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.1
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
17-01	M	The proposed modification would add "sequence and overlap" as well as insertion limits to the LCO. These changes do not add any new requirements; as sequence, overlap, and insertion limits are currently specified in the COLR figure defining rod insertion limits vs RATED THERMAL POWER for that portion of the LCO Applicability where these limits provide safety analysis inputs (at or above hot zero power, i.e., \geq 0% RTP. [The COLR will be revised to address the entire CTS LCO 3.1.3.6 Applicability]. The proposed modification would include addition of an SR to periodically verify the overlap and sequence limits that were specifically added per ITS.
17-02	M	This proposed change adds a requirement, that if the bank insertion limits are exceeded, to verify that the SDM is within limits, or initiate boration to restore the SDM to within limits.
17-03	LS21	This change adds an additional 2 hours to the AOT to be in MODE 3. This is consistent with NUREG-1431.
17-04	LS8	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.1

TECH SPECH CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-01 LG	In accordance with TSTF-9, Rev 1 this change would move the specified limit for SDM from TS to the COLR.	Yes	No, already in CTS.	Yes	Yes
01-02 M	MODE 2 with $K_{eff} < 1.0$ would be added to Applicability of the SDM specification.	No, different CTS	No, different CTS.	Yes	Yes
01-03 LS1	The ACTION statement would be modified to reflect that the requirement to initiate boration at a specified rate with fluid at a specified boron concentration is generalized to simply require boration.	Yes	Yes	Yes	Yes
01-04 LS2	The requirement of SR to verify SDM within 1 hour of detecting an inoperable rod and once per 12 hours thereafter would be deleted from the SDM LCO.	Yes	Yes	Yes	Yes
01-05 LG	The list of specific items to be considered in the performance of a SDM verification is moved to the ITS 3.1.1 Bases.	Yes	Yes	Yes	Yes
01-06 A	This change revises the SDM LCO Applicability to MODE 2 with $K_{eff} < 1.0$, MODE 3, and MODE 4. This change also creates a new core reactivity LCO based on ITS 3.1.2.	Yes	Yes	No, see CN 1-02-M and CTS.	No, see CN 1-02-M and CTS.
01-07 LS16	Changes the time required for the initiation of boration from "immediately" to "within 15 minutes."	Yes	Yes	No, already in CTS.	No, already in CTS.
01-08 A	The technical contents of this SR (verification of SDM through compliance with rod insertion limits) in MODE 1 and MODE 2 with $K_{eff} \geq 1.0$ have been incorporated into LCO 3.1.6 of the ITS.	Yes	Yes	No, see Amendment 89.	No, see Amendment 103.
01-09 A	Moves requirement to verify estimated critical rod position prior to criticality to ITS SR 3.1.6.1.	Yes	Yes	No, see Amendment 89.	No, see Amendment 103.
01-10 M	CTS SR 4.1.1.1.e is modified by this change to be applicable to MODE 2 with $k_{eff} < 1.0$ as well as the current MODES 3 and 4. This is consistent with NUREG 1431. See also CN 01-06-A.	Yes	Yes	No, see Amendment 89.	No, see Amendment 103.

TECH SPECH CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-01 A	This LCO will be combined with the SDM - $T_{avg} > 200^{\circ}\text{F}$ LCO, in accordance with Traveler TSTF-136.	Yes	Yes	Yes	Yes
03-01 A	The footnote referring to CTS special test exceptions would be deleted.	Yes	Yes	Yes	Yes
03-02 LS3	ACTION Statement A.1 of TS for MTC would be revised to require achieving MODE 2 with $k_{eff} < 1.0$ instead of achieving HOT STANDBY if the BOL MTC limit is exceeded and revised rod withdrawal limits cannot be established.	Yes	Yes	Yes	Yes
03-03 A	The statement that administrative withdrawal limits required to meet ACTION Statement A.1 are in addition to insertion limits of another specification would be removed. This is an example of a redundant requirement to meet another TS.	Yes	Yes	Yes	Yes
03-04 LG	ACTION Statement A.2 is addressed prior to exiting ACTION Statement A.1, as discussed in the ITS 3.1.3 Bases.	Yes	Yes	Yes	Yes
03-05 TR2	The requirement to submit a special report to the NRC would be deleted.	Yes	Yes	Yes	Yes
03-06 LS4	This change would incorporate the provisions of ITS 3.1.3 for suspension of MTC testing near the end of the cycle when further significant changes to the MTC would not occur and result in exceeding the EOL limit.	Yes	Yes	Yes	Yes
03-07 LG	The negative EOL moderator temperature limit is moved to the COLR.	Yes	No, already moved to the COLR.	No, already moved to the COLR.	No, already moved to the COLR.

TECH SPECH CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
04-01 LS5	This change would alter the ACTION statement shutdown requirement time limit from a combination of 15 minutes to restore T_{avg} to within limits followed by 15 minutes to be in MODE 3, if T_{avg} could not be restored, to a single 30 minute limit to exit the Applicability if T_{avg} were not within its limit. In addition, the ACTION statement would be changed to require achieving MODE 2 with $k_{eff} < 1.0$ instead of achieving HOT STANDBY if the LCO is not met (refer to TSTF-26).	Yes	Yes	Yes	Yes
04-02 LS6	The SR interval to measure RCS loop average temperature is revised to 12 hours in accordance with industry Traveler TSTF-27, Rev 2.	Yes	Yes	Yes	Yes
04-03 A	The LCO for Minimum Temperature for Criticality, CTS 3.1.1.4, is moved to ITS 3.4.2 in the RCS Section.	Yes	Yes	Yes	Yes
05-01 M	The SR that requires a comparison of measured reactivity to predicted would be modified to add the requirement to compare core reactivity against the predicted prior to entry into MODE 1 after refueling outages.	Yes	Yes	Yes	Yes
05-02 LS7	This proposed change would specify that the overall core reactivity balance comparison shall be done every 31 EFPD after burnup exceeds 60 EFPD.	Yes	Yes	Yes	Yes
05-03 LG	The list of specific items to be considered in the performance of a reactivity balance verification is moved to the ITS 3.1.2 Bases.	Yes	Yes	Yes	Yes
05-04 A	The SR requiring SDM to be verified prior to initial operation in MODE 1 after each refueling is effectively performed under other specifications. This SR required a SDM verification prior to operation above 5 percent power after each refueling with the control rod banks at maximum insertion limits and is being deleted since it is redundant.	Yes	Yes	Yes	Yes

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3..." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R" (Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1

10CFR50.92 EVALUATION
FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The ACTION statement would be modified to reflect that the requirement to initiate boration at a specified rate with fluid at a specified boron concentration is generalized to simply require boration. As described in the ITS Bases, the required flow rate and boron concentration should be selected depending on plant conditions, available equipment, and the magnitude of the deviation between the actual and required SDM. The ITS Bases allow the operator to use the "best source available for the plant conditions." This is an example of maintaining the overall safety requirement in TS but removing procedural details from the TS allowing the plant operator the ability to select the appropriate procedure and equipment for the existing plant condition.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The ACTION statement that would be modified requires that SDM be restored if not within limits by boration at a specific flow rate with a specific concentration of boron. The proposed change would eliminate details regarding flow rates and concentrations from the TS; however the overall requirement to restore SDM would remain. Removal of the details of system operation would not affect the probability of an accident occurring. For consequences of an accident to be affected, an accident that is impacted by SDM would have to occur during the short 1 or 2 hour time period that SDM is not within limit. The probability of that occurrence is negligible because of the short duration expected to return SDM to within limits. Therefore, there would be no significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes may affect the timing of SDM restoration depending on the equipment selected by the operator to perform the boration. The change involves no hardware modifications or changes in the manner in which plant systems perform their functions. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

There will be no reduction in any margin of safety. The SDM limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_Q , F_{2H}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS1" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A surveillance in the SDM specification requires SDM to be verified in the event of detecting an inoperable rod. Since it applies to inoperable (untrippable) rods, it should only be applicable in MODES 1 and 2 []. The rods are used to maintain SDM in MODES 1 and 2 by maintaining the rods within insertion limits. The requirements for rod alignment limits in CTS specify ACTIONS to be taken upon detecting an inoperable rod. The ACTIONS include verifying SDM within 1 hour. Deletion of the CTS surveillances to verify SDM when a rod(s) is inoperable in the shutdown MODES [3 through 5] accomplishes the following:

- 1) Deletes an inappropriate Applicability statement. The surveillance should not apply in those MODES when the rods are not required to be OPERABLE and,
- 2) Deletes redundant requirements. The requirements are properly and fully addressed in the specifications related to rod alignment OPERABILITY and insertion limits.

If a rod is declared inoperable after shutting down to MODE 3 (or other shutdown modes), the TS definition of SDM requires the inoperable rod to be accounted for in the SDM calculation per ITS SR 3.1.1.1. If a rod were to become inoperable during rod testing in the shutdown modes, there would be no adverse effects on safety because the definition of SDM accounts for a rod failure prior to performing the tests.

Implicit in ITS LCO 3.1.1 and SR 3.1.1.1 is the need to reperform the SDM calculation if any of these effects have changed since the last 24 hour calculation.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Elimination of the SRs would have no effect on the probability of an accident. The requirements for maintaining SDM with an untrippable rod and during rod testing assure that there would be no effect on the consequences of any accidents for which SDM is a factor. Therefore, there would be no increase in the probability or consequences of a previously evaluated accident as a result of eliminating the SR.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The SR being eliminated by this change requires periodic checks of SDM. Eliminating these checks would not affect the manner of operation of the plant or any plant systems so that the occurrence of a new kind of accident could result. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

As noted in the introductory paragraphs above, the TS definition of SDM requires the inoperable rod to be accounted for in SDM calculations. Further, SDM accounts for rod movement during testing, so an untrippable rod during testing would not have an adverse impact on SDM. As long as the SDM limits continue to be met as required, no reduction in a margin of safety could result. Based on the previous discussion, the plant conditions required for rod testing and by other specifications assure the SDM requirements would be met. The SDM limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_{Q, F_{dH}^N} , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS2" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

ACTION Statement A.1 would be revised to require achieving MODE 2 with $k_{\text{eff}} < 1.0$ instead of achieving HOT STANDBY if the BOL MTC limit is exceeded and revised rod withdrawal limits cannot be established within 24 hours. This change corrects the discrepancy between the BOL Applicability and the ACTION, while ensuring that the plant is taken to a condition in which the LCO is not applicable. Revising the CTS, albeit to correct an inconsistency, represents a relaxation in ACTION Statement A.1.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The ACTION of taking the reactor to MODE 2 with $k_{\text{eff}} < 1.0$ instead of MODE 3 would have no effect on the probability of any accident occurring. MTC is an initial Condition assumed in accident analyses, and therefore if an accident were to occur while the MTC was outside the limits, the consequences of an accident could be exacerbated. However, placing the reactor in MODE 2 with $k_{\text{eff}} < 1.0$ assures that the consequences would be bounded by safety analyses should an accident occur. Therefore, there would be no increase in the probability or consequences of a previously evaluated accident as a result of making the proposed change.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change would not create the possibility of a new or different accident, because the plant or its systems would not be operated differently. The original requirement was to achieve MODE 3, HOT STANDBY. To achieve MODE 3, it is necessary to pass through MODE 2 with $k_{\text{eff}} < 1.0$. Therefore, there are no physical alterations to any plant equipment, and cause no changes in the methods by which any safety system performs its function. There are no changes to the operation of the plant or equipment. Therefore, this change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The margins of safety in question are those in the design basis accident analyses (DBA) that rely on MTC as an initial Condition. As noted in the evaluation of Criterion 1 above, placing the plant in MODE 2 with $k_{eff} < 1.0$ assures that the accidents will not violate the assumptions of the analyses. The MTC limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_Q, F_{DH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS3" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change would incorporate the provisions of ITS 3.1.3 allowing suspension of MTC testing near the end of the cycle when further significant changes to the MTC would not occur and result in exceeding the EOL limit. This represents a relaxation in performing the SR.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The change would allow the suspension of surveillance testing for the lower bound MTC limit near the end of reactor core life. In order to implement this change, additional analysis must be performed to define a surveillance MTC value below which the actual MTC would not fall as the core neared its end-of-cycle (EOC) condition. The MTC value, which becomes a limit established in the COLR, is conservatively selected to assure, that if met the MTC would not exceed the EOC limiting value. It is possible to establish a surveillance limit because of the gradual manner in which MTC changes near the end of core life. MTC is an initial condition assumed in accident analyses. Changes in the manner in which MTC is monitored would not affect the probability of an accident. Also, the consequences of accidents that depend on MTC as an initial Condition would not be increased if MTC were maintained within limit. The suspension of surveillance for MTC near the end of core life would be based on a conservative analysis of MTC behavior and operating experience regarding the slow manner in which MTC varies over time near the end of core life. The suspension of surveillance would occur at a time when there is negligible chance that the lower MTC limit value would be exceeded. Therefore, the proposed change in MTC surveillance would involve no increase in either the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes deal with the frequency of monitoring a parameter (MTC) that is an initial condition of accident analyses. The limits on MTC would not be changed. Changes in SR frequency would not lead to changes in plant or plant system operations or other conditions that could cause an accident of a new or different type. Thus, the proposed change does not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

As noted in the evaluation of Criterion 1 above, the proposed changes would not include any changes in the limits for MTC; therefore, the margins of safety afforded by MTC limits would not be affected. The surveillance limit used to define the suspension of MTC monitoring would be selected using conservative analyses and knowledge of the manner in which MTC varies over core life. Therefore, there is little chance that core MTC values could exceed the EOC limit. The MTC limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_{α} , $F_{\Delta H}^N$, LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed change associated with NSHC "LS4" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed change would make two changes to the ACTION statement. First, it would alter the ACTION statement shutdown requirement time limit from a combination of 15 minutes to restore T_{avg} to within limits followed by 15 minutes to be in MODE 3, if T_{avg} could not be restored, to a single 30 minute limit to be in MODE 3 if T_{avg} were not within its limit. Second, the ACTION statement would be revised to require achieving MODE 2 with $k_{eff} < 1.0$ instead of achieving HOT STANDBY if the LCO is not met (refer to TSTF-26). Regarding the first change, both the current requirement and the ITS requirement are essentially equivalent in that the plant is now required to be in MODE 3 within 30 minutes after discovering that a parameter is not within its limits, if the parameter is not restored to within its limits in that 30 minute time period. If the LCO can be satisfied at any time during the 30 minute time frame, the plant shutdown can be terminated. Regarding the second change, it represents a relaxation in current ACTION statement requirements for plant shutdown and is the subject of this evaluation.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The ACTION of taking the reactor to MODE 2 with $k_{eff} < 1.0$ instead of MODE 3 would have no effect on the probability of any accident occurring. T_{avg} is an initial condition assumed in accident analyses, and therefore if an accident were to occur while the T_{avg} was outside the limits, the consequences of an accident could be exacerbated. However, placing the reactor in MODE 2 with $k_{eff} < 1.0$ assures that the consequences would be bounded by safety analyses should an accident occur. Therefore, there would be no increase in the probability or consequences of a previously evaluated accident as a result of making the proposed change.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change would not create the possibility of a new or different accident because the plant or its systems would not be operated any differently. The original requirement was to achieve MODE 3, HOT STANDBY. To achieve MODE 3, it is necessary to pass through MODE 2 with $k_{eff} < 1.0$. Therefore, there would be no operational changes to contribute to the possibility of a new accident resulting from the proposed change. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The margins of safety in question are those in the DBA analyses that rely on T_{avg} as an initial Condition. As noted in the evaluation of Criterion 1 above, placing the plant in MODE 2 with $K_{eff} < 1.0$ assures that the accidents will not violate the assumptions of the analyses. The minimum T_{avg} for criticality is not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_Q, F_{dH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS5" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed change would revise the SR for verifying that RCS temperature (T_{avg}) is within limits by changing the frequency to once per 12 hours in accordance with TSTF-27, Rev. 2. The current frequency requirements were within 15 minutes prior to achieving reactor criticality, which is redundant and unnecessary since T_{avg} must be within its limit prior to entering the LCO Applicability, and at least once per 30 minutes when the reactor is critical and the ($T_{avg}-T_{ref}$) deviation alarm is not reset. The RCS temperature is maintained within limit: (1) to assure that the MTC is within the limits assumed in the accident analyses, (2) to assure that the neutron detectors are not adversely affected by neutron attenuation caused by low coolant temperature, (3) to assure that the RCS and pressurizer response to thermal-hydraulic transients is as predicted, and (4) to assure that the reactor vessel temperature is above the nil-ductility transition reference temperature.

The plant design incorporates monitoring of T_{avg} and provides an alarm, the ($T_{avg}-T_{ref}$) deviation alarm, as T_{avg} approaches its limit. This alarm Condition requires a response by the operating staff. Therefore, at any time that T_{avg} is approaching its limiting value, the plant operators would receive an alarm and initiate corrective ACTION.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The CTS requires that the RCS average temperature is required to be verified within 15 minutes prior to reactor criticality. No additional verification is required during reactor criticality unless the ($T_{avg}-T_{ref}$) deviation alarm actuated. Therefore, the CTS relies on the ($T_{avg}-T_{ref}$) deviation alarm to assure T_{avg} is within limits during reactor operation. The proposed change would introduce a 12 hour requirement to verify T_{avg} independent of the ($T_{avg}-T_{ref}$) deviation alarm. Therefore, the proposed change would provide additional assurance beyond the CTS SR requirement that T_{avg} was within the limits assumed in accident and transient analyses.

With regard to the requirement to verify temperature within 15 minutes of achieving reactor criticality, the ($T_{avg}-T_{ref}$) deviation alarm will still provide warning that RCS temperature is not within limit. In addition, during an approach to criticality, the plant is operated such that rapid or significant temperature changes in the RCS are avoided. Since the specification has no CTS.4.0.4 exception, T_{avg} must still be within limit prior to entering the LCO Applicability, i.e. prior to criticality.

Based on the foregoing discussion, the proposed change would provide additional assurance that RCS T_{avg} would remain within limits assumed in accident analyses during reactor operation. Therefore, the proposed change would not involve a significant increase in the probability or consequences of a previously evaluated accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change deals with the frequency of monitoring a parameter (RCS temperature) that is an initial Condition of accident and transient analyses. Changes in SR frequency would not lead to changes in plant system operations or other conditions that could cause an accident of a new or different type. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

As noted in the evaluation of Criterion 1 above, the main method of monitoring RCS temperature, during normal plant operation and during approach to criticality, is via the $(T_{avg} - T_{ref})$ deviation alarm. This situation would not be altered by the proposed changes. However, the proposed change would add an additional requirement to verify RCS temperature every 12 hours. The minimum T_{avg} for criticality is not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, $F_Q, F_{\Delta H}^N$, LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS6" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed change would specify that the overall core reactivity balance comparison shall be done every 31 EFPD after burnup exceeds 60 EFPD. This is in accordance with NUREG-1431 and clarifies when the 31 EFPD surveillance should start. The CTS SR specifies a frequency of 31 EFPD. The delay in initiating the monthly surveillance is acceptable because of the slow rate of changes in the core due to fuel depletion and the presence of other indicators for prompt determination of an anomaly. As noted in the Bases for ITS 3.1.3, the reactivity balance normalization must be done within the first 60 EFPDs after each fuel loading. This allows sufficient time for core conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change would delay implementing the periodic surveillance until after the initial 60 EFPD after startup. The current specification requires the SR to be performed every 31 effective full power days (EFPD). The proposed change would delay implementing the periodic surveillance until after the initial 60 EFPD after startup. The Bases to ITS 3.1.2 state that the 60 EFPD would allow sufficient time for core parameters to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations. A requirement to perform a reactivity balance prior to entering MODE 1 after each refueling would remain in the TS. Adopting the proposed change to the SR would have a negligible effect on the probability or consequences of accidents. The initial reactivity balance that is performed prior to MODE 1 operation provides assurance that the core design is acceptable and initial safe operation would be assured. During the initial 60 EFPD of operation, other parameters provide indication that the core is operating according to design. These indications include the TS requirements for axial flux difference, quadrant power tilt ratio, and hot channel factors. This provides a check of the core Conditions and design calculations and assures that safe operation may proceed until the core conditions reach steady state. Core conditions are used as input assumptions in accident analyses; they do not affect the probability of occurrence of an accident. While they would affect the consequences of postulated accidents, the initial reactivity balance and the availability of other indicators of core performance assure that the impact on accident consequences would be negligible. Therefore, the proposed change to core reactivity surveillance would have an insignificant effect on the probability or consequences of a previously evaluated accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

Core reactivity is used as an initial assumption of accident analyses. The proposed change to the surveillance of core reactivity does not involve changes in the operation of plant systems and equipment such that a new accident could result. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

During the initial 60 EFPD, the margins of safety that depend on core reactivity would be assured by the initial reactivity balance performed prior to MODE 1 operation and by the availability of other indicators of core performance that would alert the operators to an anomaly. There are no changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_Q, F_{dH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS7" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, the requirement to reduce the high neutron flux setpoint to \leq 85 percent of RTP would be deleted. This requirement is one of the provisions for continued plant operation, at reduced power, with a misaligned rod. Removing this requirement is acceptable because the underlying safety limits are not of a nature that require immediate shutdown of the plant if they are exceeded. This is evidenced by the allowance of 72 hours to verify peaking factors. It is assumed that during this 72 hour period an event will not occur which will raise the power level and cause a high neutron flux trip at 100 percent RTP. If a power excursion would occur from the 75 percent RTP ACTION statement limit, the initial peaking factors would not be critical to the analysis; since the analysis is based on the peaking factors at 100 percent RTP. Therefore, the risk of a reactor trip caused by adjusting the power range trip setpoints is not justified by the potential consequences of failing to reduce the trip setpoints.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The concern with operation while a rod is misaligned involves potential reduction in SDM and potential core power distributions that are not consistent with accident analysis assumptions. While the probability of an accident would not be affected by the proposed change, the consequences could potentially be affected if the accident analysis assumptions were violated. However, the remaining ACTIONS required for operation in this condition provide compensatory measures that would assure, that should an accident occur, the consequences would be acceptable. These additional ACTIONS are verification of SDM, reduction in reactor power to 75 percent RTP, development of a power distribution map, and a reevaluation of affected safety analyses. The verification of SDM within 1 hour assures that reactor shutdown can be performed in accordance with the accident analyses. The power distribution map, required within 72 hours, assures that longer-term operation would not violate analysis assumptions. The reduction in power, required within 2 hours, assures that local heat generation rates would not cause core design criteria to be exceeded. Based on these additional ACTIONS, the consequences of an accident would not be significantly changed as a result of the proposed change. Therefore, the proposed TS change would not involve any significant increase in the probability or consequences of a previously evaluated accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change would eliminate a requirement to reset the high neutron flux reactor trip setpoint to a lower value. This would not have any affect on the potential accidents that may occur. The setpoint reduction requirement was commensurate with the requirement to reduce reactor power to 75 percent RTP. Operating the plant under these conditions without a reduced trip setpoint would not result in conditions that could cause a new or different type of accident to occur. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The required reduction in reactor power is intended to assure that the margins of safety in the accident analyses are maintained while operating with a misaligned rod. Also, the other Required ACTIONS are intended to assure the assumptions of the safety analyses remain valid. Eliminating the requirement to reset reactor high power trips would have negligible adverse affect on the margins of safety, because the reduction in power tends to increase the available margins and because of the low probability of occurrence of an event that would be terminated by high neutron flux. The rod OPERABILITY and alignment limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_o, F_{DH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS9" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10 10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The requirement to maintain RCS $T_{avg} \geq 541^\circ\text{F}$ during rod drop testing would be revised to maintain $T_{avg} \geq 500^\circ\text{F}$. NUREG-1431 allows the tests to be performed at temperatures as low as 500°F . Because the RCS coolant is more dense at lower temperatures, the rod drop time would be greater at the lower temperatures than at the higher temperatures. In addition, the RCS is borated such that the SDM remains within its limits for the conditions existing during these tests. Nevertheless, this change, which allows more flexibility on plant conditions for conducting rod drop testing, is a relaxation in plant operations under the TS.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves the temperature at which rod drop testing is performed. Rod drop time is assumed as an initial condition of accident analyses that depend on reactor scram to mitigate the event. Performance of rod drop time tests would have no effect on the probability of an accident; therefore, altering the temperature for testing has no effect on the probability of an accident. Also, the performance of the test at lower RCS temperature is more conservative from the standpoint of drop time; thus if the rods pass the test at lower temperature, they will be assured of performing as required at the operating reactor temperatures. Therefore, the rods will remain OPERABLE as assumed in accident analyses. Therefore, the proposed change would not result in a significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves a change to the temperature at which rod drop times are measured. This surveillance does not involve any physical alteration to any plant equipment, and causes no change in the method by which any safety-related system performs its function. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

OPERABILITY of the rods would continue to be demonstrated after the proposed change is implemented. Therefore, the rods would continue to perform the mitigating functions assumed in the safety analyses. The rod OPERABILITY and alignment limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, $F_Q, F_{\Delta H}^N$, LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS10" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, a 4 hour Completion Time is specified to verify rod position after movement of a rod with inoperable indicators more than 24 steps in one direction. This is justified in the ITS Bases as an acceptable Completion Time to perform the verification of rod position using the movable incore detectors. The current requirement to perform the verification "immediately" is intended to reflect a quick starting time. A Completion Time of 4 hours also would assure a prompt start time as stated in the ITS Bases; however, since a flux map can be obtained in much less than 4 hours, the change would represent a relaxation in start time.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves performing flux mapping to indirectly determine the position of rods with inoperable digital position indication. The intent of the ACTION statement that requires a flux map to be obtained is to assure that the rod positions are known after significant rod motion has occurred. The difference between an "immediate" start of a flux map, specified in the current ACTION, and a 4 hour completion, which is proposed, would mean that the rod position in the latter case may not be known for a longer period of time. The period may even approach 2 or 3 hours. However, as noted in the Bases to ITS 3.1.7, the 4 hour period for verifying rod position has been determined to be acceptable on the basis that operation for this time period would not result in undesirable power distributions in the core that could occur from long-term operation with a misaligned rod. It should be noted that the TS require that the rods also have demand position indication available. Demand position indication would provide additional indication of the position of rods, however, at reduced reliability because demand position is based on signals sent to the rods not on feedback from the rod. However, demand position will provide accurate indication unless a rod is stuck in place. The combination of loss of digital position and one or more sticking rods, and an event that depends on rod position occurring during the period of time (4 hour completion) involved is very unlikely. Therefore, based on the foregoing, the proposed change would not result in a significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves the timing of alternative rod position measurements. The change does not involve any physical alternation to any plant equipment, and causes no change in the method by which any safety-related system performs its function. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The margins of safety for accident analyses that depend on rod position may be affected by misalignment of rods and by power distributions that have not been assumed in accident analyses. However, in the case of the proposed change, the likelihood of the combination of events required to obtain an actual undetected misalignment is extremely unlikely and the Completion Time proposed has been determined to be acceptable from the standpoint of power distribution. There are no changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, $F_Q, F_{\Delta H}^N$, LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS12" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS13
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS [3.1.3.1] ACTIONS are revised to delete reference causes of control rod inoperability due to rod control urgent failure or other electrical problems in the rod control system. The corresponding ITS 3.1.4 Condition B only address a misaligned rod. NUREG-1431, Rev. 1, is based on the position that the OPERABILITY of both shutdown rods and control rods is solely contingent upon the rod being able to perform its safety function. NUREG-1431 defines the rod safety function as trippability, i.e., capable of being tripped and tripping within the require time interval (rod drop time). Routine movement of control rods is not part of the control rod safety function. This change is acceptable since ITS 3.1.4 clarifies rod OPERABILITY, and focuses the ACTIONS on rod untrippability and rod misalignment, consistent with the intended safety functions of the control and shutdown rods.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The proposed change to the TS does not involve a significant hazards consideration based on the evaluation of the proposed operation of the plant in accordance with the following criteria:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any hardware changes or impact the ability of the control rods to perform their safety function. In the event of a rod control urgent failure alarm or other electrical problem in the rod control system, routine control rod movement is impacted. However, routine movement is not part of the safety function of the control rod. Routine movement may be necessary to assure compliance with other reactivity control and power distribution limit specifications. In the event of failure to satisfy one of these other specifications, appropriate compensatory measures are provided in those specifications. The proposed change also does not affect the compensatory measures required for a misaligned control rod. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in controlling parameters. The proposed change will still ensure the control rod safety function is capable of being performed and the proposed change does not affect the actions provided for a misaligned control rod. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

3. Does this change involve a significant reduction in a margin of safety?

The deletion of the condition for control rod inoperability due to rod control urgent failure or other electrical problems in the rod control system is considered acceptable since in this condition the rods are still capable of performing their safety function. Additionally, all aspects associated with the inability to move the control rods are adequately addressed in the ACTIONS of the affected Reactivity Control or Power Distribution Limits TS and the appropriate ACTIONS provided for a misaligned rod. Since the ability of the control rods to perform their safety function remains unchanged, there is no change in the margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS13" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The specification ACTION statement would be revised to apply to shutdown "banks" instead of shutdown "rods." This change is consistent with NUREG-1431. The CTS ACTION statement permits one or more "rods" to be inserted beyond the limits. The proposed ITS Condition A would allow 1 or more "banks" to be inserted beyond the limit. Permitting a bank to be inserted beyond the limits would likely involve more than 1 rod. Therefore, the proposed specification would be less restrictive than the current one.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The shutdown rods positioned within insertion limits are a major accident mitigation system for accidents that require a reactor trip. However, the shutdown rod position would have no effect on initiating an accident requiring reactor trip. Thus, the proposed changes would have no effect on the probability of accidents previously evaluated. The consequences of accidents requiring reactor trip or a rod ejection accident may be made worse by having a bank of rods inserted beyond the insertion limits. However, the consequences are not significant because the proposed TS changes would incorporate a provision to verify SDM or initiate boration within one hour of detecting the misaligned bank of rods. Thus, for those events which rely on the shutdown rods providing SDM, the required SDM would, within a short time, be restored. The probability that an accident requiring reactor trip would occur during the time that it would take to either restore the bank to within limits or to borate to restore SDM would be extremely small. Therefore, the proposed change would not result in a significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not involve any physical alteration to any plant equipment, and causes no change in the method by which any safety-related system performs its function. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

As discussed in the evaluation of Criterion 1 above, the proposed changes include compensatory measures to be taken if a shutdown bank is discovered to be inserted beyond the limits. The purpose of these measures is to regain the margin in safety analyses that may be lost because of the reduced worth of the shutdown rods. These measures include a time period for their accomplishment, and should the time requirement not be met, the plant must be shut down. Therefore, the total scope of the proposed change includes mitigating factors to assure safety margins are met if continued plant operation is planned. The shutdown rod insertion limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_o, F_{DH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS14" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The requirement for inoperable DRPI is changed from "with a maximum of one per bank" to "one per group for one or more groups." This change is consistent with NUREG-1431. However, the change from "bank" to "group" would result in additional rods with inoperable DRPI because the plant has 15 groups of rods and only 9 banks. Entry into this condition for 1 rod per group is acceptable because the Required ACTIONS, if applied to each nonindicating rod, provide appropriate compensatory actions. Position verification of the nonindicating rod within each group within 8 hours is adequate to allow continued full POWER OPERATION since this frequent monitoring ensures that the probability of having a rod significantly out of position and the simultaneous occurrence of an event sensitive to rod position is small.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed modification involves ACTIONS to be taken if DRPIs are inoperable. It does not involve changes in operating conditions or hardware changes that would affect the probability of an accident occurring. Monitoring rod positions and taking corrective actions are not a precursor to or assumed to be an initiator of any analyzed accidents.

The required actions to be taken if DRPIs are inoperable would ensure that the position of rods are within assumed limits or the reactor would be shutdown. Therefore, the proposed changes would not result in a significant increase in the consequences of accidents that rely on rods being within assumed limits.

Therefore, the proposed changes would not result in a significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed modification involves actions to be taken if DRPIs are inoperable. It does not involve changes in operating conditions or hardware changes that would result in plant transients or other perturbations that may result in an accident occurring. The changes do not involve a physical alteration or installation of new equipment or changes to parameters used to operate the plant. Therefore, this proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change would allow a greater number of rods to have inoperable position indication. However, each of the rods with inoperable indication would be subject to alternative monitoring methods to assure that its position was within limits. In addition, normal plant operations do not involve excessive rod movement, and the frequency that nonindicating rod position is verified ensures that rod position would be maintained within limits. There are no changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_o, F_{DH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the foregoing information, it has been determined that the proposed changes associated with NSHC "LS15" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The ACTION statement would be modified to reflect that the requirement to initiate boration would be within "15 minutes." This change is consistent with NUREG-1431. This specific time replaces the term "immediately." This is meant to clearly specify a completed ACTION of "initiate." The requirement can be met only if boration is already taking place at 15 minutes. This time period provides adequate time for the operator to evaluate, align, and start the required systems.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The accident analysis assumes adequate minimum SDM as an initial assumption. The immediate initiation of boration is an action used to provide early restoration of minimum SDM. The action of restoring SDM can not effect the probability of an accident. The difference between "immediately" and the more defined, "within 15 minutes" may represent an increase in time to restoration of SDM but this increase has a negligible impact on the probability or consequences of an accident. Therefore, the probability or consequences of an accident previously evaluated is not significantly increased.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The purpose of immediate initiation of boration is to assure early restoration of minimum SDM. The slight delay in the initiation of boration does not involve any physical alternation to any plant equipment, and causes no change in the method by which any safety-related system performs its function. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The margin of safety is based upon the initial assumption that the minimum SDM is met. This assumption is not effected by the insignificant increase in the time to restore minimum SDM. Therefore, there is no reduction in the margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS16" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed activity would add required ACTIONS if the overall core reactivity balance was not within ± 1 percent $\Delta k/k$ of the predicted values. In the CTS, there are no Required ACTIONS; thus LCO 3.0.3 would be entered. LCO 3.0.3 requires, that within 1 hour, ACTIONS be initiated to place the plant in a condition in which the LCO did not apply. Because this particular SR is only required in MODES 1 and 2, LCO 3.0.3 would further require that the plant be placed in HOT STANDBY (MODE 3) within the following 6 hours. The proposed change, consistent with NUREG-1431, would allow 72 hours to evaluate the safety analyses and establish appropriate operating restrictions and/or SRs. If these activities were not completed within the 72 hour period, then the plant would be placed in MODE 3 within the following 6 hours.

The requirement to periodically compare the measured and predicted overall core reactivity balances provides assurance that the analytical predictions upon which the safety analyses are based accurately represent the actual core response. Should an anomaly develop between measured and predicted core reactivity, an evaluation of the core design and safety analysis must be performed. Core conditions are evaluated to determine their consistency with input to design calculations. Measured core and process parameters are evaluated to determine that they are within the bounds of the safety analysis, and safety analysis calculational models are reviewed to verify that they are adequate for representation of the core conditions. The required Completion Time of 72 hours is based on the low probability of a DBA occurring during this period, and allows sufficient time to assess the physical Condition of the reactor and complete any required evaluations of the core design and safety analyses.

Following evaluations of the measurement, the core design, and the safety analysis, the cause of the reactivity anomaly may be resolved. If it is concluded that the reactor core is acceptable for continued operation, then the predicted core reactivity balance may be renormalized and Power Operation may continue. If operation restriction or additional SRs are necessary to ensure the reactor core is acceptable for continued operation, then they must be defined.

The Required Completion time of 72 hours is adequate for preparing whatever operating restrictions or surveillance that may be required to allow continued reactor operation.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed changes has no effect on the probability of an accident. Although a small effect, the proposed change may slightly reduce the probability of an accident by allowing additional time to resolve discrepancies, and thus avoid an unnecessary plant transient (shutdown).

Satisfaction of the SR acceptance criterion provides assurance that the core-related reactivity parameters used in the safety analysis adequately represent the actual core conditions. During the 72 hour action time following an initial failure of the SR acceptance criterion, ACTIONS are established which would ensure continued agreement between the safety analysis and the actual core conditions; thereby, maintaining the validity of the safety analyses. Therefore, there is no effect on the consequences of an accident previously evaluated.

Because the available time is increased from 1 to 72 hours, the probability of an accident occurring during the time period when the plant condition is under review is slightly increased; however, the increase is small and has been previously found to be acceptable by the NRC staff through the approval of NUREG-1431.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

Operation for a period of time with a discrepancy between the measured and predicted core reactivity balances is allowed by the CTS; therefore, there is no possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO. Thus, for the purposes of the accident analyses, it assumed that the agreement between the predicted and measured core reactivity balance is within an acceptable range. These assumptions remain valid since there is no design, operation, maintenance, or testing revision associated with this change. Therefore, there is no significant reduction in margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS17" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS20 10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed activity would add additional Required ACTIONS, which would be applicable to situations where more than 1 DRPI per bank is inoperable. The new Required ACTIONS would avoid unnecessary plant shutdowns per TS 3.0.3 yet maintain constancy with the overall protection afforded by related specifications. For example, related specifications associated with known control rod misalignments do not invoke compensatory measures as restrictive as TS 3.0.3. The situation addressed by this proposed change is one in which some misalignments or other OPERABILITY concerns, sufficient compensatory actions may be taken during the proposed 24 hour AOT in order to maintain an adequate level of plant safety.

DCPP has 53 full length rod cluster control assemblies (RCCAs) arranged in four control banks and four shutdown banks. With the exception of shutdown banks C and D, each bank is divided into two groups. Each group, in turn consists of several RCCAs which move together. Each RCCA has a position indicator channel which displays the position of the assembly. The indication of RCCA position, in accordance with Regulatory Guide (RG) 1.97, is a Category 3 variable (i.e., non-Class 1E, performance grade). Fully inserted RCCAs are further indicated by a rod at bottom signal which actuates a local alarm and a control room annunciator. Group demand position is also indicated.

RCCAs move in preselected banks, and the banks are moved in the same preselected sequence. In the banks with two groups, the rods comprising a group operate in parallel through multiplexing thyristors. The two groups in these banks move sequentially such that the first group is within one step of the second group in the bank. A defined sequence of actuation (and deactuation) of the stationary gripper, movable gripper, and lift coils of a mechanism is required to withdraw the RCCA attached to the mechanism.

Two separate systems are provided to sense and display control rod positions as described below:

a. DRPI system

The DRPI system measures the actual position of each control rod, using a detector which consists of discrete coils mounted concentrically with the rod drive pressure housing. The coils are located axially along the pressure housing and magnetically sense the entry and presence of the rod drive shaft through its centerline. For each detector, the coils are interlaced into two data channels of information, the DRPI system can continue to function (at reduced accuracy) when one channel fails. Multiplexing is used to transmit the digital position signals from the containment electronics to the control board display unit.

The control board display unit contains a column of light emitting diode (LEDs) for each rod. At any given time, the one LED illuminated in each column show the position for that particular rod. Each rod has its position displayed to ± 4 steps throughout its range of travel from rod bottom to 228 steps.

Included in the system is a rod at the bottom signal for each rod that operates a local alarm. Also, a control room annunciator is actuated when any shutdown rod or control bank A rod is at bottom.

b. Demand Position System

The demand position system counts pulses generated in the rod drive control system to provide a digital readout of the demanded bank position.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS20 (Continued)

The position and DRPI systems are separate systems as a result of operations requirements (i.e., no safety criteria were involved in the separation), operating procedures required the reactor operator to compare the demand and indicated (actual) readings from the DRPI system so as to verify operation of the rod control system.

The proposed Required ACTION has an AOT of 24 hours as well as compensatory actions to use the movable incore detectors to ascertain rod position, to monitor and record RCS temperature, to place rod control in the manual mode, and to limit rod motion to the extent possible via the use of other reactivity control mechanisms such as boration and dilution. The 24 hour AOT provides sufficient time to troubleshoot and restore the DRPI system to operation while avoiding the plant challenges associated with an unnecessary shutdown. Monitoring and recording RCS temperature would allow early detection of mispositioned dropped rods. Overall plant safety would be enhanced by maintaining steady-state operation, as compared with the large rod movements, and potential challenges, required during an unnecessary shutdown in conduction with the loss of DRPI. The proposed Required ACTION is consistent with the overall protection afforded by the related specifications, in that acceptable power distribution limits are maintained, the minimum SDM is maintained, and the potential effects of rod misalignment on associated accident analysis are limited.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Because no design changes are involved with this proposed change, the impact on the plant safety analysis design basis would involve a reactivity transient induced by operator error associated with the loss of position indications. The analysis results for the events in FSAR Section 15.4.1 to 15.4.3 are not dependent upon operators acts of omission or commission. The assumed reactivity insertion rates are based on conservative, worst case scenarios independent of whether they are due to equipment malfunction or human error. Loss of RCCA position indication would not affect the assumed reactivity insertion rates. Further, the protection systems assumed in the analyses of these events are unaffected by the proposed change.

The worst case reactivity transient of this nature (the withdrawal of a single RCCA) has been analyzed in FSAR Section 15.4.3 assuming that the operators ignore RCCA position indication. Whether indication is lost, as is the case covered by the proposed ACTION statement, or disregarded, does not change the method of analysis or the results of the analysis.

The accident analysis are initiated from within the conditions defined by the TS LCO and they remain unchanged; therefore, the accident analyses are unaffected. Therefore the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS20 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiator are introduced by the proposed change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no affect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS20" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS21
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed change would revise the shutdown requirement for control rod banks not within limits from "Be in at least HOT STANDBY within 6 hours" to "Be in at least HOT STANDBY within the next 6 hours." This change would provide additional time to place the plant in MODE 3 because the 6 hour limit would not commence until after the time periods allowed for completing other actions, such as restoring the control bank position within 2 hours. The CTS require the 6 hour period to commence at the time the LCO is not met. The proposed change is in accordance with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The control rod insertion LCO is intended to assure that the control rods are in position to mitigate accidents or transients that depend on a reactor trip and that reactor power distribution is in accordance with the assumptions used in accident analyses. If control rods are outside of specified limits, the plant should be placed in a MODE for which the LCO is not applicable, i.e., MODE 3. As noted in the Bases of NUREG-1431, 8 hours is a reasonable time, based on operating experience, for reaching the required MODE from full power Conditions, in an orderly manner without challenging plant systems.

The proposed shutdown requirement Completion Time change would result in an extension of time to achieve MODE 3 from 6 hours (per CTS) to a maximum of 8 hours (2 hours to attempt to complete other mitigating actions followed by 6 hours to achieve MODE 3). The proposed change would not change the plant design or operations such that an accident or transient could be initiated. By allowing a shutdown time based on operating experience, the change would reduce the chances of an operator error or challenge to plant systems that could result from the more restrictive requirements in the CTS. Thus, the change would have no adverse effect on the probability of occurrence of an accident.

The proposed change would not affect the method of operation of plant systems and involves only the time requirement to achieve a reactor shutdown when the control rods are not within limits. The probability that an accident would occur during the 2 hour time extension allowed by the proposed change would be negligible. Also, during the 2 hour period, the other Required ACTIONS are being performed. These include returning control rods to within limits, restoration or SDM as necessary, and reduction in reactor power. Therefore, as time in the ACTION statement passes, the plant is being brought closer to Conditions for which the accident assumptions are valid. Thus, the proposed change would have a negligible effect on the consequences of accidents previously analyzed.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS21 (Continued)

Therefore, the proposed change would not result in a significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

Operation in accordance with the proposed change would not introduce any new failure modes for plant systems and components. Only the duration of operation in the ACTION statement is affected. The proposed change is administrative in nature and does not involve any physical alteration to any plant equipment, and causes no change in the method by which any safety-related system performs its function. Therefore, this proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The margins of safety involved with this proposed change are those associated with accidents that rely on control rod position to assure reactor trip effectiveness and to assure power distribution limits are maintained. When the rod position is not within limits, the LCO initiates the corrective action to restore the margins by specifying mitigating actions. While the margins of safety may be affected by failure to meet the LCO, the additional 2 hours to achieve MODE 3 allowed by the proposed change has no effect on them. The control rod insertion limits are not changed nor are there any changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_0, F_{DH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS-21" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS22
10 CFR 50.92 EVALUATION FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The current SR requiring shutdown rod insertion to be verified within 15 minutes prior to withdrawing control rods during approaches to criticality would be deleted. This requirement has essentially been incorporated into the ITS LCO 3.1.5 Applicability which would require that the shutdown banks meet the LCO when in MODE 2 with any control bank not fully inserted. The requirement to perform this check prior to entering the LCO Applicability is covered in plant startup procedures which require the operator to closely monitor rod position.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92 (c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Under the CTS, shutdown rod insertion is required to be verified within limit (withdrawn to at least [225] steps) within 15 minutes prior to control rod withdrawal. Since the specification has no CTS 4.0.4 exception, shutdown rod insertion must be within limit prior to entering the LCO Applicability. The current SR requires an arbitrary estimate of when the plant is 15 minutes away from control rod withdrawal. This has no basis from the accident analyses, which are satisfied as long as the shutdown rods satisfy their insertion limit prior to control rod withdrawal.

Based on the foregoing discussion, the proposed change would not involve a significant increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

This change will not impact plant system operations or other conditions that could cause an accident of a new or different type. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS22 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The shutdown rod insertion limit is not changed nor are there are changes to accident analysis assumptions, methodologies, credited protection/mitigation equipment, or event acceptance criteria. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on the overpower limits, DNBR limits, F_Q, F_{QH}^N , LOCA PCT, peak local power density, or any other margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS-22" resulting from the conversion to the ITS format satisfy the NSCH standards of 10 CFR 50.92(c), and accordingly a no NSCH finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR2 10CFR50.92 EVALUATION FOR RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change in accordance with NUREG-1431, Rev. 1, removes the requirement for a special report to be generated and submitted to the NRC. Reporting to the NRC will be done commensurate with the reporting requirements of 10CFR50.72 and 50.73.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92 (c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change is purely an administrative reporting change and cannot affect any accident probability or consequences.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

This change is purely an administrative reporting change and cannot create any new accident or affect any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

This change is purely an administrative reporting change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "TR-2" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92(c), and does not involve a significant hazards consideration.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR3
10 CFR 50.92 EVALUATION
FOR
RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN TECHNICAL SPECIFICATIONS

This proposed revision is to remove reference to specific post-maintenance tests from the CTS. Post-maintenance testing programs are controlled via plant administrative procedures in accordance with licensee controlled document (ITS Section 5.4.1 commitments to NRC RG 1.33, "Quality Assurance Program Requirements Operation" and ANS 3.2-ANSI N18.7, "Administrative Controls and Quality Assurance for the Operational Phase of Nuclear Power Plants)." Specific post-maintenance testing requirements are contingent on the type and scope of maintenance actually performed as well as the availability and viability of test equipment, techniques, etc. Removal of specific testing requirements from the CTS and reliance on normal post-maintenance testing programs addressed by licensee controlled documents allow flexibility to modify testing to address the circumstances of the maintenance performed while still assuring OPERABILITY of equipment returned to service.

This proposed TS change has been evaluated and it has been determined that it involves NSCH. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92 (c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This is an administrative change which removes specific post-maintenance test requirements from the CTS. The testing, or equivalent testing, to assure equipment OPERABILITY prior to return to service would still be done as required by normal plant maintenance retest programs. Therefore, this change would not result in any increase in the probability or consequences of an accident previously evaluated.
2. Does the change create the possibility of a new or different kind of accident from any previously evaluated?

This is an administrative change and does not create a new or different kind of accident from any previously evaluated.
3. Does this change involve a significant reduction in margin of safety?

This is an administrative change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed change associated with NSHC "TR-3" does not meet the requirements of 10 CFR 50.92© and does not involve a significant hazards consideration satisfies the NSHC standards of 10 CFR 50.92(c), and accordingly a NSCH finding is justified.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions -** The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions -** The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications -** The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes-** Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts -** The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.1 SHUTDOWN MARGIN (SDM)

BASES

BACKGROUND

According to GDC 26 (Ref. 1), the reactivity control systems must be redundant and capable of holding the reactor core subcritical when shut down under cold conditions. Maintenance of the SDM ensures that postulated reactivity events will not damage the fuel.

SDM requirements provide sufficient reactivity margin to ensure that acceptable fuel design limits will not be exceeded for normal shutdown and anticipated operational occurrences (AOOs). As such, the SDM defines the degree of subcriticality that would be obtained immediately following the insertion of all shutdown and control rods, assuming that the single rod cluster assembly of highest reactivity worth is fully withdrawn.

The system design requires that two independent reactivity control systems be provided, and that one of these systems be capable of maintaining the core subcritical under cold conditions. These requirements are provided by the use of movable control assemblies and soluble boric acid in the Reactor Coolant System (RCS). The Rod Control Rod System can compensate for the reactivity effects of the fuel and water temperature changes accompanying power level changes over the range from full load to no load. In addition, the Rod Control Rod System, together with the boration system, provides the SDM during power operation and is capable of making the core subcritical rapidly enough to prevent exceeding acceptable fuel damage limits, assuming that the rod of highest reactivity worth remains fully withdrawn. The soluble boron Chemical and Volume Control System can control the soluble boron concentration to compensate for fuel depletion during operation and all xenon burnout reactivity changes and can maintain the reactor subcritical under cold conditions.

During power operation, SDM control is ensured, assuming that core reactivity is within design limit of LCO 3.1.2, by operating with the shutdown banks fully withdrawn and the control banks within the limits of LCO 3.1.76, "Control Bank Insertion Limits." When the unit is in the shutdown and refueling modes, the SDM requirements are met by means of adjustments to the RCS boron concentration

APPLICABLE
SAFETY ANALYSIS

The minimum required SDM is assumed as an initial condition in safety analyses. The safety analysis (Ref. 2) establishes an SDM that ensures specified acceptable fuel design limits are not exceeded for normal operation and AOOs, with the assumption of the highest worth rod stuck out on scram. For MODE 5, the primary safety analysis that relies on the SDM limits is the boron dilution analysis.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.1 SHUTDOWN MARGIN (SDM)

BASES

The acceptance criteria for the SDM requirements are that specified acceptable fuel design limits are not exceeded. This is done by ensuring that:

- a. The reactor can be made subcritical from all operating conditions, transients, and Design Basis Events;
- b. The reactivity transients associated with postulated accident conditions are controllable within acceptable limits (departure from nucleate boiling ratio (DNBR), fuel centerline temperature limits for AOOs, and $\leq 280\ 200$ cal/gm energy deposition average fuel pellet enthalpy at the hot spot in irradiated fuel for the rod ejection accident, Ref. 5); and
- c. The reactor will be maintained sufficiently subcritical to preclude inadvertent criticality in the shutdown condition.

The most limiting accidents for the SDM requirements ~~is based on a~~ are the main steam line break (MSLB) and inadvertent boron dilution accidents, as described in the accident

BASES

APPLICABLE
SAFETY ANALYSIS
(continued)

analysis FSAR (Refs. 2 and 3). In addition to the limiting MSLB transient, the SDM requirement is also used in the analyses of the following events:

- a. Inadvertent boron dilution;
- b. An uncontrolled rod withdrawal from subcritical or low power condition;
- c. Start of an inactive reactor coolant pump (RCP); and
- d. Rod ejection.

The increased steam flow resulting from a pipe break in the main steam system causes an increased energy removal from the affected steam generator (SG), and consequently the RCS. This results in a reduction of the reactor coolant temperature. The resultant coolant shrinkage causes a reduction in pressure. In the presence of a negative moderator temperature coefficient, this cooldown causes an increase in core reactivity. As RCS temperature decreases, the severity of an MSLB decreases until the MODE 5 value is reached. The most limiting MSLB, with respect to potential fuel damage before a reactor trip occurs, is a guillotine break of a main steam line inside containment initiated at the end of core life with RCS T_{avg} equal to 547°F. The positive reactivity addition from the moderator temperature decrease will terminate when the affected SG boils dry, thus terminating RCS heat removal and cooldown. Following the MSLB, a post trip return to power may occur; however, no fuel damage occurs as a result of the post trip return to power, and THERMAL POWER does not violate the Safety Limit (SL) requirement of SL 2.1.1.

~~In addition to the limiting MSLB transient, the SDM requirement is also used in the analyses of the following events:~~

- ~~a. Inadvertent boron dilution;~~
- ~~b. An uncontrolled rod withdrawal from subcritical or low power condition; and~~
- ~~c. Start of an inactive reactor coolant pump (RCP); and~~
- ~~d. Rod ejection.~~

BASES

APPLICABLE
SAFETY ANALYSIS
(continued)

In the boron dilution analysis, the required SDM defines the reactivity difference between an initial subcritical boron concentration and the corresponding critical boron concentration. These values, in conjunction with the configuration of the RCS and the assumed dilution flow rate, directly affect the results of the analysis. This event is most limiting at the beginning of core life, when critical boron concentrations are highest.

Depending on the system initial conditions and reactivity insertion rate, the uncontrolled rod withdrawal transient is terminated by either a high power level trip or a high pressurizer pressure trip. In all cases, power level, RCS pressure, linear heat rate, and the DNBR do not exceed allowable limits.

The ejection of a control rod rapidly adds reactivity to the reactor core, causing both the core power level and heat flux to increase with corresponding increases in reactor coolant temperatures and pressure. The ejection of a rod also produces a time dependent redistribution of core power.

The startup of an inactive RCP in MODES 1 or 2 is precluded. In MODE 3, the startup of an inactive RCP can not result in a "cold water" criticality, even if the maximum difference in temperature exists between the SG and the core. The maximum positive reactivity addition that can occur due to an inadvertent start is less than half the minimum required

(Continued)

BASES

APPLICABLE
SAFETY ANALYSIS
(continued)

SDM. Startup of an idle RCP cannot, therefore, produce a return to power from the hot standby condition.

SDM satisfies Criterion 2 of the 10CFR50.36(c)(2)(iii). Even though it is not directly observed from the control room, SDM is considered an initial condition process variable because it is periodically monitored to ensure that the unit is operating within the bounds of accident analysis assumption.

LCO

SDM is a core design condition that can be ensured during operation through control rod positioning (control and shutdown banks) and through the soluble boron concentration.

The MSLB (Ref. 2) and the boron dilution (Ref. 3) accidents are the most limiting analyses that establish the SDM value of the LCO. For MSLB accidents, if the LCO is violated, there is a potential to exceed the DNBR limit and to exceed 10 CFR 100, "Reactor Site Criteria," limits (Ref. 4). For the boron dilution accident, if the LCO is violated, the minimum required time assumed for operator action to terminate dilution may no longer be applicable sufficient. The required SDM is specified in the COLR.

APPLICABILITY

In MODE 2 with $k_{\text{eff}} < 1.0$ and in MODES 3, and 4, and 5 the SDM requirements are applicable to provide sufficient negative reactivity to meet the assumptions of the safety analyses discussed above. ~~In MODE 5, SDM is addressed by LCO 3.1.2, "SHUTDOWN MARGIN (SDM) $T_{\text{SDM}} \leq 200^{\circ}\text{F.}$ "~~ In MODE 6, the shutdown reactivity requirements are given in LCO 3.9.1, "Boron Concentration." In MODES 1 and 2, SDM is ensured by complying with LCO 3.1.65, "Shutdown Bank Insertion Limits," and LCO 3.1.76, "Control Bank Insertion Limits"

ACTIONS

A.1

If the SDM requirements are not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. It is assumed that boration will be continued until the SDM requirements are met.

In the determination of the required combination of boration flow rate and boron concentration, there is no unique requirement that must be satisfied. Since it is imperative to raise the boron concentration of the RCS as soon as possible, the borated water source should be a highly concentrated solution, such as that normally found in the boric acid storage tank, or the refueling water storage tank. The operator should borate with the best source available for the plant conditions.

BASES

~~In determining the boration flow rate, the time in core life must be considered. For instance, the most difficult time in core life to increase the RCS boron concentration is at the beginning of cycle when the boron concentration may approach or exceed 2000 ppm. Assuming that a value of 1% $\Delta k/k$ must be recovered and a boration flow rate of [] gpm, it is possible to increase the boron concentration of the RCS by 100 ppm in approximately 35 minutes. If a boron worth of 10 pcm/ppm is assumed, this combination of the RCS~~

SURVEILLANCE
REQUIREMENTSSR 3.1.1.1

In MODES 1 and 2, SDM is verified by observing that the requirements of LCO 3.1.65 and LCO 3.1.76 are met. In the event that a rod is known to be untrippable, however, SDM

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(Continued)

verification must account for the worth of the untrippable rod as well as another rod of maximum worth.

In MODES 2 (with $k_{eff} < 1.0$), 3, 4, and 5, the SDM is verified by performing a reactivity balance calculation, considering the listed reactivity effects (SDM verification must account for the worth of the untrippable rod as well as another rod of maximum worth):

- a. RCS boron concentration;
- b. Control and shutdown rod position;
- c. RCS average temperature;
- d. Fuel burnup based on gross thermal energy generation;
- e. Xenon concentration;
- f. Samarium concentration; and
- g. Isothermal temperature coefficient (ITC).

Using the ITC accounts for Doppler reactivity in this calculation because the reactor is subcritical, and the fuel temperature will be changing at the same rate as the RCS.

The Frequency of 24 hours is based on the generally slow change in required boron concentration and the low probability of an accident occurring without the required SDM. This allows time for the operator to collect the required data, which includes performing a boron concentration analysis, and complete the calculation.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.3 3.1.2 Core Reactivity

BASES

BACKGROUND

According to GDC 26, GDC 28, and GDC 29 (Ref. 1), reactivity shall be controllable, such that subcriticality is maintained under cold conditions, and acceptable fuel design limits are not exceeded during normal operation and anticipated operational occurrences. Therefore, reactivity balance is used as a measure of the predicted versus measured core reactivity during power operation. The periodic confirmation of core reactivity is necessary to ensure that Design Basis Accident (DBA) and transient safety analyses remain valid. A large reactivity difference could be the result of unanticipated changes in fuel, control rod worth, or operation at conditions not consistent with those assumed in the predictions of core reactivity, and could potentially result in a loss of SDM or violation of acceptable fuel design limits. Comparing predicted versus measured core reactivity validates the nuclear methods used in the safety analysis and supports the SDM demonstrations (LCO 3.1.1, "SHUTDOWN MARGIN (SDM) $\rightarrow 200^{\circ}\text{F}$ ") in ensuring the reactor can be brought safely to cold, subcritical conditions.

When the reactor core is critical or in normal power operation, a reactivity balance exists and the net reactivity is zero. A comparison of predicted and measured reactivity is convenient under such a balance, since parameters are being maintained relatively stable under steady state power conditions. The positive reactivity inherent in the core design is balanced by the negative reactivity of the control components, thermal feedback, neutron leakage, and materials in the core that absorb neutrons, such as burnable absorbers producing zero net reactivity. Excess reactivity can be inferred from the boron letdown curve (or critical boron curve), which provides an indication of the soluble boron concentration in the Reactor Coolant System (RCS) versus cycle burnup. Periodic measurement of the RCS boron concentration for comparison with the predicted value with other variables fixed (such as rod height, temperature, pressure, and power), provides a convenient method of ensuring that core reactivity is within design expectations and that the calculational models used to generate the safety analysis are adequate.

(Continued)

In order to achieve the required fuel cycle energy output, the uranium enrichment, in the new fuel loading and in the fuel remaining from the previous cycle, provides excess positive reactivity beyond that required to sustain steady state operation throughout the cycle. When the reactor is critical at RTP and moderator temperature, the excess positive reactivity is compensated by burnable absorbers (if any), control rods, whatever neutron poisons (mainly xenon and samarium) are present in the fuel, and the RCS boron concentration.

When the core is producing THERMAL POWER, the fuel is being depleted and excess reactivity is decreasing. As the fuel depletes, the RCS boron concentration is reduced to decrease negative reactivity and maintain constant THERMAL POWER. The boron letdown curve is based on steady state operation at RTP. Therefore, deviations from the predicted boron letdown curve may indicate deficiencies in the design analysis, deficiencies in the calculational models, or abnormal core conditions, and must be evaluate.

APPLICABLE
SAFETY ANALYSIS

The acceptance criteria for core reactivity are that the reactivity balance limit ensures plant SAFETY ANALYSES operation is maintained within the assumptions of the safety analyses.

Accurate prediction of core reactivity is either an explicit or implicit assumption in the accident analysis evaluations. Every accident evaluation (Ref. 2) is, therefore, dependent upon accurate evaluation of core reactivity. In particular, SDM and reactivity transients, such as control rod withdrawal accidents or rod ejection accidents, are very sensitive to

(Continued)

accurate prediction of core reactivity. These accident analysis evaluations rely on computer codes that have been qualified

(Continued)

APPLICABLE
SAFETY ANALYSIS
(continued)

against available test data, operating plant data, and analytical benchmarks. Monitoring reactivity balance additionally ensures that the nuclear methods provide (continued) an accurate representation of the core reactivity.

Design calculations are performed for each fuel cycle for the purpose of predetermining reactivity behavior and the RCS boron concentration requirements for reactivity control during fuel depletion as well as providing inputs to the safety analysis.

The comparison between measured and predicted initial core reactivity provides a validation of the calculational models used to predict core reactivity. If the measured and predicted RCS boron concentrations for identical core conditions at beginning of cycle (BOC) do not agree, then the assumptions used in the reload cycle design analysis or the calculational models used to predict soluble boron requirements may not be accurate. If reasonable agreement between measured and predicted core reactivity exists at BOC, then the prediction may be normalized to the measured boron concentration. Thereafter, any significant deviations in the measured boron concentration from the predicted boron letdown curve that develop during fuel depletion may be an indication that the calculational model is not adequate for core burnups beyond BOC, or that an unexpected change in core conditions has occurred.

The normalization of predicted RCS boron concentration to the measured value is typically performed after when deemed necessary shall be performed after reaching RIP following startup from a refueling outage, with the control rods in their normal positions for power operation. The normalization is performed at BOC conditions, so that core reactivity relative to predicted values can be continually monitored and evaluated as core conditions change during the cycle.

Core reactivity satisfies Criterion 2 of 10CFR50.36(c)(2)(11).

LCO

Long term core reactivity behavior is a result of the core physics design and cannot be easily altered once the core design is fixed. During operation, therefore, the LCO can only be ensured through measurement and tracking, and appropriate actions taken as necessary. Large differences between actual and predicted core reactivity may indicate that the assumptions of the DBA and transient analyses are no longer valid, or that the uncertainties in the Nuclear Design Methodology are larger than expected. A limit on the reactivity balance of $\pm 1\% \Delta k/k$ has been established based on engineering judgment. A 1% deviation in reactivity from that predicted is larger than expected for normal operation and should therefore be evaluated.

(Continued)

When measured core reactivity is within 1% $\Delta k/k$ of the predicted value at steady state thermal conditions, the core is considered to be operating within acceptable design limits. Since deviations from the limit are normally detected by comparing predicted and measured steady state RCS critical boron concentrations, the difference between measured and predicted values would be approximately 100 ppm (depending on the boron worth) before the limit is reached. These values are well within the uncertainty limits for analysis of boron concentration samples, so that spurious violations of the limit due to uncertainty in measuring the RCS boron concentration are unlikely.

APPLICABILITY

The limits on core reactivity must be maintained during MODES 1 and 2 because a reactivity balance must exist when the reactor is critical or producing THERMAL POWER. As the fuel depletes, core conditions are changing, and confirmation of the reactivity balance ensures the core is operating as designed. This Specification does not apply in MODES 3, 4, and 5 because the reactor is shut down and the reactivity balance is not changing.

In MODE 6, fuel loading results in a continually changing core reactivity. Boron concentration requirements (LCO 3.9.1, "Boron Concentration") ensure that fuel

(Continued)

movements are performed within the bounds of the safety analysis. An SDM demonstration is Core reactivity and control rod worth measurements are required during the first startup following operations that could have altered core reactivity (e.g., fuel movement, control rod replacement, control rod shuffling).

ACTIONS

A.1 and A.2

Should an anomaly develop between measured and predicted core reactivity, an evaluation of the core design and safety analysis must be performed. Core conditions are evaluated to determine their consistency with input to design calculations. Measured core and process parameters are evaluated to determine that they are within the bounds of the safety analysis, and safety analysis calculational models are reviewed to verify that they are adequate for representation of the core conditions. The required Completion Time of 72 hours is based on the low probability of a DBA occurring during this period, and allows sufficient time to assess the physical condition of the reactor and complete the evaluation of the core design and safety analysis.

Following evaluations of the core design and safety analysis, the cause of the reactivity anomaly may be resolved. If the cause of the reactivity anomaly is a mismatch in core conditions at the time of RCS boron concentration sampling, then a recalculation of the RCS boron concentration requirements may be performed to demonstrate that core reactivity is behaving as expected. If an unexpected physical change in the condition of the core has occurred, it must be evaluated and corrected, if possible. If the cause of the reactivity anomaly is in the calculation technique, then the calculational models must be revised to provide more accurate predictions. If any of these results are demonstrated, and it is concluded that the reactor core is acceptable for continued operation, then the boron letdown curve and the boron concentration requirement for SDM may be renormalized and power operation may continue. If operational restrictions or additional SRs are necessary to ensure the reactor core is acceptable for continued operation, then they must be defined.

The required Completion Time of 72 hours is adequate for preparing whatever operating restrictions or surveillances that may be required to allow continued reactor operation.

(Continued)

B.1

If the core reactivity cannot be restored to within the 1% $\Delta k/k$ limit, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. If the SDM for MODE 3 is not met, then the boration required by SR 3-1-1.1 LCO 3-1-1 Required Action A.1 would occur. The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant system.

SURVEILLANCE
REQUIREMENTS

SR 3-1-3-1 3.1.2.1

Core reactivity is verified by periodic comparisons of measured and predicted RCS boron concentrations. The comparison is made, considering that other core conditions are fixed or stable, including control rod position, moderator temperature, fuel temperature, fuel depletion, xenon concentration, and samarium concentration. The Surveillance is performed prior to entering MODE 1 as an initial check on core conditions and design calculations at BOC. The SR is modified by a Note. The Note indicates that the normalization (adjustment, only if necessary) of predicted core reactivity to the measured value must take place within the first 60 effective full power days (EFPD) after each fuel loading. This allows sufficient time for core conditions to reach steady state, but prevents operation for a large fraction of the fuel cycle without establishing a benchmark for the design calculations. The required subsequent Frequency of 31 EFPD, following the initial

(Continued)

60 EFPD after entering MODE 1, is acceptable, based on the slow rate of core changes due to fuel depletion and the presence of other indicators (QPTR, AFD, etc.) for prompt indication of an anomaly.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.4 3.1.3 Moderator Temperature Coefficient (MTC)

BASES

BACKGROUND

According to GDC 11 (Ref. 1), the reactor core and its interaction with the Reactor Coolant System (RCS) must be designed for inherently stable power operation, even in the possible event of an accident. In particular, the net reactivity feedback in the system must compensate for any unintended reactivity increases.

The MTC relates a change in core reactivity to a change in reactor coolant temperature (a positive MTC means that reactivity increases with increasing moderator temperature; conversely, a negative MTC means that reactivity decreases with increasing moderator temperature). The reactor is designed to operate with a negative MTC over the largest possible range of fuel cycle operation. Therefore, a coolant temperature increase will cause a reactivity decrease, so that the coolant temperature tends to return toward its initial value. Reactivity increases that cause a coolant temperature increase will thus be self limiting, and stable power operation will result.

MTC values are predicted at selected burnups during the safety evaluation analysis and are confirmed to be acceptable by measurements. Both ~~initial and~~ Reload cores are designed so that the beginning of cycle (BOC) MTC is less than zero when THERMAL POWER is at RTP. The actual value of the MTC is dependent on core characteristics, such as fuel loading and reactor coolant soluble boron concentration. The core design may require additional fixed distributed poisons to yield an MTC at BOC within the range analyzed in the plant accident analysis. The end of cycle (EOC) MTC is also limited by the requirements of the accident analysis. Fuel cycles that are designed to achieve high burnups or that have changes to other characteristics are evaluated to ensure that the MTC does not exceed the EOC limit.

The limitations on MTC are provided to ensure that the value of this coefficient remains within the limiting conditions assumed in the FSAR accident and transient analyses.

If the LCO limits are not met, the unit response during transients may not be as predicted. The core could violate criteria that prohibit a return to criticality, or the departure from nucleate boiling ratio criteria of the approved correlation may be violated, which could lead to a loss of the fuel cladding integrity.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.4 3.1.3 Moderator Temperature Coefficient (MTC)

BASES

The SRs for measurement of the MTC at the beginning and near the end of the fuel cycle are adequate to confirm that the MTC remains within its limits, since this coefficient changes slowly, due principally to the reduction in RCS boron concentration associated with fuel burnup.

APPLICABLE
SAFETY ANALYSES

The acceptance criteria for the specified MTC are:

- a. The MTC values must remain within the bounds of those used in the accident analysis (Ref. 2); and
- b. The MTC must be such that inherently stable power operations result during normal operation and accidents, such as overheating and overcooling events.

The FSAR, Chapter 15 (Ref. 2), contains analyses of accidents that result in both overheating and overcooling of the reactor core. MTC is one of the controlling parameters for core reactivity in these accidents. Both the most positive value and most negative value of the MTC are important to safety, and both values must be bounded. Values used in the analyses consider worst case conditions to ensure that the accident results are bounding (Ref. 3).

(Continued)

BASES

APPLICABLE
SAFETY ANALYSIS
(Ref. 2 (Continued))

The consequences of accidents that cause core overheating must be evaluated when the MTC is positive. Such accidents include the rod withdrawal transient from either zero or RTP, loss of main feedwater flow, and loss of forced reactor coolant flow. The consequences of accidents that cause core overcooling must be evaluated when the MTC is negative. Such accidents include sudden feedwater flow increase and sudden decrease in feedwater temperature.

In order to ensure a bounding accident analysis, the MTC is assumed to be its most limiting value for the analysis conditions appropriate to each accident. The bounding value is determined by considering rodged and unrodged conditions, whether the reactor is at full or zero power, and whether it is the BOC or EOC life. The most conservative combination appropriate to the accident is then used for the analysis (Ref. 2).

MTC values are bounded in reload safety evaluations assuming steady state conditions at BOC and EOC. An EOC measurement is conducted at conditions when the RCS boron concentration reaches a boron concentration equivalent to 300 ppm at an equilibrium, all rods out, RTP condition. The measured value may be extrapolated to project the EOC value, in order to confirm reload design predictions.

The most negative MTC value equivalent to the most positive moderator density coefficient (MDC) was obtained by incrementally correcting the MDC used in the FSAR analyses to nominal operating conditions. These corrections involved: (1) a conversion of the MDC used in the FSAR accident analyses to its equivalent MTC, based on the rate of change of moderator density with temperature at RATED THERMAL POWER conditions, and (2) adding margin to this value to account for the largest difference in MTC observed between an EOC, all rods withdrawn, RATED THERMAL POWER condition and an envelope of those most adverse conditions of moderator temperature and pressure, rods inserted to their insertion limits, axial power skewing, and xenon concentration that can occur in normal operation within technical specification limits and lead to a significantly more negative EOC MTC at RATED THERMAL POWER. These corrections transformed the MDC value used in the FSAR accident analyses into the limiting EOC MTC value. The 300 ppm surveillance limit MTC value represents a conservative value (with corrections for burnup and soluble boron) at a core condition of 300 ppm equilibrium boron concentration and is obtained by adding an allowance for burnup and soluble boron concentration changes to the limiting EOC MTC value.

(Continued)

MTC satisfies Criterion 2 of the 10CFR50.36(c)(2)(iii). Even though it is not directly observed and controlled from the control room, MTC is considered an initial condition process variable because of its dependence on boron concentration.

LCO

LCO 3.1.43 requires the MTC to be within specified limits of the COLR to ensure that the core operates within the assumptions of the accident analysis. During the reload core safety evaluation, the MTC is analyzed to determine that its values remain within the bounds of the original accident analysis during operation.

Assumptions made in safety analyses require that the MTC be less positive than a given upper bound and more positive than a given lower bound. The MTC is most positive near BOC when core reactivity and required boron concentration are at their maximum values; this upper bound must not be exceeded. This maximum upper limit is evaluated near BOC, all rods out (ARO), hot zero power conditions. At EOC the MTC takes on its most negative value, when the lower bound becomes important. This LCO exists to ensure that both the upper and lower bounds are not exceeded.

During operation, therefore, the conditions of the LCO can only be ensured through measurement. The Surveillance checks at BOC and EOC on MTC provide confirmation that the MTC is behaving as anticipated so that the acceptance criteria are met.

The LCO establishes a maximum positive value that cannot be exceeded. The BOC positive limit and the EOC negative limit are established in the COLR to allow specifying limits for

(Continued)

BASES

LCO
(Continued)

each particular cycle. This permits the unit to take advantage of improved fuel management and changes in unit operating schedule.

APPLICABILITY

Technical Specifications place both LCO and SR values on MTC, based on the safety analysis assumptions described above.

In MODE 1, the limits on MTC must be maintained to ensure that any accident initiated from THERMAL POWER operation will not violate the design assumptions of the accident analysis. In MODE 2 with the reactor critical, the upper limit must also be maintained to ensure that startup and subcritical accidents (such as the uncontrolled control rod assembly or group withdrawal) will not violate the assumptions of the accident analysis. The lower MTC limit must be maintained in MODES 2 and 3, in addition to MODE 1, to ensure that cooldown accidents will not violate the assumptions of the accident analysis. In MODES 4, 5, and 6, this LCO is not applicable, since no Design Basis Accidents using the MTC as an analysis assumption are initiated from these MODE.

ACTIONS

A.1

If the upper MTC limit is violated, administrative withdrawal limits for control banks must be established to maintain the MTC within its limits. The MTC becomes more negative with control bank insertion and decreased boron concentration. A Completion Time of 24 hours provides enough time for evaluating the MTC measurement and computing the required bank withdrawal limits.

As cycle burnup is increased, the RCS boron concentration will be reduced. The reduced boron concentration causes the MTC to become more negative. Using physics calculations, the time in cycle life at which the calculated MTC will meet the LCO requirement can be determined. At this point in core life Condition A no longer exists. The unit is no longer in the Required Action, so the administrative withdrawal limits are no longer in effect.

B.1

If the required administrative withdrawal limits are not established within 24 hours, the unit must be brought to MODE 2 with $k_{eff} < 1.0$ to prevent operation with an MTC that is more positive than that assumed in safety analyses.

(Continued)

BASES

The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

C.1

Exceeding the EOC MTC limit means that the safety analysis assumptions for the EOC accidents that use a bounding negative MTC value may be invalid. If the EOC MTC limit is exceeded, the plant must be brought to a MODE or condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 4 within 12 hours.

The allowed Completion Time is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

(Continued)

BASES

SURVEILLANCE
REQUIREMENTSSR 3.1.4.1 3.1.3.1

This SR requires measurement of the MTC at BOC prior to entering MODE 1 in order to demonstrate compliance with the most positive MTC LCO. Meeting the BOC limit prior to entering MODE 1 ensures that the limit will also be met at higher power levels.

The BOC MTC value for ARO will be inferred from isothermal temperature coefficient measurements obtained during the physics tests after refueling. The ARO value can be directly compared to the BOC MTC limit of the LCO. If required, measurement results and predicted design values can be used to establish administrative withdrawal limits for control banks.

SR 3.1.4.2 3.1.3.2 and SR 3.1.4.3

In similar fashion, the LCO demands that the MTC be less negative than the specified value for EOC full power conditions. This measurement may be performed at any THERMAL POWER, but its results must be extrapolated to the conditions of RTP and all banks withdrawn in order to make a proper comparison with the LCO value. Because the RTP MTC value will gradually become more negative with further core depletion and boron concentration reduction, a 300 ppm SR value of MTC should necessarily be less negative than the EOC LCO limit. The 300 ppm SR value is sufficiently less negative than the EOC LCO limit value to ensure that the LCO limit will be met when the 300 ppm Surveillance criterion is met.

SR 3.1.4.3 2 is modified by a ~~three~~ Notes that include the following requirements:

1. The SR is required to be performed once each cycle within 7 effective full power days (EFPDs) after reaching the equivalent of an equilibrium RTP all rods out (ARO) boron concentration of 300 ppm.

a2. If the 300 ppm Surveillance limit is exceeded, it is possible that the EOC limit on MTC could be reached before the planned EOC. Because the MTC changes slowly with core depletion, the Frequency of 14 EFPD is sufficient to avoid exceeding the EOC limit.

(Continued)

BASES

b3. The Surveillance limit for RTP boron concentration of 60 ppm is conservative. If the measured MTC at 60 ppm is less negative than the 60 ppm Surveillance limit, the EOC limit will not be exceeded because of the gradual manner in which MTC changes with core burnu.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.5 3.1.4

BASES

BACKGROUND

The OPERABILITY (i.e., trippability) of the shutdown and control rods is an initial assumption in all safety analyses that assume rod insertion upon reactor trip. Maximum rod misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," GDC 26, "Reactivity Control System Redundancy and Capability" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Plants" (Ref. 2).

Mechanical or electrical failures may cause a control rod to become inoperable or to become misaligned from its group. Control rod inoperability or misalignment may cause increased power peaking, due to the asymmetric reactivity distribution and a reduction in the total available rod worth for reactor shutdown. Therefore, control rod alignment and OPERABILITY are related to core operation in design power peaking limits and the core design requirement of a minimum SDM.

Limits on control rod alignment have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

Rod cluster control assemblies (RCCAs), or rods, are moved by their control rod drive mechanisms (CRDMs). Each CRDM moves its RCCA one step (approximately $\frac{1}{8}$ inch) at a time, but at varying rates (steps per minute) depending on the signal output from the Rod Control System.

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3-1.5 3-1.4

BASES

The RCCAs are divided among four control banks and four shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control. A group consists of two or more RCCAs that are electrically paralleled to step simultaneously. A bank of RCCAs consists of two groups that are moved in a staggered fashion, but always within one step of each other. All units have four control banks and at least two shutdown banks. Control banks contain two rod groups. Two shutdown banks (A and B) contain two rod groups and the remaining two shutdown banks (C and D) contain one rod group.

The shutdown banks are maintained either in the fully inserted or fully withdrawn position. The control banks are moved in an overlap pattern, using the following withdrawal sequence: When control bank A reaches a predetermined height in the core, control bank B begins to move out with control bank A. Control bank A stops at the position of maximum withdrawal, and control bank B continues to move out. When control bank B reaches a predetermined height, control bank C begins to move out with control bank B. This sequence continues until control banks A, B, and C are at the fully withdrawn position, and control bank D is approximately halfway withdrawn. The insertion sequence is the opposite of the withdrawal sequence. The control rods are arranged in a radially symmetric pattern, so that control bank motion does not introduce radial asymmetries in the core power distributions.

The axial position of shutdown rods and control rods is indicated by two separate and independent systems, which are the Bank Demand Position Indication System (commonly called group step counters) and the Digital Rod Position Indication (DRPI) System. The Bank Demand Position Indication System counts the pulses from the rod control system that moves the rods. There is one step counter for each group of rods. Individual rods in a

(Continued)

BASES

BACKGROUND
position (continued)

group all receive the same signal to move and should, therefore, all be at the same indicated by the group step counter for that group. The Bank Demand Position Indication System is considered highly precise (± 1 step or $\pm \frac{5}{8}$ inch). If a rod does not move one step for each demand pulse, the step counter will still count the pulse and incorrectly reflect the position of the rod.

The DRPI System provides a highly accurate indication of actual control rod position, but at a lower precision than the step counters. This system is based on inductive analog signals from a series of coils spaced along a hollow tube. To increase the reliability of the system, the inductive coils are connected alternately to data system A or B. Thus, if one data system fails, the DRPI will go on half accuracy with an effective coil spacing of 7.5 inches, which is 12 steps. Therefore, the normal indication accuracy of the DRPI System is ± 6 steps (± 3.75 inches), and the maximum uncertainty is ± 12 steps between the group step counter and DRPI, the maximum deviation between actual rod position and the demand position could be 24 steps, or 15 inches. The DRPI system is capable of monitoring rod position within at least ± 12 steps with either full accuracy or half accuracy.

APPLICABLE
SAFETY ANALYSIS

Control rod misalignment accidents are analyzed in the safety analysis (Ref. 3). The acceptance criteria for addressing rod inoperability or misalignment are that:

- a. There be no violations of:
 1. Specified acceptable fuel design limits, or
 2. Reactor Coolant System (RCS) pressure boundary integrity; and
- b. The core remains subcritical after accident transients.

Two types of misalignment are distinguished. During movement of a control or shutdown rod group, one rod may stop moving, while the other rods in the group continue. This condition may cause excessive power peaking. The second type of misalignment occurs if one rod fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition requires an evaluation to determine that sufficient reactivity worth is held in the rods to meet the SDM requirement, with the maximum worth rod stuck fully withdrawn.

(Continued)

BASES

Two types of analysis are performed in regard to static rod misalignment (Ref. 3). With control banks at their insertion limits, one type of analysis considers the case when any one rod is completely inserted into the core. The second type of analysis considers the case of a completely withdrawn single rod from a bank inserted to its insertion limit. Satisfying limits on departure from nucleate boiling ratio in both of these cases bounds the situation when a rod is misaligned from its group by 12 steps.

Another type of misalignment occurs if one RCCA fails to insert upon a reactor trip and remains stuck fully withdrawn. This condition is assumed in the evaluation to determine that the required SDM is met with the maximum worth RCCA also fully withdrawn (Ref. 4).

The Required Actions in this LCO ensure that either deviations from the alignment limits will be corrected or that THERMAL POWER will be adjusted so that excessive local linear heat rates (LHRs) will not occur, and that the requirements on SDM and ejected rod worth are preserved.

Continued operation of the reactor with a misaligned rod is allowed if the heat flux hot channel factor ($F_0(Z)$) and the nuclear enthalpy hot channel factor (F_{AH}^N) are verified to be within their limits in the COLR and the safety analysis is verified to remain valid. When a control rod is misaligned, the assumptions that are used to determine the rod

(Continued)

BASES

APPLICABLE
SAFETY ANALYSIS
(continued)

insertion limits, AFD limits, and quadrant power tilt limits are not preserved. Therefore, the limits may not preserve the design peaking factors, and $F_0(Z)$ and $F_{\Delta H}^N$ must be verified directly by incore mapping. Bases Section 3.2 (Power Distribution Limits) contains more complete discussions of the relation of $F_0(Z)$ and $F_{\Delta H}^N$ to the operating limits.

Shutdown and control rod OPERABILITY and alignment are directly related to power distributions and SDM, which are initial conditions assumed in safety analyses. Therefore they satisfy Criterion 2 of 10CFR50.36(c)(2)(ii).

LCO /

The limits on shutdown or control rod alignments ensure that the assumptions in the safety analysis will remain valid. The requirements on OPERABILITY ensure that upon reactor trip, the assumed reactivity will be available and will be inserted. The OPERABILITY requirements (i.e., trippability to meet SDM) are separate from the alignment requirements, which ensure that the RCCAs and banks maintain the correct power distribution and rod alignment. The rod OPERABILITY requirement is satisfied provided the rod will fully insert in the required time assumed in the safety analyses. Rod control malfunctions that result in the inability to move a rod (e.g., rod urgent failures), but do not impact trippability, do not necessarily result in rod inoperability.

The requirement to maintain the rod alignment to within plus or minus 12 steps of their group step counter demand position is conservative. The minimum misalignment assumed in safety analysis is 24 steps (15 inches), and in some cases a total misalignment from fully withdrawn to fully inserted is assumed.

The requirement to maintain rod alignment is met by comparing individual rod DRPI indication and bank demand position indication to be within plus or minus 12 steps. If one of these position indicators become inoperable, the conditions of this LCO are still met by compliance with LCO 3.1.7.

Failure to meet the requirements of this LCO may produce unacceptable power peaking factors and LHRs, or unacceptable SDMs, all of which may constitute initial conditions inconsistent with the safety analysis.

(Continued)

BASES

APPLICABILITY

The requirements on RCCA OPERABILITY and alignment are applicable in MODES 1 and 2 because these are the only MODES in which neutron (or fission) power is generated, and the OPERABILITY (i.e., trippability) and alignment of rods have the potential to affect the safety of the plant. In MODES 3, 4, 5, and 6, the alignment limits do not apply because the control rods are typically fully inserted and the reactor is shut down and not producing fission power. In the shutdown MODES, the OPERABILITY of the shutdown and control rods has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the RCS. See LCO 3.1.1, "SHUTDOWN MARGIN (SDM) $\geq 200^\circ\text{F}$," for SDM in MODES 2 with $K_{eff} < 1.0$, 3, 4, and 5 and LCO 3.9.1, "Boron Concentration," for boron concentration requirements during refuelin.

ACTIONS

A.1.1 and A.1.2

When one or more rods are inoperable (i.e., untrippable), there is a possibility that the required SDM may be adversely affected. Under these conditions, it is important to determine the SDM, and if it is less than the required value, initiate boration until the required SDM is recovered. The Completion Time of 1 hour is adequate for determining SDM and, if necessary, for initiating emergency boration and restoring SDM.

With an inoperable rod(s), this ACTION provides for verification of SDM; this is most simply accomplished by verifying rod insertion limits are met. Additionally, actions could include calculation of the current SDM and boration to meet limits specified in the COR or proceed

(Continued)

BASES

ACTION
(continued)

to MODE 3. These actions are consistent with those specified in LCO 3.1.5 and LCO 3.1.6.

A rod is considered trippable if it was demonstrated OPERABLE during the last performance of SR 3.1.4.2 and met the rod drop time criteria during the last performance of SR 3.1.4.3.

In this situation, SDM verification must account for the absence of the negative reactivity of the untrippable rod(s), as well as the rod of maximum worth.

A.2

If the inoperable rod(s) cannot be restored to OPERABLE status, the plant must be brought to a MODE or condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.

The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

B.1

When a rod becomes misaligned, it can usually be moved and is still trippable (i.e., OPERABLE). If the rod can be realigned within the Completion Time of 1 hour, local xenon redistribution during this short interval will not be significant, and operation may proceed without further restriction.

An alternative to realigning a single misaligned RCCA to the group demand position is to align the remainder of the group to the position of the misaligned RCCA. However, this must be done without violating the bank sequence, overlap, and insertion limits specified in LCO 3.1.6 3.1.5, "Shutdown Bank Insertion Limits," and LCO 3.1.7 3.1.6, "Control Bank Insertion Limits." The Completion Time of 1 hour gives the operator sufficient time to adjust the rod positions in an orderly manner.

B.2.1.1 and B.2.1.2

With a misaligned rod, SDM must be verified to be within limit or boration must be initiated to restore SDM to within limit.

(Continued)

BASES

In many cases, realigning the remainder of the group to the misaligned rod may not be desirable. For example, realigning control bank B to a rod that is misaligned 15 steps from the top of the core would require a significant power reduction, since control bank D must be fully inserted and control bank C must be inserted to approximately 100 steps to 115 steps.

Power operation may continue with one RCCA OPERABLE (i.e. trippable) but misaligned, provided that SDM is verified within 1 hour. The Completion Time of 1 hour represents the time necessary for determining the actual unit SDM and, if necessary, aligning and starting the necessary systems and components to initiate boration.

B.2.2, B.2.3, B.2.4, B.2.5, and B.2.6

For continued operation with a misaligned rod, RTP reactor power must be reduced, SDM must periodically be verified within limits, hot channel factors ($F_0(Z)$ and $F_{\Delta H}^N$) must be verified within limits, and the safety analyses must be re-evaluated to confirm continued operation is permissible. Reduction of power to 75% RTP ensures that local LHR increases due to a misaligned RCCA will not cause the core design criteria to be exceeded (Ref. 3). The Completion

(Continued)

BASES

ACTION
 reduction
 (continued)

Time of 2 hours gives the operator sufficient time to accomplish an orderly power without challenging the Reactor Protection System.

When a rod is known to be misaligned, there is a potential to impact the SDM. Since the core conditions can change with time, periodic verification of SDM is required. A Frequency of 12 hours is sufficient to ensure this requirement continues to be met.

Verifying that $F_0(Z)$ and $F_{\Delta H}^N$ are within the required limits ensures that current operation at 75% RTP with a rod misaligned is not resulting in power distributions that may invalidate safety analysis assumptions at full power. The Completion Time of 72 hours allows sufficient time to obtain flux maps of the core power distribution using the incore flux mapping system and to calculate $F_0(Z)$ and $F_{\Delta H}^N$.

Once current conditions have been verified acceptable, time is available to perform evaluations of accident analysis to determine that core limits will not be exceeded during a Design Basis Event for the duration of operation under these conditions. A Completion Time of 5 days is sufficient time to obtain the required input data and to perform the analysis.

The following accident analyses require re-evaluation for continued operation with a misaligned rod:

Rod Cluster Control Assembly Insertion Characteristics

Rod Cluster Control Assembly Misalignment

Loss of Reactor Coolant from Small Ruptured Pipes or from Cracks in Large Pipes Which Actuate the Emergency Core Cooling System

Single Rod Cluster Control Assembly Withdrawal at Full Power

Major Reactor Coolant System Pipe Ruptures (Loss of Coolant Accident)

Major Secondary Coolant System Pipe Rupture

Rupture of a Control Rod Drive Mechanism Housing (Rod Cluster Control Assembly Ejection)

(Continued)

BASES

C.1

When Required Actions cannot be completed within their Completion Time, the unit must be brought to a MODE or Condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours, which obviates concerns about the development of undesirable xenon or power distributions. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging the plant systems.

D.1.1 and D.1.2

More than one control rod becoming misaligned from its group-average demand position is not expected, and has the potential to reduce SDM. Therefore, SDM must be evaluated. One hour allows the operator adequate time to determine SDM. Restoration of the required SDM, if necessary, requires increasing the RCS boron concentration to provide negative reactivity, as described in the Bases of LCO 3.1.1. The required Completion Time of 1 hour for initiating boration is reasonable, based on the time required for potential xenon redistribution, the low probability of an accident occurring, and the steps required to

(Continued)

BASES

ACTIONS
and (continued)

complete the action. This allows the operator sufficient time to align the required valves start the boric acid pumps. Boration will continue until the required SDM is restored.

Additionally, the requirements of LCO 3.1.5, "Shutdown Bank Insertion Limits," and LCO 3.1.6, "Control Bank Insertion Limits," apply if the misaligned rods are not within the required insertion limits.

D.2

If more than one rod is found to be misaligned or becomes misaligned because of bank movement, the unit conditions fall outside of the accident analysis assumptions. Since automatic bank sequencing would continue to cause misalignment, the unit must be brought to a MODE or Condition in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.

The allowed Completion Time is reasonable, based on operating experience, for reaching MODE 3 from full power conditions in an orderly manner and without challenging plant system.

SURVEILLANCE
REQUIREMENTS

SR 3.1.5.1 3.1.4

Verification that individual rod positions are within alignment limits at a Frequency of 12 hours provides a history that allows the operator to detect a rod that is beginning to deviate from its expected position. ~~If the rod position deviation monitor is inoperable, a Frequency of 4 hours accomplishes the same goal.~~ The specified Frequency takes into account other rod position information that is continuously available to the operator in the control room, so that during actual rod motion, deviations can immediately be detected.

(Continued)

BASES

SR 3-1-5-2 3-1-4-2

Verifying each rod is OPERABLE would require that each rod be tripped. However, in MODES 1 and 2, tripping each rod would result in radial or axial power tilts, or oscillations. Exercising each individual rod every 92 days provides confidence that all rods continue to be OPERABLE without exceeding the alignment limit, even if they are not regularly tripped. Moving each rod by 10 steps will not cause radial or axial power tilts, or oscillations, to occur. The 92 day Frequency takes into consideration other information available to the operator in the control room and SR 3-1-5-1 3-1-4-1, which is performed more frequently and adds to the determination of OPERABILITY of the rods. Between or during required performances of SR 3-1-5-2 3-1-4-2 (determination of rod OPERABILITY by movement), if a rod(s) is discovered to be immovable, but remains trippable, the rod(s) is considered to be OPERABLE. At any time, if a rod(s) is immovable, a determination of the trippability (OPERABILITY) of the rod(s) must be made, and appropriate action taken.

SR 3-1-5-3 3-1-4-3

Verification of rod drop times allows the operator to determine that the maximum rod drop time permitted is consistent with the assumed rod drop time used in the safety analysis. Measuring rod drop times prior to reactor criticality, after reactor vessel head removal, ensures that the reactor internals and rod drive mechanism will not interfere with rod motion or rod drop time, and that no degradation in these systems has occurred that would adversely affect rod motion or drop time. This testing is performed with all RCPs operating and the average moderator temperature $\geq 500^{\circ}\text{F}$ to simulate a reactor trip under actual conditions.

(Continued)

BASES

This Surveillance is performed during a plant outage, due to the plant conditions needed to perform the SR and the potential for an unplanned plant transient if the Surveillance were performed with the reactor at power.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3-1.6 3-1.5 Shutdown Bank Insertion Limits

BASES

BACKGROUND

The insertion limits of the shutdown and control rods are initial assumptions in all safety analyses that assume rod insertion upon reactor trip. The insertion limits directly affect core power and fuel burnup distributions and assumptions of available ejected rod worth, SDM and initial reactivity insertion rate.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," GDC 26, "Reactivity Control System Redundancy and Capability," GDC 28, "Reactivity Limits" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 2). Limits on rod insertion have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

The rod cluster control assemblies (RCCAs) are divided among four control banks and four shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control. A group consists of two or more RCCAs that are electrically paralleled to step simultaneously. A bank of RCCAs consists of two groups that are moved in a staggered fashion, but always within one step of each other. ~~All plants have four control banks and at least two shutdown banks.~~ ~~four control banks contain two rod groups. Two shutdown banks (A and B) contain two rod groups and the remaining two shutdown banks (C and D) consist of a single group.~~ See LCO 3-1.6 3-1.4, "Rod Group Alignment Limits," for control and shutdown rod OPERABILITY and alignment requirements, and LCO 3-1.8 3-1.7, "Rod Position Indication," for position indication requirements.

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.6 3.1.5 Shutdown Bank Insertion Limits

BASES

The control banks are used for precise reactivity control of the reactor. The positions of the control banks are normally automatically controlled by the Rod Control System, but they can also be manually controlled. They are capable of adding negative reactivity very quickly (compared to borating). The control banks must be maintained above designed insertion limits and are typically near the fully withdrawn position during normal full power operations. Hence, they are not capable of adding a large amount of positive reactivity. Boration or dilution of the Reactor Coolant System (RCS) compensates for the reactivity changes associated with large changes in RCS temperature. The design calculations are performed with the assumption that the shutdown banks are withdrawn first. The shutdown banks can be fully withdrawn without the core going critical. This provides available negative reactivity in the event of boration errors. The shutdown banks are controlled manually by the control room operator. During normal unit operation, the shutdown banks are either fully withdrawn or fully inserted. The shutdown banks must be completely withdrawn from the core, prior to withdrawing any control banks during an approach to criticality. The shutdown banks are then left in this position until the reactor is shut down. They affect core power and burnup distribution, and add negative reactivity to shut down the reactor upon receipt of a reactor trip signal.

APPLICABLE
SAFETY ANALYSIS

On a reactor trip, all RCCAs (shutdown banks and control banks), except the most reactive RCCA, are assumed to insert into the core. The shutdown banks shall be at or above their insertion limits and available to insert the maximum amount of negative reactivity on a reactor trip signal. The control banks may be partially inserted in the core, as allowed by LCO 3.1.7 3.1.6, "Control Bank Insertion Limits." The shutdown bank and control bank insertion limits are established to ensure that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM (see LCO 3.1.1, "SHUTDOWN MARGIN - (SDM) $T_{avg} > 200^{\circ}\text{F}$," and LCO 3.1.2, "SHUTDOWN MARGIN (SDM) $T_{avg} < 200^{\circ}\text{F}$ ") following a reactor trip from full power. The combination of control banks and shutdown banks (less the most reactive RCCA, which is assumed to be fully withdrawn) is sufficient to take the reactor from full power conditions at rated temperature to zero power, and to

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.6 ~~3.1.5~~ Shutdown Bank Insertion Limits

BASES

APPLICABLE
SAFETY ANALYSIS
(Continued)

maintain the required SDM at rated no load temperature (Ref. 3). The shutdown bank insertion limit also limits the reactivity worth of an ejected shutdown rod.

The acceptance criteria for addressing shutdown and control rod bank insertion safety limits and inoperability or misalignment is that:

- a. There be no violations of:
 1. Specified acceptable fuel design limits, or
 2. RCS pressure boundary integrity; and
- b. The core remains subcritical after accident transients.

As such, the shutdown bank insertion limits affect safety analysis involving core reactivity and SDM (Ref. 3).

The shutdown bank insertion limits preserve an initial condition assumed in the safety analyses and, as such, satisfy Criterion 2 of ~~10CFR50.36(c)(2)(ii)~~.

LCO

The shutdown banks must be within their insertion limits any time the reactor is critical or approaching criticality. This ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip.

The shutdown bank insertion limits are defined in the COLR.

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B ~~3.1.6~~ 3.1.5 Shutdown Bank Insertion Limits

BASES

APPLICABILITY

The shutdown banks must be within their insertion limits, with the reactor in MODES 1 and 2. The applicability in MODE 2 begins at initial control bank withdrawal, during an approach to criticality, and continues throughout MODE 2, until all control bank rods are again fully inserted by reactor trip or by shutdown. This ensures that a sufficient amount of negative reactivity is available to shut down the reactor and maintain the required SDM following a reactor trip. The shutdown banks do not have to be within their insertion limits in MODE 3, unless an approach to criticality is being made. In MODE 3, 4, 5, or 6, the shutdown banks are typically fully inserted in the core and contribute to the SDM. Refer to LCO 3.1.1 and ~~LCO 3.1.2~~ for SDM requirements in MODES 2 with ~~K_{eff} > 1.0~~ 3, 4, and 5. LCO 3.9.1, "Boron Concentration," ensures adequate SDM in MODE 6.

The Applicability requirements have been modified by a Note indicating the LCO requirement is suspended during SR 3.1.5-24.2. This SR verifies the freedom of the rods to move, and requires the shutdown bank to move below the LCO limits, which would normally violate the LCO.

ACTIONS .

A.1.1, A.1.2 and A.2

When one or more shutdown banks is not within insertion limits, 2 hours is allowed to restore the shutdown banks to within the insertion limits. This is necessary because the available SDM may be significantly reduced, with one or more of the shutdown banks not within their insertion limits. Also, verification of SDM or initiation of boration within 1 hour is required, since the SDM in MODES 1 and 2 is ensured by adhering to the control and shutdown bank insertion limits (see LCO 3.1.1). If shutdown banks are not within their insertion limits, then SDM will be verified by performing a reactivity balance calculation, considering the effects listed in the Bases for SR 3.1.1.1.

The allowed Completion Time of 2 hours provides an acceptable time for evaluating and repairing minor problems without allowing the plant to remain in an unacceptable condition

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3-1-6 3-1-5 Shutdown Bank Insertion Limits

BASES

ACTIONS
(continued)

for an extended period of time. Additionally, the requirements of LCO 3-1-5 3-1-4, "Rod Group Alignment Limits," apply if one or more shutdown rods are not within the required alignment limits.

B.1

If the shutdown banks cannot be restored to within their insertion limits within 2 hours, the unit must be brought to a MODE where the LCO is not applicable. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3-1-6-1 3-1-5-1

Verification that the shutdown banks are within their insertion limits prior to an approach to criticality ensures that when the reactor is critical, or being taken critical, the shutdown banks will be available to shut down the reactor, and the required SDM will be maintained following a reactor trip. This SR and Frequency ensure that the shutdown banks are withdrawn before the control banks are withdrawn during a unit startup.

Since the shutdown banks are positioned manually by the control room operator, a verification of shutdown bank position at a Frequency of 12 hours, after the reactor is taken critical, is adequate to ensure that they are within their insertion limits. Also, the 12 hour Frequency takes into account other information available in the control room for the purpose of monitoring the status of shutdown rods.

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.7 3.1.6 Control Bank Insertion Limits

BASES

BACKGROUND

The insertion limits of the shutdown and control rods are initial assumptions in all safety analyses that assume rod insertion upon reactor trip. The insertion limits directly affect core power and fuel burnup distributions and assumptions of available SDM, and initial reactivity insertion rate.

The applicable criteria for these reactivity and power distribution design requirements are 10 CFR 50, Appendix A, GDC 10, "Reactor Design," GDC 26, "Reactivity Control System Redundancy and Capability," GDC 28, "Reactivity Limits" (Ref. 1), and 10 CFR 50.46, "Acceptance Criteria for Emergency Core Cooling Systems for Light Water Nuclear Power Reactors" (Ref. 2). Limits on rod insertion have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

The rod cluster control assemblies (RCCAs) are divided among four control banks and four shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control. A bank of RCCAs consists of two groups that are moved in a staggered fashion, but always within one step of each other. All plants have four control banks and at least two shutdown banks. A group consists of two or more RCCAs that are electrically paralleled to step simultaneously and are moved in a staggered fashion, but always within one step of each other. Two shutdown banks (C and D) consist of a single group. See LCO 3.1.6 3.1.4, "Rod Group Alignment Limits," for control and shutdown rod OPERABILITY and alignment requirements, and LCO 3.1.8 3.1.7, "Rod Position Indication," for position indication requirements.

The control bank insertion limits are specified in the COLR. An example is provided for information only in Figure B 3.1.7 1. The control banks are required to be at or above the insertion limit lines.

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3-1.7 3-1.6 Control Bank Insertion Limits

BASES

Figure B 3-1.7-1 The COLR also indicates how the control banks are moved in an overlap pattern. Overlap is the distance traveled together by two control banks. The predetermined position of control bank C, at which control bank D will begin to move with bank C on a withdrawal, will be at 118 steps for a fully withdrawn position of 231 steps. The fully withdrawn position is defined in the COLR. The control banks are used for precise reactivity control of the reactor. The positions of the control banks can be controlled manually, or automatically by the Rod Control System. They are capable of altering reactivity very quickly (compared to borating or diluting).

The power density at any point in the core must be limited, so that the fuel design criteria are maintained. Together, LCO 3-1.5 3-1.4, "Rod Group Alignment Limits," LCO 3-1.6 3-1.5, "Shutdown Bank Insertion Limits," LCO 3-1.7 3-1.6, "Control Bank Insertion Limits," LCO 3.2.3, "AXIAL FLUX DIFFERENCE (AFD)," and LCO 3.2.4, "QUADRANT POWER TILT RATIO (QPTR)," provide limits on control component operation and on monitored process variables, which ensure that the core operates within the fuel design criteria.

The shutdown and control bank insertion and alignment limits, AFD, and QPTR are process variables that together characterize and control the three dimensional power distribution of the reactor core. Additionally, the control bank insertion limits control the reactivity that could be added in the event of a rod ejection accident, and the shutdown and control bank insertion limits ensure the required SDM is maintained assuming LCO 3-1.2 Core Reactivity is met for core reactivity.

Operation within the subject LCO limits will prevent fuel cladding failures that would breach the primary fission product barrier and release fission products to the reactor coolant in the

(Continued)

BASES

BACKGROUND

event of a loss of coolant accident (LOCA), loss of flow, ejected rod, or other accident (continued) requiring termination by a Reactor Trip System (RTS) trip function.

APPLICABLE
SAFETY ANALYSES

The shutdown and control bank insertion limits, AFD, and QPTR LCOs are required to prevent power distributions that could result in fuel cladding failures in the event of a LOCA, loss of flow, ejected rod, or other accident requiring termination by an RTS trip function.

The acceptance criteria for addressing shutdown and control bank insertion limits and inoperability or misalignment are that:

- a. There be no violations of:
 - 1. Specified acceptable fuel design limits, or
 - 2. Reactor Coolant System pressure boundary integrity; and
- b. The core remains subcritical after accident transients.

As such, the shutdown and control bank insertion limits affect safety analysis involving core reactivity and power distributions (Ref. 3).

The SDM requirement is ensured by limiting the control and shutdown bank insertion limits so that allowable inserted worth of the RCCAs is such that sufficient reactivity is available in the rods to shut down the reactor to hot zero power with a reactivity margin that assumes the maximum worth RCCA remains fully withdrawn upon trip (Ref. 4).

Operation at the insertion limits or AFD limits may approach the maximum allowable linear heat generation rate or peaking factor with the allowed QPTR present. Operation at the insertion limit may also indicate the maximum ejected RCCA worth could be equal to the limiting value in fuel cycles that have sufficiently high ejected RCCA worths.

The control and shutdown bank insertion limits ensure that safety analyses assumptions for SDM, ejected rod worth, and power distribution peaking factors are preserved (Ref. 5).

The insertion limits satisfy Criterion 2 of 10CFR50.36(c)(2)(1), in that they are initial conditions assumed in the safety analysis.

(Continued)

BASES

LCO

The limits on control banks sequence, overlap, and physical insertion, as defined in the COLR, must be maintained because they serve the function of preserving power distribution, ensuring that the SDM is maintained, ensuring that ejected rod worth is maintained, and ensuring adequate negative reactivity insertion is available on trip. The overlap between control banks provides more uniform rates of reactivity insertion and withdrawal and is imposed to maintain acceptable power peaking during control bank motion.

APPLICABILITY

The control bank sequence, overlap, and physical insertion limits shall be maintained with the reactor in MODES 1 and 2 with $k_{eff} \geq 1.0$. These limits must be maintained, since they preserve the assumed power distribution, ejected rod worth, SDM, and reactivity rate insertion assumptions. Applicability in MODES 3, 4, and 5 is not required, since neither the power distribution nor ejected rod worth assumptions would be exceeded in these MODES.

The applicability requirements have been modified by a Note indicating the LCO requirements are suspended during the performance of SR 3.1.5-212. This SR verifies the freedom of the rods to move, and requires the control bank to move below the LCO limits, which would violate the LCO.

(Continued)

BASES

ACTIONS

A.1.1, A.1.2, A.2, B.1.1, B.1.2, and B.2

When the control banks are outside the acceptable insertion limits, they must be restored to within those limits. This restoration can occur in two ways:

- a. Reducing power to be consistent with rod position; or
- b. Moving rods to be consistent with power.

Also, verification of SDM or initiation of boration to regain SDM is required within 1 hour, since the SDM in MODES 1 and 2 normally ensured by adhering to the control and shutdown bank insertion limits (see LCO 3.1.1, "SHUTDOWN MARGIN - (SDM) \rightarrow 200°F") has been upset. If control banks are not within their insertion limits, then SDM will be verified by performing a reactivity balance calculation, considering the effects listed in the Bases for SR 3.1.1.1.

Similarly, if the control banks are found to be out of sequence or in the wrong overlap configuration, they must be restored to meet the limits. Failure of sequence or overlap support equipment does not require entering the ACTIONS as long as sequence and overlap limits are maintained.

Operation beyond the LCO limits is allowed for a short time period in order to take conservative action because the simultaneous occurrence of either a LOCA, loss of flow accident, ejected rod accident, or other accident during this short time period, together with an inadequate power distribution or reactivity capability, has an acceptably low probability.

The allowed Completion Time of 2 hours for restoring the banks to within the insertion, sequence, and overlap limits provides an acceptable time for evaluating and repairing minor problems without allowing the plant to remain in an unacceptable condition for an extended period of time.

Additionally, the requirements of LCO 3.1.4, "Rod Group Alignment Limits," apply if one or more control rods are not within the required alignment limits.

(Continued)

BASES

C.1

If Required Actions A.1 and A.2, or B.1 and B.2 cannot be completed within the associated Completion Times, the plant must be brought to MODE 3, where the LCO is not applicable. The allowed Completion Time of 6 hours is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3.1.7-16.1

This Surveillance is required to ensure that the reactor does not achieve criticality with the control banks below their insertion limits.

The estimated critical position (ECP) depends upon a number of factors, one of which is xenon concentration. If the ECP was calculated long before criticality, xenon concentration could change to make the ECP substantially in error. Conversely, determining the ECP immediately before criticality could be an unnecessary burden. There are a number of unit parameters requiring operator attention at that point. Performing the ECP calculation within 4 hours prior to criticality avoids a large error from changes in xenon concentration, but allows the operator some flexibility to schedule the ECP calculation with other startup activities.

(Continued)

BASES

SURVEILLANCE
REQUIREMENT

SR 3.1.7-26.2

Verification of the control bank insertion limits at a Frequency of 12 hours is sufficient to ensure OPERABILITY and to detect control banks that may be approaching the insertion (continued) limits since, normally, very little rod motion occurs in 12 hours. ~~If the insertion limit monitor becomes inoperable, verification of the control bank position at a frequency of 4 hours is sufficient to detect control banks that may be approaching the insertion limits.~~

SR 3.1.7-36.3

When control banks are maintained within their insertion limits as checked by SR ~~3.1.7-2 3.1.6.2~~ above, it is unlikely that their sequence and overlap will not be in accordance with requirements provided in the COLR. ~~The verification of compliance with the sequence and overlap limits specified in the COLR consists of an observation that the static rod positions of those control banks not fully withdrawn from the core are within the limits specified in the COLR. Bank sequence and overlap must also be maintained during rod movement, implicit within the LCO. A Frequency of 12 hours is consistent with the insertion limit check above in SR ~~3.1.7.2 3.1.6.2~~.~~

B 3.1 REACTIVITY CONTROL SYSTEM

B 3.1-8 3.17 Rod Position Indication

BASES

BACKGROUND

According to GDC 13 (Ref. 1), instrumentation to monitor variables and systems over their operating ranges during normal operation, anticipated operational occurrences, and accident conditions must be OPERABLE. LCO 3.1-8 3.17 is required to ensure OPERABILITY of the control rod position indicators to determine control rod positions and thereby ensure compliance with the control rod alignment and insertion limits.

The OPERABILITY, including position indication, of the shutdown and control rods is an initial assumption in all safety analyses that assume rod insertion upon reactor trip. Maximum rod misalignment is an initial assumption in the safety analysis that directly affects core power distributions and assumptions of available SDM. Rod position indication is required to assess OPERABILITY and misalignment.

Mechanical or electrical failures may cause a control rod to become inoperable or to become misaligned from its group. Control Rod inoperability or misalignment may cause increased power peaking, due to the asymmetric reactivity distribution and a reduction in the total available rod worth for reactor shutdown. Therefore, control rod alignment and OPERABILITY are related to core operation in design power peaking limits and the core design requirement of a minimum SDM.

Limits on control rod alignment and OPERABILITY have been established, and all rod positions are monitored and controlled during power operation to ensure that the power distribution and reactivity limits defined by the design power peaking and SDM limits are preserved.

Rod cluster control assemblies (RCCAs), or rods, are moved out of the core (up or withdrawn) or into the core (down or inserted) by their control rod drive mechanisms. The RCCAs are divided among four control banks and four shutdown banks. Each bank may be further subdivided into two groups to provide for precise reactivity control.

The axial position of shutdown rods and control rods are determined by two separate and independent systems: the Bank Demand Position Indication System (commonly called group step counters) and the Digital Rod Position Indication (DRPI) System.

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEM

B 3-1-8 3-17 Rod Position Indication

BASES

The Bank Demand Position Indication System counts the pulses from the Rod Control System that move the rods. There is one step counter for each group of rods. Individual rods in a group all receive the same signal to move and should, therefore, all be at the same position indicated by the group step counter for that group. The Bank Demand Position Indication System is considered highly precise (± 1 step or $\pm \frac{5}{8}$ inch). If a rod does not move one step for each demand pulse, the step counter will still count the pulse and incorrectly reflect the position of the rod.

The DRPI System provides a highly accurate indication of actual ~~control rod position~~, but at a lower precision than the step counters. This system is based on inductive analog signals from a series of coils spaced along a hollow tube with a center to center distance of 3.75 inches, which is 6 steps. To increase the reliability of the system, the inductive coils are connected alternately to data system A or B. Thus, if one data system fails, the DRPI will go on half accuracy with an effective coil spacing of 7.5 inches, which is 12 steps. Therefore, the normal indication accuracy of DRPI System is ~~± 6 steps (± 3.75 inches), and the maximum uncertainty is ± 12 step (± 7.5 inches).~~ With an indicated deviation of 12 steps between the group step counter and DRPI, the maximum deviation between actual rod position and the demand position and the demand position could be 24 steps or 15 inches. The DRPI system is capable of monitoring rod position within at least ± 12 steps with either full accuracy or half accuracy.

(Continued)

BASES

APPLICABLE
SAFETY ANALYSIS

Control and shutdown rod position accuracy is essential during power operation. Powerpeaking, ejected rod worth, or SDM limits may be violated in the event of a Design Basis Accident (Ref. 2), with control or shutdown rods operating outside their limits undetected. Therefore, the acceptance criteria for rod position indication is that rod positions must be known with sufficient accuracy in order to verify the core is operating within the bank sequence, overlap, design peaking limits, ejected rod worth, and with minimum SDM (LCO 3.1.6 3.1.5, "Shutdown Bank Insertion Limits," and LCO 3.1.7 3.1.6, "Control Bank Insertion Limits"). The rod positions must also be known in order to verify the alignment limits are preserved (LCO 3.1.5 3.1.4, "Rod Group Alignment Limits"). Control Rod positions are continuously monitored to provide operators with information that ensures the plant is operating within the bounds of the accident analysis assumptions.

The control rod position indicator channels satisfy Criterion 2 of 10CFR50.36(c)(2)(ii). The control rod position indicators monitor control rod position, which is an initial condition of the accident.

LCO

LCO 3.1.8 3.1.7 specifies that the DRPI System and the Bank Demand Position Indication System be OPERABLE for each control rod. For the control rod position indicators to be OPERABLE requires meeting the SR of the LCO and the following:

- a. The DRPI System on either full accuracy or half accuracy indicates within 12 steps of the group step counter demand position as required by LCO 3.1.5 3.1.4, "Rod Group Alignment Limits"; and
- b. The Bank Demand Indication System has been reset in the fully inserted position, fully withdrawn position or to the DRPI System.

The 12 step agreement limit between the Bank Demand Position Indication System and the DRPI System indicates that the Bank Demand Position Indication System is adequately calibrated, and can be used for indication of the measurement of control rod bank position.

A deviation of less than the allowable limit, given in LCO 3.1.5 3.1.4, in position indication for a single rod, ensures high confidence that the position uncertainty of the corresponding control rod group is within the assumed values used in the analysis (that specified control rod group insertion limits).

(Continued)

BASES

These requirements ensure that ~~control~~ rod position indication during power operation and PHYSICS TESTS is accurate, and that design assumptions are not challenged. OPERABILITY of the position indicator channels ensures that inoperable, misaligned, or mispositioned ~~control~~ rods can be detected. Therefore, power peaking, ejected rod worth, and SDM can be controlled within acceptable limits.

APPLICABILITY

The requirements on the DRPI and step counters are only applicable in MODES 1 and 2 (consistent with LCO 3-1-5 3-1-4, LCO 3-1-6 3-1-5, and LCO 3-1-7 3-1-6), because these are the only MODES in which power is generated, and the OPERABILITY and alignment of rods have the potential to affect the safety of the plant. In the shutdown MODES, the OPERABILITY of the shutdown and control banks has the potential to affect the required SDM, but this effect can be compensated for by an increase in the boron concentration of the Reactor Coolant System.

ACTIONS

The ACTIONS table is modified by a Note indicating that a separate Condition entry is allowed for each inoperable rod position indicator and each demand position indicator per bank. This is acceptable because the Required Actions for each Condition provide appropriate compensatory actions for each inoperable position indicator.

(Continued)

BASES

ACTIONS
(continued)

A.1

When one DRPI per group fails, the position of the rod may still be determined indirectly by use of the movable incore detectors. The Required Action may also be ensuring at least once per hours that F_{ij} satisfies LCO 3.2.1, F_{ij} satisfies LCO 3.2.2, and SDM is within the limits provided in the COLR, provided the nonindicating rods have not been moved. Based on experience, normal power operation does not require excessive movement of banks. If a bank has been significantly moved, the Required Action of C.1 or C.2 below is required. Therefore, verification of RCCA position within the Completion Time of 8 hours is adequate for allowing continued full power operation, since the probability of simultaneously having a rod significantly out of position and an event sensitive to that rod position is small.

A.2

Reduction of THERMAL POWER to $\leq 50\%$ RTP puts the core into a condition where rod position is not significantly affecting core peaking factors (Ref. 3).

The allowed Completion Time of 8 hours is reasonable, based on operating experience, for reducing power to $\leq 50\%$ RTP from full power conditions without challenging plant systems and allowing for rod position determination by Required Action A.1 above.

B.1 and B.2

When more than one DRPI per group fail, additional actions are necessary to ensure that acceptable power distribution limits are maintained, minimum SDM is maintained, and the potential effects of rod misalignment on associated accident analyses are limited. The indirect position determination available via movable incore detectors will minimize the potential for rod misalignment.

(Continued)

BASES

The position of the rods can be determined indirectly by use of the movable incore detectors. The Required Action may also be satisfied by ensuring at least once per 8 hours that F_0 satisfies LCO 3.2.1, F_H satisfies LCO 3.2.2, and SHUTDOWN MARGIN is within the limits provided in the CLR, provided that the nonindicating rods have not moved. Verification of RCCA position once per 8 hours is adequate for allowing continued full power operation for a limited, 24 hour period, since the probability of simultaneously having a rod significantly out of position and an event sensitive to that rod position is small. The 24 hour Allowed Outage Time provides sufficient time to troubleshoot and restore the DRPI system to operation while avoiding the plant challenges associated with a shutdown without full rod position indication.

Based on operating experience, normal power operation does not require excessive rod movement. If one or more control rods has been significantly moved, the Required Action of C.1 or C.2 below is required.

B.1 and B.2C.1 and C.2

These Required Actions clarify that when one or more rods with inoperable position indicators DRPIs have been moved in excess of 24 steps in one direction, since the position was last determined, the Required Actions of A.1 and A.2 or B.1 are still appropriate but must be initiated promptly under Required Action B.1 C.1 to begin indirectly verifying that these rods are still properly positioned, relative to their group positions.

If, within 4 hours, the rod positions have not been determined, THERMAL POWER must be reduced to $\leq 50\%$ RTP within 8 hours to avoid undesirable power distributions that could result from continued operation at $> 50\%$ RTP, if one or more rods are misaligned by

(Continued)

BASES

more than 24 steps. The allowed Completion Time of 4 hours provides an acceptable period of time to verify the rod positions using the movable incore detectors.

C.1.1 and C.1.2D.1.1 and D.1.2

With one demand position indicator per bank inoperable, the rod positions can be determined by the DRPI System. Since normal power operation does not require excessive movement of rods, verification by administrative means that the rod position indicators are

(Continued)

BASES

ACTIONS
 (continued)

OPERABLE and the most withdrawn rod and the least withdrawn rod are ≤ 12 steps apart within the allowed Completion Time of once every 8 hours is adequate.

C.2D.2

Reduction of THERMAL POWER to $\leq 50\%$ RTP puts the core into a condition where rod position is not significantly affecting core peaking factors limits (Ref. 3). The allowed Completion Time of 8 hours provides an acceptable period of time to verify the rod positions per Required Actions C.1.1 D.1.1 and C.1.2 D.1.2 or reduce power to $\leq 50\%$ RTP.

D.1E.1

If the Required Actions cannot be completed within the associated Completion Time, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. The allowed Completion Time is reasonable, based on operating experience, for reaching the required MODE from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
 REQUIREMENTS

SR 3.1.8.1

Verification that the DRPI agrees with the demand position within 12 steps ensures that the DRPI is operating correctly. Verification at 24, 48, 120, and 228 steps withdrawn for the control and shutdown banks provides assurance that the DRPI is operating correctly over the full range of indication. ~~Since the DRPI does not display the actual shutdown rod positions between 18 and 210 steps, only points within the indicated ranges are required in comparison.~~

~~The 18 month frequency is based on the need to preform This surveillance under conditions that apply during a plant outage and the is performed prior to reactor criticality after each removal of the reactor head since there is potential for unnecessary plant transients if the SR were performed with the reactor at power. - Operating experience has shown these components usually pass the SR when performed at a Frequency of once every 18 months. Therefore, the frequency was concluded to be acceptable from a reliability standpoint.~~

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.10 PHYSICS TESTS Exceptions - MODE 2

BASES

BACKGROUND

The primary purpose of the MODE 2 PHYSICS TESTS exceptions is to permit relaxations of existing LCOs to allow certain PHYSICS TESTS to be performed.

Section XI of 10 CFR 50, Appendix B (Ref. 1), requires that a test program be established to ensure that structures, systems, and components will perform satisfactorily in service. All functions necessary to ensure that the specified design conditions are not exceeded during normal operation and anticipated operational occurrences must be tested. This testing is an integral part of the design, construction, and operation of the plant. Requirements for notification of the NRC, for the purpose of conducting tests and experiments, are specified in 10 CFR 50.59 (Ref. 2).

The key objectives of a test program are to (Ref. 3):

- a. Ensure that the facility has been adequately designed;
- b. Validate the analytical models used in the design and analysis;
- c. Verify the assumptions used to predict unit response;
- d. Ensure that installation of equipment in the facility has been accomplished in accordance with the design; and
- e. Verify that the operating and emergency procedures are adequate.

To accomplish these objectives, testing is performed prior to initial criticality, during startup, during low power operations, during power ascension, at high power, and after each refueling. The PHYSICS TESTS requirements for reload fuel cycles ensure that the operating characteristics of the core are consistent with the design predictions and that the core can be operated as designed (Ref. 4).

(Continued)

B 3.1 REACTIVITY CONTROL SYSTEMS

B 3.1.10 PHYSICS TESTS Exceptions - MODE 2

BASES

PHYSICS TESTS procedures are written and approved in accordance with established formats. The procedures include all information necessary to permit a detailed execution of the testing required to ensure that the design intent is met. PHYSICS TESTS are performed in accordance with these procedures and test results are approved prior to continued power escalation and long term power operation.

The PHYSICS TESTS required for reload fuel cycles (Ref. 4) in MODE 2 are listed below: typically include:

- a. Critical Boron Concentration - Control Rods Withdrawn;
- b. Critical Boron Concentration - Control Rods Inserted;
- c. Control Rod Worth; and
- d. Isothermal Temperature Coefficient (ITC). and
- e. Neutron Flux Symmetry.

The first four tests are performed in MODE 2, and the last test can be performed in either MODE 1 or 2. These and other supplementary tests may be required to calibrate the nuclear instrumentation or to diagnose operational problems. These tests may cause the

(Continued)

BASES

BACKGROUND
(continued)

- operating controls and process variables to deviate from their LCO requirements during their performance.
- a. ~~The Critical Boron Concentration Control Rods Withdrawn Test measures the critical boron concentration at hot zero power (HZP). With all rods out, the lead control bank is at or near its fully withdrawn position. HZP is where the core is critical ($k_{eff} = 1.0$), and the Reactor Coolant System (RCS) is at design temperature and pressure for zero power. Performance of this test should not violate any of the referenced LCOs.~~
- b. ~~The Critical Boron Concentration Control Rods Inserted Test measures the critical boron concentration at HZP, with a bank having a worth of at least 1% $\Delta k/k$ when fully inserted into the core. This test is used to measure the boron reactivity coefficient. With the core at HZP and all banks fully withdrawn, the boron concentration of the reactor coolant is gradually lowered in a continuous manner. The selected bank is then inserted to make up for the decreasing boron concentration until the selected bank has been moved over its entire range of travel. The reactivity resulting from each incremental bank movement is measured with a reactivity computer. The difference between the measured critical boron concentration with all rods fully withdrawn and with the bank inserted is determined. The boron reactivity coefficient is determined by dividing the measured bank worth by the measured boron concentration difference. Performance of this test could violate LCO 3.1.5, "Rod Group Alignment Limits"; LCO 3.1.6, "Shutdown Bank Insertion Limit"; or LCO 3.1.7, "Control Bank Insertion Limits."~~
- c. ~~The Control Rod Worth Test is used to measure the reactivity worth of selected control banks. This test is performed at HZP and has three alternative methods of performance. The first method, the Boron Exchange Method, varies the reactor coolant boron concentration and moves the selected control bank in response to the changing boron concentration. The reactivity changes are measured with a reactivity computer. This sequence is repeated for the remaining control banks. The second method, the Rod Swap Method, measures the worth of a predetermined reference bank using the Boron Exchange Method above. The reference bank is then nearly fully inserted into the core. The selected bank is then inserted into the core as the reference bank is withdrawn. The HZP critical conditions are then determined with the selected bank fully inserted into the core.~~

(Continued)

BASES

~~The worth of the selected bank is inferred, based on the position of the reference bank with respect to the selected bank. This sequence is repeated as necessary for the remaining control banks. The third method, the Boron Endpoint Method, moves the selected control bank over its entire length of travel and then varies the reactor coolant boron concentration to achieve HZP criticality again. The difference in boron concentration is the worth of the selected control bank. This sequence is repeated for the remaining control banks. Performance of this test could violate LCO 3.1.5, LCO 3.1.6, or LCO 3.1.7.~~

- d- ~~The ITC Test measures the ITC of the reactor. This test is performed at HZP and has two methods of~~

(Continued)

BASES

BACKGROUND
 (continued)

~~performance. The first method, the Slope Method, varies RCS temperature in a slow and continuous manner. The reactivity change is measured with a reactivity computer as a function of the temperature change. The ITC is the slope of the reactivity versus the temperature plot. The test is repeated by reversing the direction of the temperature change, and the final ITC is the average of the two calculated ITCs. The second method, the Endpoint Method, changes the RCS temperature and measures the reactivity at the beginning and end of the temperature change. The ITC is the total reactivity change divided by the total temperature change. The test is repeated by reversing the direction of the temperature change, and the final ITC is the average of the two calculated ITCs. Performance of this test could violate LCO 3.4.2, "RCS Minimum Temperature for Criticality."~~

- ~~e. The Flux Symmetry Test measures the degree of azimuthal symmetry of the neutron flux at as low a power level as practical, depending on the test method employed. This test can be performed at HZP (Control Rod Worth Symmetry Method) or at $\leq 30\%$ RTP (Flux Distribution Method). The Control Rod Worth Symmetry Method inserts a control bank, which can then be withdrawn to compensate for the insertion of a single control rod from a symmetric set. The symmetric rods of each set are then tested to evaluate the symmetry of the control rod worth and neutron flux (power distribution). A reactivity computer is used to measure the control rod worths. Performance of this test could violate LCO 3.1.5, LCO 3.1.6, or LCO 3.1.7. The Flux Distribution Method uses the incore flux detectors to measure the azimuthal flux distribution at selected locations with the core at $\leq 30\%$ RT.~~

APPLICABLE
 SAFETY ANALYSES

The fuel is protected by LCOs that preserve the initial conditions of the core assumed during the safety analyses. The methods for development of the LCOs that are excepted by this LCO are described in the Westinghouse Reload Safety Evaluation Methodology Report (Ref. 5). The above mentioned PHYSICS TESTS, and other tests that may be required to calibrate nuclear instrumentation or to diagnose operational problems, may require the operating control or process variables to deviate from their LCO limitations.

(Continued)

BASES

The FSAR defines requirements for initial testing of the facility, including PHYSICS TESTS. Tables [14.1.1 and 14.1.2] summarize the zero, low power, and power tests. Requirements for reload fuel cycle PHYSICS TESTS are defined in ANSI/ANS 19.6.1-1985 (Ref. 4). Reload fuel cycle PHYSICS TESTS are performed in accordance with Technical Specification requirements, fuel vendor guidelines, and established industry practices. Although these PHYSICS TESTS are generally accomplished within the limits for all LCOs, conditions may occur when one or more LCOs must be suspended to make completion of PHYSICS TESTS possible or practical. This is acceptable as long as the fuel design criteria are not violated. When one or more of the requirements specified in LCO 3.1.3, "Moderator Temperature Coefficient (MTC)," LCO 3.1.4, LCO 3.1.5, LCO 3.1.6, and LCO 3.4.2 are suspended for PHYSICS TESTS, the fuel design criteria are preserved as long as the power level is limited to $\leq 5\%$ RTP, the reactor coolant temperature is kept $\geq 531^\circ\text{F}$, and SDM is $\geq [1.6]\% \Delta k/k$ within the limits provided in the COLR.

The PHYSICS TESTS include measurement of core nuclear parameters or the exercise of control components that affect process variables. Among the process variables involved are AFD and QPTR, which represent initial conditions of the unit safety analyses. Also involved are the movable control components (control and shutdown rods), which are required to shut down the reactor. The limits for these variables are specified for each fuel cycle in the COLR. PHYSICS TESTS meet the criteria for inclusion in the Technical Specifications, since the components and process variable LCOs suspended during PHYSICS TESTS meet Criteria 1, 2, and 3 of the NRC Policy Statement 10 CFR 50.36(c)(2)(1).

BASES

Reference 6 allows special test exceptions (STEs) to be included as part of the LCO that they affect. It was decided, however, to retain this STE as a separate LCO because it was less cumbersome and provided additional clarity.

LCO

This LCO allows the reactor parameters of MTC and minimum temperature for criticality to be outside their specified limits. In addition, it allows selected control and shutdown rods to be positioned outside of their specified alignment and insertion limits. Operation beyond specified limits is permitted for the purpose of performing PHYSICS TESTS and poses no threat to fuel integrity, provided the SRs are met.

The requirements of LCO 3.1.4 ~~3~~, LCO 3.1.5 ~~4~~, LCO 3.1.6 ~~5~~, LCO 3.1.7 ~~6~~, and LCO 3.4.2 may be suspended during the performance of PHYSICS TESTS provided:

- a. RCS lowest ~~operating~~ loop average temperature is \geq [531] °F; and
- b. SDM is \rightarrow [1.6] % $\Delta k/k$. ~~within the limits provided in the COLR.~~
~~and~~
- c. ~~THERMAL POWER IS \leq 5% RTP~~

APPLICABILITY

This LCO is applicable ~~in MODE 2~~ when performing low power PHYSICS TESTS. The applicable PHYSICS TESTS are performed in MODE 2 at HZP. ~~Other PHYSICS TESTS are performed in MODE 1 and are addressed in LCO 3.1.9, "PHYSICS TESTS Exceptions MODE 1."~~

ACTIONS

A.1 and A.2

If the SDM requirement is not met, boration must be initiated promptly. A Completion Time of 15 minutes is adequate for an operator to correctly align and start the required systems and components. The operator should begin boration with the best source available for the plant conditions. Boration will be continued until SDM is within limit.

(Continued)

BASES

Suspension of PHYSICS TESTS exceptions requires restoration of each of the applicable LCOs to within specification.

B.1

When THERMAL POWER is > 5% RTP, the only acceptable action is to open the reactor trip breakers (RTBs) to prevent operation of the reactor beyond its design limits. Immediately opening the RTBs will shut down the reactor and prevent operation of the reactor outside of its design limits.

C.1

When the RCS lowest operating loop's T_{avg} is < 531°F, the appropriate action is to restore T_{avg} to within its specified limit. The allowed Completion Time of 15 minutes provides time for restoring T_{avg} to within limits without allowing the plant to remain in an unacceptable condition for an extended period of time. Operation with the reactor critical and with an operating loop's temperature below 531°F could violate the assumptions for accidents analyzed in the safety analyses.

D.1

(Continued)

BASES

If the Required Actions cannot be completed within the associated Completion Time, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within an additional 15 minutes. The Completion Time of 15 additional minutes is reasonable, based on operating experience, for reaching MODE 3 in an orderly manner and without challenging plant systems.

SURVEILLANCE
 REQUIREMENTS

SR 3.1.108.1

The required power range and intermediate range neutron detectors must be verified to be OPERABLE in MODE 2 by LCO 3.3.1, "Reactor Trip System (RTS) Instrumentation." A CHANNEL OPERATIONAL TEST is performed on each OPERABLE power range and intermediate range channels within 12 hours prior to initiation of the PHYSICS TESTS. This will ensure that the RTS is properly aligned to provide the required degree of core protection during the performance of the PHYSICS TESTS. The 12 hour time limit is sufficient to ensure that the instrumentation is OPERABLE shortly before initiating PHYSICS TESTS.

SR 3.1.108.2

Verification that the RCS lowest operating loop T_{avg} is $\geq 531^{\circ}\text{F}$ will ensure that the unit is not operating in a condition that could invalidate the safety analyses. Verification of the RCS temperature at a Frequency of 30 minutes during the performance of the PHYSICS TESTS will ensure that the initial conditions of the safety analyses are not violated.

SR 3.1.108.3

Verification that the THERMAL POWER is $\geq 5\%$ RIP will ensure that the plant is not operating in a condition that could invalidate the safety analyses. Verification of the THERMAL POWER at a Frequency of 1 hour during the performance of the PHYSICS TESTS will ensure that the initial conditions of the safety analyses are not violated.

SR 3.1.108.4

Verification that the SDM is within limits specified in the COLR ensures that, for the specific RCCA and RCS temperature manipulations performed during PHYSICS TESTS, the plant is not operating in a condition that could invalidate the safety analysis assumptions.

(Continued)

BASES

~~The SDM is verified by performing a reactivity balance calculation, considering the following reactivity effects:~~

- ~~a. RCS boron concentration;~~
- ~~b. Control bank position;~~
- ~~c. RCS average temperature;~~
- ~~d. Fuel burnup based on gross thermal energy generation;~~
- ~~e. Xenon concentration;~~
- ~~f. Samarium concentration; and~~
- ~~g. Isothermal temperature coefficient (ITC).~~

~~Using the ITC accounts for Doppler reactivity in this calculation because the reactor is subcritical, and the fuel temperature will be changing at the same rate as the RCS.~~

(Continued)

BASES

The SDM for physics testing during tests where traditional SDM monitoring techniques are not adequate is determined for the most restrictive test based on design calculations. Plant conditions are monitored during these tests to verify adequate SDM.

The Frequency of 24 hours is based on the generally slow change in required boron concentration and on the low probability of an accident occurring without the required SD.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(3 Pages)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3/4.1

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE NUMBER

JUSTIFICATION

- 3.1-1 In accordance with TSTF-9, Rev. 1, this change would relocate the specified limit for SDM from ITS to the COLR. This change occurs in several specifications including the specification for SDM and those specifications with ACTIONS that require verifying SDM within limits.
- 3.1-2 The Note for SR 3.1.2.1 indicates that predicted reactivity values may be adjusted (normalized) to correspond to the measured core reactivity prior to exceeding a fuel burnup of 60 EFPD after each refueling. However, both the Bases for Specification 3.1.3 and the CTS requirements in Specification 3.1.1.5 state that the normalization shall be done prior to exceeding a fuel burnup of 60 EFPD after each refueling.
- 3.1-3 Not applicable to DCCP. See Conversion Comparison Table (Enclosure 6B).
- 3.1-4 SR 3.1.4.2 of NUREG-1431, Rev. 1 would be deleted. In accordance with TSTF-13, Rev. 1, the intent of this SR is only to determine the next frequency for SR 3.1.4.3. Performance of SR 3.1.4.2 is not necessary to assure that the LCO is met; SR 3.1.4.3 fulfills that purpose. Therefore, SR 3.1.4.2 may be deleted. In addition, the note in the frequency column of SR 3.1.4.2 would be moved to become Note 1 in the surveillance column of SR 3.1.4.3. This is for clarification purposes. As discussed in CN 3.1-9, section renumbering results in SR 3.1.4.3 of NUREG-1431, Rev. 1 becoming ITS SR 3.1.3.2.
- 3.1-5 Per CTS [3.1.3.1], the words "with all" have been removed from ITS LCO 3.1.4. This is a clarification that ensures the proper interpretation of the LCO. The change makes it clear that only one channel of DRPI is necessary to meet the alignment accuracy requirement of the LCO. With the word "all" in the statement, it may be possible for those unfamiliar with the DRPI design to interpret the LCO as applying to all channels of DRPI.
- 3.1-6 LCO 3.1.4 would be split into two separate statements to clarify that the alignment limit is separate from OPERABILITY of the control rod. The Condition A wording is broadened from "untrippable" to "inoperable" to ensure the Condition encompasses all causes of inoperability. Previous wording was ambiguous for rods that, for instance, had slow drop times but were still trippable. These slow rods are inoperable rods, and the change clarifies the appropriate ACTIONS. The Bases are changed to reflect the changes to the LCO and Condition A. These changes are based on TSTF-107.
- 3.1-7 This change to the ISTS would incorporate, into LCO 3.1.7, an ACTION statement that was previously approved as part of the Callaway and Wolf Creek licensing basis as revised in Enclosure 2. The ACTION statement would permit continued POWER OPERATION for up to 24 hours with more than one DRPI channel per rod group inoperable. The ACTION statement specifies additional Required ACTIONS beyond those applicable to the Condition of 1 DRPI channel per group inoperable. The Bases for this change also would be incorporated into the Bases for the plant ITS. These changes are consistent with Traveler WOG-73, Rev.1. The note under the ACTIONS is changed to be consistent with the new Required Actions.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3/4.1

CHANGE
NUMBER

JUSTIFICATION

3.1-19

Not used.

3.1-20

Consistent with CTS 3/4.10.3, "Physics Tests," ITS LCO 3.1.8 and its Condition C and SR 3.1.8.2 are modified to refer to "operating" RCS loops. If an operating loop were secured while operating in MODE 2, Required Action A.1 of ITS 3.4.4 directs the plant to be in MODE 3 within 6 hours. However, depending on initial power level and plant Conditions, securing an RCS loop may result in a loop's average temperature of [531]°F fairly quickly due to the reverse flow through the secured loop and the cooling achieved by the steam generator. In this scenario, it would not be appropriate to invoke Required Action C.1 of ITS 3.1.8 with its 15 minute Completion Time to restore loop average temperature to within limits since the flow in the secured loop is not passing through the core and ITS LCO 3.4.4 provides appropriate corrective ACTION, consistent with CTS.

ENCLOSURE 6B

CONVERSION COMPARISON TABLE - NUREG-1431

Conversion Comparison Table

(3 Pages)

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.1

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.1-1	In accordance with industry Traveler TSTF-9, Rev. 1, this change would relocate the specified limits for SDM from several TS to the COLR.	Yes	Yes	Yes	Yes
3.1-2	Changes the note to SR 3.1.2.1, which deals with verifying core reactivity within limits, to state that the normalization of predicted reactivity values to correspond to measured values shall be done prior to exceeding a fuel burnup of 60 EFPD after each refueling.	Yes	Yes	No, maintaining ITS wording.	No, maintaining ITS wording.
3.1-3	The Wolf Creek ITS LCO 3.1.6 Required Action C.1 is revised from "Be in MODE 3." to "Be in MODE 2 with $k_{eff} < 1.0$."	No	No	Yes	No
3.1-4	In accordance with industry Traveler TSTF-13, Rev. 1, SR 3.1.4.2, which requires verifying MTC within the 300 ppm boron limit, is deleted and the note in that SR is moved to the SR that requires the lower MTC limit to be verified. The deleted SR is not a requirement separate from the lower MTC verification SR, but is essentially a clarification of when the SR for the lower MTC limit should be performed.	Yes	Yes	Yes	Yes
3.1-5	Per CTS [3.1.3.1], the words "with all" are removed from the LCO for control rod alignment limits. This ensures that the number of channels of DRPI required to be OPERABLE will not be misconstrued.	Yes	Yes	Yes	Yes
3.1-6	In accordance with TSTF - 107, the change provides additional clarification that the alignment limits in the LCO are separate from the OPERABILITY of a control rod.	Yes	Yes	Yes	Yes
3.1-7	An ACTION statement that was previously approved as part of the current licensing basis of Callaway and Wolf Creek would be added to ITS 3.1.7, as revised in Enclosure 2. The ACTION statement would permit operation for up to 24 hours with more than one digital rod position indicator per group inoperable.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.1

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.1-8	In accordance with TSTF - 89, the requirement to compare DRPI against group demand position would be required whenever the reactor vessel head is removed, not every 18 months.	Yes	Yes	Yes	Yes
3.1-9	This change would eliminate ITS 3.1.2 because the SDM requirements for MODE 5 have been incorporated into Specification 3.1.1 in accordance with Traveler TSTF-136.	Yes	Yes	Yes	Yes
3.1-10	Several surveillances (e.g., rod position deviation monitor and rod insertion limit monitor in this section) contain ACTIONS in the form of increased surveillance frequency to be performed in the event of inoperable alarms. These ACTIONS are relocated from the TS to licensee controlled documents. This is consistent with TSTF-110, Rev 1.	Yes	Yes	Yes	Yes
3.1-11	Not Used.	N/A	N/A	N/A	N/A
3.1-12	The required ACTIONS for inoperable DRPI are revised per the current licensing basis to note that the use of movable incore detectors for rod position verification is an indirect assessment at best. The position of some rods can not be ascertained by this method.	Yes	Yes	Yes	Yes
3.1-13	In accordance with traveler TSTF-14, Rev. 3, the LCO and SR are modified to verify that THERMAL POWER \leq 5% RTP. This provides an LCO requirement to correspond to Condition B which requires RTP to be within limit.	Yes	Yes	Yes	Yes
3.1-14	Not used.	N/A	N/A	N/A	N/A
3.1-15	In accordance with TSTF-12, Rev. 1, this change would delete its LCOs 3.1.9 and 3.1-11. This change and TSTF-136 rennumbers ITS 3.1.10 to ITS 3.1.8.	Yes	Yes	Yes	Yes

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

**Methodology for Cross-Reference Tables
(Continued)**

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).
Note:	The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

3.2.5	3/4 2-21

Methodology (2 Pages)

3/4.2 POWER DISTRIBUTION LIMITS

3/4.2.1 AXIAL FLUX DIFFERENCE

LIMITING CONDITIONS FOR OPERATION

3.2.1 The indicated AXIAL FLUX DIFFERENCE (AFD) shall be maintained within the limits specified in the CORE OPERATING LIMITS REPORT (COLR).

APPLICABILITY: MODE 1 ABOVE ~~GREATER THAN OR EQUAL TO~~ 50 PERCENT RATED THERMAL POWER*. 01-12-A

ACTION:

- a. With the indicated AXIAL FLUX DIFFERENCE outside of the limits specified in the COLR.
- ~~1. Either restore the indicated AFD to within the limits within 15 minutes, or~~ 01-13-A
 2. Reduce THERMAL POWER to less than 50% of RATED THERMAL POWER within 30 minutes and reduce the Power Range Neutron Flux High Trip setpoints to less than or equal to 55 percent of RATED THERMAL POWER within the next 4 hours. 01-16-LS9
- ~~b. THERMAL POWER shall not be increased above 50% of RATED THERMAL POWER unless the indicated AFD is within the limits specified in the COLR.~~ 01-12-A

SURVEILLANCE REQUIREMENTS

4.2.1.1 The indicated AXIAL FLUX DIFFERENCE shall be determined to be within its limits during POWER OPERATION above 50 percent of RATED THERMAL POWER by:

- a. Monitoring the indicated AFD for each OPERABLE excore channel:
1. At least once per 7 days when the AFD Monitor Alarm is OPERABLE, and 01-07-LG
 - ~~2. At least once per hour when the AFD Monitor Alarm is inoperable.~~ 01-07-LG

4.2.1.2 The indicated AFD shall be considered outside of its limits when at least 2 OPERABLE excore channels are indicating the AFD to be outside the limits. 01-09-A

~~*See Special Test Exceptions Specification 3.10.2~~ 01-01-A

~~THIS PAGE WAS INTENTIONALLY DELETED~~

~~THIS PAGE WAS INTENTIONALLY DELETED.~~

~~THIS PAGE INTENTIONALLY LEFT BLANK~~

POWER DISTRIBUTION LIMITS

3/4.2.2 HEAT FLUX HOT CHANNEL FACTOR-F₀(Z)

LIMITING CONDITION FOR OPERATION

3.2.2 F₀(Z) as approximated by F₀^R(Z) and F₀^H(Z) shall be within the limits specified in the COLR shall be limited by the following relationships:

02-01-LG

$$\frac{F(Z)}{Q} < \frac{[F^{RTP}]}{Q} [K(Z)] \text{ for } P > 0.5$$

$$\frac{F(Z)}{Q} < \frac{[F^{RTP}]}{0.5Q} [K(Z)] \text{ for } P \leq 0.5$$

where $\frac{F^{RTP}}{Q}$ = the F limit at RATED THERMAL POWER (RTP) specified in the CORE OPERATING LIMITS REPORT (COLR),

and $P = \frac{\text{THERMAL POWER}}{\text{RATED THERMAL POWER}}$, and

$K(Z) =$ the normalized F₀(Z) for a given core height specified in the COLR.

APPLICABILITY: MODE 1

ACTION:

With ~~F₀^R(Z)~~ E₀(Z) exceeding its limit:

02-01-LG

- a. Reduce THERMAL POWER at least 1% for each 1% ~~F₀^R(Z)~~ E₀(Z) exceeds the limit within 15 minutes and similarly reduce the Power Range Neutron Flux-High Trip Setpoints within the next 72 4 hours; POWER OPERATION may proceed for up to a total of 72 hours; subsequent POWER OPERATION may proceed provided the Overpower ΔT Trip Setpoints have been reduced at least 1% for each 1% ~~F₀^R(Z)~~ E₀(Z) exceeds the limit. The Overpower ΔT Trip Setpoint reduction shall be performed with the reactor in at least HOT STANDBY.
 - 02-02-LS3
 - 02-01-LG
 - 02-11-LS15
- b. Identify and correct the cause of the out-of-limit condition prior to increasing THERMAL POWER above the reduced limit required by ACTION a., above; THERMAL POWER may then be increased provided F₀(Z) is demonstrated through incore mapping to be within its limit.

(new) If the above ACTIONS are not completed within required completion time, be in MODE 2 within the next 6 hours.

~~THIS PAGE INTENTIONALLY LEFT BLANK~~

POWER DISTRIBUTION LIMITS

SURVEILLANCE REQUIREMENTS

~~4.2.2.1 The provisions of Specification 4.0.4 are not applicable.~~

02-07-A

4.2.2.2 $F_0(Z)$ shall be evaluated to determine if ~~it~~ $E_0(Z)$ is within its limits by:

~~(new) Verifying $F_0^C(Z)$ and $F_0^M(Z)$ satisfy the relationships in the COLR~~

02-01-LG

~~a. Using the moveable incore detectors to obtain a power distribution map at any THERMAL POWER greater than 5% of RATED THERMAL POWER.~~

~~b. Increasing the measured $F_0(Z)$ component of the power distribution map by 3% to account for manufacturing tolerances and further increasing the value by 5% to account for measurement uncertainties.~~

02-01-LG

~~c. Satisfying the following relationship:~~

~~$$F_0^M(Z) \leq \frac{E_0^{RTP}}{P} \times K(Z)$$
 for $P > 0.5$
$$P \times W(Z)$$~~

~~$$F_0^M(Z) \leq \frac{E_0^{RTP}}{W(z) \times 0.5} \times K(Z)$$
 for $P \leq 0.5$~~

~~where $F_0^M(Z)$ is the measured $F_0(z)$ increased by the allowances for manufacturing tolerances and measurement uncertainty, E_0^{RTP} is the F_0 limit, $K(z)$ is the normalized $F_0(z)$ as a function of core height, P is the relative THERMAL POWER, and $W(z)$ is the cycle dependent function that accounts for power distribution transients encountered during normal operation. F_0^{RTP} , $K(z)$, and $W(z)$ are specified in the COLR.~~

02-07-A

~~d. Measuring $F_0^M(z)$, $F_0^C(Z)$ and $F_0^N(Z)$ according to the following schedule:~~

02-12-A

~~(new) Once after each refueling prior to THERMAL POWER exceeding 75% RTP~~

02-05-M

~~1. Once within 12 24 hours after Upon achieving equilibrium conditions after exceeding by 20% or more of RATED THERMAL POWER, the THERMAL POWER at which $F_0^C(Z)$ $E_0(z)$ was last determined.* or and~~

02-06-A

~~2. At least once per 31 Effective Full Power Days (EFPD) thereafter, whichever occurs first.~~

~~e. With measurements indicating~~

~~maximum
$$\frac{F_0^M(Z)}{K(Z)}$$
 over z~~

~~has increased since the previous determination of $F_0^M(Z)$ either of the following actions shall be taken:~~

~~*During power escalation at the beginning of each cycle following shutdown, power level may be increased until a an equilibrium power level for extended operation has been achieved and a power distribution map obtained.~~

02-07-A

POWER DISTRIBUTION LIMITS

SURVEILLANCE REQUIREMENTS (Continued)

- 1) $F_0^M(Z)$ shall be increased over that specified in Specification 4.2.2.2.c by an appropriate factor specified in the COLR, or 02-01-LG
- 2) $F_0^M(Z)$ shall be measured at least once per 7 EFPD until two successive maps indicate that
- maximum $F_0^{CM}(Z)$ is not increasing.
over Z $K(Z)$

~~f. With the relationship specified in Specification 4.2.2.2.c above not being satisfied:~~

- ~~1) Calculate the percent $F_0(Z)$ if $F_0^M(Z)$ exceeds its limit by the following expression:~~

$$\left\{ \left(\frac{\text{maximum over } z \left[\frac{F_0^M(z) \times W(z)}{F_0^{RIP}} \right] - 1}{p} \times K(z) \right) \right\} \times 100 \text{ for } p \geq 0.5$$

$$\left\{ \left(\frac{\text{maximum over } z \left[\frac{F_0^M(z) \times W(z)}{F_0^{RIP}} \right] - 1}{0.5} \times K(z) \right) \right\} \times 100 \text{ for } p < 0.5$$

2. ~~Either one of the following actions shall be taken:~~ 02-14-M
- a) ~~Place the core in an equilibrium condition where the limit in Specification 4.2.2.2.c is satisfied. Power level may then be increased provided the Within 4 hours, reduce AFD limits of Specification 3.2.1 are reduced at least 1% AFD for each percent $F_0^M(Z)$ exceeds its limit, or be in Mode 2 within the next 6 hours.~~ 02-03-M

POWER DISTRIBUTION LIMITS

SURVEILLANCE REQUIREMENTS

~~b) Comply with the requirements of Specification 3.2.2 for $F_0(Z)$ exceeding its limit by the percent calculated.~~

02-09-M

~~g. The limits specified in Specification 4.2.2.2.c, 4.2.2.2.e, and 4.2.2.2.f above are not applicable in the following core plane regions:~~

02-01-LG

- ~~1. Lower core region from 0 to 15%, inclusive.~~
- ~~2. Upper core region from 85 to 100%, inclusive.~~

~~4.2.2.3 When $F_0(Z)$ is measured pursuant to Specification 4.10.2.2, an overall measured $F_0(Z)$ shall be obtained from power distribution map and increased by 3% to account for manufacturing tolerances and further increased by 5% to account for measurement uncertainty.~~

POWER DISTRIBUTION LIMITS

3/4.2.3 RCS FLOW RATE AND NUCLEAR ENTHALPY RISE HOT CHANNEL FACTOR

LIMITING CONDITION FOR OPERATION

3.2.3 $F_{\Delta U}^N$ shall be within the limits specified in the COLR. The combination of indicated Reactor Coolant System (RCS) total flow rate and R shall be maintained within the region of allowable operation shown on Table 3.2-1 Figure 3.2-3a for Unit 1 and Table 3.2-2 Figure 3.2-3b for Unit 2 for four loop operation.

03-01-LG

03-07-A

Where:

03-08-A

a. $R = \frac{F_{\Delta U}^N}{F_{\Delta U}^{RTP} [1.0 + PF_{\Delta U} (1.0 - P)]}$ for LOPAR fuel

$R = \frac{F_{\Delta U}^N}{F_{\Delta U}^{RTP} [1.0 + PF_{\Delta U} (1.0 - P)]}$ for VANTAGE 5 fuel

03-01-LG

b. $P = \frac{\text{THERMAL POWER}}{\text{RATED THERMAL POWER}}$

c. $F_{\Delta U}^N$ = Measured values of $F_{\Delta U}^N$ obtained by using the movable incore detectors to obtain a power distribution map. The measured values of $F_{\Delta U}^N$ shall be used to calculate R since Figure 3.2-3a for Unit 1 and Figure 3.2-3b for Unit 2 include measurement uncertainties of 2.4% for flow and 4% for incore measurement of $F_{\Delta U}^N$.

d. $F_{\Delta U}^{RTP}$ = The $F_{\Delta U}^N$ limits at Rated Thermal Power (RTP) specified in the Core Operating Limits Report (COLR).

e. $PF_{\Delta U}$ = The Power Factor Multipliers specified in the COLR.

APPLICABILITY: MODE 1.

ACTION:

With $F_{\Delta U}^N$ not within its limit, or with the combination of RCS total flow rate and R outside the region of acceptable operation shown on Table 3.2-1 Figure 3.2-3a for Unit 1 and Table 3.2-2 Figure 3.2-3b for Unit 2:

03-07-A

03-08-A

a. Within 2 hours either:

03-09-M

1. Restore the combination of RCS total flow rate and R to within the above limits, or

03-07-A

2. Within 4 hours either:

03-02-LS5

Restore $F_{\Delta U}^N$ to within limits, or

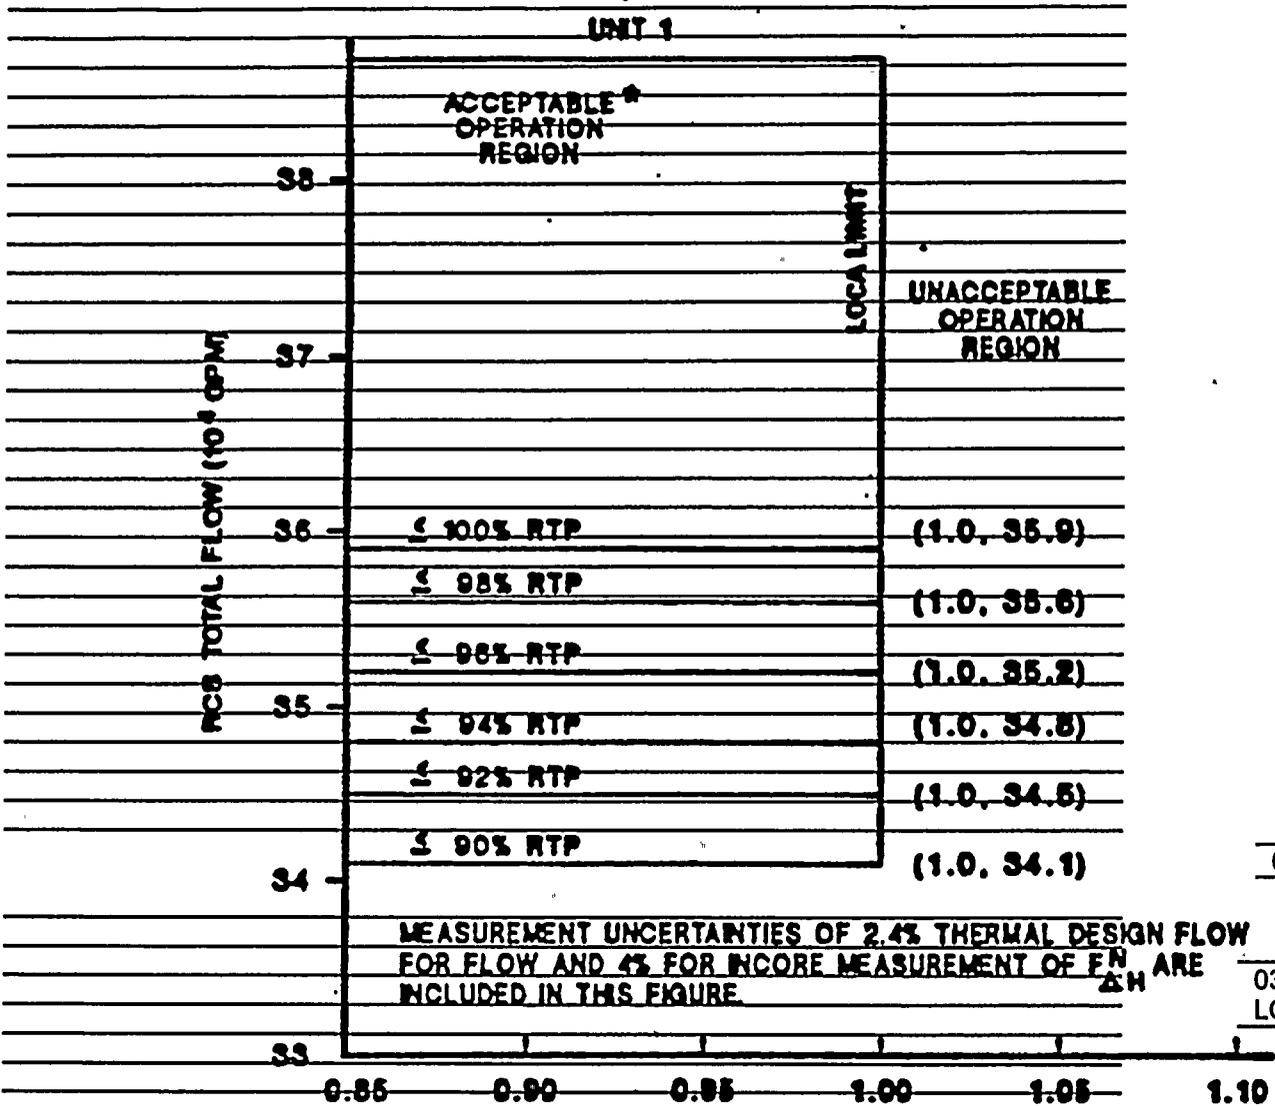

03-07-A

Reduce THERMAL POWER to less than 50% of RATED THERMAL POWER and reduce the Power Range Neutron Flux - High Trip Setpoint to less than or equal to 55% of RATED THERMAL POWER within the next 68 4-hours.

02-02-LS3

(new)* Actions b. and c. must be completed whenever $F_{\Delta U}^N$ exceeds its limit

03-05-M

03-08-A

03-10-LG

$$R = \frac{F_{\Delta H}^N}{F_{\Delta H}^{RTP}} (1.0 + PF_{\Delta H} (1.0 - P))$$

LOPAR FUEL

$$R = \frac{F_{\Delta H}^N}{F_{\Delta H}^{RTP}} (1.0 + PF_{\Delta H} (1.0 - P))$$

VANTAGE 5 FUEL

POWER DISTRIBUTION LIMITS

LIMITING CONDITION FOR OPERATION

ACTION (Continued)

- b. Within 24 hours of initially being outside the above limits, verify that F_{RH} is within limits through incore flux mapping and RCS total flow rate comparison that the combination of R and RCS total flow rate are restored to within the above limits, or reduce THERMAL POWER to less than 5% of RATED THERMAL POWER within the next 6 2 hours. 03-07-A
03-01-LG
03-04-LS6
- c. Identify and correct the cause of the out-of-limit condition prior to increasing THERMAL POWER above the reduced THERMAL POWER limit required by ACTION a.2 and/or b. above; subsequent POWER OPERATION may proceed provided that F_{RH} the combination of R and indicated RCS total flow rate are as demonstrated, through incore flux mapping and RCS total flow rate comparison, to be within limits the region of acceptable operation shown on Figure 3.2 3a for Unit 1 and Figure 3.2 3b for Unit 2 prior to exceeding the following THERMAL POWER levels: 03-05-M
03-07-A
03-01-LG
1. A nominal 50% of RATED THERMAL POWER, 03-06-A
 2. A nominal 75% of RATED THERMAL POWER, and
 3. Within 24 hours of attaining greater than or equal to 95% of RATED THERMAL POWER.

~~(new) With the above required Actions and Completion Times not met, be in Mode 2 within the next 6 hours.~~ 03-03-M

SURVEILLANCE REQUIREMENTS

- 4.2.3.1 The provisions of Specification 4.0.4 are not applicable.
- 4.2.3.2 F_{RH} The combination of indicated RCS total flow rate and R shall be determined to be within limits the region of acceptable operation of Figure 3.2 3a for Unit 1 and Figure 3.2 3b for Unit 2. 02-07-A
03-07-A
- a. Prior to operation above 75% of RATED THERMAL POWER after each fuel loading, and 05-10-A
 - b. At least once per 31 Effective Full Power Days.
- 4.2.3.3 The indicated RCS total flow rate shall be verified to be within the region of acceptable operation of ~~Table 3.2 1~~ Figure 3.2 3a for Unit 1 and ~~Table 3.2 2~~ Figure 3.2 3b for Unit 2 at least once per 12 hours when the value of R, obtained per Specification 4.2.3.2, is assumed to exist. 03-08-A
03-07-A
- 4.2.3.4 The RCS total flow rate indicators shall be subjected to a CHANNEL CALIBRATION at least once per 18 months. 05-03-LG
- 4.2.3.5 The RCS total flow rate shall be determined by measurement at least once per 18 months.

~~# THERMAL POWER does not have to be reduced to comply with this Action.~~ 03-06-A

POWER DISTRIBUTION LIMITS

3/4.2.4 QUADRANT POWER TILT RATIO

LIMITING CONDITION FOR OPERATION

3.2.4 THE QUADRANT POWER TILT RATIO shall not exceed 1.02.

APPLICABILITY: MODE 1 ABOVE 50% OF RATED THERMAL POWER*.

ACTION:

- a. With the QUADRANT POWER TILT RATIO determined to exceed 1.02 but less than or equal to 1.09: 04-06-LS13
 - 1. ~~Calculate the QUADRANT POWER TILT RATIO at least once per hour until either:~~ 04-02-LS10
 - a) ~~The QUADRANT POWER TILT RATIO is reduced to within its limit, or~~
 - b) ~~THERMAL POWER is reduced to less than 50% of RATED THERMAL POWER.~~
 - 2. Within 2 hours either:
 - a) ~~Reduce the QUADRANT POWER TILT RATIO to within its limit, or~~
 - b) Reduce THERMAL POWER at least 3% from RATED THERMAL POWER for each 1% of indicated QUADRANT POWER TILT RATIO in excess of 1 and similarly reduce the Power Range Neutron Flux High Trip Setpoints within the next 4 hours. 04-05-LS11
04-06-LS13
- ~~(new *) At least once per 12 hours, calculate QUADRANT POWER TILT RATIO and reduce THERMAL POWER by at least 3% from RATED THERMAL POWER for each 1% of QUADRANT POWER TILT RATIO in excess of 1, and~~ 04-05-LS11
04-06-LS13
- ~~(new) Within 24 hours, and once per 7 days thereafter, confirm that the Heat Flux Hot Channel Factor $F_{CH}(Z)$ is within its limit by performing Surveillance Requirement 4.2.2.2 and confirm that Nuclear Enthalpy Rise Hot Channel Factor F_{NH} is within its limit by performing Surveillance Requirement 4.2.3.2.~~ 04-05-LS11
- ~~(new **) Prior to increasing THERMAL POWER above the limit of Actions a.2.b and new*~~ 04-05-LS11
- ~~Re-evaluate the safety analyses and confirm that the results remain valid for the duration of operation under this condition, and then~~ 04-06-LS13
- ~~Normalize excore detectors to eliminate tilt.~~ 04-01-A
- ~~After Action (new**) is implemented and within 24 hours after reaching RTP or within 48 hours after increasing THERMAL POWER above the limit of Required Actions a.2.b and (new*), confirm that $F_{CH}(Z)$ is within its limits by performing Surveillance Requirement 4.2.2.2 and that F_{NH} is within its limits by performing Surveillance Requirement 4.2.3.2, and~~ 04-05-LS11
- ~~If the requirements above are not met, reduce thermal power to \leq 50% RATED THERMAL POWER within the next 4 hours.~~ 04-05-LS11
- 3. ~~Verify that the QUADRANT POWER TILT RATIO is within its limit within 24 hours after exceeding the limit or reduce THERMAL POWER to less than 50% of RATED THERMAL POWER within the next 2 hours and reduce the Power Range Neutron Flux High Trip Setpoints to less than or equal to 55% of RATED THERMAL POWER within the next 4 hours; and~~ 04-06-LS13
04-05-LS11

~~4. Identify and correct the cause of the out of limit condition prior to increasing THERMAL POWER; subsequent POWER OPERATION above 50% of RATED THERMAL POWER may proceed provided that the QUADRANT POWER TILT RATIO is verified within its limit at least once per hour for 12 hours or until verified acceptable at 95% or greater RATED THERMAL POWER.~~

04-05-LS11

~~b. With the QUADRANT POWER TILT RATIO determined to exceed 1.09 due to misalignment of either a shutdown or control rod:~~

04-06-LS13

~~1. Calculate the QUADRANT POWER TILT RATIO at least once per hour until either:~~

~~*See Special Test Exceptions Specification 3.10.2~~

01-01-A

POWER DISTRIBUTION LIMITS

LIMITING CONDITION FOR OPERATION

ACTION (Continued)

- a) ~~The QUADRANT POWER TILT RATIO is reduced to within its limit, or~~
- b) ~~THERMAL POWER is reduced to less than 50% of RATED THERMAL POWER.~~
- 2- ~~Reduce THERMAL POWER at least 3% from RATED THERMAL POWER for each 1% of indicated QUADRANT POWER TILT RATIO in excess of 1, within 30 minutes;~~
- 3- ~~Verify that the QUADRANT POWER TILT RATIO is within its limit within 2 hours after exceeding the limit or reduce THERMAL POWER to less than 50% of RATED THERMAL POWER within the next 2 hours and reduce the Power Range Neutron Flux High Trip Setpoints to less than or equal to 55% of RATED THERMAL POWER within the next 4 hours; and~~
- 4- ~~Identify and correct the cause of the out of limit condition prior to increasing THERMAL POWER; subsequent POWER OPERATION above 50% of RATED THERMAL POWER may proceed provided that the QUADRANT POWER TILT RATIO is verified within its limit at least once per hour for 12 hours or until verified acceptable at 95% or greater RATED THERMAL POWER.~~
- e- ~~With the QUADRANT POWER TILT RATIO determined to exceed 1.09 due to causes other than the misalignment of either a shutdown or control rod, calculate the QUADRANT POWER TILT RATIO at least once per hour until THERMAL POWER is reduced to less than 50% of RATED THERMAL POWER and:~~ 04-06-LS13
- 1- ~~Reduce THERMAL POWER to less than 50% of RATED THERMAL POWER within 2 hours and reduce the Power Range Neutron Flux High Trip Setpoints to less than or equal to 55% of RATED THERMAL POWER within the next 4 hours, and~~
- 2- ~~Identify and correct the cause of the out of limit condition prior to increasing THERMAL POWER; subsequent POWER OPERATION above 50% of RATED THERMAL POWER may proceed provided that the QUADRANT POWER TILT RATIO is verified within its limit at least once per hour for 12 hours or until verified at 95% or greater RATED THERMAL POWER.~~
- d- ~~The provisions of Specification 3.0.4 are not applicable to POWER OPERATION above 50% of RATED THERMAL POWER.~~ 04-07-A

POWER DISTRIBUTION LIMITS

SURVEILLANCE REQUIREMENTS

4.2.4.1 The QUADRANT POWER TILT RATIO shall be determined to be within the limit above 50% of RATED THERMAL POWER by:*

a. Calculating the ratio at least once per 7 days when the alarm is OPERABLE, and 01-07-LG

b. Calculating the ratio at least once per 12 hours during steady-state operation when the alarm is inoperable. 01-07-LG

4.2.4.2 The QUADRANT POWER TILT RATIO shall be determined to be within the limit when above 75% of RATED THERMAL POWER with one Power Range channel inoperable by using the movable incore detectors to confirm that the normalized symmetric power distribution, obtained from the 4 pairs of symmetric thimble locations or from a full incore flux map per specification 3.3.3.2, is consistent with the indicated QUADRANT POWER TILT RATIO at least once per 12 hours.** 04-03-LG

(new)* With input from one Power Range Neutron Flux channel inoperable and THERMAL POWER \geq 75% RTP, the remaining three power range channels can be used for calculating QPTR. SR 4.2.4.2 may be performed in lieu of this surveillance. 04-09-A
04-04-LS12

(new)** Not required to be performed until 12 hours after input from one or more Power Range Neutron Flux channels are inoperable with THERMAL POWER \geq 75% RTP. 04-04-LS12

POWER DISTRIBUTION LIMITS

3/4.2.5 DNB PARAMETERS

LIMITING CONDITION FOR OPERATION

3.2.5 The following DNB related parameters shall be maintained within the limits shown on Table 3.2-1:

- a. Reactor Coolant System T_{avg} , and
- b. Pressurizer Pressure.

APPLICABILITY: MODE 1.

ACTION:

With any of the above parameters exceeding its limit, restore the parameter to within its limit within 2 hours or reduce THERMAL POWER to less than 5% of RATED THERMAL POWER within the next 4 hours.

05-06-LS8

SURVEILLANCE REQUIREMENTS

4.2.5.1 Each of the parameters of Table 3.2-1 shall be verified to be within their limits at least once per 12 hours.

TABLE 3.2-1

PARAMETER

LIMITS

Actual Reactor Coolant System T_{avg}

$\leq 584.3^{\circ}\text{F}$

Actual Pressurizer Pressure

$\geq 2212 \text{ psia}^*$

05-01-LG

* Limit not applicable during either a THERMAL POWER ramp in excess of 5% RATED THERMAL POWER per minute or a THERMAL POWER step in excess of 10% RATED THERMAL POWER.

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. **Deletions** - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. **Additions** - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. **Modifications** - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. **Administrative** - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions** - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions** - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications** - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative** - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

Methodology For Mark-Up of Current TS
(Continued)

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.2

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	Removes reference to the special test exception in accordance with the format of NUREG-1431. This modification is acceptable because it is an administrative change which does not change the requirement only the format.

01-05	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-06	LS2	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-07	LG	As described in industry Traveler TSTF-110 which modifies NUREG-1431 requirements, several surveillances contain ACTIONS (in the form of increased surveillance frequency) to be performed in the event of inoperable alarms. These ACTIONS are moved to licensee-controlled documents. The alarms themselves do not directly relate to the limiting condition for operation (LCO) limits. This detail is not required to be in the TS to provide adequate protection of the public health and safety. Therefore, moving this detail is acceptable.
01-08		Not used.
01-09	A	To be consistent with NUREG 1431, the description of when the axial flux difference (AFD) is considered to be outside its [limits] will be a note to the ITS LCO, instead of the CTS surveillance requirement (SR). The technical content is equivalent. Therefore, this change is acceptable.
01-10	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-11	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-12	A	Applicability of the CTS is changed from greater than 50 percent rated thermal power (RTP) to greater than or equal to 50 percent RTP. The requirement to meet AFD limits prior to increasing power above 50 percent would be deleted. The applicability change is consistent with the AFD allowed operational space in the CORE OPERATING LIMITS REPORT (COLR), which is defined for 50 percent RTP and above. The elimination of the requirement to meet AFD requirements would have no impact on plant operations because it is understood that it is necessary to comply with improved technical specification (ITS) requirements.

**CHANGE
NUMBER****NSHC****DESCRIPTION**

01-13	A	The ACTION statement regarding restoring AFD to within limits within 15 minutes would be deleted. This has no effect on the time allowed for completion of required actions and restoring AFD to within limits is implicit in requirements for exiting the ACTION statement. Therefore, this change is administrative.
01-14		Not used.
01-15	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-16	LS9	Eliminates the requirement to reduce the power range neutron flux - high reactor trip setpoints when AFD is outside the RELAXED AXIAL OFFSET CONTROL (RAOC) limits.
02-01	LG	In accordance with NUREG-1431, the proposed change moves the details of the entire CTS LCO of the allowable $F_Q(Z)$ values, including the $K(Z)$ and $W(Z)$ parameters to the CORE OPERATING LIMITS REPORT (COLR) and/or Bases. Previously, only the full power value of $F_Q(Z)$, in addition to $K(Z)$ and $W(Z)$ had been in the COLR. Now, the dependence of $F_Q(Z)$ on THERMAL POWER is also located in the COLR. Details of the $F_Q(Z)$ measurement, including the treatment of uncertainties, are moved to the Bases. The Required Actions are rewritten for consistency with NUREG-1431. The specific changes include the more appropriate use of $F_Q^C(Z)$ and $F_Q^W(Z)$ versus $F_Q(Z)$.
02-02	LS3	The Required Actions are rewritten for consistency with NUREG-1431 and industry Traveler TSTF-95. The specific changes include the relaxation of the Completion Time requirement to reduce the high neutron flux reactor Trip Setpoints [from 4 hours] to 72 hours. The reduction of the setpoints is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the amount of work required to be done to reduce the setpoints, the small likelihood of a severe transient in this time period, and the prompt reduction in THERMAL POWER required upon discovery of the out-of-limit condition.
02-03	M	For consistency with NUREG-1431, the requirement is added to be in at least MODE 2 within 6 hours should any of the ACTIONS not be completed within the required time. This requirement is more restrictive than the previous requirement to enter CTS 3.0.3, which allowed 1 hour before the 6 hour shutdown requirement became effective.
02-04	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-05	M	Consistent with NUREG-1431, $F_Q^C(Z)$ and $F_Q^W(Z)$ must be verified to be within limits prior to exceeding 75 percent RTP after each refueling. This requirement is not explicit in the CTS. The TS are made more restrictive by stating this requirement.
02-06	A	Consistent with the Bases of CTS 4.0.3, which allows 24 hours for completing SRs that become applicable when an exception to Specification 4.0.4 is allowed, the frequency for assessing $F_Q(Z)$ is clarified by requiring that the measurement be performed within 24 hours after reaching equilibrium Conditions.

**CHANGE
NUMBER****NSHC****DESCRIPTION**

02-07	A	The footnote allowing the power to be increased until the THERMAL POWER for extended operation has been achieved has been incorporated in the note preceding SR 3.2.1.1 and SR 3.2.2.1 in the ITS allowing power to be increased until an equilibrium power level has been achieved. This footnote replaces the Specification 4.0.4 exemption in the CTS. Therefore, the change is administrative, and no technical changes would result.
02-08	LS4	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-09	M	The optional action to comply with CTS 3.2.2, if $F_o^W(Z)$ exceeds its limit would be deleted. This eliminates an option and is more restrictive.
02-10		Not used.
02-11	LS15	The proposed change, consistent with NUREG-1431, would delete the requirement that the reactor be in at least HOT STANDBY while performing the overpower ΔT Trip Setpoint reduction. It is sufficient to reduce power 1 percent for each 1 percent $F_o(z)$ exceeds its limit and then perform the required trip setpoint reduction at reduced power. The CTS requirement to be in at least HOT STANDBY is not a Westinghouse design basis requirement.
02-12	A	$F_o^W(Z)$ must be verified to be within limits whenever $F_o(Z)$ is measured as required by the CTS.
02-13	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-14	M	This change is similar to CN 02-08-LS4 for the JLS. For DCP, there is currently no time limit; therefore, the imposition of a time limit is a more restrictive change.
03-01	LG	The details of the $F_{\Delta H}^N$ limits would be moved to the COLR. Previously, the equation for the dependence of $F_{\Delta H}^N$ on THERMAL POWER had been located in the LCO and the COLR. The full power limit value of $F_{\Delta H}^N$ and the power factor multiplier had been located only in the COLR. Now, the equation is also located only in the COLR. Definitions and details of the measurement, including the treatment of uncertainties, are moved to the Bases. The Required Actions are rewritten for consistency with NUREG-1431. The changes are acceptable because they remove details not required to be in TS to support operational safety.
03-02	LS5	The Completion Times would be revised to be consistent with NUREG-1431. The adequacy of these completion times is discussed in the applicable Bases section of NUREG-1431. In summary, 4 hours (versus 2 hours in the CTS) is provided to attempt to restore $F_{\Delta H}^N$ to within its limit or to reduce power to below 50 percent RTP.
03-03	M	The requirement to reduce power to less than or equal to 5 percent RTP (exit MODE 1) within the next 6 hours is added in lieu of the use of CTS LCO 3.0.3. This requirement is more restrictive than the previous requirement to enter LCO 3.0.3, because LCO 3.0.3 allowed 1 hour before the 6-hour shutdown requirement became effective.
03-04	LS6	With the Nuclear Enthalpy Rise Hot Channel Factor ($F_{\Delta H}^N$) having been outside its limits, the current TS require that within 24 hours after exceeding the $F_{\Delta H}^N$ limit, an incore flux map be performed to verify that the $F_{\Delta H}^N$ has been restored

CHANGE NUMBER

NSHC

DESCRIPTION

to within its limits. If this activity is not completed, the CTS require that the plant be taken to MODE 2 within the next 2 hours. The proposed change, revises the time allowed to reduce the reactor power to a Condition where the LCO does not apply (MODE 2, < 5 percent RTP) to be consistent with NUREG-1431. The adequacy of these Completion Times are discussed in the applicable Bases section of NUREG-1431. In summary, 6 hours (versus 2 hours in the CTS) is provided to perform an orderly shutdown of the plant. The proposed change is acceptable based on operational experience regarding performance of an orderly plant shutdown together with the negligible probability of an accident occurring during the extended shutdown interval.

03-05

M

If the enthalpy rise hot channel factor ACTION statements requiring flux mapping and correction of the cause or power reductions are entered, they must be completed, even if compliance with the LCO is restored. These requirements from NUREG-1431 are more restrictive than the corresponding requirements from CTS.

03-06

A

Consistent with NUREG-1431, a note would be added to state that THERMAL POWER does not need to be reduced below the power required by ACTION A. in order to comply with the series of flux maps required by ACTION C. This is a clarification of the CTS in that if compliance with the LCO is restored prior to reducing power level below 50 percent, flux maps need only be performed for those plateaus traversed. If power level did not drop below 95 percent, no flux map would be required. No flux map would be required by ACTION C, but would be required by ACTION [B].

03-07

A

The Parameter R, which is a derived value based on $F_{\Delta H}^N$, would be deleted. Using a combination of reactor coolant system (RCS) total flow rate and R to determine operation in the acceptable region of CTS Figures 3.2-3a and 3.2-3b would be deleted. RCS total flow would be moved to the departure from nucleate boiling (DNB) parameters specification. $F_{\Delta H}^N$ would be a separate specification from the requirements of RCS flow.

This is an administrative change since the limit for R in Figures 3.2-3a and 3.2-3b is a constant value (1.00); therefore, the equation deriving the Parameter R can be reduced and shown in terms of $F_{\Delta H}^N$.

03-08

A

Figures 3.2-3a and 3.2-3b would be revised to display only parameters RCS flow and power level in tables. The tables show required reduction in power level to account for reduced RCS total flow. The parameter R would be deleted since it is a constant value. This is an administrative change since the only change is in the presentation of these figures.

03-09

M

The allowed ACTIONS for reduced RCS flow would be deleted and replaced with the more restrictive ITS requirement to restore RCS flow within 2 hours.

03-10

LG

The note on measurement uncertainty for flow is moved to the Bases.

04-01

A

Clarifies that when the excore detectors are calibrated, the quadrant power tilt is zeroed out. (The QUADRANT POWER TILT RATIO (QPTR) is normalized to unity.) This requirement from NUREG-1431 as modified by Traveler TSTF-25, is consistent with the CTS ACTION requirements for verifying QPTR is within limit during power escalation subsequent to identifying and correcting the cause of QPTR out of limit.

04-02

LS10

The required CTS ACTION to calculate QPTR once per hour until THERMAL

CHANGE
NUMBER

NSHC

DESCRIPTION

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
		POWER was within limit or reduced to less than 50 percent RTP would be eliminated and replaced by new requirements from NUREG-1431. This represents a reduction in requirements for monitoring and reducing power.
04-03	LG	The details regarding obtaining QPTR using the incore detectors would be moved to the Bases.
04-04	LS12	<p>The CTS does not contain any provisions for determining QPTR with more than one inoperable input; thus, LCO 3.0.3 would be entered and the plant would be shut down. The proposed change would allow for the use of the movable incore detector system to determine an equivalent QPTR with one or more inoperable excore detector inputs to the QPTR calculation. In addition, the frequency is clarified by a note which says that the SR is not required until 12 hours after input from one or more power range channels is lost.</p> <p>If the movable incore detector system is used to determine an equivalent QPTR, the QPTR calculation is not based on information gained from any OPERABLE excore indications and therefore is independent of the number of OPERABLE excore detectors. The frequency specified in the CTS for the determination of an equivalent QPTR with the movable incore detectors (every 12 hours) would be retained. Further justification for this frequency is based on the fact that under normal circumstances, QPTR would not be expected to change significantly within a 12 hour period. If a significant change in QPTR were to occur, it would likely be the result of control rod misalignment which would be detectable immediately by means of the rod deviation monitor or rod bottom lights.</p>
04-05	LS11	ACTIONS requiring QPTR to be restored within 24 hours, QPTR to be verified during return to power, and to reset power range neutron flux-high trip setpoint to \leq 55 percent RTP would be eliminated. The ITS would add requirements for measuring $F_Q(Z)$ and $F_{\Delta H}^N$ (instead of QPTR) and performing safety analyses to verify peaking factors are acceptable prior to return to power.
04-06	LS13	ACTIONS involving QPTRs of 1.09 would be eliminated in conformance with NUREG-1431. While the requirements in CTS regarding QPTRs in excess of 1.09 due to misalignment of control rods would be addressed by the ITS requirements associated with rod group misalignment limits, the CTS ACTIONS regarding QPTRs in excess of 1.09 due to other causes would be replaced by less restrictive requirements. The CTS require that the QPTR be calculated once per hour and that power be reduced to less than 50 percent RTP within 2 hours and the power range neutron flux high Trip Setpoint be reduced within the next 4 hours. In addition, the CTS require identification and correction of the cause of the tilt condition and periodic verification that QPTR is within limits during any subsequent ascension to RTP. The ITS would require: (1) that QPTR be calculated only once per 12 hours, (2) only a 3 percent RTP reduction for each 1 percent of QPTR in excess of 1.0 and no reduction in flux trip setpoints, and (3) verification of peaking factors prior to and following power ascension and a reevaluation of safety analyses prior to power ascension. However, the requirements of the ITS are acceptable because: (1) the QPTR would be expected to change slowly over time so a less frequent calculation of QPTR would be acceptable; (2) once the operating staff commences a power reduction, in accordance with ITS requirements, the effect of any flux tilt will tend to be mitigated by reducing the flux and establishing greater margin to fuel design limits, and the reduction of power required by the ITS would result in a plant transient that generally would be less severe than the reduction to less than 50 percent as required by CTS. Further, eliminating the trip setpoint reduction is acceptable because a QPTR in excess of limits does not necessarily imply that accident analysis assumptions have been

CHANGE
NUMBER

NSHC

DESCRIPTION

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
		violated; and (3) the ITS required ACTIONS prior to and subsequent to power ascension provide assurance that POWER OPERATION at or near RTP will be in accordance with the safety analyses, and therefore acceptable.
04-07	A	The statement that Specification 3.0.4 does not apply is no longer needed as revised ACTIONS permit continued operation for an unlimited period of time.
04-08		Not used.
04-09	A	Consistent with NUREG-1431, a note is added to permit 3 OPERABLE excore channels to be used to calculate QPTR when 1 channel is inoperable and power is \leq 75 percent.
04-10	LS14	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-01	LG	The designation of how instrument uncertainties are treated (nominal, in the analysis or in the development of the TS limit) is moved to the Bases. The movement of this level of detail out of the specification is consistent with NUREG-1431 and is an example of removing unnecessary details from the TS in accordance with 10 CFR 50.36.
05-02	LS7	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-03	LG	Consistent with NUREG-1431, the requirement to perform a CHANNEL CALIBRATION on the RCS flow meters at least once per 18 months and the requirement to normalize the channels are moved to the Bases for the RCS flow low reactor trip function in ITS Section 3.3.1.
05-04	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-05	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-06	LS8	In accordance with NUREG-1431, if any of the DNB related parameters of pressure, temperature, or RCS flow are found to be outside their limits, the time period required to perform a power reduction would be extended to 6 hours. The DNB related parameters of RCS average temperature, pressurizer pressure, and RCS flow rate are maintained within specified limits in order to ensure consistency with the assumed initial conditions of the accident analyses. The limits placed on the RCS temperature, pressure, and flow ensure that the minimum departure from nucleate boiling ratio (DNBR) will be met for each of the transients analyzed. Compliance with the above limits is verified every 12 hours. If a parameter is found to be outside the required limit, 2 hours are allowed in order to restore the parameter to within the limit. If the parameter is not restored to compliance within the required time, the plant must be shut down. The revised Completion Time of 6 hours is acceptable to allow transition to the required plant Conditions in an orderly manner without unnecessarily initiating any undue plant transients and on the small likelihood of a severe event occurring during the extended time period.
05-07	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-08		Not used.
05-09	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).

**CHANGE
NUMBER**

NSHC

DESCRIPTION

05-10

A

The CTS requirement to verify RCS flow rate within limits prior to operation above 75 percent RTP after each fuel loading and at least every 31 effective full power days (EFPDs) would be eliminated from the ITS SRs for DNB parameters. This is acceptable based on the requirement to verify $F_{\Delta H}^N$ within limits prior to operation above 75 percent RTP after each fuel loading and every 31 EFPDs. Since the LCO, ACTION and SRs for $F_{\Delta H}^N$ would address any RCS flow rate problems, the RCS flow rate SR can be considered to duplicate the requirements of the $F_{\Delta H}^N$ ITS SR.

05-11

A

Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, AI, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3...." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R" (Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility, involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3

10CFR50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With the heat flux hot channel factor (F_o) or the enthalpy rise hot channel factor ($F_{\Delta H}^N$) outside their respective limits, the CTS require the THERMAL POWER and the power range neutron flux - high reactor Trip Setpoints be reduced. The CTS allow [4] hours for the completion of the setpoint reduction. As written, the Completion Time presents an unnecessary burden on the operation of the plant. A Completion Time of 72 hours will allow time to perform a second flux map to confirm the results, or determine that the Condition was temporary, without implementing an unnecessary trip setpoint change. During the Trip Setpoint change, there is increased potential for human error resulting in a plant transient. Following a significant power reduction, at least 24 hours required to reestablish steady-state xenon Conditions prior to taking a flux map, and approximately 12 hours to obtain the flux map and analyze the data. An increased potential for inadvertent reactor trip can be created through requiring the Trip Setpoints to be reduced within the same time frame that a unit power reduction is taking place, and within the current Completion Time. Setpoint adjustment is estimated to take approximately 4 hours per channel (review of plant Conditions supportive of removing channels from service, tripping of bistables, setpoint adjustments, and channel restoration), adding 2 hours for necessary initial preparations (procedure preparations, calibration equipment checks, obtaining tools and approvals), it is reasonable to expect a total of 18 hours. Further, setpoint changes should only be required for extended operation in this Condition. Finally, the basis for making this setpoint change are the same as the NUREG-1431 Bases provided for the 72 hour Completion Time of LCO 3.2.1, Required ACTION A.4., which is also a setpoint reduction. Therefore, a Completion Time of 72 hours for any required setpoint change maintains consistency within the ITS.

The proposed change, consistent with industry Traveler TSTF95, would allow 72 hours for the completion of the setpoint reduction. The reduction of the setpoints is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the amount of work required to be done to reduce the setpoints, the small likelihood of a severe transient in this time period, and the prompt reduction in THERMAL POWER required upon discovery of the out-of-limit Condition.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed change has no effect on the probability of an accident.

Because the accident analyses are initiated from within the Conditions defined by the TS LCO and these LCOs are unchanged, the accident analyses are unaffected. This change extends the time allowed for a

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3 (continued)

conservative ACTION to be taken. The time extension allows the reactor Trip Setpoint reduction to be performed in a more deliberate manner, thereby, reducing the potential for inadvertent reactor trips introduced during the setpoint reduction. Furthermore, the prompt reduction in THERMAL POWER required upon discovery of the out-of-limit Condition restores the margins of the accident analyses for those transients which do not involve positive reactivity excursions. Due to the small likelihood of an event during the additional delay in the time allowed to reset the reactor Trip Setpoints, there is not a significant effect on the consequences of an accident previously analyzed.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed increase in the time allowed to reduce the reactor Trip Setpoints. Therefore, there is no possibility for a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no effect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, ITS is concluded that the activities associated with NSHC "LS3" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c) and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5

10 CFR 50.92 EVALUATION FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With the nuclear enthalpy rise hot channel factor ($F_{\Delta H}^N$) outside its limits, the CTS allow 2 hours to restore the $F_{\Delta H}^N$ to within its limits prior to initiating other actions. The proposed change, consistent with NUREG-1431, would allow 4 hours for the same activities to be completed. The peaking factor may be brought to within its limits by rod realignment or by reducing the power to within the power-dependent $F_{\Delta H}^N$. The completion time of 4 hours provides an acceptable time to restore $F_{\Delta H}^N$ to within its limits without allowing the plant to remain in an unacceptable condition for an extended period of time and without imposing any rapid power reduction transients on the plant.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed change has no effect on the probability of an accident.

Because the accident analyses are initiated from within the conditions defined by the TS LCO and these LCOs are unchanged, the accident analyses are unaffected. This change extends the time allowed for an action to be taken. The time extension allows for power reductions to be performed in a more deliberate manner; thereby, reducing the potential for inadvertent transients initiated during the power reduction. Furthermore, the prompt action to reduce reactor power places the plant in a better situation to withstand a transient without any increased consequences. Therefore, it is concluded that the additional time allowed to reduce the reactor Trip Setpoints, after the initial power reduction, does not result in a significant increase in the consequences of any accident previously analyzed.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed increase in the time allowed to bring the $F_{\Delta H}^N$ to within its limits. Therefore, there is no possibility for a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no effect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5
(continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS5" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With the nuclear enthalpy rise hot channel factor ($F_{\Delta H}^N$) having been outside its limits, the TS require that within 24 hours after exceeding the $F_{\Delta H}^N$ limit, an incore flux map be performed to verify that the $F_{\Delta H}^N$ has been restored to within its limits. If this activity is not completed, the CTS require that the plant be taken to MODE 2 within the next 2 hours. The proposed change, consistent with NUREG-1431, would allow 6 hours for the same activity to be completed. This time frame is reasonable, based on operating experience regarding the time required to reach MODE 2 from full power Conditions in an orderly manner and without challenging plant systems. The LCO is not applicable in MODE 2.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed change has no effect on the probability of an accident.

Because the accident analyses are initiated from within the conditions defined by the TS LCO and these LCOs are unchanged, the accident analyses are unaffected. This change extends the time allowed for an action to be taken. The time extension allows the power reduction to MODE 2 to be performed in a more deliberate manner; thereby, reducing the potential for inadvertent transients initiated during the power reduction and minimizing challenges to the plant systems. However, due to the small likelihood of a transient during the additional time period and because the reactor operators are taking positive steps to either comply with the specification or to reduce reactor power, the consequences of the accident analyses are not significantly affected by this change.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed increase in the time allowed to bring to MODE 2. Therefore, there is no possibility for a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no effect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
(continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS6" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The DNB related parameters of RCS average temperature, pressurizer pressure, and RCS flow rate are maintained within specified limits in order to ensure consistency with the assumed initial Conditions of the accident analyses. The limits placed on the RCS temperature, pressure, and flow ensure that the minimum departure from DNBR will be met for each of the transients analyzed. Compliance with the above limits is verified every 12 hours. If a parameter is found to be outside the required limit, 2 hours are allowed in order to restore the parameter to within the limit. If the parameter is not restored to compliance within the required time, the plant must be shut down.

This proposed change would extend the time allowed for the required plant shutdown from 4 hours to 6 hours. The Completion Time of 6 hours is reasonable to reach the required plant Conditions in an orderly manner and without unnecessarily initiating any undue plant transients.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed change has no effect on the probability of an accident.

Because the accident analyses are initiated from within the Conditions defined by the TS LCO and these LCOs are unchanged, the accident analyses are unaffected. The occurrence of a DNB challenging event while degraded DNB parameters existed would be expected to affect the consequences of the event. However, the proposed change would not increase the probability of an accident or transient and the additional time to shut the plant down would tend to avoid inadvertent transients. This change extends the time in which the plant is required to be shutdown from 4 hours to 6 hours. This relatively small increase in the shutdown time allows for a more orderly plant shutdown which minimizes the potential for initiating another, unnecessary plant transient during the shutdown process. The 2-hour extension to perform the shutdown does not result in any significant increase in the consequences due to the small likelihood of an event during this time frame and the orderly power reduction in progress. Hence, there will be no effect on any of the accident analysis assumptions and the consequences of the accident analyses are unaffected by this change.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed extension of the time required to shut down the plant. Therefore, there is no possibility for a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change only affects the Completion Time required to shut down the plant if selected DNB parameters are not within limits. The proposed change does not affect any LCO. Because the accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO, the proposed change does not affect any of the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no affect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS8" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With the AFD not within the limits specified in the COLR, the CTS required that the THERMAL POWER be reduced to less than 50 percent RTP and that the power range neutron flux - high reactor Trip Setpoints be reduced to less than or equal to 55 percent RTP within the next 4 hours. The requirement to reduce the high neutron flux reactor Trip Setpoints is proposed to be deleted in conformance with NUREG-1431. The proposed change is considered to be acceptable because reducing the power level to < 50 percent RTP maintains the plant in a Condition where the AFD is not a significant accident analysis input and the probability of an accident or transient that would cause an increase in reactor power, for which reduced Trip Setpoints would provide additional protection, is very low.

There are no AFD limits below 50 percent RTP. A rise to \geq 50 percent RTP with AFD outside the limits does not immediately create an unacceptable situation, and a reactor trip or timely operator action depending on the rapidity of the power transient, would successfully terminate the event. Rapid power excursions resulting from events that are peaking factor limiting would likely be terminated by normal reactor trip signals or reactor trip on safety injection. Slower transients would be terminated by the operator or, for large AFD deviations, the overtemperature ΔT reactor trip. The overtemperature ΔT reactor Trip Setpoint is automatically reduced when AFDs deviate sufficiently from the required operating area. Thus, reducing the high neutron flux setpoint provides an additional level of accident mitigation which would not be necessary in most cases.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves only the compensatory measures required for the Condition where AFD is outside limits; it does not involve any new operating activities or hardware changes. Thus the proposed change has no effect on the probability of an accident.

Since the reactor trip system and operator action will continue to provide an adequate level of protection for transients involving Conditions where AFD is not within limits, the proposed change would have an insignificant effect on the results of accidents or transients. Therefore, the proposed change will have an insignificant effect on the consequences of any accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed deletion of an overly restrictive reactor Trip Setpoint reduction. Therefore, there is no possibility for a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change retains the requirement to reduce power to < 50 percent RTP within 30 minutes. This provides an acceptable level of protection when AFD is not within limits. The REACTOR TRIP SYSTEM also would continue to provide an adequate level of protection against an unlikely accident and transient that may occur. Further, resetting the Trip Setpoints involves some risk of causing a plant trip and consequential transient. Therefore, the proposed change would not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS9" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The required CTS ACTION to calculate QPTR once per hour until THERMAL POWER was reduced to less than 50 percent RTP would be eliminated and replaced by new requirements from NUREG-1431. This represents a reduction in requirements for monitoring and reducing power. With QPTR not within limit, the CTS require a calculation of QPTR at least once per hour until either the QPTR is restored or THERMAL POWER is reduced to < 50 percent RTP. The comparable ITS ACTIONS would require QPTR to be calculated at least once per 12 hours and continue to reduce THERMAL POWER by at least 3 percent for each 1 percent that QPTR exceeds 1.00 until either QPTR is restored to within its limit or 50 percent RTP is achieved. The 12-hour frequency is sufficient because, as stated in the NUREG-1431 Bases, further changes in QPTR would be relatively slow. The once per hour frequency is excessive considering the slow rate of flux change and potentially would divert the attention of control room staff from corrective action with respect to QPTR.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves only the compensatory measures to be taken should the QPTR be outside its limit. The frequency with which QPTR is calculated is not assumed in the initiating events for any accident previously evaluated. In addition, the change does not involve any new operating activities or hardware changes. Therefore, the proposed change would not significantly increase the probability of an accident previously evaluated.

Once THERMAL POWER has been reduced appropriately in proportion to the amount that QPTR exceeds 1.0, any additional change would be sufficiently slow that a 12-hour interval for recalculating QPTR will provide an adequate level of protection. Therefore, the proposed change will not significantly increase the consequences of any accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not involve a physical alteration to the plant; no new or different kind of equipment will be installed. Also, the manner in which the plant would be operated would not be altered. Thus, the change will not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will continue to ensure that the plant is maintained in safe condition while QPTR is in excess of its limit. Additionally, calculating QPTR once per 12 hours as opposed to every hour while

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10 (continued)

QPTR is in excess of its limit would avoid the diversion of personnel resources from corrective actions with regard to meeting the LCO. Therefore, the proposed change will not involve a significant reduction in any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS10" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS ACTIONS requiring QPTR to be restored within 24 hours or reduce power to < 50 percent RTP and requiring verification of QPTR during return to full power operation would be eliminated in accordance with NUREG-1431. Also, the requirement to reset power range neutron high-flux Trip Setpoint during the power reduction and after a required reduction to \leq 50 percent RTP would be eliminated. The ITS would add requirements for measuring $F_0(Z)$ and $F_{\Delta H}^N$ (instead of QPTR) and performing safety analyses to verify peaking factors are acceptable prior to return to power.

The ITS focus on maintaining the peaking factors $F_0(Z)$ and $F_{\Delta H}^N$ within limits rather than the QPTR. This is appropriate because QPTR is a monitored parameter that is indicative of peaking factor problems. The ITS require verification that $F_0(Z)$ and $F_{\Delta H}^N$ are within limits within 24 hours by performing SRs that can directly measure flux shapes in the core. If $F_0(Z)$ or $F_{\Delta H}^N$ are not within limits, the Conditions for those TS will specify the Required ACTIONS. Since the peaking factors are of prime importance, the ITS will ensure that the power distribution remains consistent with the initial conditions assumed in safety analyses. The proposed Completion Time takes into consideration the rate at which peaking factors are likely to change and the time required to stabilize the plant and perform a flux map.

The ITS would retain the 2-hour requirement to reduce power proportionally to the percent that QPTR exceeds its limit. This would result in a power reduction that would provide additional margin to fuel design limits during a flux tilt Condition to assure that design limits are not challenged by local flux peaking. These design margins are set conservatively and provide further assurance that operation during the 24-hour period would not challenge fuel design limits.

The ITS would require a reevaluation of the safety analyses prior to increasing reactor power above the reduced power required by the QPTR limit. Finally, the ITS would require a confirmation that $F_0(Z)$ and $F_{\Delta H}^N$ are within limit following the power increase.

The proposed changes also would eliminate the requirements to reset the power range neutron flux -- high Trip Setpoints. First, the requirement to reduce the setpoints within 4 hours following power reductions proportional to the percent QPTR exceeds the limit would be eliminated. Second, the requirement to reduce the setpoints to \leq 55 percent RTP within 4 hours of reaching 50 percent RTP would be eliminated. The former change is acceptable on the basis that the likelihood of an event occurring during the power reduction phase and during the 24 hour period prior to verifying peaking factors within limits is small. The latter change is acceptable on the basis that the ITS would require peaking factors to be determined in the same time frame as the CTS, and the peaking factor ITS have their own requirements, with appropriate Completion Times, for reducing reactor power and resetting the power range neutron flux -- high Trip Setpoints.

This proposed TS changes have been evaluated and it has been determined that they involve NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21.(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11 (continued)

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves only the compensatory measures to be taken should the QPTR be outside its limit. These compensatory measures are not assumed in the initiating events for any accident previously evaluated. Therefore, the proposed change will not affect the probability of any accident previously evaluated. Furthermore, the proposed changes to these compensatory measures, which are derived from NUREG-1431, would continue to provide acceptable levels of protection. Therefore, the proposed changes will not significantly increase the consequences of any accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not involve a physical alteration to the plant; no new or different kinds of equipment would be installed. The changes would not alter the manner in which the plant would be operated. Thus, the changes would not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed changes will continue to ensure that the plant is maintained in a safe condition within the envelope of the safety analyses while QPTR is in excess of its limit. Therefore, the proposed changes will not involve a significant reduction in any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS11" resulting from the conversion to the ITS format satisfy the NSHC of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12

10 CFR 50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The QPTR is defined as the ratio of the maximum of the four excore detector calibrated output to the average of the four excore detector calibrated outputs for the upper half of the detectors and the lower half of the detectors. If 1 of the excore detector inputs to the QPTR calculation becomes inoperable, the CTS allow the use of the moveable incore detector system to determine an equivalent QPTR. [If, at or below 75 percent RTP, one of the excore detector inputs to the QPTR calculation becomes inoperable, the CTS allow the use of the remaining three detectors to determine an equivalent QPTR.] Further, if the moveable incore detector system is used to determine an equivalent QPTR, the current Specifications do not contain any provisions for determining QPTR with more than one inoperable unit; thus LCO 3.0.3 would be entered and the plant would be shut down.

The proposed change would allow for the use of the movable incore detector system to determine an equivalent QPTR with 1 or more inoperable excore detector inputs to the QPTR calculation. If the movable incore detector system is used to determine an equivalent QPTR, the QPTR calculation is not based on information gained from any operable excore indications, and therefore is independent of the number of operable excore detectors. The frequency specified in the CTS for the determination of an equivalent QPTR with the movable incore detectors (every 12 hours) would be retained. The frequency is clarified by a note which says that the SR is not required until 12 hours after input from 1 or more power range channels become inoperable. Further justification for this frequency is based on the fact that under normal circumstances, QPTR would not be expected to change significantly within a 12 hour period. If a significant change in QPTR were to occur, it would likely be the result of control rod misalignment which would be detectable immediately by means of the rod deviation monitor or rod bottom lights.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed change has no effect on the probability of an accident.

This change makes available an option to ensure that continued plant operation (quadrant power tilt) is within the assumptions of the accident analyses without imposing an unnecessary transient on the plant. The limits on the quadrant power tilt ratio LCO are unchanged. Because the accident analyses are initiated from within the Conditions defined by the TS LCOs, and these LCOs are unchanged, the accident analyses are unaffected. Therefore, there will be no effect on any of the accident analysis assumptions and the consequences of the accident analyses are unaffected by this change.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed alternate method of determining an equivalent QPTR with more than 1 inoperable excore detector inputs. Therefore, there is no possibility for a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no affect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS12" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO HAZARDS CONSIDERATIONS

NHSC LS13

10 CFR 50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

ACTIONS involving QPTRs or 1.09 would be eliminated in conformance with NUREG-1431. While the requirements in CTS regarding QPTRs in excess of 1.09 due to misalignment of control rods would be addressed by the ITS requirements associated with rod group misalignment limits, the CTS ACTIONS regarding QPTRs in excess of 1.09 due to other causes would be replaced by less restrictive requirements. The CTS require that the QPTR be calculated once per hour and that power be reduced to less than 50 percent RTP within 2 hours and the power range neutron flux high Trip Setpoint be reduced within the next 4 hours. In addition, the CTS require identification and correction of the cause of the tilt condition and periodic verification that QPTR is within limits during any subsequent ascension to RTP. The ITS would require: (1) that QPTR be calculated only once per 12 hours, (2) only a 3 percent RTP reduction for each 1 percent of QPTR in excess of 1.0 and no reduction in flux trip setpoints, and (3) verification of peaking factors prior to and following power ascension and a reevaluation of safety analyses prior to power ascension.

The proposed changes are acceptable because:

- (1) The QPTR would be expected to change slowly over time so a less frequent calculation of QPTR would be acceptable;
- (2) Once the operating staff commences a power reduction in accordance with its ITS requirements, the effect of any flux tilt will tend to be mitigated by reducing the flux and establishing greater margin to fuel design limits.

The reduction of power required by the ITS would result in a plant transient that generally would be less severe than the reduction to less than 50 percent as required by CTS, and eliminating the trip setpoint reduction is acceptable because a QPTR in excess of limits does not necessarily imply that accident analysis assumptions have been violated; and

- (3) the ITS Required ACTIONS prior to and subsequent to power ascension provide assurance that power operation at or near RTP will be in accordance with the safety analyses, and therefore acceptable.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated, or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated, or Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed changes do not involve any new methods of operating the plant or hardware changes; thus the proposed change has no effect on the probability of an accident.

The proposed change involves only the compensatory measures to be taken should the QPTR be outside its limit. These compensatory measures are not assumed in the initiating events for any accident

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS13 (continued)

previously evaluated. Therefore, the proposed changes will not affect the probability of any accident previously evaluated. Furthermore, the proposed changes to these compensatory measures, which are derived from NUREG-1431, would continue to provide acceptable levels of protection. Therefore, there will be no effect on any of the accident analysis assumptions and the consequences of the accident analyses are unaffected by this change.

Therefore, the proposed changes will not significantly increase the probability or consequences of any accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not involve a physical alteration to the plant; no new or different kinds of equipment would be installed. The changes would not alter the manner in which the plant would be operated. Thus, the changes would not create the possibility of a new or different kind of accident from any accident previously evaluated.

The proposed change involves only the compensatory measures to be taken should the QPTR be outside its limit. The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed alternate methods of dealing with QPTRs in excess of 1.09. Therefore, there is no possibility for a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The proposed changes, which involve implementing NUREG-1431 requirements, will continue to ensure that the plant is maintained in a safe condition within the envelope of the safety analyses while QPTR is in excess of its limit. While different actions are taken in response to QPTR in excess of 1.09, the proposed changes would assure that accident analysis assumptions continue to be met. Therefore, the proposed changes will not involve a significant reduction in any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS13" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NHSC LS15

10 CFR 50.92 EVALUATION FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With the heat flux hot channel factor ($F_o(z)$) outside its limit, the CTS require that THERMAL POWER be reduced at least 1 percent for each 1% $F_o(z)$ exceeds the limit within 15 minutes and that the power range neutron flux - high trip setpoints be reduced within the next 4 hours. POWER OPERATION may proceed for up to a total of 72 hours; subsequent POWER OPERATION may proceed provided the overpower ΔT Trip Setpoints have been reduced at least 1 percent for each 1 percent $F_o(z)$ exceeds the limit. The CTS require that the overpower ΔT Trip Setpoint reduction be performed with the reactor in at least HOT STANDBY. The proposed change, consistent with NUREG-1431, would delete the requirement that the reactor be in at least HOT STANDBY while performing the overpower ΔT Trip Setpoint reduction. It is sufficient to reduce power 1 percent for each 1 percent $F_o(z)$ exceeds its limit and then perform the required Trip Setpoint reduction at reduced power. The CTS requirement to be in at least HOT STANDBY is not a Westinghouse design basis requirement.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any new operating activities or hardware changes; thus the proposed change has no effect on the probability of an accident.

Because the accident analyses are initiated from within the conditions defined by the TS LCO and these LCOs are unchanged, the accident analyses are unaffected. This change removes from the TS the requirement that the plant be in at least HOT STANDBY while performing the overpower ΔT Trip Setpoint reduction. The magnitude of the setpoint reduction would remain unchanged and the maximum permissible THERMAL POWER before and after the setpoint reduction would remain unchanged. Hence, there will be no effect on any of the

IV. SPECIFIC NO HAZARDS CONSIDERATIONS

NHSC LS15 (continued)

accident analysis assumptions and the consequences of the accident analyses are unaffected by this change.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The assumptions of the accident analyses are unaffected by the proposed change. No new permutations or event initiators are introduced by the proposed deletion of the requirement to be in at least HOT STANDBY while performing the setpoint reduction. Therefore, there is no possibility for a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from Conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no effect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS15" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

"struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

Methodology	(1 Page)

BASES

BACKGROUND

The purpose of the limits on the values of $F_0(Z)$ is to limit the local (i.e., pellet) peak power density. The value of $F_0(Z)$ varies along the axial height (Z) of the core.

$F_0(Z)$ is defined as the maximum local fuel rod linear power density divided by the average fuel rod linear power density, assuming nominal fuel pellet and fuel rod dimensions. Therefore, $F_0(Z)$ is a measure of the peak fuel pellet power within the reactor core.

During power operation, the global power distribution is limited by LCO 3.2.3, "AXIAL FLUX DIFFERENCE (AFD)," and LCO 3.2.4, "QUADRANT TILT POWER RATIO (QPTR)," which are directly and continuously measured process variables. These LCOs, along with LCO 3.1.7 ~~6~~, "Control Bank Insertion Limits," maintain the core limits on power distributions on a continuous basis.

$F_0(Z)$ varies with fuel loading patterns, control bank insertion, fuel burnup, and changes in axial power distribution.

~~$F_0(Z)$ is measured periodically using the incore detector system. $F_0(Z)$ is not directly measurable but is inferred from a power distribution map obtained with the movable incore detector system. The results of the three-dimensional power distribution map are analyzed to derive a measured value for $F_0(Z)$. These measurements are generally taken with the core at or near steady-state equilibrium conditions.~~

~~Using the measured three-dimensional power distributions, it is possible to derive a measured value for $F_0(Z)$. However, because this value represents a steady-state equilibrium condition, it does not include the variations in the value of $F_0(Z)$ that are present during nonequilibrium situations, such as load following.~~

~~To account for these possible variations, a transient $F_0(Z)$ is also calculated based on the steady state value of $F_0(Z)$. In this case the steady state $F_0(Z)$ is adjusted by an elevation dependent factor, $W(Z)$, that accounts for the calculated worst-case transient conditions.~~

Core monitoring and control under nonsteady state conditions are accomplished by operating the core within the limits of

BASES

BACKGROUND
(continued)

the appropriate LCOs, including the limits on
AFD, QPTR, and control rod insertion.

APPLICABLE
SAFETY ANALYSES

This LCO's principal effect is to preclude core power distributions that violate could lead to violation of the following fuel design criteria criterion:

- a. During a large break loss of coolant accident (LOCA), the peak cladding temperature must not exceed 2200°F (Ref. 1);
- b. During a the Condition 2 partial loss of forced reactor coolant flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hot fuel rod in the core does not experience a departure from nucleate boiling (DNB) condition;
- c. During an ejected rod accident, the average fuel pellet enthalpy at the hot spot in irradiated energy deposition to the fuel must not exceed 280 cal/gm (Ref. 2); and
- d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. 3).

Limits on $F_0(Z)$ ensure that the value of the initial total peaking factor assumed in the accident analyses remains valid. Other criteria must also be met (e.g., maximum cladding oxidation, maximum hydrogen generation, coolable geometry, and long term cooling). However, the LOCA peak cladding temperature is typically most limiting.

$F_0(Z)$ limits assumed in the LOCA analysis are typically limiting relative to (i.e., lower than) the $F_0(Z)$ limit assumed in safety analyses for other postulated accidents. Therefore, this LCO provides conservative limits for other postulated accidents.

$F_0(Z)$ satisfies Criterion 2 of 10 CFR 50.36(g)(2)(1) the NRC Policy Statement.

BASES
LCO

The Heat Flux Hot Channel Factor, F₀(Z), shall be limited by the following relationships:

$$F_0(Z) \leq \frac{GFQ}{P} K(Z) \quad \text{for } P > 0.5$$

$$F_0(Z) \leq \frac{GFQ}{0.5} K(Z) \quad \text{for } P < 0.5$$

$$F_0(Z) \leq \frac{GFQ}{P} K(Z) \quad \text{for } P > 0.5$$

$$F_0(Z) \leq \frac{GFQ}{0.5} K(Z) \quad \text{for } P \leq 0.5$$

where: $GFQ = F_0^{RTP}$ and is the F₀(Z) limit at RATED THERMAL POWER (RTP) provided in the COLR.

K(Z) is the normalized F₀(Z) normalization factor for as a function of core height provided in the COLR, and

$$P = \frac{\text{THERMAL POWER}}{\text{RTP}}$$

For this facility, the actual values of F_0^{RTP} , GFQ and K(Z) are given in the COLR; however, F_0^{RTP} , GFQ is normally a number on the order of [2.32] 2.45, and K(Z) is a function that looks like the one provided in Figure B 3.2.1B-1.

For Relaxed Axial Offset Control operation, F₀(Z) is approximated by F₀^c(Z) and F₀^m(Z). Thus, both F₀^c(Z) and F₀^m(Z) must meet the preceding limits on F₀(Z).

An F₀^c(Z) evaluation requires obtaining an incore flux map in MODE 1. From the incore flux map results we obtain the measured value (F₀^m(Z)) of F₀(Z). Then, the computed heat flux hot channel factor, F₀^c(Z) is obtained by the equation:

$$F_0^c(Z) = F_0^m(Z) [1.0815] (1.03) (1.05) = F_0^m(Z)$$

where [1.0815] 1.03 is a factor that accounts for fuel manufacturing tolerances and 1.05 is a factor that accounts for flux map measurement uncertainty.

F₀^c(Z) is an excellent approximation for F₀(Z) when the reactor is at the steady state power at which the incore flux map was taken.

(continued)

BASES

LCO
(continued)

The expression for $F_0^H(Z)$ is:

$$F_0^H(Z) = F_0^C(Z) W(Z)$$

where $W(Z)$ is a cycle dependent function that accounts for power distribution transients encountered during normal operation. $W(Z)$ is included in the COLR.

The $F_0(Z)$ limits define limiting values for core power peaking that precludes peak cladding temperatures above 2200°F during either a large or small break LOCA.

This LCO requires operation within the bounds assumed in the safety analyses. ~~Calculations are performed in the core design process to confirm that the core can be controlled in such a manner during operation that it can stay within the LOCA $F_0(Z)$ limits. If $F_0(Z)$ cannot be maintained within the LCO limits, reduction of the core power is required.~~

Violating the LCO limits for $F_0(Z)$ may produce unacceptable consequences if a design basis event occurs while $F_0(Z)$ is outside its specified limits.

~~If the power distribution measurements are performed at a power level less than 100% RTP, then the $F_0^H(Z)$ and $F_0^C(Z)$ values that would result from measurements if the core was at 100% RTP should be inferred from the available information. A comparison of these inferred values with F_0^H assures compliance with the LCO at all power levels.~~

APPLICABILITY

The $F_0(Z)$ limits must be maintained in MODE 1 to prevent core power distributions from exceeding the limits assumed in the safety analyses. Applicability in other MODES is not required because there is either insufficient stored energy in the fuel or insufficient energy being transferred to the reactor coolant to require a limit on the distribution of core power.

ACTIONS

A.1

Reducing THERMAL POWER by $\geq 1\%$ RTP for each 1% by which $F_0^C(Z)$ exceeds its limit, maintains an acceptable absolute power density. $F_0^C(Z)$ is $F_0^H(Z)$ multiplied by a factor ξ which accounting for manufacturing tolerances and measurement uncertainties. $F_0^H(Z)$ is the measured value of $F_0(Z)$. The Completion Time of 15 minutes provides an acceptable time to reduce power in an orderly manner and without allowing the plant to remain in an unacceptable condition for an extended period of time.

(continued)

BASES

 ACTIONS
 (continued)
A.2

A reduction of the Power Range Neutron Flux-High trip setpoints by $\approx 1\%$ for each 1% by which $F_0^c(Z)$ exceeds its limit, is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the small likelihood of a severe transient in this time period and the preceding prompt reduction in THERMAL POWER in accordance with Required Action A.1.

A.3

Reduction in the Overpower ΔT trip setpoints by $\approx 1\%$ for each 1% by which $F_0^c(Z)$ exceeds its limit, is a conservative action for protection against the consequences of severe transients with unanalyzed power distributions. The Completion Time of 72 hours is sufficient considering the small likelihood of a severe transient in this time period, and the preceding prompt reduction in THERMAL POWER in accordance with Required Action A.1.

A.4

Verification that $F_0^c(Z)$ has been restored to within its limit, by performing SR 3.2.1.1 prior to increasing THERMAL POWER above the limit imposed by Required Action A.1, ensures that core conditions during operation at higher power levels are consistent with safety analyses assumptions. Inherent in this action is identification of the cause of the out of limit condition, and the correction of the cause, to the extent necessary to allow safe operation at the higher power level. The allowable power level is determined by extrapolating $F_0^c(Z)$. SR 3.2.1.1 must be satisfied prior to increasing power above the extrapolated allowable power level or restoration of any reduced Reactor Trip System setpoints.

B.1

If it is found that the maximum calculated value of $F_0(Z)$ that can occur during normal maneuvers, $F_0^m(Z)$, exceeds its specified limits, there exists a potential for $F_0^c(Z)$ to become excessively high if a normal operational transient occurs. Reducing the AFD by $\approx 1\%$ for each 1% by which $F_0^m(Z)$ exceeds its limit within the allowed Completion Time of 4 hours, restricts the axial flux

(continued)

BASES

distribution such that even if a transient occurred, core peaking factors limits are not exceeded.

ACTIONS
(continued)C.1

If Required Actions A.1 through A.4 or B.1 are not met within their associated Completion Times, the plant must be placed in a mode or condition in which the LCO requirements are not applicable. This is done by placing the plant in at least MODE 2 within 6 hours.

This allowed Completion Time is reasonable based on operating experience regarding the amount of time it takes to reach MODE 2 from full power operation in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3.2.1.1 and SR 3.2.1.2 are modified by a Note. The Note applies during the first power ascension after a refueling during power ascensions following a plant shutdown (leaving MODE 1). The note allows for power ascensions if the surveillances are not current. It states that THERMAL POWER may be increased until an equilibrium power level has been achieved at which a power distribution map can be obtained. This allowance is modified, however, by one of the Frequency conditions that requires verification that $F_0^c(Z)$ and $F_0^m(Z)$ are within their specified limits after a power rise of more than 10% 20% RTP over the THERMAL POWER at which they were last verified to be within specified limits. Because $F_0^c(Z)$ and $F_0^m(Z)$ could not have previously been measured in this for a reload core, there is a second Frequency condition, applicable only for reload cores, that requires determination of these parameters before exceeding 75% RTP. This ensures that some determination of $F_0^c(Z)$ and $F_0^m(Z)$ are made at a lower power level at which adequate margin is available before going to 100% RTP. Also, this Frequency condition, together with the Frequency condition requiring verification of $F_0^c(Z)$ and $F_0^m(Z)$ following a power increase of more than 10% 20%, ensures that they are verified as soon as within 12 24 hours from when equilibrium conditions are achieved at RTP (or any other level for extended operation) → is achieved. Equilibrium conditions are achieved when the core is sufficiently stable such that the uncertainties associated with the measurement are valid. In the absence of these Frequency conditions, it is possible to increase power to RTP and operate for 31 days without verification of $F_0^c(Z)$ and $F_0^m(Z)$. The Frequency condition is not intended to require verification of these parameters after every 10% 20% increase in power level above the last verification. It only requires verification after a power level is achieved for extended

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

operation that is 10% 20% higher than that power at which F₀ was last measured.

SR 3.2.1.1

Verification that F₀^c(Z) is within its specified limits involves increasing F₀^m(Z) to allow for manufacturing tolerance and measurement uncertainties in order to obtain F₀^c(Z). Specifically, F₀^m(Z) is the measured value of F₀(Z) obtained from incore flux map results and F₀^c(Z) = F₀^m(Z) [1.0015] (1.03) (1.05) (Ref. 4 2). F₀^c(Z) is then compared to its specified limits.

The limit with which F₀^c(Z) is compared varies inversely with power above 50% RTP and directly with a function called K(Z) provided in the COLR.

Performing this Surveillance in MODE 1 prior to exceeding 75% RTP ensures (and meeting the 100% RTP F₀(Z) limit) provides assurance that the F₀^c(Z) limit is met when RTP is achieved, because peaking factors generally decrease as power level is increased.

If THERMAL POWER has been increased by ≥ 10% 20% RTP since the last determination of F₀^c(Z), another evaluation of this factor is required [12] 24 hours after achieving equilibrium conditions at this higher power level (to ensure that F₀^c(Z) values are being reduced sufficiently with power increase to stay within the LCO limits).

The Frequency of 31 EFPD is adequate to monitor the change of power distribution with core burnup because such changes are slow and well controlled when the plant is operated in accordance with the Technical Specifications (TS).

SR 3.2.1.2

~~The nuclear design process includes calculations performed to determine that the core can be operated within the F₀(Z) limits.~~ Because flux maps are taken in steady state equilibrium conditions, the variations in power distribution resulting from normal operational maneuvers are not present in the flux map data. These variations are, however, conservatively calculated by considering a wide range of unit maneuvers in normal operation. The maximum peaking factor increase over steady state values, calculated as a function of core elevation, Z, is called W(Z). Multiplying the measured total peaking factor, F₀^c(Z), by W(Z) gives the

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.2.1.2 (continued)

maximum $F_0(Z)$ calculated to occur in normal operation, $F_0^M(Z)$.

The limit with which $F_0^M(Z)$ is compared varies inversely with power and directly with the function $K(Z)$ provided in the COLR.

The $W(Z)$ curve is provided in the COLR for discrete core elevations. Flux map data are typically taken for 30 to 75 core elevations. $F_0^C(Z)$ evaluations are not applicable for the following axial core regions, measured in percent of core height:

- a. Lower core region, from 0 to 15% inclusive; and
- b. Upper core region, from 85 to 100% inclusive.

The top and bottom 15% of the core are excluded from the evaluation because of the low probability that these regions would be more limiting in the safety analyses and because of the difficulty of making a precise measurement in these regions.

This Surveillance has been modified by a Note that may require that more frequent surveillances be performed. ~~When $F_0^M(Z)$ is evaluated and found to be within its limit measured determined,~~ an evaluation of the expression below is required to account for any increase to $F_0^M(Z)$ that may occur and cause the $F_0(Z)$ limit to be exceeded before the next required $F_0(Z)$ evaluation.

If the two most recent $F_0(Z)$ evaluations show an increase in the expression

$$\text{maximum over } z \quad \left[\frac{F_0^C(Z)}{K(Z)} \right]$$

it is required to meet the $F_0(Z)$ limit with the last $F_0^M(Z)$ increased by a factor of ~~[1.02] = 2 percent which is specified in the COLR,~~ or to evaluate $F_0(Z)$ more frequently, each 7 EFPD. These alternative requirements prevent $F_0(Z)$ from exceeding its limit for any significant period of time without detection.

(continued)

BASES

SURVEILLANCE
REQUIREMENTSSR 3.2.1.2 (continued)

Performing the Surveillance in MODE 1 prior to exceeding 75% RTP or at a reduced power at any other time, ensures and meeting the 100% RTP F₀(Z) limit, provides assurance that the F₀(Z) limit ~~is~~ will be met when RTP is achieved, because peaking factors are generally decreased as power level is increased.

F₀(Z) is verified at power levels $\geq 10\%$ ~~20%~~ RTP above the THERMAL POWER of its last verification, ~~[12]~~ 24 hours after achieving equilibrium conditions to ensure that F₀(Z) is within its limit at higher power levels.

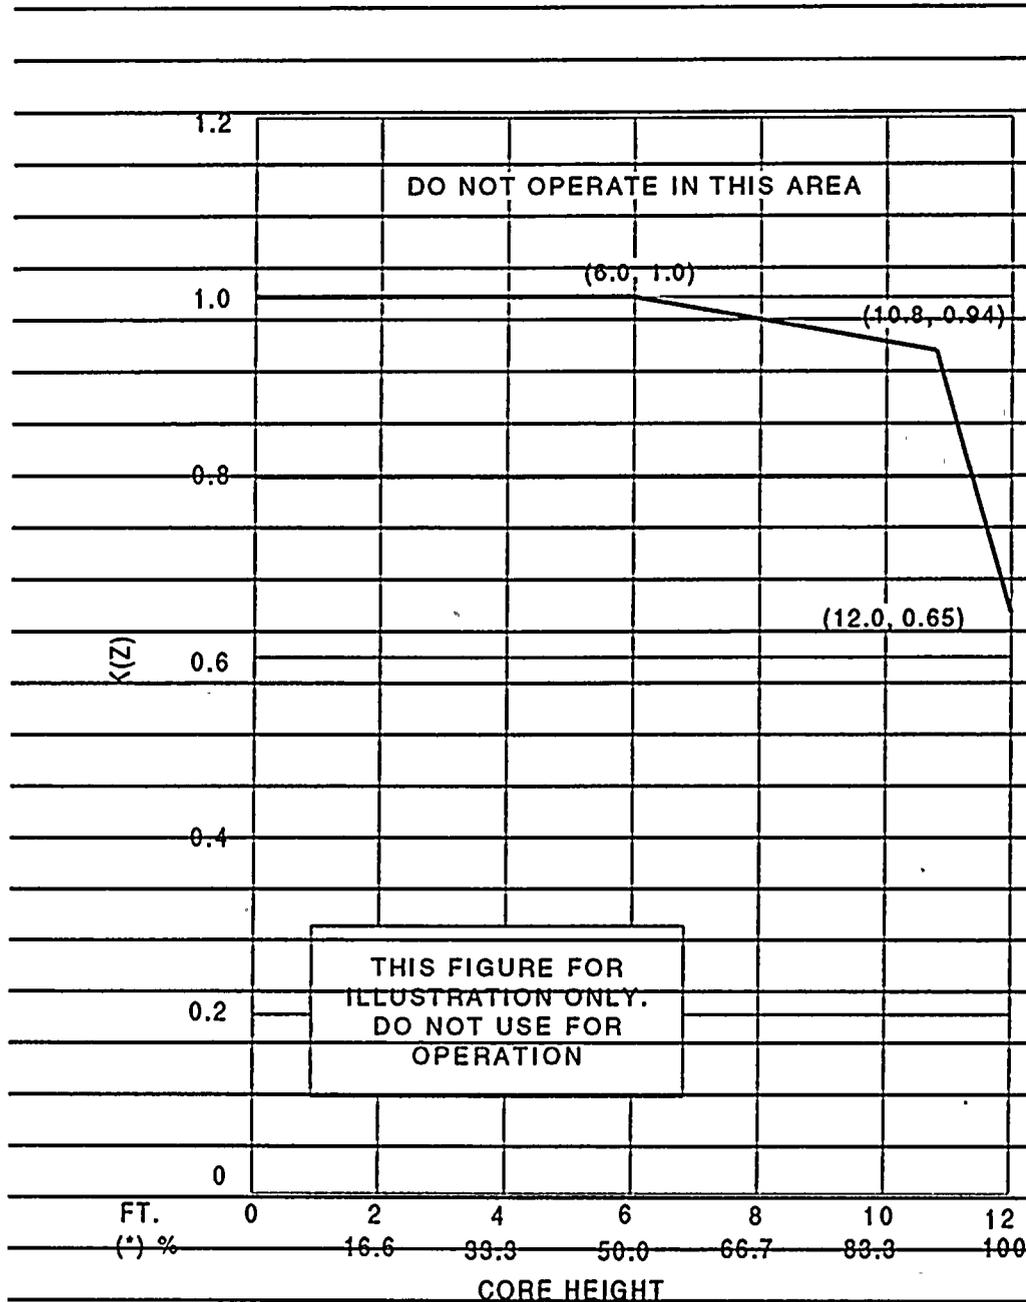

The Surveillance Frequency of 31 EFPD is ~~normally~~ adequate to monitor the change of power distribution with core burnup. The Surveillance may be done more frequently if required by the results of F₀(Z) evaluations.

The Frequency of 31 EFPD is adequate to monitor the change of power distribution because such a change is sufficiently slow, when the plant is operated in accordance with the TS, to preclude adverse peaking factors between 31 day surveillances.

K(Z) - Normalized F₉(Z) as a Function of Core Height

(continued)

B 3.2.2 Nuclear Enthalpy Rise Hot Channel Factor ($F_{\Delta H}^N$)

BASES

BACKGROUND

The purpose of this LCO is to establish limits on the power density at any point in the core so that the fuel design criteria are not exceeded and the accident analysis assumptions remain valid. The design limits on local (pellet) and integrated fuel rod peak power density are expressed in terms of hot channel factors. Control of the core power distribution with respect to these factors ensures that local conditions in the fuel rods and coolant channels do not challenge core integrity at any location during either normal operation or a postulated accident operational transients and any transient condition arising from events of moderate frequency analyzed in the safety analyses.

$F_{\Delta H}^N$ is defined as the ratio of the integral of the linear power along the fuel rod with the highest integrated power to the average integrated fuel rod power. Therefore, $F_{\Delta H}^N$ is a measure of the maximum total power produced in a fuel rod. $F_{\Delta H}^N$ is sensitive to fuel loading patterns, bank insertion, and fuel burnup. $F_{\Delta H}^N$ typically increases with control bank insertion and typically decreases with fuel burnup.

$F_{\Delta H}^N$ is not directly measurable but is inferred from a power distribution map obtained with the movable incore detector system. Specifically, the results of the three dimensional power distribution map are analyzed by a computer to determine $F_{\Delta H}^N$. This factor is calculated at least every 31 EFPD. However, during power operation, the global power distribution is monitored by LCO 3.2.3, "AXIAL FLUX DIFFERENCE (AFD)," and LCO 3.2.4, "QUADRANT POWER TILT RATIO (QPTR)," which address directly and continuously measured process variables. Compliance with these LCOs along with the LCOs governing shutdown and control rod insertion and alignment, maintains the core limits on power distribution on a continuous basis.

The COLR provides peaking factor limits that ensure that the design basis value of the departure from nucleate boiling (DNB) is met for normal operation, operational transients, and any transient condition arising from events of moderate frequency. The DNB design basis precludes DNB and is met by limiting the minimum local DNB heat flux ratio to [1.3] using the [W3] CHF correlation. All DNB limited transient events are assumed to begin with an $F_{\Delta H}^N$ value that satisfies the LCO requirements.

(continued)

BASES

BACKGROUND
(continued)

Operation outside the LCO limits may produce unacceptable consequences if a DNB limiting event occurs. The DNB design basis ensures that there is no overheating of the fuel that results in possible cladding perforation with the release of fission products to the reactor coolant.

APPLICABLE
SAFETY ANALYSES

Limits on F_{AH}^N preclude core power distributions that exceed the following fuel design limits:

- a. There must be at least 95% probability at the 95% confidence level (the 95/95 DNB criterion) that the hottest fuel rod in the core does not experience a DNB condition;
- b. During a large break loss of coolant accident (LOCA), peak cladding temperature (PCT) must not exceed 2200°F;
- c. During an ejected rod accident, the energy deposition to the average fuel pellet enthalpy at the hot spot in irradiated fuel must not exceed 280 cal/gm [Ref. 1]; and
- d. Fuel design limits required by GDC 26 (Ref. 2) for the condition when control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn.

~~For transients that may be DNB limited, the Reactor Coolant System flow and F_{AH}^N are the core parameters of most importance. The limits on F_{AH}^N ensure that the DNB design basis is met for normal operation, operational transients, and any transients arising from events of moderate frequency. The DNB design basis is met by limiting the minimum DNBR to the 95/95 DNB criterion of [1.3] using the [W3] CHF applicable to a specific DNBR correlation. This value provides a high degree of assurance that the hottest fuel rod in the core does not experience a DNB condition.~~

The allowable F_{AH}^N limit increases with decreasing power level. This functionality in relationship between power and F_{AH}^N is included in the analyses that provide the Reactor Core Safety Limits (SLs) of SL 2.1.1. Therefore, any DNB events in which the calculation of the core limits is modeled implicitly use

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

this variable value of F^N_{AH} in the analyses. Likewise, all transients that may be DNB limited are assumed to begin with an limiting initial F^N_{AH} as a function of power level defined by the COLR F^N_{AH} limit equation in the COLR.

The LOCA safety analysis indirectly models also uses F^N_{AH} as an input parameter. The Nuclear Heat Flux Hot Channel Factor (F₀(Z)) and the axial peaking factors are inserted directly into the LOCA safety analyses that verify the acceptability of the resulting peak cladding temperature [Ref. 3].

The fuel is protected in part by compliance with Technical Specifications, which ensure that the initial conditions assumed in the safety and accident analyses remain valid. The following LCOs ensure this:
LCO 3.2.3, "AXIAL FLUX DIFFERENCE (AFD)," LCO 3.2.4, "QUADRANT POWER TILT RATIO (QPTR)," LCO 3.1.7 6, "Control Bank Insertion Limits," LCO 3.2.2, "Nuclear Enthalpy Rise Hot Channel Factor (F^N_{AH})," and LCO 3.2.1, "Heat Flux Hot Channel Factor (F₀(Z))."

F^N_{AH} and F₀(Z) are measured periodically using the movable incore detector system. Measurements are generally taken with the core at, or near, steady state conditions. Core monitoring and control under transient conditions (Condition 1 events) are accomplished by operating the core within the limits of the LCOs on AFD, QPTR, and Bank Insertion Limits.

F^N_{AH} satisfies Criterion 2 of the NRC Policy Statement 10 CFR 50.36(c)(2)(ii).

LCO

F^N_{AH} shall be maintained within the limits of the relationship provided in the COLR.

The F^N_{AH} limit identifies is representative of the coolant flow channel with the maximum enthalpy rise. This channel has the least heat removal capability and thus the highest probability for a DNB condition.

The limiting value of F^N_{AH}, described by the equation contained in the COLR, is the design radial peaking factor used in the unit safety analyses.

A power multiplication factor in this equation includes an additional margin allowance for higher radial peaking factors from reduced

(continued)

BASES

LCO
(continued)

thermal feedback and greater control rod insertion at low power levels. The limiting value of F^N is allowed to increase 0.3% by a cycle dependent factor, PF_{LD}, specified in the COER for every a 1% RTP reduction in THERMAL POWER.

If the power distribution measurements are performed at a power level less than 100% RTP then the F^N values that would result from measurements if the core was at 100% RTP should be inferred from the available information. A comparison of these inferred values with F^N assures compliance with the LCO at all power levels.

APPLICABILITY

The F^N limits must be maintained in MODE 1 to preclude core power distributions from exceeding the fuel design limits for DNBR and PCT. Applicability in other modes is not required because there is either insufficient stored energy in the fuel or insufficient energy being transferred to the coolant to require a limit on the distribution of core power. Specifically, the design bases events that are sensitive to F^N in other modes (MODES 2 through 5) have significant margin to DNB, and therefore, there is no need to restrict F^N in these modes.

ACTIONS

A.1.1

With F^N exceeding its limit, the unit is allowed 4 hours to restore F^N to within its limits. This restoration may, for example, involve realigning any misaligned rods or reducing power enough to bring F^N within its power dependent limit. When the F^N limit is exceeded, the DNBR limit is not likely to be violated in steady state operation, because events that could significantly perturb the F^N value (e.g., static control rod misalignment) are considered in the safety analyses. However, the DNBR limit may be violated if a DNB limiting event occurs. Thus, the allowed Completion Time of 4 hours provides an acceptable time to restore F^N to within its limits without allowing the plant to remain in an unacceptable condition for an extended period of time. The restoration of the peaking factor to within its limits by power reduction or control rod movement does not restore compliance with the LCO. Thus, this condition can not be exited until a valid surveillance demonstrates compliance with the LCO.

Condition A is modified by a Note that requires that Required Actions A.2 and A.3 must be completed whenever Condition A is entered. Thus, if power is not reduced because this Required Action is completed within the 4 hour time period, Required Action A.2 nevertheless requires another measurement and calculation of F^N within 24 hours in accordance with SR 3.2.2.1.

However, if power is reduced below 50% RTP, Required Action A.3 requires that another determination of F^N must be done prior to exceeding 50% RTP, prior to exceeding

(continued)

BASES

ACTIONS

A.1.1 (continued)

75% RTP, and within 24 hours after reaching or exceeding 95% RTP; however, THERMAL POWER does not have to be reduced to comply with these requirements. In addition, Required Action A.2 is performed if power ascension is delayed past 24 hours.

A.1.2.1 and A.1.2.2

If the value of F^N is not restored to within its specified limit either by adjusting a misaligned rod or by reducing THERMAL POWER, the alternative option is to reduce THERMAL POWER to < 50% RTP in accordance with Required Action A.1.2.1 and reduce the Power Range Neutron Flux-High to \leq 55% RTP in accordance with Required Action A.1.2.2. Reducing RTP THERMAL POWER to < 50% RTP increases the DNB margin and does not likely cause the DNBR limit to be violated in steady state operation. The reduction in trip setpoints ensures that continuing operation remains at an acceptable low power level with adequate DNBR margin. The allowed Completion Time of 4 hours for Required Action A.1.2.1 is consistent with those allowed for in Required Action A.1.1 and provides an acceptable time to reach the required power level from full power operation without allowing the plant to remain in an unacceptable condition for an extended period of time. The Completion Times of 4 hours for Required Actions A.1.1 and A.1.2.1 are not additive.

The allowed Completion Time of 72 hours to reset the trip setpoints per Required Action A.1.2.2 recognizes that, once power is reduced, the safety analysis assumptions are satisfied and there is no urgent need to reduce the trip setpoints; however, for extended operations at the reduced power level, the reduced trip setpoints are required to protect against involving positive reactivity excursions. This is a sensitive operation that may inadvertently trip-actuate the Reactor Protection System.

A.2

Once actions have been taken to restore F^N to within its limits per Required Action A.1.1, or the power level has been reduced to < 50% RTP per Required Action A.1.2.1, an incore flux map (SR 3.2.2.1) must be obtained and the measured value of F^N verified not to exceed the allowed limit at the lower power level. The unit is provided 20 additional hours to perform this task over and above the 4 hours allowed by either Action A.1.1 or Action A.1.2.1. The Completion Time of 24 hours is acceptable because of the increase in the DNB margin, which

(continued)

BASES

ACTIONS

A.2 (continued)

is obtained at lower power levels, and the low probability of having a DNB limiting event within this 24 hour period. Additionally, operating experience has indicated that this Completion Time is sufficient to obtain the incore flux map, perform the required calculations, and evaluate F^N_{AH}.

A.3

Verification that F^N_{AH} is within its specified limits after an out of limit occurrence ensures that the cause that led to the F^N_{AH} exceeding its the F^N_{AH} limit is identified to the extent necessary, and corrected, and that subsequent operation proceeds within the LCO limit. This Action demonstrates that the F^N_{AH} limit is within the LCO limits prior to exceeding 50% RTP, again prior to exceeding 75% RTP, and within 24 hours after THERMAL POWER is ≥ 95% RTP. SR 3.2.2.1 must be satisfied prior to increasing power above the extrapolated allowable power level or restoration of any reduced Reactor Trip System setpoints. When F^N_{AH} is measured at reduced power levels, the allowable power level is determined by evaluating F^N_{AH} for higher power levels.

This Required Action is modified by a Note that states that THERMAL POWER does not have to be reduced prior to performing this Action.

B.1

When Required Actions A.1.1 through A.3 cannot be completed within their required Completion Times, the plant must be placed in a mode in which the LCO requirements are not applicable. This is done by placing the plant in at least MODE 2 within 6 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience regarding the time required to reach MODE 2 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.2.1

SR 3.2.2.1 is modified by a Note. The Note applies during power ascensions following a plant shutdown (leaving MODE 1). The Note allows for power ascensions if the surveillances are not current. It states that THERMAL POWER may be increased until an equilibrium power level has been achieved at which a power distribution map can be obtained. Equilibrium conditions are achieved when the core is sufficiently stable such that uncertainties associated with the measurement are valid.

The value of F^N_{AH} is determined by using the movable incore detector system to obtain a flux distribution map. A data reduction computer program then calculates the maximum value of F^N_{AH} from the measured flux distributions. The measured value of F^N_{AH} must be multiplied by 1.04 to account for

(continued)

SURVEILLANCE
REQUIREMENTS

SR 3.2.2.1 (continued)

measurement uncertainty before making comparisons to the F_{NH} limit.

After each refueling, F_{NH} must be determined in MODE 1 prior to exceeding 75% RTP. This requirement ensures that F_{NH} limits are met at the beginning of each fuel cycle. Performing this Surveillance in MODE 1 prior to exceeding 75% RTP, or at a reduced power level at any other time, and meeting the 100% RTP F_{NH} limit, provides assurance that the F_{NH} limit is met when RTP is achieved because peaking factors generally decrease as power level is increased.

The 31 EFPD Frequency is acceptable because the power distribution changes relatively slowly over this amount of fuel burnup. Accordingly, this Frequency is short enough that the F_{NH} limit cannot be exceeded for any significant period of operation.

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.3B AXIAL FLUX DIFFERENCE (AFD) (~~Relaxed Axial Offset Control (RAOC) Methodology~~)

BASES

BACKGROUND

The purpose of this LCO is to establish limits on the values of the AFD in order to limit the amount of axial power distribution skewing to either the top or bottom of the core. By limiting the amount of power distribution skewing, core peaking factors are consistent with the assumptions used in the safety analyses. Limiting power distribution skewing over time also minimizes the xenon distribution skewing, which is a significant factor in axial power distribution control.

~~Relaxed Axial Offset Control (RAOC) is a calculational procedure that defines the allowed operational space of the AFD versus THERMAL POWER. The AFD limits are selected by considering a range of axial xenon distributions that may occur as a result of large variations of the AFD. Subsequently, power peaking factors and power distributions are examined to ensure that the loss of coolant accident (LOCA), loss of flow accident, and anticipated transient limits are met. Violation of the AFD limits invalidate the conclusions of the accident and transient analyses with regard to fuel cladding integrity.~~

~~The AFD is monitored on an automatic basis using the unit plant process computer, which has an AFD monitor alarm. The computer determines the 1 minute average of each of the OPERABLE excore detector outputs and provides an alarm message immediately if the AFD for two or more OPERABLE excore channels is outside its specified limits.~~

Although the RAOC defines limits that must be met to satisfy safety analyses, typically an operating scheme, ~~Constant Axial Offset Control (CAOC)~~, is used to control axial power distribution in day to day operation (Ref. 1). ~~CAOC~~ This requires that the AFD be controlled within a narrow tolerance band around a burnup dependent target to minimize the variation of axial peaking factors and axial xenon distribution during unit maneuvers.

~~The CAOC This operating space is typically smaller and lies within the RAOC operating space. Control within the CAOC This operating space constrains the variation of axial xenon distributions and axial power distributions. RAOC calculations assume a wide range of xenon distributions and then confirm that the resulting power distributions satisfy the requirements of the accident analyses.~~

(continued)

BASES (continued)

APPLICABLE

The AFD is a measure of the axial power distribution skewing SAFETY ANALYSES to either the top or bottom half of the core. The AFD is sensitive to many core related parameters such as control bank positions, core power level, axial burnup, axial xenon distribution, and, to a lesser extent, reactor coolant temperature and boron concentration.

The allowed range of the AFD is used in the nuclear design process to confirm that operation within these limits produces core peaking factors and axial power distributions that meet safety analysis requirements.

The RAOC methodology (Ref. 2) establishes a xenon distribution library with tentatively wide AFD limits. One dimensional axial power distribution calculations are then performed to demonstrate that normal operation power shapes are acceptable for the LOCA and loss of flow accident, and for initial conditions of anticipated transients. The tentative limits are adjusted as necessary to meet the safety analysis requirements.

The limits on the AFD ensure that the Heat Flux Hot Channel Factor ($F_0(Z)$) is not exceeded during either normal operation or in the event of xenon redistribution following power changes. The limits on the AFD also restrict the range of power distributions that are used as initial conditions in the analyses of Condition 2, 3, or 4 II, III, or IV events. This compliance with these limits ensures that the fuel cladding integrity is maintained for these postulated accidents. The most important Condition 4 IV event is the LOCA. The most important Condition 3 III event is the complete loss of forced RCS flow accident. The most important Condition 2 II events are uncontrolled bank withdrawal and boration or dilution accidents. Condition 2 II accidents simulated to begin from within the AFD limits are used to confirm the adequacy of the Overpower ΔT and Overtemperature ΔT trip setpoints.

The limits on the AFD satisfy Criterion 2 of the NRC Policy Statement 10 CFR 50.36(c)(2)(ii).

LCO

The shape of the power profile in the axial (i.e., the vertical) direction is largely under the control of the operator through the manual operation of the control banks or automatic motion of control banks. The automatic motion

(continued)

BASES

LCO
(continued)

of the control banks is in response to temperature deviations resulting from manual operation of the Chemical and Volume Control System to change boron concentration or from power level turbine load changes.

Signals are available to the operator from the Nuclear Instrumentation System (NIS) excore neutron detectors (Ref. 3). Separate signals are taken from the top and bottom power range detectors. The AFD is defined as the difference in normalized flux signals between the top and bottom excore detectors in each detector well. For convenience, this flux difference is converted to provide flux difference units expressed as a percentage and labeled as $\% \Delta$ flux or $\% \Delta I$.

The AFD limits are provided in the COLR. -
~~Figure B 3.2.3B 1 shows typical RAOC AFD limits.~~ The AFD limits for RAOC do not depend on the target flux difference. However, the target flux difference AFD may be used to minimize changes in the axial power distribution.

Violating this LCO on the AFD could produce unacceptable consequences if a Condition 2, 3, or 4 T1, T2, or IV event occurs while the AFD is outside its specified limits.

 APPLICABILITY

The AFD requirements are applicable in MODE 1 greater than or equal to 50% RTP when the combination of THERMAL POWER and core peaking factors are of primary importance in safety analysis.

For AFD limits developed using RAOC methodology, the value of the AFD does not affect the limiting accident consequences with THERMAL POWER < 50% RTP and for lower operating power MODES.

 ACTIONS

A.1

As an alternative to restoring the AFD to within its specified limits, Required Action A.1 requires a THERMAL POWER reduction to < 50% RTP. This places the core in a condition for which the value of the AFD is not important in the applicable safety analyses. A Completion Time of

(continued)

BASES

ACTIONSA.1 (continued)

30 minutes is reasonable, based on operating experience, to reach 50% RTP without challenging plant systems.

SURVEILLANCE
REQUIREMENTSSR 3.2.3.1

~~The AFD is monitored on an automatic basis using the unit process computer, which has an AFD monitor alarm. The computer determines the 1 minute average of each of the OPERABLE excore detector outputs and provides an alarm message immediately if the AFD for two or more OPERABLE excore channels is outside its specified limits.~~

This Surveillance verifies that the AFD, as indicated by the ~~each OPERABLE~~ NIS excore channel, is within its specified limits, and is consistent with the status of the AFD monitor alarm. ~~With the AFD monitor alarm inoperable, the AFD is monitored every hour to detect operation outside its limit. The Frequency of 1 hour is based on operating experience regarding the amount of time required to vary the AFD, and the fact that the AFD is closely monitored. With the AFD monitor alarm OPERABLE, the Surveillance Frequency of 7 days is adequate considering that the AFD is monitored by a computer and any deviation from requirements is alarmed.~~

AXIAL FLUX DIFFERENCE Acceptable Operation Limits
as a Function of RATED THERMAL POWER

(continued)

B 3.2 POWER DISTRIBUTION LIMITS

B 3.2.4 QUADRANT POWER TILT RATIO (QPTR)

BASES

BACKGROUND

The QPTR limit ensures that the gross radial power distribution remains consistent with the design values used in the safety analyses. Precise radial power distribution measurements are made during startup testing, after refueling, and periodically during power operation.

The power density at any point in the core must be limited so that the fuel design criteria are maintained. Together, LCO 3.2.3, "AXIAL FLUX DIFFERENCE (AFD)," LCO 3.2.4, and LCO 3.1.7.6, "Control Bank Insertion Limits," provide limits on process variables that characterize and control the three dimensional power distribution of the reactor core. Control of these variables ensures that the core operates within the fuel design criteria and that the power distribution remains within the bounds used in the safety analyses.

APPLICABLE
SAFETY ANALYSES

This LCO precludes core power distributions that violate the following fuel design criteria:

- a. During a large break loss of coolant accident, the peak cladding temperature must not exceed 2200°F (Ref. 1);
- b. During a ~~the Condition II partial~~ loss of forced reactor coolant flow accident, there must be at least 95% probability at the 95% confidence level (the 95/95 departure from nucleate boiling (DNB) criterion) that the hot fuel rod in the core does not experience a DNB condition;
- c. During an ejected rod accident, ~~the energy deposition to the average fuel pellet enthalpy at the hot spot in irradiated fuel~~ must not exceed 280 cal/gm (Ref. 2); and
- d. The control rods must be capable of shutting down the reactor with a minimum required SDM with the highest worth control rod stuck fully withdrawn (Ref. 3).

The LCO limits on the AFD, the QPTR, the Heat Flux Hot Channel Factor ($F_0(Z)$), the Nuclear Enthalpy Rise Hot

(continued)

BASES

APPLICABLE
SAFETY ANALYSES

(continued)

Channel Factor (F_{ch}^N), and control bank insertion are established to preclude core power distributions that exceed the safety analyses limits.

The QPTR limits ensure that F_{ch}^N and $F_0(Z)$ remain below their limiting values by preventing an undetected change in the gross radial power distribution.

In MODE 1, the F_{ch}^N and $F_0(Z)$ limits must be maintained to preclude core power distributions from exceeding design limits assumed in the safety analyses.

The QPTR satisfies Criterion 2 of the NRC Policy Statement ~~10 CFR 50.36(c)(2)(ii)~~.

LCO

The QPTR limit of 1.02, at above which corrective action is required, provides a margin of protection for both the DNB ratio and linear heat generation rate contributing to excessive power peaks resulting from X-Y plane power tilts. A limiting QPTR of 1.02 can be tolerated before the margin for uncertainty in $F_0(Z)$ and (F_{ch}^N) is possibly challenged.

APPLICABILITY

The QPTR limit must be maintained in MODE 1 with THERMAL POWER > 50% RTP to prevent core power distributions from exceeding the design limits.

Applicability in MODE 1 \leq 50% RTP and in other MODES is not required because there is either insufficient stored energy in the fuel or insufficient energy being transferred to the reactor coolant to require the implementation of a QPTR limit on the distribution of core power. The QPTR limit in these conditions is, therefore, not important. Note that the F_{ch}^N and $F_0(Z)$ LCOs still apply, but allow progressively higher peaking factors at 50% RTP or lower.

ACTIONS

A.1

With the QPTR exceeding its limit, a power level reduction of 3% RTP for each 1% by which the QPTR exceeds 1.00 is a conservative tradeoff of total core power with peak linear power. The Completion Time of 2 hours allows sufficient

(continued)

BASES

ACTIONS

A.1 (continued)

time to identify the cause and correct the tilt. Note that the power reduction itself may cause a change in the tilted condition.

A.2

After completion of Required Action A.1, the QPTR ~~alarm may still be in its alarmed state may still exceed its limits.~~ As such, any additional changes in the QPTR are detected by requiring a check of the QPTR once per 12 hours thereafter. If the QPTR continues to increase, THERMAL POWER has to be reduced accordingly. A 12 hour Completion Time is sufficient because any additional change in QPTR would be relatively slow.

A.3

The peaking factors F_{AH}^N and $F_0(Z)$ are of primary importance in ensuring that the power distribution remains consistent with the initial conditions used in the safety analyses. Performing SRs on F_{AH}^N and $F_0(Z)$ within the Completion Time of 24 hours ensures that these primary indicators of power distribution are within their respective limits. A Completion Time of 24 hours takes into consideration the rate at which peaking factors are likely to change, and the time required to stabilize the plant and perform a flux map. If these peaking factors are not within their limits, the Required Actions of these Surveillances provide an appropriate response for the abnormal condition. If the QPTR remains above its specified limit, the peaking factor surveillances are required each 7 days thereafter to evaluate F_{AH}^N and $F_0(Z)$ with changes in power distribution. Relatively small changes are expected due to either burnup and xenon redistribution or correction of the cause for exceeding the QPTR limit.

A.4

Although F_{AH}^N and $F_0(Z)$ are of primary importance as initial conditions in the safety analyses, other changes in the power distribution may occur as the QPTR limit is exceeded

(continued)

BASES

ACTIONS

A.4 (continued)

and may have an impact on the validity of the safety analysis. A change in the power distribution can affect such reactor parameters as bank worths and peaking factors for rod malfunction accidents. When the QPTR exceeds its limit, it does not necessarily mean a safety concern exists. It does mean that there is an indication of a change in the gross radial power distribution that requires an investigation and evaluation that is accomplished by examining the incore power distribution. Specifically, the core peaking factors and the quadrant tilt must be evaluated because they are the factors that best characterize the core power distribution. This re-evaluation is required to ensure that, before increasing THERMAL POWER to above the limit of Required Actions A.1 and A.2, the reactor core conditions are consistent with the assumptions in the safety analyses.

A.5

If the QPTR has exceeded remains above the 1.02 limit and a re-evaluation of the safety analysis is completed and shows that safety requirements are met, the excore detectors are normalized to eliminate the indicated tilt recalibrated to show a zero QPTR prior to increasing THERMAL POWER to above the limit of Required Actions A.1 and A.2. This is done to detect any subsequent significant changes in QPTR.

Required Action A.5 is modified by a Note that states that the indicated tilt is not eliminated QPTR is not zeroed out until after the re-evaluation of the safety analysis has determined that core conditions at RTP are within the safety analysis assumptions (i.e., Required Action A.4). This Note is intended to prevent any ambiguity about the required sequence of actions.

A.6

Once the excore detectors are normalized to eliminate the indicated tilt flux tilt is zeroed out (i.e., Required Action A.5 is performed), it is acceptable to return to full power operation. However, as an added check that the core power distribution at RTP is consistent with the safety analysis assumptions, Required Action A.6 requires verification that $F_0(Z)$ and F_{AH}^N are within their specified limits within 24 hours of reaching RTP. As an added precaution, if the peaking factor verification cannot be performed within 24 hours due to the non-equilibrium core conditions, a maximum time of 48 hours is allowed for the completion of the verification.

(continued)

BASES

ACTIONS

A.6 (continued)

~~core power does not reach RTP within 24 hours, but is increased slowly, then the peaking factor surveillances must be performed within 48 hours of the time when the ascent to power was begun. These Completion Times are intended to allow adequate time to increase THERMAL POWER to above the limit of Required Actions A.1 and A.2, while not permitting the core to remain with unconfirmed power distributions for extended periods of time.~~

Required Action A.6 is modified by a Note that states that the peaking factor surveillances may only be done after must be completed when the excore detectors have been normalized to eliminate the indicated tilt calibrated to show zero tilt (i.e., Required Action A.5). The intent of this Note is to have the peaking factor surveillances performed at operating power levels, which can only be accomplished after are only required if the excore detectors are calibrated were normalized to show zero tilt and the core returned to power per Required Action A.5.

B.1

If Required Actions A.1 through A.6 are not completed within their associated Completion Times, the unit must be brought to a MODE or condition in which the requirements do not apply. To achieve this status, THERMAL POWER must be reduced to $\leq 50\%$ RTP within 4 hours. The allowed Completion Time of 4 hours is reasonable, based on operating experience regarding the amount of time required to reach the reduced power level without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.2.4.1

SR 3.2.4.1 is modified by two Notes. Note 1 allows QPTR to be calculated with three power range channels if THERMAL POWER is $\leq 75\%$ RTP and the input from one Power Range Neutron Flux channel is inoperable. Note 2 allows performance of SR 3.2.4.2 in lieu of SR 3.2.4.1, if more than one input from Power Range Neutron Flux channels are inoperable.

~~Input from a Power Range Neutron Flux channel is considered to be OPERABLE if the upper and lower detector currents are obtainable. The remaining portion of the channel (the electronics required to provide the channel input to the QPTR alarm) need not be OPERABLE.~~

This Surveillance verifies that the QPTR, as indicated by the Nuclear Instrumentation System (NIS) excore channels, is

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.2.4.1 (continued)

within its limits. The Frequency of 7 days takes into account other information and alarms available to the operator in the control room. ~~When the QPTR alarm is OPERABLE is acceptable because of the low probability that this alarm can remain inoperable without detection.~~

~~When the QPTR alarm is inoperable, the Frequency is increased to 12 hours. This Frequency is adequate to detect any relatively slow changes in QPTR, because for those causes of QPT that occur quickly (e.g., a dropped rod), there typically are other indications of abnormality that prompt a verification of core power tilt.~~

SR 3.2.4.2

This Surveillance is modified by a Note, which states that it is not required until 12 hours after only when the input from one or more Power Range Neutron Flux channels are is inoperable and the THERMAL POWER is \approx 75% RTP.

With an NIS power range channel inoperable, tilt monitoring for a portion of the reactor core becomes degraded. Large tilts are likely detected with the remaining channels, but the capability for detection of small power tilts in some quadrants is decreased. Performing SR 3.2.4.2 at a Frequency of 12 hours provides an accurate alternative means for ensuring that any tilt remains within its limits.

For purposes of monitoring the QPTR when one or more power range channels is are inoperable, the moveable incore detectors are used to confirm that the normalized symmetric power distribution is consistent with the indicated QPTR and any previous data indicating a tilt. The incore detector monitoring is performed with a full incore flux map or two sets of four thimble locations with quarter core symmetry. The two sets of four symmetric thimbles is a set of eight unique detector locations. These locations are C-8, E-5, E-11, H-3, H-13, L-5, L-11, and N-8 for three and four loop cores.

The symmetric thimble flux map can be used to generate symmetric thimble "tilt." This can be compared to a reference symmetric thimble tilt, from the most recent full

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.2.4.2 (continued)

core flux map, to generate an incore QPTR. Therefore, incore QPTR can be used to confirm that QPTR is within limits.

With one NIS channel inoperable, the indicated tilt may be changed from the value indicated with all four channels OPERABLE. To confirm that no change in tilt has actually occurred, which might cause the QPTR limit to be exceeded, the incore result may be compared against previous flux maps either using the symmetric thimbles as described above or a complete flux map. Nominally, quadrant tilt from the Surveillance should be within 2% of the tilt shown by the most recent flux map data.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is

Methodology For Mark-up of NUREG-1431 Bases

"struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases, as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

ENCLOSURE 6A

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(2 Pages)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3/4.2

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.2-01	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 6B).
3.2-02	Consistent with the CTS, retain the requirement for performing F_0 after a 20 percent change in power (versus the 10 percent value specific in the ITS).
3.2-03	Consistent with Traveler TSTF-98, Rev. 1, the factor by which the F_0 must be adjusted on increasing F_0 measurements is moved to the COLR. This change is acceptable because the factor is normally contained in the COLR, and it removes detail not required to be contained in TS.
3.2-04	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 6B).
3.2-05	In accordance with Traveler TSTF-25, clarify that the excore detectors are normalized to indicate zero tilt. This is only a clarification of NUREG-1431 wording and is acceptable.
3.2-06	Consistent with Traveler TSTF-95, the time allowed for resetting the power range neutron flux - high setpoint if F_0 or $F_{\Delta H}^N$ is outside their limits is extended from 8 hours to 72 hours. As written, the Completion Time of 8 hours to reduce the power range neutron flux-high Trip Setpoints presents an unjustified burden on the operation of the plant. A Completion Time of 72 hours will allow time to perform a second flux map to confirm the results, or determine that the Condition was temporary, without implementing an unnecessary Trip Setpoint change, during which there is increased potential for a plant transient and human error. Following a significant power reduction, at least 24 hours are required to reestablish steady state xenon prior to taking a flux map, and approximately 8 to 12 hours to obtain a flux map, and analyze the data. A significant potential for human error can be created through requiring the Trip Setpoints to be reduced within the same time frame that a unit power reduction is taking place, and within the current 8 hour period. Setpoint adjustment is estimated to take approximately, 4 hours per channel (review of plant Condition supportive of removing channels from service, tripping of bistables, setpoint adjustments, and channel restoration), adding 2 hours for necessary initial preparations (procedure preps, calibration equipment checks, obtaining tools, and approvals), it is reasonable to expect a total of 18 hours. Further, setpoint changes should only be required for extended operation in this Condition. Finally, the Bases for making this setpoint change is the same as the NUREG Bases provided for the 72 hour Completion Time of LCO 3.2.1 Required Action A.4, which is also a setpoint reduction. In summary, this change is acceptable because it would permit time to perform required flux mapping, permit orderly resetting of the high flux Trip Setpoints, and reduce the chances of an inadvertent reactor trip during the required power reduction.
3.2-07	Consistent with Traveler TSTF-97; the Note in SR 3.2.1.2 is revised by removing the phrase "is within limits and" to clarify that the actions to be taken if $F_0^c(Z)$ is increasing are required regardless of whether $F_0^c(Z)$ is within its limits.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3/4.2

- 3.2-08 Consistent with Traveler TSTF-99, the LCO 3.2.1 (F_o Methodology), Required ACTION B.1. Completion Time for the reduction of the AFD limits if $F_o^w(Z)$ is not within limits is increased from 2 hours to 4 hours. This makes it consistent with the Completion Time associated with Required ACTION A.2. of LCO 3.2.1 (F_{xy} methodology). The change is acceptable because it eliminates an inconsistency in the ITS.
- 3.2-09 For consistency with CTS 3.2.4 and ITS 3.3.1, Condition D, the breakpoints for the Applicability of the surveillances in the notes in ITS SR 3.2.4.1 and SR 3.2.4.2 are modified to be applicable at less than or equal to 75 percent RTP, and greater than 75 percent RTP, respectively. This is an administrative change that retains CTS requirements.
- 3.2-10 Consistent with Traveler TSTF-110, this change moves requirements for increased surveillance frequencies in the event of inoperable alarms to licensee controlled documents. This change is acceptable because it removes requirements regarding alarms and alarm responses that are not necessary to be in the TS to protect public health and safety.
- 3.2-11 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.2-12 Consistent with CTS, the required time for completion of a flux map for determination of the heat flux hot channel factor is changed from 12 hours to 24 hours after achieving equilibrium Conditions. The proposed change affects SR 3.2.1.1 and SR 3.2.2.1. The proposed time (24 hours) is a reasonable time period for the completion of the surveillance and does not allow for plant operation in an uncertain condition for a protracted time period. This change is consistent with the TS requirements of Specification 3.0.4 (and associated Bases) that allow 24 hours for the completion of a surveillance after prerequisite plant conditions are attained and for which an exception to Specification 4.0.4 was provided.
- 3.2-13 This change retains the CTS for the performance of peaking factor determinations following plant shutdowns. The CTS, through the exemption to Specification 4.0.4, allows prerequisite plant conditions to be obtained prior to requiring that the surveillance be completed.
- 3.2-14 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.2-15 This change incorporates Traveler TSTF-109. ACTION A.2. would require the QPTR be determined rather than performing a specific surveillance because more than one surveillance can be used to determine QPTR. SR 3.2.4.1 was revised to retain allowance that SR 3.2.4.2 may be performed in lieu of SR 3.2.4.1. The note for SR 3.2.4.2 is changed to require performance if one "or more" QPTR inputs are inoperable with RTP > 75 percent. These changes are acceptable because they clarify the ITS regarding frequency and use of incore flux monitoring for QPTR measurement. The changes reflect that incore detectors provide an acceptable QPTR determination during all plant Conditions.
- 3.2-16 This change would require both transient and static F_o measurements be determined when performed for Required ACTIONS 3.2.4 A.3 and A.6. The intent of the Required ACTIONS is to verify that $F_o(Z)$ is within its limit. $F_o(Z)$ is approximated by $F_o^c(Z)$ (which is obtained via SR 3.2.1.1) and $F_o^w(Z)$ (which is obtained via SR 3.2.1.2). Thus, both $F_o^c(Z)$ and $F_o^w(Z)$ must be established to verify $F_o(Z)$. This change is consistent with Traveler WOG-105.
- 3.2-17 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.2-18 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.2-19 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).

Functional Units 20, 21, 22, and 24 are not consistently numbered in the CTS between Table 3.3-1 and 4.3-1, however their nomenclature is consistent as is the APPLICABILITY, ACTIONS and Surveillances. The Functional Unit grouping that follows is per CTS Table 3.3-1 Functional Unit description and number except for Functional Unit 24 that is only shown on Table 4.3-1. Those Functional Units with mixed numbers show both, and the * Functional Units are from Table 4.3-1.

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used

Methodology for Cross-Reference Tables
(Continued)

to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another

Methodology for Cross-Reference Tables
(Continued)

document (e.g., requirements already adequately addressed by regulations).

NA This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).

Note: The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

3/4.3 INSTRUMENTATION

3/4.3.1 REACTOR TRIP SYSTEM INSTRUMENTATION

LIMITING CONDITION FOR OPERATION

3.3.1 As a minimum, the Reactor Trip System instrumentation channels and interlocks of Table 3.3-1 shall be OPERABLE with ~~RESPONSE TIMES as shown in Table 3.3-2.~~

01-35-LG

APPLICABILITY: As shown in Table 3.3-1.

ACTION: *

01-01-A

As shown in Table 3.3-1.

SURVEILLANCE REQUIREMENTS

4.3.1.1 Each Reactor Trip System instrumentation channel and interlock and the automatic trip logic shall be demonstrated OPERABLE by performance of the Reactor Trip System Instrumentation Surveillance Requirements specified in Table 4.3-1.

4.3.1.2 The ~~required~~ REACTOR TRIP SYSTEM RESPONSE TIME of each Reactor trip function shall be demonstrated ~~verified~~ to be within its limit at least once per 18 months on a ~~STAGGERED TEST BASIS~~. Each test shall include at least one train such that both trains are tested at least once per 36 months and one channel per function such that all channels are tested at least once every N times 18 months where N is the total number of redundant channels in a specific Reactor trip function as shown in the "Total No. of Channels" column of Table 3.3-1.

01-02-LG

01-03-LS1

~~(new) * Separate Condition entry allowed for each function.~~

TABLE NOTATIONS

* When the Reactor Trip System breakers are in the closed position and the Control Rod Drive System is capable of rod withdrawal or all rods are not fully inserted.	01-55-LS39
#The provisions of Specification 3.0.4 are not applicable.	01-05-A
##Below the P-6 (Intermediate Range Neutron Flux Interlock) Setpoint.	
###Below the P-10 (Low Setpoint Power Range Neutron Flux Interlock) Setpoint.	
(new) ** Not required to be performed until 12 hours after input from one Power Range Neutron Flux channel to QPTR is inoperable and THERMAL POWER is > 75% RTP.	01-53-A
(new) (f) With the RTB's open or the Rod Control System incapable of withdrawal. In this condition, source range function does not provide reactor trip but does provide indication.	01-47-A
(new) (j) Above the P-9 (Power Range Neutron Flux) Interlock.	01-48-LS4
(new) (k) Including any reactor trip bypass breakers that are racked in and closed for bypassing an RTB.	01-14-A
(new) (d) Above the P-6 (Intermediate Range Neutron Flux) Interlock.	01-07-LS3
(new) (g) Above the P-7 (Low Power Reactor Trips Block) Interlock.	01-19-LS8

ACTION STATEMENTS

ACTION 1 - With the number of channels OPERABLE one less than the Minimum REQUIRED Channels OPERABLE requirement, restore the inoperable channel to OPERABLE status within 48 hours or be in at least HOT STANDBY within the next 6 hours.	01-04-LG
ACTION 2 - With the number of OPERABLE channels one less than the Total Number of REQUIRED Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:	01-43-A
a. The inoperable channel is placed in the tripped condition within 6 hours.	
b. The Minimum Channels OPERABLE requirement is met; however, the inoperable channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.1.1 and set point adjustment, and	01-04-LG 01-17-A
c. Either, THERMAL POWER is restricted to less than or equal to 75% of RATED THERMAL POWER and the Power Range Neutron Flux Trip Setpoint is reduced to less than or equal to 85% of RATED THERMAL POWER within 4 (2) hours; or, if the power range neutron flux input to the QUADRANT POWER TILT RATIO is inoperable, the QPTR is monitored per Specification 4.2.4.2*** when THERMAL POWER is greater than or equal to 50% of RATED THERMAL POWER.	01-18-LS7 01-53-A 01-56-A
(new) Otherwise be in MODE 3 within 12 hours.	01-18-LS7
(new) ACTION 2.1 With one Channel Inoperable, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied (Note: The inoperable channel may be bypassed for up to 4 hours for surveillance testing of other channels per Specification 4.3.1.1 and setpoint adjustment):	01-06-LS2
a. Place the inoperable channel in tripped condition within 6 hours, or	
b. Be in MODE 3 within 12 hours.	01-17-A

TABLE 3.3-1 (Continued)

ACTION STATEMENTS (Continued)

ACTION 3 -	With the number of channels OPERABLE one less than the Minimum REQUIRED Channels OPERABLE requirement and with the THERMAL POWER level:	01-04-LG
a.	Below the P-6 (Intermediate Range Neutron Flux Interlock) Setpoint, restore the inoperable channel to OPERABLE status prior to increasing THERMAL POWER above the P-6 Setpoint, and	01-07-LS3
b.	Above the P-6 Setpoint, but below 10% of RATED THERMAL POWER, within 24 hours restore the inoperable channel to OPERABLE status prior to increasing or reduce Thermal Power to less than P-6, or increase THERMAL POWER above 10% of RATED THERMAL POWER.	01-07-LS3
ACTION 3.1 (new)	With two Intermediate Range Neutron Flux Channels inoperable and with the THERMAL POWER level above the P-6 Setpoint but below 10% of RATED THERMAL POWER, immediately suspend operations involving positive reactivity additions and, within 2 hours, reduce THERMAL POWER to less than the P-6 Setpoint.	01-07-LS3
ACTION 4 -	With the number of channels OPERABLE one less than the Minimum REQUIRED Channels OPERABLE requirement immediately suspend all operations involving positive reactivity changes.	01-04-LG 01-08-M
ACTION 4.1 (new)	With no source range neutron flux channels OPERABLE immediately open the reactor trip breakers	01-08-M
ACTION 5 -	With the number of channels OPERABLE one less than the Minimum REQUIRED Channels OPERABLE requirement, immediately suspend operations involving positive reactivity additions and verify compliance with the SHUTDOWN MARGIN requirements of Specification 3.1.1.1 or 3.1.1.2, as applicable, within 1 hour and at least once per 12 hours thereafter.	01-04-LG 01-09-M
ACTION 6 -	With the number of OPERABLE channels one less than the Total Number of REQUIRED Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:	01-43-A
a.	The inoperable channel is placed in the tripped condition within 6 hours, and or	01-19-LS8
b.	Reduce Thermal Power to < P-7 within 12 hours. The Minimum Channels OPERABLE requirement is met; however,	01-04-LG
	Note: The inoperable channel or one additional channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.1.1.	
ACTION 7 -	With the number of OPERABLE channels less than the Total Number of Required Channels, STARTUP and/or POWER OPERATION may proceed provided the inoperable channel(s) is (are) placed in the tripped condition within 6 hours or THERMAL POWER is decreased < P-9 in 10 hours.	01-43-A 01-48-LS4
	NOTE: The inoperable low Autostop oil pressure channel may be bypassed for up to 4 hours for surveillance testing of other channels.	
ACTION 8 -	With less than the Minimum Number of Required Channels OPERABLE, within 1 hour determine by observation of the associated permissive annunciator window(s) that the interlock is in its required state for the existing plant condition, or apply Specification 3.0.3 be in at least HOT STANDBY within 7 hours.	01-04-LG 01-52-LG 01-12-M
ACTION 8.1 (new)	With one or more Required Channels inoperable, within 1 hour verify the interlock is in its required state for the existing plant condition or be in at least MODE 2 within 7 hours.	01-12-M

TABLE 3.3-1 (Continued)
ACTION STATEMENTS (Continued)

ACTION 9	With less than the Minimum Number of Channels OPERABLE, operation may continue provided the inoperable channel is placed in the tripped condition within the next 6 hours.	01-49-LS18
ACTION 10	With the number of channel trains OPERABLE one less than the Minimum Total Number of Required Channels, OPERABLE requirement, restore the inoperable train to operable status within 1 hour or be in at least HOT STANDBY within 6 hours; however, one channel train may be bypassed for up to 2 hours for maintenance or surveillance testing per Specification 4.3.1.1, provided the other channel is OPERABLE.	01-04-LG 01-13-LS6
ACTION 11	With the number of OPERABLE channels or trains one less than the Minimum Required Channels or trains, OPERABLE requirement, restore the inoperable channel or train to OPERABLE status within 48 hours or open the Reactor trip breakers within the next hour, fully insert all rods and place the Rod control System in a condition incapable of rod withdrawal.	01-04-LG 01-55-LS39
ACTION 12	With one of the diverse trip features (Undervoltage or shunt trip attachment) inoperable, restore it to OPERABLE status within 48 hours or declare the breaker inoperable and apply ACTION 10 or be in at least HOT STANDBY within the next 6 hours. The breaker shall not be bypassed while one of the diverse trip features is inoperable except for the time required for performing maintenance to restore the breaker to OPERABLE status.	01-14-A
ACTION 13	With the number of OPERABLE channels one less than the Total Number of Required Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:	01-43-A
	a. The Minimum Channels OPERABLE requirement is met, and	01-04-LG
	b. The inoperable channel is placed in the tripped conditions within 6 hours; however, the inoperable channel may be bypassed for up to 72 hours for surveillance testing per Specification 4.3.1.1 or for performing maintenance.	
ACTION 26	With the number of OPERABLE channels one less than the Minimum Required Channels, OPERABLE requirement, restore the inoperable Channel to OPERABLE status within 6 hours or be in at least HOT STANDBY within the next 6 hours; however, one channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.1.1, provided the other channel is OPERABLE.	01-04-LG
ACTION 27	With the number of OPERABLE channels less than the Total Number of Required Channels, STARTUP and/or POWER OPERATION may proceed provided that within 6 hours, for the affected RCS Loop Delta-T channel(s), either:	01-43-A
	a. The Trip Time Delay threshold power level for zero seconds time delay is adjusted to 0% RTP, or	01-43-A
	b. With the number of OPERABLE channels one less than the Total Number of Required Channels, the affected Steam Generator Water Level-Low-Low channels are placed in the tripped condition.	
ACTION 28	With the number of OPERABLE channels one less than the Total Number of Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:	01-50-A
	a. The inoperable channel is placed in the trip condition within 6 hours, and	
	b. The Minimum Channels OPERABLE requirement is met; however, the inoperable channel may be bypassed for up to 4 hours for surveillance testing of other channels per Specification 4.3.1.1.	

TABLE 3.3-2

REACTOR TRIP SYSTEM INSTRUMENTATION RESPONSE TIMES

<u>FUNCTIONAL UNIT</u>	<u>RESPONSE TIME</u>	<u>01-35-LG</u>
1. Manual Reactor Trip	N.A.	
2. Power Range, Neutron Flux	≤ 0.5 second (1)

16. Underfrequency-Reactor Coolant Pumps	< 0.6 second	

(1) Neutron detectors are exempt from response time testing. Response time of the neutron flux signal portion of the channel shall be measured from detector output or input to the first electronic component in channel. 01-41-A

(2) Does not include Trip Time Delays. Response times include the transmitters, Eagle-21 Process Protection cabinets, Solid State Protection System cabinets and actuation devices only. This reflects the response times necessary for THERMAL POWER in excess of 50% RTP. 01-35-LG

TABLE 4.3-1 (Continued)

TABLE NOTATIONS

*	- When the Reactor Trip System breakers are closed and the Control Rod Drive System is capable of rod withdrawal or all rods not fully inserted.	<u>01-55-LS39</u>
##	- Below P-6 (Intermediate Range Neutron Flux Interlock) Setpoint.	
###	- Below P-10 (Low Setpoint Power Range Neutron Flux Interlock) Setpoint.	
(1)	- If not performed in previous 31 <u>92</u> days.	<u>01-24-LS9</u>
(1a)	If not performed in previous 31 days	<u>01-24-LS9</u>
(2)	- Heat balance only, above 15% of RATED THERMAL POWER. During startup in MODE 1 above 15% of RATED THERMAL POWER, the required heat balance shall be performed prior to exceeding 30% of RATED THERMAL POWER, or within 24 hours, whichever occurs first. Adjust channel if absolute difference greater than 2%. The provisions of Specification 4.0.4 are not applicable for entry into MODE 2 or 1.	<u>01-25-A</u>
(3)	- Compare incore to excore axial flux difference above within 24 hours after Thermal Power is greater than or equal to 1550% of RATED THERMAL POWER and at least once per 31 Effective Full Power days. Re-Calibrate if the absolute difference is greater than or equal to 3%. The provisions of Specification 4.0.4 are not applicable for entry into MODE 2 or 1.	<u>01-25-A</u>
(4)	- Neutron detectors may be excluded from CHANNEL CALIBRATION.	
(5)	- Detector plateau curves shall be obtained and evaluated for the source range neutron flux channels. For the Intermediate Range and Power Range Neutron Flux channels a test shall be performed that shows allowed variances of detector voltage do not effect detector operation. For the Intermediate Range and Power Range Neutron Flux Channels the provisions of Specification 4.0.4 are not applicable for entry into MODE 2 or 1.	<u>01-26-LG</u>
(6)	- Incore - Excore Calibration, above within 24 hours after Thermal Power is a 75% of RATED THERMAL POWER and at least once per 92 Effective Full Power days. The provisions of Specification 4.0.4 are not applicable for entry into MODE 2 or 1.	<u>01-25-A</u>
(7)	- Each train shall be tested at least every 62 <u>31</u> days on a STAGGERED TEST BASIS.	
(8)	- Quarterly Surveillances in MODES 3*, 4* and 5* performed quarterly and prior to startup shall also include verification that permissives P-6 and P-10 are in their required state for existing plant conditions by observation of the permissive annunciator window.	<u>01-28-A</u>
(9)	- Setpoint verification is not applicable.	
(10)	The TRIP ACTUATING DEVICE OPERATIONAL TEST shall separately verify the OPERABILITY of the undervoltage and shunt trip attachments of the Reactor Trip Breakers.	<u>01-32-LG</u>
(11)	- Deleted	
(12)	- Deleted	
(13)	- Deleted	

TABLE 4.3-1 (Continued)

TABLE NOTATIONS

(14) —	The TRIP ACTUATING DEVICE OPERATIONAL TEST shall independently verify the OPERABILITY of the undervoltage and shunt trip circuits for the Manual Reactor Trip Function. The test shall also verify the OPERABILITY of the Bypass Breaker trip circuit(s).	<u>01-32-LG</u>
(15) -	Test local manual shunt trip prior to placing breaker in service.	
(16) —	Test automatic undervoltage trip.	<u>01-32-LG</u>
(19) —	The CHANNEL OPERATIONAL TEST shall be performed within 12 hours after reducing power below P-10 for the power range and intermediate range instrumentation and within 4 hours after reducing power below P-6 for the source range instrumentation, if not performed within the previous 92 days. With the Rod Control System capable of rod withdrawal, or all rods not fully inserted, the COT is not required prior to entering MODE 3 from MODE 2 until 4 hours after entering MODE 3.	<u>01-22-M</u>
(20) —	Surveillance shall also include verification that permissives P-6 (new) and P-10 are in their required state for existing plant conditions.	<u>01-22-M</u>
(22) — (new)	Includes verification of time constants.	<u>01-23-A</u>

INSTRUMENTATION

3/4.3.2 ENGINEERED SAFETY FEATURES ACTUATION SYSTEM INSTRUMENTATION

LIMITING CONDITION FOR OPERATION

3.3.2 The Engineered Safety Features Actuation System (ESFAS) instrumentation channels and interlocks shown in Table 3.3-3 shall be OPERABLE with their Trip Setpoints set consistent with the values shown in the Trip Setpoint column of Table 3.3-4 and with RESPONSE TIMES as shown in Table 3.3-5.

APPLICABILITY: As shown in Table 3.3-3.

ACTION: ✖

- a. With an ESFAS Instrumentation Channel or Interlock Trip Setpoint less conservative than the value shown in the Trip Setpoint column but more conservative than the value shown in the Allowable Values column of Table 3.3-4, adjust the Setpoint consistent with the Trip Setpoint value.
- b. With an ESFAS Instrumentation Channel or Interlock Trip Setpoint less conservative than the value shown in the Allowable Values column of Table 3.3-4, declare the channel inoperable and apply the applicable ACTION statement requirements of Table 3.3-3 until the channel is restored to OPERABLE status with its Trip Setpoint adjusted consistent with the Trip Setpoint value.

SURVEILLANCE REQUIREMENTS

4.3.2.1 Each ESFAS instrumentation channel and interlock and the automatic actuation logic and relays shall be demonstrated/verified OPERABLE by the performance of the Engineered Safety Feature Actuation System Instrumentation Surveillance Requirements specified in Table 4.3-2.

4.3.2.2 The required ENGINEERED SAFETY FEATURES RESPONSE TIME of each ESFAS function shall be demonstrated/verified to be within the limit at least once per 18 months on a STAGGERED TEST BASIS**. Each test shall include at least one train such that both trains are tested at least once per 36 months and one channel per function such that all channels are tested at least once per N times 18 months where N is the total number of redundant channels in a specific ESFAS function as shown in the "Total No. of Channels" column of Table 3.3-3.

(new) * Separate ACTION entry is allowed for each Functional Unit.

(new) ** Not required to be performed for the turbine driven auxiliary feedwater pump until 24 hours after steam generator pressure ≥650 psig.

TABLE NOTATIONS

- # Trip function may be blocked in this MODE below the P11 (Pressurizer Pressure Interlock) Setpoint.
- ## Trip function automatically blocked above P-11 (Pressurizer Pressure Interlock) Setpoint and is automatically blocked below P-11 when Safety Injection on Steam Line Pressure-Low is not blocked.
- ### For Mode 3, the Trip Time Delay associated with the Steam Generator Water Level-Low-Low channel must be less than or equal to 464.1 seconds.

02-36-M

(new) ** When associated DG is required to be OPERABLE by LCO 3.8.1.2, "AC Sources Shutdown."

(new) (a) Not applicable when all MSIVs are closed and deactivated

02-07-LS11

(new) (b) Not applicable when all MFIVs, main feedwater regulating valves, and main feedwater regulating bypass valves are closed and deactivated or isolated by a closed manual isolation valve.

02-07-LS11

ACTION STATEMENTS

ACTION 14 - With the number of OPERABLE channels one less than the Minimum Required Channels OPERABLE requirement, restore the inoperable channel to OPERABLE status within 6 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours; however, one channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1, provided the other channel is OPERABLE.

01-04-LG

~~ACTION 15 - With the number of OPERABLE Channels less than the Required Channels, declare the affected emergency Diesel Generator(s) inoperable and comply with the ACTION statements of Specification 3.8.1.1; however, one channel may be bypassed for up to 2 hours for surveillance testing per Specification 4.3.2.1.~~

02-48-LS28

01-43-A

ACTION 16 - With the number of OPERABLE Channels one less than the Total Number of Required Channels, declare the affected Emergency Diesel Generator(s) inoperable and comply with the ACTION statements of Specification 3.8.1.1; however, one channel may be bypassed for up to 2 hours for surveillance testing per Specification 4.3.2.1.

01-43-A

02-11-A

~~ACTION 17 - With the number of OPERABLE channels one less than the Total Number of Channels one containment pressure channel inoperable, operation may proceed provided the inoperable channel is placed in the bypassed condition and the Minimum Channels OPERABLE requirement is met within 6 hours, or be in MODE 3 in 12 hours and in MODE 5 in 42 hours.~~

01-43-A

02-15-M

01-04-LG

Note: one additional channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1.

~~(new) ACTION 17.1 - With one containment pressure channel inoperable, operation may proceed provided the inoperable channel is placed in the bypassed condition within 6 hours, or be in MODE 3 in 12 hours and in MODE 4 in 18 hours. Note: one additional channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1.~~

02-15-M

ACTION 18 - With less than the Minimum Required Channels OPERABLE requirement, comply with ACTION 37, and operation may continue beyond the 4 hour period provided the containment purge supply and exhaust valves (RCV 11, 12, FGV 660, 661, 662, 663, 664) are maintained closed.

01-04-LG

02-05-M

02-39-LG

03-14-LS29

ACTION 19 - With the number of OPERABLE channels one less than the Minimum Channels OPERABLE requirement one channel inoperable, restore the inoperable channel to OPERABLE status within 48 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

01-04-LG

ACTION 20 - With the number of OPERABLE channels one less than the Total Number of Channels one channel inoperable, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:

02-08-M

01-43-A

- a. The inoperable channel is placed in the tripped condition within 6 hours, and or
- b. Be in MODE 3 in 12 hours and in MODE 4 in 18 hours. NOTE: The Minimum Channels OPERABLE requirement is met; however, the inoperable channel or one additional channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1.

01-04-LG

ACTION 20.1 - With one channel inoperable, STARTUP and/or POWER OPERATION may proceed (new) provided the following conditions are satisfied:

02-29-M

- a. The inoperable channel is placed in the bypassed condition within 6 hours, and the inoperable channel is returned to an OPERABLE status within 72 hours, or
- b. Immediately enter 3.0.3.

NOTE: One additional channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1

ACTION 20.2 - With one channel inoperable, STARTUP and/or POWER OPERATION may (new) proceed provided the following conditions are satisfied:

02-08-M

- a. The inoperable channel is placed in the tripped condition within 6 hours, or
- b. Be in MODE 3 in 12 hours and in MODE 5 in 42 hours. NOTE: The inoperable channel or one additional channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1.

TABLE 3.3-3 (Continued)

ACTION STATEMENTS (Continued)

ACTION 21 - With the number of OPERABLE channels less than the Minimum Number of Required Channels OPERABLE, within 1 hour determine by observation of the associated permissive annunciator window(s) that the interlock is in its required state for the existing plant condition, or apply Specification 3.0.3 be in MODE 3 in 7 hours and MODE 4 in 13 hours.	<u>01-04-LG</u> <u>02-14-M</u> <u>01-52-LG</u>
ACTION 22 - With the number of OPERABLE Channels one less than the Minimum Required Channels OPERABLE requirement, restore the inoperable channel to OPERABLE status within 6 hours or be in at least HOT STANDBY within the next 6 hours and in at least HOT SHUTDOWN within the following 6 hours; however, one channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1 provided the other channel is OPERABLE.	<u>01-04-LG</u>
ACTION 23 - With the number of OPERABLE channels one less than the Total Number of Required Channels, restore the inoperable channel to OPERABLE status within 48 hours or be in at least HOT STANDBY within 6 hours and in at least HOT SHUTDOWN within the following 6 hours.	<u>01-43-A</u>
ACTION 24 - With the number of OPERABLE channels one less than the Total Number of Required Channels, restore the inoperable channel to OPERABLE status within 48 hours or declare the associated pump or valve inoperable and take the ACTION required by Specification 3.7.1.5 or 3.7.1.2 as applicable.	<u>01-43-A</u>
ACTION 25 - With the number of OPERABLE channels one less than the Minimum Required Channels OPERABLE requirement, restore the inoperable channel to OPERABLE status within 6 hours or be in at least HOT STANDBY within the next 6 hours; however, one channel may be bypassed for up to 4 hours for surveillance testing per Specification 4.3.2.1 provided the other channel is OPERABLE.	<u>01-04-LG</u>
ACTION 29 - With the number of OPERABLE channels less than the Total Number of Required Channels, STARTUP and/or POWER OPERATION may proceed provided that within 6 hours, for the affected RCS Loop Delta-T channel(s), either:	<u>01-43-A</u>
a. The Trip Time Delay threshold power level for zero seconds time delay is adjusted to 0% RTP, or	
b. With the number of OPERABLE channels one less than the Total Number of Required Channels, the affected Steam Generator Water Level-Low-Low channels are placed in the tripped condition.	<u>01-43-A</u>
ACTION 35 - With the number of OPERABLE channels one less than the Total Number of Required Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:	<u>01-43-A</u>
a. The inoperable channel is placed in the trip condition within 6 hours, and or be in MODE 2 in 12 hours	<u>02-08-M</u>
b. The Minimum Channels OPERABLE requirement is met; however, The inoperable channel may be bypassed for up to 4 hours for surveillance testing of other channels per Specification 4.3.2.1.	<u>01-04-LG</u>
ACTION 35.2 - With the number of OPERABLE channels one less than the Required Channels, STARTUP and/or POWER OPERATION may proceed provided the following conditions are satisfied:	<u>02-08-M</u>

a. The inoperable channel is placed in the trip condition within 6 hours or

b. Be in MODE 2 in 6 hours for Function 6.g. or be in MODE 3 in 12 hours for Function 5.b.

NOTE: The inoperable channel may be bypassed for up to 4 hours for surveillance testing of other channels per Specification 4.3.2.1.

TABLE NOTATIONS

- (1) Diesel generator starting delay not included because offsite power available.
- (2) Notation deleted.
- (3) Diesel generator starting and loading delays included.
- (4) Diesel generator starting delay not included because offsite power is available. Response time limit includes opening of valves to establish SI path and attainment of discharge pressure for centrifugal charging pumps (where applicable). Sequential transfer of charging pump suction from the VCT to the RWST (RWST valves open, then VCT valves close) is included.
- (5) Diesel generator starting and sequence loading delays included. Offsite power is not available. Response time limit includes opening of valves to establish SI path and attainment of discharge pressure for centrifugal charging pumps. Sequential transfer of charging pump suction from the VCT to the RWST (RWST valves open, then VCT valves close) is included.
- (6) The maximum response time of 48.5 seconds is the time from when the containment pressure exceeds the High-High Setpoint until the spray pump is started and the discharge valve travels to the fully open position assuming off-site power is not available. The time of 48.5 seconds includes the 28-second maximum delay related to ESF loading sequence. Spray riser piping fill time is not included. The 80-second maximum spray delay time does not include the time from LOCA start to "P" signal.
- (7) Diesel generator starting and sequence loading delays included. Sequential transfer of charging pump suction from the VCT to the RWST (RWST valves open, then VCT valves close) is not included. Response time limit includes opening of valves to establish SI flow path and attainment of discharge pressure for centrifugal charging pumps, SI, and RHR pumps (where applicable).
- (8) Does not include Trip Time Delays. Response times include the transmitters, Eagle 21 Process Protection cabinets, Solid State Protection System cabinets and actuation devices only. This reflects the response times necessary for THERMAL POWER in excess of 50% RTP.

TABLE NOTATIONS

- (1) Each train shall be tested at least every 62 days on a STAGGERED TEST BASIS.
- (2) For the Containment Ventilation Exhaust Radiation - High monitor only, a CHANNEL FUNCTIONAL TEST shall be performed at least once every 3192 days.
- (3) Trip function automatically blocked above P-11 (Pressurizer Pressure Interlock) setpoint and is automatically blocked below P-11 when Safety Injection on Steam Line Pressure-Low is not blocked.
- (4) DELETED
- (5) For Mode 3, the Trip Time Delay associated with the Steam Generator Water Level-Low-Low channel must be less than or equal to

464.1 seconds.

(6) Includes verification of time constants where applicable.

INSTRUMENTATION

03-01-A

3/4.3.3 MONITORING INSTRUMENTATION

RADIATION MONITORING FOR PLANT OPERATIONS

LIMITING CONDITION FOR OPERATION

3.3.3.1 The radiation monitoring instrumentation channels for plant operations shown in Table 3.3-6 shall be OPERABLE with their Alarm/Trip Setpoints within the specified limits.

APPLICABILITY: As shown in Table 3.3-6.

ACTION: ¶

01-01-A

- a. With a radiation monitoring channel Alarm/Trip Setpoint for plant operations exceeding the value shown in Table 3.3-6, ~~adjust the Setpoint to within the limit within 4 hours or declare the channel inoperable.~~
- b. With one or more radiation monitoring channels for plant operations inoperable, take the ACTION shown in Table 3.3-6.
- c. The provisions of Specification 3.0.3 are not applicable ~~for the Fuel Building Radioactivity instrumentation.~~

03-02-M

03-06-A

SURVEILLANCE REQUIREMENTS

4.3.3.1 Each radiation monitoring instrumentation channel for plant operations shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST for the MODES and at the frequencies shown in Table 4.3-3.

~~(New) * Separate condition entry is allowed for each function.~~

*With fuel in the spent fuel pool or new fuel storage vault.

**With irradiated fuel in the spent fuel pool. During movement of irradiated fuel assemblies in the fuel handling building.

***One channel for each normal intake to the Control Room Ventilation System (common to both units).

(a) Action 32 is not applicable to the Fuel Storage Area Monitors following installation of RM-45A and 45B.

(b) The requirements for Fuel Handling Building Ventilation Mode Change are applicable following installation of RM-45A and 45B.

TABLE 3.3-6 (Continued)

ACTION STATEMENTS

ACTION 30 -	With less than the Minimum Required Channels OPERABLE requirement, operation may continue for up to 30 days provided an appropriate portable continuous monitor with the same Alarm Setpoint or an individual qualified in radiation protection procedures with a radiation dose rate monitoring device is provided in the fuel storage pool area. Restore the inoperable monitors to OPERABLE status within 30 days or suspend all operations involving fuel movement in the fuel storage pool areas.	<u>01-43-A</u>
ACTION 31 -	With the number of OPERABLE channels less than required by the Minimum Required Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.4.6.1. The provisions of Specification 3.0.4 are not applicable.	<u>03-01-A</u> <u>01-43-A</u>
ACTION 32 -	With the number of OPERABLE channels less than required by the Minimum Required Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.9.12.	<u>01-43-A</u>
ACTION 33 -	With the number of OPERABLE channels less than required by the Minimum Required Channels OPERABLE requirement, comply with the ACTION requirements of Specification 3.9.9.	<u>01-43-A</u>
ACTION 34 -	With the number of OPERABLE channels one less than required by the Minimum Required Channels OPERABLE requirement, within 4-hour 7 days initiate and maintain operation of the Control Room Ventilation System in a recirculation the pressurization mode with the HEPA filter and charcoal adsorber bank in operation; or when in MODE 1-4 be in MODE 3 in 6 hours and in MODE 5 in 36 hours; or during fuel movement, immediately suspend CORE ALTERATIONS and movement of irradiated fuel assemblies; or when in MODE 5 or 6, immediately initiate actions to restore one CRVS train to OPERABLE status.	<u>01-43-A</u> <u>03-05-LS14</u> <u>03-15-M</u>
(New) ACTION 35	With no OPERABLE channels, immediately place one CRVS train in the pressurization mode and enter the applicable ACTIONS for one train made inoperable by CRVS actuation instrumentation; or when in MODE 1-4 be in MODE 3 in 6 hours and in MODE 5 in 36 hours; or during fuel movement, immediately suspend CORE ALTERATIONS and movement of irradiated fuel assemblies; or when in MODE 5 or 6, immediately initiate actions to restore one CRVS train to OPERABLE status.	<u>03-15-M</u>
(New) ACTION 37	With the number of OPERABLE channels one less than required by the Required Channels, restore the affected channel to OPERABLE status within 4 hours.	<u>03-14-LS29</u>

^a With fuel in the spent fuel pool or new fuel storage vault.

(a) The requirements for Fuel Handling Building Ventilation Mode Change are applicable following installation of RM-45A and 45B.

(New) (b) Each train shall be tested at least once every 62 days on a STAGGERED TEST BASIS.

(New) (c) Verification of setpoint is not required.

INSTRUMENTATION

MOVABLE INCORE DETECTORS

04-01-R

LIMITING CONDITION FOR OPERATION

~~3.3.3.2 The Movable Incore Detection System shall be OPERABLE with:~~

- ~~a. At least 75% of the detector thimbles,~~
- ~~b. A minimum of two detector thimbles per core quadrant, and~~
- ~~c. Sufficient movable detectors, drive, and readout equipment to map these thimbles.~~

~~APPLICABILITY: When the Movable Incore Detection System is used for:~~

- ~~a. Recalibration of the Excore Neutron Flux Detection System, or~~
- ~~b. Monitoring the QUADRANT POWER TILT RATIO, or~~
- ~~c. Measurement of F_{NH} , $F_Q(Z)$ and F_{xy} .~~

ACTION:

~~With the Movable Incore Detection System inoperable, do not use the system for the above applicable monitoring or calibration functions. The provisions of Specification 3.0.3 are not applicable.~~

SURVEILLANCE REQUIREMENTS

~~4.3.3.2 The Movable Incore Detection System shall be demonstrated OPERABLE at least once per 24 hours by normalizing each detector output when required for:~~

- ~~a. Recalibration of the Excore Neutron Flux Detection System, or~~
- ~~b. Monitoring the QUADRANT POWER TILT RATIO, or~~
- ~~c. Measurement of F_{NH} , $F_Q(Z)$ and F_{xy} .~~

INSTRUMENTATION

SEISMIC INSTRUMENTATION

05-01-R

LIMITING CONDITION FOR OPERATION

3.3.3.3 The seismic monitoring instrumentation# shown in Table 3.3-7 shall be OPERABLE.

APPLICABILITY: At all times.

ACTION:

- a. With one or more seismic monitoring instruments inoperable for more than 30 days, prepare and submit a Special Report to the Commission pursuant to Specification 6.9.2 within the next 10 days outlining the cause of the malfunction and the plans for restoring the instrument(s) to OPERABLE status.
- b. The provisions of Specification 3.0.3 are not applicable.

SURVEILLANCE REQUIREMENTS

4.3.3.3.1 Each of the above seismic monitoring instruments shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST at the frequencies shown in Table 4.3-4.

4.3.3.3.2 Each of the above seismic monitoring instruments actuated during a seismic event shall be restored to OPERABLE status within 24 hours and a CHANNEL CALIBRATION, as applicable, performed within 10 days following the seismic event. Data shall be retrieved from actuated instruments and analyzed to determine the magnitude of the vibratory ground motion. A Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 14 days describing the magnitude, frequency spectrum and resultant effect upon facility features important to safety.

#The seismic monitoring instrumentation is common to both units but located in Unit 1 or common areas.

INSTRUMENTATION

METEOROLOGICAL INSTRUMENTATION

06-01-R

LIMITING CONDITION FOR OPERATION

3.3.3.4 The meteorological monitoring instrumentation channels# shown in Table 3.3-8 shall be OPERABLE.

APPLICABILITY: At all times.

ACTION:

- a. With one or more required meteorological monitoring channels inoperable for more than 7 days, prepare and submit a Special Report to the Commission pursuant to Specification 6.9.2 within the next 10 days outlining the cause of the malfunction and the plans for restoring the channel(s) to OPERABLE status.
- b. The provisions of Specification 3.0.3 are not applicable.

SURVEILLANCE REQUIREMENTS

4.3.3.4 Each of the above meteorological monitoring instrumentation channels shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK and CHANNEL CALIBRATION at the frequencies shown in Table 4.3-5.

#The meteorological monitoring instrumentation channels are common to both units.

INSTRUMENTATION

REMOTE SHUTDOWN INSTRUMENTATION AND CONTROLS

LIMITING CONDITION FOR OPERATION

3.3.3.5 The remote shutdown monitoring instrumentation and control functions shown in Table 3.3-9 shall be OPERABLE.

APPLICABILITY: MODES 1, 2 and 3.

ACTION:

- a. With less than the minimum required Function(s) of Table 3.3-9 operable, restore the inoperable Function(s) to OPERABLE status within 30 days or be in ~~MODE 3~~ within 6 hours and ~~HOT SHUTDOWN~~ within the next 12 hours.
- b. The provisions of Specification 3.0.4 are not applicable.
- c. Separate entry into Action a. is allowed for each Function in Table 3.3-9.

07-05-A

SURVEILLANCE REQUIREMENTS

4.3.3.5.1 Each remote shutdown monitoring instrumentation channel shall be demonstrated OPERABLE by performance of the CHANNEL CHECK and CHANNEL CALIBRATION at the frequencies shown in Table 4.3-6.

4.3.3.5.2 Verify each required control circuit and control transfer switch is capable of performing the intended function at least once every 18 months.

INSTRUMENTATION

ACCIDENT MONITORING INSTRUMENTATION

LIMITING CONDITION FOR OPERATION

3.3.3.6 The accident monitoring instrumentation channels functions shown in Table 3.3-10 shall be OPERABLE.

08-01-A

APPLICABILITY: MODES 1, 2 and 3.

ACTION:

- a. With the number of OPERABLE accident monitoring instrumentation channels less than the Required Number of Channels but at least one accident monitoring channel OPERABLE shown in Table 3.3-10, restore the inoperable channel(s) to OPERABLE status within 30 days or be in at least HOT SHUTDOWN within the next 12 hours, prepare and submit a Special Report to the alternate method of monitoring the appropriate parameter(s) cause of the inoperability, and plans and schedule for restoring the channel to OPERABLE status. 08-11-LS30
- b. With the number of OPERABLE accident monitoring instrumentation channels for one or more instrument functions except the containment recirculation sump level narrow range, the main steam line radiation monitor, the containment area radiation monitor high range, and the plant vent radiation monitor high range less than the Minimum Channels OPERABLE requirements of Table 3.3-10, except for the Containment Hydrogen Concentration, restore at least one the inoperable channel(s) to OPERABLE status within 48 hours 7 days or be in at least HOT SHUTDOWN within the next 12 hours, enter the Action Required references in Table 3.3-10. 08-11-LS30
- c. With the number of OPERABLE channels for the containment recirculation sump level narrow range less than the Minimum Channels OPERABLE requirement As required by the Action Requirements of Table 3.3-10, except for the Containment Hydrogen Concentration monitors, restore the inoperable channel to OPERABLE status within 30 days or be in at least HOT STANDBY within 6 hours or be in at least HOT SHUTDOWN within the next 12 hours. 08-11-LS30
- d. With the number of OPERABLE channels for the main steam line radiation monitor, or the containment area radiation monitor high range or the plant vent radiation monitor high range less than the Minimum Channels OPERABLE requirements As required by the Action Requirements of Table 3.3-10, initiate the preplanned alternate method of monitoring the appropriate parameter(s) within 72 hours and either restore the inoperable channel(s) to OPERABLE status within 7 days or prepare and submit a Special Report to the Commission pursuant to Specification 6.9.2 within 14 days that provides actions taken, identifies the alternate method of monitoring the appropriate parameter(s) cause of the inoperability and plans and schedule for restoring the channels to OPERABLE status. 08-11-LS30
08-04-LS17
- e. The provisions of Specification 3.0.4 are not applicable.

(New) Separate Condition entry is allowed for each function

01-01-A

INSTRUMENTATION

SURVEILLANCE REQUIREMENTS

4.3.3.6 Each accident monitoring instrumentation channel shall be demonstrated OPERABLE by performance of the CHANNEL CHECK ~~once per 31 days for each required instrument that is normally energized~~ and CHANNEL CALIBRATION ~~at the frequencies shown in Table 4.3-7, once per 18 months;~~

08-11-LS30

INSTRUMENTATION

CHLORINE DETECTION SYSTEMS

11-01-R

LIMITING CONDITION FOR OPERATION

~~3.3.3.7 Two independent Chlorine Detection Systems, # with their Alarm/Trip Setpoints adjusted to actuate at a chlorine concentration of less than or equal to 5 ppm, shall be OPERABLE.~~

~~APPLICABILITY: All MODES, when bulk chlorine gas is stored on the plant site.~~

ACTION:

- ~~a. With one Chlorine Detection System inoperable, restore the inoperable system to OPERABLE status within 7 days or within the next 6 hours initiate and maintain operation of the Control Room Ventilation System in a recirculation mode with the HEPA filter and charcoal absorber system in operation.~~
- ~~b. With both Chlorine Detection Systems inoperable, within 1 hour initiate and maintain operation of the Control Room Ventilation System in a recirculation mode with the HEPA filter and charcoal absorber system in operation.~~

SURVEILLANCE REQUIREMENTS

~~4.3.3.7 Each Chlorine Detection System shall be demonstrated OPERABLE by performance of a CHANNEL CHECK at least once per 12 hours and a CHANNEL FUNCTIONAL TEST at least once per 31 days. At least once per 18 months, the following inspections and maintenance shall be performed:~~

- ~~a. Check constant head bottle level and refill as necessary.~~
- ~~b. Clean the sensing cells.~~
- ~~c. Check flow meter operation and clean or replace filters and air lines as necessary.~~
- ~~d. Check air pump for proper operation, and~~
- ~~e. Verify that the detector responds to chlorine.~~

~~#The Chlorine Detection System is common to both units and is installed in the normal intakes to the Control Room Ventilation System.~~

~~THIS PAGE INTENTIONALLY LEFT BLANK~~

INSTRUMENTATION

EXPLOSIVE GAS EFFLUENT MONITORING INSTRUMENTATION

09-01-LG

LIMITING CONDITION FOR OPERATION

3.3.3.9 Deleted

3.3.3.10 The explosive gas monitoring instrumentation channels (ANR-75 or ANR-76) shall be OPERABLE with their Alarm/Trip Setpoints set to ensure that the limits of Specification 3.11.2.5 are not exceeded.

APPLICABILITY: During GASEOUS RADWASTE SYSTEM operation.

ACTION:

- a. With an explosive gas monitoring instrumentation channel (ANR-75 or ANR-76) Alarm/Trip Setpoint less conservative than required by the above specification, declare the channel inoperable and follow action b. below.
- b. With only one OPERABLE explosive gas monitoring instrumentation channel, operation of this system may continue for up to 14 days. After 14 days or with no channels OPERABLE, operation of this system may continue provided grab samples are collected at least once per 4 hours and analyzed within the following 4 hours.
- c. The provisions of Specification 3.0.3 are not applicable.

SURVEILLANCE REQUIREMENTS

4.3.3.9 Deleted

4.3.3.10.1 Each explosive gas monitoring instrumentation channel shall be demonstrated OPERABLE by performance of a daily CHANNEL CHECK and a monthly CHANNEL FUNCTIONAL TEST.

4.3.3.10.2 Each explosive gas monitoring instrumentation channel shall be demonstrated OPERABLE by performance of a quarterly CHANNEL CALIBRATION. The CHANNEL CALIBRATION shall include the use of standard gas samples containing a nominal:

- a. Two volume percent oxygen, balance nitrogen, and
- b. Four volume percent oxygen, balance nitrogen.

INSTRUMENTATION

3/4.3.4 TURBINE OVERSPEED PROTECTION

10-01-R

LIMITING CONDITION FOR OPERATION

~~3.3.4.1 At least one Turbine Overspeed Protection System shall be OPERABLE.~~

~~APPLICABILITY: MODES 1, 2 and 3 (during turbine operation).~~

ACTION:

- ~~a. With one stop valve or one control valve per high pressure turbine steam line inoperable or with one reheat stop valve or one reheat intercept valve per low pressure turbine steam line inoperable, restore the inoperable valve(s) to OPERABLE status within 72 hours, or isolate the turbine from the steam supply within the next 6 hours.~~
- ~~b. With the above required Turbine Overspeed Protection System otherwise inoperable, within 6 hours isolate the turbine from the steam supply.~~

SURVEILLANCE REQUIREMENTS

~~4.3.4.1.1 The provisions of Specification 4.0.4 are not applicable.~~

~~4.3.4.1.2 The above required Turbine Overspeed Protection System shall be demonstrated OPERABLE:~~

- ~~a. At least once per quarter by cycling and direct observation of the movement of each of the following valves through at least one complete cycle from the running position:
 - ~~1) Four high pressure turbine stop valves,~~
 - ~~2) Four high pressure turbine control valves,~~
 - ~~3) Six low pressure turbine reheat stop valves, and~~
 - ~~4) Six low pressure turbine reheat intercept valves.~~~~
- ~~b. At least once per 18 months by performance of a CHANNEL CALIBRATION on the Turbine Overspeed Protection Systems.~~
- ~~c. At least once per 40 months by disassembling at least one of each of the above valves and performing a visual and surface inspection of valve seats, disks and stems and verifying no unacceptable flaws or corrosion.~~

Methodology For Mark-Up of Current TS

This enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. Deletions - Material is no longer in the specifications. (this includes material which is moved to the Bases of the TS).
2. Additions - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. Modifications - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. Administrative - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is :

- | | |
|------------------|---|
| Deletions - | The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin. |
| Additions - | The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin. |
| Modifications - | The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin. |
| Administrative - | The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the markup of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS. |

Methodology For Mark-Up of Current TS

(Continued)

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS markup. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.3

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	A Note, "Separate Condition entry is allowed for each Function," is added to the ACTIONS for the Reactor Trip System, ESFAS, [Remote Shutdown also applies to each required ASP control], and Accident Monitoring Instrumentation. This change clarifies those situations where the current TS ACTION Statements are not uniquely associated with a particular Function or where the required channels are specified on a per steam line, per loop, per SG, per bus, etc., basis. This change is consistent with current operating practices and NUREG-1431. []
01-02	LG	The CTS require that response time testing be performed on each reactor trip and ESFAS function every 18 months and that alternate trains be tested in successive tests. The CTS description of the channel testing protocol matches the improved TS definition of STAGGERED TEST BASIS. However, several trip functions do not require response time testing, as indicated by N.A. in the tables of response time limits [(presently located in Tables 3.3-2 and 3.3-5 of the CTS, which are being to the FSAR per CN 01-35-LG)]. The improved TS specify that required response time testing be performed on a STAGGERED TEST BASIS and do not impose any requirements as to which train should be tested. Therefore, the word "requirement" is added to the CTS and the requirement to ensure that each train is tested every 36 months is moved to the Bases for ITS SR 3.3.1.16 and SR 3.3.2.10.
01-03	LS1	In CTS SR 4.3.1.2 and 4.3.2.2, the active verb is changed from "demonstrated" to "verified." This allows Reactor Trip System and ESFAS sensor response time verifications to be performed per WCAP-13632-P-A Revision 2, "Elimination of Pressure Sensor Response Time Testing Requirements." This change is consistent with Traveler TSTF-111 Rev. 1, which revises the Bases for ITS SR 3.3.1.16 and SR 3.3.2.10 to allow the elimination of pressure sensor response time testing.

CHANGE
NUMBER

NSHC

DESCRIPTION

01-04

LG

In CTS Tables [3.3-1 and 3.3-3], the ["Channels to Trip" and] "Minimum Channels OPERABLE" columns are deleted, consistent with NUREG-1431. [The channel trip logic is moved to the Bases.] ACTION Statements are also revised to delete references to "Minimum Channels OPERABLE" requirements. The ITS terminology, "Required Channels," is used. The logic coincidence information has been moved to the ITS Bases for each applicable specification. OPERABILITY requirements for each Function are addressed by the Required Channels and applicable Conditions in the ITS.

01-05

A

The LCO 3.0.4 exception [footnote #] in CTS Table 3.3-1 is deleted entirely. ACTION Statement [8] in CTS Table 3.3-1 permits continued operation for an unlimited period of time. Therefore, no exception to ITS LCO 3.0.4 is needed for this ACTION Statement. [] This change is consistent with NUREG 1431.

01-06

LS2

Consistent with NUREG-1431, a new ACTION Statement [2.1] is created which is essentially the same as current ACTION Statement [6], and is similar to current ACTION Statement [2], but does not require a reduction in THERMAL POWER to less than 75% RTP or the measurement of the QPTR if above 75% RTP. This new ACTION Statement is applied to the Power Range Neutron Flux, High Positive Rate [, High Negative Rate] trip and Low Setpoint trip functions. The latter is an administrative change only since its Trip Setpoint of 25% RTP and APPLICABILITY (below P-10) are well below the reduced power of 75% RTP. The Power Range Neutron Flux, High Positive Rate [and High Negative Rate] trip[s] are rate functions and their effectiveness is not improved by reducing power; therefore, this new ACTION Statement is also applied to [these trips], as discussed in LS-2.

CHANGE
NUMBER

NSHC

DESCRIPTION

01-07

LS3

With one intermediate range neutron flux channel inoperable, current ACTION Statement [3.a] applies below the P-6 interlock. For those times that the plant is above P-6 but below 10% RTP (the P-10 interlock setpoint), current ACTION Statement [3.b] applies. ACTION Statement [3.b] is revised to establish a 24 hour Completion Time for channel restoration or changing the power level to either below P-6 or above P-10. The intermediate range neutron flux channels provide protection between these power levels and the APPLICABLE MODES have been revised to indicate this via new footnote [(d)]. With the revised APPLICABILITY, current ACTION Statement [3.a] is deleted since it is outside the new APPLICABILITY. The source range neutron flux detectors provide protection below P-6 and the power range neutron flux detectors provide protection above P-10. The addition of the 24 hour Completion Time (CTS has no Completion Time) limits the window of operation during which the intermediate range neutron flux trip function provides protection in a 1 of 1 logic configuration and ensures the low probability of occurrence of a reactivity transient during this time period that would require an intermediate range flux trip. Although this change is less restrictive since a power increase is an allowed option, the ACTION Statement would ensure protection by entering the range of the four power range neutron flux channels.

With both intermediate range neutron flux channels inoperable in MODE 1 (below P-10) and MODE 2 (above P-6), LCO 3.0.3 would be entered under the CTS and the plant would have to be in MODE 3 within 7 hours. With both intermediate channels inoperable, new ACTION Statement [3.1] requires immediate suspension of operations involving positive reactivity additions and a power reduction below P-6 within 2 hours. New ACTION Statement [3.1] is less restrictive since a reduction to MODE 3 would no longer be required; however, the CTS are overly conservative in this area. Below P-6 the source range channels provide protection; therefore, the required ACTION for both intermediate range channels inoperable should be to exit plant conditions where this trip function provides protection. New ACTION Statement [3.1] will preclude any power level increase and require a controlled power reduction to less than P-6 where the source range channels provide protection. The 2 hour Completion Time ensures the low probability of occurrence of an event during this period that may require the protection afforded by the intermediate range neutron flux trip. These actions actually provide a more timely and appropriate redress to the condition than entering LCO 3.0.3.

These changes are consistent with NUREG-1431.

CHANGE
NUMBER

NSHC

DESCRIPTION

01-08

M

Current ACTION Statement [4], for one source range channel inoperable in MODE 2 below P-6, is revised to require the immediate suspension of operations involving positive reactivity changes. The CTS does not specify the timing for this ACTION. A new ACTION Statement [4.1] is added to address the condition where both source range channels are inoperable in MODE 2 below P-6 []. The new ACTION Statement [4.1] requires that the RTBs be opened immediately. This action essentially accomplishes the reactor trip function. In such a condition with the CTS, LCO 3.0.3 would have been entered. This is more conservative since immediate rod insertion will take the plant to MODE 3 [] much more quickly than[the 7 hours] allowed by LCO 3.0.3. These changes are consistent with NUREG-1431.

01-09

M

This change revises CTS ACTION 5 to require the immediate suspension of positive reactivity additions. Reference to specification 3.1.1.2 is deleted since the ITS reference is only to 3.1.1.1 which is more conservative for MODE 5. These changes are consistent with NUREG-1431.

01-10

LS32

Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).

01-11

LS5

Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).

01-12

M

New ACTION Statement [8.1] is created to differentiate between those RTS interlocks required to be operable in MODE 1 only, and those interlocks required to be operable in MODES 1 and 2. If the interlock function is required to be operable in MODE 1 only and the LCO and ACTION requirements are not met, then new ACTION Statement [8.1] requires that the unit be taken to MODE 2 within 7 hours.

In addition, current ACTION Statement [8] is revised for those interlocks required to be OPERABLE in MODES 1 and 2. If one channel is inoperable, the interlock must be determined to be in its required state or the plant must be in at least HOT STANDBY within 7 hours.

The changes to current ACTION Statement [8] and the addition of new ACTION Statement [8.1] are more restrictive, consistent with NUREG-1431. Current ACTION Statement [8] will continue to apply to Functional Units [22.a and 22.e.] Revised ACTION Statement [8] and new ACTION Statement [8.1] provide one less hour to exit APPLICABILITY, i.e. 7 hours, than the current ACTION Statement [8] which has the 1 hour interlock state verification or entry into LCO 3.0.3 which allows an additional 1 hour plus 6 hours to exit APPLICABILITY, for a total of 8 hours.

CHANGE
NUMBER

NSHC

DESCRIPTION

01-13

LS6

[ACTION Statement [10] is revised to note that the 2 hour [train and] reactor trip breaker bypass allowance for [train or] breaker surveillance testing can also be used for maintenance. This change does not impact the conclusions of WCAP-10271-P-A, Supplement 2, Rev. 1 since there is no change to the bypass time. This change is consistent with Traveler TSTF-168.] ACTION Statement [10] is [also] revised to require restoration of an inoperable RTB within 1 hour or the plant must be in HOT STANDBY within the next 6 hours, consistent with NUREG-1431. This is less restrictive since an additional hour is provided for the transition to MODE 3.

01-14

A

In the ISTS Table 3.3.1-1, Function 20, the Reactor Trip Breaker (RTB) Undervoltage and Shunt Trip Mechanisms are separate from the RTB Functional Unit. The CTS have been revised to reflect these requirements.

New [footnote (b) has] been added to the RTB Functional Unit to note that the same OPERABILITY requirements and ACTIONS apply to a bypass breaker if it is racked in and closed for bypassing an RTB. The bypass breakers were already handled in this fashion. ACTION [12] in CTS Table 3.3-1 has been revised accordingly.

01-15

A

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

01-16

LS40

The requirement to verify the setpoint during the quarterly TADOT for RCP Underfrequency [and RCP Undervoltage] is deleted, consistent with NUREG-1431.

01-17

A

Consistent with NUREG-1431, LCO 3.3.1 Required ACTION D Note, CTS Table 3.3-1 ACTION Statement 2 and new ACTION Statement 2.1 have been modified by a Note that allows the bypass to be used for surveillance testing or setpoint adjustment. Setpoint adjustment can be performed at power and may be required by other Technical Specifications. The reason for placing the channel in bypass does not affect the impact of having the channel in bypass.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

01-18

LS7

The CTS requirement to reduce the Power Range Neutron Flux Trip setpoint in the event a power range flux channel is inoperable is deleted. This deletion is consistent with NUREG-1431, and justified by:

- 1) The loss of one channel does not impact the reliability of the Reactor Trip System because the affected channel is placed in trip. It may, however, impact the tilt monitoring for a portion of the reactor core. If the plant wishes to remain at 100% RTP, then the QPTR must be measured using the movable incore detectors. Otherwise, the power level must be reduced to 75% RTP. If the plant chooses to reduce power rather than measure QPTR using the movable incore detectors, the peaking factor surveillances must still be performed on the required frequency.
- 2) The loss of one channel does not necessarily indicate any core tilt, but rather the inability to measure core tilt with the excore instrumentation. On this basis, there is no justification for reducing the Trip Setpoint, and incurring the potential for a reactor trip, when there is no indication of an abnormal condition existing in the core.

NUREG-1431 also allows 12 hours to reduce the thermal power to less than 75% RTP rather than the 4 hours required by the CTS.

If the Power Range Neutron Flux trip function is inoperable, but the input to the QPTR is operable, the ISTS do not require that the QPTR be monitored every 12 hours.

If the above ACTIONS are not completed, the plant must be in MODE 3 within 12 hours. (See also CN 1-53-A).

01-19

LS8

This change reflects a revision to current ACTION Statement [6]. If the requirements of current ACTION Statement [6] are not met, LCO 3.0.3 would be entered. In accordance with the ISTS, this ACTION Statement is revised to state that if the ACTION requirements are not met, the plant must be taken below the P-7 interlock setpoint within the next 6 hours. [The APPLICABLE MODES for Functional Units 9, 11, 12, 15, and 16 in CTS Table 3.3-1 are also revised to add new footnote (g).]

01-20

A

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

CHANGE
NUMBER

NSHC

DESCRIPTION

01-21

A

The monthly and quarterly channel calibrations associated with Notes (3), (4), and (6) of CTS Table 4.3-1 have been moved from the Power Range Neutron Flux-High Setpoint Function to the Overtemperature [ΔT] Function. This change clarifies the relationship of these surveillances to the f_1 (ΔI) penalty portion of the Overtemperature [ΔT] Function. The primary purpose of these surveillances is to verify correct f_1 (ΔI) input to Overtemperature [ΔT]. Although these surveillances affect all power range neutron flux channels, and appropriate action must be taken for any affected power range neutron flux channel, this change groups the surveillances with the most appropriate reactor trip function for OPERABILITY concerns.

[] The applicable portions of CTS Table 4.3-1 Notes (3) and (6) are incorporated directly into ITS SR 3.3.1.3 and SR 3.3.1.6, as discussed in CN 1-25-A. Note (4) has been deleted from the daily, monthly, and quarterly surveillances associated with Notes (2), (3), and (6) of CTS Table 4.3-1 since these surveillances are not CHANNEL CALIBRATIONS, rather they are comparisons and adjustments as needed. These changes are consistent with NUREG-1431.

01-22

M

Quarterly COTs have been added to CTS Table 4.3-1 for the Power Range Neutron Flux-Low and Intermediate Range Neutron Flux trip functions in the event extended operation within their APPLICABILITY (i.e., MODE 1 below P-10 and MODE 2) takes place. The CTS only require a COT prior to startup for these functions. New Note [(19)] has been added to require that the new quarterly COT be performed within 12 hours after reducing power below P-10 for the power range and intermediate range instrumentation (P-10 is the dividing point marking the APPLICABILITY for these trip functions), if not performed within the previous 92 days. [In addition, new Note (20) has been added] such that the P-6 and P-10 interlocks are verified to be in their required state during all COTs on the Power Range Neutron Flux-Low and Intermediate Range Neutron Flux trip functions. These changes are consistent with NUREG-1431 and traveler WOG-106.

01-23

A

This change adds new Note [(22)] to CTS Table 4.3-1 and new Note [(56)] to CTS Table 4.3-2 that explicitly require the 18-month calibrations to include verifications of affected time constants, consistent with NUREG-1431.

**CHANGE
NUMBER**

01-24

NSHC

LS9

DESCRIPTION

This change reflects a relaxation in the performance of COTs prior to startup, consistent with NUREG-1431. These COTs, for the Power Range Neutron Flux - Low, Intermediate Range Neutron Flux, and Source Range Neutron Flux trip functions, will not be required if performed within the previous 92 days. Note [(1)] of CTS Table 4.3-1 has been revised to extend this period from 31 days to 92 days. Note [(1a)] is added for use with the turbine trip function TADOTs, for which no such change was provided.

CHANGE
NUMBER

NSHC

DESCRIPTION

01-25

A

NUREG-1431 incorporates the CTS 4.0.4 exception for the surveillances covered by CTS Table 4.3-1 Notes (2), (3), and (6) into the ISTS SR 3.3.1.2, 3.3.1.3, and 3.3.1.6 surveillance frequencies. In the CTS, these surveillances have no time requirements [except for Note (2)]. In general, the combined effect of CTS 4.0.3 and CTS 4.0.4 would allow [24 hours] for the completion of a surveillance if it were not performed upon entry into the specified MODE or other condition for that surveillance. CTS 4.0.3 allows [24 hours] for the completion of a surveillance once the appropriate MODE or condition is established. In the improved TS, the TS 4.0.4 exceptions are incorporated as a NOTE in each affected surveillance. In converting to the NUREG-1431 format, ITS SR 3.3.1.2, SR 3.3.1.3, and SR 3.3.1.6 require these surveillances to be performed within [24] hours after THERMAL POWER is greater than or equal to 15% RTP (CTS Note (2) for the comparison of NIS power to calorimetric power), within [24] hours after 50% RTP (CTS Note (3) for the comparison of excore Axial Flux Difference (AFD) to incore AFD), and [after achieving equilibrium conditions (per CTS 4.2.2.2.d.1) with THERMAL POWER greater than or equal to 75%] RTP (CTS Note (6) for the incore-excore calibration), respectively. Since these surveillances are conditional on THERMAL POWER levels greater than the MODE 2 to MODE 1 breakpoint, there is no need to retain the CTS 4.0.4 exception, as discussed in ITS Section 1.4, as long as the ITS Surveillance Notes allow the plant to reach conditions appropriate for the performance of the surveillances.

The power level at which the monthly surveillance is performed to compare incore vs. excore AFD, and adjustment of the NIS as required by Note (3) of CTS Table 4.3-1, is changed from $\geq 15\%$ RTP to $\geq 50\%$ RTP. This change is also precipitated by the conversion to the ITS format which replaces the CTS 4.0.4 exception with a finite time interval after exceeding a specified power level. With the deletion of the CTS 4.0.4 exception, the specified power level in ITS SR 3.3.1.3 should reflect the applicable safety analysis basis consistent with the [APPLICABILITY and] Required ACTIONS of ITS LCO 3.2.3 (AFD) and LCO 3.2.4 (QPTR). As with the changes discussed above, there is no need to retain the CTS 4.0.4 exception as long as the ITS Surveillance Notes allow the plant to reach conditions appropriate for the performance of the surveillances.

These changes are considered administrative in nature in that they simply reflect the incorporation of the CTS 4.0.4 exceptions into the improved TS.

CHANGE
NUMBER

NSHC

DESCRIPTION

01-26	LG	This change moves the details concerning NIS detector calibration to the Bases for ITS SR 3.3.1.11, consistent with NUREG-1431. This information is more appropriately controlled outside of the TS while the calibration requirement itself and its Frequency are unchanged.
01-27	LS10	Surveillances on the Source Range Neutron Flux trip function are reorganized to reflect plant status in accordance with NUREG-1431. New Note [(19)] requires that the quarterly COT be performed within 4 hours after reducing power below the respective source range instrumentation Applicabilities, if not performed within the previous [92] days. Since the COT is valid for [92] days, there is no need to repeat it if one has been performed within the prior [quarter]. The 4 hour allowance permits a normal shutdown to proceed without a delay for testing in MODE 2 and for a short time in MODE 3 until the Reactor Trip Breakers are opened and this trip function no longer provides protection. Since the CTS has no Specification 4.0.4 exception, this 4 hour allowance is less restrictive.
01-28	A	Note [8] is revised to require the P-6 and P-10 interlock verification to be performed during all source range COTs. These permissives are verified to be in their correct state prior to entry into MODES 3, 4, and 5 during shutdown and after leaving MODES 3, 4, and 5 during startup. These changes are consistent with NUREG-1431.
01-29	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-30	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-31	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-32	LG	[] [Note (10) of CTS Table 4.3-1 is deleted since it is redundant; every TADOT requires independent UVTA and STA verification per ITS SR 3.3.1.4, not just those TADOTs following maintenance or adjustment.] Notes [(14) and (16) applicable to the RTBs and the RTB bypass breakers] of CTS Table 4.3-1 are moved to the Bases for ITS SR 3.3.1.14. These changes are consistent with NUREG-1431.
01-33	TR1	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-34	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

CHANGE
NUMBER

NSHC

DESCRIPTION

01-35	LG	This change moves response time limit tables to the updated FSAR per Generic Letter 93-08 and NUREG-1431.
01-36	M	This change adds a requirement to perform a Channel Calibration on Functional Unit 17 every 18 months. This change is consistent with NUREG-1431.
01-37	A	In the CTS, the "Minimum Channels OPERABLE" is one less than the "Total Number of Channels" for Functional [22.c] (P-8), [22.d](P-9), and [22.e] (P-10) in Table 3.3-1 and Functional Unit [8.a] (P-11) in Table [3.3-3]. For these Reactor Trip System and ESFAS interlocks, current ACTION Statements [8 and 21] for an inoperable channel are based on the "Minimum Channels OPERABLE" columns in Tables 3.3-1 and [3.3-3]. In the improved TS, only the "Total Number of Channels" information is retained in the LCO and that column is relabeled as the "Required Channels", as discussed in CN 1-04-LG and CN 1-43-A. Required ACTIONS in improved TS 3.3.1 Conditions S and T and improved TS 3.3.2 Condition L are tied to the Required Channels. Therefore, the required permissive channels for these Functional Units are revised in the CTS. Refer also to CN 01-51-LG for P-7.
01-38	R	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-39	A	This change adds Note [5] to Functional Units [2.b,3, and 4] in CTS Table 4.3-1. Note [5] is currently listed against Functional Unit [2.a]. Testing methodology and the timing of that testing for the power range channels apply to all power range functions, not just power range-high. As such, this is an administrative change only. ITS SR 3.3.1.11 applies to all power range functions in a similar manner.
01-40	LS41	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-41	A	This change moves the first sentence of note (1) of Table 3.3-2 to ITS SR 3.3.1.16, and moves the rest of Note (1) to the Bases.
01-42	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

CHANGE
NUMBER

NSHC

DESCRIPTION

01-43	A	The "Total Number of Channels" columns in CTS Tables 3.3-1 and [3.3-3] and the ["Minimum Channels OPERABLE"] column in CTS Table [3.3-6] and the reference to them in the ACTIONS are relabeled as the "Required Channels" consistent with NUREG-1431. ACTION Statements are revised to use the ITS terminology, "Required Channels". Changing the column titles is purely administrative. The numbers in the columns are adjusted, if necessary. Where the numbers are adjusted, those changes are described in different CNS.
01-44	A	The "MODES For Which Surveillance Is Required" columns in CTS Tables 4.3-1 and 4.3-2 [] are deleted since this information is enveloped by CTS Tables 3.3-1 and [3.3-3] and is redundant given the integrated OPERABILITY/ SR format in improved TS Tables 3.3.1-1 and 3.3.2-1.
01-45	M	The Overtemperature [ΔT], Overpower [ΔT], Pressurizer Pressure - High, and Steam Generator Water Level - Low-Low trip functions, which currently reference ACTION Statement [6], are now referenced to new ACTION Statement [2.1], consistent with ITS 3.3.1 Condition E. This change is more restrictive since one less hour is available under new ACTION Statement [2.1] than under the combination of current ACTION Statement [6] and LCO 3.0.3.
01-46	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
01-47	A	A new note (f) is added and applied to the Functional Unit 6.c. The note is for clarification only as the CTS Table 3.3-1 indicates that only 1 channel is required to be OPERABLE and that there is no trip function under these conditions.
01-48	LS4	CTS ACTION 7 is revised to allow a reduction in power below P-9 in lieu of tripping the inoperable channel. The ACTION is also revised to allow bypassing a tripped channel for four hours for surveillance testing other channels. Note (j) is added to Table 3.3-1, Applicable Modes for Functional Unit 17.a and b that states that the requirements are only applicable above P-9.
01-49	LS18	CTS ACTION 9 is deleted and revised ACTION 6 is used which allows a power reduction below P-7 in lieu of tripping the inoperable channel. Note (g) is added that specifies that Functional Unit 19 of the CTS does not have to be applied until the power level associated with P-7 is reached. ACTION 6 also allows the tripped channel to be bypassed for up to 4 hours to perform surveillance testing on other channels.

CHANGE NUMBER

NSHC

DESCRIPTION

01-50	A	ACTION [28] of the CTS duplicates CTS ACTION [6] and is deleted.
01-51	LG	This change moves the description of the P-7 inputs, i.e., P-10 and P-13, to the Bases since they are duplicated by Functional Units [20.e and 20.f]. The Required Channels column for P-7 lists "1 per train" since this is a more appropriate convention for a logic function. These changes are consistent with NUREG-1431. [This change also deletes the surveillance requirements for P-7 per CN 3.3-54 in the ITS since the COTs and channel calibration apply to P-10 and P-13 not to the P-7 logic function.]
01-52	LG	This change moves the specifics on how to verify permissive functions of ACTIONS [8] and [21] to the Bases, consistent with NUREG-1431. This information is more appropriately controlled outside of the TS while the underlying requirement to verify proper permissive operation is unchanged.
01-53	A	CTS Table 3.3-1 ACTION Statement [2.c] is revised to be consistent with ITS SR 3.2.4.2, as discussed in CN 4-04-LS-12 in the 3/4.2 package.
01-54	LS37	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-55	LS39	APPLICABILITY Note [*] and ACTION Statement [11] for Functional Units [1, 6.b, 20, and 21] of CTS Table 3.3-1 are modified to provide an alternative to opening the reactor trip breakers (RTBs) while still assuring that the function and intent of opening the RTBs is met. As currently worded, these ACTION Statements result in a feedwater isolation signal (FWIS) when in MODE 3 with a T_{avg} less than [554°F. FSAR Table 7.3-3 and FSAR Figure 7.2-1 (sht. 13) detail the FWIS generation on the coincidence of P-4 and low T_{avg} .] A more generic action, which assures the rods are fully inserted and cannot be withdrawn, replaces the specific method of precluding rod withdrawal. The revised APPLICABILITY and ACTION Statements still assure rod withdrawal is precluded. This change does not involve any safety impact and is consistent with traveler TSTF-135.
01-56	A	The DCPP CTS 3.3.1 ACTION 2.c requires that power be reduced to less than 75% or that SR 4.2.4.2 be performed whenever power is $\geq 50\%$. This power level requirement should be $\geq 75\%$ since if power is decreased below 75% per the first part of Action 2.c, the required ACTION is complete and in addition, SR 4.2.4.2 is only required for power levels $\geq 75\%$ with one power range detector inoperable.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

01-57	LG	CTS Table 3.3-1 Functional Units [12.a and 12.b] are combined per Traveler TSTF-169. The Required Channels, ACTION Statement, and Surveillance Requirements are the same for both Functional Units. The only difference between the two is the APPLICABILITY which could lead to entry into ACTION Statement 6 for Functional Unit [12.a], followed by a power reduction below P-8 exiting the APPLICABILITY and required ACTIONS for that Functional Unit, and subsequent re-entry into ACTION Statement 6 for Functional Unit [12.b]. This would involve an improper cumulative AOT of 12 hours before tripping an inoperable channel, beyond that evaluated in WCAP-10271 and its Supplements. The relationships between these Functional Units and permissives P-7 and P-8 are moved to the ITS 3.3.1 Bases.
01-58	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
01-59		Not Used.
01-60		Not Used.
01-61	M	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-01	A	The Engineered Safety Features Actuation System Instrumentation [Trip Setpoints and] Allowable Values are moved to ITS Table 3.3.2-1.
02-02	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-03	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-04	LG	The requirements stipulated in ACTIONS a and b are moved to ITS Table 3.3.2-1, with explicit direction contained in the ITS ACTIONS Bases.
02-05	M	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-06	LS33	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).

CHANGE
NUMBER

NSHC

DESCRIPTION

02-07

LS11

[Note (a) is added to CTS Table 3.3-3 for the Steam Line Isolation Functional Units 4.a, 4.b, 4.c, 4.d, and 4.e to state that the LCO requirements are not applicable in MODES 2 and 3 when the MSIVs are closed and deactivated]. Note [(b)] is added to CTS Table [3.3-3] for the Feedwater Isolation and Turbine Trip Function [Functional Units 5.a, and 5.b] to state that the LCO requirements are not applicable when the [MFIVs, MFRVs or the associated bypass valves] are closed [and deactivated or isolated by a closed manual valve]. When these valves are closed [and deactivated or isolated by a closed manual valve], they are already performing their safety function. These changes are consistent with NUREG-1431.

02-08

M

[This change revises ACTION 20 and 35 in CTS Table 3.3-3 and adds new ACTION 20.2 and 35.2 which are applicable to Functional Units 1.c, 1.d, 1.ef, 4.c, 4.d, 4.e, 5.b, 6.dc.1)a, and 6.d]. These ACTION Statements, written to reflect the APPLICABILITY of the affected channels and consistency with ITS 3.3.2 [Conditions D and I], are more restrictive, by one hour, than the current ACTION Statement[s] which invoke[] LCO 3.0.3 if the inoperable channel is not placed in trip within 6 hours.

02-09

LG

Separate ESFAS entries for the motor-driven and turbine-driven auxiliary feedwater pumps are no longer necessary, consistent with NUREG-1431. The only difference in the requirements (an SR 4.0.4 exception for response time testing of the turbine-driven auxiliary feedwater pump) has been addressed in the ITS by a Note in Surveillance Requirement 3.3.2.10. [The details of which actuation signal starts which pump is moved to the Bases for SI and RCP undervoltage].

02-10

M

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

02-11

A

The Functional Unit for Loss of Power [CTS 7.a, 7.b] is moved to improved TS 3.3.5.

02-12

M

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

02-13

A

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

02-14

M

This change modifies ACTION Statement [21] for permissive P-11 [] to provide specific shutdown requirements to exit APPLICABILITY in lieu of applying LCO 3.0.3. This change is more restrictive by one hour, consistent with NUREG-1431.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

02-15	M	ACTION Statement [17] has been expanded to specify additional actions and options if an inoperable channel is not placed in bypass within the specified time period. In the CTS, this would have required an entry into LCO 3.0.3, which would necessitate that the plant initiate a shutdown within 1 hour and be in the next mode in 6 hours. In the ITS, the requirements to place the inoperable channel in bypass within a time constraint and the reduction, by 1 hour, in the time to exit APPLICABILITY are more restrictive than the CTS. [As a result of the revision to ACTION 17, a new ACTION 17.1 was created for Functional Unit 4.c that requires entry to MODE 4 if the required ACTIONS are not met.]
02-16	LS12	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-17	LS13	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-18	LS31	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-19	LG	This change moves functions provided by a Safety Injection signal and the AFW pump start entries [] for Functional Units [6.d, and 6.e] in CTS Table [3.3-3] to the ITS 3.3.2 Bases, consistent with NUREG-1431.
02-20	A	The Functional Unit for Containment Ventilation Isolation is moved to ITS 3.3.6. There are no technical differences introduced by this process[].
02-21	LS22	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-22		Not Used.
02-23	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-24	LS19	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-25	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-26	LS21	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-27	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
02-28	LG	This change moves information inserted by LA 114/112 on containment spray and safety injection coincidence to the Bases, consistent with NUREG-1431.
02-29	M	A new functional unit 9 is added, per a License Amendment Request, that incorporates ACTION 20.1(new) and Surveillances for the residual heat removal (RHR) pump trip from low refueling water storage tank level.
02-30	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-31	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-32	LS23	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-33	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-34	LS34	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-35	A	Note (2) of the CTS Table 4.3.2 is revised. The testing frequency was relaxed from monthly (M) to quarterly (Q) via License Amendment 102/101, but the Note was not revised nor was it shown as applicable to Functional Unit 3.c.4).
02-36	M	This change revises the APPLICABILITY of Functional Unit 7 to require OPERABILITY when the associated DG is required to be OPERABLE by LCO 3.8.2 of the ITS. This change is consistent with NUREG-1431.
02-37	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-38	LS35	Delete MODE 4 APPLICABILITY from the Manual Initiation of MSIVs since the valves are not required to be OPERABLE in MODE 4 per CTS 3.7.1.5 or ITS 3.7.2.
02-39	LG	Move valve numbers in CTS ACTION 18 dealing with containment ventilation isolation to the Bases, consistent with NUREG-1431.
02-40	A	This administrative change affects the manner in which the CTS 4.0.4 exception for testing the TDAFW pump is presented. The exception allows entry into MODE 3 to perform the TDAFW pump response time testing. In NUREG-1431, the CTS 4.0.4 exception from [CTS 3.7.1.2 has been interpreted so that it allows response time testing to be deferred as] is reflected in the ITS SR 3.3.2.10 NOTE.

NUMBER**

NSHC

DESCRIPTION

02-41	LS36	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-42	LS38	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-43	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-44	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-45	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-46	LS42	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-47	M	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-48	LS28	A new Action 15 is added and applied to Functional Unit 7. a. 2) and 7. b. 1) that allows the affected Emergency Diesel Generator to be declared inoperable and requires entry into Specification 3.8.1.1 when more than one relay per bus is inoperable. Current ACTION 16 does not address the above situation and requires entry into LCO 3.0.3. This change is consistent with NUREG-1431.
03-01	A	The requirements of this specification [CTS 3.3.3.1] are moved to [four] separate specifications in the improved TS. The RCS Leakage Detection requirements are moved to improved TS 3.4.15. [The Fuel Building requirements are moved to improved TS 3.3.8.] The Control Room requirements are moved to improved TS 3.3.7. [The Containment Ventilation Isolation requirements are moved to improved TS 3.3.6.]
03-02	M	The requirements stipulated in ACTION [a] are moved to ITS Tables [3.3.6-1, 3.3.7-1 and 3.3.8-1], with explicit direction contained in the ITS ACTIONS Bases. The 4 hour AOT for setpoint adjustment is eliminated.
03-03	LG	The requirements associated with the criticality monitors are moved to a licensee controlled document. These monitors are required by 10CFR70.24; however, there is no requirement for [them] to be in the Technical Specifications [as criticality monitors. They are retained, however, as initiators of the Iodine Removal mode of the FHBVS for a fuel handling accident until RM-44A and 44B are installed in accordance with License Amendment 70/69]. Since Part 70 is invoked in the operating license, these monitors will be retained in the plant design.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

03-04	M	This change adds the APPLICABILITY for movement of irradiated fuel assemblies consistent with NUREG-1431. The CTS APPLICABILITY of "All" MODES does not cover the movement of irradiated fuel assemblies when the core is offloaded.
03-05	LS14	ACTION Statement [34] for the [Control Room Air Intake] [] radiation monitors have extended Completion Times, from [1 hour] to 7 days for one required channel inoperable, consistent with NUREG-1431.
03-06	A	ACTION [c] of CTS LCO 3.3.3.1 is revised to state the Specification 3.0.3 exception is [retained only for the Fuel Handling Building Radioactivity Instrumentation]. The LCO 3.0.3 exception is not needed in ITS 3.3.7 or ITS 3.4.15 since Required Actions are provided with the appropriate remedial measures for all combinations of failures, including shutdown actions, or reference is made to the associated plant system TS for the systems affected by the inOperability of the radiation monitors. [].
03-07	LS16	The APPLICABILITY for the Fuel Building Exhaust radiation monitors has been revised to read "during movement of irradiated fuel assemblies in the fuel [handling] building." [The REQUIRED CHANNELS for Instrument 1.b. has been revised from one as specified by the CTS to two as specified by NUREG-1431 to provide protection against a single failure that could prevent the transfer of the FHBVS to the iodine removal mode.]
03-08	M	The CTS have been revised to include manual initiation of the fuel handling building and manual and automatic initiation of the control room pressurization system. These systems are not classified as ESF functions in the CTS even though CTS surveillance 4.7.5.1e.2) requires that the CRVS automatically switches to the pressurization mode on a Phase "A" signal. The FHBVS is not an ESF function since its only function is to mitigate a fuel handling accident. This revision incorporates the Actuation Logic, Master Relay, and Slave Relay Tests included in NUREG-1431 for the CRVS and the TADOT for the manual actuation of both systems. The automatic actuation tests are conducted as part of the CTS, and the relay tests are currently performed even though not specifically called out in the CTS.
03-09	LS-24	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
03-10	LG	The DCP descriptive information related to the Required Channels per normal intake is moved to the Bases.

CHANGE NUMBER

NSHC

DESCRIPTION

03-11	M	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
03-12	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
03-13	M	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
03-14	LS29	This proposed change adds an ACTION and an allowed outage time of 4 hours for one inoperable Containment Ventilation Radiation instrumentation or actuation channel. The CTS via ACTIONS 18 and 33 requires that for one or two instruments or channels inoperable that CTS 3.6.3 or 3.9.9 be entered. The revised TS will require that ITS 3.6.3 or 3.9.4 be entered if the instrument or channel cannot be returned to an OPERABLE status within the revised AOT. This change is consistent with the requirements of NUREG-1431.
03-15	M	This change revises CTS ACTION 34 to require appropriate MODE changes or condition changes for the CRVS with one inoperable normal intake monitor and new ACTION 36 specifies actions for two inoperable normal intake monitors. The CTS requires that if the required ACTIONS for one inoperable CRVS monitor is not met that LCO 3.0.3 be entered. In addition, the CTS does not specify a required action if both monitors are inoperable. NUREG-1431 requires that for the above conditions that appropriate actions be taken to place the plant in a condition of non-APPLICABILITY. These ACTIONS specify a shutdown requirement for MODES 1-4 that is one hour less than LCO 3.0.3, and immediate ACTION for inoperability in MODE 5 or 6, and immediate action for inoperability during fuel movement. These changes are consistent with NUREG-1431. Refer also to CN 03-08-M, CN 03-04-M, and CN 3.3-51.
03-16	A	NOT USED ITS 3.3.6 for DCPD includes MODES 1-4 and during movement of irradiated fuel assemblies within containment, in addition to MODE 6, in the LCO APPLICABILITY. These requirements are inferred in CTS 3.6.3 and are repeated here for clarity.
03-17	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
04-01	R	DCPD LCO 3.3.3.2, Movable Incore Detectors, is relocated to a licensee controlled document, see Attachment 21, page 11.
05-01	R	DCPD LCO 3.3.3.3, Seismic Instrumentation, is relocated to a licensee controlled document, see LAR 95-07.

DESCRIPTION

06-01	R	DCPP LCO 3.3.3.4, Meterological Instrumentation, is relocated to a licensee controlled document, see Attachment 21, page 13.
07-01	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-02	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-03		Not Used.
07-04	LS15	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-05	A	Consistent with the ITS, the modifications would clarify the requirement to be in HOT SHUTDOWN in 12 hours by replacing the requirement with a new requirement to be in HOT STANDBY in 6 hours and in HOT SHUTDOWN in the next 6 hours.
07-06	LG	The Readout Location and Total No. of Channels columns in CTS Table [3.3-9] have been moved to the Bases of improved TS 3.3.4. [Descriptive information related to the controls is also moved to the Bases.]
07-07		Not Used.
07-08	TR2	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-09	LS43	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-10	LS26	In the CTS, the determination that the steam generators are available for decay heat removal, using instrumentation available at the remote shutdown panel, is based on steam generator level and auxiliary feedwater flow to the steam generator. In the ITS, it is recognized that either of these indications is sufficient.
07-11	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-12	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
08-01	A	This change, consistent with NUREG-1431, revises "Channel" and "Instrument" to "Function."
08-02		Not Used.

CHANGE
NUMBER

NSHC

DESCRIPTION

08-03	A	This change revises CTS Table [3.3-10] to clarify the number of channels required to be Operable. This is an administrative change which deletes the "Minimum Channels Operable" column []. The required ACTIONS are now based on one channel inoperable or two channels inoperable, rather than "less than the Total Number" or "less than Minimum Number." This change is consistent with NUREG-1431.
08-04	LS17	Consistent with NUREG-1431 (ITS 3.3.3 Required ACTIONS C.1, E.1, and G.1), this change deletes the requirement to initiate an alternate means of monitoring within 72 hours when two channels of Containment Radiation Level [or RVLIS] are inoperable as specified in CTS [3.3.3.6 ACTION d. In addition, a special report is required within 14 days that identifies the alternate method of monitoring the appropriate parameter(s), as well as the current special report requirements].
08-05	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
08-06	LG	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
08-07	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
08-08	LS27	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
08-09		Not Used.
08-10		Not Used.
08-11	LS30	This change revises the DCCP CTS 3.3.3.6 to conform to NUREG-1431 and revises CTS Table 3.3-10 to both add and delete instruments per the Reviewer's Note on ISTS Table 3.3.3-1.
09-01	LG	The explosive gas monitoring instrumentation will be controlled by the Explosive Gas Monitoring Program established in accordance with ITS 5.5.12, see Attachment 21, page 15.
10-01	R	The Turbine Overspeed Protection System is relocated to a licensee controlled document, see LAR 95-07.
11-01	R	LCO 3.3.3.7, Chlorine Detection Systems, is relocated to a licensee controlled document, see LAR 95-07.

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-01 A	A Note, "Separate Condition entry is allowed for each Function," is added to the ACTIONS for the Reactor Trip System, ESFAS, [] and Accident Monitoring Instrumentation. This change clarifies those situations where the CTS ACTION Statements are not uniquely associated with a particular Function or where the required channels are specified on a per steam line, per loop, per SG, per bus, etc., basis.	Yes	Yes	Yes, see also CN 2-46-LS-42.	Yes, see also CN 2-46-LS-42.
01-02 LG	The improved TS specify that required response time testing be performed on a STAGGERED TEST BASIS and do not impose any requirements as to which train should be tested. The requirement to ensure that each train is tested every 36 months is moved to the Bases for SR 3.3.1.16 and SR 3.3.2.10.	Yes	Yes	Yes	Yes
01-03 LS1	Changing "demonstrated" to "verified" allows Reactor Trip System and ESFAS sensor response time verifications to be performed per WCAP-13632-P-A Revision 2. This change is consistent with traveler TSTF-111.	Yes	No, see CN 1-58-A.	Yes	Yes
01-04 LG	In CTS Tables [3.3-1 and 3.3-3], the ["Channels to Trip" and] "Minimum Channels OPERABLE" columns are deleted. [] The ACTION Statements have been revised accordingly.	Yes	Yes	Yes	Yes
01-05 A	The LCO 3.0.4 exception [footnote #] in CTS Table 3.3-1 is deleted entirely. ACTION Statement [8] in CTS Table 3.3-1 permits continued operation for an unlimited period of time. Therefore, no exception to ITS LCO 3.0.4 is needed for this ACTION Statement. []	Yes	No, not in CTS.	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-06 LS2	A new ACTION Statement [2.1] is created which does not require a reduction in THERMAL POWER to less than 75% RTP or the measurement of the QPTR if above 75% RTP.	Yes	Yes	Yes	Yes
01-07 LS3	<p>With one intermediate range neutron flux channel inoperable when the plant is above P-6 but below 10% RTP (the P-10 interlock setpoint), current ACTION Statement [3.b] is revised to establish a 24 hour Completion Time for channel restoration or changing the power level to either below P-6 or above P-10. Although this change is less restrictive since a power increase is an allowed option, the ACTION Statement would ensure protection by entering the range of the four power range neutron flux channels. The Applicability for Functional Unit 5 is revised such that current ACTION Statement [3.a] can be deleted.</p> <p>With both intermediate range neutron flux channels inoperable when the plant is above P-6 but below P-10, LCO 3.0.3 would be entered under the CTS and the plant would have to be in MODE 3 within 7 hours. New ACTION Statement [3.1] requires immediate suspension of operations involving positive reactivity additions and a power reduction below P-6 within 2 hours.</p>	Yes	Yes	Yes	Yes
01-08 M	Current ACTION Statement [4], for one source range channel inoperable in MODE 2 below P-6, is revised to require "immediate" suspension of operations involving positive reactivity changes and a new ACTION Statement [4.1] is added to address the condition where both source range channels are inoperable in MODE 2 below P-6 [] to require immediate opening of the RTBs.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-09 M	This DCPD-specific change revises CTS ACTION 5 to require the suspension of positive reactivity additions. Reference to specification 3.1.1.2 is deleted since the ITS reference is only to 3.1.1.1 which is more conservative for MODE 5.	Yes	No	No	No
01-10 LS32	<p>This Callaway-specific change redefines the Actions for the source range neutron flux channels in MODES 3, 4, and 5. The source range neutron flux channels are required to provide input to the Reactor Trip System to mitigate potential uncontrolled rod withdrawal events only when the Rod Control System is capable of rod withdrawal or all rods are not fully inserted (see CN 1-55-LS-39).</p> <p>If one source range neutron flux channel is inoperable in MODES 3, 4, and 5 when rod motion is possible, ACTION Statement 5.a is entered. If the channel is not restored within 48 hours, the Applicability is exited by inserting all rods and precluding rod withdrawal. If both source range channels are inoperable when rod motion is possible, new ACTION Statement 4.1 is entered and the reactor trip breakers are immediately opened.</p> <p>The current Action Statement 5.a requirements regarding the suspension of positive reactivity changes and closure of dilution source valves are deleted since they are not related to the reactor trip function.</p>	No	No	No	Yes

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-11 LS5	[New] ACTION Statement [39] is applied to the Low Fluid Oil Pressure and Turbine Stop Valve Closure trip functions. Rather than entry into LCO 3.0.3 if current ACTION Statements [6 and 11] are not met or if multiple low fluid oil pressure channels are inoperable, the new ACTION Statement requires inoperable channels to be tripped within 6 hours or power reduced below P-9 within 10 hours.	No, see CN 1-48-LS-4.	Yes	Yes	Yes
01-12 M	New ACTION Statement [8.1] is created to differentiate between those RTS interlocks required to be operable in MODE 1 only, and those interlocks required to be operable in MODES 1 and 2. If the interlock function is required to be operable in MODE 1 only and the LCO and ACTION requirements are not met, then new ACTION Statement [8.1] requires that the unit be taken to MODE 2 within 7 hours. In addition, current ACTION Statement [8] is revised for those interlocks required to be OPERABLE in MODES 1 and 2. If one channel is inoperable, the interlock must be determined to be in its required state or the plant must be in at least HOT STANDBY within 7 hours.	Yes	Yes	Yes	Yes
01-13 LS6	[ACTION Statement [10] is revised to note that the 2 hour [train and] reactor trip breaker bypass allowance for [train or] breaker surveillance testing can also be used for maintenance.] ACTION Statement [10] is [also] revised to require restoration of an inoperable RTB within 1 hour or the plant must be in HOT STANDBY within the next 6 hours. This is less restrictive since an additional hour is provided for the transition to MODE 3.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-14 A	In the ISTS Table 3.3.1-1, Function 20, the Reactor Trip Breaker (RTB) Undervoltage and Shunt Trip Mechanisms are separate from the RTB Functional Unit. The CTS have been revised to reflect these requirements. New [footnote (k) has] been added to the RTB Functional Unit to note that the same OPERABILITY requirements and ACTIONS apply to a bypass breaker if it is racked in and closed for bypassing an RTB. The bypass breakers were already handled in this fashion. ACTION Statement [12] in CTS Table 3.3-1 has been revised accordingly.	Yes	Yes	Yes	Yes
01-15 A	The Applicability for the Reactor Trip on Turbine Trip function is modified by new footnote [(c)] such that this function is only required to be OPERABLE above the P-9 interlock setpoint (50% RTP). This is acceptable since the trip function is blocked below P-9. [New] ACTION Statement [39] is applied to the Low Fluid Oil Pressure and Turbine Stop Valve Closure trip functions.	No, see CN 1-48-LS-4.	No, already in CTS.	Yes	Yes
01-16 LS40	The requirement to verify the setpoint during the quarterly TADOT for RCP Underfrequency [and RCP Undervoltage] is deleted.	Yes	Yes	Yes	Yes
01-17 A	The bypass allowance can be used for surveillance testing or setpoint adjustment. Setpoint adjustment can be performed at power and may be required by other Technical Specifications.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-18 LS7	The CTS requirement to reduce the Power Range Neutron Flux Trip setpoints in the event a power range flux channel is inoperable is deleted. The time to reduce power below 75% RTP is increased from 4 hours to 12 hours and, if actions are not completed as required, the unit must be in MODE 3 in 12 hours. (See also CN 1-53-A.)	Yes	Yes	Yes	Yes
01-19 LS8	If the requirements of current ACTION Statement [6] are not met, LCO 3.0.3 would be entered. In accordance with the ISTS, this ACTION Statement is revised to state that, if the ACTION requirements are not met, the plant must be taken below the P-7 interlock setpoint within the next 6 hours. [The Applicability for Functional Units 9, 11, 12, 15, and 16 in CTS Table 3.3-1 is also revised to add new footnote (g).]	Yes	No, see CN 1-61-M.	Yes	Yes
01-20 A	Callaway's current ACTION Statement 31 is reformatted per NUREG-1431 Rev. 1 to require restoration of an inoperable channel within 6 hours or the plant must be taken to MODE 3 within 12 hours. This is an administrative change since the total time to exit the Applicability is unchanged.	No	No	No	Yes
01-21 A	This change reflects the reorganization of the surveillances on the incore/excore axial flux difference. There is no change to the surveillances or how they are performed. See also CN 1-25-A.	Yes	Yes	Yes	Yes
01-22 M	Quarterly COTs have been added for power range - low and intermediate range flux channels. [The requirement to verify the state of P-6 and P-10 has been added for these COTs.]	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-23 A	This change adds notes to the RTS and ESFAS SR Tables 4.3-1 and 4.3-2 that explicitly require the 18-month calibrations to include verifications of affected time constants where applicable.	Yes	Yes	Yes	Yes
01-24 LS9	The COTs for the Power Range Neutron Flux - Low setpoint, the Intermediate Range Neutron Flux and the Source Range Neutron Flux trip functions will no longer be required if performed within the previous 92 days (extended from 31 days). Note [1a] is added for use with the turbine trip functions, for which no such change was provided.	Yes	Yes	Yes	Yes
01-25 A	NUREG-1431 Rev. 1 incorporates the CTS 4.0.4 exception from Table 4.3-1 Notes (2), (3), and (6) into the ITS SR 3.3.1.2, 3.3.1.3, and 3.3.1.6 surveillance frequencies.	Yes	Yes	Yes	Yes
01-26 LG	This change moves detail concerning NIS detector operation and testing to the BASES for ITS SR 3.3.1.11.	Yes	Yes	Yes	Yes
01-27 LS10	Surveillances on the Source Range Neutron Flux trip function are reorganized to reflect plant status in accordance with NUREG-1431. New Note [(19)] requires that the quarterly COT be performed within 4 hours after reducing power below the respective source range instrumentation Applicabilities, if not performed within the previous [92] days. Since the COT is valid for [92] days, there is no need to repeat it if one has been performed within the prior [quarter]. Since the CTS has no Specification 4.0.4 exception, this 4 hour allowance is less restrictive.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-28 A	Note [8] is revised to require the P-6 and P-10 interlock verification to be performed during all source range COTs. These permissives are verified to be in their correct state prior to entry into MODES 3, 4, and 5 during shutdown and after leaving MODES 3, 4, and 5 during startup.	Yes	Yes	Yes	Yes
01-29 LG	This change moves the details regarding measurement of loop-specific ΔT values to the BASES for ITS SR 3.3.1.6.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
01-30 M	Boron Dilution Mitigation System (BDMS) signal blocking and surveillance requirements are moved to ITS LCO 3.3.9. This is a more restrictive requirement since the BDMS, other than the inputs from the source range channels, currently has no LCO or ACTION requirements.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
01-31 A	One-time surveillance waivers are deleted. They are no longer applicable.	No, not in CTS.	Yes	Yes	Yes
01-32 LG	[] [Note (10) of CTS Table 4.3-1 is deleted since it is redundant; every TADOT requires independent UVTA and STA verification per ITS SR 3.3.1.4, not just those TADOTs following maintenance or adjustment.] Notes [(14) and (16)] of CTS Table 4.3-1 are moved to the BASES for ITS SR 3.3.1.14.	Yes	Yes	Yes	Yes
01-33 TR1	The BDMS actuation SR is changed to allow the use of an actual signal, if and when one occurs, to satisfy surveillance requirements.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-34 A	Callaway's current ACTION Statement 5.b requirements for two inoperable source range channels are divided between the reactor trip, indication, and BDMS functions served by the source range channels. New ACTION Statement 4.1, added to CTS Table 3.3-1, retains the requirement to open the reactor trip breakers to serve the reactor trip function. The ACTION Statement 5.b requirements that are not related to reactor trip are moved to ITS 3.3.9. See also CN 1-30-M.	No	No	No	Yes
01-35 LG	This change moves response time limit tables to the updated FSAR per Generic Letter 93-08 and NUREG-1431 Rev. 1.	Yes	No, already moved to TRM.	No, already moved to USAR Section 16.3.	No, already moved to FSAR Section 16.3.
01-36 M	This DCCP-specific change adds a requirement to perform a Channel Calibration on Functional Unit 17 every 18 months.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-37 A	In the CTS, the "Minimum Channels OPERABLE" is one less than the "Total Number of Channels" for Functional Units [22.c] (P-8), [22.d](P-9), and [22.e](P-10) in Table 3.3-1 and Functional Unit [8.a](P-11) in Table [3.3-3]. For these Reactor Trip System and ESFAS interlocks, current ACTION Statements [8 and 21] for an inoperable channel are based on the "Minimum Channels OPERABLE" columns in Tables 3.3-1 and [3.3-3]. In the improved TS, only the "Total Number of Channels" information is retained in the LCO and that column is relabeled as the "Required Channels", as discussed in CN 1-04-LG and CN 1-43-A. Required Actions in improved TS 3.3.1 Conditions S and T and improved TS 3.3.2 Condition L are tied to the Required Channels. Therefore, the required permissive channels for these Functional Units are revised in the CTS. Refer also to CN 1-51-LG for P-7.	Yes	Yes	Yes	Yes
01-38 R	The source range channel operability requirements in MODES 3, 4, and 5 when incapable of rod withdrawal are relocated to a licensee controlled document.	No, see CN 1-09-M.	Yes, relocated to the TRM.	Yes, relocated to Chapter 16.3 of the USAR.	No, see Cns 1-10-LS-32, 1-32-M, and 1-34-A.
01-39 A	This change adds Note [(5)] to Functional Units [2.b, 3, and 4] in CTS Table 4.3-1.	Yes	Yes	Yes	Yes
01-40 LS41	Surveillance intervals applied to Notes (3) and (6) of CTS Table 4.3-1 will be defined in terms of effective full power days (EFPD). However, EFPD may be longer than calendar days as specified in the CTS. Therefore, this change is considered less restrictive.	No, already in CTS.	No, already in CTS.	Yes	Yes
01-41 A	This DCCP-specific change moves the first sentence of note (1) of Table 3.3-2 to ITS SR 3.3.1.16, and moves the rest of note (1) to the Bases.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-42 M	This change adds direction to ACTIONS 7, 11, and 13 in CTS Table 3.3-1 to be in MODE 3 within 12 hours, in lieu of LCO 3.0.3 entry, if inoperable EAM/TTD timer(s) or channel(s) aren't tripped within 6 hours.	No, not in current design or TS.	No, not in current design or TS.	No, not in current design or TS.	Yes
01-43 A	The "Total Number of Channels" columns in CTS Tables 3.3-1 and [3.3-3] and the ["Minimum Channels OPERABLE"] column in CTS Table [3.3-6] and the references to them in the ACTIONS are relabeled as the "Required Channels" consistent with NUREG-1431 Rev. 1. ACTION Statements have been revised accordingly.	Yes	Yes	Yes	Yes
01-44 A	This change deletes the "MODES For Which Surveillance Is Required" column in CTS Tables 4.3-1[, 4.3-2 and 4.3-3].	Yes	Yes	Yes	Yes
01-45 M	The Overtemperature [ΔT], Overpower [ΔT], Pressurizer Pressure - High, and Steam Generator Water Level - Low-Low trip functions, which currently reference ACTION Statement [6], are now referenced to new ACTION Statement [2.1], consistent with ITS 3.3.1 Condition E. This change is more restrictive since one less hour is available under new ACTION Statement [2.1] than under the combination of current ACTION Statement [6] and LCO 3.0.3.	Yes	Yes	Yes	Yes
01-46 A	ACTION Statement 13 of CTS Table 3.3-1 and ACTION Statement 36 of CTS Table 3.3-3 are revised to reflect operating and testing options that have existed since the SG Water Level Low-Low EAM/TTD design was implemented, but were not listed in the TS since they were not necessarily the options of choice.	No, not in current design or TS.	No, not in current design or TS.	No, not in current design or TS	Yes, reviewed in OL Amendment No. 43 dated April 14, 1989.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-47 A	For DCP, a new note (f) is added and applied to the Functional Unit 6.c. The note is for clarification only as the CTS Table 3.3-1 indicates that only 1 channel is required to be OPERABLE and that there is no trip function under these conditions.	Yes	No	No	No
01-48 LS4	For DCP, CTS ACTION 7 is revised to allow a reduction in power below P-9 in lieu of tripping the inoperable channel. The action is also revised to allow bypassing a tripped channel for four hours for surveillance testing other channels. Note (j) is added to Table 3.3-1, Applicable Modes for Functional Unit 17.a and b that states that the requirements are only applicable above P-9.	Yes	No	No	No
01-49 LS18	For DCP, CTS ACTION 9 is deleted and revised ACTION 6 is used which allows a power reduction below P-7 in lieu of tripping the inoperable channel. Note (g) is added that specifies that Functional Unit 19 of the CTS does not have to be applied until the power level associated with P-7 is reached. ACTION 6 also allows the tripped channel to be bypassed for up to 4 hours to perform surveillance testing on other channels.	Yes	No	No	No
01-50 A	ACTION [28] of the CTS duplicates CTS ACTION [6] and is deleted.	Yes	Yes	No, not in CTS.	No, not in current TS.
01-51 LG	This change moves the description of the P-7 inputs, i.e., P-10 and P-13, to the Bases since they are duplicated by Functional Units [22.e and 22.f] and lists "1 per train" under the Required Channels column. [This change also deletes the surveillance requirements for P-7 per CN 3.3-54 in the ITS since the COTs and channel calibration apply to P-10 and P-13 not to P-7 logic function.]	Yes	Yes	Yes	Yes

NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-04 LG	The requirements stipulated in ACTIONS a and b are moved to ITS Table 3.3.2-1, with explicit direction contained in the ITS ACTIONS Bases.	Yes	Yes	Yes	Yes
02-05 M	The Functional Unit for Containment Purge Isolation, CTS 3.c, is moved to improved TS 3.3.6. Improved TS 3.3.6 adds requirements on the OPERABILITY of the containment purge radiation monitors and extends the Applicability to the Manual Initiation and BOP ESFAS actuation logic to include during movement of irradiated fuel assemblies within containment and Core Alterations.	No, see CN 02-20-A.	No, see CN 2-20-A.	Yes	Yes
02-06 LS33	Functional Unit 4.a.1 of curret TS Table 3.3-3 has been deleted.	No, retained in CTS.	No, see CN 2-25-A.	No, see CN 2-25-A.	Yes
02-07 LS11	[Note (a) is added to CTS Table 3.3-3 for the Steam Line Isolation Function to state that the LCO requirements are not applicable in MODES 2 and 3 when the MSIVs are closed and deactivated]. Note [(b)] is added to CTS Table [3.3-3] for the Feedwater Isolation and Turbine Trip Function to state that the LCO requirements are not applicable when the [MFIVs, MFRVs and the associated bypass valves] are closed [and deactivated or isolated by a closed manual valve].	Yes	Yes	Yes	Yes
02-08 M	[This change revises ACTION 20 and 35 in CTS Table 3.3-3 and adds new ACTION 35.2 which are applicable to Units 1.c, 1.d, 1.f, 4.d, 4.e, 5.b, 6.c.2.a, and 6.d]. These ACTION Statements, written to reflect the Applicability of the affected channels, are more restrictive, by one hour, than the current ACTION Statement[s] which invoke[] LCO 3.0.3 if the inoperable channel is not placed in trip within 6 hours.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-09 LG	Separate ESFAS entries for the motor-driven and turbine-driven auxiliary feedwater pumps are no longer necessary. The only difference in the requirements (an SR 4.0.4 exception for response time testing of the turbine-driven auxiliary feedwater pump) has been addressed in the ITS by a Note in Surveillance Requirement 3.3.2.10. [The details of which actuation signal starts which pump is moved to the Bases for SI and RCP undervoltage.]	Yes, moved to Bases.			
02-10 M	New ACTION Statement [19.1] is added to CTS Table [3.3-3] for one inoperable Main Feedwater Pump trip - AFW start channel. This is a more restrictive change since it reduces by 1 hour the Completion Time to reach MODE 3 as compared with entry into LCO 3.0.3.	No, not in CTS.	Yes	Yes	Yes
02-11 A	The Functional Unit for Loss of Power [CTS 7.a, 7.b] is moved to improved TS 3.3.5.	Yes	Yes	Yes	Yes
02-12 M	This Functional Unit [CTS 9.a-9.d] is moved to improved TS 3.3.7. The Applicable MODES have been expanded to include movement of irradiated fuel assemblies to cover fuel handling accidents.	No, not in CTS.	Yes	Yes	Yes
02-13 A	This Functional Unit [CTS 10] is moved to ITS 3.8.1.	No, not in CTS.	Yes	Yes	Yes
02-14 M	This change modifies ACTION Statement [21] for permissive P-11 [] to provide specific shutdown requirements to exit Applicability, in lieu of applying LCO 3.0.3. This change is more restrictive by one hour.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-15 M	Action Statement [17] has been expanded to specify additional actions and options if an inoperable channel is not placed in bypass within the specified time period. In the ITS, the requirements to place the inoperable channel in bypass within a time constraint and the reduction, by 1 hour, in the time to exit Applicability are more restrictive than the CTS. [As a result of the revision to ACTION 17, a new ACTION 17.1 was created for Functional Unit 4.c that requires entry to MODE 4 if the ACTIONS are not met.]	Yes	Yes	Yes	Yes
02-16 LS12	ACTION Statement [26] for an inoperable channel in the CTS Table [3.3-3] Functional Unit [9.a-9.c] is modified to be consistent with NUREG-1431 Rev. 1 (7 day AOT in ITS 3.3.7).	No, not in CTS.	Yes	Yes	Yes
02-17 LS13	The monthly TADOT has been extended to quarterly.	No, not in CTS.	Yes	No, retained CTS.	No, retained CTS.
02-18 LS31	CTS Table 3.3-3 ACTION Statement 19 is revised to reflect ITS 3.3.5 for the Loss of Power Functional Unit.	No, see CN 2-48-LS28.	No, see CN 2-32-LS-23.	Yes	Yes
02-19 LG	This change moves functions provided by a Safety Injection signal and the AFW pump start entries [] for Functional Units [6.d, and 6.e] in CTS Table [3.3-3] to the ITS 3.3.2 Bases.	Yes	Yes	Yes	Yes
02-20 A	The Functional Unit for Containment Vent Isolation is moved to ITS 3.3.6. There are no technical differences introduced by this process[].	Yes	Yes	No, see CN 2-05-M.	No, see CN 2-05-M.
02-21 LS22	In CPSES CTS Table 3.3-2, Action 17.1 replaces Action 17 for RWST Level Low-Low and Action 17.2 replaces Action 17 for SG Water Level - High High.	No	Yes	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-22	Not Used.	N/A	N/A	N/A	N/A
02-23 A	This change revises ACTIONS [14, 27, 27a, 34, and 34a] in CTS Table 3.3-3 to clarify that the 12 hour AOT to get to MODE 3 includes 6 hours for restoration followed by a 6 hour shutdown to MODE 3.	No, already in CTS.	No, already in CTS.	Yes	Yes
02-24 LS19	At CPSES, the Required Action for an inoperable SI sequencer is revised per ITS 3.8.1 Condition F to extend the time available for restoration of an inoperable SI sequencer from 6 hours to 12 hours.	No	Yes	No	No
02-25 A	The requirement for manual actuation of a single main steam isolation valve has been moved from CTS Table [3.3-3]. Operability of individual lines is addressed under ITS LCO 3.7.2.	No, retained CTS.	Yes	Yes	Yes
02-26 LS21	The Required Action for an inoperable Control Room [Isolation] [Manual Initiation, SSPS, or BOP-ESFAS] channel is modified to provide appropriate actions with the number of OPERABLE channels [two] less than the number of Required Channels.	No, not in CTS.	Yes	Yes	Yes
02-27 A	The CPSES Action Statement for the loss of offsite power - start motor driven auxiliary feedwater pumps is modified to require that if the Action Statements are not satisfied, the plant be taken to MODE 4 to exit the LCO Applicability. The CTS requires that MODE 5 be entered; however, because the function is only applicable in MODES 1, 2, and 3, the LCO would be exited prior to MODE 5, and MODE 5 entry is not a requirement.	No	Yes	No	No
02-28 LG	This change moves DCPD information inserted by LA 114/115 on containment spray and safety injection coincidence to the Bases.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-29 M	A new functional unit 9 is added to the DCPD CTS, per a License Amendment Request, that incorporates ACTION 20.1 (new) and the appropriate Surveillances for the residual heat removal (RHR) pump trip from low refueling water storage tank (RWST) level.	Yes	No	No	No
02-30 A	This change deletes Note (3) from Functional Unit 2.b. The slave relays listed in Note (3) were never associated with containment spray.	No, not in CTS.	No, not in CTS.	Yes	Yes
02-31 A	The *** Note for Functional Unit 6.g of CTS Table 3.3-3 is deleted. This note is no longer needed given that the ITS provides separate Condition entry on a per pump basis, as evaluated under CN 2-46-LS42, and given the adoption of ITS LCO 3.0.6 and the Safety Function Determination Program.	No, not in CTS.	No, not in CTS.	Yes	Yes
02-32 LS23	These changes affect the ACTION STATEMENTS for inoperable undervoltage or degraded voltage relays. For all trip functions, new statements are added which require that the diesel generator, which was made inoperable by the inoperable undervoltage or degraded voltage relay, may be declared inoperable in lieu of entering LCO 3.0.3. If the number of OPERABLE channels per bus is less than the Required Number, one hour is now allowed to restore the channel to operability before compensatory actions are required.	No, see CN-02-48-LS28.	Yes	No, see CN 2-18-LS-31.	No, see CN 2-18-LS-31.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-33 A	ACTION Statements 27a and 34a of CTS Table 3.3-3 are revised to delete information regarding the loss of one MSFIS channel since no restoration activity is required. See also CN 1-43-A. CTS Table 3.3-3 is revised to correct the implication that the MSFIS PLCs are associated with, or a part of, the SSPS. System design is described in the ITS 3.3.2 Bases. CTS Table 4.3-2 is revised to show that the quarterly SR is actually an Actuation Logic Test of the MSFIS PLC logic, initiated from the SSPS slave relays.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
02-34 LS34	ACTION Statement 19 of CTS Table 3.3-3 Functional Units 8a and 8b is revised to require an inoperable loss of power channel to be placed in trip within 6 hours and an allowance to be bypassed for surveillance testing for up to 4 hours is added rather than the current 1 hour and 2 hours, respectively. This is consistent with ISTS 3.3.5 Condition A.	No, maintained CTS.	No, can not bypass these channels.	Yes	Yes
02-35 A	Note (2) of DCPD CTS Table 4.3.2 is revised. The testing frequency was relaxed from monthly (M) to quarterly (Q) via License Amendment 102/101 but the note was not revised.	Yes	No	No	No
02-36 M	This change revises the APPLICABILITY of Functional Unit 7 to require operability when the associated DG is required to be OPERABLE by LCO 3.8.2 of the ITS.	Yes	No, see CN 2-32-LS-23.	No, see CN 2-18-LS-31.	No, see CN 2-18-LS-31.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-37 LG	CTS 3.3.2 Functional Unit 6.a requirement for manual initiation of an Auxiliary Feedwater pump is being deleted. The CTS Action Statement 24 with one channel inoperable requires declaring the applicable feedwater pump inoperable and entering the ACTIONS required by CTS 3.7.1.2. Therefore, this is consistent with the NUREG-1431 ITS 3.3.2 which does not have this Function identified and ITS 3.7.5 which has the ACTIONS consistent with those in the CTS ACTION 24.	No, retained CTS.	No, not in CTS.	Yes	No, retained in ITS.
02-38 LS35	For DCPD, delete MODE 4 Applicability from the Manual Initiation of MSIVs since the valves are not required to be OPERABLE in MODE 4 per CTS 3.7.1.5 or ITS 3.7.2.	Yes	No	No	No
02-39 LG	Move valve numbers in CTS ACTION 18 dealing with containment ventilation isolation to the Bases.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
02-40 A	This administrative change affects the manner in which the CTS 4.0.4 exception for testing the TDAFW pump is presented. The exception allows entry into MODE 3 to perform the TDAFW pump response time testing. In NUREG-1431, the CTS 4.0.4 exception from [CTS 3.7.1.2 has been interpreted so that it allows response time testing to be deferred as] is reflected in the ITS SR 3.3.2.10 NOTE.	Yes	Yes	No, already in CTS	No, already in CTS
02-41 LS36	ACTIONS Statements 27a and 34a of CTS Table 3.3-3 for the Automatic Actuation Logic and Actuation Relays (MSFIS), Functional Units 4.b.2 and 5.a.2, are revised to specify action "with the number of channels less than the required channels". Those ACTION Statements currently require action "with the number of OPERABLE channels <u>one</u> less than the minimum number of channels", but no action exists if none of the required channels per train are OPERABLE.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-42 LS38	This change revises the Applicability and ACTION Statement 37 for Functional Unit 6.d.1).c) of CTS Table 3.3-3 to reflect MODES 1 and 2 only. There is no Vessel ΔT in MODE 3 and no OPERABILITY requirements should be imposed. The maximum TTD should always be enabled in MODE 3.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
02-43 LG	Callaway's Operability requirements associated with the shutdown portion of one sequencer required to be OPERABLE in MODES 5 and 6, and which corresponds to the required DG, are moved to ITS 3.8.2 with the explicit link found in the ITS 3.8.2 LCO Bases.	No	No	No	Yes
02-44 A	Current Action Statement 32 of TS Table 3.3-3 for Functional Unit 32, RWST Level - Low-Low Coincident with Safety Injection, is revised to delete the last paragraph that states a channel may be tripped for up to 4 hours for surveillance testing to reflect the practical application of this allowance.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
02-45 LG	CTS Table 4.3-2 Note (3) is revised to move the "during refueling" clarification of the 18 month surveillance interval for the seven slave relays to the Bases for ITS SR 3.3.2.6, SR 3.3.6.5, and SR 3.3.7.5.	No, not in CTS.	No, not in CTS.	Yes	Yes
02-46 LS42	Relaxations associated with separate Condition entry for the RCP-Undervoltage, RCP-Underfrequency, and Auxiliary Feedwater - Trip of all Main Feedwater Pumps Functions are justified.	No, not in CTS.	No, already in CTS.	Yes	Yes
02-47 M	This change adds the Automatic Actuation Logic and Actuation Relays Function to the ESFAS Functional Unit for [Control Room Emergency Recirculation].	No, see CN 3-08-M.	Yes	No, already in CTS.	No, already in CTS.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-48 LS28	A new Action 15 is added and applied to function 7.a.2) and 7.b.1) that allows the affected Emergency Diesel Generator to be declared inoperable and requires entry into Specification 3.8.1.1 when more than one relay per bus is inoperable. Current ACTION 16 does not address the above situation and requires entry into LCO 3.0.3. This change is consistent with NUREG-1431.	Yes	No, see CN 2-23-LS23.	No, see CN 2-18-LS31.	No, see CN 2-18-LS31.
03-01 A	The requirements of this specification [CTS 3.3.3.1] are moved to [four] separate specifications in the improved TS. The RCS Leakage Detection requirements are moved to improved TS 3.4.15. [The Fuel Building requirements are moved to improved TS 3.3.8.] The Control Room requirements are moved to improved TS 3.3.7. [The Containment Ventilation Isolation is moved to improved TS 3.3.6.]	Yes	Yes	Yes	Yes
03-02 M	The requirements stipulated in ACTION [a] are moved to ITS Tables [3.3.6-1, 3.3.7-1 and 3.3.8-1], with explicit direction contained in the ITS ACTIONS Bases. The 4 hour AOT for setpoint adjustment is eliminated.	Yes	Yes	Yes	Yes
03-03 LG	The requirements associated with the criticality monitors are moved to a licensee controlled document. These monitors are required by 10CFR70.24; however, there is no requirement for [them] to be in the Technical Specifications [as criticality monitors. They are retained, however, as initiators of the Iodine Removal mode of the FHBVS for a fuel handling accident until RM-45A/B are installed].	Yes, moved to FSAR.	No, not in CTS.	Yes, moved to USAR Section 16.3.	Yes, moved to FSAR Section 16.3.
03-04 M	This change adds the Applicability for movement of irradiated fuel assemblies. The CTS Applicability of "All" MODES does not cover the movement of irradiated fuel assemblies when the core is offloaded.	Yes	Yes	No, see CN 3-12-A.	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
03-05 LS14	ACTION Statement [34] for the [Control Room Air Intake] [] radiation monitors have extended Completion Times, from [1 hour] to 7 days for one required channel inoperable.	Yes	Yes	Yes	Yes
03-06 A	ACTION c of CTS LCO 3.3.3.1 is revised to state the Specification 3.0.3 exception is [retained only for the Fuel Handling Building Radioactivity Instrumentation].	Yes	Yes	Yes	Yes
03-07 LS16	The Applicability for the Fuel [Handling] Building Exhaust radiation monitors has been revised to read "during movement of irradiated fuel assemblies in the fuel [handling] building." [The REQUIRED CHANNELS for Instrument 1.b. has been revised from one as specified by the CTS to two as specified by NUREG-1431 to provide single failure protection.]	Yes	No, not in CTS.	Yes	Yes
03-08 M	The DCPD CTS have been revised to include manual initiation of the fuel handling building and automatic initiation of the control room pressurization system. These systems are not classified as ESF functions in the CTS. This revision incorporates the Actuation Logic, Master Relay, and Slave Relay Tests included in NUREG-1431 for the CRVS and the TADOT for the manual actuation of both systems.	Yes	No	No	No
03-09 LS24	The CPSES Surveillance frequency for the performance of a CHANNEL OPERABILITY TEST for the radiation monitoring instrumentation channels would be extended from once per 31 days to once per 92 days. This change is consistent with the ITS.	No	Yes	No	No
03-10 LG	The DCPD descriptive information related to the Required Channels per normal intake is moved to the Bases.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
03-11 M	The CPSES ACTION STATEMENT for an inoperable gaseous radioactivity monitor is modified to require that the inoperable channel be restored within 4 hours. If not restored, continued operation is permitted (similar to the CTS allowance) provided the containment vent isolation valves are closed. The change is more restrictive or administrative in nature in that no time limits for the completion of any actions are specified in the CTS.	No	Yes	No	No
03-12 A	Wolf Creek's use of the Applicability "All" includes MODES 1, 2, 3, 4, 5, 6, and movement of irradiated fuel assemblies.	No, see CN 3-04-M.	No, see CN 3-04-M.	Yes	No, see CN 3-04-M.
03-13 M	The proposed change would provide an ACTION STATEMENT for the case where the number of Control Room air intake radiation level instrumentation channels was two less than required number of channels. The ACTION STATEMENT would require that the air supply from the affected air intake be secured or that the emergency recirculation mode be initiated and maintained. Otherwise, restore one channel within one hour or shutdown to MODE 3 in 6 hours and MODE 5 in the next 30 hours.	No, see CN 3-15-M.	Yes	No, already in CTS.	No, already in CTS.
03-14 LS29	This proposed change adds an ACTION and an allowed outage time of 4 hours for one inoperable Containment Ventilation Radiation instrumentation or actuation channel to the DCPD CTS.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
03-15 M	This change revises DCPD CTS ACTION 34 and adds new ACTION 36 to require appropriate MODE changes or condition changes for the CRVS with one or two inoperable normal intake monitors. These actions specify a shutdown requirement for MODES 1-4 that is one hour less than LCO 3.0.3, and immediate action for inoperability in MODE 5 or 6, and immediate action for inoperability during fuel movement. Refer also to CN 03-08-M, CN 03-04-M, and CN 3.3-51.	Yes	No	No	No
03-16 A	ITS 3.3.6 for DCPD includes MODES 1-4 and during movement of irradiated fuel assemblies within containment, in addition to MODE 6, in the LCO Applicability. These requirements are inferred in CTS 3.6.3 and are repeated here for clarity.	Yes	No	No	No
03-17 A	The CPSES restrictions on opening of the containment pressure relief valves is moved from the Radiation Monitoring Instrumentation specification in the CTS to ITS 3.6.3 and the ITS Administrative Controls Section 5.5.1 for the ODCM.	No	Yes	No	No
04-01 R	DCPD LCO 3.3.3.2, Movable Incore Detectors, is relocated to a licensee controlled document.	Yes, see Attachment 21, page 11.	No	No	No
05-01 R	DCPD LCO 3.3.3.3, Seismic Instrumentation, is relocated to a licensee controlled document.	Yes, see LAR 95-07	No	No	No
06-01 R	DCPD LCO 3.3.3.4, Meteorological Instrumentation, is relocated to a licensee controlled document.	Yes, see Attachment 21, page 13.	No	No	No

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
07-01 A	The requirements of CTS Table [3.3-9] are redefined on a functional basis with Required Channels. The point at which ACTION Statements are entered is unchanged.	No, already in CTS.	Yes	Yes	Yes
07-02 M	The shutdown requirement for inoperable Remote Shutdown controls is changed from HOT STANDBY to HOT SHUTDOWN.	No, already in CTS.	Yes	No, already in CTS.	No, already in CTS.
07-03	Not used.	N/A	N/A	N/A	N/A
07-04 LS15	This change extends the Remote Shutdown AOT from 7 days to 30 days.	No, already in CTS.	Yes	Yes	Yes
07-05 A	Consistent with the ITS, the modifications would clarify the requirement to be in HOT SHUTDOWN in 12 hours by replacing the requirement with a new requirement to be in HOT STANDBY in 6 hours and in HOT SHUTDOWN in the next 6 hours.	Yes	Yes	No, already in CTS.	No, already in CTS.
07-06 LG	The Readout Location and Total No. of Channels columns in CTS Table [3.3-9] have been moved to the Bases of improved TS 3.3.4. [Descriptive information related to the controls is also moved to the Bases.]	Yes	Yes	Yes	Yes
07-07	Not used.	N/A	N/A	N/A	N/A
07-08 TR2	The CPSES requirement to submit a special report if the number of remote shutdown monitoring instruments is less than the required number would be deleted from the CTS. This requirement is covered by other regulatory requirements.	No	Yes	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
07-09 LS43	Clarification is provided that Channel Checks are only required for normally energized instrumentation channels by adding "for each required instrumentation channel that is normally energized", per ITS [SR 3.3.3.1 and SR 3.3.4.1] to CTS [4.3.3.5.1 and 4.3.3.6].	No, retained CTS.	Yes	No, retained CTS.	Yes
07-10 LS26	In the CTS, the determination that the steam generators are available for decay heat removal, using instrumentation available at the remote shutdown panel, is based on steam generator level <u>and</u> auxiliary feedwater flow to the steam generator. In the ITS, it is recognized that either of these indications is sufficient.	Yes	Yes	No, not in CTS.	No, not in CTS.
07-11 A	CTS SR 4.3.3.5.3 is deleted. This is duplicated in CTS 3.7.1.2 and covered in ITS 3.7.5 for AFW System operability requirements.	No, not in CTS.	No, not in CTS.	Yes	No, retained in ITS.
07-12 A	New Note excludes neutron detectors from CHANNEL CALIBRATION consistent with CTS Table 4.3-1, Functional Unit 6, Note 4 and with improved TS SR 3.3.4.3.	No, not in CTS.	No, already in CTS.	Yes	Yes
08-01 A	This change, consistent with NUREG-1431 Rev. 1, revises "Channel" and "Instrument" to "Function."	Yes	Yes	Yes	Yes
08-02	Not used.	N/A	N/A	N/A	N/A
08-03 A	This change revises CTS Table [3.3-10] to clarify the number of channels required to be Operable. This is an administrative change which deletes the "Minimum Channels Operable" column []. The required actions are now based on one channel inoperable or two channels inoperable, rather than "less than the Total Number" or "less than Minimum Number."	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.3

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
08-04 LS17	Consistent with NUREG-1431 Rev. 1 (ITS 3.3.3 Required Actions C.1, E.1, and G.1), this change deletes the requirement to initiate an alternate means of monitoring within 72 hours when two channels of Containment Radiation Level [, main steam line radiation monitors or the plant vent radiation high range] are inoperable as specified in C[TS 3.3.3.6 ACTION d].	Yes	Yes	Yes	Yes
08-05 A	In conjunction with CN 8-03-A, this change rearranges the ACTION Statements for the single channel Functions (i.e., SG Water Level - Wide Range and AFW Flow Rate). No change in AOT is requested, therefore this is an administrative change.	No, see CN 8-11-LS-30.	No, not in CTS.	Yes	Yes
08-06 LG	Specific equipment ID numbers are moved to the ITS Bases.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
08-07 A	This CPSES-specific change revises the definition of Core Exit Temperature thermocouple channels. The change clarifies that 2 Core Exit Temperature thermocouple channels per quadrant per train with each channel consisting of 1 thermocouple, is the same as 2 channels per quadrant with each channel consisting of 2 thermocouples.	No	Yes	No	No

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3...." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"

10CFR50.92 EVALUATION

FOR

ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"

(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION
BASES, FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"

(Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

In CTS SR [4.3.1.2 and 4.3.2.2], the active verb is changed from "demonstrated" to "verified." This allows Reactor Trip System and ESFAS sensor response time verifications to be performed per WCAP-13632-P-A Revision 2, "Elimination of Pressure Sensor Response Time Test Requirements." This change is consistent with Traveler TSTF-111, Rev. 1 which revises the Bases for ITS SR 3.3.1.16 and SR 3.3.2.10 to allow the elimination of pressure sensor response time testing.

In 1975 response time testing (RTT) requirements were included in the Westinghouse Standard Technical Specifications and were required for all plants licensed after that date.

The CTS contain definitions for both Reactor Trip System and Engineered Safety Feature (ESF) response times. The response time definitions are:

"The REACTOR TRIP SYSTEM RESPONSE TIME shall be the time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until loss of stationary gripper coil voltage."

"The ESF RESPONSE TIME shall be that time interval from when the monitored parameter exceeds its ESF actuation setpoint at the channel sensor until the ESF equipment is capable of performing its safety function (i.e., the valves travel to their required positions, pump discharge pressures reach their required values, etc.). Times shall include diesel generator starting and sequence loading delays where applicable."

The current {method requires} that the response time may be measured by any series of sequential, overlapping, or total channel test measurements such that the total channel response time is measured. This approach is also consistent with ISA Standard 67.06. Given this guidance and the complexity of testing an entire instrument channel from the sensor to the final device, plant surveillance procedures test the channels in several steps. One individual step is the instrument sensor. Separate procedures using specialized test equipment are used solely for testing the sensors.

The purpose of this evaluation is to determine if the deletion of periodic response time testing could be justified for specific pressure, level, and flow functions that utilize pressure and differential pressure sensors. IEEE Standard 338-1977 defines a basis for eliminating RTT. Section 6.3.4 states:

"Response time testing of all safety-related equipment, per se, is not required if, in lieu of response time testing, the response time of the safety system equipment is verified by functional testing, calibration check, or other tests, or both."

WCAP-13632-P-A Rev. 2 provides the technical justification for deletion of periodic response time testing of selected pressure sensing instruments. The program described in the WCAP utilizes the methods contained in EPRI Report NP-7243 Rev. 1, "Investigation of Response Time Testing Requirements," for justifying elimination of response time testing surveillance requirements on certain pressure and differential pressure sensors. The EPRI report justifies the elimination of response time testing based on Failure Modes and Effects Analysis (FMEA) that show that component degradation that impacts pressure sensor response time can be detected in other routine tests such as calibration tests. The report concludes that sensor RTT is redundant to other technical specification surveillance requirements such as sensor calibrations. The EPRI report only applies to those specific sensors included in the FMEA.

To address other sensors installed in Westinghouse designed plants, the WCAP contains a similarity analysis to sensors in the EPRI report or an FMEA to provide justification for elimination of response time

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

testing requirements for those other sensors. The specific sensors installed at [Callaway] and that require RTT are listed below:

- Steam Generator Water Level	Rosemount/Model 1154
- Pressurizer Pressure	Rosemount/Model 1154
- Steamline Pressure	Barton/Model 763 and Rosemount/Model 1154
- Containment Pressure	Rosemount/Model 1154
- Reactor Coolant Flow	Rosemount/Model 1154

The basis for eliminating periodic response time testing for each sensor is discussed in the WCAP and/or the EPRI report. These reports provide justification that any sensor failure that significantly degrades response time will be detectable during surveillance testing such as calibration and channel checks.

The applicability of the generic analysis of WCAP-13632-P-A Revision 2 has been confirmed for [DCPP]. Each of the above transmitters is included in Table 9-1 of WCAP-13632. In addition, the following discussion addresses the four actions raised in the NRC SER dated September 5, 1995:

- (a) A hydraulic response time test will be performed on any new or refurbished transmitter, prior to declaring the affected channel operable, to determine an initial sensor-specific response time value.
- (b) A hydraulic response time test will be performed on units that use capillary tubes after initial installation of replacement transmitters or following any maintenance or modification activity that could damage the capillary tubing or degrade the response time characteristics of installed sensors.
- (c) [DCPP] does not utilize pressure sensors that incorporate a variable damping feature in the RTS or ESFAS channels that are required to have their response times verified.
- (d) {DCPP has established an enhanced monitoring program for those Rosemount transmitters that require monitoring per NRC Bulletin 90-01 and Supplement 1. Some of those transmitters are RTS or ESFAS transmitters that require RTT. These transmitters will remain in the enhanced monitoring program until they are replaced or the alternative method of performing periodic drift monitoring as described below is initiated:
 1. Ensure that operators and technicians are aware of the Rosemount transmitter loss of fill-oil issue and make provisions to ensure that technicians monitor for sensor response time degradation during the performance of calibrations and functional tests of these transmitters, and
 2. Review and revise surveillance testing procedures, if necessary to ensure that calibrations are being performed using equipment designed to provide a step function or fast ramp in the process variable and that allows simultaneous monitoring of both the input and output response of the transmitter under test. Thus allowing, with reasonable assurance, the recognition of significant response time degradation.}

Based on these results, the Technical Specifications are revised to indicate that the system response time shall be verified utilizing a sensor response time justified by the methodology described in WCAP-13632-P-A Revision 2. Allocations for sensor response times may be obtained from: (1) historical records based on acceptable response time tests (hydraulic, noise, or power interrupt tests), (2) in-place, onsite, or offsite (e.g. vendor) test measurements, or (3) utilizing vendor engineering specifications.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The same RTS and ESFAS instrumentation is being used. The time response allocations/modeling assumptions in the Chapter 15 analyses are still the same, only the method of verifying time response is changed. The proposed change will not modify any system interface and could not increase the likelihood of an accident since these events are independent of this change. The proposed activity will not change, degrade or prevent actions or alter any assumptions previously made in evaluating the radiological consequences of an accident described in the FSAR. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change will not alter the normal method of plant operation. No transmitter performance requirements will be affected. This change does not alter the performance of the pressure and differential pressure transmitters used in the plant protection systems. All sensors will still have response time verified by test before placing the sensor in operational service and after any maintenance that could affect response time. Changing the method of periodically verifying instrument response for certain sensors (assuring equipment operability) from time response testing to calibration and channel checks will not create any new accident initiators or scenarios. Periodic surveillance of these instruments will detect significant degradation in the sensor response characteristic. No new transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. This change does not affect the total system response time assumed in the safety analysis. The periodic system response time verification method for selected pressure and differential pressure sensors is modified to allow use of actual test data or engineering data. The method of verification still provides assurance that the total system response is within that defined in the safety analysis, since calibration tests will detect any degradation which might significantly affect sensor response time. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS1" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A new ACTION Statement [2.1] is created which is essentially the same as current ACTION Statement [6], and is similar to current ACTION Statement [2], but does not require a reduction in THERMAL POWER to less than 75% RTP or the measurement of the QPTR if above 75% RTP. This new ACTION Statement is applied to the Power Range Neutron Flux, High Positive Rate [, High Negative Rate] trip functions. Since these are rate functions, their effectiveness is not improved by reducing power.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards, as applied to the relaxation applicable to the power range neutron flux, high positive rate [and high negative rate] trip functions:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the ACTION associated with an inoperable channel in the power range neutron flux, high positive rate [and high negative rate] trip function. No power reduction below 75% RTP or QPTR monitoring above 75% RTP would be required since these actions have no basis for this rate trip function.

The high positive rate [and high negative rate] trip functions are insensitive to the static power level. The proposed change will not affect any of the analysis assumptions for any of the accidents previously evaluated. [] The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in required ACTION will not affect the normal method of plant operation and, in fact, will relieve the operators from performing actions not required for plant safety. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS2" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With one intermediate range neutron flux channel inoperable, current ACTION Statement [3.a] applies below the P-6 interlock. For those times that the plant is above P-6 but below 10% RTP (the P-10 interlock setpoint), current ACTION Statement [3.b] applies. ACTION Statement [3.b] is revised to establish a 24 hour Completion Time for channel restoration or changing the power level to either below P-6 or above P-10. The intermediate range neutron flux channels provide protection between these power levels and the APPLICABLE MODES have been revised accordingly. The source range neutron flux detectors provide protection below P-6 and the power range neutron flux detectors provide protection above P-10. The addition of the 24 hour Completion Time (current TS has no Completion Time) limits the window of operation during which the intermediate range neutron flux trip function provides protection in a 1 of 1 logic configuration and ensures the low probability of occurrence of a reactivity transient occurring during this time period that would require an intermediate range flux trip. Although this change is less restrictive since a power increase is an allowed option, the ACTION Statement would ensure protection by entering the range of the four power range neutron flux channels.

With both intermediate range neutron flux channels inoperable in MODE 1 (below P-10) and MODE 2 (above P-6), LCO 3.0.3 would be entered under the current TS and the plant would have to be in MODE 3 within 7 hours. With both intermediate channels inoperable, new ACTION Statement [3.1] requires immediate suspension of operations involving positive reactivity additions and a power reduction below P-6 within 2 hours. New ACTION Statement [3.1] is less restrictive since a reduction to MODE 3 would no longer be required; however, the current TS are overly conservative in this area. Below P-6 the source range channels provide protection; therefore, the required action for both intermediate range channels inoperable should be to exit plant conditions where this trip function provides protection. New ACTION Statement [3.1] will preclude any power level increase and require a controlled power reduction to less than P-6 where the source range channels provide protection. The 2 hour Completion Time ensures the low probability of occurrence of an event during this period that may require the protection afforded by the intermediate range neutron flux trip. These actions actually provide a more timely and appropriate redress to the condition than entering LCO 3.0.3.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards, as applied to the relaxations applicable to the intermediate range neutron flux trip function:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3 (continued)

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change relaxes the ACTIONS associated with inoperable intermediate range neutron flux channel(s). With one or both intermediate range neutron flux channels inoperable above the P-6 interlock but below 10% RTP, timely actions would be taken to exit plant conditions that may rely on this trip function for protection. The proposed change in the ACTION Statements will not affect any of the analysis assumptions for any of the accidents previously evaluated. No FSAR Chapter 15 analyses specifically credit this trip function. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in required ACTIONS will not impact the normal method of plant operation; however, operational flexibility will be added by allowing a power increase as a corrective measure if one intermediate range neutron flux channel is inoperable. The option of increasing power is consistent with the philosophy of placing the plant in a condition where protection is assured, in this case by the power range neutron flux channels. No new accidents are created since rod withdrawal events are analyzed with the initial power level at full power as well as subcritical; or low power startup conditions, i.e. the change in power level does not create a new kind of accident. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS3" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The APPLICABILITY for the Reactor Trip on Turbine Trip function is modified such that this function is only required to be OPERABLE above the P-9 interlock setpoint (15% RTP). This is acceptable since the trip function is blocked below P-9. CTS ACTION Statement 7 is revised accordingly and new note (j) is applied to Functional Units 17.a. and b. for the trip functions associated with Low Autostop Oil Pressure and Turbine Stop Valve Closure. The ACTION is also revised to allow bypassing a tripped Low Autostop Oil Pressure channel for up to four hours for surveillance testing other channels.

Current ACTION Statement 7 allows continued operation with one inoperable channel as long as it is placed in trip within 6 hours. There is no associated action if an inoperable channel is not placed in trip within 6 hours nor is there an action for multiple inoperable channels; therefore, LCO 3.0.3 would be invoked. Revised ACTION Statement 7 allows continued operation with one or more inoperable channels as long as they are placed in trip within 6 hours or THERMAL POWER is reduced below P-9 within 10 hours, thus LCO 3.0.3 would no longer be applicable.

Revised ACTION Statement 7 is consistent with the ITS philosophy of reducing power to enter a condition where a function is not required to be OPERABLE. This is less restrictive than the CTS which would require entry into LCO 3.0.3. Entry into LCO 3.0.3 is overly conservative in the above situations since this trip function provides an anticipatory reactor trip function only above P-9.

A note is added per NUREG-1431 to allow the Low Auto Stop Oil Pressure trip to be bypassed for up to four hours. There is no need for the 4 hour bypass allowance for surveillance testing of the Turbine Stop Valve Closure, since all 4 channels are required to trip the turbine; however, the bypass allowance is desirable when 2 channels satisfy the trip logic to reduce the possibility of a spurious trip during testing. Bypassing one channel for testing changes the trip coincidence to a two out of two thus maintaining its operability with only a slight reduction in reliability. In addition, the potential for a turbine trip during the bypass period for other than a Low Autostop Oil Pressure trip is small. The reduction in reliability is acceptable since the potential for a transient due to a reactor trip is reduced by allowing the bypass.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4 (continued)

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the ACTIONS associated with inoperable channel(s) in the Reactor Trip on Turbine Trip function by keeping the end point of the shutdown action above the CTS requirement if inoperable channel(s) are not placed in trip within 6 hours or if multiple Low Autostop Oil Pressure channels are inoperable. The new ACTION Statement would reduce power to less than P-9 (50% RTP) in these situations as compared to entry into LCO 3.0.3 (power \leq 5% RTP) in the current TS. The proposed change in the ACTION statements will not affect any of the analysis assumptions for any of the accidents previously evaluated. This trip function is anticipatory only and is not credited in any FSAR Chapter 15 accident analyses. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in ACTIONS will not affect the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS4" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, an NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

[ACTION Statement [10] is revised to note that the 2 hour [train and] reactor trip breaker bypass allowance for [train or] breaker surveillance testing can also be used for maintenance. This change does not impact the conclusions of WCAP-10271-P-A, Supplement 2, Rev. 1 since there is no change to the bypass time.] ACTION Statement [9] is [also] revised to require restoration of an inoperable Reactor Trip Breaker (RTB) within 1 hour or the plant must be in HOT STANDBY within the next 6 hours. This is less restrictive than the current TS since an additional hour is provided for the transition to MODE 3.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. As noted in the Bases of NUREG-1431 Rev. 1, the Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. The 1 hour and 6 hour Completion Times are equal to the time allowed by current LCO 3.0.3 for shutdown actions. The proposed shutdown requirement Completion Time change would result in an additional hour to achieve MODE 3. By allowing a shutdown time based on operating experience, this change would reduce the chances of an operator error or challenge to plant systems that could result from the more restrictive requirement in the current TS. The probability that an accident would occur during the 1 hour extension allowed by the proposed change is extremely small. [Use of the 2 hour [train or] reactor trip breaker bypass allowance for maintenance will not change the unavailabilities used to determine core damage frequencies in WCAP-10271-P-A, Supplement 2, Rev. 1 since the bypass time allowance is not extended.] The proposed change will not affect any of the analysis assumptions for any of the accidents previously evaluated. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change will not affect the normal method of plant operation. Only the duration of operation in the action statement is affected. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS6" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

In current ACTION Statement [2c], the requirement to reduce the power range neutron flux high trip setpoint is deleted. The loss of one power range neutron flux channel does not impact the reliability of the reactor trip system because the channel is required to be placed in trip. With an NIS power range channel inoperable, tilt monitoring for a portion of the reactor core becomes degraded. To address the impact on measuring QPTR, the QPTR TS provides conditional notes to the surveillances that verify QPTR. Although the loss of one power range channel may affect the ability to measure QPTR, there is no basis for reducing the power range high flux trip setpoint and increasing the potential for an inadvertent reactor trip. The existing surveillance requirements in the QPTR TS provide adequate remedial measures (increased surveillance frequency and/or different method for monitoring QPTR) when an inoperable power range channel affects the input to QPTR.

In addition, monitoring of QPTR every 12 hours will no longer be required if the input to the QPTR from the power range neutron flux channels remains OPERABLE. A consistent completion time of 12 hours is imposed on either of the three required actions, i.e. power derate, QPTR surveillance, or shutdown to MODE 3.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the ACTION associated with an inoperable power range neutron flux channel. The inoperable channel is placed in the tripped condition, therefore the reliability of the RTS is unaffected. A consistent completion time of 12 hours is imposed on either of the three required actions, i.e. power derate, QPTR surveillance, or shutdown to MODE 3. While this represents a relaxation for the power derate completion time, currently 4 hours, this time is not an assumption in any accident analysis. For the purposes of the FSAR Chapter 15 accident analyses, placing the inoperable channel in trip within 6 hours, which is unchanged, satisfies the analysis assumptions on RTS availability. This relaxation is contrasted by the more restrictive change that

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7 (continued)

if the derate or QPTR surveillance can not be performed, the plant must be shutdown to MODE 3. Currently, failure to meet ACTION Statement 2 would place the plant in LCO 3.0.3, with 7 more hours to get to MODE 3. The proposed change in the ACTION Statement will not affect any of the analysis assumptions for any of the accidents previously evaluated. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in the ACTION Statement will not affect the normal method of plant operation, but will reduce the possibility of an unplanned plant transient that might occur during the adjustment of the high flux trip setpoint. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS7" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change reflects a revision to current ACTION Statement [6]. If the requirements of current ACTION Statement [6] are not met, LCO 3.0.3 would be entered. This ACTION Statement is revised to state that if the ACTION requirements are not met, THERMAL POWER must be reduced to below the P-7 interlock setpoint within the next 6 hours. Most of the Functional Units that impose ACTION Statement [6], Pressurizer Pressure - Low, Pressurizer Water Level - High, Reactor Coolant Flow - Low, Two Loops (above P-7 and below P-8), RCP Undervoltage, and RCP Underfrequency, are automatically blocked below P-7 and an Applicability Note has been added accordingly. The Reactor Coolant Flow - Low (Single Loop) reactor trip function does not have to be OPERABLE below the P-8 setpoint; however, the Required Action must take the plant below the P-7 setpoint, if an inoperable channel is not tripped within 6 hours, due to the shared components between this function and the Reactor Coolant Flow - Low (Two Loops) trip function.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the ACTION Statement associated with an inoperable channel in CTS Table 3.3-1 Functional Units [9, 11, 12.a, 12.b, 14, and 15] by keeping the end point of the shutdown action above the CTS requirement if an inoperable channel isn't placed in trip within 6 hours. The new ACTION Statement would reduce power to less than P-7 (10% RTP) within the next 6 hours in this situation as compared to entry into LCO 3.0.3 (power \leq 5% RTP) in the current TS. The proposed change in the ACTION Statement will not affect any of the analysis assumptions for any of the accidents previously evaluated. An LCO 3.0.3 shutdown to \leq 5% RTP is not required to meet the initial conditions of any accident analysis crediting these trip functions. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8 (continued)

change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in the ACTION Statement will not affect the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS8" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change reflects a relaxation in the performance of COTs prior to startup. These COTs, for the Power Range Neutron Flux-Low, Intermediate Range Neutron Flux, and Source Range Neutron Flux trip functions, will not be required if performed within the previous 92 days. Note [(1)] of current TS Table 4.3-1 has been revised to extend this period from 31 days to 92 days. Since the COT is valid for 92 days at all other times, there should be no need to repeat it during startup if one has been performed within the prior quarter.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. A Channel Operational Test demonstrates channel operability every 92 days, consistent with the requirements of WCAP-10271 and its Supplement 1 for the RTS. Since it remains valid for that time period, there is no need to perform another COT during startup if one had been performed within the prior 92 days. This will not affect the operability or functionality of the NIS channels. Their calibration is still valid and daily channel checks are still performed. The proposed change will not affect any of the analysis assumptions for any of the accidents previously evaluated. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in the COT performance Note will

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 (continued)

not affect the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS9" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Surveillances on the Source Range Neutron Flux trip function are reorganized to reflect plant status in accordance with NUREG-1431 Rev. 1. New Note [(19)] requires that the quarterly COT be performed within 4 hours after reducing power below the respective source range instrumentation Applicabilities, if not performed within the previous [92] days. Since the COT is valid for [92] days, there is no need to repeat it if one has been performed within the prior [quarter]. The 4 hour allowance permits a normal shutdown to proceed without a delay for testing in MODE 2 and for a short time in MODE 3 until the Reactor Trip Breakers are opened and this trip function no longer provides protection. Since the current TS has no Specification 4.0.4 exception, this 4 hour allowance is less restrictive.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. This change allows a 4 hour deferral of a Channel Operational Test after entering the Applicability of the source range trip. This will not affect the operability or functionality of the source range channels. Their calibration is still valid and daily channel checks are still performed. The probability that an accident would occur during the 4 hour extension allowed by the proposed change is extremely small. The proposed change will not affect any of the analysis assumptions for any of the accidents previously evaluated. No FSAR Chapter 15 accident analyses credit this reactor trip function. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change will not affect the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS10" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

[Note (a) is added to current TS Table 3.3-3 for the Steam Line Isolation Function to state that the LCO requirements are not applicable in MODES 2 and 3 when the MSIVs are closed and deactivated.]
Note [(b)] is added to current TS Table [3.3-3] for the Feedwater Isolation and Turbine Trip Function to state that the LCO requirements are not applicable when the [MFIVs, MFRVs and the associated bypass valves] are closed and deactivated [or isolated by a closed manual isolation valve]. When these valves are closed and deactivated [or isolated by a closed manual isolation valve], they are already performing their safety function.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the Applicability associated with the [Steam Line Isolation and] Feedwater Isolation ESFAS functions. Those functions are accomplished when the associated valves are closed and deactivated [or isolated by a closed manual isolation valve], whether that closure is as a result of automatic isolation circuitry or operator action. Operability requirements on actuation circuitry are not applicable if the valves are closed and deactivated [or isolated by a closed manual isolation valve]. The proposed change will not affect any of the analysis assumptions for any of the accidents previously evaluated. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in Applicability will not affect the normal method of plant operation as it recognizes the safety function is accomplished as long as the valves are closed and deactivated [or isolated by a closed manual isolation valve]. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS11" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

ACTION Statement[s] [30 and 38] in current TS Table [3.3-6] for the [Fuel Building Radioactivity monitors and Control Room Air Intake Gaseous Radioactivity monitors] have been revised to allow 7 days for restoration of an inoperable channel prior to isolation of the normal ventilation systems and initiation of the ESF HVAC systems. The current allowed outage time (AOT) for [both] ACTION Statement[s] is [72 hours]. The 7 day AOT for one channel inoperable is the same as that allowed by the ACTION Statement[s] of current TS LCO[s] 3.7.6 and 3.7.7] for one train of the mechanical portion of the [ESF] HVAC system inoperable.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the AOT associated with an inoperable radiation monitor channel in the ESF HVAC systems for the [fuel building and] control room. The proposed change in the AOT will not affect any of the analysis assumptions for any of the accidents previously evaluated. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Mechanical portions of the systems can be inoperable, rendering one train inoperable, for up to 7 days. Therefore, this AOT change has effectively been approved by the precedent established in the plant systems TS. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in AOT will not impact the normal method of plant operation. More thorough troubleshooting and restoration activities are possible with an extended AOT. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no adverse effect on control room habitability conditions of offsite doses. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS14" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The Applicability for the [Fuel Building Gaseous Radioactivity] monitors in current TS Table 3.3-6 is revised to read "during movement of irradiated fuel assemblies in the fuel building." The current TS Applicability, at all times with irradiated fuel in the fuel storage areas or fuel [handling] building, is overly restrictive since the radiation monitors' function is to ensure automatic actuation of the [Fuel Handling Building Ventilation System to the iodine removal mode] when the potential for a fuel handling accident exists. That potential exists only when fuel assemblies are being moved. These monitors could also provide a mitigation function in the event the spent fuel pool were excessively drained; however, that scenario is not credible given the design provisions to ensure spent fuel pool integrity and the monitoring system provided to measure pool level and annunciate low level, as described in FSAR Sections [9.1.2, 9.1.3, and 9.3.3].

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the Applicability for the [Fuel Building Gaseous Radioactivity] monitors. The proposed change in the Applicability will not affect any of the analysis assumptions for any of the accidents previously evaluated. The only accident analysis crediting these radiation monitors is the Fuel Handling Accident in the fuel building. The Applicability ensures the monitors' availability for that accident by virtue of the operability requirements imposed any time irradiated fuel is moved in the fuel building. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in Applicability will not impact the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. Offsite doses in the event of a Fuel Handling Accident will not be affected. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS16" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change deletes the requirement to initiate the preplanned alternate method of monitoring containment radiation [or reactor vessel water level] within 72 hours when two channels are inoperable. This makes ACTION [c] of current TS LCO [3.3.3.6] the same as ACTION [b], except that a plant shutdown is not needed if the 7 day AOT is not met for these functions with preplanned alternates. Containment radiation indication is used to assess whether the fuel cladding and reactor coolant pressure boundaries have been breached such that a significant portion of the core activity inventory is available for release to the environs. The preplanned alternate for this variable uses the PASS system which is administratively controlled outside the TS. [The preplanned alternates for RVLIS include a combination of the core exit thermocouples, RCS wide range hot and cold leg temperature, wide range RCS pressure, pressurizer level, and RCS subcooling monitor indications to verify adequate core cooling.] These variables are already continuously monitored under the LCO and do not require an action directing that they be initiated.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change involves a relaxation regarding the deletion of the 72 hour initiation of the preplanned alternate method of monitoring containment radiation [or reactor vessel water level] if two channels are inoperable. The proposed change in the ACTION Statement will not affect any of the analysis assumptions for any of the accidents previously evaluated. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change will not impact the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS17" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS18
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The APPLICABILITY for the Reactor Trip on Reactor Coolant Pump Breaker Position above P-7 Trip function is modified such that this function is only required to be OPERABLE above the P-7 interlock setpoint (10% RTP). This is acceptable since the trip function is blocked below P-7. CTS ACTION Statement 9 is deleted and revised ACTION 6 and new note (g) is applied to Functional Unit 19 for the trip functions associated with Reactor Coolant Pump Breaker Position. The ACTION is also revised to allow bypassing a tripped Reactor Coolant Pump Breaker Position channel for up to four hours for surveillance testing other channels.

Current ACTION Statement 9 applies to the Reactor Coolant Pump Breaker Position trip function and allows continued operation with one inoperable channel as long as it is placed in trip within 6 hours. There is no associated action if an inoperable channel is not placed in trip within 6 hours nor is there an action for multiple inoperable channels; therefore, LCO 3.0.3 would be invoked. Revised ACTION Statement 6 allows continued operation with one or more inoperable channels as long as they are placed in trip within 6 hours or THERMAL POWER is reduced below P-7 within 12 hours, thus LCO 3.0.3 would no longer be applicable.

Revised ACTION Statement 6 is consistent with the ITS philosophy of reducing power to enter a condition where a function is not required to be OPERABLE. This is less restrictive than the CTS which would require entry into LCO 3.0.3. Entry into LCO 3.0.3 is overly conservative in the above situations since this trip function provides an anticipatory reactor trip function only above P-7.

A note is added per NUREG-1431 to allow the Reactor Coolant Pump Breaker Position trip to be bypassed for up to four hours. The bypass allowance is desirable when 2 channels satisfy the trip logic to reduce the possibility of a spurious trip during testing. Bypassing one channel for testing changes the trip coincidence to a two out of three versus two out of four thus maintaining trip operability with only a slight reduction in reliability. In addition, the potential for a reactor trip during the bypass period is small. The reduction in reliability is acceptable since the potential for a transient due to a reactor trip is reduced by allowing the bypass.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves a no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

LS18 (continued)

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the ACTIONS associated with an inoperable channel by keeping the end point of the shutdown action above the CTS requirement if the inoperable channel is not placed in trip within 6 hours. The new ACTION Statement would reduce power to less than P-7 (10% RTP) in these situations as compared to entry into LCO 3.0.3 (power \leq 5% RTP) in the current TS. The proposed change in the ACTION statements will not affect any of the analysis assumptions for any of the accidents previously evaluated. This trip function is anticipatory only and is not credited in any FSAR Chapter 15 accident analyses. The proposed change will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in ACTIONS will not affect the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS18" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, an NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS26
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The Remote Shutdown System is required to provide equipment at appropriate locations outside the control room with a capability to place and maintain the unit in a safe condition in MODE 3 (prior to control room evacuation, the reactor would have been verified to be shutdown). Under this condition, decay heat would be removed from the RCS through the steam generators. Steam is released through the main steam safety and/or relief valves and steam generator inventory is maintained by the Auxiliary Feedwater System. Indication of either the steam generator level or the auxiliary feedwater flow rate is sufficient to ensure that the steam generator inventory is being replenished.

In the CTS, the determination that the steam generators are available for decay heat removal, using instrumentation available at the remote shutdown panel, is based on steam generator level and auxiliary feedwater flow to the steam generator. In the ITS, it is recognized that either of these indications is sufficient; therefore, the decay heat removal via steam generators function may be satisfied through the availability of either of these two functions.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change to require only one of two available indications of the capability to use the steam generators to remove decay heat from the RCS can not affect the probability of an accident. The consequences of the accidents considered in the safety analyses are largely independent of operator action; however, even with the reduced requirements for indication of steam generator heat removal capability, sufficient information is available to the reactor operators such that the assumed operator actions will not be affected. Therefore, neither the probability nor the consequences of an accident previously evaluated will be affected by this change.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change will not alter the normal method of plant operation. There will be no decrease in the information available to the reactor operator in the event of an accident that would lead the operator to take inappropriate actions. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change affects neither the relevant event acceptance criteria for any analyzed event nor any assumed failure point. Therefore, there will be no effect on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS26" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10.CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS28
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change incorporates a new required ACTION for CTS 3.3.2 Table 3.3-3, Functional Unit 7.a.2) and 7.b.1). This new ACTION 15 would require that for either one or two relays per bus inoperable, that the associated DG be declared inoperable and that the ACTION Statements for TS 3.8.1.1 be met. The CTS do not have an ACTION for two inoperable relays, thus LCO 3.0.3 must be entered. License Amendment 97-02 which included ACTION 15 was submitted on February 27, 1997.

Two levels of undervoltage detection and automatic transfer are provided for the 4kV vital buses to start the DGs and to transfer vital loads to the DGs. The first level of undervoltage protection (FLUR) detects the loss of bus voltage and has sufficient time delay to allow the transfer of the vital buses to the startup transformer.

The second level of undervoltage protection (SLUR) is intended to protect against a degraded voltage condition, and has two sequential time delays for DG starting and loading.

The load shed FLUR and SLUR contacts are each connected in series for two-out-of-two logic. This assures that a single failure of a load shed FLUR or SLUR does not cause an unnecessary transfer of the vital buses to the DGs. Since both relays are required to be OPERABLE to cause an undervoltage actuation, the current ACTION 16 recognizes that the undervoltage function will not operate with one relay inoperable. Inoperability of the second relay does not change conditions recognized by the current ACTION Statement, thus the ACTION Statement should be the same for one or two relays inoperable.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the required actions in that LCO 3.0.3 is not required to be entered. However, the condition of two relays inoperable does not change the fact that with one relay inoperable, the undervoltage actuation will not actuate. The proposed change will not affect the probability of any accident initiators nor will it affect the ability of the safety-related equipment to perform its intended

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS28 (continued)

function. Therefore, neither the probability nor the consequences of an accident previously evaluated will be affected by this change.

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in ACTION will not alter the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change affects neither the relevant event acceptance criteria for any analyzed event nor any assumed failure point. Therefore, there will be no effect on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS28" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS29
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed change adds a new ACTION 37 which allows 4 hours for restoration of an inoperable train or channel if one of the required channels of the Containment Ventilation Isolation Radiation Monitor instrumentation is inoperable in accordance with NUREG-1431. The CTS via ACTIONS 18 and 33 requires that for one or two instrument or actuation channels inoperable that CTS LCO 3.6.3 or LCO 3.9.9 be entered as applicable. The revised specification will require that the ITS LCO 3.6.3 or 3.9.4 be entered if the instrument or actuation channel cannot be restored to an OPERABLE condition within the allowed outage time (AOT). Both of these specifications require that if the penetrations cannot be closed automatically that the penetrations be closed in the manner specified. The 4 hours allowed to restore the affected channel is justified based on the low probability of events requiring containment ventilation actuation during this time period, and recognition that the remaining channel is OPERABLE and would respond.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the required actions in that the AOT for one monitor or channel is permitted to be 4 hours. The proposed addition of the AOT will not affect the probability of any accident initiators nor will it affect the ability of the safety-related equipment to perform its intended function. Therefore, neither the probability nor the consequences of an accident previously evaluated will be affected by this change.

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in AOT will not alter the normal method of plant operation. More thorough trouble shooting and restoration activities are possible with this additional AOT. No new accident scenarios, transient precursors, failure mechanisms, or

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS29 (continued)

limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change affects neither the relevant event acceptance criteria for any analyzed event nor any assumed failure point. Therefore, there will be no effect on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS29" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

NSHC LS30
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change to CTS 3/4.3.3.6, "Accident Monitoring Instrumentation," revises the instrumentation used for monitoring plant conditions following an accident. The post accident monitoring instrumentation listed in TS Table 3.3-10 is revised to include all Diablo Canyon Power Plant (DCPP) Regulatory Guide (RG) 1.97, "Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant and Environs Conditions During and Following an Accident," Type A and Category 1 instrumentation.

The following DCPP RG 1.97 Type A and/or Category 1 accident monitoring instrumentation is added to TS Table 3.3-10:

- a. Containment Pressure (Wide Range)
- b. Steam Generator Water Level (Wide Range)
- c. Neutron Flux (Wide Range NIS)
- d. Containment Isolation Valve Position
- e. Containment Hydrogen Concentration
- f. Condensate Storage Tank Level

The following non-type A and non-Category 1 DCPP RG 1.97 instrumentation is deleted from TS Table 3.3-10:

- a. Reactor Coolant System (RCS) Subcooling Margin Monitor
- b. Power Operated Relief Valve (PORV) Position Indicator
- c. PORV Block Valve Position Indicator
- d. Safety Valve Position Indicator
- e. Main Steam Line Radiation Monitor
- f. Plant Vent Radiation Monitor-High Range

ACTION Statement a. is modified to allow an outage time of 30 days, versus the CTS 7 days, for one channel less than the required number of channels, but at least one channel OPERABLE. If the channel(s) cannot be restored to operable status within 30 days, a special report is required to be submitted to report the alternate method of monitoring the appropriate parameter(s), cause of the inoperability and plans and schedule for restoring the channel to OPERABLE status. This change eliminates a shutdown requirement for any single redundant channel inoperable.

ACTION Statement b. is modified to address no operable channel(s) for one or more instrument functions. It requires one channel to be restored to operable status within 7 days, versus the CTS 48 hour requirement, otherwise enter the Action Requirement referenced in Table 3.3-10. All exceptions to the ACTION Statement currently included in the TS are deleted. The requirement for a plant shutdown for an inoperable RVLIS and containment area radiation monitor channels inoperable is eliminated and replaced with a requirement to submit a Special Report.

Revised ACTION Statement c. requires the plant to be in Mode 3 within 6 hours and Mode 4 within the next 6 hours for all Functions except the containment Hydrogen Concentration monitors, and will require that the plant be in MODE 3 within 6 hours for both Containment Hydrogen Concentration monitors inoperable. This ACTION Statement will not be applicable to RVLIS and the containment area radiation monitor high range channels.

New ACTION Statement d. will be applicable to RVLIS and the containment area radiation high range monitor channels and requires a special report to be submitted in accordance with Technical Specification 6.9.2.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS30
(continued)

CTS Table 3.3-10 is modified accordingly.

NUREG-1431 changes (1) the allowed outage time (AOT) for TS 3/4.3.3.6 from 7 days to 30 days for one inoperable channel for one or more functions; (2) the AOT for two channels inoperable from 48 hours to 7 days and (3) allows other relaxations. NUREG-1431 also specifies that all RG 1.97 Type A and Category 1 accident monitoring instrumentation must be included in each plant's TS. Specific Justification of the changes is provided below.

Addition and Deletion of Accident Monitoring Instrumentation

The addition of Type 1 and Category A instrumentation provides assurance that instrumentation which provides indication of the variables considered critical for monitoring plant conditions following a DBA are available during an accident. The removal of instrumentation that is not classified as Type A or Category 1 reduces the chance of an unnecessary shutdown and the associated risks.

The change of the required number of containment recirculation sump and containment area radiation monitoring channels is a conservative change that makes revised ACTION Statement a. applicable to these channels.

Action Statement a.

Replacing the shutdown requirement with a requirement to submit a Special Report will eliminate the risk associated with a unit shutdown, yet still provide assurance that the affected channel will be restored in a timely manner.

Action Statement b.

Increasing the AOT from 48 hours to 7 days for the condition when no accident monitoring instrumentation channels for a particular function are operable provides additional time to diagnose and correct a problem, provides alternate means for monitoring the accident parameter, and could avoid the risk associated with unnecessary plant transients and shutdowns.

Revised Action Statements c. and d.

The revision of the current ACTION Statements c. and d. is an administrative change that eliminates confusing Action Statements by deleting the numerous exceptions to the action statements. The shutdown and special report requirements previously contained in these ACTION Statements are revised per NUREG-1431.

The additional Type A and/or Category 1 instrumentation provides assurance that all necessary information is available to operators to allow for proper mitigation of the consequences of an accident.

Although non-Type A/non-Category 1, instrumentation may be useful in determining plant conditions, it is not necessary to include these instruments in the TS. An evaluation of the non-Type A instrumentation in TS 3/4.3.3.6 was performed in accordance with 10CFR50.36(c)(2)(ii). A probabilistic risk assessment (PRA) evaluation for DCPD indicated that instruments which are non-Type A in TS 3/4.3.3.6 did not contain constraints or prime importance in limiting the likelihood or severity of accident sequences which are commonly found to dominate offsite health effects and do not significantly contribute to risk.

The specific criteria used to determine if an accident sequence was risk dominant for core damage frequency was any sequence that had a probability of occurring greater than 1E-6 per reactor year (as a conservative initial determination). For off-site health effects, any sequence whose frequency of serious radioactive releases is commonly found to be greater than 1E-7 per reactor year, was considered to be a dominant risk. The following non-Type A instrumentation is currently included in TS 3/4.3.3.6:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS30 (continued)

- Reactor Coolant System Subcooling Margin Monitor (B2)
- PORV Position Indicator (D2)
- PORV Block Valve Position Indicator (D2)
- Safety Valve Position Indicator (D2)
- Main Steam Line Radiation Monitor (D2)
- Plant Vent Area Radiation Monitor - High Range (E2)
- Reactor Vessel Level Indication System (B1)
- Containment Area Radiation Monitor - High Range (E1)

Although the non-Type A equipment was determined not to be risk significant, because of the information provided, it was determined that non-Type A/Category 1 equipment should remain in the TS. Non-Type A/non-Category 1 equipment that is being deleted from the TS is proposed to be relocated to plant Equipment Control Guidelines.

Action Statement a.

Increased AOT

Two channels provide indication for the Type A instrumentation included in proposed TS 3/4.3.3.6, except for containment isolation valve (CIV) position, auxiliary feedwater (AFW) flow and steam generator (SG) water level (wide range) channels. Loss of one of two channels would not cause a loss of function. The other channel would still be available to provide indication of the parameter. Increasing the AOT from 7 days to 30 days could avoid a shutdown and the associated risks while still providing assurance that indication of the parameter is available while assuring that an out of service channel is returned to service in a timely manner.

For the CIV position, the important information is the status of the containment penetrations. The TS requires one position indicator for each active containment isolation valve. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve and prior knowledge of passive valve or via system boundary status. If a normally active CIV is known to be closed and deactivated, position indication is not needed to determine status.

Neither the AFW flow rate indication nor the SG water level wide range channels are redundant. The purpose of the AFW flow indication channel is to provide indication of AFW flow provided to the SG so that adequate decay heat removal capability from the RCS via the SGs can be verified. Similarly, the SG water level channel indicates the water level in the SGs so that adequate decay heat removal from the RCS via the SGs can be verified. Both the AFW flow indication and the SG water level wide range channels provide verification of decay heat removal. Since both the AFW flow and SG level channels monitor decay heat removal capability in a different way, they serve as diverse indications of the same parameter. Consequently, the loss of either channel would not prevent an operator from monitoring the decay heat removal capability from the RCS via each SG.

Since either redundant or diverse means of indication exist for each Type A channel, the monitoring of the function will not be lost as a result of one channel failure, and increasing the AOT from 7 days to 30 days will not have a significant affect on the health and safety of the public. Since the non-Type A/Category 1 instrumentation does not significantly affect risk, increasing the AOT from 7 days to 30 days for this instrumentation will not have a significant affect on the risk to the health and safety of the public.

Elimination of Shutdown Requirement from ACTION a.

The removal of the shutdown requirement could avoid a plant shutdown and the associated risks. The reporting requirements specify that alternate means of monitoring these parameters and a

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS30 (continued)

schedule for repairing the channels be submitted to the NRC. This reporting requirement will provide assurance that the channels will be repaired in a timely manner. As a result of the alternate means of monitoring the affected parameter, and the redundant channel available, the required function will not be lost during the time when one channel is inoperable.

Action Statement b.

The 7 day AOT for the complete loss of monitoring for a function is allowed because of the relatively low probability of an event requiring the accident monitoring instrumentation and the availability of alternate means to obtain the required information (diverse instrumentation or other non-Regulatory Guide 1.97 instrument channels to monitor the function).

Additionally, the probability of an accident occurring during the time when both channels are out of service is small. The probability of a LOCA requiring the operability of post accident monitoring channels is $1E-6$ per reactor year.

For all channels except the high range containment area radiation monitor and RVLIS, a shutdown is required if the AOT is exceeded. This assures that, for the complete loss of a monitoring function that is deemed risk significant, the plant is placed in a condition in which the function is no longer required in a timely manner.

The shutdown requirement for both the high range containment area radiation monitor and the RVLIS are proposed to be replaced with a reporting requirement. These channels are non-Type A channels. Since these channels were identified as non-risk significant, removing the shutdown requirement for these channels will have no significant negative impact on safety. The reporting requirements specify that alternate means of monitoring these parameters and a schedule for repairing the channels be submitted to the NRC. This reporting requirement will provide assurance that the channels will be repaired in a timely manner.

Current Action Statements c. and d.

The revision of the current Action Statements c. and d. is an administrative change.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS30 (continued)

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

None of the changes alter the plant configuration or operation. Consequently, this change does not significantly increase the probability of an accident as defined in the FSAR Update. Additionally, no post accident monitoring channel initiates an accident. Except for the increased instrument allowed outage time, the change is essentially a reformatting and deletion of obsolete statements. The evaluation identifies that there is a low probability of an event which would require the accident monitoring instrumentation and that there are alternate means to obtain the required information if the accident monitoring function is required. Consequently, the change does not have a significant affect on the probability or consequences of any previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

None of the changes require physical alteration to any plant system or change the method by which any safety-related system performs its function. Therefore, the proposed changes do not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

None of the changes will change any accident analysis assumptions, initial conditions, or results. Consequently, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS30" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c) and; accordingly, an NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS35
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The Applicable Modes or Other Specified Conditions in the CTS include Mode 4 for the manual initiation of Steam Line Isolation. However, neither the CTS 3.7.1.5 Main Steam Isolation Valves nor NUREG-1431 ITS 3.7.1.2 requires the valves to be OPERABLE in MODE 4. In MODE 4, the Steam Generator energy is low and requiring the manual initiation circuitry to be OPERABLE without the valves being OPERABLE serves no purpose. Therefore, the MODE 4 OPERABILITY requirement has been deleted.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The CTS do not require the MSIVs to be OPERABLE in MODE 4. There is no change in the Operability requirements of the MSIVs; therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in Applicability will not affect the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS35" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c) and; accordingly, an NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS39
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

APPLICABILITY Note [*] and ACTION Statements [11] for Functional Units [1, 6.b, and 20] of current TS Table 3.3-1 are modified to provide an alternative to opening the reactor trip breakers (RTBs) while still assuring that the function and intent of opening the RTBs is met. As currently worded, these ACTION Statements result in a feedwater isolation signal (FWIS) when in MODE 3 with a T_{avg} less than [554°F. FSAR Table 7.3-13 and FSAR Figure 7.2-1 (sht. 13) detail the FWIS generation on the coincidence of P-4 and low T_{avg} .] A more generic action, which assures the rods are fully inserted and cannot be withdrawn, replaces the specific method of precluding rod withdrawal. The revised Applicability and ACTION Statements still assure rod withdrawal is precluded. This change does not involve any safety impact and is consistent with Traveler TSTF-135. The proposed change allows more freedom in how rod withdrawal is precluded and is thus less restrictive. However, the intent of using physical plant characteristics to prevent rod withdrawal is not diminished. The specification now acknowledges that the Rod Control System can be effectively disabled by means other than opening the RTBs.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the requirement to preclude rod withdrawal using physical plant characteristics. The specification does not allow administrative control or other means which could be conceived as less stringent. The specification does allow for alternative means to opening the RTBs for precluding rod withdrawal. These means, if used, would be as effective as opening the RTBs, such as removing power to the Rod Control System. Therefore, there should be no increase in the probability or consequences of a previously evaluated accident.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

Inadvertent rod withdrawal accidents have been previously evaluated. This change does not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS39 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will preclude rod withdrawal with the same level of assurance that opening of the RTBs provided. No reduction in the margin of safety will result from this change.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS39" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c) and; accordingly, an NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS40
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS require that the setpoints be verified during quarterly TADOTs for the Reactor Coolant Pump (RCP) Underfrequency [and RCP Undervoltage] functions. The setpoint is adequately confirmed during the 18 month calibrations.

The proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The setpoint for the RCP Underfrequency [and RCP Undervoltage functions are] selected such that the Allowable value is not expected to be exceeded during the 18 months between calibrations. This function is not an initiator for an accident previously analyzed but the function is used to provide a reactor trip signal to mitigate certain accidents. However, because the function is not expected to exceed its Allowable Value bases on the 18 month calibration, it is concluded that the proposed change would not involve a significant increase in the consequences of any accident previously analyzed.

2. Does the change create the possibility of a new or different kind of accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change will not alter the normal method of plant operation. No new transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS40 (continued)

nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS40" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a NSHC finding is justified.

3.3 INSTRUMENTATION

3.3.1 Reactor Trip System (RTS) Instrumentation

LCO 3.3.1 The RTS instrumentation for each Function in Table 3.3.1-1 shall be OPERABLE.

APPLICABILITY: According to Table 3.3.1-1.

ACTIONS

-----NOTE-----
Separate Condition entry is allowed for each Function.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one or more required channels inoperable.	A.1 Enter the Condition referenced in Table 3.3.1-1 for the channel(s).	Immediately
B. One Manual Reactor Trip channel inoperable.	B.1 Restore channel to OPERABLE status.	48 hours
	<u>OR</u> B.2-1 Be in MODE 3.	54 hours
	<u>AND</u> B.2.2 Open reactor trip breakers (RTBs).	<u>3.3-106</u> 55 hours

3.3 INSTRUMENTATION

3.3.2 Engineered Safety Feature Actuation System (ESFAS) Instrumentation

LCO 3.3.2 The ESFAS instrumentation for each Function in Table 3.3.2-1 shall be OPERABLE.

APPLICABILITY: According to Table 3.3.2-1.

ACTIONS

-----NOTE-----
Separate Condition entry is allowed for each Function.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one or more required channels or trains inoperable.	A.1 Enter the Condition referenced in Table 3.3.2-1 for the channel(s) or train(s).	Immediately
B. One channel or train inoperable.	B.1 Restore channel or train to OPERABLE status.	48 hours
	<u>OR</u> B.2.1 Be in MODE 3.	54 hours
	<u>AND</u> B.2.2 Be in MODE 5.	84 hours

(continued)

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>C. One train inoperable.</p>	<p>C.1 -----NOTE----- One train may be bypassed for up to 4 hours for surveillance testing provided the other train is OPERABLE. ----- Restore train to OPERABLE status. <u>OR</u> C.2.1 Be in MODE 3. <u>AND</u> C.2.2 Be in MODE 5.</p>	<p style="text-align: right;"><u><u>B</u></u></p> <p>6 hours</p> <p>12 hours</p> <p>42 hours</p>
<p>D. One channel inoperable.</p>	<p>D.1 -----NOTE----- The inoperable channel or one additional channel may be bypassed for up to 4 hours for surveillance testing of other channels. ----- Place channel in trip. <u>OR</u> D.2.1 Be in MODE 3. <u>AND</u> D.2.2 Be in MODE 4. <u>AND</u> D.2.3 Be in MODE 5 for Function 1. c.</p>	<p style="text-align: right;"><u><u>3.3-37</u></u></p> <p style="text-align: right;"><u><u>B</u></u></p> <p>6 hours</p> <p>12 hours</p> <p>18 hours</p> <p style="text-align: right;"><u><u>3.3-66</u></u></p> <p>42 hours</p>

<p>N: One channel inoperable</p>	<p>N:1 Restore channel to OPERABLE status</p> <p>OR</p> <p>N:2:1 Declare associated pump or valve inoperable</p> <p>AND</p> <p>N:2:2 Comply with REQUIRED ACTION of 3.7.5 or 3.7.2 as applicable</p>	<p>48 hours <u>3.3-58</u></p> <p>Immediately</p> <p>Immediately</p>

SURVEILLANCE REQUIREMENTS

-----NOTE-----
Refer to Table 3.3.2-1 to determine which SRs apply for each ESFAS Function.

SURVEILLANCE		FREQUENCY
SR 3.3.2.1	Perform CHANNEL CHECK.	12 hours
SR 3.3.2.2	Perform ACTUATION LOGIC TEST.	31 days on a STAGGERED TEST BASIS
SR 3.3.2.3	NOT USED NOTE The continuity check may be excluded. Perform ACTUATION LOGIC TEST.	3.3-60 31 days on a STAGGERED TEST BASIS
SR 3.3.2.4	Perform MASTER RELAY TEST.	31 days on a STAGGERED TEST BASIS
SR 3.3.2.5	Perform COT.	92 days
SR 3.3.2.6	Perform SLAVE RELAY TEST.	[92] da ys 18 months B-PS
(continued)		
SR 3.3.2.7	Not Used NOTE Verification of relay setpoints not required. Perform TADOT.	3.3-60 [92] days

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE	FREQUENCY
<p>SR 3.3.2.8 -----NOTE----- Verification of setpoint not required for manual initiation functions. ----- Perform TADOT.</p>	<p>18 months <u>B</u></p>
<p>SR 3.3.2.9 -----NOTE----- This Surveillance shall include verification that the time constants are adjusted to the prescribed values. ----- Perform CHANNEL CALIBRATION.</p>	<p>18 months <u>B</u></p>
<p>SR 3.3.2.10 -----NOTE----- Not required to be performed for the turbine driven AFW pump until 24 hours after SG pressure is \geq [1000] 650 psig. ----- Verify ESFAS RESPONSE TIMES are within limit.</p>	<p><u>B</u> <u>B-PS</u> 18 months on a STAGGERED TEST BASIS</p>

(continued)

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE	FREQUENCY
SR 3.3.2.11 -----NOTE----- Verification of setpoint not required. ----- Perform TADOT.	<div style="text-align: right;"> <u>3.3-61</u> Once per reactor trip breaker cycle 18 months </div>

3.3 INSTRUMENTATION

3.3.3 Post Accident Monitoring (PAM) Instrumentation

LCO 3.3.3 The PAM instrumentation for each Function in Table 3.3.3-1 shall be OPERABLE.

APPLICABILITY: MODES 1, 2 and 3.

ACTIONS

NOTES-----

1. LCO 3.0.4 is not applicable.
2. Separate Condition entry is allowed for each Function.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one required channel inoperable but at least one valid channel OPERABLE.	A.1 Restore required channel to OPERABLE status.	30 days <u>3.3-71</u>
B. Required Action and associated Completion Time of Condition A not met.	B.1 Initiate action in accordance with Specification 5.6.8.	Immediately
C. -----NOTE----- Not applicable to hydrogen monitor channels. ----- One or more Functions with two required channels inoperable OPERABLE.	C.1 Restore one channel to OPERABLE status.	7 days <u>3.3-71</u>

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION
<p>NOTE: Only applicable in MODES 1 and 2</p> <p>D. Two hydrogen monitor channels inoperable.</p>	D.1 Restore one hydrogen monitor channel to OPERABLE status.	72 hours <u>3.3-68</u>
E. Required Action and associated Completion Time of Condition C or D not met.	E.1 Enter the Condition referenced in Table 3.3.3-1 for the channel.	Immediately
F. As required by Required Action E.1 and referenced in Table 3.3.3-1.	F.1 Be in MODE 3. <u>AND</u> F.2 Be in MODE 4.	6 hours 12 hours
G. As required by Required Action E.1 and referenced in Table 3.3.3-1.	G.1 Initiate action in accordance with Specification 5.6.8.	Immediately
H. As required by Required Action E.1 and referenced in Table 3.3.3-1.	H.1 Be in MODE 3	6 hours <u>3.3-68</u>

SURVEILLANCE REQUIREMENTS

-----NOTE-----
SR 3.3.3.1 and SR 3.3.3.2 apply to each PAM instrumentation Function in Table 3.3.3-1.

SURVEILLANCE	FREQUENCY
SR 3.3.3.1 Perform CHANNEL CHECK for each required instrumentation channel that is normally energized.	31 days

SR 3.3.3.2

-----NOTE-----

1 Neutron detectors are excluded from CHANNEL CALIBRATION.

2 CHANNEL CALIBRATION for Containment Area Radiation may consist of an electronic calibration of the channel, not including the detector, for range decades above 10 R/h and a one point calibration check of the detector below 10 R/h with an installed or portable gamma source

3.3-20

Perform CHANNEL CALIBRATION.

18 months

NOTE

Reviewer's Note: This table is for illustration purposes only. It does not attempt to encompass every function used at every unit, but does contain the types of functions commonly found.

ED

FUNCTION/INSTRUMENT OR CONTROL PARAMETER	REQUIRED NUMBER OF FUNCTIONS
1. Reactivity Control	
a. Source Range Neutron Flux.	{1}
b. Reactor Trip Breaker Position	1 per trip breaker
	<u>B</u>
c. Manual Reactor Trip	{2}
2. Reactor Coolant System (RCS) Pressure Control	
a. Pressurizer Pressure of RCS Wide Range Pressure	1
b. Pressurizer Power Operated Relief Valve (PORV) Control and Block Valve Control	{1, controls must be for PORV & block valve on same line}
3. Decay Heat Removal via Steam Generators (SGs)	
a. RCS Hot Leg Temperature {loop 1 only}	1 per loop
b. RCS Cold Leg Temperature {loop 1 only}	1 per loop
c. AFW Controls Condensate Storage Tank Level	{1}2 of any 3 pumps
d. SG Pressure	1 per SG
e. Condensate Storage Tank Level	1
4. RCS Inventory Control	
a. Pressurizer Level	1
b. Charging Pump Controls	{1}2 of 2 pumps
c. Charging Flow	1
5. Safety Support Systems	
a. Emergency Diesel Generator Control	3 of 3 diesel generators
b. Component Cooling Water Control	any 2 of 3 pumps
c. Auxiliary Saltwater Control	2 of 2 pumps

3.3 INSTRUMENTATION

3.3.5 Loss of Power (LOP) Diesel Generator (DG) Start Instrumentation

LCO 3.3.5 ~~[[Three] One channels per bus of the loss of voltage DG start Function and two channels for initiation of load shed Function and [[three] two channels per bus of the degraded voltage Function with one timer per bus for DG start and initiation of load shed Function shall be OPERABLE.~~

3.3-133

APPLICABILITY: MODES 1, 2, 3, and 4.
When associated DG is required to be OPERABLE by LCO 3.8.2, "AC Sources - Shutdown."

ACTIONS

-----NOTE-----
Separate Condition entry is allowed for each Function.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more Functions with one or more channels per bus inoperable.	A.1 -----NOTE----- The inoperable One channel may be bypassed for up to 4 2 hours for surveillance testing of other channels. ----- Place channel in trip. Declare the associated DG inoperable and enter the applicable Condition(s) and Required Action(s).	3.3-104 6 hours immediately
B. One or more Functions with two or more channels per bus inoperable.	B.1 Restore all but one channel to OPERABLE status.	1 hour 3.3-104

(continued)

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
C Required Action and associated Completion Time not met.	C.1 Enter applicable Condition(s) and Required Action(s) for the associated DG made inoperable by LOP DG start instrumentation.	Immed iate y <u>3.3-104</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
 SR 3.3.5.1 NOT USED Perform CHANNEL CHECK.	12 hours

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

"struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

B 3.3 INSTRUMENTATION

B 3.3.1 Reactor Trip System (RTS) Instrumentation

BASES

BACKGROUND

The RTS initiates a unit shutdown, based on the values of selected unit parameters, to protect against violating the core fuel design limits and Reactor Coolant System (RCS) pressure boundary during anticipated operational occurrences (A00s) and to assist the Engineered Safety Features (ESF) Systems in mitigating accidents.

The protection and monitoring systems have been designed to assure safe operation of the reactor. This is achieved by specifying limiting safety system settings (LSSS) in terms of parameters directly monitored by the RTS, as well as specifying LCOs on other reactor system parameters and equipment performance.

The LSSS, defined in this specification as the Trip Setpoints, in conjunction with the LCOs, establish the threshold for protective system action to prevent exceeding acceptable limits during Design Basis Accidents (DBAs).

During A00s, which are those events expected to occur ~~one or more times~~ more than once during the unit life, the acceptable limits are:

1. The Departure from Nucleate Boiling Ratio (DNBR) shall be maintained above the Safety Limit (SL) value to prevent departure from nucleate boiling (DNB);
2. Fuel centerline melt shall not occur; and
3. The RCS pressure SL of ~~2750 psia~~ 2735 psig shall not be exceeded.

Operation within the SLs of Specification 2.0, "Safety Limits (SLs)," also maintains the above values and assures that offsite dose will be within the 10 CFR 50 and 10 CFR 100 criteria during A00s.

Accidents are events that are analyzed even though they are not expected to occur during the unit life. The acceptable limit during accidents is that offsite dose shall be maintained within an acceptable fraction of 10 CFR 100 limits. Different accident categories are allowed a

(continued)

BASES

BACKGROUND
(continued)

different fraction of these limits, based on probability of occurrence. Meeting the acceptable dose limit for an accident category is considered having acceptable consequences for that event.

The RTS instrumentation is segmented into four distinct but interconnected modules as illustrated in Figure [], FSAR, Chapter [7] (Ref. 1), and as identified below:

1. Field transmitters or process sensors: provide a measurable electronic signal based upon the physical characteristics of the parameter being measured;
2. Signal Process Control and Protection System, including Analog/Digital Protection System, Nuclear Instrumentation System (NIS), field contacts, and protection channel sets: provides signal conditioning, bistable setpoint comparison, process algorithm actuation, compatible electrical signal output to protection system devices, and control board/control room/miscellaneous indications;
3. Solid State Protection System (SSPS), including input, logic, and output bays: initiates proper unit shutdown and/or ESF actuation in accordance with the defined logic, which is based on the bistable outputs from the signal process control and protection system; and
4. Reactor trip switchgear, including reactor trip breakers (RTBs) and bypass breakers: provides the means to interrupt power to the control rod drive mechanisms (CRDMs) and allows the rod cluster control assemblies (RCCAs), or "rods," to fall into the core and shut down the reactor. The bypass breakers allow testing of the RTBs at power.

Field Transmitters or Sensors

To meet the design demands for redundancy and reliability, more than one, and often as many as four, field transmitters or sensors are used to measure unit parameters. To account for the calibration tolerances and instrument drift, which are assumed to occur between calibrations, statistical allowances are provided in the Trip Setpoint and Allowable

(continued)

BASES

BACKGROUND

Field Transmitters or Sensors (continued)

Values. The OPERABILITY of each transmitter or sensor can be evaluated when its "as found" calibration data are compared against its documented acceptance criteria.

Signal Process Control and Protection System

Generally, three or four channels of process control equipment are used for the signal processing of unit parameters measured by the field instruments. The process control equipment provides signal conditioning, comparable output signals for instruments located on the main control board, and comparison of measured input signals with setpoints established by safety analyses. These setpoints are defined in the FSAR (References 1, 2, 3, 9, 10, & 11) Chapter [7] (Ref. 1), Chapter [6] (Ref. 2), and Chapter [15] (Ref. 3). If the measured value of a unit parameter exceeds the predetermined setpoint, an output from a bistable is forwarded to the SSPS for decision evaluation, except in the case of the seismic turbine stop valve position, auto stop oil pressure, 12 kV bus and RCP breaker inputs which do not go through signal conditioning. Channel separation is maintained up to and through the input bays. However, not all unit parameters require four channels of sensor measurement and signal processing. Some unit parameters provide input only to the SSPS, while others provide input to the SSPS, the main control board, the unit computer, and one or more control systems.

Generally, if a parameter is used only for input to the protection circuits, three channels with a two-out-of-three logic are sufficient to provide the required reliability and redundancy. If one channel fails in a direction that would not result in a partial Function trip, the Function is still OPERABLE with a two-out-of-two logic. If one channel fails, such that a partial Function trip occurs, a trip will not occur and the Function is still OPERABLE with a one-out-of-two logic.

Generally, if a parameter is used for input to the SSPS and a control function, four channels with a two-out-of-four logic are sufficient to provide the required reliability and redundancy. In the case of the Digital Feedwater Control System (DFWCS), the median/signal select (MSS) feature prevents control/protection interaction even though there are only three inputs and 2-out-of-3 logic. The circuit must be able to withstand both an input failure to the control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function actuation. Again, a single failure will neither cause nor

(continued)

BASES

BACKGROUND

Signal Process Control and Protection System (continued)

prevent the protection function actuation. These requirements are described in IEEE-279-1971 (Ref. 4). The actual number of channels required for each unit parameter is specified in Reference 1.

Two logic channels are required to ensure no single random failure of a logic channel will disable the RTS. The logic channels are designed such that testing required while the reactor is at power may be accomplished without causing trip.

Trip Setpoints and Allowable Values

The Trip Setpoints are the nominal values at which the bistables are set. Any bistable is considered to be properly adjusted when the "as left" value is within the band for CHANNEL CALIBRATION accuracy (i.e., \pm rack calibration + comparator setting accuracy).

The Trip Setpoints used in the bistables are based on the analytical limits stated in Reference 1. The selection of these Trip Setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, instrument drift, and severe environment errors for those RTS channels that must function in harsh environments as defined by 10 CFR 50.49 (Ref. 5), the Trip Setpoints and Allowable Values specified in Table 3.3.1-1 in the accompanying LCO are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the Trip Setpoints, including their explicit uncertainties, is provided in the "RTS/ESFAS Setpoint Methodology WCAP-11082 Rev. 2, Westinghouse Setpoint Methodology for Protection Systems Diablo Canyon Station - Egel 21 Version, May 1993 (Ref. 6). The actual nominal Trip Setpoint entered into the bistable is more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a COT. One example of such a change in measurement error is drift during the surveillance interval. If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.

(continued)

BASES

BACKGROUND
(continued)

Trip Setpoints and Allowable Values

Setpoints in accordance with the Allowable Value ensure that SLs are not violated during AOOs (and that the consequences of DBAs will be acceptable, providing the unit is operated from within the LCOs at the onset of the AOO or DBA and the equipment functions as designed). Note that in the accompanying LCO 3.3.1, the Trip Setpoints of Table 3.3.1-1 are the LSSS.

Each channel of the process control equipment can be tested on line to verify that the signal or setpoint accuracy is within the specified allowance requirements of Reference 2. Once a designated channel is taken out of service for testing, a simulated signal is injected in place of the field instrument signal or in the case of the Power Range channels the test signal is added to the field instrument signal. The process equipment for the channel in test is then tested, verified, and calibrated. SRs for the channels are specified in the SRs section.

The Trip Setpoints and Allowable Values listed in Table 3.3.1-1 are based on the methodology described in Reference 6, which incorporates all of the known uncertainties applicable for each channel. The magnitudes of these uncertainties are factored into the determination of each Trip Setpoint. All field sensors and signal processing equipment for these channels are assumed to operate within the allowances of these uncertainty magnitudes.

Solid State Protection System

The SSPS equipment is used for the decision logic processing of outputs from the signal processing equipment bistables. To meet the redundancy requirements, two trains of SSPS, each performing the same functions, are provided. If one train is taken out of service for maintenance or test purposes, the second train will provide reactor trip and/or ESF actuation for the unit. If both trains are taken out of service or placed in test, a reactor trip will result. Each train is packaged in its own cabinet for physical and electrical separation to satisfy separation and independence requirements. The system has been designed to trip in the event of a loss of power, directing the unit to a safe shutdown condition.

(continued)

BASES

BACKGROUND

Solid State Protection System (continued)

The SSPS performs the decision logic for actuating a reactor trip or ESF actuation, generates the electrical output signal that will initiate the required trip or actuation, and provides the status, permissive, and annunciator output signals to the main control room of the unit.

The bistable outputs from the signal processing equipment or relay contact input (RCP breaker, 12KV UV/UF, seismic, etc.) are sensed by the SSPS equipment and combined into logic matrices that represent combinations indicative of various unit upset and accident transients. If a required logic matrix combination is completed, the system will initiate a reactor trip or send actuation signals via master and slave relays to those components whose aggregate function best serves to alleviate the condition and restore the unit to a safe condition. Examples are given in the Applicable Safety Analyses, LCO, and Applicability sections of this Bases.

Reactor Trip Switchgear

The RTBs are in the electrical power supply line from the control rod drive motor generator set power supply to the CRDMs. Opening of the RTBs interrupts power to the CRDMs, which allows the shutdown rods and control rods to fall into the core by gravity. Each RTB is equipped with a bypass breaker to allow testing of the RTB while the unit is at power. During normal operation the output from the SSPS is a voltage signal that energizes the undervoltage coils in the RTBs and bypass breakers, if in use. When the required logic matrix combination is completed, the SSPS output voltage signal is removed, the undervoltage coils are de-energized, the breaker trip lever is actuated by the de-energized undervoltage coil, and the RTBs and bypass breakers are tripped open. This allows the shutdown rods and control rods to fall into the core. In addition to the de-energization of the undervoltage coils, each reactor trip breaker is also equipped with an automatic shunt trip device that is energized to trip the breaker open upon receipt of a reactor trip signal from the SSPS. Either the undervoltage coil or the shunt trip mechanism is sufficient by itself, thus providing a diverse trip mechanism.

The decision logic matrix Functions are described in the functional diagrams included in Reference 2. In addition to

(continued)

BASES

BACKGROUND

Reactor Trip Switchgear (continued)

the reactor trip or ESF, these diagrams also describe the various "permissive interlocks" that are associated with unit conditions. Each train has a built in testing device that can automatically test the decision logic matrix Functions and the actuation devices while the unit is at power. When any one train is taken out of service for testing, the other train is capable of providing unit monitoring and protection until the testing has been completed. The testing device is semiautomatic to minimize testing time.

APPLICABLE SAFETY ANALYSES, LCO, and APPLICABILITY

The RTS functions to maintain the SLs applicable limits during all AOOs and mitigates the consequences of DBAs in all MODES in which the RTBs are closed.

Each of the analyzed accidents and transients can be detected by one or more RTS Functions. The accident analysis described in Reference 3 takes credit for most RTS trip Functions. RTS trip Functions not specifically credited in the accident analysis are qualitatively credited in the safety analysis and the NRC staff approved licensing basis for the unit. These RTS trip Functions may provide protection for conditions that do not require dynamic transient analysis to demonstrate Function performance. They may also serve as backups to RTS trip Functions that were credited in the accident analysis.

The LCO requires all instrumentation performing an RTS Function, listed in Table 3.3.1-1 in the accompanying LCO, to be OPERABLE. Failure of any instrument renders the affected channel(s) inoperable and reduces the reliability of the affected Functions.

The LCO generally requires OPERABILITY of four or three channels in each instrumentation Function, two channels of Manual Reactor Trip in each logic Function, and two trains in each Automatic Trip Logic Function. Generally four OPERABLE instrumentation channels in a two-out-of-four configuration are required when one RTS channel is also used as a control system input. In the case of the DFWCS, the MSS feature prevents control/protection interaction even though there are only three inputs and a 2-out-of-3 logic. This configuration accounts for the possibility of the shared channel failing in such a manner that it creates a transient that requires RTS action. In

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

this case, the RTS will still provide protection, even with random failure of one of the other three protection channels. Three operable instrumentation channels in a two-out-of-three configuration are generally required when there is no potential for control system and protection system interaction that could simultaneously create a need for RTS trip and disable one RTS channel. The two-out-of-three and two-out-of-four configurations allow one channel to be tripped during maintenance or testing without causing a reactor trip. Specific exceptions to the above general philosophy exist and are discussed below.

Reactor Trip System Functions

The safety analyses and OPERABILITY requirements applicable to each RTS Function are discussed below:

1. Manual Reactor Trip

The Manual Reactor Trip ensures that the control room operator can initiate a reactor trip at any time by using either of two reactor trip switches in the control room. A Manual Reactor Trip accomplishes the same results as any one of the automatic trip Functions. It is used by the reactor operator to shut down the reactor whenever any parameter is rapidly trending toward its Trip Setpoint.

The LCO requires two Manual Reactor Trip channels to be OPERABLE. Each channel is controlled by a manual reactor trip switch. Each channel activates the reactor trip breaker in both trains. Two independent channels are required to be OPERABLE so that no single random failure will disable the Manual Reactor Trip Function.

In MODE 1 or 2, manual initiation of a reactor trip must be OPERABLE ~~(1 out of 2 coincidence)~~. These are the MODES in which the shutdown rods and/or control rods are partially or fully withdrawn from the core. In MODE 3, 4, or 5, the manual initiation Function must also be OPERABLE if the shutdown rods or control rods are withdrawn or the Control Rod Drive (CRD) System is capable of withdrawing the shutdown rods or the control rods. In this condition, inadvertent control rod withdrawal is

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

1. Manual Reactor Trip (continued)

possible. In MODE 3, 4, or 5, manual initiation of a reactor trip does not have to be OPERABLE if the CRD System is not capable of withdrawing the shutdown rods or control rods. If the rods cannot be withdrawn from the core, there is no need to be able to trip the reactor because all of the rods are inserted. In MODE 6, neither the shutdown rods nor the control rods are permitted to be withdrawn and the CRDMs are disconnected from the control rods and shutdown rods. Therefore, the manual initiation Function is not required.

2. Power Range Neutron Flux

The NIS power range detectors are located external to the reactor vessel and measure neutrons leaking from the core. The NIS power range detectors provide input to the Rod Control System and the ~~Steam Generator (SG) Water Level Control System~~. Therefore, the actuation logic must be able to withstand an input failure to the control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function actuation. Note that this Function also provides a signal to prevent automatic and manual rod withdrawal prior to initiating a reactor trip. Limiting further rod withdrawal may terminate the transient and eliminate the need to trip the reactor.

a. Power Range Neutron Flux-High

The Power Range Neutron Flux-High trip Function ensures that protection is provided, from all power levels, against a positive reactivity excursion leading to DNB ~~during power operations. These can be caused by rod withdrawal or reductions in RCS temperature, fuel damage.~~ Reactivity excursions can be caused by rod withdrawal or inadvertent CVCS malfunction, or for example, by sudden changes in RCS coolant temperature such as a feedwater system malfunction (Ref. 12).

The LCO requires all four of the Power Range Neutron Flux-High channels to be OPERABLE (2-out-of-4 coincidence).

In MODE 1 or 2, when a positive reactivity excursion could occur, the Power Range Neutron Flux-High trip must be OPERABLE. This Function

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

a. Power Range Neutron Flux-High (continued)

will terminate the reactivity excursion and shut down the reactor prior to reaching a power level that could damage the fuel. In MODE 3, 4, 5, or 6, the NIS power range detectors cannot detect neutron levels in this range. In these MODES, the Power Range Neutron Flux-High does not have to be OPERABLE because the reactor is shut down and reactivity excursions into the power range are extremely unlikely. Other RTS Functions and administrative controls provide protection against reactivity additions when in MODE 3, 4, 5, or 6.

b. Power Range Neutron Flux-Low

The LCO requirement for the Power Range Neutron Flux-Low trip Function ensures that protection is provided against a positive reactivity excursion from low power or subcritical conditions.

The LCO requires all four of the Power Range Neutron Flux-Low channels to be OPERABLE (2 out of 4 coincidence).

In MODE 1, below the Power Range Neutron Flux (P-10 setpoint), and in MODE 2, the Power Range Neutron Flux-Low trip must be OPERABLE. This Function may be manually blocked by the operator when two out of four power range channels are greater than approximately or equal to 10% RTP (P-10 setpoint). This Function is automatically unblocked when three out of four power range channels are below the P-10 setpoint. Above the P-10 setpoint, positive reactivity additions are mitigated by the Power Range Neutron Flux-High trip Function.

In MODE 3, 4, 5, or 6, the Power Range Neutron Flux-Low trip Function does not have to be OPERABLE because the reactor is shut down and the NIS power range detectors cannot detect neutron levels in this range. Other RTS trip Functions and administrative controls provide protection

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

b. Power Range Neutron Flux-Low (continued)

against positive reactivity additions or power excursions in MODE 3, 4, 5, or 6.

3. Power Range Neutron Flux Rate

The Power Range Neutron Flux Rate trips use the same channels as discussed for Function 2 above.

a. Power Range Neutron Flux-High Positive Rate

The Power Range Neutron Flux-High Positive Rate trip Function ensures that protection is provided against rapid increases in neutron flux that are characteristic of an RCCA drive rod housing rupture and the accompanying ejection of the RCCA. This Function complements the Power Range Neutron Flux-High and Low Setpoint trip Functions to ensure that the criteria are met for a rod ejection from the power range.

The LCO requires all four of the Power Range Neutron Flux-High Positive Rate channels to be OPERABLE (~~2-out~~
~~of 4 coincidence~~).

In MODE 1 or 2, when there is a potential to add a large amount of positive reactivity from a rod ejection accident (REA), the Power Range Neutron Flux-High Positive Rate trip must be OPERABLE. In MODE 3, 4, 5, or 6, the Power Range Neutron Flux-High Positive Rate trip Function does not have to be OPERABLE because other RTS trip Functions and administrative controls will provide protection against positive reactivity additions. Also, since only the shutdown banks may be withdrawn in MODE 3, 4, or 5, the remaining complement of control bank worth ensures a sufficient degree of SDM in the event of an REA. In MODE 6, no rods are withdrawn and the SDM is increased during refueling operations. The reactor vessel head is also removed or the closure bolts are detensioned preventing any pressure buildup. In addition, the NIS power range detectors cannot detect neutron levels present in this mode.

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

b. Power Range Neutron Flux-High Negative Rate

The Power Range Neutron Flux-High Negative Rate trip Function ensures that protection is provided for multiple rod drop accidents. At high power levels, a multiple rod drop accident could cause local flux peaking that would result in an unconservative local DNBR. DNBR is defined as the ratio of the heat flux required to cause a DNB at a particular location in the core to the local heat flux. The DNBR is indicative of the margin to DNB. No credit is taken for the operation of this Function for those rod drop accidents in which the local DNBRs will be greater than the limit.

The LCO requires all four Power Range Neutron Flux-High Negative Rate channels to be OPERABLE (~~2-out-of-4 coincidence~~).

In MODE 1 or 2, when there is potential for a multiple rod drop accident to occur, the Power Range Neutron Flux-High Negative Rate trip must be OPERABLE. In MODE 3, 4, 5, or 6, the Power Range Neutron Flux-High Negative Rate trip Function does not have to be OPERABLE because the core is not critical and DNB is not a concern. Also, since only the shutdown banks may be withdrawn in MODE 3, 4, or 5, the remaining complement of control bank worth ensures a sufficient degree of SDM in the event of an REA. In MODE 6, no rods are withdrawn and the required SDM is increased during refueling operations. In addition, the NIS power range detectors cannot detect neutron levels present in this MODE.

4. Intermediate Range Neutron Flux

The Intermediate Range Neutron Flux trip Function ensures that protection is provided against an uncontrolled RCCA bank rod withdrawal accident from a subcritical condition during startup. This trip Function provides redundant protection to the Power Range Neutron Flux-Low Setpoint trip Function. The NIS intermediate range detectors are located external to the reactor vessel and measure neutrons leaking from the core. The NIS intermediate range detectors

(continued)

BASES

APPLICABLE SAFETY ANALYSES, LCO, and APPLICABILITY 4. Intermediate Range Neutron Flux (continued)

do not provide any input to control systems. Note that this Function also provides a signal to prevent automatic and manual rod withdrawal prior to initiating a reactor trip. Limiting further rod withdrawal may terminate the transient and eliminate the need to trip the reactor.

The LCO requires two channels of Intermediate Range Neutron Flux to be OPERABLE (1-out-of-2 coincidence). Two OPERABLE channels are sufficient to ensure no single random failure will disable this trip Function.

Because this trip Function is important only during startup, there is generally no need to disable channels for testing while the Function is required to be OPERABLE. Therefore, a third channel is unnecessary.

In MODE 1 below the P-10 setpoint, and in MODE 2 above the P-6 setpoint, when there is a potential for an uncontrolled RCCA bank rod withdrawal accident during reactor startup, the Intermediate Range Neutron Flux trip must be OPERABLE. Above the P-10 setpoint, the Power Range Neutron Flux-High Setpoint trip and the Power Range Neutron Flux-High Positive Rate trip provide core protection for a rod withdrawal accident. In MODE 3, 4, or 5, the Intermediate Range Neutron Flux trip does not have to be OPERABLE because the control rods must be fully inserted and only the shutdown rods may be withdrawn. The reactor cannot be started up in this condition. The core also has the required SDM to mitigate the consequences of a positive reactivity addition accident. In MODE 6, all rods are fully inserted and the core has a required increased SDM. Also, the NIS intermediate range detectors cannot detect neutron levels present in this MODE.

5. Source Range Neutron Flux

The LCO requirement for the Source Range Neutron Flux trip Function ensures that protection is provided against an uncontrolled RCCA bank rod withdrawal accident from a subcritical condition during startup. This trip Function provides redundant protection to

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

5. Source Range Neutron Flux (continued)

the Power Range Neutron Flux-Low Setpoint and ~~Intermediate Range Neutron Flux trip Functions~~. In MODES 3, 4, and 5, administrative controls also prevent the uncontrolled withdrawal of rods. The NIS source range detectors are located external to the reactor vessel and measure neutrons leaking from the core. The NIS source range detectors do not provide any inputs to control systems. The source range trip is the only RTS automatic protection function required in MODES 2 below P-6, 3, 4, and 5 with the Rod Control System capable of rod withdrawal or all rods not fully inserted. Therefore, the functional capability at the specified Trip Setpoint is assumed to be available.

The LCO requires two channels of Source Range Neutron Flux to be OPERABLE. Two OPERABLE channels are sufficient to ensure no single random failure will disable this trip Function. The LCO also requires one channel of the Source Range Neutron Flux to be OPERABLE in MODE 3, 4, or 5 with RTBs open or the control rods incapable of withdrawal. In this case, the source range Function is to provide control room indication and input to the Boron Dilution Protection System (BDPS). The outputs of the Function to RTS logic are not required OPERABLE in MODE 6 or when the RTBs are open or all rods are fully inserted and the Rod Control System is incapable of withdrawal.

The Source Range Neutron Flux Function provides protection for control rod withdrawal from subcritical, boron dilution and control rod ejection events. The Function also provides visual neutron flux indication in the control room.

In MODE 2 when below the P-6 setpoint during a reactor startup, the Source Range Neutron Flux trip must be OPERABLE (1-out-of-2 coincidence). Above the P-6 setpoint, the Intermediate Range Neutron Flux trip and the Power Range Neutron Flux-Low Setpoint trip will provide core protection for reactivity accidents. Above the P-6 setpoint, the NIS source range neutron flux trip may be manually blocked and the high voltage to the detectors may be de-energized; detectors are de-energized and inoperable. Below the P-6 setpoint, the source range neutron flux trip is automatically reinstated and the high voltage to the detectors is automatically energized.

In MODE 3, 4, or 5 with the reactor shut down, but with the Rod Control System capable of rod withdrawal or all rods not fully inserted, the Source Range Neutron Flux trip Function must also be OPERABLE (1-out-of-2 coincidence). If the CRD System is capable of rod withdrawal, the Source Range Neutron Flux trip must be

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

5. Source Range Neutron Flux (continued)

~~OPERABLE~~ to provide core protection against a rod withdrawal accident. If the ~~CRD Rod Control~~ System is not capable of rod withdrawal, the source range detectors are not required to trip the reactor. However, their monitoring Function must be OPERABLE to monitor core neutron levels and provide indication of reactivity changes that may occur as a result of events like an ~~uncontrolled~~ boron dilution. ~~These inputs are provided to the BDPS.~~ The requirements for the NIS source range detectors in MODE 6 are addressed in LCO 3.9.3, "Nuclear Instrumentation."

6. Overtemperature ΔT

The Overtemperature ΔT trip Function is provided to ensure that the design limit DNBR is met. This trip Function also limits the range over which the Overpower ΔT trip Function must provide protection and ~~it protects against vessel exit bulk boiling and ensures that the exit quality is within the limits defined by the DNBR correlation.~~ The inputs to the Overtemperature ΔT trip include ~~a~~ pressure, coolant temperature, axial power distribution, and reactor power as indicated by loop ΔT assuming full reactor coolant flow. Protection from violating the DNBR limit is assured for those transients that are slow with respect to delays from the core to the measurement system. ~~The Function monitors both variation in power and flow since a decrease in flow has the same effect on ΔT as a power increase.~~ The Overtemperature ΔT trip Function uses each loop's ΔT as a measure of reactor power and is compared with a setpoint that is automatically varied with the following parameters:

- reactor coolant average temperature—the Trip Setpoint is varied to correct for changes in coolant density and specific heat capacity with changes in coolant temperature;
- pressurizer pressure—the Trip Setpoint is varied to correct for changes in system pressure; and
- axial power distribution— $f(\Delta I)$, the Trip Setpoint is varied to account for imbalances in the axial power distribution as detected by the
- NIS upper and lower power range detectors. If axial peaks are greater than the design limit, as indicated by the difference between the upper and lower NIS power range detectors, the Trip Setpoint is reduced in accordance with Note 1 of Table 3.3.1-1.
- Dynamic compensation is included for system piping delays from the core to the temperature measurement system.

ΔT_0 , as used in the overtemperature and overpower ΔT trips, represents the 100 percent RTP value of ΔT as measured by the

(continued)

BASES

plant for each loop. For the initial startup of a refueled core, ΔT_0 is initially assumed to be the same as the last measured ΔT value from the previous cycle until ΔT is measured again at full power. Accurate determination of the loop specific ΔT values should be made quarterly when performing the incore/excore recalibration at steady-state conditions (i.e., power distributions not affected by xenon or other transient conditions). The variation in indicated ΔT between loops is due to the variance in both real hot leg temperatures and hot leg temperature measurement biases. The real hot leg temperature variance between loops is primarily caused by asymmetrical flow in the upper plenum, and the difference in hot leg temperature measurement bases, primarily caused by differences in hot leg temperature streaming error between loops. The change in the indicated loop ΔT s with burn up is caused primarily by the change in the hot leg streaming biases as the radial power distribution changes.

The Overtemperature ΔT trip Function is calculated for each loop as described in Note 1 of Table 3.3.1-1. Trip occurs if Overtemperature ΔT is indicated in two loops. ~~At some units,~~ The pressure and temperature signals are used for other control functions. ~~For these units, thus~~ the actuation logic must be able to withstand an input failure to the control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function actuation. Note that this function also provides a signal to generate a turbine runback prior to reaching the Trip Setpoint. A turbine runback will reduce turbine power and reactor power. A reduction in power will normally alleviate the Overtemperature ΔT condition and may prevent a reactor trip.

The LCO requires all four channels of the Overtemperature ΔT trip Function to be OPERABLE ~~for two and four loop units (the LCO requires all three channels on the Overtemperature ΔT trip Function to be OPERABLE for three loop units)~~. Note that the Overtemperature ΔT Function receives input from channels shared with other RTS Functions. Failures that affect multiple Functions require entry into the Conditions applicable to all affected Functions.

In MODE 1 or 2, the Overtemperature ΔT trip must be OPERABLE to prevent DNB ~~(2-out-of-4 coincidence)~~. In MODE 3, 4, 5, or 6, this trip Function does not have to be OPERABLE because the reactor is not operating and there is insufficient heat production to be concerned about DNB.

7.

Overpower ΔT

The Overpower ΔT trip Function ensures that protection is provided to ensure the integrity of the fuel (i.e., no fuel pellet melting and less than 1% cladding strain) under all possible overpower conditions for Condition I and II event (Ref. 12). This trip Function also limits the required range of the Overtemperature ΔT trip Function and provides a backup to the Power Range Neutron Flux-High Setpoint trip. The Overpower ΔT trip Function ensures that the allowable heat generation rate (kW/ft) of the fuel is not exceeded. It uses the ΔT of each loop as a measure of reactor power with a setpoint that is automatically varied with the following parameters:

- reactor coolant average temperature—the Trip Setpoint is varied to correct for changes in coolant density and specific heat capacity with changes in coolant temperature; and
- rate of change of reactor coolant average temperature—including dynamic compensation for the delays between the core and the temperature measurement system.

ΔT_0 , as used in the overtemperature and overpower ΔT trips, represents the 100 percent RTP value of ΔT as measured by the plant for each loop. For the initial startup of a refueled core, ΔT_0 is initially assumed to be the same as the last measured ΔT value from the previous cycle until ΔT is measured again at full power. Accurate determination of the loop specific ΔT values should be made quarterly when performing the incore/excore recalibration at steady-state conditions (i.e., power distributions not affected by xenon or other transient conditions). The variation in indicated ΔT between loops is due to the variance in both real hot leg temperatures and hot leg temperature measurement biases. The real hot leg temperature variance between loops is primarily caused by asymmetrical flow in the upper plenum, and the difference in hot leg temperature measurement biases is primarily caused by differences in hot leg temperature streaming error between loops. The change in the indicated loop ΔT s with burn up is caused primarily by the change in the hot leg streaming biases as the radial power distribution changes.

The Overpower ΔT trip Function is calculated for each loop as per Note 2 of Table 3.3.1-1. Trip occurs if Overpower ΔT is indicated in two loops. ~~At some units, the temperature signals are used for other control functions. At these units, thus,~~ the actuation logic must be able to withstand an input failure to the control system, which may then require the protection function actuation and a single failure in the remaining channels providing the protection function actuation. Note that this Function also provides a signal to

APPLICABILITY
(continued)

power and reactor power. A reduction in power will normally alleviate the Overpower ΔT condition and may prevent a reactor trip.

The LCO requires four channels ~~for two and four loop units (three channels for three loop units)~~ of the Overpower ΔT trip Function to be OPERABLE (2-out-of-4 coincidence). Note that the Overpower ΔT trip Function receives input from ~~consequences of small steamline breaks, as reported in WCAP 9227, Ref. 11, and steamline breaks with coincident control rod withdrawal (Ref. 12).~~

(continued)

BASES

APPLICABLE SAFETY ANALYSES, LCO, and APPLICABILITY

7. Overpower ΔT (continued)

channels shared with other RTS Functions. Failures that affect multiple Functions require entry into the Conditions applicable to all affected Functions.

In MODE 1 or 2, the Overpower ΔT trip Function must be OPERABLE. These are the only times that enough heat is generated in the fuel to be concerned about the heat generation rates and overheating of the fuel. In MODE 3, 4, 5, or 6, this trip Function does not have to be OPERABLE because the reactor is not operating and there is insufficient heat production to be concerned about fuel overheating and fuel damage.

8. Pressurizer Pressure

The same sensors provide input to the Pressurizer Pressure-High and -Low trips and the Overtemperature ΔT trip. ~~At some units, the Pressurizer Pressure channels are also used to provide input to the Pressurizer Pressure Control System. For these units thus, the actuation logic must be able to withstand an input failure to the control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function actuation.~~

a. Pressurizer Pressure-Low

The Pressurizer Pressure-Low trip Function ensures that protection is provided against violating the DNBR limit due to low pressure.

The LCO requires four channels ~~for two and four loop units (three channels for three loop units)~~ of Pressurizer Pressure-Low to be OPERABLE (2-out-of-4 coincidence).

In MODE 1, when DNB is a major concern, the Pressurizer Pressure-Low trip must be OPERABLE. This trip Function is automatically enabled on increasing power by the P-7 ~~Low Pressure Permissive~~ interlock (NIS power range P-10 or turbine impulse pressure greater than approximately 10% of full power equivalent

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

a. Pressurizer Pressure - Low (continued)

(P-13)). On decreasing power, this trip Function is automatically blocked below P-7. Below the P-7 setpoint, ~~no conceivable power distributions can occur that would cause DNB concerns. There is insufficient heat production to be concerned about DNB~~

b. Pressurizer Pressure - High

The Pressurizer Pressure - High trip Function ensures that protection is provided against overpressurizing the RCS. This trip Function operates in conjunction with the pressurizer relief and safety valves to prevent RCS overpressure conditions.

The LCO requires four channels ~~for two and four loop units (three channels for three loop units)~~ of the Pressurizer Pressure - High to be OPERABLE ~~(2-out-of-4 coincidence)~~.

The Pressurizer Pressure - High LSSS is selected to be below the pressurizer safety valve actuation pressure and above the power operated relief valve (PORV) setting. This setting minimizes challenges to safety valves while avoiding unnecessary reactor trip for those pressure increases that can be controlled by the PORVs.

In MODE 1 or 2, the Pressurizer Pressure - High trip must be OPERABLE to help prevent RCS overpressurization and minimize challenges to the relief and safety valves. In MODE 3, 4, 5, or 6, the Pressurizer Pressure - High trip Function does not have to be OPERABLE because transients that could cause an overpressure condition will ~~usually~~ be slow to occur. Therefore, the operator will have sufficient time to evaluate unit conditions and take corrective actions. ~~Additionally, two low temperature overpressure protection systems channels provide overpressure protection with the PORVs when below MODE-4 the low temperature cut-off specified in the pressure and temperature limits report (PTLR).~~

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

9. Pressurizer Water Level-High

The Pressurizer Water Level-High trip Function provides a backup signal for the Pressurizer Pressure-High trip and also provides protection against water relief through the pressurizer safety valves. These valves are designed to pass steam in order to achieve their design energy removal rate. A reactor trip is actuated prior to the pressurizer becoming water solid. The LCO requires three channels of Pressurizer Water Level-High to be OPERABLE. The pressurizer level channels are used as input to the Pressurizer Level Control System. A fourth channel is not required to address control/protection interaction concerns. The level channels do not actuate the safety valves, and the high pressure reactor trip is set below the safety valve setting. Therefore, with the slow rate of charging available, pressure overshoot due to level channel failure cannot cause the safety valve to lift before reactor high pressure trip.

In MODE 1, when there is a potential for overfilling the pressurizer, the Pressurizer Water Level-High trip must be OPERABLE (2-out-of-3 coincidence). This trip Function is automatically enabled on increasing power by the P-7 interlock. On decreasing power, this trip Function is automatically blocked below P-7. Below the P-7 setpoint, transients that could raise the pressurizer water level will be slow and the operator will have sufficient time to evaluate unit conditions and take corrective actions.

10. Reactor Coolant Flow-Low

a. ~~Reactor Coolant Flow Low (Single Loop)~~

~~The Reactor Coolant Flow Low (Single Loop) trip Function ensures that protection is provided against violating the DNBR limit due to low flow in one or more RCS loops, while avoiding reactor trips due to normal variations in loop flow. Above the P-8 setpoint, which is approximately 48 RTP, a loss of flow in any RCS loop will actuate a reactor trip. Each RCS loop has three flow detectors to monitor flow. The flow signals are not used for any control system input.~~

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

~~a. Reactor Coolant Flow Low (Single Loop)
(continued)~~

~~The LCO requires three Reactor Coolant Flow Low channels per loop to be OPERABLE in MODE 1 above P 8. In MODE 1 above the P 8 setpoint, a loss of flow in one RCS loop could result in DNB conditions in the core. In MODE 1 below the P 8 setpoint, a loss of flow in two or more loops is required to actuate a reactor trip (Function 10.b) because of the lower power level and the greater margin to the design limit DNBR.~~

~~b. Reactor Coolant Flow Low (Two Loops)~~

The Reactor Coolant Flow-Low (Two Loops) trip Function ensures that protection is provided against violating the DNBR limit due to low flow in two or more RCS loops while avoiding reactor trips due to normal variations in loop flow.

~~Above the P-7 setpoint and below the P-8 setpoint, a loss of flow in two or more loops will initiate a reactor trip. Each loop has three flow detectors to monitor flow. The flow signals are not used for any control system input.~~

The LCO requires three Reactor Coolant Flow-Low channels per loop to be OPERABLE (2 out of 3 coincidence in one loop).

In MODE 1 above the P-7 setpoint and below the P-8 setpoint, the Reactor Coolant Flow-Low (Two Loops) trip must be OPERABLE. Below the P-7 setpoint, all reactor trips on low flow are automatically blocked since no conceivable power distributions could occur that would cause a DNB concern at this low power level there is insufficient heat production to be concerned about DNB. Above the P-7 setpoint, the reactor trip on low flow in two or more RCS loops is automatically enabled. Above the P-8 setpoint, a loss of flow in any one loop will actuate a reactor trip because of the higher power level and the reduced margin to the design limit DNBR.

11. Reactor Coolant Pump (RCP) Breaker Position

~~Both RCP Breaker Position trip Functions operate together on two sets of auxiliary contacts, with one set on each RCP breaker. These Functions anticipate the Reactor Coolant Flow Low trips to avoid RCS heatup that would occur before the low flow trip actuates.~~

a. Reactor Coolant Pump Breaker Position (Single Loop)
~~NOT USED~~

~~The RCP Breaker Position (Single Loop) trip Function ensures that protection is provided against violating the DNBR limit due to a loss of flow in one RCS loop. The position of each RCP breaker is monitored. If one RCP breaker is open above the P-8 setpoint, a reactor trip is initiated. This trip Function will generate a reactor trip before the Reactor Coolant Flow Low (Single Loop) Trip Setpoint is reached.~~

~~The LCO requires one RCP Breaker Position channel per RCP to be OPERABLE. One OPERABLE channel is sufficient for this trip Function because the RCS Flow Low trip alone provides sufficient protection of unit SLs for loss of flow events. The RCP Breaker Position trip serves only to anticipate the low flow trip, minimizing the thermal transient associated with loss of a pump.~~

~~This Function measures only the discrete position (open or closed) of the RCP breaker, using a position switch. Therefore, the Function has no adjustable trip setpoint with which to associate an LSSS.~~

~~In MODE 1 above the P-8 setpoint, when a loss of flow in any RCS loop could result in DNB conditions in the core, the RCP Breaker Position (Single Loop) trip must be OPERABLE. In MODE 1 below the P-8 setpoint, a loss of flow in two or more loops is required to actuate a reactor trip because of the lower power level and the greater margin to the design limit DNBR.~~

b. Reactor Coolant Pump Breaker Position (Two Loops)

The RCP Breaker Position (~~Two Loops~~) trip Function ensures that protection is provided against violating the DNBR limit due to a loss of flow in two or more RCS loops. The position of each RCP breaker is monitored. Above the P-7 setpoint and below the P-8 setpoint, a loss of flow in two or more loops will initiate a reactor trip. This trip Function will generate a reactor trip before the Reactor Coolant Flow-Low (~~Two Loops~~) Trip Setpoint is reached.

The LCO requires one RCP Breaker Position channel per RCP to be OPERABLE (~~2-out-of-4 coincidence~~). One OPERABLE channel is sufficient for this Function because the RCS Flow-Low trip alone provides sufficient protection of unit SLs for loss of flow events. The RCP Breaker Position trip serves only to anticipate the low flow trip, minimizing the thermal transient associated with loss of an RCP.

This Function measures only the discrete position (open or closed) of the RCP breaker, using a position switch. Therefore, the Function has no adjustable trip setpoint with which to associate an LSSS.

In MODE 1 above the P-7 setpoint and below the P-8 setpoint, the RCP Breaker Position (~~Two Loops~~) trip must be OPERABLE. Below the P-7 setpoint, all reactor trips on loss of flow are automatically blocked since no conceivable power distributions could occur that would cause a DNB concern at this low power level there is insufficient heat production to be concerned about DNB. Above the P-7 setpoint, the reactor trip on loss of flow in two RCS loops is automatically enabled. Above the P-8 setpoint, a loss of flow in any one loop will actuate a reactor trip because of the higher power level and the reduced margin to the design limit DNBR.

12. Undervoltage Reactor Coolant Pumps

The Undervoltage RCPs reactor trip Function ensures that protection is provided against violating the DNBR limit due to a loss of flow in two or more RCS loops. The voltage to each RCP bus is monitored by two relays each. Above the P-7 setpoint, a loss of voltage detected on two or more RCP buses, i.e. a complete loss of flow event will initiate a reactor trip. For this event, the under voltage trip Function will generate a reactor trip before the Reactor Coolant Flow-Low (Two Loops) Trip Setpoint is reached. Time delays are incorporated into the Undervoltage RCPs channels to prevent reactor trips due to momentary electrical power transients.

The LCO requires three Undervoltage RCPs channels (one per phase) per bus to be OPERABLE (1 per bus both buses).

In MODE 1 above the P-7 setpoint, the Undervoltage RCP trip must be OPERABLE. Below the P-7 setpoint, all reactor trips on loss of flow are automatically blocked since no conceivable power distributions could occur that would cause a DNB concern at this low power level, since there is insufficient heat production to be concerned about DNB. Above the P-7 setpoint, the reactor trip on loss of flow in two or more of four RCS loops is automatically enabled. This Function uses the same relays as the ESFAS Function 6.f. "Undervoltage Reactor Coolant Pump (RCP)" start of the auxiliary feedwater (AFW) pumps.

13. Underfrequency Reactor Coolant Pumps

The Underfrequency RCPs reactor trip Function ensures that protection is provided against violating the DNBR limit due to a loss of flow in two or more RCS loops from a major network frequency disturbance. An underfrequency condition will slow down the pumps, thereby reducing their coastdown time following a pump trip. The proper An adequate coastdown time is required so that reactor heat can be removed immediately after reactor trip. The frequency of each RCP bus is monitored. Above the P-7 setpoint, a loss of frequency detected on two or more by two relays on one RCP buses will initiate a reactor trip. This trip Function will generate a reactor trip before the Reactor Coolant Flow-Low (Two Loops) Trip Setpoint is reached. Time delays are incorporated into the Underfrequency RCPs channels to prevent reactor trips due to momentary electrical power transients.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

13. Underfrequency Reactor Coolant Pumps (continued)

The LCO requires three two Underfrequency RCPs channels per bus to be OPERABLE (1-per-bus both busses).

In MODE 1 above the P-7 setpoint, the Underfrequency RCPs trip must be OPERABLE. Below the P-7 setpoint, all reactor trips on loss of flow are automatically blocked since no conceivable power distributions could occur that would cause a DNB concern at this low power level since there is insufficient heat production to be concerned about DNB. Above the P-7 setpoint, the reactor trip on loss of flow in two or more RCS loops is automatically enabled.

14. Steam Generator Water Level - Low Low

The SG Water Level - Low Low trip Function ensures that protection is provided against a loss of heat sink and actuates the AFW System prior to uncovering the SG tubes in the event of a loss of feedwater flow to one or more SGs. The SGs are the heat sink for the reactor. In order to act as a heat sink, the SGs must contain a minimum amount of water. A narrow range low low level in any SG is indicative of a loss of heat sink for the reactor. The level transmitters provide input to the SG Level Control System. Therefore, the actuation logic must be able to withstand an input failure to the control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function actuation. This Function also performs the ESFAS function of starting the AFW pumps on low low SG level.

The LCO requires four three channels of SG Water Level - Low Low per SG (1-per-SG in one SG) and four channels of RCS ΔT (1/loop) to be OPERABLE. The installation of the median signal selector (MSS) and four channels of RCS ΔT (1/loop) effectively eliminates the possibility that a single random failure could cause a control system action that results in a condition requiring protection action, and also prevent proper operation of a protection system channel designed to protect against the condition. Thus, the MSS prevents interaction between the feedwater control and reactor protection systems in accordance with the requirements of IEEE 279-1971, "Criteria for Protection Systems for Nuclear Power Generating Stations." Removal of this interaction eliminates the need for the low feedwater flow reactor trip. The MSS will functionally separate steam generator narrow range level protection channels (low-low steam generator water level trip) to provide compliance with IEEE 279-1971 and satisfy the original design basis for four loop units in which these channels are shared between protection and control. In two, three, and four loop units where three SG Water Levels are dedicated to the RTS, only three channels per SG are required to be OPERABLE. This trip is actuated on two out of three low-low water level signals occurring in any steam generator. If a low-low water level condition is detected in one steam generator, signals shall be generated to trip the reactor and start the motor

(continued)

BASES

driven auxiliary feedwater pumps. If a low-low water level condition is detected in two or more steam generators, a signal is generated to start the turbine driven auxiliary feedwater pump as well.

The signals to actuate reactor trip and start auxiliary feedwater pumps may be delayed through the use of a Trip Time Delay (TTD) system for reactor power levels below 50% of RTP. Low-low water level in any protection set in any steam generator will generate a signal which starts an elapsed time trip delay timer. The allowable trip time delay is based upon the prevailing power level at the time the low-low level trip setpoint is reached. If power level rises after the trip time delay setpoints have been determined, the trip time delay is re-determined (i.e., decreased) according to the increase in power level. However, the trip time delay is not changed if the power level decreases after the delay has been determined. The use of this delay allows added time for natural steam generator level stabilization or operator intervention to avoid an inadvertent protection system actuation.

In MODE 1 or 2, when the reactor requires a heat sink, the SG Water Level - Low Low trip must be OPERABLE. The normal source of water for the SGs is the Main Feedwater (MFW) System (not safety related). The MFW System is only in operation in MODE 1 or 2. The AFW System is the safety related backup source of water to

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

14. Steam Generator Water Level-Low Low (continued)

ensure that the SGs remain the heat sink for the reactor. During normal startups and shutdowns, the AFW System provides feedwater to maintain SG level. In MODE 3, 4, 5, or 6, the SG Water Level-Low Low Function does not have to be OPERABLE because the MFW System is not in operation and the reactor is not operating or even critical. Decay heat removal is accomplished by the AFW System in MODE 3 (and 4 prior to going on RHR) and by the Residual Heat Removal (RHR) System in MODE 4, 5, or 6.

15. Steam Generator Water Level-Low, Coincident With Steam Flow/Feedwater Flow Mismatch

~~NOT USED~~

~~SG Water Level Low, in conjunction with the Steam Flow/Feedwater Flow Mismatch, ensures that protection is provided against a loss of heat sink and actuates the AFW System prior to uncovering the SG tubes. In addition to a decreasing water level in the SG, the difference between feedwater flow and steam flow is evaluated to determine if feedwater flow is significantly less than steam flow. With less feedwater flow than steam flow, SG level will decrease at a rate dependent upon the magnitude of the difference in flow rates. There are two SG level channels and two Steam Flow/Feedwater Flow Mismatch channels per SG. One narrow range level channel sensing a low level coincident with one Steam Flow/Feedwater Flow Mismatch channel sensing flow mismatch (steam flow greater than feed flow) will actuate a reactor trip.~~

~~The LCO requires two channels of SG Water Level Low coincident with Steam Flow/Feedwater Flow Mismatch.~~

~~In MODE 1 or 2, when the reactor requires a heat sink, the SG Water Level Low coincident with Steam Flow/Feedwater Flow Mismatch trip must be OPERABLE. The normal source of water for the SGs is the MFW System (not safety related). The MFW System is only in operation in MODE 1 or 2. The AFW System is the safety related backup source of water to ensure that the SGs remain the heat sink for the reactor. During normal startups and shutdowns, the AFW System provides feedwater to maintain SG level. In MODE 3, 4, 5,~~

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

15. Steam Generator Water Level-Low, Coincident With Steam Flow/Feedwater Flow Mismatch (continued)

~~or 6, the SG Water Level-Low coincident with Steam Flow/Feedwater Flow Mismatch Function does not have to be OPERABLE because the MFW System is not in operation and the reactor is not operating or even critical. Decay heat removal is accomplished by the AFW System in MODE 3 and by the RHR System in MODE 4, 5, or 6. The MFW System is in operation only in MODE 1 or 2 and, therefore, this trip Function need only be OPERABLE in these MODES.~~

16. Turbine Trip

a. Turbine Trip-Low Fluid Auto Stop Oil Pressure

The Turbine Trip-Low Fluid Auto Stop Oil Pressure trip Function anticipates the loss of heat removal capabilities of the secondary system following a turbine trip. This trip Function acts to minimize the pressure/temperature transient on the reactor. Any turbine trip from a power level below the P-9 setpoint, approximately less than or equal to 50% power, will not actuate a reactor trip. Three pressure switches monitor the control trip oil pressure in the Turbine Electrohydraulic Control System. A low pressure condition sensed by two-out-of-three pressure switches will actuate a reactor trip. These pressure switches do not provide any input to the control system. The unit is designed to withstand a complete loss of load and not sustain core damage or challenge the RCS pressure limitations. Core protection is provided by the Pressurizer Pressure-High trip Function and RCS integrity is ensured by the pressurizer safety valves.

The LCO requires three channels of Turbine Trip-Low Fluid Autostop Oil Pressure to be OPERABLE in MODE 1 above P-9 (2-out-of-3 coincidence).

Below the P-9 setpoint, a turbine trip does not actuate a reactor trip. In MODE 2, 3, 4, 5, or 6, there is no potential for a turbine trip.

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

a. Turbine Trip-Low Fluid Auto Stop Oil Pressure (continued)

and the Turbine Trip-Low Fluid Auto Stop Oil Pressure trip Function does not need to be OPERABLE.

b. Turbine Trip-Turbine Stop Valve Closure

The Turbine Trip-Turbine Stop Valve Closure trip Function anticipates the loss of heat removal capabilities of the secondary system following a turbine trip ~~from a power level below the P-9 setpoint, approximately 50% power.~~

~~This action will not actuate a reactor trip.~~ The trip Function anticipates the loss of secondary heat removal capability that occurs when the stop valves close.

Tripping the reactor in anticipation of loss of secondary heat removal acts to minimize the pressure and temperature transient on the reactor. ~~Any turbine trip from a power level below the P-9 setpoint, less than or equal to a maximum setpoint of 50 percent power, will not actuate a reactor trip.~~ This trip Function will not and is not required to operate in the presence of a single channel failure. The unit is designed to withstand a complete loss of load and not sustain core damage or challenge the RCS pressure limitations. Core protection is provided by the Pressurizer Pressure-High trip Function, and RCS integrity is ensured by the pressurizer safety valves. This trip Function is diverse to the Turbine Trip-Low Fluid Auto Stop Oil Pressure trip Function. Each turbine stop valve is equipped with one limit switch that inputs to the RTS. If all four limit switches indicate that the stop valves are all closed, a reactor trip is initiated ~~above P-9.~~

The LSSS for this Function is set to assure channel trip occurs when the associated stop valve is completely closed.

The LCO requires four Turbine Trip-Turbine Stop Valve Closure channels, one per valve, to be OPERABLE in MODE 1 above P-9. All four channels must trip to cause reactor trip.

Below the P-9 setpoint, a load rejection can be accommodated by the Steam Dump ~~and Reactor Control Systems~~. In MODE 2, 3, 4, 5, or 6, there is no potential for

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

b. Turbine Trip - Turbine Stop Valve Closure
(continued)

a load rejection, and the Turbine Trip - Stop Valve Closure trip Function does not need to be OPERABLE.

17. Safety Injection Input from Engineered Safety Feature Actuation System

The SI Input from ESFAS ensures that if a reactor trip has not already been generated by the RTS, the ESFAS automatic actuation logic will initiate a reactor trip upon any signal that initiates SI. This is a condition of acceptability for the small break LOCA but rod insertion is not credited for the large break LOCA (Ref. 3). However, other transients and accidents take credit for varying levels of ESF performance and rely upon rod insertion, except for the most reactive rod that is assumed to be fully withdrawn, to ensure reactor shutdown. Therefore, a reactor trip is initiated every time an SI signal is present.

Trip Setpoint and Allowable Values are not applicable to this Function. The SI Input is provided by relay logic in the SSPS circuitry of ESFAS. Therefore, there is no measurement signal with which to associate an LSSS.

The LCO requires two trains of SI Input from ESFAS to be OPERABLE in MODE 1 or 2 (1-out-of-2 coincidence).

A reactor trip is initiated every time an SI signal is present. Therefore, this trip Function must be OPERABLE in MODE 1 or 2, when the reactor is critical, and must be shut down in the event of an accident. In MODE 3, 4, 5, or 6, the reactor is not critical, and this trip Function does not need to be OPERABLE.

18. Reactor Trip System Interlocks

Reactor protection interlocks are provided to ensure reactor trips are in the correct configuration for the current unit status. They back up operator actions to ensure protection system Functions are not bypassed during unit conditions under which the safety analysis assumes the Functions are not bypassed. Therefore, the interlock Functions do not need to be OPERABLE

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

18. Reactor Trip System Interlocks (continued)

when the associated reactor trip functions are outside the applicable MODES. These are:

a. Intermediate Range Neutron Flux, P-6

The Intermediate Range Neutron Flux, P-6 interlock is actuated when any NIS intermediate range channel goes approximately one decade above the minimum channel reading. If both channels drop below the setpoint, the permissive will automatically be defeated. The LCO requirement for the P-6 interlock ensures that the following functions are performed:

- on increasing power, the P-6 interlock allows the manual block of the NIS Source Range Neutron Flux reactor trip and allows the high voltage to be de-energized. This prevents a premature block of the source range trip and allows the operator to ensure that the intermediate range is OPERABLE prior to leaving the source range, and when the source range trip is blocked, the high voltage to the detectors is also removed;
- on decreasing power, the P-6 interlock automatically energizes the NIS source range detectors and enables the NIS Source Range Neutron Flux reactor trip; and
- on increasing power, the P-6 interlock provides a backup block signal to the source range flux doubling circuit. Normally, this function is manually blocked by the control room operator during the reactor startup.

The LCO requires two channels of Intermediate Range Neutron Flux, P-6 interlock to be OPERABLE in MODE 2 when below the P-6 interlock setpoint (1-out-of-2 coincidence).

Above the P-6 interlock setpoint, the NIS Source Range Neutron Flux reactor trip will be blocked, and this function will no longer be necessary.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

a. Intermediate Range Neutron Flux, P-6 (continued)

In MODE 3, 4, 5, or 6, the P-6 interlock does not have to be OPERABLE because the NIS Source Range is providing core protection.

b. Low Power Reactor Trips Block, P-7

The Low Power Reactor Trips Block, P-7 interlock is actuated by input from either the Power Range Neutron Flux, P-10, or the Turbine Impulse Pressure, P-13 interlock. The LCO requirement for the P-7 interlock ensures that the following Functions are performed:

(1) on increasing power, the P-7 interlock automatically enables reactor trips on the following Functions:

- Pressurizer Pressure-Low;
- Pressurizer Water Level-High;
- Reactor Coolant Flow-Low (Two Loops);
- RCPs Breaker Open (Two Loops);
- Undervoltage RCPs; and
- Underfrequency RCPs.

These reactor trips are only required when operating above the P-7 setpoint (approximately 10% power). The reactor trips provide protection against violating the DNBR limit. Below the P-7 setpoint, the RCS is capable of providing sufficient natural circulation without any RCP running.

(2) on decreasing power, the P-7 interlock automatically blocks reactor trips on the following Functions:

- Pressurizer Pressure-Low;

(continued)

BASES

APPLICABLE
SAFETY, ANALYSES,
LCO, and
APPLICABILITY

b. Low Power Reactor Trips Block, P-7 (continued)

- Pressurizer Water Level - High;
- Reactor Coolant Flow - Low (Two Loops);
- RCP Breaker Position (Two Loops);
- Undervoltage RCPs; and
- Underfrequency RCPs.

Trip Setpoint and Allowable Value are not applicable to the P-7 interlock because it is a logic Function and thus has no parameter with which to associate an LSSS. The P-7 train is operable if the P-10 and P-13 interlocks are in their required states based on plant conditions.

The P-7 interlock is a logic Function with train and not channel identity. Therefore, the LCO requires one channel per train of Low Power Reactor Trips Block, P-7 interlock to be OPERABLE in MODE 1 (1-out-of-2 coincidence).

The low power trips are blocked below the P-7 setpoint and unblocked above the P-7 setpoint. In MODE 2, 3, 4, 5, or 6, this Function does not have to be OPERABLE because the interlock performs its Function when power level drops below 10% power, which is in MODE 1.

c. Power Range Neutron Flux, P-8

The Power Range Neutron Flux, P-8 interlock is actuated at approximately 48-85% power as determined by two-out-of-four NIS power range detectors. The P-8 interlock automatically enables the Reactor Coolant Flow - Low (Single Loop) and RCP Breaker Position (Single Loop) reactor trips on low flow in one or more RCS loops on increasing power. The LCO requirement for this trip Function ensures that protection is provided against a loss of flow in any RCS loop that could result in DNB conditions in the core when greater than approximately 48-85% power. On decreasing

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

c. Power Range Neutron Flux, P-8 (continued)

power, the reactor trip on low flow in any loop is automatically blocked.

The LCO requires four channels of Power Range Neutron Flux, P-8 interlock to be OPERABLE in MODE 1.

In MODE 1, a loss of flow in one RCS loop could result in DNB conditions, so the Power Range Neutron Flux, P-8 interlock must be OPERABLE. In MODE 2, 3, 4, 5, or 6, this Function does not have to be OPERABLE because the core is not producing sufficient power to be concerned about DNB conditions.

d. Power Range Neutron Flux, P-9

The Power Range Neutron Flux, P-9 interlock is actuated at approximately less than or equal to 50% power as determined by two-out-of-four NIS power range detectors. The LCO requirement for this Function ensures that the Turbine Trip-Low Fluid Auto Stop Oil Pressure and Turbine Trip-Turbine Stop Valve Closure reactor trips are enabled above the P-9 setpoint. Above the P-9 setpoint, a turbine trip will may challenge the pressurizer PORVs due to the mismatch between reactor power and cause a load rejection beyond the capacity capacities of the Steam Dump and Reactor Control Systems. A reactor trip is automatically initiated on a turbine trip when it is above the P-9 setpoint, to minimize the transient on the reactor.

The LCO requires four~~three~~ channels of Power Range Neutron Flux, P-9 interlock to be OPERABLE in MODE 1 (~~2-out-of-3 coincidence~~).

~~In MODE 1, a turbine trip could cause a load rejection beyond the capacity of the Steam Dump System, so the Power Range Neutron Flux interlock must be OPERABLE. In MODE 2, 3, 4, 5, or 6, this Function does not have to be OPERABLE because the reactor is not at a power level sufficient to have a significant load rejection beyond the capacity capacities of the Steam Dump and Reactor Control Systems.~~

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

e. Power Range Neutron Flux, P-10

The Power Range Neutron Flux, P-10 interlock is actuated at approximately 10% power, as determined by two-out-of-four NIS power range detectors. If power level falls below 10% RTP on 3 of 4 channels, the nuclear instrument trips will be automatically unblocked. The LCO requirement for the P-10 interlock ensures that the following Functions are performed:

- on increasing power, the P-10 interlock allows the operator to manually block the Intermediate Range Neutron Flux reactor trip. Note that blocking the reactor trip also blocks the signal to prevent automatic and manual rod withdrawal;
- on increasing power, the P-10 interlock allows the operator to manually block the Power Range Neutron Flux-Low reactor trip;
- on increasing power, the P-10 interlock automatically provides a back up signal to block the Source Range Neutron Flux reactor trip, and also to de-energize the NIS source range detectors high voltage and allows manual block of the IR rod stop;
- the P-10 interlock provides one of the two inputs to the P-7 interlock; and
- on decreasing power, the P-10 interlock automatically enables the Power Range Neutron Flux-Low reactor trip and the Intermediate Range Neutron Flux reactor trip (and rod stop).
- on decreasing power, the P-10 interlock automatically defeats the block of the source range neutron flux trip and with P-6 energizes the source range high voltage.

The LCO requires ~~four~~ ^{three} channels of Power Range Neutron Flux, P-10 interlock to be OPERABLE in MODE 1 or 2 (~~2-out of 3~~).

OPERABILITY in MODE 1 ensures the Function is available to perform its decreasing power Functions in the event of a reactor shutdown. This Function must be OPERABLE in MODE 2 to ensure that core protection is provided during a

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

e. Power Range Neutron Flux, P-10 (continued)

startup or shutdown by the Power Range Neutron Flux-Low and Intermediate Range Neutron Flux reactor trips. In MODE 3, 4, 5, or 6, this Function does not have to be OPERABLE because the reactor is not at power and the Source Range Neutron Flux reactor trip provides core protection.

f. Turbine Impulse Chamber Pressure, P-13

The Turbine Impulse Chamber Pressure, P-13 interlock is actuated when the pressure in the first stage of the high pressure turbine is greater than approximately 10% of the rated full thermal power pressure equivalent. This interlock is determined by one-out-of-two pressure detectors. The LCO requirement for this Function ensures that one of the inputs to the P-7 interlock is available.

The LCO requires two channels of Turbine Impulse Chamber Pressure, P-13 interlock to be OPERABLE in MODE 1 (1-out-of-2 coincidence).

The Turbine Impulse Chamber Pressure, P-13 interlock must be OPERABLE when the turbine generator is operating. The interlock Function is not required OPERABLE in MODE 2, 3, 4, 5, or 6 because the turbine generator is not operating.

19. Reactor Trip Breakers

This trip Function applies to the RTBs exclusive of individual trip mechanisms. The LCO requires two OPERABLE trains of trip breakers. A trip breaker train consists of the trip logic and all trip breakers associated with a single RTS logic train that are racked in, closed, and capable of supplying power to the CRD Control Rod System. Thus, the train may consist of the main breaker, bypass breaker, or main breaker and bypass breaker, depending upon the system configuration. Two OPERABLE trains ensure no single random failure can disable the RTS trip capability.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

19. Reactor Trip Breakers (continued)

These trip Functions must be OPERABLE in MODE 1 or 2 when the reactor is critical (1-out-of-2 coincidence). In MODE 3, 4, or 5, these RTS trip Functions must be OPERABLE when the RTBs or associated bypass breakers are closed, and the GRD Control Rod System is capable of rod withdrawal or all rods are not fully inserted.

20. Reactor Trip Breaker Undervoltage and Shunt Trip Mechanisms

The LCO requires both the Undervoltage and Shunt Trip Mechanisms to be OPERABLE for each RTB that is in service. The trip mechanisms are not required to be OPERABLE for trip breakers that are open, racked out, incapable of supplying power to the GRD Rod Control System, or declared inoperable under Function 19 above. OPERABILITY of both trip mechanisms on each breaker ensures that no single trip mechanism failure will prevent opening any breaker on a valid signal.

These trip Functions must be OPERABLE in MODE 1 or 2 when the reactor is critical (1-out-of-2 coincidence). In MODE 3, 4, or 5, these RTS trip Functions must be OPERABLE when the RTBs and associated bypass breakers are closed, and the GRD Rod Control System is capable of rod withdrawal or all rods are not fully inserted.

21. Automatic Trip Logic

The LCO requirement for the RTBs (Functions 19 and 20) and Automatic Trip Logic (Function 21) ensures that means are provided to interrupt the power to allow the rods to fall into the reactor core. Each RTB is equipped with an undervoltage coil and a shunt trip coil to trip the breaker open when needed. Each RTB is equipped with a bypass breaker to allow testing of the trip breaker while the unit is at power. The reactor trip signals generated by the RTS Automatic Trip Logic cause the RTBs and associated bypass breakers to open and shut down the reactor.

The LCO requires two trains of RTS Automatic Trip Logic to be OPERABLE (1-out-of-2 coincidence). Having two OPERABLE channels ensures that random failure of a single logic channel will not prevent reactor trip.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
LCO, and
APPLICABILITY

21. Automatic Trip Logic (continued)

These trip Functions must be OPERABLE in MODE 1 or 2 when the reactor is critical. In MODE 3, 4, or 5, these RTS trip Functions must be OPERABLE when the RTBs and associated bypass breakers are closed, and the GRD Control Rod System is capable of rod withdrawal or all rods are not fully inserted.

22. Seismic Trip

The seismic trip system operates to shut down reactor operations should ground accelerations exceed a preset level in any two of the three orthogonal directions monitored (one vertical, two horizontal).

Three triaxial sensors (accelerometers) are anchored to the containment base in three separate locations 120 degrees apart. Each senses acceleration in three mutually orthogonal directions. Output signals are generated when ground accelerations exceed the preset level. These signals are transmitted to the Trains A and B Solid State Protection System (SSPS). If two of the three sensors in any direction produce simultaneous outputs, the logic produces trains A and B reactor trip signals.

The RTS instrumentation satisfies Criterion 3 of 10 CFR 50.36(c)(2)(ii) the NRC Policy Statement.

ACTIONS

A Note has been added to the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed in Table 3.3.1-1.

In the event a channel's Trip Setpoint is found nonconservative with respect to the Allowable Value, or the transmitter, instrument loop, signal processing electronics, or bistable is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the LCO Condition(s) entered for the protection Function(s) affected. When the Required Channels in Table 3.3.1-1 are specified (e.g., on a per steam line, per loop, per basis), then the Condition may be entered separately for each steam line, loop, SG, etc. as appropriate.

When the number of inoperable channels in a trip Function exceed those specified in one or other related Conditions associated with a trip Function, then the unit is outside the safety analysis. Therefore, LCO 3.0.3 must be immediately entered if applicable in the current MODE of operation.

~~Reviewer's Note: Certain LCO Completion Times are based on approved topical reports. In order for a licensee to use these times, the licensee must justify the Completion Times as required by the staff Safety Evaluation Report (SER) for the topical report.~~

(continued)

BASES

ACTIONS

A.1 (continued)

Condition A applies to all RTS protection Functions. Condition A addresses the situation where one or more required channels for one or more Functions are inoperable at the same time. The Required Action is to refer to Table 3.3.1-1 and to take the Required Actions for the protection functions affected. The Completion Times are those from the referenced Conditions and Required Actions.

B.1, B.2.1, and B.2.2

Condition B applies to the Manual Reactor Trip in MODE 1 or 2. This action addresses the train orientation of the SSPS for this Function. With one channel inoperable, the inoperable channel must be restored to OPERABLE status within 48 hours. In this Condition, the remaining OPERABLE channel is adequate to perform the safety function.

The Completion Time of 48 hours is reasonable considering that there are two automatic actuation trains and another manual initiation channel OPERABLE, and the low probability of an event occurring during this interval.

If the Manual Reactor Trip Function cannot be restored to OPERABLE status within the allowed 48 hour Completion Time, the unit must be brought to a MODE in which the requirement does not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 additional hours (54 hours total time) followed by opening the RTBs within 1 additional hour (55 hours total time). The 6 additional hours to reach MODE 3 and the 1 hour to open the RTBs are reasonable, based on operating experience, to reach MODE 3 and open the RTBs exit the applicability from full power operation in an orderly manner and without challenging unit systems. With the RTBs open and the unit in MODE 3, Condition C is entered if the Manual Reactor Trip Function has not been restored and the Rod Control System is capable of rod withdrawal or all rods are not fully inserted this trip Function is no longer required to be OPERABLE.

C.1 and C.2.1, and C.2.2

Condition C applies to the following reactor trip Functions in MODE 3, 4, or 5 with the RTBs closed and the CRD Rod Control System capable of rod withdrawal or all rods not fully inserted:

(continued)

BASES

ACTIONS

C.1 and C.2.1 and C.2.2 (continued)

- Manual Reactor Trip;
- RTBs;
- RTB Undervoltage and Shunt Trip Mechanisms; and
- Automatic Trip Logic.

This action addresses the train orientation of the SSPS for these Functions. With one channel or train inoperable, the inoperable channel or train must be restored to OPERABLE status within 48 hours. If the affected Function(s) cannot be restored to OPERABLE status within the allowed 48 hour Completion Time, the unit must be placed in a MODE in which the requirement does not apply. To achieve this status, the RTBs must be opened rods must be fully inserted and the Rod Control System rendered incapable of rod withdrawal within the next hour. The additional hour provides sufficient time to accomplish the action in an orderly manner. With the RTBs open, rods fully inserted and the Rod Control System rendered incapable of rod withdrawal, these Functions are no longer required.

The Completion Time is reasonable considering that in this Condition, the remaining OPERABLE train is adequate to perform the safety function, and given the low probability of an event occurring during this interval.

Condition C is modified by a Note stating that the transition from MODE 5 to MODE 5 with the Rod Control System capable of rod withdrawal or all rods not fully inserted is not permitted for Functions 19, 20, or 21. This Note specifies an exception to ECG 3.0.4 for this MODE 5 transition and avoids placing the plant in a condition where control rods can be withdrawn while the reactor trip system is degraded. This note is in addition to the requirements of ECG 3.0.4 which preclude the transition from either MODE 3 or MODE 4 to MODE 3 or MODE 4 with the Rod control System capable of rod withdrawal or all rods not fully inserted for Functions 19, 20, or 21 with one channel or train inoperable.

D.1.1, D.1.2, D.2.1, D.2.2, and D.3

Condition D applies to the Power Range Neutron Flux-High Function.

The NIS power range detectors provide input to the GRDRod Control System and the SG Water Level Control System and, therefore, have a two-out-of-four trip logic. A known inoperable channel must be placed in the tripped condition. This results in a partial trip condition requiring only one-out-of-three logic for actuation. The 6 hours allowed to place the inoperable channel in the tripped condition is justified in WCAP-10271-P-A (Ref. 7).

(continued)

BASES

ACTIONS

D.1.1, D.1.2, D.2.1, D.2.2, and D.3 (continued)

In addition to placing the inoperable channel in the tripped condition, THERMAL POWER must be reduced to $\leq 75\%$ RTP within 12 hours. Reducing the power level prevents operation of the core with radial power distributions beyond the design limits. With one of the NIS power range detectors inoperable, 1/4 of the radial power distribution monitoring capability is lost.

As an alternative to the above actions, the inoperable channel can be placed in the tripped condition within 6 hours and the QPTR monitored once every 12 hours as per SR 3.2.4.2, QPTR verification. Calculating QPTR every 12 hours compensates for the lost monitoring capability due to the inoperable NIS power range channel and allows continued unit operation at power levels $\geq 75\%$ RTP. The 6 hour Completion Time and the 12 hour Frequency are consistent with LCO 3.2.4, "QUADRANT POWER TILT RATIO (QPTR)."

As an alternative to the above Actions, the plant must be placed in a MODE where this Function is no longer required OPERABLE. Twelve hours are allowed to place the plant in MODE 3. This is a reasonable time, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging plant systems. If Required Actions cannot be completed within their allowed Completion Times, LCO 3.0.3 must be entered.

The Required Actions have been modified by a Note that allows placing the inoperable channel in the bypass condition for up to 4 hours while performing routine surveillance testing of other channels. The Note also allows placing the inoperable channel in the bypass condition to allow setpoint adjustments of other channels when required to reduce the setpoint in accordance with other Technical Specifications. The 4 hour time limit is justified in Reference 7.

Required Action D.2.2 has been modified by a Note which ~~only requires states that SR 3.2.4.2 is not required to be performed until 12 hours after input from one of the Power Range Neutron Flux channel input to QPTR becomes inoperable and thermal power is $> 75\%$ RTP.~~ Failure of a component in the Power Range Neutron Flux Channel which renders the High Flux Trip Function inoperable may not affect the capability to monitor QPTR. As such, determining QPTR using ~~this the~~ movable incore detectors once per 12 hours may not be necessary.

(continued)

BASES

ACTIONS
(continued)

E.1 and E.2

Condition E applies to the following reactor trip Functions:

- Power Range Neutron Flux—Low;
- Overtemperature ΔT ;
- Overpower ΔT ;
- Power Range Neutron Flux—High Positive Rate;
- Power Range Neutron Flux—High Negative Rate;
- Pressurizer Pressure—High; and
- SG Water Level—Low Low; and
- ~~SG Water Level—Low coincident with Steam Flow/Feedwater Flow Mismatch.~~

A known inoperable channel must be placed in the tripped condition within 6 hours. Placing the channel in the tripped condition results in a partial trip condition requiring only one-out-of-two logic for actuation of the two-out-of-three trips and one-out-of-three logic for actuation of the two-out-of-four trips. The 6 hours allowed to place the inoperable channel in the tripped condition is justified in Reference 7.

If the operable channel cannot be placed in the trip condition within the specified Completion Time, the unit must be placed in a MODE where these Functions are not required OPERABLE. An additional 6 hours is allowed to place the unit in MODE 3. Six hours is a reasonable time, based on operating experience, to place the unit in MODE 3 from full power in an orderly manner and without challenging unit systems.

The Required Actions have been modified by a Note that allows placing the inoperable channel in the bypassed condition for up to 4 hours while performing routine surveillance testing of the other channels. The Note also allows placing the inoperable channel in the bypass condition to allow setpoint adjustments of other channels when required to reduce the setpoint in accordance with other Technical Specifications. The 4 hour time limit is justified in Reference 7.

(continued)

BASESACTIONS
(continued)F.1 and F.2

Condition F applies to the Intermediate Range Neutron Flux trip when THERMAL POWER is above the P-6 setpoint and below the P-10 setpoint and one channel is inoperable. Above the P-6 setpoint and below the P-10 setpoint, the NIS intermediate range detector performs the monitoring Functions. If THERMAL POWER is greater than the P-6 setpoint but less than the P-10 setpoint, 24 hours is allowed to reduce THERMAL POWER below the P-6 setpoint or increase to THERMAL POWER above the P-10 setpoint. The NIS Intermediate Range Neutron Flux channels must be OPERABLE when the power level is above the capability of the source range, P-6, and below the capability of the power range, P-10. If THERMAL POWER is greater than the P-10 setpoint, the NIS power range detectors perform the monitoring and protection functions and the intermediate range is not required. The Completion Times allow for a slow and controlled power adjustment above P-10 or below P-6 and take into account the redundant capability afforded by the redundant OPERABLE channel, the overlap of the power range detectors, and the low probability of its failure during this period. This action does not require the inoperable channel to be tripped because the Function uses one-out-of-two logic. Tripping one channel would trip the reactor. Thus, the Required Actions specified in this Condition are only applicable when channel failure does not result in reactor trip.

G.1 and G.2

Condition G applies to two inoperable Intermediate Range Neutron Flux trip channels in MODE 2 when THERMAL POWER is above the P-6 setpoint and below the P-10 setpoint. Required Actions specified in this Condition are only applicable when channel failures do not result in reactor trip. Above the P-6 setpoint and below the P-10 setpoint, the NIS intermediate range detector performs the monitoring Functions. With no intermediate range channels OPERABLE, the Required Actions are to suspend operations involving positive reactivity additions immediately. This will preclude any power level increase since there are no OPERABLE Intermediate Range Neutron Flux channels. The operator must also reduce THERMAL POWER below the P-6 setpoint within two hours. Below P-6, the Source Range Neutron Flux channels will be able to monitor the core power

(continued)

BASES

ACTIONS

G.1 and G.2 (continued)

level. The Completion Time of 2 hours will allow a slow and controlled power reduction to less than the P-6 setpoint and takes into account the low probability of occurrence of an event during this period that may require the protection afforded by the NIS Intermediate Range Neutron Flux trip.

H.1

~~Condition H applies to the Intermediate Range Neutron Flux trip when THERMAL POWER is below the P-6 setpoint and one or two channels are inoperable. Below the P-6 setpoint, the NIS source range performs the monitoring and protection functions. The inoperable NIS intermediate range channel(s) must be returned to OPERABLE status prior to increasing power above the P-6 setpoint. The NIS intermediate range channels must be OPERABLE when the power level is above the capability of the source range, P-6, and below the capability of the power range, P-10.~~

I.1

Condition I applies to one inoperable Source Range Neutron Flux trip channel when in MODE 2, below the P-6 setpoint, and performing a reactor startup. With the unit in this Condition, below P-6, the NIS source range performs the monitoring and protection functions. With one of the two channels inoperable, operations involving positive reactivity additions shall be suspended immediately.

This will preclude any power escalation. With only one source range channel OPERABLE, core protection is severely reduced and any actions that add positive reactivity to the core must be suspended immediately.

J.1

Condition J applies to two inoperable Source Range Neutron Flux trip channels when in MODE 2, below the P-6 setpoint, and performing a reactor startup, or in MODE 3, 4, or 5 with the RTBs closed and the GRD Rod Control System capable of rod withdrawal or all rods not fully inserted. With the unit in this Condition, below P-6, the

(continued)

BASES

ACTIONS

J.1 (continued)

NIS source range performs the monitoring and protection functions. With both source range channels inoperable, the RTBs must be opened immediately. With the RTBs open, the core is in a more stable condition and the unit enters Condition L.

K.1 and K.2.1 and K.2.2

Condition K applies to one inoperable source range channel in MODE 3, 4, or 5 with the RTBs closed and the CRD Rod Control System capable of rod withdrawal or all rods not fully inserted. With the unit in this Condition, below P-6, the NIS source range performs the monitoring and protection functions. With one of the source range channels inoperable, 48 hours is allowed to restore it to an OPERABLE status. If the channel cannot be returned to an OPERABLE status, 1 additional hour is allowed to fully insert all rods and place the Rod Control System in a condition incapable of rod withdrawal to open the RTB. Once these ACTIONS are completed the RTBs are open the core is in a more stable condition, and the unit enters Condition L. The allowance of 48 hours to restore the channel to OPERABLE status, and the additional hour to open the RTBs, fully insert all rods and place the Rod Control System in a condition incapable of rod withdrawal, are justified in Reference 7.

L.1, L.2, and L.3

Condition L applies when the required number of OPERABLE Source Range Neutron Flux channels is not met in MODE 3, 4, or 5 with the RTBs open or with the Rod Control System incapable of rod withdrawal and all rods fully inserted. With the unit in this Condition, the NIS source range performs the monitoring and protection functions. With less than the required number of source range channels OPERABLE, operations involving positive reactivity additions shall be suspended immediately. This will preclude any power escalation. In addition to suspension of positive reactivity additions, all valves that could add unborated water to the RCS must be closed within 1 hour as specified in LCO 3.9.2. The isolation of unborated water sources will preclude a boron dilution accident.

Also, the SDM must be verified within 1 hour and once every 12 hours thereafter as per SR 3.1.1.1, SDM verification. With no source range channels OPERABLE, core protection is severely reduced. Verifying the SDM within 1 hour allows

(continued)

BASES

ACTIONS

L.1, L.2, and L.3 (continued)

sufficient time to perform the calculations and determine that the SDM requirements are met. The SDM must also be verified once per 12 hours thereafter to ensure that the core reactivity has not changed. Required Action L.1 precludes any positive reactivity additions; therefore, core reactivity should not be increasing, and a 12 hour Frequency is adequate. The Completion Times of within 1 hour and once per 12 hours are based on operating experience in performing the Required Actions and the knowledge that unit conditions will change slowly.

M.1 and M.2

Condition M applies to the following reactor trip Functions:

- Pressurizer Pressure - Low;
- Pressurizer Water Level - High;
- Reactor Coolant Flow - Low;
- RCP Breaker Position (~~Two Loops~~);
- Undervoltage RCPs; and
- Underfrequency RCPs.

With one channel inoperable, the inoperable channel must be placed in the tripped condition within 6 hours. Placing the channel in the tripped condition results in a partial trip condition requiring only one additional channel to initiate a reactor trip above the P-7 setpoint (~~above P-8 for the Reactor Coolant Flow-Low reactor trip function~~) ~~and below the P-8 setpoint~~. These Functions do not have to be OPERABLE below the P-7 setpoint because there are no loss of flow trips below the P-7 setpoint. The 6 hours allowed to place the channel in the tripped condition is justified in Reference 7. An additional 6 hours is allowed to reduce THERMAL POWER to below P-7 if the inoperable channel cannot be restored to OPERABLE status or placed in trip within the specified Completion Time. ~~The Reactor Coolant Flow - Low reactor trip function does not have to be OPERABLE below the P-8 setpoint; however, the Required Action must take the plant below the P-7 setpoint if an inoperable channel is not tripped within 6 hours, due to the shared components between this function and the Reactor Coolant Flow - Low trip function.~~

Allowance of this time interval takes into consideration the redundant capability provided by the remaining redundant

(continued)

BASES
ACTIONS

M.1 and M.2 (continued)

OPERABLE channel, and the low probability of occurrence of an event during this period that may require the protection afforded by the Functions associated with Condition M.

The Required Actions have been modified by a Note that allows placing the inoperable channel in the bypassed condition for up to 4 hours while performing routine surveillance testing of the other channels. The 4 hour time limit is justified in Reference 7.

N.1 and N.2

~~NOT USED~~

~~Condition N applies to the Reactor Coolant Flow Low (Single Loop) reactor trip Function. With one channel inoperable, the inoperable channel must be placed in trip within 6 hours. If the channel cannot be restored to OPERABLE status or the channel placed in trip within the 6 hours, then THERMAL POWER must be reduced below the P-8 setpoint within the next 4 hours. This places the unit in a MODE where the LCO is no longer applicable. This trip Function does not have to be OPERABLE below the P-8 setpoint because other RTS trip Functions provide core protection below the P-8 setpoint. The 6 hours allowed to restore the channel to OPERABLE status or place in trip and the 4 additional hours allowed to reduce THERMAL POWER to below the P-8 setpoint are justified in Reference 7.~~

~~The Required Actions have been modified by a Note that allows placing the inoperable channel in the bypassed condition for up to 4 hours while performing routine surveillance testing of the other channels. The 4 hour time limit is justified in Reference 7.~~

O.1 and O.2

~~NOT USED~~

~~Condition O applies to the RCP Breaker Position (Single Loop) reactor trip Function. There is one breaker position device per RCP breaker. With one channel inoperable, the inoperable channel must be restored to OPERABLE status within 6 hours. If the channel cannot be restored to OPERABLE status within the 6 hours, then THERMAL POWER must be reduced below the P-8 setpoint within the next 4 hours.~~

(continued)

BASES

ACTIONS

0.1 and 0.2 (continued)

~~This places the unit in a MODE where the LCO is no longer applicable. This Function does not have to be OPERABLE below the P-8 setpoint because other RTS Functions provide core protection below the P-8 setpoint. The 6 hours allowed to restore the channel to OPERABLE status and the 4 additional hours allowed to reduce THERMAL POWER to below the P-8 setpoint are justified in Reference 7. The Required Actions have been modified by a Note that allows placing the inoperable channel in the bypassed condition for up to 4 hours while performing routine surveillance testing of the other channels. The 4 hour time limit is justified in Reference 7.~~

P.1 and P.2

Condition P applies to Turbine Trip on Low Fluid Auto Stop Oil Pressure or on Turbine Stop Valve Closure. With one or more channels inoperable, the inoperable channel must be placed in the trip condition within 6 hours. If placed in the tripped condition, this results in a partial trip condition requiring for the Turbine Trip on Turbine Stop Valve Closure function, where four-of-four channels are required to initiate a reactor trip, hence more than one channel may be placed in trip. For the Turbine Trip on Low Auto Stop Oil Pressure function, if one channel is placed in trip, only one additional channel is required to initiate a reactor trip. If the channel cannot be restored to OPERABLE status or placed in the trip condition, then power must be reduced below the P-9 setpoint within the next 4 hours. The 6 hours allowed to place the inoperable channel in the tripped condition and the 4 hours allowed for reducing power are justified in Reference 7.

The Required Actions have been modified by a Note that allows placing the an inoperable Low Auto Stop Oil Pressure channel in the bypassed condition for up to 4 hours while performing routine surveillance testing of the other channels. The 4 hour time limit is justified in Reference 7.

Q.1 and Q.2

Condition Q applies to the SI Input from ESFAS reactor trip and the RTS Automatic Trip Logic in MODES 1 and 2. These actions address the train orientation of the RTS for these Functions. With one train inoperable, 6 hours are allowed to restore the train to OPERABLE status (Required Action Q.1) or the unit must be placed in MODE 3 within the

(continued)

BASES

ACTIONS

Q.1 and Q.2 (continued)

next 6 hours. The Completion Time of 6 hours (Required Action Q.1) is reasonable considering that in this Condition, the remaining OPERABLE train is adequate to perform the safety function and given the low probability of an event during this interval. The Completion Time of 6 hours (Required Action Q.2) is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging unit systems.

The Required Actions have been modified by a Note that allows bypassing one train up to [4] hours for surveillance testing, provided the other train is OPERABLE.

R.1 and R.2

Condition R applies to the RTBs in MODES 1 and 2. These actions address the train orientation of the RTS for the RTBs. With one train inoperable, 1 hour is allowed to restore the train to OPERABLE status or the unit must be placed in MODE 3 within the next 6 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging unit systems. The 1 hour and 6 hour Completion Times are equal to the time allowed by LCO 3.0.3 for shutdown actions in the event of a complete loss of RTS Function. Placing the unit in MODE 3 removes the requirement for this particular Function.

The Required Actions have been modified by ~~two~~ three Notes. Note 1 allows one ~~channel~~ RTB to be bypassed for up to 2 hours for surveillance testing or maintenance, provided the other ~~channel~~ train is OPERABLE. Note 2 allows one RTB to be bypassed ~~only for the time required for performing~~ for up to 2 hours for maintenance on undervoltage or shunt trip mechanisms per Condition U if the other RTB train is OPERABLE. Note 3 allows one RTB to be bypassed for up to 4 hours for logic surveillance testing per Condition Q provided the other train is OPERABLE. The ~~2-hour~~ time limits are ~~is~~ justified in Reference 7 ~~5~~ and 13.

S.1 and S.2

Condition S applies to the P-6 and P-10 interlocks. With one ~~or more required channels inoperable~~ for one out of two or ~~two out of four coincidence logic~~, the associated interlock must be verified by observation of the associated ~~permissive annunciator window~~ to be in its required state for the existing unit condition

(continued)

BASES

ACTIONS

S.1 and S.2 (continued)

within 1 hour or the unit must be placed in MODE 3 within the next 6 hours. Verifying the interlock status manually accomplishes the interlock's Function. The Completion Time of 1 hour is based on operating experience and the minimum amount of time allowed for manual operator actions. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging unit systems. The 1 hour and 6 hour Completion Times are equal to the time allowed by LCO 3.0.3 for shutdown actions in the event of a complete loss of RTS Function.

T.1 and T.2

Condition T applies to the P-7, P-8, P-9, and P-13 interlocks. With ~~one or more required channel(s) inoperable for one out of two or two out of four coincidence logic~~, the associated interlock must be ~~verified by observation of the associated permissive annunciator window to be in its required state for the existing unit condition~~ within 1 hour or the unit must be placed in MODE 2 within the next 6 hours. These actions are conservative for the case where power level is being raised. Verifying the interlock status manually accomplishes the interlock's Function. The Completion Time of 1 hour is based on operating experience and the minimum amount of time allowed for manual operator actions. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 2 from full power in an orderly manner and without challenging unit systems.

U.1, U.2.1, and U.2.2

Condition U applies to the RTB Undervoltage and Shunt Trip Mechanisms, or diverse trip features, in MODES 1 and 2. With one of the diverse trip features inoperable, it must be restored to an OPERABLE status within 48 hours or the unit must be placed in a MODE where the requirement does not apply. This is accomplished by placing the unit in MODE 3 within the next 6 hours (54 hours total time) ~~followed by opening the RTBs in 1 additional hour (55 hours total time)~~. The Completion Time of 6 hours is a reasonable time, based on operating experience, to reach MODE 3 from full power in an orderly manner and without challenging unit systems.

(continued)

BASES
ACTIONS

U.1, U.2.1, and U.2.2 (continued)

~~With the RTBs open and the unit in MODE 3, Condition C is entered if the inoperable trip mechanism has not been restored and the Rod Control System is capable of rod withdrawal or all rods are not fully inserted, this trip function is no longer required to be OPERABLE. The affected RTB shall not be bypassed while one of the diverse features is inoperable except for the time required to perform maintenance to restore the inoperable trip mechanism to OPERABLE status, consistent with Ref. 13, one of the diverse features. The allowable time for performing maintenance of the diverse features is 2 hours for the reasons stated under Condition R.~~

The Completion Time of 48 hours for Required Action U.1 is reasonable considering that in this Condition there is one remaining diverse feature for the affected RTB, and one OPERABLE RTB capable of performing the safety function and given the low probability of an event occurring during this interval.

V.1

NOT USED

~~With two RTS trains inoperable, no automatic capability is available to shut down the reactor, and immediate plant shutdown in accordance with LCO 3.0.3 is required.~~

W.1

~~Condition W applies to the Seismic Trip, in MODES 1 and 2. With one of the channels inoperable, START UP and/or POWER OPERATION may proceed provided the inoperable channel is placed in trip within the next 6 hours. If a direction is inoperable, then the channel must be considered inoperable. Placing the channel in the tripped condition creates a partial trip condition requiring only one out of two logic for actuation for that particular location.~~

~~The Required Actions have been modified by a Note that allows placing the inoperable channel in the bypassed condition for up to 72 hours while performing routine surveillance testing of the other channels. The allowed 72 hour bypass time is reasonable based on the low probability of an event occurring while the channel is bypassed and on the time required to perform the required surveillance testing.~~

X.1

~~Condition X applies to the Trip Time Delay (TTD) circuitry for the SFG Water Level-Low Low trip function when THERMAL POWER is less than or equal to 50% RTP in MODES 1 and 2. With one or more TTD circuitry delay timers inoperable, adjust the threshold power level for no time delay to 0% RTP, or place the affected SFG-low low level in trip. The Completion Time of 6 hours is based on Reference 7.~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

The SRs for each RTS Function are identified by the SRs column of Table 3.3.1-1 for that Function.

A Note has been added to the SR Table stating that Table 3.3.1-1 determines which SRs apply to which RTS Functions.

Note that each channel of process protection supplies both trains of the RTS. When testing Channel I, Train A and Train B must be examined. Similarly, Train A and Train B must be examined when testing Channel II, Channel III, and Channel IV (if applicable). The CHANNEL CALIBRATION and COTs are performed in a manner that is consistent with the assumptions used in analytically calculating the required channel accuracies.

~~Reviewer's Note: Certain Frequencies are based on approval topical reports. In order for a licensee to use these times, the licensee must justify the Frequencies as required by the staff SER for the topical report.~~

Performance of the CHANNEL CHECK once every 12 hours ensures that gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the unit staff based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit.

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.3.1.1

The Frequency is based on operating experience that demonstrates channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.1.2

SR 3.3.1.2 compares the calorimetric heat balance calculation to the NIS channel output output power indications every 24 hours. If the calorimetric exceeds the NIS channel output power indications by > 2% RTP, the NIS is not declared inoperable, but the score channel gains must be adjusted consistent with the calorimetric power. If

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.1.2 (continued)

the NIS channel ~~output power indications~~ cannot be properly adjusted, the channel is declared inoperable.

Two Notes modify SR 3.3.1.2. The first Note indicates that the NIS channel ~~output power indications~~ shall be adjusted consistent with the calorimetric results if the absolute difference between the NIS channel ~~output power indications~~ and the calorimetric is $> 2\%$ RTP. The second Note clarifies that this Surveillance is required only if reactor power is $\geq 15\%$ RTP and that ~~12~~ ~~24~~ hours is

~~allowed for performing the first Surveillance after reaching 15% RTP but prior to exceeding 30% RTP.~~ At lower power levels, calorimetric data are inaccurate.

The Frequency of every 24 hours is adequate. It is based on unit operating experience, considering instrument reliability and operating history data for instrument drift. Together these factors demonstrate the change in the absolute difference between NIS and heat balance calculated powers rarely exceeds 2% in any 24 hour period.

In addition, control room operators periodically monitor redundant indications and alarms to detect deviations in channel outputs.

SR 3.3.1.3

SR 3.3.1.3 compares the incore system to the NIS channel output every 31 EFPD. If the absolute difference is $\geq 3\%$, the NIS channel is still OPERABLE, but must be readjusted.

If the NIS channel cannot be properly readjusted, the channel is declared inoperable. This Surveillance is performed to verify the $f(\Delta I)$ input to the overtemperature ΔT Function.

Two Notes modify SR 3.3.1.3. Note 1 indicates that the excore NIS channel shall be adjusted if the absolute difference between the incore and excore AFD is $\geq 3\%$. Note 2 clarifies that the Surveillance is required only if reactor power is ~~$\geq 50\%$~~ ~~[15%]~~ RTP and that 24 hours is allowed for performing the first Surveillance after reaching ~~50%~~ ~~[15%]~~ RTP.

The Frequency of every 31 EFPD is adequate. It is based on unit operating experience, considering instrument reliability and operating history data for instrument drift. Also, ~~since the slow changes in neutron flux are slow during the fuel cycle can be detected during this interval, the expected change in the absolute difference between the incore and excore AFD will be less than 3 percent AFD during this interval.~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.3.1.4

SR 3.3.1.4 is the performance of a TADOT every 31 days on a STAGGERED TEST BASIS. This test shall verify OPERABILITY by actuation of the end devices.

The RTB test shall include separate verification of the undervoltage and shunt trip mechanisms. Independent verification of RTB undervoltage and shunt trip Function is not required for the bypass breakers. No capability is provided for performing such a test at power. The independent test for bypass breakers is included in SR 3.3.1.14. The bypass breaker test shall include a local manual shunt trip only. A Note has been added to indicate that this test must be performed on the bypass breaker prior to placing it in service.

The Frequency of every 31 days on a STAGGERED TEST BASIS is adequate. It is based on industry operating experience, considering instrument reliability and operating history data.

SR 3.3.1.5

SR 3.3.1.5 is the performance of an ACTUATION LOGIC TEST. The SSPS is tested every 31 days on a STAGGERED TEST BASIS, using the semiautomatic tester. The train being tested is placed in the bypass condition with the RTB bypass breaker installed, thus preventing inadvertent actuation. Through the semiautomatic tester, all possible logic combinations, with and without applicable permissives, are tested for each protection function including operation of the P-7 permissive which is a logic function only. The Frequency of every 31 days on a STAGGERED TEST BASIS is adequate. It is based on industry operating experience, considering instrument reliability and operating history data.

SR 3.3.1.6

SR 3.3.1.6 is a calibration of the excore channels to the incore channels. If the measurements do not agree, the excore channels are not declared inoperable but must be calibrated to agree with the incore detector measurements. If the excore channels cannot be adjusted, the channels are declared inoperable. This Surveillance is performed to verify the $f(\Delta I)$ input to the overtemperature ΔT Function.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.1.6 (continued)

A Note modifies SR 3.3.1.6. The Note states that this Surveillance is required only if reactor power is > 50 75% RTP and that ~~[24] hours after achieving equilibrium conditions with thermal power >75% RTP is allowed for performing the first surveillance after reaching 50 75% RTP.~~

The Frequency of 92 EFPD is adequate. It is based on industry operating experience, considering instrument reliability and operating history data for instrument drift.

SR 3.3.1.7

SR 3.3.1.7 is the performance of a COT every ~~[92]~~ days.

A COT is performed on each required channel to ensure the entire channel will perform the intended Function.

Setpoints must be within the Allowable Values specified in Table 3.3.1-1.

~~The difference between the current "as found" values and the previous test "as left" values must be consistent with the drift allowance used in the setpoint methodology. The setpoint shall be left set consistent with the assumptions of the current unit specific setpoint methodology trip setpoint value.~~

~~The "as found" and "as left" values must also be recorded and reviewed for consistency with the assumptions of Reference 7.~~

SR 3.3.1.7 is modified by two notes. a-Note 1 that provides a 4 hour delay in the requirement to perform this Surveillance for source range instrumentation when entering MODE 3 from MODE 2. This Note allows a normal shutdown to proceed without a delay for testing in MODE 2 and for a short time in MODE 3 until the RTBs are open and SR 3.3.1.7 is no longer required to be performed. If the unit is to be in MODE 3 with the RTBs closed for > 4 hours this Surveillance must be performed prior to 4 hours after entry into MODE 3. Note 2 requires that the quarterly COT for the source range instrumentation shall include verification by observation of the associated permissive annunciator window that the P-6 and P-10 interlocks are in their required state for the existing unit conditions.

The Frequency of ~~[92]~~ days is justified in Reference 7.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)SR 3.3.1.8

SR 3.3.1.8 is the performance of a COT as described in SR 3.3.1.7 except and it is modified by a the same Note that this test shall include verification that the P-6 and P-10 interlocks are in their required state for the existing unit conditions by observation of the associated permissive annunciator window. The Frequency is modified by a Note that allows this surveillance to be satisfied if it has been performed within 92 days of the Frequencies prior to reactor startup, 12 hours after reducing power below P-10 and four hours after reducing power below P-10 and P-6, as discussed below. The Frequency of "prior to startup" ensures this surveillance is performed prior to critical operations and applies to the source, intermediate and power range low instrument channels. The Frequency of "4 12 hours after reducing power below P-10" (applicable to intermediate and power range low channels) and "4 hours after reducing power below P-6" (applicable to source range channels) allows a normal shutdown to be completed and the unit removed from the MODE of Applicability for this surveillance without a delay to perform the testing required by this surveillance. The Frequency of every 92 days thereafter applies if the plant remains in the MODE of Applicability after the initial performances of prior to reactor startup, 12 hours after reducing power below P-10 and four hours after reducing power below P-10 or P-6. The MODE of Applicability for this surveillance is < P-10 for the power range low and intermediate range channels and < P-6 for the source range channels. Once the unit is in MODE 3, this surveillance is no longer required. If power is to be maintained < P-10 for more than 12 hours or < P-6 for more than 4 hours, then the testing required by this surveillance must be performed prior to the expiration of the 12 hour or 4 hour limit as applicable. Four hours is a reasonable time. These time limits are reasonable based on operating experience to complete the required testing or place the unit in a MODE where this surveillance is no longer required. This test ensures that the NIS source, intermediate, and power range low channels are OPERABLE prior to taking the reactor critical and after reducing power into the applicable MODE (< P-10 or < P-6) for the periods discussed above > 4 hours.

SR 3.3.1.9

SR 3.3.1.9 is the performance of a TADOT and is performed every [92] days, as justified in Reference 7.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.1.9 (continued)

The SR is modified by a Note that excludes verification of setpoints from the TADOT. Since this SR applies to RCP undervoltage and underfrequency relays, setpoint verification requires elaborate bench calibration and is accomplished during the CHANNEL CALIBRATION.

SR 3.3.1.10

A CHANNEL CALIBRATION is performed every ~~[18]~~ months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

CHANNEL CALIBRATIONS must be performed consistent with the assumptions of the unit specific DCCP setpoint methodology. ~~The difference between the current "as found" values and the previous test "as left" values must be consistent with the drift allowance used in the setpoint methodology.~~

The Frequency of ~~18~~ months is based on the ~~assumption of an 18-month assumed~~ calibration interval in the determination of the magnitude of equipment drift in the setpoint methodology.

SR 3.3.1.10 is modified by a Note stating that this test shall include verification that the time constants are adjusted to the prescribed values where applicable.

SR 3.3.1.11

SR 3.3.1.11 is the performance of a CHANNEL CALIBRATION, as described in SR 3.3.1.10, every ~~[18]~~ months. This SR is modified by ~~a few three~~ Notes stating Note 1 states that neutron detectors are excluded from the CHANNEL CALIBRATION. Note 2 states that the test shall include verification that the time constants are adjusted to the prescribed values where applicable. The CHANNEL CALIBRATION for the power range neutron detectors consists of a normalization of the detectors based on a power calorimetric and flux map performed above 15% RTP. The CHANNEL CALIBRATION for the source range ~~and intermediate range~~ neutron detectors consists of obtaining the detector

(continued)

BASES

SURVEILLANCE
REQUIREMENTSSR 3.3.1.11 (continued)

plateau or preamp discriminator curves, evaluating those curves, and comparing the curves to the manufacturer's data. For the intermediate range and power range channels, a test shall be performed that shows allowed variances of detector voltage do not effect detector operation. This Surveillance SR is also modified by Note 2.3 stating that this surveillance is not required to be performed until reactor power exceeds P-6 for the NIS power range detectors for entry into MODE 2 or 1, and is not required for the NIS intermediate range detectors for entry into MODE 2, because the unit must be in at least MODE 2 to perform the test for the intermediate range detectors and MODE 1 for the power range detectors. The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed on the [18] month Frequency. The source range plateau curves are obtained under the conditions that apply during a plant outage.

The 18 month Frequency is based on past operating experience, which has shown these components usually pass the Surveillance when performed on the 18 month Frequency. The conditions for obtaining the source range plateau curves and the power and intermediate range detector voltages are described above. The other remaining portions of the CHANNEL CALIBRATIONS may be performed either during a plant outage or during plant operation.

SR 3.3.1.12

SR 3.3.1.12 is the performance of a CHANNEL CALIBRATION of the seismic trip, as described in SR 3.3.1.10, every [18] months. This SR is modified by a Note stating that this test shall include verification of the RCS resistance temperature detector (RTD) bypass loop flow rate.

CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

This test will verify the rate lag compensation for flow from the core to the RTDs.

The Frequency is justified by the assumption of an 18 month calibration interval in the determination of the magnitude of equipment drift in the setpoint analysis.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.3.1.13

SR 3.3.1.13 is the performance of a COT of RTS interlocks every ~~18~~ months.

The Frequency is based on the known reliability of the interlocks and the multichannel redundancy available, and has been shown to be acceptable through operating experience.

SR 3.3.1.14

SR 3.3.1.14 is the performance of a TADOT of the Manual Reactor Trip, RCP Breaker Position, ~~Seismic Trip~~ and the SI Input from ESFAS. This TADOT is performed every ~~18~~ months. The test shall independently verify the OPERABILITY of the undervoltage and shunt trip mechanisms for the Manual Reactor Trip Function for the Reactor Trip Breakers and Reactor Trip Bypass Breakers. The Reactor Trip Bypass Breaker test shall include testing of the automatic undervoltage trip.

The Frequency is based on the known reliability of the Functions and the multichannel redundancy available, and has been shown to be acceptable through operating experience.

The SR is modified by a Note that excludes verification of setpoints from the TADOT. The Functions affected have no setpoints associated with them.

SR 3.3.1.15

SR 3.3.1.15 is the performance of a TADOT of Turbine Trip Functions. This TADOT is as described in SR 3.3.1.4, except that this test is performed prior to reactor startup. A Note states that this Surveillance is not required if it has been performed within the previous 31 days. Verification of the Trip Setpoint does not have to be performed for this Surveillance. Performance of this test will ensure that the turbine trip Function is OPERABLE prior to taking the reactor critical. This test cannot be performed with the reactor at power and must therefore be performed prior to reactor startup.

SR 3.3.1.16

SR 3.3.1.16 verifies that the individual channel/train actuation response times are less than or equal to the maximum values assumed in the accident analysis. Response time testing acceptance criteria are included in ~~Technical Requirements Manual, Section 15 (Ref. 8)~~ the FSAR (Ref. 1). Individual component response times are not modeled in the analyses.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.1.16 (continued)

The analyses model the overall or total elapsed time, from the point at which the parameter exceeds the trip setpoint value at the sensor to the point at which the equipment reaches the required functional state (i.e., control and shutdown rods fully inserted in the reactor core).

For channels that include dynamic transfer Functions (e.g., lag, lead/lag, rate/lag, etc.), the response time test may be performed with the transfer Function set to one, with the resulting measured response time compared to the appropriate FSAR response time. Alternately, the response time test can be performed with the time constants set to their nominal value, provided the required response time is analytically calculated assuming the time constants are set at their nominal values. The response time may be measured by a series of overlapping tests such that the entire response time is measured.

The response time testing for the SG water level low-low does not include trip time delays. Response times include the transmitters, Eagle-21 process protection cabinets, solid state protection system cabinets, and actuation devices only. This reflects the response times necessary for THERMAL POWER in excess of 50 percent RTP. For those functions without a specified response time, SR 3.3.1.16 is not applicable.

Response time may be verified by actual response time tests in any series of sequential, overlapping or total channel measurements, or by the summation of allocated sensor response times with actual response time tests on the remainder of the channel. Allocations for sensor response times may be obtained from: (1) historical records based on acceptable response time tests (hydraulic noise or power interrupt tests), (2) in-place, onsite, or offsite (e.g. vendor) test measurements, or (3) utilizing vendor engineering specifications. WCAP-13632 P-A Revision 2, "Elimination of Pressure Sensor Response Time Testing Requirements" (Ref. 8) provides the basis and methodology for using allocated sensor response times in the overall verification of the channel response time for specific sensors identified in the WCAP. Response time verification for other sensor types must be demonstrated by test.

The allocations for sensor response times must be verified prior to placing the component in operational service and re-verified following maintenance that may adversely affect response time. In general, electrical repair work does not impact response time provided the parts used for repair are of the same type and value. One example where response time could be affected is replacing the sensing assembly of a transmitter.

As appropriate, each channel's response time must be verified every [18] months on a STAGGERED TEST BASIS. Each verification shall include at least one train such that both trains are verified at least once per 36 months. Testing of the final actuation devices is included in the testing verification. Response times cannot be

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.1.16 (continued)

determined during unit operation because equipment operation is required to measure response times. Experience has shown that these components usually pass this surveillance when performed at the 18 month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

SR 3.3.1.16 is modified by a Note stating that neutron detectors are excluded from RTS RESPONSE TIME testing. This Note is necessary because of the difficulty in generating an appropriate detector input signal. Excluding the detectors is acceptable because the principles of detector operation ensure a virtually instantaneous response. Response time of the neutron flux signal portion of the channel shall be measured from detector output or input to the first electronic component in the channel.

SR 3.3.1.17

SR 3.3.1.5 is the performance of an ACTUATION LOGIC TEST for the Seismic trip. The frequency of every 18 months is based on instrument reliability and operating history data.

B 3.3 INSTRUMENTATION

B 3.3.2 Engineered Safety Feature Actuation System (ESFAS) Instrumentation

BASES

BACKGROUND The ESFAS initiates necessary safety systems, based on the values of selected unit parameters, to protect against violating core design limits and the Reactor Coolant System (RCS) pressure boundary, and to mitigate accidents.

The ESFAS instrumentation is segmented into three distinct but interconnected modules as identified below:

- Field transmitters or process sensors and instrumentation: provide a measurable electronic signal based on the physical characteristics of the parameter being measured;
- Signal processing equipment including analog digital protection system, field contacts, and protection channel sets: provide signal conditioning, bistable setpoint comparison, process algorithm actuation, compatible electrical signal output to protection system devices, and control board/control room/miscellaneous indications; and
- Solid State Protection System (SSPS) including input, logic, and output bays: initiates the proper unit shutdown or engineered safety feature (ESF) actuation in accordance with the defined logic and based on the bistable outputs from the signal process control and protection system.

Field Transmitters or Sensors

To meet the design demands for redundancy and reliability, more than one, and often as many as four, field transmitters or sensors are used to measure unit parameters. In many cases, field transmitters or sensors that input to the ESFAS are shared with the Reactor Trip System (RTS). In some cases, the same channels also provide control system inputs. To account for calibration tolerances and instrument drift, which are assumed to occur between calibrations, statistical allowances are provided in the Trip Setpoint and Allowable

(continued)

BASES

BACKGROUND

Field Transmitters or Sensors (continued)

Values. The OPERABILITY of each transmitter or sensor can be evaluated when its "as found" calibration data are compared against its documented acceptance criteria.

Signal Processing Equipment

Generally, three or four channels of process control equipment are used for the signal processing of unit parameters measured by the field instruments. The process control equipment provides signal conditioning, comparable output signals for instruments located on the main control board, and comparison of measured input signals with setpoints established by safety analyses. These setpoints are defined in FSAR, Chapter {6} (Ref. 1), Chapter {7} (Ref. 2), and Chapter {15} (Ref. 3). If the measured value of a unit parameter exceeds the predetermined setpoint, an output from a bistable is forwarded to the SSPS for decision evaluation. Channel separation is maintained up to and through the input bays. However, not all unit parameters require four channels of sensor measurement and signal processing. Some unit parameters provide input only to the SSPS, while others provide input to the SSPS, the main control board, the unit computer, and one or more control systems.

Generally, if a parameter is used only for input to the protection circuits, three channels with a two-out-of-three logic are sufficient to provide the required reliability and redundancy. If one channel fails in a direction that would not result in a partial Function trip, the Function is still OPERABLE with a two-out-of-two logic. If one channel fails such that a partial Function trip occurs, a trip will not occur and the Function is still OPERABLE with a one-out-of-two logic.

Generally, if a parameter is used for input to the SSPS and a control function, four channels with a two-out-of-four logic are sufficient to provide the required reliability and redundancy. In the case of the Digital Feedwater Control System (DFWCS), the median/signal select (MSS) feature prevents control/protection interaction even though there are only three inputs and 2-out-of-3 logic. The circuit must be able to withstand both an input failure to the control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function

(continued)

BASES

BACKGROUND

Signal Processing Equipment (continued)

actuation. Again, a single failure will neither cause nor prevent the protection function actuation.

These requirements are described in IEEE-279-1971 (Ref. 4). The actual number of channels required for each unit parameter is specified in Reference 2.

The channels are designed such that testing required to be performed at power may be accomplished without causing an ESF actuation.

Trip Setpoints and Allowable Values

The Trip Setpoints are the nominal values at which the bistables are set. Any bistable is considered to be properly adjusted when the "as left" value is within the band for CHANNEL CALIBRATION accuracy.

The Trip Setpoints used in the bistables are based on the analytical limits stated in Reference 2. The selection of these Trip Setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account. To allow for calibration tolerances, instrumentation uncertainties, instrument drift, and severe environment errors for those ESFAS channels that must function in harsh environments as defined by 10 CFR 50.49 (Ref. 5), the Trip Setpoints and Allowable Values specified in Table 3.3.2-1 in the accompanying LCO are conservatively adjusted with respect to the analytical limits. A detailed description of the methodology used to calculate the Trip Setpoints, including their explicit uncertainties, is provided in the "RTS/ESFAS Setpoint Methodology Study" Study" WCAP-11082, Rev. 2, "Westinghouse Setpoint Methodology for Protection Systems Diablo Canyon Station - Eagle 21 Version" May 1993 (Ref. 6). The actual nominal Trip Setpoint entered into the bistable is more conservative than that specified by the Allowable Value to account for changes in random measurement errors detectable by a COT. One example of such a change in measurement error is drift during the surveillance interval. If the measured setpoint does not exceed the Allowable Value, the bistable is considered OPERABLE.

Setpoints in accordance with the Allowable Value ensure that the consequences of Design Basis Accidents (DBAs) will be acceptable, providing the unit is operated from within the LCOs at the onset of the DBA and the equipment functions as designed.

(continued)

BASES

BACKGROUND

Trip Setpoints and Allowable Values (continued)

Each ~~Certain~~ channels can be tested on line to verify that the signal processing equipment and setpoint accuracy is within the specified allowance requirements of Reference 2. Once a designated channel is taken out of service for testing, a simulated signal is injected in place of the field instrument signal. The process equipment for the channel in test is then tested, verified, and calibrated. SRs for the channels are specified in the SR section.

The Trip Setpoints and Allowable Values listed in Table 3.3.2-1 are based on the methodology described in Reference 6, which incorporates all of the known uncertainties applicable for each channel. The magnitudes of these uncertainties are factored into the determination of each Trip Setpoint. All field sensors and signal processing equipment for these channels are assumed to operate within the allowances of these uncertainty magnitudes.

Solid State Protection System

The SSPS equipment is used for the decision logic processing of outputs from the signal processing equipment bistables. To meet the redundancy requirements, two trains of SSPS, each performing the same functions, are provided. If one train is taken out of service for maintenance or test purposes, the second train will provide ESF actuation for the unit. If both trains are taken out of service or placed in test, a reactor trip will result. Each train is packaged in its own cabinet for physical and electrical separation to satisfy separation and independence requirements.

The SSPS performs the decision logic for most ESF equipment actuation; generates the electrical output signals that initiate the required actuation; and provides the status, permissive, and annunciator output signals to the main control room of the unit.

The bistable outputs from the signal processing equipment are sensed by the SSPS equipment and combined into logic matrices that represent combinations indicative of various

(continued)

BASES

BACKGROUND

Solid State Protection System (continued)

transients. If a required logic matrix combination is completed, the system will send actuation signals via master and slave relays to those components whose aggregate Function best serves to alleviate the condition and restore the unit to a safe condition. Examples are given in the Applicable Safety Analyses, LCO, and Applicability sections of this Bases.

Each SSPS train has a built in testing device that can automatically test the decision logic matrix functions and the actuation devices while the unit is at power. When any one train is taken out of service for testing, the other train is capable of providing unit monitoring and protection until the testing has been completed. The testing device is semiautomatic to minimize testing time.

The actuation of ESF components is accomplished through master and slave relays. The SSPS energizes the master relays appropriate for the condition of the unit. Each master relay then energizes one or more slave relays, which then cause actuation of the end devices. The master and slave relays are routinely tested to ensure operation. The test of the master relays energizes the relay, which then operates the contacts and applies a low voltage to the associated slave relays. The low voltage is not sufficient to actuate the slave relays but only demonstrates signal path continuity. The SLAVE RELAY TEST actuates the devices if their operation will not interfere with continued unit operation. For the latter case, actual component operation is prevented by the SLAVE RELAY TEST circuit, and slave relay contact operation is verified by a continuity check of the circuit containing the slave relay. ~~For slave relays in the ESF actuation system circuit that are Potter & Brumfield type MDR relays, the SLAVE RELAY TEST is performed on a refueling frequency. The test frequency is based on relay reliability assessments presented in WCAP-13878 "Reliability Assessment of Potter and Brumfield MDR Series Relays," WCAP-13900 "Extension of Slave Relay Surveillance Test Intervals," and WCAP-14117, "Reliability Assessment of Potter and Brumfield MDR Series Relay." These reliability assessments are relay specific and apply only to Potter and Brumfield MDR series relays which are the only relays used in the ESF actuation system. Note that for normally energized applications, the relays may have to be replaced periodically in accordance with the guidance given in WCAP-13878 for MDR relays.~~

~~Reviewer's Note: No one unit ESFAS incorporates all of the Functions listed in Table 3.3.2-1. In some cases (e.g., Containment Pressure High 3, Function 2.c), the table reflects several different implementations of the same Function. Typically, only one of these implementations are used at any specific unit.~~

(continued)

BASES (continued)

APPLICABLE SAFETY ANALYSES, LCO, AND APPLICABILITY Each of the analyzed accidents can be detected by one or more ESFAS Functions. One of the ESFAS Functions is the primary actuation signal for that accident. An ESFAS Function may be the primary actuation signal for more than one type of accident. An ESFAS Function may also be a secondary, or backup, actuation signal for one or more other accidents. For example, Pressurizer Pressure-Low is a primary actuation signal for small loss of coolant accidents (LOCAs) and a backup actuation signal for steam line breaks (SLBs) outside containment. Functions such as manual initiation, not specifically credited in the accident safety analysis, are qualitatively credited in the safety analysis and the NRC staff approved licensing basis for the unit. These Functions may provide protection for conditions that do not require dynamic transient analysis to demonstrate Function performance. These Functions may also serve as backups to Functions that were credited in the accident analysis (Ref. 3).

The LCO requires all instrumentation performing an ESFAS Function to be OPERABLE. Failure of any instrument renders the affected channel(s) inoperable and reduces the reliability of the affected Functions.

The LCO generally requires OPERABILITY of four or three channels in each instrumentation function and two channels in each logic and manual initiation function. The two-out-of-three and the two-out-of-four configurations allow one channel to be tripped or bypassed during maintenance or testing without causing an ESFAS initiation. Two logic or manual initiation channels are required to ensure no single random failure disables the ESFAS.

The required channels of ESFAS instrumentation provide unit protection in the event of any of the analyzed accidents. ESFAS protection functions are as follows:

1. Safety Injection

Safety Injection (SI) provides two primary functions:

1. Primary side water addition to ensure maintenance or recovery of reactor vessel water level (coverage of the active fuel for heat removal, clad integrity, and for limiting peak clad temperature to < 2200°F); and

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

1. Safety Injection (continued)
2. Boration to ensure recovery and maintenance of SDM ($k_{eff} < 1.0$).

These functions are necessary to mitigate the effects of high energy line breaks (HELBs) both inside and outside of containment. The SI signal is also used to initiate other Functions such as:

- Phase A Isolation;
- Containment Purge ~~Ventilation~~ Isolation;
- Reactor Trip;
- Turbine Trip ~~from Reactor Trip with P-9;~~
- Feedwater Isolation ~~and Feedwater Pump Turbine Trip;~~
- Start of motor driven auxiliary feedwater (AFW) pumps;
- ~~Control room ventilation isolation; to pressurization mode; and Auxiliary Building to Building and Safeguards or safeguards only mode;~~
- ~~Enabling automatic switchover of Emergency Core Cooling Systems (ECCS) suction to containment sump.~~
- ~~Start the diesel generators (DGs) and transfer to the startup bus;~~
- ~~Start the containment fan cooler units (CFCUs) in low speed;~~
- ~~Start the component cooling water and auxiliary salt water pumps;~~
- ~~Input to containment spray pump and discharge valve auto start (with containment spray signal);~~
- ~~Isolate SG sample blowdown lines~~

These other functions ensure:

- Isolation of nonessential systems through containment penetrations;
- Trip of the turbine and reactor to limit power generation;
- Isolation of main feedwater (MFW) to limit secondary side mass losses;

(continued)

BASES

- Start of AFW to ensure secondary side cooling capability;

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

1. Safety Injection (continued)

- ~~Enabling ECCS suction from the refueling water storage tank (RWST) switchover on low low RWST level to ensure continued cooling via use of the containment sump.~~
- ~~Start the DGs to compensate for a possible loss of offsite power (LOCALDOP)~~
- ~~Start the components associated with the accident heat removal systems~~

a. Safety Injection-Manual Initiation

The LCO requires one channel per train to be OPERABLE. The operator can initiate SI at any time by using either of two switches in the control room. This action will cause actuation of all components in the same manner as any of the automatic actuation signals.

The LCO for the Manual Initiation Function ensures the proper amount of redundancy is maintained in the manual ESFAS actuation circuitry to ensure the operator has manual ESFAS initiation capability.

Each channel consists of one ~~push-button control switch~~ and the interconnecting wiring to the actuation logic cabinet. Each ~~push-button control switch~~ actuates both trains. This configuration does not allow testing at power.

b. Safety Injection-Automatic Actuation Logic and Actuation Relays

This LCO requires two trains to be OPERABLE. Actuation logic consists of all circuitry housed within the actuation subsystems, including the initiating relay contacts responsible for actuating the ESF equipment.

Manual and automatic initiation of SI must be OPERABLE in MODES 1, 2, and 3. In these MODES, there is sufficient energy in the primary and secondary systems to warrant automatic initiation of ESF systems. Manual Initiation is also required in MODE 4 even though automatic actuation is not required. In this MODE, adequate time is available to manually actuate required components in the event of a DBA, but

(continued)

BASES

APPLICABLE

SAFETY ANALYSES,
LCO, and
APPLICABILITY

b. Safety Injection-Automatic Actuation Logic and Actuation Relays
(continued)

because of the large number of components actuated on a SI, actuation is simplified by the use of the manual actuation push-buttons control switches. Automatic actuation logic and actuation relays must be OPERABLE in MODE 4 to support system level manual initiation.

These Functions are not required to be OPERABLE in MODES 5 and 6 because there is adequate time for the operator to evaluate unit conditions and respond by manually starting individual systems, pumps, and other equipment to mitigate the consequences of an abnormal condition or accident. Unit pressure and temperature are very low and many ESF components are administratively locked out or otherwise prevented from actuating to prevent inadvertent overpressurization of unit systems.

c. Safety Injection-Containment Pressure-High \pm

This signal provides protection against the following accidents:

- SLB inside containment;
- LOCA; and
- Feed line break inside containment.

Containment Pressure-High \pm provides no input to any control functions. Thus, three OPERABLE channels are sufficient to satisfy protective requirements with a two-out-of-three logic. The transmitters (d/p cells) and electronics are located outside of containment with the sensing line (high pressure side of the transmitter) located inside containment.

Thus, the high pressure Function will not experience any adverse environmental conditions and the Trip Setpoint reflects only steady state instrument uncertainties.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

c. Safety Injection - Containment Pressure - High \pm
(continued)

Containment Pressure - High \pm must be OPERABLE in MODES 1, 2, 3 and 4 when there is sufficient energy in the primary and secondary systems to pressurize the containment following a pipe break. In MODES 4, 5, and 6, there is insufficient energy in the primary or secondary systems to pressurize the containment.

d. Safety Injection - Pressurizer Pressure - Low

This signal provides protection against the following accidents:

- Inadvertent opening of a steam generator (SG) relief or safety valve;
- SLB;
- A spectrum of rod cluster control assembly ejection accidents (rod ejection);
- Inadvertent opening of a pressurizer relief or safety valve;
- LOCAs; and
- SG Tube Rupture.

~~At some units Pressurizer pressure provides both control and protection functions: input to the Pressurizer Pressure Control System, reactor trip, and SI. Therefore, the actuation logic must be able to withstand both an input failure to control system, which may then require the protection function actuation, and a single failure in the other channels providing the protection function actuation. Thus, four OPERABLE channels are required to satisfy the requirements with a two-out-of-four logic. For units that have dedicated protection and control channels, only three protection channels are necessary to satisfy the protective requirements.~~

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

d. Safety Injection - Pressurizer Pressure - Low
(continued)

The transmitters are located inside containment, with the taps in the vapor space region of the pressurizer, and thus possibly experiencing adverse environmental conditions (LOCA, SLB inside containment, rod ejection). Therefore, the Trip Setpoint reflects the inclusion of both steady state and adverse environmental instrument uncertainties.

This Function must be OPERABLE in MODES 1, 2, and 3 (above P-11) to mitigate the consequences of an HELB inside containment. This signal may be manually blocked by the operator below the P-11 setpoint. Automatic SI actuation below this pressure setpoint is then performed by the Containment Pressure - High \pm signal.

This Function is not required to be OPERABLE in MODE 3 below the P-11 setpoint. Other ESF functions are used to detect accident conditions and actuate the ESF systems in this MODE. In MODES 4, 5, and 6, this Function is not needed for accident detection and mitigation.

e. Safety Injection - Steam Line Pressure

(1) Steam Line Pressure - Low

Steam Line Pressure - Low provides protection against the following accidents:

- SLB;
- Feed line break; and
- Inadvertent opening of an SG relief or an SG safety valve.

Steam Line Pressure - Low provides an input to the DFACS any-control functions. The MSS function prevents the excursion of one of the inputs from causing a process disturbance that would require protective action from the remaining channels on the affected steam line. Thus, three OPERABLE channels on each steam line are sufficient to satisfy the protective

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

(1) Steam Line Pressure - Low (continued)

requirements with a two-out-of-three logic on each steam line.

With the ~~some~~ transmitters typically located inside the steam tunnels penetration area, it is possible for them to experience adverse environmental conditions during a secondary side break. Therefore, the Trip Setpoint reflects both steady state and adverse environmental instrument uncertainties.

This Function is anticipatory in nature and has a typical lead/lag ratio of 50/5.

Steam Line Pressure - Low must be OPERABLE in MODES 1, 2, and 3 (above P-11) when a secondary side break or stuck open valve could result in the rapid depressurization of the steam lines. This signal may be manually blocked by the operator below the P-11 setpoint. Below P-11, feed line break is not a concern. Inside containment SLB will be terminated by automatic SI actuation via Containment Pressure - High \pm , and outside containment SLB will be terminated by the Steam Line Pressure - Negative Rate - High signal for steam line isolation. This Function is not required to be OPERABLE in MODE 4, 5, or 6 because there is insufficient energy in the secondary side of the unit to cause an accident.

(2) ~~NOT USED~~

~~Steam Line Pressure - High Differential Pressure Between Steam Lines~~

~~Steam Line Pressure - High Differential Pressure Between Steam Lines provides protection against the following accidents:~~

(2) ~~Steam Line Pressure High Differential
Pressure Between Steam Lines~~ (continued)

- ~~Inadvertent opening of an SG relief or an SG safety valve.~~

~~Steam Line Pressure High Differential Pressure Between Steam Lines provides no input to any control functions. Thus, three OPERABLE channels on each steam line are sufficient to satisfy the requirements, with a two out of three logic on each steam line.~~

~~With the transmitters typically located inside the steam tunnels, it is possible for them to experience adverse environmental conditions during an SLB event. Therefore, the Trip Setpoint reflects both steady state and adverse environmental instrument uncertainties. Steam line high differential pressure must be OPERABLE in MODES 1, 2, and 3 when a secondary side break or stuck open valve could result in the rapid depressurization of the steam line(s). This function is not required to be OPERABLE in MODE 4, 5, or 6 because there is not sufficient energy in the secondary side of the unit to cause an accident.~~

f. g.

~~NOT USED~~

~~Safety Injection High Steam Flow in Two Steam Lines Coincident With T_{avg} Low Low or Coincident With Steam Line Pressure Low~~

~~These Functions (1.f and 1.g) provide protection against the following accidents:~~

- ~~SLB; and~~
- ~~the inadvertent opening of an SG relief or an SG safety valve.~~

~~Two steam line flow channels per steam line are required OPERABLE for these functions. The steam line flow channels are combined in a one out of~~

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

f. g. ~~Safety Injection High Steam Flow in Two Steam Lines Coincident With T_{avg} Low Low or Coincident With Steam Line Pressure Low~~ (continued)

~~two logic to indicate high steam flow in one steam line. The steam flow transmitters provide control inputs, but the control function cannot cause the events that the Function must protect against. Therefore, two channels are sufficient to satisfy redundancy requirements. The one out of two configuration allows online testing because trip of one high steam flow channel is not sufficient to cause initiation. High steam flow in two steam lines is acceptable in the case of a single steam line fault due to the fact that the remaining intact steam lines will pick up the full turbine load. The increased steam flow in the remaining intact lines will actuate the required second high steam flow trip. Additional protection is provided by Function 1.e.(2), High Differential Pressure Between Steam Lines.~~

~~One channel of T_{avg} per loop and one channel of low steam line pressure per steam line are required OPERABLE. For each parameter, the channels for all loops or steam lines are combined in a logic such that two channels tripped will cause a trip for the parameter. For example, for three loop units, the low steam line pressure channels are combined in two out of three logic. Thus, the Function trips on one out of two high flow in any two out of three steam lines if there is one out of one low low T_{avg} trip in any two out of three RCS loops, or if there is a one out of one low pressure trip in any two out of three steam lines. Since the accidents that this event protects against cause both low steam line pressure and low low T_{avg} , provision of one channel per loop or steam line ensures no single random failure can disable both of these Functions. The steam line pressure channels provide no control inputs. The T_{avg} channels provide control inputs, but the control function cannot initiate events that the Function acts to mitigate.~~

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

f. g. ~~Safety Injection High Steam Flow in Two Steam Lines Coincident With T_{avg} Low Low or Coincident With Steam Line Pressure Low~~

~~The Allowable Value for high steam flow is a linear function that varies with power level. The function is a ΔP corresponding to 44% of full steam flow between 0% and 20% load to 114% of full steam flow at 100% load. The nominal trip setpoint is similarly calculated.~~

~~With the transmitters typically located inside the containment (T_{avg}) or inside the steam tunnels (High Steam Flow), it is possible for them to experience adverse steady state environmental conditions during an SLB event. Therefore, the Trip Setpoint reflects both steady state and adverse environmental instrument uncertainties. The Steam Line Pressure Low signal was discussed previously under Function 1.e.(1).~~

~~This Function must be OPERABLE in MODES 1, 2, and 3 (above P 12) when a secondary side break or stuck open valve could result in the rapid depressurization of the steam line(s). This signal may be manually blocked by the operator when below the P 12 setpoint. Above P 12, this Function is automatically unblocked. This Function is not required OPERABLE below P 12 because the reactor is not critical, so feed line break is not a concern. SLB may be addressed by Containment Pressure High 1 (inside containment) or by High Steam Flow in Two Steam Lines coincident with Steam Line Pressure Low, for Steam Line Isolation, followed by High Differential Pressure Between Two Steam Lines, for SI. This Function is not required to be OPERABLE in MODE 4, 5, or 6 because there is insufficient energy in the secondary side of the unit to cause an accident.~~

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

2. Containment Spray

Containment Spray coincident with an SI signal provides three primary functions:

1. Lowers containment pressure and temperature after an HELB in containment;
2. Reduces the amount of radioactive iodine in the containment atmosphere; and
3. Adjusts the pH of the water in the containment recirculation sump after a large break LOCA.

These functions are necessary to:

- Ensure the pressure boundary integrity of the containment structure;
- Limit the release of radioactive iodine to the environment in the event of a failure of the containment structure; and
- Minimize corrosion of the components and systems inside containment following a LOCA.

The containment spray actuation signal coincident with SI starts the containment spray pumps and aligns the discharge of the pumps to the containment spray nozzle headers in the upper levels of containment. Water is initially drawn from the RWST by the containment spray pumps and mixed with a sodium hydroxide solution from the spray additive tank. When the RWST reaches the low level setpoint, the spray pumps suction are manually tripped and spray flow can then be shifted to the containment sump RHR system if continued containment spray is required. Containment spray is actuated manually by Containment Pressure High 3 or Containment Pressure - High High coincident with an SI signal.

a. Containment Spray - Manual Initiation

The operator can manually initiate containment spray at any time from the control room if an SI signal is present by simultaneously turning ~~two~~ both Containment Isolation Phase "B" / containment spray actuation Actuate Trains A & B switches in the same train. Because an inadvertent actuation of containment spray could have such serious consequences, two switches must be turned

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and

a. Containment Spray—Manual Initiation (continued)

~~simultaneously and an SI signal must be present to initiate APPLICABILITY containment spray. There are two sets of two switches each in the control room. Simultaneously turning the two switches in either set will actuate containment spray in both trains in the same manner as the automatic actuation signal. Two Manual Initiation switches in each train are required to be OPERABLE. to ensure no single failure disables the Manual Initiation Function. Note that Manual Initiation of containment spray also actuates Phase B containment isolation and CVI.~~

b. Containment Spray—Automatic Actuation Logic and Actuation Relays

Automatic actuation logic and actuation relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b.

Manual and automatic initiation of containment spray must be OPERABLE in MODES 1, 2, 3, and 4 when there is a potential for an accident to occur, and sufficient energy in the primary or secondary systems to pose a threat to containment integrity due to overpressure conditions. Manual initiation is also required in MODE 4, even though automatic actuation is not required. In this MODE, adequate time is available to manually actuate required components in the event of a DBA. However, because of the large number of components actuated on a containment spray, actuation is simplified by the use of the manual actuation push buttons. Automatic actuation logic and actuation relays must be OPERABLE in MODE 4 to support system level manual initiation. In MODES 5 and 6, there is insufficient energy in the primary and secondary systems to result in containment overpressure. In MODES 5 and 6, there is also adequate time for the operators to evaluate unit conditions and respond, to mitigate the consequences of abnormal conditions by manually starting individual components.

c. Containment Spray - Containment Pressure

This signal provides protection against a LOCA or an SLB inside containment. The transmitters (d/p cells) are located outside of containment with the sensing line (high pressure side of the transmitter) located inside containment. The transmitters and electronics are located outside of containment. Thus, they will not experience any adverse environmental conditions and the Trip Setpoint reflects only steady state instrument uncertainties.

This is one of the only Functions that requires the bistable output to energize to perform its required action. It is not desirable to have a loss of power actuate containment spray, since the consequences of an inadvertent actuation of containment spray could be serious. Note that this Function also has the inoperable channel placed in bypass rather than trip to decrease the probability of an inadvertent actuation.

~~Two different logic configurations are typically used. Three and four loop units use four channels in a two-out-of-four logic configuration. This configuration may be called the Containment Pressure - High 3 Setpoint for three and four loop units, and Containment Pressure - High High Setpoint for other units. Some two loop units use three sets of two channels, each set combined in a one out of two configuration, with these outputs combined so that two out of three sets tripped initiates containment spray. This configuration is called Containment Pressure - High 3 Setpoint. Since containment pressure is not used for control, both of these arrangements exceed the minimum redundancy requirements. Additional redundancy is warranted because this Function is energize to trip. Containment Pressure - [High 3] [High High] must be OPERABLE in MODES 1, 2, 3 and 4 when there is sufficient energy in the primary and secondary sides to pressurize the containment following a pipe break. In MODES 4, 5, and 6, there is insufficient energy in the primary and secondary~~

c. Containment Spray - Containment Pressure
(continued)

sides to pressurize the containment and reach the
Containment Pressure - ~~High-3~~ (High High) setpoints.

3. Containment Isolation

Containment Isolation provides isolation of the containment atmosphere, and all process systems that penetrate containment, from the environment. This function is necessary to prevent or limit the release of radioactivity to the environment in the event of a large break LOCA.

There are two separate Containment Isolation signals, Phase A and Phase B. Phase A isolation isolates all automatically isolable process lines, except component cooling water (CCW), at a relatively low containment pressure indicative of primary or secondary system leaks. For these types of events, forced circulation cooling using the reactor coolant pumps (RCPs) and SGs is the preferred (but not required) method of decay heat removal. Since CCW is required to support RCP operation, not isolating CCW on the low pressure Phase A signal enhances unit safety by allowing operators to use forced RCS circulation to cool the unit. Isolating CCW on the low pressure signal may force the use of feed and bleed cooling, which could prove more difficult to control.

Phase A containment isolation is actuated automatically by SI, or manually via the automatic actuation logic. All process lines penetrating containment, with the exception of CCW, are isolated. CCW is not isolated at this time to permit continued operation of the RCPs with cooling water flow to the thermal barrier heat exchangers and ~~air~~ oil coolers. All process lines not equipped with remote operated isolation valves are manually closed, or otherwise isolated, prior to reaching MODE 4.

Manual Phase A Containment Isolation is accomplished by either of two switches in the control room. Either switch actuates both trains. Note that manual

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

3. Containment Isolation (continued)

actuation of Phase A Containment Isolation also actuates Containment ~~Purge and Exhaust Ventilation~~ Isolation.

The Phase B signal isolates CCW. This occurs at a relatively high containment pressure that is indicative of a large break LOCA or an SLB. For these events, forced circulation using the RCPs is no longer desirable. Isolating the CCW at the higher pressure does not pose a challenge to the containment boundary because the CCW System is a closed loop inside containment. Although some system components do not meet all of the ASME Code requirements applied to the containment itself, the system is continuously pressurized to a pressure greater than the Phase B setpoint. Thus, routine operation demonstrates the integrity of the system pressure boundary for pressures exceeding the Phase B setpoint. Furthermore, because system pressure exceeds the Phase B setpoint, any system leakage prior to initiation of Phase B isolation would be into containment. Therefore, the combination of CCW System design and Phase B isolation ensures the CCW System is not a potential path for radioactive release from containment.

Phase B containment isolation is actuated by ~~Containment Pressure High 3~~ or Containment Pressure-High High, or manually, via the automatic actuation logic, as previously discussed. For containment pressure to reach a value high enough to actuate ~~Containment Pressure High 3~~ or Containment Pressure-High High, a large break LOCA or SLB must have occurred and containment spray must have been actuated. RCP operation will no longer be required and CCW to the RCPs is, therefore, no longer necessary. The RCPs can be operated with seal injection flow alone and without CCW flow to the thermal barrier heat exchanger.

Manual Phase B Containment Isolation is accomplished by the same switches that actuate Containment Spray. When the two switches ~~in either set~~ are ~~turned~~ operated simultaneously, Phase B Containment Isolation and Containment Spray will be actuated in both trains.

(continued)

a. Containment Isolation - Phase A Isolation

(1) Phase A Isolation - Manual Initiation

Manual Phase A Containment Isolation is actuated by either of two switches in the control room. Either switch actuates both trains. Note that manual initiation of Phase A Containment Isolation also actuates Containment Purge Ventilation Isolation.

(2) Phase A Isolation - Automatic Actuation Logic and Actuation Relays

Automatic Actuation Logic and Actuation Relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b.

Manual and automatic initiation of Phase A Containment Isolation must be OPERABLE in MODES 1, 2, 3 and 4, when there is a potential for an accident to occur. Manual initiation is also required in MODE 4 even though automatic actuation is not required. In this MODE, adequate time is available to manually actuate required components in the event of a DBA, but because of the large number of components actuated on a Phase A Containment Isolation, actuation is simplified by the use of the manual actuation push buttons. Automatic actuation logic and actuation relays must be OPERABLE in MODE 4 to support system level manual initiation. In MODES 5 and 6, there is insufficient energy in the primary or secondary systems to pressurize the containment to require Phase A Containment Isolation. There also is adequate time for the operator to evaluate unit conditions and manually actuate individual isolation valves in response to abnormal or accident conditions.

(3) Phase A Isolation - Safety Injection

Phase A Containment Isolation is also initiated by all Functions that initiate SI. The Phase A Containment Isolation

(continued)

requirements for these Functions are the same as the requirements for their SI function. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead, Function 1, SI, is referenced for all initiating Functions and requirements.

b. Containment Isolation-Phase B Isolation

Phase B Containment Isolation is accomplished by Manual Initiation, Automatic Actuation Logic and Actuation Relays, and by Containment Pressure channels (the same channels that actuate Containment Spray, Function 2). The Containment Pressure trip of Phase B Containment Isolation is energized to trip in order to minimize the potential of spurious trips that may damage the RCPs.

(1) Phase B Isolation-Manual Initiation

(2) Phase B Isolation-Automatic Actuation Logic and Actuation Relays

Manual and automatic initiation of Phase B containment isolation must be OPERABLE in MODES 1, 2, and 3, and 4 when there is a potential for an accident to occur. ~~Manual initiation is also required in MODE 4 even though automatic actuation is not required. In this MODE, adequate time is available to manually actuate required components in the event of a DBA. However, because of the large number of components actuated on a Phase B containment isolation, actuation is simplified by the use of the manual actuation push buttons switches. Automatic actuation logic and actuation relays must be OPERABLE in MODE 4 to support system level manual initiation. In MODES 5 and 6, there is insufficient energy in the primary or secondary systems to pressurize the containment to require Phase B containment~~

isolation. There also is adequate time for the operator to evaluate unit conditions and manually actuate individual isolation valves in response to abnormal or accident conditions.

- (3) Phase B Isolation - Containment Pressure

The basis for containment pressure MODE applicability is as discussed for ESFAS Function 2.c above.

4. Steam Line Isolation

Isolation of the main steam lines provides protection in the event of an SLB inside or outside containment. Rapid isolation of the steam lines will limit the steam break accident to the blowdown from one SG, at most. For an SLB upstream of the main steam isolation valves (MSIVs), inside or outside of containment, closure of the MSIVs limits the accident to the blowdown from only the affected SG. For an SLB downstream of the MSIVs, closure of the MSIVs terminates the accident as soon as the steam lines depressurize. ~~For units that do not have steam line check valves, Steam Line Isolation also mitigates the effects of a feed line break and ensures a source of steam for the turbine driven AFW pump during a feed line break.~~

a. Steam Line Isolation - Manual Initiation

Manual initiation of Steam Line Isolation can be accomplished from the control room ~~via an individual switch on each valve. There are two switches in the control room and either switch can initiate action to immediately close all MSIVs.~~ The LCO requires two ~~one~~ channels ~~per valve~~ to be OPERABLE.

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

b. Steam Line Isolation - Automatic Actuation Logic and Actuation Relays

Automatic actuation logic and actuation relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b.

Manual and automatic initiation of steam line isolation must be OPERABLE in MODES 1, 2, and 3 when there is sufficient energy in the RCS and SGs to have an SLB or other accident. This could result in the release of significant quantities of energy and cause a cooldown of the primary system. The Steam Line Isolation Function is required in MODES 2 and 3 unless all MSIVs are closed and ~~deactivated~~. In MODES 4, 5, and 6, there is insufficient energy in the RCS and SGs to experience an SLB or other accident releasing significant quantities of energy.

c. Steam Line Isolation - Containment Pressure - High 2 High

This Function actuates closure of the MSIVs in the event of a LOCA or an SLB inside containment to ~~maintain at least one unfaulted SG as a heat sink for the reactor, and to limit the mass and energy release to containment to a single SG.~~ The transmitters (d/p cells) are located outside containment with the sensing line (high pressure side of the transmitter) located inside containment. Containment Pressure - High 2 ~~High~~ provides no input to any control functions. Thus, three OPERABLE channels are sufficient to satisfy protective requirements with two-out-of-three logic. However, for enhanced reliability, this Function was designed with four channels and a two-out-of-four logic. The transmitters and electronics are located outside of containment. Thus, they will not experience any adverse environmental conditions, and the Trip Setpoint reflects only steady state instrument uncertainties.

Containment Pressure - High 2 ~~High~~ must be OPERABLE in MODES 1, 2, and 3, when there is sufficient energy in the primary and secondary side to pressurize the containment following a pipe

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

c. Steam Line Isolation—Containment Pressure—High 2
(continued)

break. This would cause a significant increase in the containment pressure, thus allowing detection and closure of the MSIVs. The Steam Line Isolation Function remains OPERABLE in MODES 2 and 3 unless all MSIVs are closed and ~~de-activated~~. ~~The actions~~ are taken to assure that the valve cannot be inadvertently opened. In MODE 4, the increase in containment pressure following a pipe break would occur over a relatively long time period such that manual action could reasonable be expected to provide protection and ESFAS Function 4.d need not be OPERABLE. In MODES 4, 5, and 6, there is not enough energy in the primary and secondary sides to pressurize the containment to the Containment Pressure—High 2 ~~High~~ setpoint.

d. Steam Line Isolation—Steam Line Pressure

(1) Steam Line Pressure—Low

Steam Line Pressure—Low provides closure of the MSIVs in the event of an SLB to maintain at least one unfaulted SG as a heat sink for the reactor, and to limit the mass and energy release to containment. This Function provides closure of the MSIVs in the event of a feed line break to ensure a supply of steam for the turbine driven AFW pump. Steam Line Pressure—Low was discussed previously under SI Function 1.e.1.

Steam Line Pressure—Low Function must be OPERABLE in MODES 1, 2, and 3 (above P-11), with any main steam valve open, when a secondary side break or stuck open valve could result in the rapid depressurization of the steam lines. This signal may be manually blocked by the operator below the P-11 setpoint. Below P-11, an inside containment SLB will be terminated by automatic actuation via Containment Pressure—High 2 ~~High~~. Stuck valve transients and outside containment SLBs will be terminated by the Steam Line Pressure—Negative Rate—High signal for Steam Line Isolation below P-11 when SI has been manually blocked. The Steam Line Isolation Function is required in MODES 2

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

(1) Steam Line Pressure - Low (continued)

and 3 unless all MSIVs are closed and ~~deactivated~~. This function is not required to be OPERABLE in MODES 4, 5, and 6 because there is insufficient energy in the secondary side of the unit to have an accident.

(2) Steam Line Pressure - Negative Rate - High

Steam Line Pressure - Negative Rate - High provides closure of the MSIVs for an SLB when less than the P-11 setpoint, to maintain at least one unfaulted SG as a heat sink for the reactor, and to limit the mass and energy release to containment. When the operator manually blocks the Steam Line Pressure - Low main steam isolation signal when less than the P-11 setpoint, the Steam Line Pressure - Negative Rate - High signal is automatically enabled. Steam Line Pressure - Negative Rate - High provides no input to any control functions. Thus, three OPERABLE channels are sufficient to satisfy requirements with a two-out-of-three logic on each steam line.

Steam Line Pressure - Negative Rate - High must be OPERABLE in MODE 3 (2 per steam line) when less than the P-11 setpoint, when a secondary side break or stuck open valve could result in the rapid depressurization of the steam line(s). In MODES 1 and 2, and in MODE 3, when above the P-11 setpoint, this signal is automatically disabled and the Steam Line Pressure - Low signal is automatically enabled. The Steam Line Isolation Function is required to be OPERABLE in MODES 2 and 3 unless all MSIVs are closed and ~~deactivated~~. In MODES 4, 5, and 6, there is insufficient energy in the primary and secondary sides to have an SLB or other accident that would result in a release of significant enough quantities of energy to cause a cooldown of the RCS.

5. Turbine Trip and Feedwater Isolation

The primary functions of the Turbine Trip and Feedwater Isolation signals are to prevent damage to the turbine due to water in the steam lines, and to stop the excessive flow of feedwater into the SGs. These functions are necessary to mitigate the effects of a high water level in the SGs, which could result in carryover of water into the steam lines and excessive cooldown of the primary system. The SG high water level is due to excessive feedwater flows.

The Function is actuated when the level in any SG exceeds the high high setpoint, and performs the following functions:

- Trips the main turbine;
- Trips the MFW pumps;
- Initiates feedwater isolation; and
- Shuts the MFW regulating valves and the bypass feedwater regulating valves ~~coincident with P-4~~.

This Function is actuated by SG Water Level - High High. The RTS also initiates a turbine trip signal whenever a reactor trip (P-4) is generated.

a. Turbine Trip and Feedwater Isolation - Automatic Actuation Logic and Actuation Relays

Automatic Actuation Logic and Actuation Relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b.

b. Turbine Trip and Feedwater Isolation - Steam Generator Water Level - High High (P-14)

This signal provides protection against excessive feedwater flow. The ESFAS SG water level

instruments provide input to the SG Water Level Control System. Therefore, the actuation logic must be able to withstand both an input failure to the control system (which may then require the protection function actuation) and a single failure in the other channels providing the protection function actuation. Thus, ~~four~~ three OPERABLE channels (narrow range instrument span each generator) are required to satisfy the requirements with a two-out-of-~~four~~ three logic and. ~~For units that have dedicated protection and control channels, only three protection channels are necessary to satisfy the protective requirements. For other units that have only three channels, a median signal selector is provided to prevent control and protection function interactions or justification is provided in NUREG-1218 (Ref. 7).~~

The transmitters (d/p cells) are located inside containment. However, the events that this Function protects against cannot cause a severe environment in containment. Therefore, the Trip Setpoint reflects only steady state instrument uncertainties.

- c. Turbine Trip and Feedwater Isolation - Safety Injection

Turbine Trip and Feedwater Isolation is also initiated by all Functions that initiate SI. The Feedwater Isolation Function requirements for these Functions are the same as the requirements for their SI function. Therefore, the requirements are not repeated in Table 3.3.2-1. Instead Function 1, SI, is referenced for all initiating functions and requirements.

Turbine Trip and Feedwater Isolation Functions must be OPERABLE in MODES 1 and 2 ~~and 3~~ except when all MFIVs, MFRVs, ~~and associated bypass valves~~ are closed and ~~de-activated~~ or isolated by a closed manual valve when the MFW System is in operation and the turbine generator may be in operation. In MODES ~~3, 4, 5, and 6,~~ 3, 4, 5, and 6, the MFW System and the turbine

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

c. Turbine Trip and Feedwater Isolation - Safety Injection (continued)

generator are not in service and this Function is not required to be OPERABLE.

6. Auxiliary Feedwater

The AFW System is designed to provide a secondary side heat sink for the reactor in the event that the MFW System is not available. The system has two motor driven pumps and a turbine driven pump, making it available during normal unit operation, during a loss of AC power, a loss of MFW, and during a Feedwater System pipe break. The normal source of water for the AFW System is the condensate storage tank (CST) (normally not safety related). A low level in the CST will automatically realign the pump suction to the Essential Service Water (ESW) System (safety related). The AFW System is aligned so that upon a pump start, flow is initiated to the respective SGs immediately.

~~a. Auxiliary Feedwater - Manual Initiation~~

~~Manual initiation of Auxiliary Feedwater can be accomplished from the Control Room. Each of the three AFW pumps has a switch for manual initiation. The LCO requires three channels to be OPERABLE.~~

a ~~b~~. Auxiliary Feedwater - Automatic Actuation Logic and Actuation Relays (Solid State Protection System)

Automatic actuation logic and actuation relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b.

SAFETY ANALYSES,
LCO, and
APPLICABILITY

e d. Auxiliary Feedwater - Steam Generator Water
Level - Low Low

Level Control System. Therefore, the actuation logic must be able to withstand both an input failure to the control system which may then require a protection function actuation and a single failure in the other channels providing the protection function actuation. Thus, ~~four~~ three OPERABLE channels (narrow range instrument span each generator) are required to satisfy the requirements with two-out-of-four ~~three~~ logic and ~~— For units that have dedicated protection and control channels, only three protection channels are necessary to satisfy the protective requirements. For other units that have only three channels, a median signal selector is provided or justification is provided in Reference 7 for level control.~~

~~This function is actuated on two out of three low-low water level signals occurring in any steam generator. If a low-low water level condition is detected in one steam generator, signals are generated to start the motor driven auxiliary feedwater pumps. If a low-low water level condition is detected in two or more steam generators, a signal is generated to start the turbine driven auxiliary feedwater pump as well.~~

~~The signals to start auxiliary feedwater pumps are delayed through the use of a Trip Time Delay (TTD) system for reactor power levels below 50% of RTP. Low-low water level in any protection set in any steam generator will generate a signal which starts an elapsed time trip delay timer. The allowable trip time delay is based upon the prevailing power level at the time the low-low level trip setpoint is reached. If power level rises after the trip time delay setpoints have been determined, the trip time delay is re-determined (i.e., decreased) according to the increase in power level. However, the trip time delay is not changed if the power level decreases after the delay has been determined. The use of this delay allows added time for natural steam generator level stabilization or operator intervention to avoid an inadvertent protection system actuation.~~

With the transmitters (d/p cells) located inside containment and thus possibly experiencing adverse environmental conditions (feed line break), the Trip Setpoint reflects the inclusion of both steady state and adverse environmental instrument uncertainties.

e. Auxiliary Feedwater - Loss of Offsite Power
(continued)

~~reactor decay heat and sensible heat removal following the reactor trip.~~

Functions 6.a through ~~6.e~~ 6.b, 6.d, and 6.g must be OPERABLE in MODES 1, 2, and 3 to ensure that the SGs remain the heat sink for the reactor except the RCS AT time delays associated with Function 6.d, are only required to be operable in MODES 1 and 2. Below Mode 2, for the trip time delay, the maximum time delay is permitted; therefore, no OPERABILITY requirement is imposed on vessel AT channels in MODE 3. SG Water Level - Low Low in any operating SG will cause the motor driven AFW pumps to start. The system is aligned so that upon a start of the pump, water immediately begins to flow to the SGs. SG Water Level - Low Low in any two operating SGs will cause the turbine driven pumps to start. These Functions do not have to be OPERABLE in MODES 5 and 6 because there is not enough heat being generated in the reactor to require the SGs as a heat sink. In MODE 4, AFW actuation does not need to be OPERABLE because either AFW or residual heat removal (RHR) will already be in operation to remove decay heat or sufficient time is available to manually place either system in operation.

f. Auxiliary Feedwater - Undervoltage Reactor Coolant Pump

A loss of power on the buses that provide power to the RCPs provides indication of a pending loss of RCP forced flow in the RCS. The Undervoltage RCP Function senses the voltage ~~downstream~~ upstream of each RCP breaker. A loss of power, ~~or an open RCP breaker,~~ on two ~~or more~~ RCPs buses, will start the turbine driven AFW pump to ensure that at least one SG contains enough water to serve as the heat sink for reactor decay heat and sensible heat removal following the reactor trip.

g. ~~h.~~ NOT USED

~~Auxiliary Feedwater - Trip of All Main Feedwater Pumps~~

~~A Trip of all MFW pumps is an indication of a loss of MFW and the subsequent need for some method of decay heat and sensible heat removal to bring the reactor back to no load temperature and pressure. A turbine~~

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

~~driven MFW pump is equipped with two pressure switches on the control air/oil~~

g ~~ii.~~ Auxiliary Feedwater Trip of All Main Feedwater Pumps (continued)

~~line for the speed control system. A low pressure signal from either of these pressure switches indicates a trip of that pump. Motor driven MFW pumps are equipped with a breaker position sensing device. An open supply breaker indicates that the pump is not running. Two OPERABLE channels per pump satisfy redundancy requirements with one out of two taken twice logic. A trip of all MFW pumps starts the motor driven and turbine driven AFW pumps to ensure that at least one SG is available with water to act as the heat sink for the reactor.~~

~~Functions 6.f and 6.g must be OPERABLE in MODES 1 and 2. This ensures that at least one SG is provided with water to serve as the heat sink to remove reactor decay heat and sensible heat in the event of an accident. In MODES 3, 4, and 5, the RCPs and MFW pumps may be normally shut down, and thus neither the pump trip is not indicative of a condition requiring automatic AFW initiation of the TDAFW pump. No other anticipatory start signals are necessary for the TDAFW pump, only low level in 2 of 4 SGs~~

h ~~ii.~~ NOT USED
Auxiliary Feedwater Pump Suction Transfer on Suction Pressure Low

~~A low pressure signal in the AFW pump suction line protects the AFW pumps against a loss of the normal supply of water for the pumps, the CST. Two pressure switches are located on the AFW pump suction line from the CST. A low pressure signal sensed by any one of the switches will cause the emergency supply of water for both pumps to be aligned, or cause the AFW pumps to stop until the emergency source of water is aligned. ESW (safety grade) is then lined up to supply the AFW pumps to ensure an adequate supply of water for the AFW System to maintain at least one of the SGs as the heat sink for reactor decay heat and sensible heat removal.~~

~~Since the detectors are located in an area not affected by HELBs or high radiation, they will not experience any adverse environmental~~

SAFETY ANALYSES
LCO, and
APPLICABILITY

~~h ii. Auxiliary Feedwater Pump Suction Transfer on
Suction Pressure Low (continued)~~

~~conditions and the Trip Setpoint reflects only steady
state instrument uncertainties.~~

~~This Function must be OPERABLE in MODES 1, 2, and 3 to
ensure a safety grade supply of water for the AFW
System to maintain the SGs as the heat sink for the
reactor. This Function does not have to be OPERABLE
in MODES 5 and 6 because there is not enough heat
being generated in the reactor to require the SGs as a
heat sink. In MODE 4, AFW automatic suction transfer
does not need to be OPERABLE because RHR will already
be in operation, or sufficient time is available to
place RHR in operation, to remove decay heat.~~

7. ~~Automatic Switchover to Containment Sump Residual Heat
Removal (RHR) Pump Trip - Refueling Water Storage Tank
(RWST) Low Level~~

At the end of the injection phase of a LOCA, the RWST will be nearly empty. Continued cooling must be provided by the ECCS to remove decay heat. The source of water for the ECCS pumps is automatically manually switched to the containment recirculation sump. This pump trip feature is blocked if the RHR pumps are already taking suction from the Containment Recirculation sump. The low head residual heat removal (RHR) pumps and containment spray pumps draw the water from the containment recirculation sump, the RHR pumps pump the water through the RHR heat exchanger, inject the water back into the RCS, and supply the cooled water to the other ECCS pumps. Switchover from the RWST to the containment sump must occur before the RWST empties to prevent damage to the RHR pumps and a loss of core cooling capability. For similar reasons, switchover must not occur before there is sufficient water in the containment sump to support ESF pump suction. Furthermore, early switchover must not occur to ensure that sufficient borated water is injected from the RWST. This ensures the reactor remains shut down in the recirculation mode.

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY
(continued)

- a. ~~Automatic Switchover to Containment Sump -
Automatic Actuation Logic and Actuation Relays~~
- ~~Automatic actuation logic and actuation relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b.~~
- b, c. ~~Automatic Switchover to Containment Sump - Refueling Water Storage Tank (RWST) Level - Low Low Coincident With Safety Injection and Coincident With Containment Sump Level - High~~

During the injection phase of a LOCA, the RWST is the source of water for all ECCS pumps. A low low level in the RWST coincident with an SI signal provides protection against a loss of water for the ECCS pumps and indicates the end of the injection phase of the LOCA. The RWST is equipped with four ~~three~~ level transmitters. These transmitters provide no control functions. Therefore, a two-out-of-~~three~~four logic is adequate to initiate the protection function actuation. Although only three channels would be sufficient, a fourth channel has been added for increased reliability.

The RWST - Low Low Allowable Value/Trip Setpoint has both upper and lower limits. The lower limit is selected to ensure switchover occurs before the RWST empties, to prevent ECCS pump damage. The upper limit is selected to ensure enough borated water is injected to ensure the reactor remains shut down. The high limit also ensures adequate water inventory in the containment sump to provide ECCS pump suction.

The transmitters are located in an area not affected by HELBs or post accident high radiation. Thus, they will not experience any adverse environmental conditions and the Trip Setpoint reflects only steady state instrument uncertainties.

~~Automatic switchover occurs only if the RWST low low level signal is coincident with SI. This prevents accidental switchover during normal~~

Sump Refueling Water Storage Tank (RWST)
Level Low Low Coincident With Safety Injection
and Coincident With Containment Sump Level High
(continued)~~

~~operation. Accidental switchover could damage ECCS pumps if they are attempting to take suction from an empty sump. The automatic switchover function requirements for the SI Functions are the same as the requirements for their SI function. Therefore, the requirements are not repeated in Table 3.3.2 1. Instead, Function 1, SI, is referenced for all initiating Functions and requirements.~~

~~Reviewer's Note: In some units, additional protection from spurious switchover is provided by requiring a Containment Sump Level High signal as well as RWST Level Low Low and SI. This ensures sufficient water is available in containment to support the recirculation phase of the accident. A Containment Sump Level High signal must be present, in addition to the SI signal and the RWST Level Low Low signal, to transfer the suctions of the RHR pumps to the containment sump. The containment sump is equipped with four level transmitters. These transmitters provide no control functions. Therefore, a two out of four logic is adequate to initiate the protection function actuation. Although only three channels would be sufficient, a fourth channel has been added for increased reliability. The containment sump level Trip Setpoint/Allowable Value is selected to ensure enough borated water is injected to ensure the reactor remains shut down. The high limit also ensures adequate water inventory in the containment sump to provide ECCS pump suction. The transmitters are located inside containment and thus possibly experience adverse environmental conditions. Therefore, the trip setpoint reflects the inclusion of both steady state and environmental instrument uncertainties.~~

~~Units only have one of the Functions, 7.b or 7.c.~~

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

~~b, c. Automatic Switchover to Containment
Sump Refueling Water Storage Tank (RWST)
Level Low Low Coincident With Safety Injection
and Coincident With Containment Sump Level High
(continued)~~

These ~~These~~ Functions must be OPERABLE in MODES 1, 2, 3, and 4 when there is a potential for a LOCA to occur, to ensure a continued supply of water for the ECCS pumps. ~~These These~~ Functions are ~~is~~ not required to be OPERABLE in MODES 5 and 6 because there is adequate time for the operator to evaluate unit conditions and respond by manually starting systems, pumps, and other equipment to mitigate the consequences of an abnormal condition or accident. System pressure and temperature are very low and many ESF components are administratively locked out or otherwise prevented from actuating to prevent inadvertent overpressurization of unit systems.

8. Engineered Safety Feature Actuation System Interlocks

To allow some flexibility in unit operations, several interlocks are included as part of the ESFAS. These interlocks permit the operator to block some signals, automatically enable other signals, prevent some actions from occurring, and cause other actions to occur. The interlock Functions back up manual actions to ensure bypassable functions are in operation under the conditions assumed in the safety analyses.

a. Engineered Safety Feature Actuation System Interlocks - Reactor Trip, P-4

The P-4 interlock is enabled when a reactor trip breaker (RTB) and its associated bypass breaker is open. ~~Once the P-4 interlock is enabled, automatic SI initiation is blocked after a [] second time delay.~~ This Function allows operators to ~~take manual control~~ manually block reactivation of SI systems after the initial phase of injection is complete. Once SI is blocked, automatic actuation of SI cannot occur until the RTBs have been manually closed. The functions of the P-4 interlock are:

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

a. Engineered Safety Feature Actuation System
Interlocks—Reactor Trip, P-4 (continued)

- Trip the main turbine;
- Isolate MFW with coincident low $T_{avg} \leq 554^{\circ}F$;
- ~~Prevent~~ ~~Allows manual block of the automatic~~ reactivation of SI after a manual reset of SI;
- Transfer the steam dump from the load rejection controller to the ~~unit~~ ~~plant~~ trip controller; and
- Prevent opening of the MFW ~~isolation~~ ~~reg~~ valves or ~~bypass~~ valves if they were closed on SI or ~~high~~ SG Water Level—High-High.

Each of the above Functions is interlocked with P-4 to avert or reduce the continued cooldown of the RCS following a reactor trip. An excessive cooldown of the RCS following a reactor trip could cause an insertion of positive reactivity with a subsequent increase in generated ~~core~~ power. To avoid such a situation, the noted Functions have been interlocked with P-4 as part of the design of the unit control and protection system.

None of the noted Functions serves a mitigation function in the unit licensing basis safety analyses. Only the turbine trip Function is explicitly assumed since it is an immediate consequence of the reactor trip Function. Neither turbine trip, nor any of the other four Functions associated with the reactor trip signal, is required to show that the unit licensing basis safety analysis acceptance criteria are ~~not~~ ~~not~~ exceeded.

The RTB position switches that provide input to the P-4 interlock only function to energize or de-energize or open or close contacts. Therefore, this Function has no adjustable trip setpoint with which to associate a Trip Setpoint and Allowable Value.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

a. Engineered Safety Feature Actuation System
Interlocks - Reactor Trip, P-4 (continued)

This Function must be OPERABLE in MODES 1, 2, and 3 when the reactor may be critical or approaching criticality. This Function does not have to be OPERABLE in MODE 4, 5, or 6 because the main turbine, the MFW System, and the Steam Dump System are not in operation.

b. Engineered Safety Feature Actuation System
Interlocks - Pressurizer Pressure, P-11

The P-11 interlock permits a normal unit cooldown and depressurization without actuation of SI or main steam line isolation. With two-out-of-three pressurizer pressure channels (discussed previously) less than the P-11 setpoint, the operator can manually block the Pressurizer Pressure-Low and Steam Line Pressure-Low SI signals and the Steam Line Pressure-Low steam line isolation signal (previously discussed). When the Steam Line Pressure-Low steam line isolation signal is manually blocked, a main steam isolation signal on Steam Line Pressure-Negative Rate-High is enabled. This provides protection for an SLB by closure of the MSIVs. With two-out-of-three pressurizer pressure channels above the P-11 setpoint, the Pressurizer Pressure-Low and Steam Line Pressure-Low SI signals and the Steam Line Pressure-Low steam line isolation signal are automatically enabled. The operator can also enable these trips by use of the respective manual reset buttons/switches. When the Steam Line Pressure-Low steam line isolation signal is enabled, the main steam isolation on Steam Line Pressure-Negative Rate-High is disabled. The Trip Setpoint reflects only steady state instrument uncertainties.

This Function must be OPERABLE in MODES 1, 2, and 3 to allow an orderly cooldown and depressurization of the unit without the actuation of SI or main steam isolation. This Function does not have to be OPERABLE in MODE 4.

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES,
LCO, and
APPLICABILITY

- b. Engineered Safety Feature Actuation System Interlocks - Pressurizer Pressure, P-11
(continued)

5, or 6 because system pressure must already be below the P-11 setpoint for the requirements of the heatup and cooldown curves to be met.

- c. ~~NOT USED~~ Engineered Safety Feature Actuation System Interlocks - T_{avg} - Low Low, P-12

~~On increasing reactor coolant temperature, the P-12 interlock reinstates SI on High Steam Flow Coincident With Steam Line Pressure Low or Coincident With T_{avg} - Low Low and provides an arming signal to the Steam Dump System. On decreasing reactor coolant temperature, the P-12 interlock allows the operator to manually block SI on High Steam Flow Coincident With Steam Line Pressure Low or Coincident with T_{avg} - Low Low. On a decreasing temperature, the P-12 interlock also removes the arming signal to the Steam Dump System to prevent an excessive cooldown of the RCS due to a malfunctioning Steam Dump System.~~

~~Since T_{avg} is used as an indication of bulk RCS temperature, this function meets redundancy requirements with one OPERABLE channel in each loop. In three loop units, these channels are used in two out of three logic. In four loop units, they are used in two out of four logic.~~

~~This function must be OPERABLE in MODES 1, 2, and 3 when a secondary side break or stuck open valve could result in the rapid depressurization of the steam lines. This function does not have to be OPERABLE in MODE 4, 5, or 6 because there is insufficient energy in the secondary side of the unit to have an accident.~~

The ESFAS instrumentation satisfies Criterion 3 of the NRC Policy Statement 10 CFR 50.36(c)(2)(ii).

ACTIONS

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed on Table 3.3.2-1.

In the event a channel's Trip Setpoint is found nonconservative with respect to the Allowable Value, or the transmitter, instrument Loop, signal processing electronics, or bistable is found inoperable, then all affected Functions provided by that channel must be declared inoperable and the LCO Condition(s)

(continued)

BASES

ACTIONS
(continued)

entered for the protection Function(s) affected. When the Required Channels in Table 3.3.2-1 are specified (e.g., on a per steam line, per loop, per SG, etc., basis), then the Condition may be entered separately for each steam line, loop, SG, etc., as appropriate.

When the number of inoperable channels in a trip function exceed those specified in one or other related Conditions associated with a trip function, then the unit is outside the safety analysis. Therefore, LCO 3.0.3 should be immediately entered if applicable in the current MODE of operation.

~~Reviewer's Note: Certain LCO Completion Times are based on approved topical reports. In order for a licensee to use these times, the licensee must justify the Completion Times as required by the staff Safety Evaluation Report (SER) for the topical report.~~

A.1

Condition A applies to all ESFAS protection functions.

Condition A addresses the situation where one or more channels or trains for one or more Functions are inoperable at the same time. The Required Action is to refer to Table 3.3.2-1 and to take the Required Actions for the protection functions affected. The Completion Times are those from the referenced Conditions and Required Actions.

(continued)

BASES

ACTIONS
(continued)

B.1, B.2.1 and B.2.2

Condition B applies to manual initiation of:

- SI;
- Containment Spray;
- Phase A Isolation; and
- Phase B Isolation.

This action addresses the train orientation of the SSPS for the functions listed above. If a channel or train is inoperable, 48 hours is allowed to return it to an OPERABLE status. Note that for containment spray and Phase B isolation, failure of one or both channels in one train renders the train inoperable. Condition B, therefore, encompasses both situations. The specified Completion Time is reasonable considering that there are two automatic actuation trains and another manual initiation train OPERABLE for each function, and the low probability of an event occurring during this interval. If the train cannot be restored to OPERABLE status, the unit must be placed in a MODE in which the LCO does not apply. This is done by placing the unit in at least MODE 3 within an additional 6 hours (54 hours total time) and in MODE 5 within an additional 30 hours (84 hours total time). The allowable Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

C.1, C.2.1 and C.2.2

Condition C applies to the automatic actuation logic and actuation relays for the following functions:

- SI;
- Containment Spray;
- Phase A Isolation;

(continued)

BASES

ACTIONS

C.1, C.2.1 and C.2.2 (continued)

- ~~Phase B Isolation; and~~
- ~~Automatic Switchover to Containment Sump.~~

This action addresses the train orientation of the SSPS and the master and slave relays. If one train is inoperable, 6 hours are allowed to restore the train to OPERABLE status. The specified Completion Time is reasonable considering that there is another train OPERABLE, and the low probability of an event occurring during this interval. If the train cannot be restored to OPERABLE status, the unit must be placed in a MODE in which the LCO does not apply. This is done by placing the unit in at least MODE 3 within an additional 6 hours (12 hours total time) and in MODE 5 within an additional 30 hours (42 hours total time). The Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

The Required Actions are modified by a Note that allows one train to be bypassed for up to [4] hours for surveillance testing, provided the other train is OPERABLE. This allowance is based on the reliability analysis assumption of WCAP-10271-P-A (Ref. 8) that 4 hours is the average time required to perform channel surveillance.

D.1, D.2.1, and D.2.2

Condition D applies to:

- ~~Containment Pressure High 1;~~
- Pressurizer Pressure - Low (~~two, three, and four loop units~~);
- Steam Line Pressure - Low;
- ~~Steam Line Differential Pressure High;~~
- ~~High Steam Flow in Two Steam Lines Coincident With T_{avg} - Low Low or Coincident With Steam Line Pressure - Low;~~

(continued)

BASES

ACTIONS

D.1, D.2.1, and D.2.2 (continued)

- Containment Pressure - ~~High-2; High - High~~
- Steam Line Pressure - Negative Rate - High;
- ~~Steam Line Pressure - Low;~~
- ~~High Steam Flow Coincident With Safety Injection Coincident With T_{avg} - Low Low;~~
- ~~High High Steam Flow Coincident With Safety Injection;~~
- ~~High Steam Flow in Two Steam Lines Coincident With T_{avg} - Low Low;~~
- SG Water level - Low Low (two, three, and four loop units);
and

~~• SG Water level - High High (P-14) (two, three, and four loop units).~~

If one channel is inoperable, 6 hours are allowed to restore the channel to OPERABLE status or to place it in the tripped condition. Generally this Condition applies to functions that operate on two-out-of-three logic (excluding ~~pressurizer pressure - low and containment pressure high - high~~). Therefore, failure of one channel places the Function in a two-out-of-two configuration. ~~One~~ ~~The inoperable~~ channel must be tripped to place the Function in a ~~one-out-of-three~~ ~~two~~ configuration that satisfies redundancy requirements.

Failure to restore the inoperable channel to OPERABLE status or place it in the tripped condition within 6 hours requires the unit be placed in MODE 3 within the following 6 hours and MODE 4 within the next 6 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. In MODE 4, these Functions are no longer required OPERABLE.

The Required Actions are modified by a Note that allows the inoperable channel ~~or one additional channel~~ to be bypassed for up to ~~4~~ hours for surveillance testing of other channels. The 6 hours allowed to restore the channel to OPERABLE status or to place the inoperable channel in the tripped condition, and the ~~4~~ hours allowed for testing, are justified in Reference 8.

(continued)

BASES

ACTIONS
(continued)

E.1, E.2.1, and E.2.2

Condition E applies to:

- ~~Containment Pressure - High~~
- Containment Spray Containment Pressure ~~High-3~~ (High, High) ~~(two, three, and four loop units); and~~
- Containment Phase B Isolation Containment Pressure - ~~High-3~~ (High, High),

None of these signals has input to a control function. Thus, two-out-of-three logic is necessary to meet acceptable protective requirements. However, a two-out-of-three design would require tripping a failed channel. This is undesirable because a single failure would then cause spurious containment spray initiation. Spurious spray actuation is undesirable because of the cleanup problems presented. Therefore, these channels are designed with two-out-of-four logic so that a failed channel may be bypassed rather than tripped. Note that one channel may be bypassed and still satisfy the single failure criterion. Furthermore, with one channel bypassed, a single instrumentation channel failure will not spuriously initiate containment spray. ~~The containment spray signal is also interlocked with SI and will not initiate without simultaneous SI and case spray signals.~~

To avoid the inadvertent actuation of containment spray and Phase B containment isolation, the inoperable channel should not be placed in the tripped condition. Instead it is bypassed. Restoring the channel to OPERABLE status, or placing the inoperable channel in the bypass condition within 6 hours, is sufficient to assure that the Function remains OPERABLE and minimizes the time that the Function may be in a partial trip condition (assuming the inoperable channel has failed high). The Completion Time is further justified based on the low probability of an event occurring during this interval. Failure to restore the inoperable channel to OPERABLE status, or place it in the bypassed condition within 6 hours, requires the unit be placed in MODE 3 within the following 6 hours ~~and MODE 4 within the next 6 hours and MODE 5 within 42 hours~~. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. In ~~MODE 4~~, these Functions are no longer required OPERABLE.

ACTIONS

(continued)

BASES

E.1, E.2.1, and E.2.2 (continued)

The Required Actions are modified by a Note that allows one additional channel to be bypassed for up to 48 hours for surveillance testing. Placing a second channel in the bypass condition for up to 4 hours for testing purposes is acceptable based on the results of Reference 8.

F.1, F.2.1, and F.2.2

Condition F applies to:

- ~~Manual Initiation of Steam Line Isolation;~~
- ~~Loss of Offsite Power;~~
- ~~Auxiliary Feedwater Pump Suction Transfer on Suction Pressure Low; and~~
- P-4 Interlock.

~~For the Manual Initiation and the P-4 Interlock Functions, this action addresses the train orientation of the SSPS. For the Loss of Offsite Power Function, this action recognizes the lack of manual trip provision for a failed channel. For the AFW System pump suction transfer channels, this action recognizes that placing a failed channel in trip during operation is not necessarily a conservative action. Spurious trip of this function could align the AFW System to a source that is not immediately capable of supporting pump suction. If a train or channel is inoperable, 48 hours is allowed to return it to OPERABLE status. The specified Completion Time is reasonable considering the nature of these Functions, the available redundancy, and the low probability of an event occurring during this interval. If the Function cannot be returned to OPERABLE status, the unit must be placed in MODE 3 within the next 6 hours and MODE 4 within the following 6 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power in an orderly manner and without challenging unit systems. In MODE 4, the unit does not have any analyzed transients or conditions that require the explicit use of the protection functions noted above.~~

(continued)

BASES

ACTIONS
(continued)

G.1, G.2.1 and G.2.2

Condition G applies to the automatic actuation logic and actuation relays for the Steam Line Isolation [~~Turbine Trip and Feedwater Isolation.~~] and AFW actuation Functions.

The action addresses the train orientation of the SSPS and the master and slave relays for these functions. If one train is inoperable, 6 hours are allowed to restore the train to OPERABLE status. The Completion Time for restoring a train to OPERABLE status is reasonable considering that there is another train OPERABLE, and the low probability of an event occurring during this interval. If the train cannot be returned to OPERABLE status, the unit must be brought to MODE 3 within the next 6 hours and MODE 4 within the following 6 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. Placing the unit in MODE 4 removes all requirements for OPERABILITY of the protection channels and actuation functions. In this MODE, the unit does not have analyzed transients or conditions that require the explicit use of the protection functions noted above.

The Required Actions are modified by a Note that allows one train to be bypassed for up to [4] hours for surveillance testing provided the other train is OPERABLE. This allowance is based on the reliability analysis (Ref. 8) assumption that 4 hours is the average time required to perform channel surveillance.

H.1 and H.2

Condition H applies to the automatic actuation logic and actuation relays for the Turbine Trip and Feedwater Isolation Function.

This action addresses the train orientation of the SSPS and the master and slave relays for this function. If one train is inoperable, 6 hours are allowed to restore the train to OPERABLE status or the unit must be placed in MODE 3 within the following 6 hours. The Completion Time for restoring a train to OPERABLE status is reasonable considering that there is another train OPERABLE, and the low probability of

(continued)

BASES

ACTIONS H.1 and H.2 (continued)

an event occurring during this interval. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging unit systems. These Functions are no longer required in MODE 3. Placing the unit in MODE 3 removes all requirements for OPERABILITY of the protection channels and actuation functions. In this MODE, the unit does not have analyzed transients or conditions that require the explicit use of the protection functions noted above.

The Required Actions are modified by a Note that allows one train to be bypassed for up to 4 hours for surveillance testing provided the other train is OPERABLE. This allowance is based on the reliability analysis (Ref. 8) assumption that 4 hours is the average time required to perform channel surveillance.

I.1 and I.2

Condition I applies to:

- SG Water Level -- High High (P-14) (two, three, and four loop units), and
- Undervoltage Reactor Coolant Pump.

If one channel of SG water level is inoperable, 6 hours are allowed to restore one channel to OPERABLE status or to place it in the tripped condition. If placed in the tripped condition, the Function is then in a partial trip condition where one-out-of-two or one-out-of-three logic will result in actuation. The 6 hour Completion Time is justified in Reference 8. Failure to restore the inoperable channel to OPERABLE status or place it in the tripped condition within 6 hours requires the unit to be placed in MODE 3 within the following 6 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging unit systems. In MODE 3, these Functions are no longer required OPERABLE. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging unit systems. In MODE 3, these Functions are no longer required OPERABLE.

If one channel of undervoltage reactor coolant pump is inoperable, 6 hours are allowed to restore one channel to OPERABLE status or to place it in the tripped condition. If placed in the tripped condition, the function is then in a

(continued)

BASES

ACTIONS

I.1 and I.2 (continued)

~~partial trip condition where one additional tripped channel will result in actuation. The 6 hour Completion Time is justified in Ref. 8. Failure to restore the inoperable channel to OPERABLE status or place it in the tripped condition within 6 hours requires the Unit to be placed in MODE 2 within the following 6 hours. The allowed Completion time of 6 hours is reasonable, based on operating experience, to reach MODE 2 from full power conditions in an orderly manner without challenging unit systems. In MODE 2, this function is no longer required OPERABLE.~~

The Required Actions are modified by a Note that allows the inoperable channel to be bypassed for up to ~~4~~ hours for surveillance testing of other channels. The 6 hours allowed to place the inoperable channel in the tripped condition, and the 4 hours allowed for a second channel to be in the bypassed condition for testing, are justified in Reference 8.

J.1 and J.2

~~NOT USED~~

~~Condition J applies to the AFW pump start on trip of all MFW pumps.~~

~~This action addresses the train orientation of the SSPS for the auto start function of the AFW System on loss of all MFW pumps. The OPERABILITY of the AFW System must be assured by allowing automatic start of the AFW System pumps. If a channel is inoperable, 48 hours are allowed to return it to an OPERABLE status. If the function cannot be returned to an OPERABLE status, 6 hours are allowed to place the unit in MODE 3. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging unit systems. In MODE 3, the unit does not have any analyzed transients or conditions that require the explicit use of the protection function noted above. The allowance of 48 hours to return the train to an OPERABLE status is justified in Reference 8.~~

K.1, K.2.1 and K.2.2

Condition K applies to:-

~~_____~~

- ~~• RWST Level Low Low Coincident with Safety Injection, and~~
- ~~• RWST Level Low Low Coincident with Safety Injection and Coincident with Containment Sump Level High.~~

(continued)

BASES

ACTIONS

K.1, K.2.1 and K.2.2 (continued)

~~RWST Level - Low, which trips both RHR pumps. Low Low Coincident With SI and Coincident With Containment Sump Level High provides actuation of switchover to the containment sump. Note that this Function requires the bistables to energize to perform their required action. The failure of up to two channels will not prevent the operation of this Function. However, placing a failed channel in the tripped condition could result in a premature switchover to the sump, prior to the injection of the minimum volume from the RWST. Placing the inoperable channel in bypass results in a two out of three logic configuration, which satisfies the requirement to allow another failure without disabling actuation of the switchover when required. Restoring the channel to OPERABLE status or placing the inoperable channel in the bypass condition within 6 hours is sufficient to ensure that the Function remains OPERABLE, and minimizes the time that the Function may be in a partial trip condition (assuming the inoperable channel has failed high/low). Placing the out-of-service channel in bypass will generate a high level signal on that channel, which will ensure that under no circumstances can a failure of an additional channel low prevent the RHR pumps from starting as the result of an SI signal. The 6 hour Completion Time is justified in Reference 8. If the channel cannot be returned to OPERABLE status or placed in the bypass condition within 6 hours, and returned to an OPERABLE status within 72 hours, the unit must be brought to MODE 3 within the following 6 hours and MODE 5 within the next 30 hours immediately enter LCO 3.0.3. The 72 hour Allowed Outage Time (AOT) is the same AOT that is allowed for one inoperable RHR pump. This comparison is reasonable because the possible consequences of losing a second level channel can, in the worst case, be no more severe than the loss of one RHR pump, and the probability of losing the level channel is even lower than that of losing an RHR pump. The allowed Completion Times for shutdown are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. In MODE 5, the unit does not have any analyzed transients or conditions that require the explicit use of the protection/pump trip functions noted above.~~

The Required Actions are modified by a Note that allows placing a second channel in the bypass condition for up to 4 hours for surveillance testing. The total of 12 hours to reach MODE 3 and 4 hours for a second channel to be bypassed is acceptable based on the results of Reference 8.

(continued)

BASES

L.1, L.2.1 and L.2.2

Condition L applies to the P-11 and ~~P-12~~ [and ~~P-14~~] interlocks.

With one or more channels inoperable, the operator must verify that the interlock is in the required state for the existing unit condition. This action manually accomplishes the function of the interlock. Determination must be made within 1 hour. The verification determination can be made by observation of the associated annunciator window(s). The 1 hour Completion Time is equal to the time allowed by

(continued)

BASES

ACTIONS

L.1, L.2.1 and L.2.2 (continued)

LCO 3.0.3 to initiate shutdown actions in the event of a complete loss of ESFAS function. If the interlock is not in the required state (or placed in the required state) for the existing unit condition, the unit must be placed in MODE 3 within the next 6 hours and MODE 4 within the following 6 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems. Placing the unit in MODE 4 removes all requirements for OPERABILITY of these interlocks.

M.1 or M.2

Condition M applies to the Trip Time Delay (TTD) for the SG low-low water level actuation of AFW pumps. With one or more TTD circuitry delay timers inoperable, 6 hours are allowed to adjust the threshold power level for no time delay to 0% RTP or to place the affected SG water level low-low channel in trip. The specified Completion Time is reasonable considering the nature of these functions, the available redundancy, and the low probability of an event occurring during this interval. If the TTD threshold power level cannot be adjusted or the affected SG water level low-low channel cannot be placed in trip, the unit must be placed in MODE 3 within the next 6 hours and MODE 4 within the following 6 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power in an orderly manner and without challenging unit systems. In MODE 4, the unit does not have any analyzed transients or conditions that require the explicit use of the protection function noted above.

N.1 or N.2 and N.2.2

Condition N applies to

- Manual Initiation of Steam Line Isolation and
- Manual Initiation of Auxiliary Feedwater

If a channel is inoperable, 48 hours is allowed to return the channel to an OPERABLE status. The specified Completion Time is reasonable considering the nature of these functions, the available redundancy, and the low probability of an event occurring during this interval. If the Function cannot be returned to OPERABLE status, the associated pump or valve shall be declared inoperable immediately and the REQUIRED ACTION of 3.7.5 or 3.7.2 as applicable complied with immediately.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

The SRs for each ESFAS Function are identified by the SRs column of Table 3.3.2-1.

A Note has been added to the SR Table to clarify that Table 3.3.2-1 determines which SRs apply to which ESFAS Functions.

Note that each channel of process protection supplies both trains of the ESFAS. When testing channel I, train A and train B must be examined. Similarly, train A and train B must be examined when testing channel II, channel III, and channel IV (if applicable). The CHANNEL CALIBRATION and COTs are performed in a manner that is consistent with the assumptions used in analytically calculating the required channel accuracies.

~~Reviewer's Note: Certain Frequencies are based on approved topical reports. In order for a licensee to use these times, the licensee must justify the Frequencies as required by the staff SER for the topical report.~~

SR 3.3.2.1

Performance of the CHANNEL CHECK once every 12 hours ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read

(continued)

BASES

ACTIONS

SR 3.3.2.1 (continued)

approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the unit staff established in ~~STP I-1A~~, based on a combination of the channel instrument uncertainties, including indication and reliability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit.

The Frequency is based on operating experience that demonstrates channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.2.2

SR 3.3.2.2 is the performance of an ACTUATION LOGIC TEST. The SSPS is tested every 31 days on a STAGGERED TEST BASIS, using the semiautomatic tester. The train being tested is placed in the bypass condition, thus preventing inadvertent actuation. Through the semiautomatic tester, all possible logic combinations, with and without applicable permissives, are tested for each protection function. In addition, the master relay coil is pulse tested for continuity. This verifies that the logic modules are OPERABLE and that there is an intact voltage signal path to the master relay coils. The Frequency of every 31 days on a STAGGERED TEST BASIS is adequate. It is based on industry operating experience, considering instrument reliability and operating history data.

SR 3.3.2.3

~~NOT USED~~

~~SR 3.3.2.3 is the performance of an ACTUATION LOGIC TEST as described in SR 3.3.2.2, except that the semiautomatic~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.2.3 (continued)

~~tester is not used and the continuity check does not have to be performed, as explained in the Note. This SR is applied to the balance of plant actuation logic and relays that do not have the SSPS test circuits installed to utilize the semiautomatic tester or perform the continuity check. This test is also performed every 31 days on a STAGGERED TEST BASIS. The Frequency is adequate based on industry operating experience, considering instrument reliability and operating history data.~~

SR 3.3.2.4

SR 3.3.2.4 is the performance of a MASTER RELAY TEST. The MASTER RELAY TEST is the energizing of the master relay, verifying contact operation and a low voltage continuity check of the slave relay coil. Upon master relay contact operation, a low voltage is injected to the slave relay coil. This voltage is insufficient to pick up the slave relay, but large enough to demonstrate signal path continuity. This test is performed every 31 days on a STAGGERED TEST BASIS. The time allowed for the testing (4 hours) and the surveillance interval are justified in Reference 8.

SR 3.3.2.5

SR 3.3.2.5 is the performance of a COT.

A COT is performed on each required channel to ensure the entire channel will perform the intended Function. Setpoints must be found within the Allowable Values specified in Table 3.3.1-1.

The difference between the current "as found" values and the previous test "as left" values must be consistent with the drift allowance used in the setpoint methodology. The setpoint shall be left set consistent with the assumptions of the current unit specific setpoint methodology.

The "as found" and "as left" values must also be recorded and reviewed for consistency with the assumptions of the

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.2.5 (continued)

surveillance interval extension analysis (Ref. 8) when applicable.

The Frequency of 92 days is justified in Reference 8.

SR 3.3.2.6

SR 3.3.2.6 is the performance of a SLAVE RELAY TEST. The SLAVE RELAY TEST is the energizing of the slave relays. Contact operation is verified in one of two ways. Actuation equipment that may be operated in the design mitigation MODE is either allowed to function, or is placed in a condition where the relay contact operation can be verified without operation of the equipment. Actuation equipment that may not be operated in the design mitigation MODE is prevented from operation by the SLAVE RELAY TEST circuit. For this latter case, contact operation is verified by a continuity check of the circuit containing the slave relay. This test is performed every ~~[92] days~~ 18 months. The Frequency is adequate, based on industry operating experience, considering instrument ~~relay~~ reliability and operating history data (Ref. 7)

SR 3.3.2.7 ~~NOT USED~~

~~SR 3.3.2.7 is the performance of a TADOT every [92] days. This test is a check of the Loss of Offsite Power, Undervoltage RCP, and AFW Pump Suction Transfer on Suction Pressure Low Functions. Each Function is tested up to, and including, the master transfer relay coils.~~

~~The test also includes trip devices that provide actuation signals directly to the SSPS. The SR is modified by a Note that excludes verification of setpoints for relays. Relay setpoints require elaborate bench calibration and are verified during CHANNEL CALIBRATION. The Frequency is adequate. It is based on industry operating experience, considering instrument reliability and operating history data.~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.3.2.8

SR 3.3.2.8 is the performance of a TADOT. This test is a check of the Manual Actuation Functions and ~~AFW pump start on trip of all MFW pumps.~~ It is performed every ~~[18]~~ months. Each Manual Actuation Function is tested up to, and including, the master relay coils. In some instances, the test includes actuation of the end device (i.e., pump starts, valve cycles, etc.). The Frequency is adequate, based on industry operating experience and is consistent with the typical refueling cycle. The SR is modified by a Note that excludes verification of setpoints during the TADOT for manual initiation Functions. The manual initiation Functions have no associated setpoints.

SR 3.3.2.9

SR 3.3.2.9 is the performance of a CHANNEL CALIBRATION.

A CHANNEL CALIBRATION is performed every ~~[18]~~ months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to measured parameter within the necessary range and accuracy.

CHANNEL CALIBRATIONS must be performed consistent with the assumptions of the unit specific setpoint methodology. ~~The difference between the current "as found" values and the previous test "as left" values must be consistent with the drift allowance used in the setpoint methodology.~~

The Frequency of ~~[18]~~ months is based on the assumption of an ~~[18]~~ month calibration interval in the determination of the magnitude of equipment drift in the setpoint methodology.

This SR is modified by a Note stating that this test should include verification that the time constants are adjusted to the prescribed values where applicable.

SR 3.3.2.10

This SR ensures the individual channel ESF RESPONSE TIMES are less than or equal to the maximum values assumed in the

(continued)

BASES

SURVEILLANCE
REQUIREMENTSSR 3.3.2.10 (continued)

accident analysis. Response Time testing acceptance criteria are included in the ~~Technical Requirements Manual, Section 15 (Ref. 9) FSAR and SR 3.3.2.10 is only applicable to those functions with a specified limit.~~ Individual component response times are not modeled in the analyses. The analyses model the overall or total elapsed time, from the point at which the parameter exceeds the Trip Setpoint value at the sensor, to the point at which the equipment in both trains reaches the required functional state (e.g., pumps at rated discharge pressure, valves in full open or closed position).

For channels that include dynamic transfer functions (e.g., lag, lead/lag, rate/lag, etc.), the response time test may be performed with the transfer functions set to one with the resulting measured response time compared to the appropriate FSAR response time. Alternately, the response time test can be performed with the time constants set to their nominal value provided the required response time is analytically calculated assuming the time constants are set at their nominal values. The response time may be measured by a series of overlapping tests such that the entire response time is measured.

ESF RESPONSE TIME tests are conducted on an ~~[18]~~ month STAGGERED TEST BASIS. Testing of the final actuation devices, which make up the bulk of the response time, is included in the testing of each channel. The final actuation device in one train is tested with each channel. Therefore, staggered testing results in response time verification of these devices every ~~[18]~~ months. The ~~[18]~~ month Frequency is consistent with the typical refueling cycle and is based on unit operating experience, which shows that random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences.

This SR is modified by a Note that clarifies that the turbine driven AFW pump is tested within 24 hours after reaching ~~[1000]~~ 650 psig in the SGs.

SR 3.3.2.11

SR 3.3.2.11 is the performance of a TADOT as described in SR 3.3.2.8, except that it is performed for the P-4 Reactor

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.2.11 (continued)

~~Trip Interlock, and the Frequency is once per RTB cycle. This
The 18 month Frequency is based on operating experience
demonstrating that undetected failure of the P-4 interlock
sometimes occurs when the RTB is cycled.~~

The SR is modified by a Note that excludes verification of setpoints during the TADOT. The Function tested has no associated setpoint.

B 3.3 INSTRUMENTATION

B 3.3.3 Post Accident Monitoring (PAM) Instrumentation

BASES

BACKGROUND

The primary purpose of the PAM instrumentation is to display unit variables that provide information required by the control room operators during accident situations. This information provides the necessary support for the operator to take the manual actions for which no automatic control is provided and that are required for safety systems to accomplish their safety functions for Design Basis Accidents (DBAs).

The OPERABILITY of the accident monitoring instrumentation ensures that there is sufficient information available on selected unit parameters to monitor and to assess unit status and behavior following an accident.

The availability of accident monitoring instrumentation is important so that responses to corrective actions can be observed and the need for, and magnitude of, further actions can be determined. These essential instruments are identified by unit specific documents in the FSAR section 7.5 (Ref. 1) addressing based upon the recommendations of Regulatory Guide 1.97 (Ref. 2) as required by Supplement 1 to NUREG-0737 (Ref. 3).

The instrument channels required to be OPERABLE by this LCO include two classes of parameters identified during unit specific implementation of Regulatory Guide 1.97 as Type A and Category I variables.

Type A variables are included in this LCO because they provide the primary information required for the control room operator to take specific manually controlled actions for which no automatic control is provided, and that are required for safety systems to accomplish their safety functions for DBAs. ~~Because the list of Type A variables differs widely between units, Table 3.3.3-1 in the accompanying LCO contains no examples of Type A variables, except for those that may also be Category I variables.~~

Category I variables are the key variables deemed risk significant because they are needed to:

(continued)

BASES

BACKGROUND
(continued)

- Determine whether other systems important to safety are performing their intended functions;
- Provide information to the operators that will enable them to determine the likelihood of a gross breach of the barriers to radioactivity release; and
- Provide information regarding the release of radioactive materials to allow for early indication of the need to initiate action necessary to protect the public, and to estimate the magnitude of any impending threat.

~~These key variables are identified by the unit specific Regulatory Guide 1.97 analyses (Ref. 1). These analyses identify the unit specific Type A and Category I variables and provide justification for deviating from the NRC proposed list of Category I variables.~~

~~Reviewer's Note: Table 3.3.3-1 provides a list of variables typical of those identified by the unit specific Regulatory Guide 1.97 analyses. Table 3.3.3-1 in unit specific Technical Specifications (TS) shall list all Type A and Category I variables identified by the unit specific Regulatory Guide 1.97 analyses, as amended by the NRC's Safety Evaluation Report (SER).~~

The specific instrument Functions listed in Table 3.3.3-1 are discussed in the LCO section.

APPLICABLE
SAFETY ANALYSES

The PAM instrumentation ensures the operability of Regulatory Guide 1.97 Type A and Category I variables so that the control room operating staff can:

- Perform the diagnosis specified in the emergency operating procedures (these variables are restricted to preplanned actions for the primary success path of DBAs), e.g., loss of coolant accident (LOCA);
- Take the specified, pre-planned, manually controlled actions, for which no automatic control is provided, and that are required for safety systems to accomplish their safety function;

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

- Determine whether systems important to safety are performing their intended functions;
- Determine the likelihood of a gross breach of the barriers to radioactivity release;
- Determine if a gross breach of a barrier has occurred; and
- Initiate action necessary to protect the public and to estimate the magnitude of any impending threat.

PAM instrumentation that meets the definition of Type A in Regulatory Guide 1.97 satisfies Criterion 3 of the NRC Policy Statement 10 CFR 50.36 (c)(2)(ii). Category I, non-Type A, instrumentation must be retained in TS because it is intended to assist operators in minimizing the consequences of accidents. Therefore, Category I, non-Type A, variables are important for reducing public risk.

LCO

The PAM instrumentation LCO provides OPERABILITY requirements for Regulatory Guide 1.97 Type A monitors, which provide information required by the control room operators to perform certain manual actions specified in the unit Emergency Operating Procedures. These manual actions ensure that a system can accomplish its safety function, and are credited in the safety analyses. Additionally, this LCO addresses Regulatory Guide 1.97 instruments that have been designated Category I, non-Type A.

The OPERABILITY of the PAM instrumentation ensures there is sufficient information available on selected unit parameters to monitor and assess unit status following an accident. This capability is consistent with the recommendations of Reference 1.

LCO 3.3.3 requires two OPERABLE channels for most Functions. Two OPERABLE channels ensure no single failure prevents operators from getting the information necessary for them to determine the safety status of the unit, and to bring the unit to and maintain it in a safe condition following an accident.

(continued)

BASES

LCO
(continued)

Furthermore, OPERABILITY of two channels allows a CHANNEL CHECK during the post accident phase to confirm the validity of displayed information. ~~More than two channels may be required at some units if the unit specific Regulatory Guide 1.97 analyses (Ref. 1) determined that failure of one accident monitoring channel results in information ambiguity (that is, the redundant displays disagree) that could lead operators to defeat or fail to accomplish a required safety function.~~

The exception to the two channel requirement is Containment Isolation Valve (CIV) Position, Auxiliary Feedwater (AFW) flow indication and Steam Generator (SG) water level (wide range). ~~In this case~~ For the CIV position, the important information is the status of the containment penetrations. The LCO requires one position indicator for each active CIV. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve and prior knowledge of a passive valve, or via system boundary status. If a normally active CIV is known to be closed and deactivated, position indication is not needed to determine status. Therefore, the position indication for valves in this state is not required to be OPERABLE.

~~Both AFW flow indication and SG water level provide indication of the status of decay heat removal capability via the SGs. Sufficient water must be contained in the SGs in order to assure that heat removal can be accomplished through boiling in the SG. Although only one channel exists for each function, the channels provide diverse indication of the same capability.~~

~~Table 3.3.3-1 provides a list of variables typical of those identified by the unit specific Regulatory Guide 1.97 (Ref. 1) analyses. Table 3.3.3-1 in unit specific TS should list includes instrumentation which is classified as either all Type A and/or Category I variables in accordance with identified by the unit specific Regulatory Guide 1.97 analyses, as amended by the NRC's SER, FSAR Section 7.5, and SER 14.~~

Type A and Category I variables are required to meet Regulatory Guide 1.97 Category I (Ref. 2) design and qualification requirements for seismic and environmental qualification, single failure criterion, utilization of emergency standby power, immediately accessible display, continuous readout, and recording of display, ~~except as exempted in SSER 31. Regulatory Guide 1.97, for certain functions, requires that the function be recorded on at least one channel. For these channels where direct and immediate trend or transient information is not essential for operator information, or both channels would be recorded per Regulatory Guide 1.97, the loss of the recorder is not considered to be a loss of function. However, the recorder should be returned to service as soon as possible and an alternate means~~

(continued)

BASES

~~of obtaining the recorded information be established if the recorder is to be out-of-service beyond the channel AOT.~~

Listed below are discussions of the specified instrument Functions listed in Table 3.3.3-1. ~~These discussions are intended as examples of what should be provided for each Function when the unit specific list is prepared.~~

(continued)

BASES

LCO
(continued)

1. Power Range and Source Range Neutron Flux (Wide Range NIS)

~~Power Range and Source Range Neutron Flux~~ indication is provided to verify reactor shutdown. The ~~two ranges are wide range NIS~~ is necessary to cover the full range of flux that may occur post accident.

Neutron flux is used for accident diagnosis, verification of subcriticality, and diagnosis of positive reactivity insertion.

2. Steam Line Pressure

~~Steam pressure is used to determine if a high energy secondary line rupture has occurred and the availability of the steam generators as a heat sink. It is also used to verify that a faulted steam generator is isolated. Steam pressure may be used to ensure proper cooldown rates or to provide a diverse indication for natural circulation cooldown.~~

3. 4. Reactor Coolant System (RCS) Hot and Cold Leg Temperatures

RCS Hot and Cold Leg Temperatures are Category I variables provided for verification of core cooling and long term surveillance.

RCS hot (~~outlet~~) and cold (~~inlet~~) leg temperatures are used to determine RCS subcooling margin. RCS subcooling margin will allow termination of safety injection (SI), if still in progress, or reinitiation of SI if it has been stopped. RCS subcooling margin is also used for unit stabilization and cooldown control. RCS hot leg temperature also provides a temperature compensating signal for the reactor vessel level instrumentation system (RVLIS).

In addition, RCS cold leg temperature is used in conjunction with RCS hot leg temperature to verify the unit conditions necessary to establish natural circulation in the RCS. The RCS cold leg temperature also provides a temperature input signal for the low temperature overpressure protection (LTOP) system.

Reactor outlet temperature inputs to the Reactor Protection System are provided by two fast response resistance elements and associated transmitters in each loop. The channels provide indication over a range of 32°F to 700°F.

(continued)

BASES

5. Reactor Coolant System Pressure (Wide Range)

RCS wide range pressure is a Category I variable provided for verification of core cooling and RCS integrity long term surveillance.

RCS pressure is used to verify delivery of SI flow to RCS from at least one train when the RCS pressure is

(continued)

BASES

LCO

5. Reactor Coolant System Pressure (Wide Range) (continued)

below the pump shutoff head. RCS pressure is also used to verify closure of manually closed spray line valves and pressurizer power operated relief valves (PORVs).

In addition to these verifications, RCS pressure is used for determining RCS subcooling margin. RCS subcooling margin will allow termination of SI, if still in progress, or reinitiation of SI if it has been stopped. RCS pressure can also be used:

- to determine whether to terminate actuated SI or to reinitiate stopped SI;
- to determine when to reset SI and shut off low head SI;
- to manually restart low head SI;
- as reactor coolant pump (RCP) trip criteria; and
- to make a determination on the nature of the accident in progress and where to go next in the procedure.

RCS subcooling margin is also used for unit stabilization and cooldown control.

RCS pressure is also related to three decisions about depressurization. They are:

- to determine whether to proceed with primary system depressurization;
- to verify termination of depressurization; and
- to determine whether to close accumulator isolation valves during a controlled cooldown/depressurization.

A two final uses of RCS pressure is are to determine whether to operate the pressurizer heaters and as an input to Reactor Vessel Water Level Instrumentation System (RVLIS).

(continued)

BASES

LCO

5. Reactor Coolant System Pressure (Wide Range) (continued)

~~In some units, RCS pressure is a Type A variable because the operator uses this indication to monitor the cooldown of the RCS following a steam generator tube rupture (SGTR) or small break LOCA. Operator actions to maintain a controlled cooldown, such as adjusting steam generator (SG) pressure or level, would use this indication. Furthermore, RCS pressure is one factor that may be used in decisions to terminate RCP operation.~~

6. Reactor Vessel Water Level

~~Reactor Vessel Water Level RVLS is provided for verification and long term surveillance of core cooling. It is also used for accident diagnosis and to determine reactor coolant inventory adequacy.~~

~~The Reactor Vessel Water Level Monitoring System RVLS provides a direct measurement of the collapsed liquid level above the fuel alignment plate. The collapsed level represents the amount of liquid mass that is in the reactor vessel above the core. Measurement of the collapsed water level is selected because it is a direct indication of the water inventory.~~

7. ~~a. Containment Wide Range Sump Water Level (Wide Range) and
b. Containment Recirculation Sump Level (Narrow Range)~~

~~Containment Wide Range Sump Water Level is provided for verification and long term surveillance of RCS integrity.~~

~~Containment Sump Water Level is used to determine:~~

- ~~• containment sump level accident diagnosis;~~
- ~~• when to begin the recirculation procedure; and~~
- ~~• whether to terminate SI, if still in progress.~~

~~Containment Recirculation Sump Level (Narrow Range) is used to verify that sufficient water is contained in the recirculation sump to allow operation of the Residual Heat Removal Pumps with the suction aligned to the containment recirculation sump. The required Regulatory Guide 1.97 recorder for this function is part of this instrument channel.~~

~~The Reactor Cavity Sump level instrumentation encompasses the range of the Containment Recirculation Sump and can be~~

(continued)

BASES

LCO
(continued)

~~Used to determine the appropriate time for swap-over of the RHR pumps from RWST to the Containment Recirculation Sump if required.~~

8. ~~a. Containment Pressure (Wide Range) and b. Containment Pressure (Normal Range)~~

~~Containment Pressure (Wide Range) is provided for verification of RCS and containment OPERABILITY.~~

~~Containment pressure is used to verify closure of main steam isolation valves (MSIVs) during a main steam line break inside containment, and containment spray Phase B isolation when High-3 high-high containment pressure is reached.~~

~~Both instruments are required to cover the Regulatory Guide 1.97 range requirements.~~

9. Containment Isolation Valve Position

~~CIV Position is provided for verification of Containment OPERABILITY, and Phase A and Phase B isolation, and containment ventilation system isolation.~~

~~When used to verify Phase A and Phase B isolation, the important information is the isolation status of the containment penetrations. The LCO requires one channel of valve position indication in the control room to be OPERABLE for each active CIV in a containment penetration flow path, i.e., two total channels of CIV position indication for a penetration flow path with two active valves. For containment penetrations with only one active CIV having control room indication, Note (b) requires a single channel of valve position indication to be OPERABLE. This is sufficient to redundantly verify the isolation status of each isolable penetration either via indicated status of the active valve, as applicable, and prior knowledge of a passive valve, or via system boundary status. If a normally active CIV is known to be closed and deactivated, position indication is not needed to determine status. Therefore, the position indication for valves in this state is not required to be OPERABLE. This function is on a per valve basis and ACTION A is entered separately for each inoperable valve indication. Note (a) to the Required Channels states that the function is not required for isolation valves whose associated penetration is isolated by at least one closed and deactivated automatic valve, closed manual valve, blind flange, or check valve with flow through the valve secured.~~

(continued)

BASES

LCO
(continued)

10. Containment Area Radiation (High Range)

Containment Area Radiation is provided to monitor for the potential of significant radiation releases and to provide release assessment for use by operators in determining the need to invoke site emergency plans. Containment radiation level is used to determine if a high energy line break (HELB) containing radioactive fluid has occurred, and whether the event is inside or outside of containment.

11. Containment Hydrogen Concentration Monitors

Containment Hydrogen Monitors are Concentration monitoring is provided to detect high hydrogen concentration conditions that represent a potential for containment breach from a hydrogen explosion. This variable is also important in verifying the adequacy of mitigating actions and is used to determine whether or not hydrogen recombiners should be started.

12. Pressurizer Level

Pressurizer Level is used to determine whether to terminate SI, if still in progress, or to reinitiate SI if it has been stopped. Knowledge of pressurizer water level is also used to verify the unit conditions necessary to establish natural circulation in the RCS and to verify that the unit is maintained in a safe shutdown condition.

13. a. Steam Generator Water Level (Wide Range) and b. Steam Generator Level (Narrow Range)

SG Water Level is provided to monitor operation of decay heat removal via the SGs. The Category I indication of SG level is the extended startup range level instrumentation. The extended startup wide range level covers a span of ≥ 6 inches to ≤ 394.582 inches above the lower tubesheet. The measured differential pressure is displayed in inches of water at 68°F.

Temperature compensation of this indication is performed manually by the operator. Redundant monitoring capability is provided by two trains of instrumentation. The uncompensated level signal is

(continued)

BASES

LCO

13. Steam Generator Water Level (Wide Range) (continued)

~~input to the unit computer, a control room indicator, and the Emergency Feedwater Control System.~~

SG Water Level ~~(Wide Range)~~ is used to:

- identify the faulted SG following a tube rupture;
- verify that the intact SGs are an adequate heat sink for the reactor;
- determine the nature of the accident in progress (e.g., verify an SGTR); and
- verify unit conditions for termination of SI during secondary unit HELBs outside containment.

~~At some units, Operator action is based on the control room indication of SG level. The RCS response during a design basis small break LOCA depends on the break size. For a certain range of break sizes, the boiler condenser reflux cooling mode of heat transfer is necessary to remove decay heat. Extended startup wide range level is a Type A variable because the operator must manually raise and control SG level to establish boiler condenser reflux cooling heat transfer. Operator action is initiated on a loss of subcooled margin. Feedwater flow is increased until the indicated extended startup wide range level reaches the boiler condenser setpoint reflux cooling initiation point.~~

~~SG Water Level (Narrow Range) is redundant to the SG wide range level and provides indication of adequate RCS heat removal capability during normal SG inventory conditions. The narrow range level covers a span from 437 inches to 581 inches above the lower tubesheet.~~

14. Condensate Storage Tank (CST) Level

CST Level is provided to ensure water supply for auxiliary feedwater (AFW). The CST provides the ensured safety grade water supply for the AFW System. ~~The CST consists of two identical tanks connected by a common outlet header. Inventory is monitored by a 0 inch to 144 inch level indication for each tank. CST Level is displayed on a control room indicator, strip chart recorder, and unit computer. In addition, a control room annunciator alarms on low level.~~

(continued)

BASES

LCO

14. Condensate Storage Tank (CST) Level (continued)

~~At some units, CST Level is considered a Type A variable because the control room meter and annunciator are is considered the primary indication used by the operator.~~

The DBAs that require AFW are the loss of electric power, steam line break (SLB), and small break LOCA.

The CST is the initial source of water for the AFW System. However, as the CST is depleted, manual operator action is necessary to replenish the CST or align suction to the AFW pumps from the hotwell ~~Fire Water Storage Tank or other alternate sources.~~

15, 16, 17, 18. In-Core Exit Temperature Thermocouples

~~In-Core Exit Temperature is Thermocouples are provided for verification and long term surveillance of core cooling.~~

An evaluation was made of the minimum number of valid core exit ~~in-core~~ thermocouples (GET) necessary for measuring core cooling. The evaluation determined the reduced complement of GETs ~~in-core thermocouple~~ necessary to detect initial core recovery and trend the ensuing core heatup. The evaluations account for core nonuniformities, including incore effects of the radial decay power distribution, excore effects of condensate runback in the hot legs, and nonuniform inlet temperatures. Based on these evaluations, ~~adequate core cooling is ensured can be adequately monitored with two valid Core Exit Temperature in-core thermocouple channels per quadrant with two GETs in-core thermocouples per required channel. The GET pair are oriented radially to permit evaluation of core radial decay power distribution. Core Exit Temperature is used to determine whether to terminate SI, if still in progress, or to reinitiate SI if it has been stopped. Core Exit Temperature is also used for unit stabilization and cooldown control.~~

~~Two OPERABLE channels of Core Exit Temperature In-Core Thermocouples are required in each quadrant to provide indication of radial distribution of the coolant temperature rise across representative regions of the core. Power distribution symmetry was considered in determining the specific number and locations provided for diagnosis of local core problems. Therefore, two randomly selected thermocouples are not sufficient to~~

(continued)

BASES

LCO 15, 16, 17, 18. Core Exit Temperature (continued)

~~meet the two thermocouples per channel requirement in any quadrant. The two thermocouples in each channel must meet the additional requirement that one is located near the center of the core and the other near the core perimeter, such that the pair of Core Exit Temperatures indicate the radial temperature gradient across their core quadrant. Unit specific evaluations in response to Item II.F.2 of NUREG 0737 (Ref. 3) should have identified the thermocouple pairings that satisfy these requirements. Two sets of two thermocouples ensure a single failure will not disable the ability to determine the radial temperature gradient.~~

19. Auxiliary Feedwater (AFW) Flow

AFW Flow is provided to monitor operation of decay heat removal via the SGs.

The AFW Flow to each SG is determined from a differential pressure measurement calibrated for a range of 0 gpm to 1200 ~~300~~ gpm. ~~Redundant monitoring capability is provided by two independent trains of instrumentation for each SG.~~ Each differential pressure transmitter provides an input to a control room indicator and the unit computer. Since the primary indication used by the operator during an accident is the control room indicator, the PAM specification deals specifically with this portion of the instrument channel.

AFW flow is used three ways:

- to verify delivery of AFW flow to the SGs;
- to determine whether to terminate SI if still in progress, in conjunction with SG water level (narrow range); and
- to regulate AFW flow so that the SG tubes remain covered.

(continued)

BASES

LCO

19. Auxiliary Feedwater Flow (continued)

~~At some units, AFW flow is a Type A variable because operator action is required to throttle flow during an SLB accident to prevent the AFW pumps from operating in runout conditions. AFW flow is also used by the operator to verify that the AFW System is delivering the correct flow to each SG. However, the primary indication used by the operator to ensure an adequate inventory is SG level (Narrow Range) during normal SG inventory conditions.~~

~~20. (new) Refueling Water Storage Tank (RWST) Water Level~~

~~RWST water level is used to verify the water source availability to the emergency core cooling system (ECCS) and Containment Spray Systems. It may also provide an indication of time for initiating cold leg recirculation from the sump following a LOCA. The RWST level signal trips the Residual Heat Removal Pumps at 33% in preparation for transfer to cold leg recirculation.~~

APPLICABILITY

The PAM instrumentation LCO is applicable in MODES 1, 2, and 3 ~~except for the Containment hydrogen Concentration monitor that is only required to be OPERABLE in MODES 1 and 2.~~ These variables are related to the diagnosis and pre-planned actions required to mitigate DBAs. The applicable DBAs are assumed to occur in MODES 1, 2, and 3. ~~In MODES 4, 5, and 6, and in MODE 2 for the Containment Hydrogen Concentration monitor, unit conditions are such that the likelihood of an event that would require PAM instrumentation is low; therefore, the PAM instrumentation is not required to be OPERABLE in these MODES.~~

ACTIONS

Note 1 has been added in the ACTIONS to exclude the MODE change restriction of LCO 3.0.4. This exception allows entry into the applicable MODE while relying on the ACTIONS even though the ACTIONS may eventually require unit shutdown. This exception is acceptable due to the passive function of the instruments, the operator's ability to respond to an accident using alternate instruments and methods, and the low probability of an event requiring these instruments.

Note 2 has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed on Table 3.3.3-1.

(continued)

BASES

ACTIONS

A.1 (continued)

The Completion Time(s) of the inoperable channel(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

Condition A applies when one or more Functions have one required channel that is inoperable, ~~but at least one OPERABLE remaining channel~~. Required Action A.1 requires restoring the inoperable channel to OPERABLE status within 30 days. The 30 day Completion Time is based on operating experience and takes into account the remaining OPERABLE channel (or in the case of a Function that has only one required channel, other non-Regulatory Guide 1.97 instrument channels to monitor the Function), the passive nature of the instrument (no critical automatic action is assumed to occur from these instruments), and the low probability of an event requiring PAM instrumentation during this interval.

B.1

Condition B applies when the Required Action and associated Completion Time for Condition A are not met. This Required Action specifies initiation of actions in Specification 5.6.8, which requires a written report to be submitted to the NRC immediately. This report discusses the results of the root cause evaluation of the inoperability and identifies proposed restorative actions. This action is appropriate in lieu of a shutdown requirement since alternative actions are identified before loss of functional capability, and given the likelihood of unit conditions that would require information provided by this instrumentation.

C.1

Condition C applies when one or more Functions have ~~two inoperable required no OPERABLE~~ channels (i.e., ~~two channels inoperable in the same Function~~). Required Action C.1 requires restoring one channel in the Function(s) to OPERABLE status within 7 days. The Completion Time of 7 days is based on the relatively low probability of an event requiring PAM instrument operation and the availability of alternate means to obtain the required information. Continuous operation with ~~two no~~ required channels ~~inoperable~~ OPERABLE in a Function is not acceptable because the alternate indications may not fully meet all performance qualification requirements applied to the PAM instrumentation. Therefore, requiring restoration

(continued)

BASES

ACTIONS

C.1 (continued)

of one inoperable channel of the Function limits the risk that the PAM Function will be in a degraded condition should an accident occur. Condition C is modified by a Note that excludes hydrogen monitor channels.

D.1

Condition D applies when two hydrogen monitor channels are inoperable. Required Action D.1 requires restoring one hydrogen monitor channel to OPERABLE status within 72 hours. The 72 hour Completion Time is reasonable based on the backup capability of the Post Accident Sampling System to monitor the hydrogen concentration for evaluation of core damage and to provide information for operator decisions. Also, it is unlikely that a LOCA (which would cause core damage) would occur during this time. Condition D is modified by a Note that limits the APPLICABILITY for the Containment Hydrogen Concentration monitor to MODES 1 and 2.

E.1

Condition E applies when the Required Action and associated Completion Time of Condition C or D are not met. Required Action E.1 requires entering the appropriate Condition referenced in Table 3.3.3-1 for the channel immediately. The applicable Condition referenced in the Table is Function dependent. Each time an inoperable channel has not met any Required Action of Condition C or D, and the associated Completion Time has expired, Condition E is entered for that channel and provides for transfer to the appropriate subsequent Condition.

F.1 and F.2

If the Required Action and associated Completion Time of Conditions C or D are not met and Table 3.3.3-1 directs entry into Condition F, the unit must be brought to a MODE where the requirements of this LCO do not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and MODE 4 within 12 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions

(continued)

BASES

ACTIONS

F.1 and F.2 (continued)

from full power conditions in an orderly manner and without challenging unit systems.

G.1

~~At this unit, Alternate means of monitoring Reactor Vessel Water Level and Containment Area Radiation have been will be developed and tested demonstrated prior to use. These alternate means may be temporarily installed if the normal PAM channel cannot be restored to OPERABLE status within the allotted time. If these alternate means are used, the Required Action is not to shut down the unit but rather to follow the directions of Specification 5.6.8, in the Administrative Controls section of the TS. The report provided to the NRC should discuss the alternate means used, describe the degree to which the alternate means are equivalent to the installed PAM channels, justify the areas in which they are not equivalent, and provide a schedule for restoring the normal PAM channels.~~

H.1

~~If the Required Action and associated Completion Time of Conditions D is not met and Table 3.3.3-1 directs entry into Condition H, the unit must be brought to a MODE where the requirements of this LCO do not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours.~~

~~The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.~~

SURVEILLANCE
REQUIREMENTS

A Note has been added to the SR Table to clarify that SR 3.3.3.1 and SR 3.3.3.2 apply to each PAM instrumentation Function in Table 3.3.3-1.

SR 3.3.3.1

Performance of the CHANNEL CHECK once every 31 days ensures that a gross instrumentation failure has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus,

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.3.1 (continued)

it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION. The high radiation instrumentation should be compared to similar unit instruments located throughout the unit.

Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties, including isolation, indication, and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are within the criteria, it is an indication that the channels are OPERABLE.

As specified in the SR, a CHANNEL CHECK is only required for those channels that are normally energized. The Containment Hydrogen Concentration monitors are maintained in a "standby" condition which does not energize all of the monitor components, thus the monitors are not considered "normally energized".

The Frequency of 31 days is based on operating experience that demonstrates that channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.3.2

A CHANNEL CALIBRATION is performed every [18] months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to measured parameter with the necessary range and accuracy. This SR is modified by a two Notes that Note 1 excludes neutron detectors from CHANNEL CALIBRATION. The calibration method for neutron detectors is specified in the Bases of LCO 3.3.1, "Reactor Trip System (RTS) Instrumentation." Note 2 discusses an allowed methodology for calibrating the Containment Radiation Level (High Range) Function. The Frequency is based on operating experience and consistency with the typical industry refueling cycle.

B 3.3 INSTRUMENTATION

B 3.3.4 Remote Shutdown System

BASES

BACKGROUND

The Remote Shutdown System provides the control room operator with sufficient instrumentation and controls to place and maintain the unit in a safe shutdown condition from a location other than the control room. This capability is necessary to protect against the possibility that the control room becomes inaccessible. A safe shutdown condition is defined as MODE 3. With the unit in MODE 3, the Auxiliary Feedwater (AFW) System and the steam generator (SG) safety valves or the SG atmospheric dump valves (ADVs) can be used to remove core decay heat and meet all safety requirements. The long term supply of water for the AFW System and the ability to borate the Reactor Coolant System (RCS) allows extended operation in MODE 3 until such time that either control is transferred back to the Control Room or a cooldown is initiated from outside the control room.

If the control room becomes inaccessible, the operators can establish control at the remote shutdown panel (hot shutdown panel), and place and maintain the unit in MODE 3. Not all controls and necessary transfer switches are located at the remote hot shutdown panel. Some controls and transfer switches will have to be operated locally at the switchgear, motor control panels, or other local stations. The unit automatically reaches MODE 3 following a unit shutdown and can be maintained safely in MODE 3 for an extended period of time.

The OPERABILITY of the remote shutdown control and instrumentation functions ensures there is sufficient information available on selected unit parameters to place and maintain the unit in MODE 3 should the control room become inaccessible.

APPLICABLE SAFETY ANALYSES

The Remote Shutdown System is required to Instrumentation Functions and the hot shutdown panel controls provides equipment at appropriate locations outside the control room with a capability to promptly shut down and maintain the unit in a safe condition in MODE 3.

The criteria governing the design and specific system requirements of the Remote Shutdown System Instrumentation Functions and controls are located in 10 CFR 50, Appendix A, GDC 19 (Ref. 1).

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

The Remote Shutdown System Instrumentation Functions and the hot shutdown panel controls is considered an important contributor to the reduction of unit risk to accidents and as such it has been retained in the Technical Specifications as indicated in the NRC Policy Statement by Criterion 4 of 10 CFR 50.36(c)(2)(iii).

LCO

The Remote Shutdown System Instrumentation Functions and the hot shutdown panel controls LCO provides the OPERABILITY requirements of the instrumentation and controls necessary to place and maintain the unit in MODE 3 from a location other than the control room. The instrumentation and controls typically required are listed in Table 3.3.4-1 in the accompanying LCO.

~~Reviewer's Note: For channels that fulfill GDC 19 requirements, the number of OPERABLE channels required depends upon the unit licensing basis as described in the NRC unit specific Safety Evaluation Report (SER). Generally, two divisions are required OPERABLE. However, only one channel per a given Function is required if the unit has justified such a design, and NRC's SER accepted the justification.~~

The controls, instrumentation, and transfer switches are required for:

- ~~Core reactivity control (initial and long term) Reactor trip indication;~~
- RCS pressure control;
- Decay heat removal via the AFW System and the SG safety valves or SG ADVs;
- RCS inventory control via charging flow; and
- Safety support systems for the above Functions, including service water auxiliary saltwater, component cooling water, and onsite power, including the diesel generators.

A Function of a Remote Shutdown System is OPERABLE if all required instrument and control channels needed to support the Remote Shutdown System Function for that function listed in Table 3.3.4-1 are OPERABLE. In some cases, Table 3.3.4-1 may indicate that the required information or control capability is available from several alternate sources. In these cases, the Function is OPERABLE as long

(continued)

BASES

LCO
(continued) as one channel of any of the alternate information or control sources is OPERABLE.

The remote shutdown instrument and control circuits covered by this LCO do not need to be energized to be considered OPERABLE. This LCO is intended to ensure the instruments and control circuits will be OPERABLE if unit conditions require that the Remote Shutdown System be placed in operation.

APPLICABILITY The Remote Shutdown System LCO is applicable in MODES 1, 2, and 3. This is required so that the unit can be placed and maintained in MODE 3 for an extended period of time from a location other than the control room until either control is transferred back to the control room or a cooldown is initiated.

This LCO is not applicable in MODE 4, 5, or 6. In these MODES, the facility is already subcritical and in a condition of reduced RCS energy. Under these conditions, considerable time is available to restore necessary instrument control functions if control room instruments or controls become unavailable.

ACTIONS

Note 1 is included which excludes the MODE change restriction of LCO 3.0.4. This exception allows entry into an applicable MODE while relying on the ACTIONS even though the ACTIONS may eventually require a unit shutdown. This exception is acceptable due to the low probability of an event requiring the Remote Shutdown System and because the equipment can generally be repaired during operation without significant risk of spurious trip.

Note 2 has been added to the ACTIONS to clarify the application of Completion Time rules. Separate Condition entry is allowed for each Function listed on Table 3.3.4-1. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

(continued)

BASES

ACTIONS
(continued)

A.1

Condition A addresses the situation where one or more required Functions of the Remote Shutdown System Instrumentation and SD panel controls are inoperable. This includes any Function listed in Table 3.3.4-1, as well as the control and transfer switches.

The Required Action is to restore the required Function to OPERABLE status within 30 days. The Completion Time is based on operating experience and the low probability of an event that would require evacuation of the control room.

B.1 and B.2

If the Required Action and associated Completion Time of Condition A is not met, the unit must be brought to a MODE in which the LCO does not apply. To achieve this status, the unit must be brought to at least MODE 3 within 6 hours and to MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.3.4.1

Performance of the CHANNEL CHECK once every 31 days ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

A channel check of the RTBs is inappropriate since their indication is local and any gross failure would be readily detected.

Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties, including indication and readability. If the channels are

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.4.1 (continued)

~~within the criteria, it is an indication that the channels are OPERABLE. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit. If the channels are normally off scale during times when Surveillance is required, the CHANNEL CHECK will verify only that they are off scale in the same direction. Offscale low current loop channels are verified to be reading at the bottom of the range and not failed downscale.~~

~~As specified in the Surveillance, a CHANNEL CHECK is only required for those channels which are normally energized.~~

The Frequency of 31 days is based upon operating experience which demonstrates that channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.4.2

SR 3.3.4.2 verifies each required Remote Shutdown System control circuit and transfer switch performs the intended function. This verification is performed from the ~~remote~~ ^{hot} shutdown panel and locally, as appropriate. Operation of the equipment from the remote shutdown panel is not necessary. The Surveillance can be satisfied by performance of a continuity check. This will ensure that if the control room becomes inaccessible, the unit can be placed and maintained in MODE 3 from the remote shutdown panel and the local control stations. The ~~{18}~~ month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. (However, this Surveillance is not required to be performed only during a unit outage.) Operating experience demonstrates that remote shutdown control channels usually pass the Surveillance test when performed at the ~~{18}~~ month Frequency.

SR 3.3.4.3

CHANNEL CALIBRATION is a complete check of the instrument loop and the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

~~The channel calibration is not applicable to the RTB indication~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.4.3 (continued)

The Frequency of [18] months is based upon operating experience and consistency with the typical industry refueling cycle.

SR 3.3.4.4

~~SR 3.3.4.4 is the performance of a TADOT every 18 months. This test should verify the OPERABILITY of the reactor trip breakers (RTBs) open and closed indication on the remote shutdown panel, by actuating the RTBs. The Frequency is based upon operating experience and consistency with the typical industry refueling outage.~~

~~NOTE: A surveillance of the reactor trip breaker OPERABILITY is not required as part of the SURVEILLANCE REQUIREMENT since a TRIP ACTUATING DEVICE OPERATIONAL TEST of the reactor trip breakers is performed as part of the SURVEILLANCE REQUIREMENT for TS 3.3.1.~~

B 3.3 INSTRUMENTATION

B 3.3.5 Loss of Power (LOP) Diesel Generator (DG) Start Instrumentation

BASES

BACKGROUND

The DGs provide a source of emergency power when offsite power is either unavailable or is insufficiently stable to degraded below a point that would allow safe unit operation. Undervoltage protection will generate an LOP start if a loss of voltage or degraded voltage condition occurs in on the switchyard 4.16KV vital bus. There are two three LOP start signals, one for each 4.16 kV vital bus.

Three undervoltage relays with inverse time characteristics are provided on each 4160 Class 1E instrument vital bus for detecting a sustained degraded voltage condition or a loss of bus voltage. The relays are combined in a two-out-of-three logic to will generate an LOP signal (first level undervoltage type relay setpoint) if the voltage is below 75% for a short time or below 90% for a long time. The DG start relays (one per bus) have an inverse time characteristic and will generate an LOP signal with a ≤ 0.8 sec time delay at ≥ 0 volts and at ≤ 10 seconds for ≥ 2583 volts. In addition, the circuit breakers for all loads, except the 4160-480 V load center transformers, are opened automatically by a similar set of first level undervoltage relays. Each of the vital 4160 kV buses has a separate pair of these relays. The relays have a two-out-of-two logic arrangement for each bus to prevent inadvertent tripping of operating loads during a loss of voltage either from a single failure in the potential circuits or from human error. One relay trips instantaneously at ≥ 2870 volts. The second of the two relays has an inverse time characteristic and a delay of ≤ 4 seconds at no voltage and a ≤ 25 second delay with ≥ 2583 volts to prevent loss of operating loads during transient voltage dips, and to permit the offsite power sources to pick up the load. The LOP start actuation is described in FSAR, Section 8.3 (Ref. 1).

Should there be a degraded voltage condition where the voltage of the vital 4160 kV buses remains at approximately 3785 kV or below, but above the setpoints of the first level undervoltage relays, the following second level undervoltage actions occur automatically:

- (1) After a ≤ 10 second time delay, the respective diesel generators will start.
- (2) After a ≤ 20 second time delay, if the undervoltage condition persists, the circuit breakers for all loads to the respective vital 4160 kV buses, except the 4160-480 V load center transformer, are opened and sequentially loaded on the DG.

Each vital 4160 kV bus has two second level undervoltage relays and one associated timer to initiate each of the above actions (1) and (2) (one timer for each action).

(continued)

BASES

Trip Setpoints and Allowable Values

The Trip Setpoints used in the relays are based on the analytical limits presented in FSAR, Chapter 15 (Ref. 2). The selection of these Trip Setpoints is such that adequate protection is provided when all sensor and processing time delays are taken into account.

The actual nominal Trip Setpoint entered into the relays is normally still more conservative than that required by the Allowable Value. If the measured setpoint does not exceed the Allowable Value, the relay is considered OPERABLE.

Setpoints adjusted in accordance with the Allowable Value ensure that the consequences of accidents will be acceptable, providing the unit is operated from within the LCOs at the onset of the accident and that the equipment functions as designed.

Allowable Values and/or Trip Setpoints are specified for each Function in the LCO. Nominal Trip Setpoints are also specified in the unit specific setpoint calculations. The nominal setpoints are selected to ensure that the setpoint measured by the surveillance procedure does not exceed the Allowable Value if the relay is performing as required. If the measured setpoint does not exceed the Allowable Value, the relay is considered OPERABLE. Operation with a Trip Setpoint less conservative than the nominal Trip Setpoint, but within the Allowable Value, is acceptable provided that operation and testing is consistent with the assumptions of the unit specific setpoint calculation. Each Allowable Value and/or Trip Setpoint specified is more conservative than the analytical limit assumed in the transient and accident analyses in order to account for instrument uncertainties appropriate to the trip function. These uncertainties are defined in the "Unit Specific RTS/ESFAS Setpoint Methodology Study" WCAP 11082, Rev. 2 Westinghouse Setpoint Methodology for Protection Systems Diablo Canyon Stations - Eagle 21 Version (Ref. 3).

APPLICABLE SAFETY ANALYSES The LOP DG start instrumentation is required for the Engineered Safety Features (ESF) Systems to function in any accident with a loss of offsite power. Its design basis is that of the ESF Actuation System (ESFAS).

Accident analyses credit the loading of the DG based on the loss of offsite power during a loss of coolant accident (LOCA). The actual DG start has historically been associated with the ESFAS actuation. The DG loading has been included in the delay time associated with each safety system component requiring DG supplied power following a loss of offsite power. The analyses assume a non-mechanistic DG loading, which does not explicitly account for each individual component of loss of power detection and subsequent actions.

(continued)

BASES

The required channels of LOP DG start instrumentation, in conjunction with the ESF systems powered from the DGs, provide unit protection in the event of any of the analyzed accidents discussed in Reference 2, in which a loss of offsite power is assumed.

The delay times assumed in the safety analysis for the ESF equipment include the 10 second DG start delay, and the appropriate sequencing delay, if applicable. The response times for ESFAS actuated equipment in LCO 3.3.2, "Engineered Safety Feature Actuation System (ESFAS) Instrumentation," include the appropriate DG loading and sequencing delay.

(continued)

BASES

APPLICABLE SAFETY ANALYSES The LOP DG start instrumentation channels satisfy Criterion 3 of the NRC Policy Statement.
(continued)

LCO The LCO for LOP DG start instrumentation requires that ~~three~~ one channels per bus of both the loss of voltage and two channels per bus for initiation of load shed and two channels per bus of degraded voltage with one timer per bus for DG start and initiation of load shed Functions shall be OPERABLE in MODES 1, 2, 3, and 4 when the LOP DG start instrumentation supports safety systems associated with the ESFAS. In MODES 5 and 6, the ~~three~~ channels must be OPERABLE whenever the associated DG is required to be OPERABLE to ensure that the automatic start of the DG is available when needed. Loss of the LOP DG Start Instrumentation Function could result in the delay of safety systems initiation when required. This could lead to unacceptable consequences during accidents. During the loss of offsite power the DG powers the motor driven auxiliary feedwater pumps. Failure of these pumps to start would leave only one turbine driven pump, as well as an increased potential for a loss of decay heat removal through the secondary system.

APPLICABILITY The LOP DG Start Instrumentation Functions are required in MODES 1, 2, 3, and 4 because ESF Functions are designed to provide protection in these MODES. Actuation in MODE 5 or 6 is required whenever the required DG must be OPERABLE so that it can perform its function on an LOP or degraded power to the vital bus.

ACTIONS In the event a channel's Trip Setpoint is found nonconservative with respect to the Allowable Value, or the channel is found inoperable, then the function that channel provides must be declared inoperable and the LCO Condition entered for the particular protection function affected.

Because the required channels are specified on a per bus basis, the Condition may be entered separately for each bus as appropriate.

A Note has been added in the ACTIONS to clarify the application of Completion Time rules. The Conditions of

(continued)

BASES

ACTIONS
(continued)

this Specification may be entered independently for each Function listed in the LCO. The Completion Time(s) of the inoperable channel(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

A.1

~~Condition A applies to the LOP DG start Function with one loss of voltage or degraded voltage channel per bus inoperable.~~

~~If one channel is inoperable, Required Action A.1 requires that channel to be placed in trip within 6 hours. With a channel in trip, the LOP DG start instrumentation channels are configured to provide a one out of three logic to initiate a trip of the incoming offsite power.~~

~~A Note is added to allow bypassing an inoperable channel for up to 4 hours for surveillance testing of other channels. This allowance is made where bypassing the channel does not cause an actuation and where at least two other channels are monitoring that parameter.~~

~~The specified Completion Time and time allowed for bypassing one channel are reasonable considering the Function remains fully OPERABLE on every bus and the low probability of an event occurring during these intervals.~~

B.1

~~Condition BA applies when one or more than one of the loss of voltage or more than one the degraded voltage channel functions (this includes both relays and timers) on a single bus are inoperable.~~

~~Required Action B.1 requires restoring all but one channel to OPERABLE status. The 1 hour Completion Time should allow ample time to repair most failures and takes into account the low probability of an event requiring an LOP start occurring during this interval.~~

(continued)

BASES

ACTIONS
(continued)

C-1

~~Condition C applies to each of the LOP DG start Functions when the Required Action and associated Completion Time for Condition A or B are not met.~~

In these circumstances the Conditions specified in LCO 3.8.1, "AC Sources - Operating," or LCO 3.8.2, "AC Sources - Shutdown," for the DG made inoperable by failure of the LOP DG start instrumentation are required to be entered immediately. The actions of those LCOs provide for adequate compensatory actions to assure unit safety.

~~A Note is added to allow bypassing an inoperable channel for up to 2 hours for surveillance testing. This allowance is made where bypassing the channel does not cause an actuation and where at least one other channel is monitoring that parameter.~~

SURVEILLANCE
REQUIREMENTS

SR-3.3.5.1

~~Performance of the CHANNEL CHECK once every 12 hours ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying that the instrumentation continues to operate properly between each CHANNEL CALIBRATION.~~

~~Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit.~~

~~The Frequency is based on operating experience that demonstrates channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.3.5.2

SR 3.3.5.2 is the performance of a TADOT. This test is performed every ~~{31 days}~~ 18 months. The test checks trip devices that provide actuation signals directly, bypassing the analog process control equipment. For these tests, the relay Trip Setpoints are verified and adjusted as necessary. The Frequency is based on the known reliability of the relays and controls and the multichannel redundancy available, and has been shown to be acceptable through operating experience.

SR 3.3.5.3

SR 3.3.5.3 is the performance of a CHANNEL CALIBRATION.

The setpoints, as well as the response to a loss of voltage and a degraded voltage test, shall include a single point verification that the trip occurs within the required time delay, ~~as shown in Reference 1.~~

A CHANNEL CALIBRATION is performed every ~~{18} months, or~~ approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

The Frequency of ~~{18} months~~ is based on operating experience and consistency with the typical industry refueling cycle and is justified by the assumption of an ~~{18} month~~ calibration interval in the determination of the magnitude of equipment drift in the setpoint analysis.

B 3.3 INSTRUMENTATION

B 3.3.6 Containment Purge and Exhaust ~~Ventilation~~ Isolation Instrumentation

BASES

BACKGROUND

Containment purge and exhaust ~~ventilation~~ isolation instrumentation closes the containment ~~ventilation~~ isolation valves in the Mini Purge System and the Shutdown Purge System. This action in conjunction with a Phase A signal isolates the containment atmosphere from the environment to minimize releases of radioactivity in the event of an accident. The Mini Purge or Vacuum/Pressure Relief System may be in use during reactor operation and the Shutdown Purge System will be in use with the OR reactor shutdown.

Containment purge and exhaust ~~ventilation~~ isolation initiates on a automatic safety injection (SI) signal through the Containment Isolation-Phase A Function, or by manual actuation of Phase A Isolation. The Bases for LCO.3.3.2, "Engineered Safety Feature Actuation System (ESFAS) Instrumentation," discuss these modes of initiation.

Four ~~two~~ radiation monitoring channels are also provided as input to the containment purge and exhaust ~~ventilation~~ isolation. The ~~four~~ ~~two~~ channels measure containment radiation at ~~two~~ locations. One channel is a containment area gamma monitor, and the other three measure radiation in a sample of the containment purge exhaust. The three purge exhaust radiation detectors are of three different types: gaseous, particulate, and iodine monitors. All four in the exhaust duct for fan E-3. Both detectors will respond to most events that release radiation to containment. Both monitors are gaseous activity monitors that will respond to noble gases, particulate and iodine. The high alarm setpoint is based upon the design basis fuel handling accident source term which does not have a particulate component. The actual high alarm setpoint is more than a factor of 500 below the design calculation earliest actuation point. Since the monitors can only be adjusted to one high alarm setpoint and no particulate is expected during a fuel handling accident, a setpoint based on site boundary noble gases is conservative. However, analyses have not been conducted to demonstrate that all credible events will be detected by more than one monitor. Therefore, for the purposes of this LCO the four channels are not considered redundant. Instead, they are treated as four one out of one Functions. Since the purge exhaust monitors constitute a sampling system, various components such as sample line valves, sample line heaters, sample pumps, and filter motors are required to support monitor OPERABILITY.

Each of the purge systems has inner and outer containment isolation valves in its supply and exhaust ducts. A high radiation signal from any one ~~either~~ of the four ~~two~~ channels initiates containment

(continued)

BASES

BACKGROUND
(continued)

~~purge ventilation isolation, which closes both inner and outer the containment ventilation isolation valves in the Mini Purge System and the Shutdown Purge System. These systems are described in the Bases for LCO 3.6.3, "Containment Isolation Valves."~~

APPLICABLE
SAFETY ANALYSES

The safety analyses assume that the containment remains intact with penetrations unnecessary for core cooling isolated early in the event, within approximately 60 seconds. The isolation of the ~~purge containment ventilation~~ valves has not been analyzed mechanistically in the dose calculations, although its ~~rapid isolation, using a conservative isolation time~~ is assumed. The containment purge and exhaust ~~ventilation isolation~~ radiation monitors act as backup to the SI signal to ensure closing of the purge and exhaust ~~containment ventilation isolation~~ valves. They are also the primary means for automatically isolating containment in the event of a fuel handling accident during shutdown. Containment isolation in turn ensures meeting the containment leakage rate assumptions of the safety analyses, and ensures that the calculated accidental offsite radiological doses are below 10 CFR 100 (Ref. 1) limits.

The containment purge and exhaust ~~ventilation~~ isolation instrumentation satisfies Criterion 3 of the ~~NRC Policy Statement 10 CFR 50.36(c)(2)(iii)~~.

LCO

The LCO requirements ensure that the instrumentation necessary to initiate Containment Purge and Exhaust ~~Ventilation~~ Isolation, listed in Table 3.3.6-1, is OPERABLE.

1. Manual Initiation
~~NOT USED~~

~~The LCO requires two channels OPERABLE. The operator can initiate Containment Purge Isolation at any time by using either of two switches in the control room. Either switch actuates both trains. This action will cause actuation of all components in the same manner as any of the automatic actuation signals.~~

~~The LCO for Manual Initiation ensures the proper amount of redundancy is maintained in the manual actuation circuitry to ensure the operator has manual initiation capability.~~

~~Each channel consists of one push button and the interconnecting wiring to the actuation logic cabinet.~~

(continued)

BASES

LCO
(continued)

2. Automatic Actuation Logic and Actuation Relays

The LCO requires two trains of Automatic Actuation Logic and Actuation Relays OPERABLE to ensure that no single random failure can prevent automatic actuation.

Automatic Actuation Logic and Actuation Relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b, SI, and ESFAS Function 3.a, Containment Phase A Isolation. The applicable MODES and specified conditions for the containment purge ventilation isolation portion of these Functions are different and less restrictive than those for their Phase A isolation and SI roles. If one or more of the SI or Phase A isolation Functions becomes inoperable in such a manner that only the Containment Purge Ventilation Isolation Function is affected, the Conditions applicable to their SI and Phase A isolation Functions need not be entered. The less restrictive Actions specified for inoperability of the Containment Purge Ventilation Isolation Functions specify sufficient compensatory measures for this case.

3. Containment Radiation

The LCO specifies ~~four~~ two required channels of radiation monitors to ensure that the radiation monitoring instrumentation necessary to initiate Containment Purge Ventilation Isolation remains OPERABLE in MODES 1-4. ~~The LCO only requires one monitor to be OPERABLE during CORE ALTERATIONS or during movement of irradiated fuel assemblies in MODES 1-4. The LCO requires only one monitor to be operable during CORE ALTERATIONS or during movement of irradiated fuel~~

~~For sampling systems, channel OPERABILITY involves more than OPERABILITY of the channel electronics. OPERABILITY may also require correct valve lineups, sample pump operation, and filter motor operation, as well as detector OPERABILITY, if these supporting features are necessary for trip to occur under the conditions assumed by the safety analyses.~~

4. Containment Isolation - Phase A

Refer to LCO 3.3.2, Function 3.a., for all initiating Functions and requirements.

(continued)

BASES (continued)

APPLICABILITY The ~~Manual Initiation~~, Automatic Actuation Logic and Actuation Relays, Containment Isolation-Phase A, and Containment Radiation Functions are required OPERABLE in MODES 1, 2, 3, and 4, and during CORE ALTERATIONS or movement of irradiated fuel assemblies within containment. Under these conditions, the potential exists for an accident that could release fission product radioactivity into containment. Therefore, the containment purge and exhaust ~~ventilation~~ isolation instrumentation must be OPERABLE in these MODES.

While in MODES 5 and 6 without fuel handling in progress, the containment purge and exhaust ~~ventilation~~ isolation instrumentation need not be OPERABLE since the potential for radioactive releases is minimized and operator action is sufficient to ensure post accident offsite doses are maintained within the limits of Reference 1.

ACTIONS The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by unit specific calibration procedures. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a ~~COTCFI and/or Channel Calibration~~, when the process instrumentation is set up for adjustment to bring it within specification. ~~Drift can also be observed during a Channel check or CFI and if observed would prompt action to correct the discrepancy.~~ If the Trip Setpoint is less conservative than the tolerance specified by the calibration procedure, the channel must be declared inoperable immediately and the appropriate Condition entered.

A Note has been added to the ACTIONS to clarify the application of Completion Time rules. The Conditions of this Specification may be entered independently for each Function listed in Table 3.3.6-1. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

A.1

Condition A applies to the failure of one containment purge ~~ventilation~~ isolation radiation monitor channel. ~~Since the four containment radiation monitors measure different parameters,~~

(continued)

BASES

ACTIONS

A.1 (continued)

~~failure of a single channel may result in loss of the radiation monitoring function for certain events. Consequently, the failed channel must be restored to OPERABLE status. The 4 hours allowed to restore the affected channel is justified by the low likelihood of events occurring during this interval, and recognition that one or more of the remaining channels will respond to most events.~~

~~A Note has been added to state that Condition A is only applicable in MODE 1, 2, 3, or 4.~~

B.1

Condition B applies to all Containment Purge and Exhaust Ventilation Isolation Functions and addresses the train orientation of the Solid State Protection System (SSPS) and the master and slave relays for these Functions. It also addresses the failure of ~~multiple~~ both radiation monitoring channels, or the inability to restore a single failed channel to OPERABLE status in the time allowed for Required Action A.1.

If a train is inoperable, ~~multiple~~ both radiation channels are inoperable, or the Required Action and associated Completion Time of Condition A are not met, operation may continue as long as the Required Action for the applicable Conditions of LCO 3.6.3 is met for each valve made inoperable by failure of isolation instrumentation.

A Note is added stating that Condition B is only applicable in MODE 1, 2, 3, or 4.

C.1 and C.2

Condition C applies to all Containment Purge and Exhaust Ventilation Isolation Functions and addresses the train orientation of the SSPS and the master and slave relays for these Functions. It also addresses the ~~failure of multiple~~ condition of no OPERABLE radiation monitoring channels, ~~or the inability to restore a single failed channel to OPERABLE status in the time allowed for Required Action A.1.~~ If a train is inoperable, ~~multiple channels are inoperable, or the Required Action and associated Completion Time of Condition A are not met~~ required radiation monitor is inoperable, operation may continue as long as the Required Action to place and maintain containment purge and exhaust Ventilation isolation

(continued)

BASES

ACTIONS

C.1 and C.2 (continued)

valves (RCV-11, 12, FGV 660, 661, 662, 663, 664) in their closed position is met or the applicable Conditions of LCO 3.9.4, "Containment Penetrations," are met for each valve made inoperable by failure of isolation instrumentation. The Completion Time for these Required Actions is Immediately.

A Note states that Condition C is applicable during CORE ALTERATIONS and during movement of irradiated fuel assemblies within containment.

SURVEILLANCE
REQUIREMENTS

A Note has been added to the SR Table to clarify that Table 3.3.6-1 determines which SRs apply to which Containment Purge and Exhaust Isolation Functions.

SR 3.3.6.1

Performance of the CHANNEL CHECK once every 12 hours ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit.

The Frequency is based on operating experience that demonstrates channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.6.1 (continued)

channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.6.2

SR 3.3.6.2 is the performance of an ACTUATION LOGIC TEST. The train being tested is placed in the bypass condition, thus preventing inadvertent actuation. Through the semiautomatic tester, all possible logic combinations, with and without applicable permissives, are tested for each protection function. In addition, the master relay coil is pulse tested for continuity. This verifies that the logic modules are OPERABLE and there is an intact voltage signal path to the master relay coils. This test is performed every 31 days on a STAGGERED TEST BASIS. The Surveillance interval is acceptable based on instrument reliability and industry operating experience.

SR 3.3.6.3

SR 3.3.6.3 is the performance of a MASTER RELAY TEST. The MASTER RELAY TEST is the energizing of the master relay, verifying contact operation and a low voltage continuity check of the slave relay coil. Upon master relay contact operation, a low voltage is injected to the slave relay coil. This voltage is insufficient to pick up the slave relay, but large enough to demonstrate signal path continuity. This test is performed every 31 days on a STAGGERED TEST BASIS. The Surveillance interval is acceptable based on instrument reliability and industry operating experience.

SR 3.3.6.4

A ~~GO/GET~~ is performed every 92 days on each required channel to ensure the entire channel will perform the intended function. The frequency is based on the staff recommendation for increasing the availability of radiation monitors according to NUREG-1366 (Ref. 2). This test verifies the capability of the instrumentation to provide the containment purge and exhaust system isolation. The

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.6.4 (continued)

~~setpoint shall be left consistent with the current unit specific calibration procedure tolerance.~~

SR 3.3.6.5

SR 3.3.6.5 is the performance of a SLAVE RELAY TEST. The SLAVE RELAY TEST is the energizing of the slave relays. Contact operation is verified in one of two ways. Actuation equipment that may be operated in the design mitigation mode is either allowed to function or is placed in a condition where the relay contact operation can be verified without operation of the equipment. Actuation equipment that may not be operated in the design mitigation mode is prevented from operation by the SLAVE RELAY TEST circuit. For this latter case, contact operation is verified by a continuity check of the circuit containing the slave relay. This test is performed every ~~[92]~~ days. The Frequency is acceptable based on instrument reliability and industry operating experience.

SR 3.3.6.6

~~There is no manual actuation of CVI except via phase A or B. This testing is performed as part of 3.3.2.~~

~~SR 3.3.6.6 is the performance of a TADOT. This test is a check of the Manual Actuation Functions and is performed every [18] months. Each Manual Actuation Function is tested up to, and including, the master relay coils. In some instances, the test includes actuation of the end device (i.e., pump starts, valve cycles, etc.).~~

~~The test also includes trip devices that provide actuation signals directly to the SSPS, bypassing the analog process control equipment. The SR is modified by a Note that excludes verification of setpoints during the TADOT. The Functions tested have no setpoints associated with them.~~

~~The Frequency is based on the known reliability of the Function and the redundancy available, and has been shown to be acceptable through operating experience.~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.3.6.7

A CHANNEL CALIBRATION is performed every [18] months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

The Frequency is based on operating experience and is consistent with the typical industry refueling cycle.

SR 3.3.6.8

This SR assures that the individual channel RESPONSE TIMES are less than or equal to the maximum values assumed in the accident analysis. Response Time testing acceptance criteria are included in the FSAR. Individual component response times are not modeled in the analyses. The analyses model the overall or elapsed time, from the point at which the parameter exceeds the Trip Setpoint value at the sensor, to the point at which the equipment in both trains reaches the required functional state (e.g., valves in full closed position). The response time may be measured by a series of overlapping tests such that the entire response time is measured.

RESPONSE TIME tests are conducted on an 18 month STAGGERED TEST BASIS. Testing of the final actuation devices, which make up the bulk of the response time, is included in the testing of each channel. The final actuation device in one train is tested with each channel. Therefore, staggered testing results in response time verification of these devices every 18 months. The 18 month Frequency is consistent with the typical refueling cycle and is based on unit operating experience, which shows that random failures of instrumentation components causing serious response time degradation, but not channel failure, are infrequent occurrences.

B 3.3 INSTRUMENTATION

B 3.3.7 Control Room Emergency Filtration Ventilation System (GREFS CRVS) Actuation Instrumentation

BASES

BACKGROUND

The GREFS CRVS provides an enclosed control room environment from which the both units can be operated following an uncontrolled release of radioactivity. During normal operation, the Auxiliary Building Ventilation System provides control room ventilation. Upon receipt of an actuation signal, the GREFS CRVS shifts from normal operation and initiates filtered ventilation and pressurization of the control room. This system is described in the Bases for LCO 3.7.10, "Control Room Emergency Filtration Ventilation System," and is common to both units.

The actuation instrumentation consists of redundant radiation monitors in the air intakes and to the control room areas. There are two detectors in each of the two normal control room air intakes. However, since they take suction from a common area, the North and South sides of the mechanical equipment room, only two detectors are required to provide protection against a single failure. A Phase "A" containment isolation signal or a high radiation signal from any either of these required detectors in the normal intake will initiate both trains of the GREFS CRVS pressurization from the pressurization intake with the lowest radiation level (each pressurization intake, one on the North end of the turbine building and one on the South, has two radiation monitors). The control room operator can also initiate GREFS CRVS pressurization trains by manual switches in the control room. The GREFS is also actuated by a safety injection (SI) signal. The SI Function is discussed in LCO 3.3.2, "Engineered Safety Feature Actuation System (ESFAS) Instrumentation."

The CRVS has two additional manually selected operating modes, smoke removal and recirculation. Neither of modes are required for the CRVS to be OPERABLE but they are useful for certain non-DBA circumstances.

APPLICABLE SAFETY ANALYSES

The control room must be kept habitable for the operators stationed there during accident recovery and post accident operations.

The GREFS CRVS acts to terminate the supply of unfiltered outside air to the control room, initiate filtration, and pressurize the control room. These actions are necessary to ensure the control room is kept habitable for the operators stationed there during accident recovery and post accident operations by minimizing the radiation exposure of control room personnel.

(continued)

BASES

In MODES 1, 2, 3, and 4, the radiation monitor actuation of the CREFS CRVS is a backup for the SI Phase A signal actuation. This ensures initiation of the CREFS CRVS during a loss of coolant accident or steam generator tube rupture involving a release of radioactive materials.

The radiation monitor actuation of the CREFS in MODES 5 and 6, during movement of irradiated fuel assemblies E and

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

~~CORE ALTERATIONS~~, is the primary means to ensure control room habitability in the event of a fuel handling or waste gas decay tank rupture accident. The GREFS CRVS ~~pressurization system~~ actuation instrumentation satisfies Criterion 3 of the NRC Policy Statement 10 CFR 50.36(c)(2)(ii).

LCO

The LCO requirements ensure that instrumentation necessary to initiate the GREFS ~~CRVS pressurization system~~ is OPERABLE.

1. Manual Initiation

The LCO requires two channels OPERABLE. The operator can initiate the GREFS ~~CRVS pressurization mode~~ at any time by using either of two switches in the control room. This action will cause actuation of all components in the same manner as any of the automatic actuation signals.

The LCO for Manual Initiation ensures the proper amount of redundancy is maintained in the manual actuation circuitry to ensure the operator has manual initiation capability.

~~Each channel consists of one push button and the interconnecting wiring to the actuation logic cabinet.~~

2. Automatic Actuation Logic and Actuation Relays

The LCO requires two trains of Actuation Logic and Relays OPERABLE to ensure that no single random failure can prevent automatic actuation ~~of the pressurization system~~.

~~Automatic Actuation Logic and Actuation Relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b., SI, in LCO 3.3.2. The applicable MODES and specified conditions for the GREFS portion of these functions are different and less restrictive than those specified for their SI roles. If one or more of the SI functions becomes inoperable in such a manner that only the GREFS function is affected, the Conditions applicable to their SI function need not be entered. The less~~

(continued)

BASES

LCO

2. Automatic Actuation Logic and Actuation Relays (continued)

~~restrictive Actions specified for inoperability of the CREFS Functions specify sufficient compensatory measures for this case.~~

3. Control Room Radiation

The LCO specifies two required Control Room Atmosphere ~~Normal Intake Radiation Monitors~~ and ~~two required Control Room Air Intake Radiation Monitors~~ at each to ensure that the radiation monitoring instrumentation necessary to initiate the CREFS ~~CRVS~~ ~~pressurization system~~ remains OPERABLE.

~~For sampling systems, channel OPERABILITY involves more than OPERABILITY of channel electronics. OPERABILITY may also require correct valve lineups, sample pump operation, and filter motor operation, as well as detector OPERABILITY, if these supporting features are necessary for trip to occur under the conditions assumed by the safety analyses.~~

4. Safety Injection

~~Refer to LCO 3.3.2. Function 1, for all initiating Functions and requirements.~~

APPLICABILITY

The CREFS ~~CRVS~~ Functions must be OPERABLE in MODES 1, 2, 3, 4, ~~and during CORE ALTERATIONS~~ and movement of irradiated fuel assemblies. The Functions must also be OPERABLE in MODES ~~5 and 6~~ when required for a waste gas decay tank rupture accident, to ensure a habitable environment for the control room operators.

ACTIONS

The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by the unit specific calibration procedures. Typically, the drift is found to be small and results in a delay of actuation rather

(continued)

BASES

ACTIONS
(continued)

than a total loss of function. This determination is generally made during the performance of a GOTCFI and/or Channel Calibration, when the process instrumentation is set up for adjustment to bring it within specification. Drift can also be observed during a Channel check or CFI and if observed would prompt action to correct the discrepancy. If the Trip Setpoint is less conservative than the tolerance specified by the calibration procedure, the channel must be declared inoperable immediately and the appropriate Condition entered.

A Note has been added to the ACTIONS indicating that separate Condition entry is allowed for each Function. The Conditions of this Specification may be entered independently for each Function listed in Table 3.3.7-1 in the accompanying LCO. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

A.1

Condition A applies to the actuation logic train Function of the CREFS CRVS, the radiation monitor channel Functions, and the manual channel Functions.

If one train is inoperable, or one radiation monitor channel is inoperable in one or more Functions, 7 days are permitted to restore it to OPERABLE status. The 7 day Completion Time is the same as is allowed if one train of the mechanical portion of the system is inoperable. The basis for this Completion Time is the same as provided in LCO 3.7.10. If the channel/train cannot be restored to OPERABLE status, one CREFS CRVS train must be placed in the emergency radiation protection pressurization mode of operation. This accomplishes the actuation instrumentation Function and places the unit in a conservative mode of operation.

~~The Required Action for Condition A is modified by a Note that requires placing one CREFS train in the toxic gas protection mode instead of the [radiation protection] mode of operation if the automatic transfer to toxic gas protection mode is inoperable. This ensures the CREFS train is placed in the most conservative mode of operation relative to the OPERABILITY of the associated actuation instrumentation.~~

(continued)

BASES

ACTIONS
 (continued)

B.1.1, B.1.2, and B.2

Condition B applies to the failure of two CREFS ~~CRVS~~ actuation trains, two radiation monitor channels, or two manual channels. The first Required Action is to place one CREFS ~~CRVS~~ train in the emergency ~~[radiation protection]~~ ~~pressurization~~ mode of operation immediately. This accomplishes the actuation instrumentation Function that may have been lost and places the unit in a conservative mode of operation. The applicable Conditions and Required Actions of LCO 3.7.10 must also be entered for the CREFS ~~CRVS~~ train made inoperable by the inoperable actuation instrumentation. This ensures appropriate limits are placed upon train inoperability as discussed in the Bases for LCO 3.7.10.

Alternatively, both trains may be placed in the emergency ~~[radiation protection]~~ ~~pressurization~~ mode. This ensures the CREFS function is performed even in the presence of a single failure.

~~The Required Action for Condition B is modified by a Note that requires placing one CREFS train in the toxic gas protection mode instead of the [radiation protection] mode of operation if the automatic transfer to toxic gas protection mode is inoperable. This ensures the CREFS train is placed in the most conservative mode of operation relative to the OPERABILITY of the associated actuation instrumentation.~~

C.1 and C.2

Condition C applies when the Required Action and associated Completion Time for Condition A or B have not been met and the unit is in MODE 1, 2, 3, or 4. The unit must be brought to a MODE in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

(continued)

BASES

ACTIONS
(continued)

D.1 and D.2

Condition D applies when the Required Action and associated Completion Time for Condition A or B have not been met ~~during CORE ALTERATIONS or~~ when irradiated fuel assemblies are being moved. Movement of irradiated fuel assemblies ~~and CORE ALTERATIONS~~ must be suspended immediately to reduce the risk of accidents that would require CREFS actuation.

E.1

Condition E applies when the Required Action and associated Completion Time for Condition A or B have not been met in MODE 5 or 6. Actions must be initiated to restore the inoperable train(s) to OPERABLE status immediately to ensure adequate isolation capability in the event of a waste gas decay tank rupture.

SURVEILLANCE
REQUIREMENTS

A Note has been added to the SR Table to clarify that Table 3.3.7-1 determines which SRs apply to which CREFS Actuation Functions.

SR 3.3.7.1

Performance of the CHANNEL CHECK once every 12 hours ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.7.1 (continued)

including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit.

The Frequency is based on operating experience that demonstrates channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.7.2

A ~~COT CFT~~ is performed once every 92 days on each required channel to ensure the entire channel will perform the intended function. This test verifies the capability of the instrumentation to provide the CREFS ~~CRVS~~ actuation. ~~The setpoints shall be left consistent with the unit specific calibration procedure tolerance.~~ The Frequency is based on the known reliability of the monitoring equipment and has been shown to be acceptable through operating experience.

SR 3.3.7.3

SR 3.3.7.3 is the performance of an ACTUATION LOGIC TEST. The train being tested is placed in the bypass condition, thus preventing inadvertent actuation. Through the semiautomatic tester, all possible logic combinations, with and without applicable permissives, are tested for each protection function. In addition, the master relay coil is pulse tested for continuity. This verifies that the logic modules are OPERABLE and there is an intact voltage signal path to the master relay coils. This test is performed every 31 days on a STAGGERED TEST BASIS. The Frequency is justified in WCAP-10271-P-A, Supplement 2, Rev. 1 (Ref. 1).

SR 3.3.7.4

SR 3.3.7.4 is the performance of a MASTER RELAY TEST. The MASTER RELAY TEST is the energizing of the master relay, verifying contact operation and a low voltage continuity

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.7.4 (continued)

check of the slave relay coil. Upon master relay contact operation, a low voltage is injected to the slave relay coil. This voltage is insufficient to pick up the slave relay, but large enough to demonstrate signal path continuity. This test is performed every 31 days on a STAGGERED TEST BASIS. The Frequency is acceptable based on instrument reliability and industry operating experience.

SR 3.3.7.5

SR 3.3.7.5 is the performance of a SLAVE RELAY TEST. The SLAVE RELAY TEST is the energizing of the slave relays. Contact operation is verified in one of two ways. Actuation equipment that may be operated in the design mitigation MODE is either allowed to function or is placed in a condition where the relay contact operation can be verified without operation of the equipment. Actuation equipment that may not be operated in the design mitigation MODE is prevented from operation by the SLAVE RELAY TEST circuit. For this latter case, contact operation is verified by a continuity check of the circuit containing the slave relay. This test is performed every ~~92] days~~ 18 months. The Frequency is acceptable based on instrument reliability and industry operating experience (Ref 1 and 2).

SR 3.3.7.6

SR 3.3.7.6 is the performance of a TADOT. This test is a check of the Manual Actuation Functions and is performed every ~~18] months~~. Each Manual Actuation Function is tested up to, and including, the master relay coils. In some instances, the test includes actuation of the end device (i.e., pump starts, valve cycles, etc.).

The test also includes trip devices that provide actuation signals directly to the Solid State Protection System, bypassing the analog process control equipment. The Frequency is based on the known reliability of the Function and the redundancy available, and has been shown to be acceptable through operating experience. The SR is modified by a Note that excludes verification of setpoints during the

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.7.6 (continued)

TADOT. The Functions tested have no setpoints associated with them.

SR 3.3.7.7

A CHANNEL CALIBRATION is performed every ~~18~~ months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy.

The Frequency is based on operating experience and is consistent with the typical industry refueling cycle.

B 3.3 INSTRUMENTATION

B 3.3.8 Fuel Handling Building Air Cleanup Ventilation System (FBACSFHBVS) Actuation Instrumentation

BASES

BACKGROUND

The FBACSFHBVS ensures that radioactive materials in the fuel building atmosphere following a fuel handling accident or a loss of coolant accident (LOCA) are filtered and adsorbed prior to exhausting to the environment. The system is described in the Bases for LCO 3.7.13, "Fuel Handling Building Air Cleanup Ventilation System." The system initiates filtered ventilation of the fuel building automatically following receipt of a high radiation signal (gaseous or particulate) or a safety injection (SI) signal from the Spent Fuel Pool Monitor or from the New Fuel Storage Vault Monitor (or from gaseous monitors 45 A/B when installed). Initiation may also be performed manually as needed from the main control room or fuel handling building.

High gaseous and particulate radiation, each monitored by from either of the two monitors, provides FBACSFHBVS initiation. Each FBACS train is initiated by high radiation detected by a channel dedicated to that train. There are a total of two channels, one for each train. Each channel contains a gaseous and particulate monitor. High radiation detected by any monitor or an SI signal from the Engineered Safety Features Actuation System (ESFAS) initiates fuel building isolation and starts the FBACS. These actions function to prevent exfiltration of contaminated air by initiating filtered ventilation, which imposes a negative pressure on the fuel building. Since the radiation monitors include an air sampling system, various components such as sample line valves, sample line heaters, sample pumps, and filter motors are required to support monitor OPERABILITY.

APPLICABLE SAFETY ANALYSES

The FBACSFHBVS ensures that radioactive materials in the fuel building atmosphere following a fuel handling accident or a LOCA are filtered and adsorbed prior to being exhausted to the environment. This action reduces the radioactive content in the fuel building exhaust following a LOCA or fuel handling accident so that offsite doses remain within the limits specified in 10 CFR 100 (Ref. 1).

The FBACSFHBVS actuation instrumentation satisfies Criterion 3 of the NRC Policy Statement 10 CFR 50.36(c)(2)(iii).

(continued)

BASES (continued)

LCO The LCO requirements ensure that instrumentation necessary to initiate the FBACSFHBVS is OPERABLE.

1. Manual Initiation

The LCO requires two channels OPERABLE. The operator can initiate the FBACSFHBVS at any time by using either of two switches: one in the control room and another in the fuel handling building. This action will cause actuation of all components in the same manner as any of the automatic actuation signals.

The LCO for Manual Initiation ensures the proper amount of redundancy is maintained in the manual actuation circuitry to ensure the operator has manual initiation capability.

~~Each channel consists of one push button and the interconnecting wiring to the actuation logic cabinet.~~

~~2. Automatic Actuation Logic and Actuation Relays~~

~~The LCO requires two trains of Actuation Logic and Relays OPERABLE to ensure that no single random failure can prevent automatic actuation.~~

~~Automatic Actuation Logic and Actuation Relays consist of the same features and operate in the same manner as described for ESFAS Function 1.b., SI, in LCO 3.3.2. The applicable MODES and specified conditions for the FBACS portion of these functions are different and less restrictive than those specified for their SI roles. If one or more of the SI functions becomes inoperable in such a manner that only the FBACS function is affected, the Conditions applicable to their SI function need not be entered. The less restrictive Actions specified for inoperability of the FBACS functions specify sufficient compensatory measures for this case.~~

3 ~~2~~. Fuel Building Radiation

The LCO specifies two required Gaseous Radiation Monitor channels and two required ~~Particulate Radiation Monitor~~ channels to ensure that the radiation monitoring instrumentation necessary to initiate the FBACS FBVS remains OPERABLE.

(continued)

BASES

LCO 3 2. Fuel Building Radiation (continued)

~~For sampling systems, channel OPERABILITY involves more than OPERABILITY of channel electronics. OPERABILITY may also require correct valve lineups, sample pump operation, filter motor operation, detector OPERABILITY, if these supporting features are necessary for actuation to occur under the conditions assumed by the safety analyses.~~

Only the Trip Setpoint is specified for each FBACSFHBVS Function in the LCO. The Trip Setpoint limits account for instrument uncertainties, which are defined in the Unit Specific Setpoint Calibration Procedure (Ref. 2).

APPLICABILITY The manual FBACS FBVS initiation must be OPERABLE in ~~MODES [1, 2, 3, and 4]~~ and when moving irradiated fuel assemblies in the fuel building, to ensure the FBACSFHBVS operates to remove fission products associated with leakage after a LOCA or a fuel handling accident. ~~The automatic FBACS actuation instrumentation is also required in MODES [1, 2, 3, and 4] to remove fission products caused by post LOCA Emergency Core Cooling Systems leakage.~~

High radiation initiation of the FBACSFHBVS must be OPERABLE in any MODE during movement of irradiated fuel assemblies in the fuel building to ensure automatic initiation of the FBACS FBVS when the potential for a fuel handling accident exists.

While in MODES 5 and 6 without fuel handling in progress, the FBACSFHBVS instrumentation need not be OPERABLE since a fuel handling accident cannot occur.

ACTIONS The most common cause of channel inoperability is outright failure or drift of the bistable or process module sufficient to exceed the tolerance allowed by unit specific calibration procedures. Typically, the drift is found to be small and results in a delay of actuation rather than a total loss of function. This determination is generally made during the performance of a ~~GOTCFI and/or Channel Calibration~~, when the process instrumentation is set up for adjustment to bring it within

(continued)

BASES

ACTIONS
(continued)

specification. If the Trip Setpoint is less conservative than the tolerance specified by the calibration procedure, the channel must be declared inoperable immediately and the appropriate Condition entered. Drift can also be observed during a Channel check or CFI and if observed would prompt action to correct the discrepancy.

Two Notes have been added to the ACTIONS to clarify the application of Completion Time rules and the Applicability of LCO 3.0.3. The Conditions of this Specification may be entered independently for each Function listed in Table 3.3.8-1 in the accompanying LCO. The Completion Time(s) of the inoperable channel(s)/train(s) of a Function will be tracked separately for each Function starting from the time the Condition was entered for that Function.

LCO 3.0.3 is not applicable while in MODE 5 or 6. However, since irradiated fuel assembly movement can occur in MODE 1, 2, 3, or 4 the ACTIONS have been modified by a Note stating that LCO 3.0.3 is not applicable. If moving irradiated fuel assemblies while in Mode 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODE 1, 2, or 3, the fuel movement is independent of reactor operations. Therefore, in either case, inability to suspend movement of irradiated fuel assemblies would not be sufficient reason to require a reactor shutdown.

A.1

Condition A applies to the actuation logic train function of the Solid State Protection System (SSPS), the radiation monitor functions, and the manual function. Condition A applies to the failure of a single actuation logic train, one or more radiation monitor channels, or manual channels. If one or more channels or trains are inoperable, a period of 730 days is allowed to restore it to OPERABLE status. If the train cannot be restored to OPERABLE status, an appropriate portable continuous monitor with the same setpoint, or an individual qualified in radiation protection procedures with a dose rate monitoring device must be in the spent fuel pool area, one FBACSFHBVS train must be placed in the Iodine Removal mode of operation immediately. This effectively accomplishes the actuation instrumentation function and places the unit area in a conservative mode of operation or provides appropriate monitoring for continued fuel movement. The 7 day Completion Time is the same as is allowed if one train of the mechanical portion of the system is inoperable. The basis for this time is the same as that provided in LCO 3.7.13.

B.1.1, B.1.2, B.2

Condition B applies to the failure of two FBACS actuation logic trains, two radiation monitors, or two manual channels. The Required Action is to place one FBACS train in operation

(continued)

BASES

~~immediately. This accomplishes the actuation instrumentation function that may have been lost and places the unit in a conservative mode of operation. The applicable Conditions and Required Actions of LCO 3.7.13 must also be entered for the FBAGS train made inoperable by the inoperable actuation instrumentation. This ensures appropriate limits are placed on train inoperability as discussed in the Bases for LCO 3.7.13.~~

(continued)

BASES

ACTIONS B.1.1, B.1.2, B.2 (continued)

~~Alternatively, both trains may be placed in the emergency [radiation protection] mode. This ensures the FBACS Function is performed even in the presence of a single failure.~~

C.1

Condition C applies when the Required Action and associated Completion Time for Condition A or B have not been met and irradiated fuel assemblies are being moved in the fuel building. Movement of irradiated fuel assemblies in the fuel building must be suspended immediately to eliminate the potential for events that could require FBACS FBVS actuation.

D.1 and D.2

~~Condition D applies when the Required Action and associated Completion Time for Condition A or B have not been met and the unit is in MODE 1, 2, 3, or 4. The unit must be brought to a MODE in which the LCO requirements are not applicable. To achieve this status, the unit must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.~~

SURVEILLANCE
REQUIREMENTS

A Note has been added to the SR Table to clarify that Table 3.3.8-1 determines which SRs apply to which FBACSFHBVS Actuation Functions.

~~Notes have been added that clarify which functions will be associated with which monitors when the new radiation monitors RM 45A and 45B are installed.~~

SR 3.3.8.1

Performance of the CHANNEL CHECK once every 12 hours ensures that a gross failure of instrumentation has not occurred. A CHANNEL CHECK is normally a comparison of the parameter indicated on one channel to a similar parameter on other channels. It is based on the assumption that instrument

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.3.8.1 (continued)

channels monitoring the same parameter should read approximately the same value. Significant deviations between the two instrument channels could be an indication of excessive instrument drift in one of the channels or of something even more serious. A CHANNEL CHECK will detect gross channel failure; thus, it is key to verifying the instrumentation continues to operate properly between each CHANNEL CALIBRATION.

Agreement criteria are determined by the unit staff, based on a combination of the channel instrument uncertainties, including indication and readability. If a channel is outside the criteria, it may be an indication that the sensor or the signal processing equipment has drifted outside its limit.

The Frequency is based on operating experience that demonstrates channel failure is rare. The CHANNEL CHECK supplements less formal, but more frequent, checks of channels during normal operational use of the displays associated with the LCO required channels.

SR 3.3.8.2

A ~~GOT~~ ~~CFM~~ is performed once every 92 days on each required channel to ensure the entire channel will perform the intended function. This test verifies the capability of the instrumentation to provide the FBACS actuation. ~~The setpoints shall be left consistent with the unit specific calibration procedure tolerance.~~ The Frequency of 92 days is based on the known reliability of the monitoring equipment and has been shown to be acceptable through operating experience.

SR 3.3.8.3

~~SR 3.3.8.3 is the performance of an ACTUATION LOGIC TEST. The actuation logic is tested every 31 days on a STAGGERED TEST BASIS. All possible logic combinations, with and without applicable permissives, are tested for each protection function. The Frequency is based on the known~~

BASES
SURVEILLANCE
REQUIREMENTS

~~SR 3.3.8.3 (continued)~~

~~reliability of the relays and controls and the multichannel
redundancy available, and has been shown to be acceptable through
operating experience.~~

SR 3.3.8.4

SR 3.3.8.4 is the performance of a TADOT. This test is a check of the manual actuation functions and is performed every ~~[18]~~ months. Each manual actuation function is tested up to, and including, the master relay coils. In some instances, the test includes actuation of the end device (e.g., pump starts, valve cycles, etc.). The Frequency is based on operating experience and is consistent with the typical industry refueling cycle. The SR is modified by a Note that excludes verification of setpoints during the TADOT. The Functions tested have no setpoints associated with them.

SR 3.3.8.5

A CHANNEL CALIBRATION is performed every ~~[18]~~ months, or approximately at every refueling. CHANNEL CALIBRATION is a complete check of the instrument loop, including the sensor. The test verifies that the channel responds to a measured parameter within the necessary range and accuracy. The Frequency is based on operating experience and is consistent with the typical industry refueling cycle.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck out" and the correct material is inserted using the "redline" feature. If the "generic" is correct, the information is "redlined". The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Methodology For Mark-up of NUREG-1431 Bases
(continued)

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the markup process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

ENCLOSURE 6A

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(10 Pages)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.3

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.3-01	This trip function or design feature is not included in the plant design or it is not credited and has no safety function.
3.3-02	For the Reactor Trip on Turbine Trip function based on turbine stop valve position, 4 of 4 channels are required to close to less than 1% open in order to generate the reactor trip signal. Thus, it is acceptable to have more than one Turbine Stop Valve Closure - reactor trip function channel inoperable and placed in trip per current TS Table 3.3-1, Functional Unit [17.b], ACTION Statement [7]. In addition, the 4 hour bypass note applies only to the [Low Auto Stop Oil Pressure] channels. ITS 3.3.1 Condition P has been revised.
3.3-03	This change to ITS 3.3.1 Condition R is consistent with the current licensing basis. A 4-hour AOT for SSPS logic surveillance testing has little usefulness if the RTBs cannot be bypassed for the duration of that testing. RTB surveillance testing retains the current 2-hour AOT.
3.3-04	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 6B).
3.3-05	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.3-06	Retains CTS power requirement of 75% RTP in the ITS SR 3.3.1.6 Note concerning when the incore/excore calibration is performed. The ISTS proposal would require unnecessary delays in the post-refuel power ascension. As per the current TS 4.0.4 exception, it is acceptable to go above 75% RTP during power ascension provided the calibration is performed within 24 hours of exceeding 75% RTP. [The Note is further revised to permit achieving equilibrium conditions (per CTS 4.2.2.2.d.1) prior to performing the required surveillance.]
3.3-07	Note 3 is added to ITS SR 3.3.1.11 to be consistent with the CTS Table 4.3-1 Note [5]. This ensures that this exception for power and intermediate range detector plateau voltage verification, as discussed in the ITS BASES for SR 3.3.1.11, is included in the Technical Specifications rather than being only found in the BASES. The note replaces the exception to LCO 3.0.4 in the current TS.
3.3-08	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.3-09	The addition of footnote [(m)] to ITS Table 3.3.1-1 for Function 10 clarifies the low flow setpoint relationship to the quantity identified as Minimum Measured Flow, consistent with the current TS.

CHANGE
NUMBER

JUSTIFICATION

- 3.3-10 [The Overtemperature ΔT setpoint equation had a bracket in the wrong place and was corrected. The $OT_{\Delta T}$ equation in NUREG-1431 Note 1 shows the lead-lag compensation associated with the term $(1 + \tau_1 S)/(1 + \tau_2 S)$ (note that CN 3.3-13 revised the tau subscripts per CTS) to be applicable to the T' term. This is incorrect. This error can also be found in Revision 4a of NUREG-0452. This error apparently was taken from Section A-3 and Figure A-1 of WCAP-8745-P and WCAP-8746 as well as from Figure 6.1-4 of WCAP-7907-P-A, "LOFTRAN Code Description," April 1984. The latter reference has been corrected in Figure 6.1-4 of WCAP-7878, "LOFTRAN Code Description and User's Manual," Revision 5, November 1989. The lead-lag compensation applies only to the measured T_{avg} . This is consistent with the manner in which the electronics have always processed the $OT_{\Delta T}$ setpoint signal, as depicted on Westinghouse drawing 8756D37 sheets 7-10 described in FSAR Section 7.2]. Another change needed for the Overtemperature ΔT setpoint equation concerns the inequality sign for the K_2 term. As defined in NUREG-1431, this term has a " \geq " sign. In this case, the Overtemperature ΔT setpoint would be conservatively decreased if T_{avg} were increasing above [576.6°F for Unit 1 and 577.6°F for Unit 2], i.e. with $(T-T')$ a positive value. However, if T_{avg} were decreasing below [576.6°F or 577.6°F, for the respective Units,] such that $(T-T')$ is a negative value, the \geq sign could result in an unwanted increase in the Overtemperature ΔT setpoint. Therefore, the inequality sign for K_2 is changed to an equal sign, consistent with the current TS. This issue is avoided in the construct of the Overtemperature ΔT setpoint by setting K_5 and K_6 to zero for decreasing T_{avg} , i.e. K_5 and K_6 are conditionally defined. In addition, the f_1 (ΔI) penalty function was corrected to reflect correct decimal point placement and to ensure a reduction in the setpoint if $(q_i - q_b)$ is outside the deadband. The f_1 (ΔI) value must be positive such that it lowers the setpoint when subtracted. The inequality signs around the deadband were corrected to reflect a zero penalty when $(q_i - q_b)$ is within the deadband. Decimal point placement corrections have been made to recognize that the penalty function gains have units of (°F or % ΔT span per % RTP).
- 3.3-11 Added "or Rod Control System incapable of rod withdrawal," which makes Note (f) the complete antithesis of Note (b).
- 3.3-12 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-13 The equations for Overtemperature ΔT and Overpower ΔT are revised to be consistent with the CTS. The value of the time constant τ_6 has always been 0 seconds and the factor utilizing this time constant has not been shown as part of the Overtemperature ΔT equation in licensing documents since the factor value has been unity. Thus, the factor utilizing this time constant has been deleted.
- 3.3-14 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-15 The CHANNEL CHECK surveillance (SR 3.3.2.1) is deleted from the P-11 [] interlock because CHANNEL CHECKS are not applicable for permissive functions. This change is consistent with the current TS.
- 3.3-16 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-17 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-18 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-19 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).

CHANGE
NUMBER

JUSTIFICATION

- 3.3-20 This change adds note 2 on [Containment Radiation Level (High Range)] calibration in ITS SR [3.3.3.2] to be consistent with current TS Table [4.3-7 Note (2)]. This note is acceptable as it reflects the unique calibration requirements of these high range radiation monitors as defined in the current TS.
- 3.3-21 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-22 Consistent with CTS [3.3.3.5], [RCP breaker indication is excluded from CHANNEL CHECKS and reactor trip breaker and RCP breaker indications are excluded from] CHANNEL CALIBRATIONS in ITS SR 3.3.4.3 since these SRs have no meaning for [these] functions.
- 3.3-23 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-24 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-25 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-26 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-27 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-28 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-29 {Not used}
- 3.3-30 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-31 The current TS require the response times associated with the [undervoltage and degraded voltage diesel generator start functions and the] containment [purge and exhaust] isolation functions to be verified against the specific response time values contained in the [FSAR]. The ITS is revised to match the current TS and the response time values are [moved to the FSAR per CN 01-35-LG]. As is done with the Reactor Trip System and the ESFAS instrumentation, this method is an appropriate way to control response times. [SR 3.3.5.4 and SR 3.3.6.8] are added to require the response time verifications.
- 3.3-32 Improved TS [3.3.6 ACTION A is modified by a Note and] Table 3.3.6-1 is changed to be consistent with current TS [3.3.2 Functional Unit 3.c and current TS 3.9.9]. Subfunctions [b, c and d] of Containment Radiation are stricken since only the gaseous [] channel provides the actuation function [and the bracketed setpoint is changed to reflect plant-specific requirements]. [The number of gaseous monitors required for CORE ALTERATIONS or during movement of irradiated fuel has been revised to one (either RM 44A or B) per the CTS].
- 3.3-33 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-34 This change adds an LCO 3.0.3 exception Note 1 to ITS 3.3.8 to reflect industry Traveler TSTF-36, Rev. 2.
- 3.3-35 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-36 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).

**CHANGE
NUMBER**

JUSTIFICATION

- 3.3-37 Several ITS Required Action Notes are modified per CTS to allow a channel to be placed in bypass for surveillance testing. []
- 3.3-38 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-39 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-40 This change adds "and setpoint adjustment" to ITS 3.3.1 Condition E, similar to the Note for Condition D. Setpoint adjustment is required by the Required Actions of other specifications. The clarity and consistency of the specification is enhanced by adding this note to Condition E, in the same manner as Condition D.
- 3.3-41 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-42 This change deletes ITS 3.3.1 Condition N per Traveler TSTF-169. Condition M is appropriate for Function 10.a to prevent sequential entry into Condition N followed by M and exceeding the evaluated Completion Time in WCAP-10271-P-A, Supplement 2, Rev. 1. With this change, there is no need to list separate Functions 10.a and 10.b and combining the Functions eliminates Applicability questions similar to the Condition M vs. N concern above.
- 3.3-43 This change revises ITS 3.3.1 Condition R Notes 1 and 2 per Traveler TSTF-168. The 2-hour AOT should not be limited to only UVTA/STA maintenance. This is consistent with the current TS and is acceptable because the specific maintenance activity which requires that a reactor trip breaker be bypassed does not affect the impact of having the breaker bypassed. []
- 3.3-44 This change revises ITS 3.3.1 Conditions S and T and ITS 3.3.2 Condition L, as well as the number of Required Channels in Tables 3.3.1-1 and 3.3.2-1, to reflect current TS ACTION Statements [8 and 21]. The Conditions apply to one or more channels [or trains, as Condition T applies to permissive P-7,] because the safety function is served with the interlock in the appropriate state for existing plant conditions. The existing plant design only requires 3 of the 4 channels (2-out-of-3 for P-11) for these interlocks to be operable.
- 3.3-45 A new CONDITION and SR are added for the current licensing basis required seismic trip.
- 3.3-46 A new CONDITION and SR are added for the current licensing basis required Steam Generator level low-low time delay trip. These changes affect both ITS 3.3.1 and 3.3.2.
- 3.3-47 Note 2 of SR 3.3.1.2 is revised to limit the power increase to less than 30% per the current licensing basis before the SR is complete.
- 3.3-48 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-49 ITS SR 3.3.1.8 is revised to extend the conditional COT frequency for power and intermediate range channels from 4 hours after reducing power below P-10 to 12 hours, based on operating experience regarding the time needed to perform the COTs. It stands to reason that if 4 hours are allowed for 2 Source Range COTs, 12 hours should be allowed for 6 Intermediate Range and Power Range COTs. The SR continues to assure that the COTs are performed in a timely manner after the requisite plant conditions are entered. This change is consistent with Traveler WOG-106.
- 3.3-50 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).

CHANGE
NUMBER

JUSTIFICATION

- 3.3-51 ITS ACTION B.2 of LCO 3.3.7 is deleted, since DCPD cannot operate with both pressurization systems running at the same time. The design of the system is such that operation of two pressurization fans would over pressurize the supply ducting to the filters.
- 3.3-52 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-53 The REQUIRED CHANNELS description for Functions 2.a and 3.b.(1), of ITS Table 3.3.2-1, are revised per the CTS to note that only two switches (one per train) exist and that both must be moved coincident for manual initiation.
- 3.3-54 Function 18.b (P-7) of ITS Table 3.3.1-1 is clarified. COTs and Channel Calibrations apply to the P-10 and P-13 inputs, not to the P-7 logic function. This change is an administrative clarification to address the relationships between these interlocks in the plant's design.
- 3.3-55 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-56 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-57 Not used.
- 3.3-58 This change adds new ITS 3.3.2 Condition [N] to reflect current TS Table 3.3-3 ACTION Statement [24] on manual AFW [and manual MSIV closure] initiation.
- 3.3-59 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-60 Consistent with the design and current TS, Surveillance Requirements 3.3.2.3 and 3.3.2.7 are not used by any function listed in Table 3.3.2-1 and are deleted.
- 3.3-61 This change revises the ITS SR 3.3.2.11 Frequency to 18 months per current TS Table 4.3-2 Functional Unit [8.c], which is the ESFAS P-4 permissive. The 18 month Frequency for the surveillance of the basic switch logic associated with the opening of the reactor trip breakers is the value specified in the current TS. [Deleted the Note stating that verification of set point is not required per the CTS.]
- 3.3-62 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-63 This change revises ITS Table 3.3.2-1 [Notes (b) and (g)] per current TS Table [3.3-3] Notes [# and ##]. This revision is a clarification to the operator that describes the circumstances under which the [Steamline Pressure Negative Rate - High, Steam Pressure-low, or Pressurizer Pressure-low functions may be or are blocked relative to the] P-11 permissive.
- 3.3-64 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-65 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-66 The MODE 4 requirement of the CTS is retained and added to Table 3.3.2-1 for SI actuated by Containment Pressure high-high. ITS 3.3.2 ACTIONS D and E are revised accordingly.
- 3.3-67 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).

CHANGE
NUMBER

JUSTIFICATION

- 3.3-68 A Note is added to state that CONDITION D is only applicable in MODES 1 and 2. A new CONDITION H is added to require entering MODE 3 if CONDITION B is not met when entered due to not meeting CONDITION D. These changes are per the CTS.
- 3.3-69 {The phrase "...that is not normally energized" is deleted per the CTS. All of the instrumentation listed is normally energized at power.}
- 3.3-70 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-71 This change revises Table 3.3.3-1 per the reviewers note to update CTS PAM instruments per the requirements of Reg. Guide 1.97.
- 3.3-72 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-73 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-74 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-75 The CHANNEL FUNCTIONAL TEST is substituted for the COT per current licensing basis.
- 3.3-76 Consistent with the current design and TS, a Trip Actuating Device Operational Test (TADOT) is not required for any of the functions explicitly listed in Table 3.3.6-1; therefore, the associated Surveillance Requirement is deleted. Note that a TADOT is required in accordance with LCO 3.3.2 for functions 3.a.1 and 2.a, as referenced in the Table.
- 3.3-77 Containment Vent Isolation is initiated by the ESFAS Phase "A" isolation signals. As such, the number of required channels and required surveillances for the manual initiation of Containment Vent Isolation are captured by the requirements for Phase "A" isolation in the ESFAS tables.
- 3.3-78 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-79 This change adds APPLICABILITY columns to ITS Tables 3.3.6-1 and 3.3.7-1 to reflect current TS with varying Functional Applicabilities. This change is consistent with the format used for the RTS and ESFAS instrumentation in the ITS and is a clearer method to present varying Applicabilities from the current TS. These changes are administrative format changes that insert the Applicabilities from the current TS into Tables 3.3.6-1 and 3.3.7-1. This change is consistent with traveler TSTF-161.
- 3.3-80 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-81 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-82 The CONDITIONS, REQUIRED ACTIONS, etc. are revised per the current licensing basis. The plant FBACS does not perform any accident mitigation functions except during the fuel handling accident
- 3.3-83 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-84 The Note of SR 3.3.4.4 is deleted since Table 3.3.4-1 does not have a neutron detector specified per the current TS.
- 3.3-85 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).

CHANGE
NUMBER

JUSTIFICATION

- 3.3-86 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-87 Not used.
- 3.3-88 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-89 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-90 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-91 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-92 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-93 ITS 3.3.1 Condition V is deleted. It is not entered from Table 3.3.1-1 nor do the Bases clarify when it would be needed, raising the concern of misinterpretation. Condition V does not replace LCO 3.0.3 requirements to assess when the plant is outside the licensing basis. There is no similar ACTION Statement in the current TS for the Reactor Trip System. This change is consistent with Traveler TSTF-135.
- 3.3-94 ITS 3.3.4 is revised per current TS [3.3.3.5] with regard to [remote shutdown panel] controls. [Remote shutdown panel] controls are added to the LCO, Condition A, and SR 3.3.4.2. By explicitly including the controls, the specification is clarified to be more than instrumentation. This change is acceptable because it does not change the meaning while retaining the clarity of the CTS.
- 3.3-95 ITS 3.3.1 Condition H, Required ACTION H.1, and the second part of Function 4 Applicability (MODE 2 below P-6) in ITS 3.3.1 are deleted since they provide no real compensatory measures. With their deletion, there is no need to repeat the > P-6 Applicability in Conditions F and G. In accordance with LCO 3.0.4, the intermediate range detectors must be OPERABLE prior to entering the Applicability of the retained part of Function 4 (i.e., MODE 2 above P-6). Condition H and Required ACTION H.1 ensure the same thing and, therefore, can be deleted. This change is consistent with Traveler TSTF-135.
- 3.3-96 [] Note 2 for ITS SR 3.3.1.3 is revised to replace the bracketed 15% RTP power level constraint with 50% RTP. The specified power level in ITS SR 3.3.1.3 should reflect the applicable safety analysis basis consistent with the [APPLICABILITY and] Required Actions of ITS LCO 3.2.3 (AFD) and LCO 3.2.4 (QPTR).
- As revised, this surveillance requirement is acceptable in that it assures the surveillance is performed after the appropriate plant conditions are attained and still provides sufficient time to perform the surveillance in a controlled manner.
- 3.3-97 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-98 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-99 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).

CHANGE
NUMBER

JUSTIFICATION

- 3.3-100 Not used.
- 3.3-101 The Note for ITS SR 3.3.1.12 is deleted since the plant design no longer includes the RTD bypass. The SR is retained and is applied to the required seismic trip instrumentation per the current licensing basis. Where cited in Table 3.3.2-1, a change to SR 3.3.1.10 has been made.
- 3.3-102 The control room (CR) does not have CR Atmosphere monitors as part of its current design. There are redundant CR intake monitors for each intake. The normal control room intakes are in an area common to both units, thus there are a total of four normal intake monitors. However, only two monitors, one from each unit, are required for the CRVS to be OPERABLE; this is explained in the Bases.
- 3.3-103 Function 11 of ITS Table 3.3.1-1 is revised per the CTS to reflect the current plant design of only a two loop trip. With this revision, ACTION O is no longer used since it was only applicable to the single loop trip.
- 3.3-104 CONDITION A of ITS 3.3.5 is revised to incorporate CTS ACTION-16. CONDITIONS B and C are not used.
- 3.3-105 Function 4.d.(2) of ITS Table 3.3.2-1 and Notes (c) and (h) are revised per current licensing basis.
- 3.3-106 ISTS 3.3.1 Required Actions B.2.2 and U.2.2 are not used, consistent with the current TS requirements of LCO 3.3.1 ACTION Statements [1, and 12] and the Applicability for ITS Table 3.3.1-1 Functions 1 and 20. The current TS provide for these Functions to be restored to OPERABLE status within 48 hours or the plant must be in HOT STANDBY within the next 6 hours when the plant is initially in MODES 1 or 2. Once HOT STANDBY has been reached, the shutdown mode applicabilities, i.e. MODES 3, 4, and 5, prevail. When in these MODES, another 48 hour AOT is allowed by the current TS or rod withdrawal must be precluded in the next one hour. Therefore, ISTS Required Actions B.2.2 and U.2.2 for Functions 1 and 20 in Table 3.3.1-1 are not necessary since the performance of Required Action B.2.1 and U.2.1 takes the plant to MODE 3, exits the Applicability, and requires entry into Condition C. This change is consistent with ITS 1.3 and 3.0.4.
- 3.3-107 Based upon operating experience to change Thermal Power in a controlled fashion without challenging the plant and consistent with the current TS which does not have a Completion Time for restoring one channel to OPERABLE status; but does prevent going above P-10 until it is restored, the Completion Time for ITS 3.3.1 Required Actions F.1 and F.2 should be increased to 24 hours. Condition F of ITS 3.3.1 is for one Intermediate Range Neutron Flux channel inoperable. Reactor protection would be provided by the OPERABLE Intermediate Range Neutron Flux channel and OPERABLE Power Range Neutron Flux channels. Indication would be available from the OPERABLE Intermediate Range Neutron Flux channel [, from OPERABLE Gamma-Metrics Neutron Flux detectors,] and from OPERABLE Power Range Neutron Flux channels with power approaching P-10. The Westinghouse Owners Group is considering a generic change on this issue, but deliberations were not completed at the time of our submittal.
- 3.3-108 Not used..

CHANGE
NUMBER

JUSTIFICATION

- 3.3-109 Not used.
- 3.3-110 Not used.
- 3.3-111 This change adds a Note to ITS SR 3.3.1.7 for source range instrumentation to verify interlocks P-6 and P-10 are in their required state for existing unit conditions. This is consistent with the current TS and is an enhancement which is easily performed and provides additional assurance that the interlocks are functioning correctly.
- 3.3-112 Not used.
- 3.3-113 Not used.
- 3.3-114 Not used.
- 3.3-115 Not used.
- 3.3-116 ACTION J of ITS 3.3.2 is not used since DCPD does not rely on motor-driven AFW pump start with loss of both main FW pumps. The function exists, but is not credited in any accident analysis and is not part of ESFAS Function 6 in the CTS.
- 3.3-117 This change to ITS 3.3.1 Condition R reflects current TS Table [3.3-1, ACTION Statement 12] which was based on NRC Generic Letter 85-09.
- 3.3-118 This change is for consistency with ITS 3.7.10 Condition [G].
- 3.3-119 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-120 ITS 3.3.1 Condition D is revised to reflect ITS SR 3.2.4.2 and CN 3.2-15 in the 3/4.2 package.
- 3.3-121 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.3-122 ITS 3.3.1 APPLICABILITY Note (b) for Functions 1, 5, 19-21 and Conditions C and K are revised to replace ACTIONS requiring the RTBs to be opened with ACTIONS that ensure subcriticality is maintained (i.e., by fully inserting all rods and ensuring the Rod Control System is incapable of rod withdrawal) yet do not initiate a feedwater isolation (P-4 and low T_{avg}) in MODE 3, consistent with Traveler TSTF-135.
- 3.3-123 This change deletes ACTION L.2 and renumbers L.3 since the requirement to close the unborated water source valves is not in the CTS and is not part of the current licensing basis. This new requirement is not applicable to DCPD which has a licensed dilution accident evaluation (refer to License Amendment 28/27). The current licensing bases in accordance with NUREG 0800, Section 15.4.6 provides adequate assurance that a dilution event will be recognized and arrested in a timely fashion.
- 3.3-124 Consistent with the current TS Table 4.3-1, Note [15], the note for ITS SR 3.3.1.4 is modified, a note is added to Table 3.3.1-1, and Function 20 are modified to clarify that the SR is required for the reactor trip bypass breaker local manual shunt trip only. The Bases for SR 3.3.1.14 clearly state that SR 3.3.1.14 includes the automatic undervoltage trip of the reactor trip bypass breakers. The Note (k) added to Table 3.3.1-1, Function 20 clarifies the Applicability of the undervoltage and shunt trip mechanisms to include those functions of the reactor trip bypass breakers when in use.

**CHANGE
NUMBER**

JUSTIFICATION

- 3.3-125 ITS SR 3.3.1.11 is modified by a Note that requires verification that the time constants are adjusted to the prescribed values. The addition of this Note is consistent with SR 3.3.1.10 and is required because SR 3.3.1.11 is used for the Power Range Neutron Flux - High Positive Rate [and High Negative Rate] trip functions which have a time constant associated with their calibration.
- 3.3-126 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-127 The MODE 2 applicability for the undervoltage RCP start of the steam-driven AFW pump is deleted and the surveillance Frequency is revised per the DCPP CTS. Thus, the Required Actions of ACTION I are revised to include entering MODE 2 for function 6.g and MODE 3 for function 5.b, and the required surveillance is changed from SR 3.3.2.7 to SR 3.3.2.8. This anticipatory start of the steam-driven AFW pump is not credited for MODE 2 operation, only the SG low level start signal is used for MODE 2 or 3.
- 3.3-128 This change revises ITS Table 3.3.4-1 to be consistent with CTS 3.3.3.5.
- 3.3-129 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-130 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-131 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-132 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-133 This change revises ITS LCO 3.3.5 and SR 3.3.5.3 to include the DG start sequence delay timers from CTS Table 3.3-4.
- 3.3-134 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.3-135 A MODE change restriction has been added to ITS 3.3.1 Condition C per the matrix discussed in CN 1-02-LS-1 of the 3.0 package (see LS-1 NSHC in the CTS Section 3/4.0, ITS Section 3.0 package).
- 3.3-136 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- {3.3-137 The Condition for Function 4.c is changed from Condition D to E consistent with the CTS. Plant design requires this Function to be bypassed, not tripped if inoperable.}

ENCLOSURE 6B

CONVERSION COMPARISON TABLE - NUREG-1431

Conversion Comparison Table

(21 Pages)

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-01	This trip function or design feature is not included in the plant design or it is not credited and has no safety function.	Yes	Yes	Yes	Yes
3.3-02	It is acceptable to have more than one Turbine Stop Valve Closure - reactor trip function channels inoperable and placed in trip per CTS Table 3.3-1, Functional Unit [16.b], ACTION Statement [11]. In addition, the 4 hour bypass note applies only to the [Low Auto Stop Oil Pressure] channels. ITS 3.3.1 Condition P has been revised.	Yes	Yes	Yes	Yes
3.3-03	This change to ITS 3.3.1 Condition R is consistent with the current licensing basis. A 4-hour AOT for SSPS logic surveillance testing has little usefulness if the RTBs cannot be bypassed for the duration of that testing. RTB surveillance testing retains the current 2-hour AOT.	Yes	No, not in CTS.	No, not in CTS.	Yes (CTS per OL Amendment No. 64 dated 10-9-91)
3.3-04	This change represents the Callaway plant design as it relates to the SG Water Level-Low Low Environmental Allowance Modifier (EAM) and Trip Time Delay (TTD) circuitry. ITS Table 3.3.1-1 and Table 3.3.2-1 entries and the associated Required Actions have been enhanced to remove the redundancy in the CTS and add shutdown actions when inoperable channels aren't tripped per their Completion Time.	No, see CN 3.3-46.	No, not in CTS.	No, not in CTS.	Yes (CTS per OL Amendment No. 43 dated 4-14-89)
3.3-05	This change to ITS SR 3.3.1.3 Note 1 represents the CTS as it relates to the Overtemperature ΔT AFD f_1 (ΔI) penalty function.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes (CTS per OL Amendment No. 84 dated 11-8-93)
3.3-06	Retains CTS power requirement of 75% RTP in the ITS SR 3.3.1.6 Note concerning when the incore/excore calibration is performed. The ISTS proposal would require unnecessary delays in the post-refuel power ascension. The Note is further revised to permit achieving equilibrium conditions (per CTS 4.2.2.2.d.1) prior to performing the required surveillance.	Yes	No, see CN 3.3-97.	No, see 3.3-97.	No; see 3.3-97.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-07	Note 3 is added to ITS SR 3.3.1.11 to be consistent with the CTS Table 4.3-1 Note [5]. This ensures that this exception, for power and intermediate range detector plateau voltage verification as discussed in the ITS BASES for SR 3.3.1.11, is included in the Technical Specifications rather than being only found in the BASES.	Yes	Yes	Yes	Yes
3.3-08	Deletes the Reviewer's Note in ITS Tables 3.3.1-1 and 3.3.2-1 and adds a Note reflecting the Allowable Value as the LSSS. Trip Setpoints are listed in the Bases.	No, retained CTS format.	Yes	Yes	Yes
3.3-09	The addition of footnote [(m)] to ITS Table 3.3.1-1 for Function 10 clarifies the low flow setpoint relationship to the quantity identified as Minimum Measured Flow, consistent with the CTS.	Yes	No, not in CTS.	No, not in CTS.	Yes, (CTS per OL Amendment No. 15 dated 4-8-86)
3.3-10	[The Overtemperature ΔT setpoint equation had a bracket in the wrong place and was corrected.] In addition, the f_1 (ΔI) penalty function was corrected and the K_2 inequality sign was changed to an equal sign..	Yes	No, see CN 3.3-38.	Yes	Yes, (CTS per OL Amendment No. 102 dated 8-21-95)
3.3-11	Added "or Rod Control System incapable of rod withdrawal," which makes Note (f) the complete antithesis of Note (b).	Yes	No, see CN 3.3-41.	No, see CN 3.3-41.	No, see CN 3.3-41.
3.3-12	Corrects typo in the inequality sign of ITS Table 3.3.2-1 Note (h).	No, see CN 3.3-105.	Yes	Yes	Yes
3.3-13	The equations for Overtemperature ΔT and Overpower ΔT are revised to be consistent with the DCPD CTS. The value of the time constant τ_6 has always been 0 seconds and the factor utilizing the time constant has not been shown as part of the equation in licensing documents since the factor value has been unity. Thus, the factors utilizing the time constant has been deleted.	Yes	No	No	No
3.3-14	Retains the monthly COT for Function 6.h of ITS Table 3.3.2-1, per CTS Table 4.3-2 Functional Unit 6.h. No TADOT is performed.	No, not in CTS.	No, not in CTS.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-15	The CHANNEL CHECK surveillance (SR 3.3.2.1) is deleted from the P-11 [] interlock because CHANNEL CHECKS are not applicable for permissive functions. This change is consistent with the CTS.	Yes	Yes	Yes	Yes
3.3-16	[Added Note (n) and] deleted SR 3.3.2.9 from Function 6.g in ITS Table 3.3.2-1. [Note (n) is added to avoid auxiliary feedwater actuations during normal plant startups and shutdowns.] These changes are consistent with CTS [Table 3.3-3 Note ### and] Table 4.3-2 Functional Unit [6.g].	No, not in CTS.	Yes	Yes, (Note [(p)] per CTS.)	Yes, (Note [(n)] per CTS, OL Amendment No. 26 dated 7-29-87)
3.3-17	New CONDITION [P] is added for Function 6.h of ITS Table 3.3.2-1, consistent with CTS Table 3.3-3 ACTION Statement [15].	No, not in CTS.	No, not in CTS.	Yes	Yes
3.3-18	Revises ITS 3.3.2 Condition K to be consistent with CTS Table 3.3-3 ACTION Statement 32, as revised per Enclosure 2, for Functional Unit 7.b.	No, not in CTS.	No, not in CTS.	No, see CN 3.3-134.	Yes, (CTS per OL Amendment No. 64 dated 10-9-91)
3.3-19	18-month test interval previously approved by NRC for selected slave relays which, if tested at power, could result in plant trips or upsets.	No, not in CTS.	No, not in CTS.	Yes (justified per SLNRC 84-0038 dated 2-27-84)	Yes (justified per SLNRC 84-0038 dated 2-27-84)
3.3-20	Added Note 2 on [Containment Radiation Level (High Range)] calibration in ITS SR [3.3.3.2] to be consistent with CTS Table [4.3-7 Note (2)].	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-21	ITS 3.3.3 was revised to reflect CTS 3.3.3.6. Containment Isolation Valve Position (and Notes) and Condensate Storage Tank Level were deleted. [Combined the power and source range neutron flux entries into a single neutron flux entry.] Consolidated the Thermocouple/Core Cooling Detection System entries. Changed number of required channels for RCS temperature to 2 for both hot and cold leg temperature. Changed Containment Pressure Wide Range to Containment Pressure Normal Range and added Refueling Water Storage Tank Level, Steam Line Pressure, and SG Water Level (Narrow Range) Functions as these are CTS requirements. Changed the required number of channels for SG Water Level (Wide Range) and AFW Flow Rate from 2 per SG to 1 per SG and added corresponding notes to Conditions A and C.	No, see CN 3.3-71.	No, see CN 3.3-70.	Yes (see Amendment No. 89)	Yes (see ULNRC-3023 dated 5-20-94 and Amendment No. 103 dated 10-20-95)
3.3-22	Consistent with CTS [3.3.3.5], [reactor trip breaker indication is excluded from CHANNEL CHECKS and from] CHANNEL CALIBRATIONS in ITS SR 3.3.4.3 since these SRs have no meaning for [this] function.	Yes	No, not in CTS.	Yes	Yes
3.3-23	CPSES-specific change that modifies ITS Surveillance Requirement 3.3.4.2 to include power circuits.	No	Yes	No	No
3.3-24	Changes ITS Table 3.3.4-1 to reflect CTS [3.3.3.5]. Deletes references to "controls" in the table (see also CN 3.3-94) and changes "Required Number of Functions" to "Required Channels" since the Table has been revised to include only instrumentation.	No, see CN 3.3-128.	Yes	Yes	Yes
3.3-25	Adds APPLICABILITY Note consistent with that found in ITS Table 3.3.1-1 (i.e., source range neutron flux is only required below the P-6 interlock). This is consistent with CTS Table 3.3-9.	No, see CN 3.3-84.	No, not in CTS.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-26.	The Pressurizer PORV and Block Valve Controls are deleted and RCP Breaker Position and AFW Suction Pressure are added to ITS Table 3.3.4-1, consistent with the current licensing basis for compliance with GDC-19. The PORVs may be used for eventual plant cooldown; however, they are not required to attain HOT STANDBY which is the basis for the listed functions. The added functions may be used to ensure decay heat removal by the SGs in attaining HOT STANDBY.	No, not in CTS.	No, see CN 3.3-24.	Yes	Yes (per FSAR Section 7.4.3 and SER Sections 7.4.2 and 7.4.3.2)
3.3-27	This change modifies ITS SR 3.3.3.2 and SR 3.3.3.3 to allow for different surveillance frequencies for the hydrogen monitors than other PAMS components. The manufacturer for the CPSES hydrogen monitors specifies a more frequent calibration frequency than that required for the other PAMS instruments. The more frequent calibration is required to assure function operability.	No	Yes	No	No
3.3-28	Tie breaker changes per CTS Table 3.3-3, ACTION Statement 19 for Functional Unit 8.b.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes (CTS per OL Amendment No. 99 dated 4-18-95)
3.3-29	{Not used}	N/A	N/A	N/A	N/A
3.3-30	The portion of Condition C [(relabelled as D per CN 3.3-74)] referring to one or more functions with one or more automatic actuation trains inoperable is revised to cover BOP-ESFAS only.	No, not in CTS.	No, not in CTS.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-31	The CTS require the response times associated with the [] containment [purge and exhaust] isolation function to be verified against the specific response time values contained in the [CTS]. The ITS is revised to match the CTS and the response time values are [moved to the FSAR]. As is done with the Reactor Trip System and the ESFAS instrumentation, this method is an appropriate way to control response times. [SR 3.3.6.8] is added to require the response time verifications.	Yes	Yes	No, will retain SRs in ITS 3.3.1 and 3.3.2 Tables.	Yes
3.3-32	ITS [3.3.6 ACTION A is modified by a Note and] Table 3.3.6-1 is changed to be consistent with CTS [3.3.2 Functional Unit 3.c and CTS 3.9.9]. Subfunctions [b, c and d] of Containment Radiation are stricken since only the gaseous [] channels provide the actuation function [and the bracketed setpoint is changed to reflect plant- specific requirements]. [The number of gaseous monitors required for CORE ALTERATIONS or during movement of irradiated fuel has been revised to one (either RM 44A or B) per the CTS]	Yes	No, see CN 3.3-73.	Yes	Yes
3.3-33	ITS Table 3.3.7-1 is revised to reflect the plant design. The CREVS is actuated by radiation monitors located in the air intakes, by a containment isolation - Phase A signal, by a containment purge isolation signal, by a fuel building ventilation isolation signal, or manually. The bracketed setpoint is revised to reflect CTS Table 3.3-6 requirements.	No, see CN 3.3-102.	No, see CN 3.3-78.	Yes	Yes
3.3-34	Revisions to add an LCO 3.0.3 exception Note 1 to ITS 3.3.8 reflect Industry Traveler TSTF-36, Rev. 2.	Yes	No, LCO does not apply.	Yes	Yes
3.3-35	ITS Table 3.3.8-1 is revised to reflect the plant design. Only the gaseous channels provide the actuation function. The bracketed setpoint is revised to reflect CTS Table 3.3-6 requirements.	No, not consistent with plant design.	No, LCO does not apply.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-36	Revisions reflect revised BDMS setpoint in CTS.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes (CTS per OL Amendment No. 94 dated 3-7-95)
3.3-37	Several ITS Required Action Notes are modified to allow a channel to be placed in bypass for surveillance testing. [This change is consistent with the CTS.]	Yes	Yes	No, not in current design or TS.	No, not in current design or TS.
3.3-38	The CPSES design uses the N-16 based overtemperature and overpower protective functions. Several changes to the setpoints, Required Actions and Surveillances of NUREG-1431 are required to maintain the current licensing basis.	No	Yes	No	No
3.3-39	ITS Table 3.3.7-1 is changed to be consistent with CTS Table 3.3-3. The Actuation Logic was split to reflect the SSPS, with only MODE 1-4 Applicability, and BOP-ESFAS portions and associated SR requirements in the CTS.	No, not in CTS.	No, not in CTS.	Yes	Yes
3.3-40	Add "and setpoint adjustment" to ITS 3.3.1 Condition E, similar to the Note for Condition D.	Yes	Yes	Yes	Yes
3.3-41	ITS 3.3.1 Condition L is deleted to match the plant-specific design and the CTS for the Source Range Neutron Flux Function in MODES 3, 4, and 5 with the Rod Control System incapable of rod withdrawal and all rods fully inserted. Under these conditions, the source range instrumentation does not provide a Reactor Trip System Function. The source range channels provide only indication [and inadvertent boron dilution mitigation] when in this Applicability. Requirements related to the source range neutron flux channels in MODES 3, 4, and 5 when all rods are fully inserted and are not capable of being withdrawn have therefore been [moved to ITS 3.3.9. Footnote (f) of ITS Table 3.3-1 is added to Function 5 and revised accordingly].	No, see CN 3.3-123.	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-42	Delete ITS 3.3.1 Condition N and combine Functions 10.a and 10.b per Traveler TSTF-169.	Yes	Yes	Yes	Yes
3.3-43	Revise ITS 3.3.1 Condition R Notes 1 and 2 per Traveler TSTF-168. The 2-hour AOT should not be limited to only UVTA/STA maintenance.	Yes	Yes	Yes	Yes
3.3-44	Revise ITS 3.3.1 Conditions S and T and ITS 3.3.2 Condition L, as well as the number of Required Channels [or trains as Condition T applies to permissive P-7] in Tables 3.3.1-1 and 3.3.2-1, to reflect CTS ACTION Statements [8 and 20].	Yes	Yes	Yes	Yes
3.3-45	A new CONDITION and SR are added for the current licensing basis required seismic trip.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
3.3-46	A new CONDITION and SR are added for the current licensing basis required Steam Generator level low-low time delay trip. These changes affect both ITS 3.3.1 and 3.3.2.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
3.3-47	Note 2 of SR 3.3.1.2 is revised to limit the power increase to less than 30% per the current licensing basis before the SR is complete.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
3.3-48	ITS SR 3.3.1.7 has a NOTE that provides a four hour delay in the requirement to perform the Surveillance for source range instrumentation when entering MODE 3 from MODE 2. Wolf Creek has deleted this NOTE in accordance with current Surveillance Requirements and the revisions made in ITS Table 3.3-1. The requirements for this Surveillance will be maintained by SR 3.3.1.8 in Table 3.3.1-1 for each applicable Function. SR 3.3.1.8 has been structured to cover NI Functions specified in ITS Table 3.3.1-1 and SR 3.3.1.7 has been structured to cover all other Functions. This similar to how the NUREG has structured SR 3.3.1.10 and SR 3.3.1.11.	No	No	Yes	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-49	ITS SR 3.3.1.8 is revised to extend the conditional COT frequency for power and intermediate range channels from 4 hours after reducing power below P-10 to 12 hours, based on operating experience regarding the time needed to perform the COTs. It stands to reason that if 4 hours are allowed for 2 Source Range COTs, 12 hours should be allowed for 6 Intermediate Range and Power Range COTs.	Yes	Yes	Yes	Yes
3.3-50	ITS SR 3.3.1.12 is deleted per the CTS. Where cited in Table 3.3.2-1, a change to SR 3.3.1.10 has been made.	No, see CN 3.3-101.	Yes	Yes	Yes
3.3-51	ITS ACTION B.2 of LCO 3.3.7 is deleted, since DCPD cannot operate CRVS with both pressurization systems running at the same time.	Yes	No	No	No
3.3-52	Added Note [(I)] to ITS Table 3.3.1-1 per the CTS as an operator aid to note the dual RTS/ESFAS functions of SG Water Level Low-Low.	No, adopted ISTS format.	Yes	Yes	Yes
3.3-53	The REQUIRED CHANNELS description for Functions 2.a and 3.b.(1), of ITS Table 3.3.2-1, are revised per the DCPD CTS to note that only two switches (one per train) exist and that both must be moved coincident for manual initiation.	Yes	No	No	No
3.3-54	Function 18.b (P-7) of ITS Table 3.3.1-1 is clarified. COTs and Channel Calibrations apply to the P-10 and P-13 inputs, not to the P-7 logic function.	Yes	Yes	No, adopted ISTS format.	Yes
3.3-55	Revise ITS SR 3.3.1.16 and SR 3.3.2.10 to verify "required" response times, accommodating those channels that have no response time requirements per the current licensing basis. [As such, line-item references to these SRs in Tables 3.3.1-1 and 3.3.2-1 can be deleted. A similar revision to the ITS SR 3.3.6 SR note has also been made regarding SR 3.3.6.8.]	No, SRs will be retained in ITS Tables for required Functions.	Yes	Yes, SRs will be retained in ITS Tables for required Functions.	Yes
3.3-56	Revise ITS 3.3.2 Condition J to reflect CTS Table [3.3-3], ACTION Statement [19] for Functional Unit [6.g].	No, See CN 3.3-116.	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-57	Not used.	N/A	N/A	N/A	N/A
3.3-58	Adds new ITS 3.3.2 Condition [N] to reflect CTS Table 3.3-3 ACTION Statement [24] on manual AFW [and manual MSIV closure] initiation.	Yes	No, not in CTS.	No, adopted ISTS format.	Yes
3.3-59	Adds new ITS 3.3.2 Condition [R] to reflect CTS Table 3.3-3 ACTION Statement [21] on BOP-ESFAS portion of AFW initiation.	No, not in CTS.	No, not in CTS.	Yes	Yes
3.3-60	Consistent with the design and CTS, Surveillance Requirement[s] 3.3.2.3 and 3.3.2.7 are deleted as they are not used by any Function listed in Table 3.3.2-1.	Yes	Yes	No, used for BOP-ESFAS.	No, used for BOP-ESFAS.
3.3-61	Change ITS SR 3.3.2.11 Frequency to 18 months per CTS Table 4.3-2 Functional Unit [8.c], which is the ESFAS P-4 permissive. [Deleted the Note stating that verification of set point is not required per the CTS.]	Yes	Yes	Yes	Yes
3.3-62	Consistent with the CPSES design and CTS, isolation of the MSIVs also requires isolation of the associated upstream drip pot isolation valves.	No	Yes	No	No
3.3-63	Revise ITS Table 3.3.2-1 [Notes (b) and (g)] per CTS Table [3.3-3] Notes [# and ##]. This revision is a clarification to the operator that describes the circumstances under which the [Steamline Pressure Negative Rate - High, Steam Pressure-low, or Pressurizer Pressure-low functions may be or are] blocked [relative to the] P-11 permissive.	Yes	Yes	Yes	Yes
3.3-64	Revise ITS Table 3.3.2-1 Note (j) to exclude the MFRVs, consistent with CTS [3.7.1.6]. []	No, already in CTS.	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-65	A Note is added to the steam generator water level - high-high trip function to reflect the CPSES design and CTS. In the CPSES design, only three channels of the four steam generator water level signals provide input to this trip function. Therefore, in order to satisfy the single failure criterion, if one of these three channels is used as input to the Steam Generator Water Level Control System, its associated bistable must be placed in the tripped state.	No	Yes	No	No
3.3-66	The DCPD-specific MODE 4 requirement of the CTS is retained and added to Table 3.3.2-1 for SI actuated by Containment Pressure High.	Yes	No	No	No
3.3-67	In PAMS, add CPSES-specific operability requirements and Required Actions for the T-hot and T-cold indications consistent with both the current licensing basis and the intent of NUREG-1431. If a T-hot indication is unavailable, equivalent information is available from the Core Exit Temperature indication which is also a RG 1.97 variable. Similarly, if a T-cold indication is unavailable, equivalent information may be derived through the use of the steam generator pressure and steam tables, because the RCS cold leg temperature closely follows the steam generator saturation temperature.	No	Yes	No	No
3.3-68	A DCPD-specific Note is added to state that CONDITION D is only applicable in MODES 1 and 2. A new CONDITION H is added to require entering MODE 3 if CONDITION B is not met when entered due to not meeting CONDITION D.	Yes	No	No	No
3.3-69	{The phrase "...that is not normally energized" is deleted per the CTS. All of the instrumentation listed is normally energized at power.	Yes	No	No	No}
3.3-70	The PAM instrumentation list is modified to reflect the CPSES design and CTS.	No, see CN 3.3-71.	Yes	No, see CN 3.3-21.	No, see CN 3.3-21.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-71	This DCPP-specific change revises Table 3.3.3-1 per the Reviewers Note to update CTS PAM instruments per the requirements of Reg. Guide 1.97, and revises ACTIONS A and C to account for those functions with only one required channel.	Yes	No, see CN 3.3-70.	No, see CN 3.3-21.	No, see CN 3.3-21.
3.3-72	The Conditions and Required Actions related to two or more radiation monitors for the Containment Ventilation Isolation System are deleted to reflect the CPSES design and CTS. CTS ACTIONS for radiation monitors are retained in the ITS.	No	Yes	No	No
3.3-73	The CPSES CTS ACTIONS for inoperable Functions are retained in the ITS.	No	Yes	No	No
3.3-74	Revise ITS 3.3.6 Conditions A, B, and C to reflect current licensing basis and add a new Condition applicable during Core Alterations or movement of irradiated fuel assemblies within containment to allow a 4 hour Completion Time to restore one inoperable radiation monitoring channel prior to isolating the purge pathway. This new Condition represents a relaxation in a previously relocated Action Statement; however, that Action Statement inappropriately calls for the same measures whether one or both purge radiation monitors are inoperable.	No, not in CTS.	No, not in CTS.	No, retained CTS.	Yes (per FSAR Section 16.3.3.7B)
3.3-75	The DCPP-specific CHANNEL FUNCTIONAL TEST is substituted for the COT per current licensing basis.	Yes	No	No	No
3.3-76	Consistent with the current design and TS, a Trip Actuating Device Operational Test (TADOT) is not required for any of the functions explicitly listed in Table 3.3.6-1; therefore, the associated Surveillance Requirement is deleted. Note that a TADOT is required in accordance with LCO 3.3.2 for functions 3.a.1 and 2.a, as referenced in the Table.	Yes	Yes	No, used for Manual Initiation Function 1.	No, used for Manual Initiation Function 1.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-77	Containment Vent Isolation is initiated by the ESFAS Phase "A" isolation signals. As such, the number of required channels and required surveillances for the manual initiation of Containment Vent Isolation are captured by the requirements for Phase "A" isolation in the ESFAS tables.	Yes	Yes	No, not in CTS.	No, not in CTS.
3.3-78	The modifications to the ITS are consistent with both the intent of the ITS and the CPSES CREFS design and CTS.	No	Yes	No	No
3.3-79	Add APPLICABILITY columns to ITS Tables 3.3.6-1 and 3.3.7-1 to reflect CTS with varying Functional Applicabilities.	Yes	Yes	Yes	Yes
3.3-80	Revise Condition B and add new Condition C to both ITS 3.3.7 and ITS 3.3.8 to reflect current ACTIONS [30 and 38 of Table 3.3-6].	No, not in CTS.	No, see CN 3.3-78.	No-see CN 3.3-81.	Yes
3.3-81	This change revises condition B and adds Condition C to both ITS 3.3.7 and ITS 3.3.8 to reflect CTS ACTIONS 27 and 30 of Table 3.3-6.	No	No	Yes	No
3.3-82	The Conditions, Required Actions, etc. are revised per the DCPD current licensing basis. The plant FBACS does not perform any accident mitigation functions except during the fuel handling accident.	Yes	No	No	No
3.3-83	Add Note [(c)] to ITS Table 3.3.8-1 to reflect the CTS.	No, see CN 3.3-82.	No, LCO does not apply.	Yes	Yes
3.3-84	The Note of SR 3.3.4.4 is deleted since Table 3.3.4-1 does not have a neutron detector specified per the DCPD CTS.	Yes	No	No	No
3.3-85	The Note in Required Action 3.3.5 A.1 would be deleted as it is inconsistent with the current CPSES design and TS.	No	Yes	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-86	Surveillance Requirement 3.3.5.2 is revised to reflect the current CPSES plant design and licensing basis. A Note is added to SR 3.3.5.2 indicating that setpoint verification is not applicable for the performance of the TADOT. This verification is performed during Channel Calibrations (see SR 3.3.5.3).	No	Yes, see also CNs 3.3-31, 3.3-130, and 3.3-131.	No	No
3.3-87	Not used.	NA	NA	NA	NA
3.3-88	Revise ITS 3.3.9 to apply in MODE 2 only below P-6 and to reflect ACTION Statement 5.b per CTS Table 3.3-1.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
3.3-89	Revise COT in ITS SR 3.3.9.3 to add the 4 hour allowance from ITS SR 3.3.1.7.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
3.3-90	Exclude neutron detectors from CHANNEL CALIBRATION ITS SR 3.3.9.4 per CTS Table 4.3-1, Functional Unit 6, Note 4.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
3.3-91	Add CHANNEL CHECK and response time surveillances (ITS SR 3.3.9.1 and SR 3.3.9.5) per CTS Table 4.3-1, Functional Unit 6, Note 12.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
3.3-92	Adds SR 3.3.4.2 Note that the ASP controls for the TDAFW pump and SG ASDs are not required to be verified prior to entry into MODE 3, consistent with CTS SR 4.3.3.5.3.	No, adopted ISTS format.	No, not in CTS.	No, adopted ISTS format.	Yes
3.3-93	ITS 3.3.1 Condition V is deleted. It is not entered from Table 3.3.1-1 nor do the Bases clarify when it would be needed, raising the concern of misinterpretation. Condition V does not replace LCO 3.0.3 requirements to assess when the plant is outside the licensing basis.	Yes	Yes	Yes	Yes
3.3-94	ITS 3.3.4 is revised per CTS [3.3.3.5] with regard to [ASP] controls.	Yes	Yes	No, adopted ISTS format.	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-95	ITS 3.3.1 Condition H, Required ACTION H.1, and the second part of Function 4 Applicability (MODE 2 below P-6) in ITS 3.3.1 are deleted since they provide no real compensatory measures. [With their deletion, there is no need to repeat the > P-6 Applicability in Conditions F and G.] In accordance with LCO 3.0.4, the intermediate range detectors must be OPERABLE prior to entering the Applicability of the retained part of Function 4 (i.e., MODE 2 above P-6). Condition H and Required ACTION H.1 ensure the same thing and, therefore, can be deleted. This change is consistent with Traveler TSTF-135.	Yes	Yes	Yes	Yes
3.3-96	[] Note 2 for ITS SR 3.3.1.3 is revised to replace the bracketed 15% RTP power level constraint with 50% RTP. The specified power level in ITS SR 3.3.1.3 should reflect the applicable safety analysis basis consistent with the [APPLICABILITY and] Required Actions of ITS LCO 3.2.3 (AFD) and LCO 3.2.4 (QPTR).	Yes	Yes	Yes	Yes
3.3-97	The NOTE for SR 3.3.1.6 of ITS 3.3.1 has been revised to state "Not required to be performed until 72 hours after achieving equilibrium conditions with THERMAL POWER \geq 75% RTP". This is consistent with the CTS Functional Unit 2.a surveillance requirement of Table 4.3-1 as modified by Note (6), and current operating experience of 72 hours for performing the SR.	No, adopted bracketed ISTS time of 24 hours; see also CN 3.3-06.	Yes	Yes	Yes
3.3-98	This change reflects the Callaway-specific modification of the main steam and feedwater isolation system (MSFIS).	No	No	No	Yes, per OL Amendment No. 117 dated 10-1-96.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-99	<p>ITS 3.3.5 Condition B is revised to allow 12 hours for one bus to restore the instrument function to the capability of continued operation in Condition A. The 12 hour allowance is based on the ITS 3.8.1.F allowance for an inoperable sequencer.</p> <p>[A new Condition C is added to ITS 3.3.5 to cover multiple channel inoperability on both ESF buses. The Completion Time of 1 hour is provided to restore the functional capability of Condition B.]</p> <p>A new Condition [D] is also added to the ACTIONS of ITS LCO 3.3.5. The new Condition provides the appropriate shutdown actions if Conditions [A, B, or C] are not satisfied when in MODES 1-4. Condition [D] is consistent with the ACTIONS required by the AC Sources ITS 3.8.1 for Modes 1-4.</p> <p>Condition C of NUREG-1431 Rev. 1 is revised to be Condition [E]. Condition [E] provides the appropriate default Condition for failure to satisfy Conditions [A, B, or C] when the loss of power instrumentation is required operable to support the diesel generator required operable in ITS LCO 3.8.2.</p>	No, see CN 3.3-104.	No, see CN 3.3-131.	Yes	Yes
3.3-100	Not used.	N/A	N/A	N/A	N/A
3.3-101	The Note for ITS SR 3.3.1.12 is deleted since the plant design no longer includes the RTD bypass. The SR is retained and is applied to the required seismic trip instrumentation per the current licensing basis. Where cited in Table 3.3.2-1, a change to SR 3.3.1.10 has been made.	Yes	No, see CN 3.3-50.	No, see CN 3.3-50.	No, see CN 3.3-50.
3.3-102	The control room (CR) does not have CR Atmosphere monitors as part of its current design. There are redundant CR intake monitors for each intake.	Yes	No, see CN 3.3-78.	No, see CN 3.3-33.	No, see CN 3.3-33.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-103	Function 11 of ITS Table 3.3.1-1 is revised per the DCPD CTS to reflect the current plant design of only a two loop trip. With this revision Condition O is no longer used, since it was only applicable to the single loop trip.	Yes	No	No	No
3.3-104	CONDITION A of ITS 3.3.5 is revised to incorporate CTS ACTIONS 15 and 16. CONDITIONS B and C are not used.	Yes	No, see CN 3.3-131.	No, see CN 3.3-99.	No, see CN 3.3-99.
3.3-105	Function 4.d.(2) of ITS Table 3.3.2-1 and notes (c) and (h) are revised per the DCPD CTS.	Yes	No, see CN 3.3-12.	No, see CN 3.3-12.	No, see CN 3.3-12.
3.3-106	Delete ISTS Required Actions B.2.2 and U.2.2. These Required Actions are not needed due to exiting the APPLICABILITY via Required Actions B.2.1 and U.2.1.	Yes	Yes	Yes	Yes
3.3-107	Based upon operating experience to change Thermal Power in a controlled fassion without challenging the plant and consistent with the CTS which does not have a Completion Time for restoring one channel to OPERABLE sttus; but does pervent going above P-10 until it is restored, the Completion Time for ITS 3.3.1 Required Actions F.1 and F.2 should be increased to 24 hours.	Yes	Yes	Yes	Yes
3.3-108	Not used.	N/A	N/A	N/A	N/A
3.3-109	Not used.	N/A	N/A	N/A	N/A
3.3-110	Not used.	N/A	N/A	N/A	N/A
3.3-111	Add a Note to ITS SR 3.3.1.7 for source range instrumentation to verify interlocks P-6 and P-10 are in their required state for existing unit conditions. This is consistent with the CTS.	Yes	Yes	No-see CN 3.3-48.	Yes
3.3-112	Not used.	N/A	N/A	N/A	N/A
3.3-113	Not used.	N/A	N/A	N/A	N/A
3.3-114	Not used.	N/A	N/A	N/A	N/A

JLS Conversion to Improved Technical Specifications Diablo Canyon Power Plant

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Methodology for Cross-Reference Tables
(Continued)

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).

Note: The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

3/4.4 REACTOR COOLANT SYSTEM

3/4.4.1 REACTOR COOLANT LOOPS AND COOLANT CIRCULATION

STARTUP AND POWER OPERATION

LIMITING CONDITION FOR OPERATION

3.4.1.1 All reactor coolant loops shall be OPERABLE and in operation.

01:01:LG

APPLICABILITY: MODES 1 and 2.

ACTION:

With less than the above required reactor coolant loops OPERABLE and in operation, be in at least HOT STANDBY within 6 hours.

01:01:LG

SURVEILLANCE REQUIREMENT

4.4.1.1 The above required reactor coolant loops shall be verified to be in operation ~~and circulating reactor coolant~~ at least once per 12 hours.

01:01:LG

REACTOR COOLANT SYSTEM

HOT STANDBY

LIMITING CONDITION FOR OPERATION

3.4.1.2 At least two of the reactor coolant loops listed below shall be OPERABLE with and either two reactor coolant loops in operation when the rod control system is capable of rod withdrawal. Reactor Trip System breakers are closed and or one reactor coolant loop in operation when the rod control system is not capable of rod withdrawal. * Reactor Trip System breakers are open.*

01-03-LS1

- a. Reactor Coolant Loop 1 and its associated steam generator and reactor coolant pump.
- b. Reactor Coolant Loop 2 and its associated steam generator and reactor coolant pump.
- c. Reactor Coolant Loop 3 and its associated steam generator and reactor coolant pump, and
- d. Reactor Coolant Loop 4 and its associated steam generator and reactor coolant pump.

01-01-LG

APPLICABILITY: MODE 3.

ACTION:

- a. With one less than the above required reactor coolant loops inoperable OPERABLE, restore the required loops to OPERABLE status within 72 hours or be in HOT SHUTDOWN within the next 12 hours.
- b. With only one reactor coolant loop in operation and the Reactor Trip System breakers in the closed position, and rod control system capable of rod withdrawal, within 1 hour restore two loops to operation OR place the rod control system in a condition incapable of rod withdrawal, open the Reactor Trip System breakers.
- c. With no RCS loops OPERABLE OR no reactor coolant loop in operation, immediately place the rod control system in a condition incapable of rod withdrawal and suspend all operations involving a reduction in boron concentration of the Reactor Coolant System and immediately initiate corrective action to return the required reactor coolant loop to operation.

ED

03-04-LS29

01-03-LS1

01-03-LS1

SURVEILLANCE REQUIREMENTS

4.4.1.2.1 At least the above required reactor coolant pumps, if not in operation, shall be determined to be OPERABLE once per 7 days by verifying correct breaker alignments and indicated power availability.

REACTOR COOLANT SYSTEM

SURVEILLANCE REQUIREMENTS (continued)

4.4.1.2.2 The required steam generators shall be determined OPERABLE by verifying secondary side water level to be greater than or equal to 15% at least once per 12 hours.

4.4.1.2.3 The required reactor coolant loop(s) shall be verified to be in operation and circulating reactor coolant at least once per 12 hours.

01:01:LG

*All reactor coolant pumps may be deenergized ~~removed from operation~~ for up to 1 hour ~~per 8 hour period~~ provided:

01:16:A

01:06:M

(1) no operations are permitted which could cause dilution of the Reactor Coolant System boron concentration, and (2) core outlet temperature is maintained at least 10°F below saturation temperature.

REACTOR COOLANT SYSTEM

HOT SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.4.1.3 At least two of the loops/trains listed below shall be OPERABLE and at least one of these loops/trains shall be in operation:*

- a. ~~Reactor Coolant Loop 1 and its associated steam generator and reactor coolant pump, **~~ 01-01:LG
- b. ~~Reactor Coolant Loop 2 and its associated steam generator and reactor coolant pump, **~~
- c. ~~Reactor Coolant Loop 3 and its associated steam generator and reactor coolant pump, **~~
- d. ~~Reactor Coolant Loop 4 and its associated steam generator and reactor coolant pump, **~~
- e. Residual Heat Removal (RHR) Train 1, and
- f. Residual Heat Removal (RHR) Train 2.

APPLICABILITY: MODE 4.

ACTION:

- a. ~~With one less than the above required loops/trains inoperable OPERABLE, immediately initiate corrective action to return the required loop/train to OPERABLE status as soon as possible; if the remaining OPERABLE loop/train is an RHR train, be in COLD SHUTDOWN within 24 hours.~~ ED
- b. ~~With no loops OPERABLE or no loop/train in operation, suspend all operations involving a reduction in boron concentration of the Reactor Coolant System and immediately initiate corrective action to return one the required coolant loop to OPERABLE status and operation /train to operation.~~ 01-07:M

~~*All reactor coolant pumps and RHR pumps may be deenergized removed from operation for up to 1 hour per 8 hour period provided: (1) no operations are permitted that would cause dilution of the Reactor Coolant System boron concentration, and (2) core outlet temperature is maintained at least 10°F below saturation temperature.~~ 01-16:A
01-08:M

~~**A reactor coolant pump shall not be started with one or more of the Reactor Coolant System cold leg temperatures less than or equal to 270°F the temperature below which LTOP is required as specified in the PTLR unless: (1) the pressurizer water level is less than 50%, or (2) secondary water temperature of each steam generator is less than 50°F above each of the Reactor Coolant System cold leg temperatures.~~ 01-17-LG

REACTOR COOLANT SYSTEM

SURVEILLANCE REQUIREMENTS

4.4.1.3.1 The required reactor coolant pump(s) and/or RHR pumps, if not in operation, shall be determined OPERABLE once per 7 days by verifying correct breaker alignments and indicated power availability.

4.4.1.3.2 The required steam generator(s) shall be determined OPERABLE by verifying secondary side water level to be greater than or equal to 15% at least once per 12 hours.

4.4.1.3.3 At least one reactor coolant loop or RHR train shall be verified to be in operation ~~and circulating reactor coolant~~ at least once per 12 hours.

0101EG

REACTOR COOLANT SYSTEM

COLD SHUTDOWN - LOOPS FILLED

LIMITING CONDITION FOR OPERATION

3.4.1.4.1 At least one residual heat removal (RHR) train shall be OPERABLE and in operation*. **and either:

01-08-LS2

- a. One additional RHR train shall be OPERABLE#, or
- b. The secondary side water level of at least two steam generators shall be greater than or equal to 15%.

APPLICABILITY: MODE 5 with reactor coolant loops filled##.

ACTION:

- a. With one of the RHR trains inoperable and with less than the required steam generator water level, immediately initiate corrective action to return the inoperable RHR train to OPERABLE status or restore the required steam generator water level as soon as possible.
- b. With ~~required RHR trains inoperable or~~ no RHR train in operation, suspend all operations involving a reduction in boron concentration of the Reactor Coolant System and immediately initiate corrective action to return the required RHR train to OPERABLE status and operation to operation.

01-10-M

SURVEILLANCE REQUIREMENTS

4.4.1.4.1.1 The secondary side water level of at least two steam generators when required shall be determined to be within limits at least once per 12 hours.

4.4.1.4.1.2 At least one RHR train shall be determined to be in operation and circulating reactor coolant at least once per 12 hours.

01-01-EG

~~(NEW) Verify correct breaker alignment and indicated power are available to the RHR pump that is not in operation at least once per 7 days~~

01-11-M

* The RHR pump may be deenergized ~~removed from operation~~ for up to ~~1~~ 1 hour per 8 hour period provided (1) no operations are permitted that would cause dilution of the Reactor Coolant System boron concentration, and (2) core outlet temperature is maintained at least 10°F below saturation temperature.

01-16-A

01-06-M

One RHR train may be inoperable for up to 2 hours for surveillance testing provided the other RHR train is OPERABLE and in operation.

A reactor coolant pump shall not be started with one or more of the Reactor Coolant System cold leg temperatures less than or equal to 270°F ~~the temperature below which~~

SURVEILLANCE REQUIREMENTS (continued)

~~LTOP is required as specified in the PTLR unless:~~

~~01:17:EG~~

(1) the pressurizer water level is less than 50%, or (2) the secondary water temperature of each steam generator is less than 50°F above each of the Reactor Coolant System cold leg temperatures.

~~** All RHR Loops may be removed from operation during planned heatup to MODE 4 when at least one RCS loop is in operation.~~

~~01:08:LS2~~

REACTOR COOLANT SYSTEM

COLD SHUTDOWN - LOOPS NOT FILLED

LIMITING CONDITION FOR OPERATION

3.4.1.4.2 Two residual heat removal (RHR) trains shall be OPERABLE# and at least one RHR train shall be in operation.*

APPLICABILITY: MODE 5 with reactor coolant loops not filled.

ACTION:

- a. With ~~one~~ less than the above required RHR trains ~~inoperable~~ OPERABLE, immediately initiate corrective action to return the required trains to OPERABLE status. ~~as soon as possible.~~ 01:12:M

- b. With ~~required RHR trains inoperable~~ OR no RHR train in operation, suspend all operations involving a reduction in boron concentration of the Reactor Coolant System and immediately initiate corrective action to return the required RHR train ~~to OPERABLE status and operation~~ to operation. 01:10:M

SURVEILLANCE REQUIREMENTS

4.4.1.4.2 At least one RHR train shall be determined to be in operation and circulating reactor coolant at least once per 12 hours. 01:01:LG

~~(new) Verify correct breaker alignment and indicated power are available to the required RHR pump that is not in operation at least once per 7 days.~~ 01:11:M

One RHR train may be inoperable for up to 2 hours for surveillance testing provided the other RHR train is OPERABLE and in operation.

* The RHR pump may be ~~de-energized~~ removed from operation for up to ~~1~~ 1 hour per ~~8~~ hour period provided: (1) no operations are permitted that would cause dilution of the Reactor Coolant System boron concentration, (2) core outlet temperature is maintained at least 10°F below saturation temperature, and (3) ~~no draining operations to further reduce the RCS water volume are permitted.~~ the reactor vessel water level is above the vessel flange. 01:16:A
01:08:M
01:20:LS27

~~This Page Intentionally Deleted~~

REACTOR COOLANT SYSTEM

OPERATING

LIMITING CONDITION FOR OPERATION

3.4.2.2 All pressurizer Code safety valves shall be OPERABLE with a lift setting of 2485 psig \pm 1%.*

APPLICABILITY: MODES 1, 2, and 3 and 4-#

~~MODE 4 with all RCS cold leg temperatures > the temperature below which LTOP is required as specified in the PTLR~~

01:17:LG

ACTION:

- a. With one pressurizer Code safety valve inoperable, either restore the inoperable valve to OPERABLE status within 15 minutes or be in at least HOT STANDBY within 6 hours and in at least HOT SHUTDOWN with any all RCS cold leg temperatures less than or equal to 270°F the temperature below which LTOP is required as specified in the PTLR within the following 6 hours.
- b. The provisions of Specification 3.0.4 may be suspended for up to 18 hours per valve for entry into and during operations in MODE 3 and 4-# for the purpose of setting the pressurizer Code safety valves under ambient (hot) conditions provided a preliminary cold setting was made prior to heatup.

01:17:LG

~~c. With two or more pressurizer safety valves inoperable, be in at least HOT STANDBY within 6 hours and in at least HOT SHUTDOWN with any RCS cold leg temperature less than or equal to the temperature below which LTOP is required as specified in the PTLR within the following 6 hours.~~

02:03:M

01:17:LG

SURVEILLANCE REQUIREMENTS

4.4.2.2 No additional requirements other than those required by Specification 4.0.5.

~~* The lift setting pressure shall correspond to ambient conditions of the valve at nominal operating temperature and pressure.~~

02:04:LG

~~# When all RCS cold leg temperatures are greater than 270°F.~~

01:17:LG

REACTOR COOLANT SYSTEM

3/4.4.3 PRESSURIZER

LIMITING CONDITION FOR OPERATION

3.4.3 The pressurizer shall be OPERABLE with a water volume of less than or equal to 1600 cubic feet (90% of span) and two groups of pressurizer heaters each having a capacity of at least 150 kW and capable of being powered from an emergency power supply.

03-05-M

APPLICABILITY: MODES 1, 2, and 3.

ACTION:

- a. With one group of pressurizer heaters inoperable, restore at least two groups to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours.
- b. With the pressurizer water level not within limit otherwise inoperable, be in at least HOT STANDBY with the Reactor Trip Breakers open all rods fully inserted and the Rod Control System incapable of rod withdrawal within 6 hours and in HOT SHUTDOWN within the following 6 hours.

03-01-LS4

03-04-LS29

SURVEILLANCE REQUIREMENTS

4.4.3.1 The pressurizer water volume shall be determined to be within its limit at least once per 12 hours.

4.4.3.2 The capacity of each of the above required groups of pressurizer heaters shall be verified by measuring heater group power at least once per 92 days. 18 months.

03-02-LG

03-03-LS28

4.4.3.3 The emergency power supply for the pressurizer heaters shall be demonstrated OPERABLE at least once per 18 months by transferring power from the normal to the emergency power supply and energizing the heaters.

REACTOR COOLANT SYSTEM

3/4.4.4 RELIEF VALVES

LIMITING CONDITION FOR OPERATION

3.4.4 All power-operated relief valves (PORVs) and their associated block valves shall be OPERABLE.

APPLICABILITY: MODES 1, 2, and 3.

NOTE: Separate condition entry is allowed for each valve.

04-01-LS5

ACTION:

a. With one or more PORV(s) inoperable because of excessive seat leakage and capable of being manually cycled, within 1 hour either restore the PORV(s) to OPERABLE status or close the associated block valve(s) and maintain power to the block valve(s), otherwise, continue restoration activities and be in at least HOT STANDBY within the next 6 hours and reduce Tavg to < 500°F and HOT SHUTDOWN within the following 6 hours.

04-02-LS6

04-05-LS31

b. With one or more PORV(s) inoperable due to causes other than excessive seat leakage, and not capable of being manually cycled, within 1 hour either restore the PORV(s) to OPERABLE status or close the associated block valve(s) and remove power from the block valve(s), and

04-02-LS6

1. With only one Class 1 PORV OPERABLE inoperable, and not capable of being manually cycled, restore at least a total of two Class 1 PORVs to OPERABLE status within the following 72 hours or continue restoration activities and be in HOT STANDBY within the next 6 hours and in HOT SHUTDOWN and reduce Tavg to < 500°F within the following 6 hours, or

04-05-LS31

2. With no both Class 1 PORVs OPERABLE inoperable and not capable of being manually cycled, immediately initiate action to restore at least one Class 1 PORV to OPERABLE status within 1 hour and follow ACTION b.1, above, with the time requirement of that ACTION statement based on the time of initial loss of the remaining inoperable Class 1 PORV or continue restoration activities and be in HOT STANDBY within the next 6 hours and HOT SHUTDOWN and reduce Tavg to < 500°F within the following 6 hours.

04-02-LS6

04-03-M

04-05-LS31

c. 1. With one or more block valve(s) inoperable, within 1 hour, place associated PORV in manual control

04-06-LS32

AND

1. Restore the block valve(s) to OPERABLE status within 72 hours, or

2. With more than one block valve inoperable, place associated PORVs in manual control within 1 hour

04-07-LS33

AND

Restore one block valve for a Class 1 PORV to OPERABLE status within 2 hours

REACTOR COOLANT SYSTEM

ACTION: (continued)

AND

restore the remaining block valves for a Class 1 PORV to OPERABLE status within 72 hours. (If the remaining block valve is for a non-Class 1 PORV, close the block valve and remove the power.)

OR

~~2. Close the PORV(s) and remove power from its associated solenoid.~~

~~Also, comply with ACTION b, as appropriate, for the isolated PORV(s).~~

~~3. If required action and associated completion times of c.1. or c.2. are not met, continue restoration activities and be in HOT STANDBY within the next 6 hours AND be in HOT SHUTDOWN and reduce Tavg to < 500°F within the following 6 hours.~~

04:05:LS31

d. The provisions of Specification 3.0.4 are not applicable.

SURVEILLANCE REQUIREMENTS

4.4.4.1 In addition to the requirements of Specification 4.0.5, each PORV shall be demonstrated OPERABLE at least once per 18 months by:

a. Operating the PORV through one complete cycle of full travel* during MODES 3 or 4 with the block valves closed, and

04:08:LS34

~~b. Performing a CHANNEL CALIBRATION of the actuation instrumentation.~~

04:04:LG

4.4.4.2 In addition to the requirements of Specification 4.0.5, each block valve shall be demonstrated OPERABLE at least once per 92 days* by operating the valve through one complete cycle of full travel unless the block valve is closed in order to meet the requirements of ACTION a, b, or c. in Specification 3.4.4.

04:08:LS34

04:09:LS36

4.4.4.3 The safety-related nitrogen supply for the PORVs shall be demonstrated OPERABLE at least once per 18 months by:

a. Isolating and venting the normal air supply, and

b. Verifying that any leakage of the Class 1 Backup Nitrogen System is within its limits, and

c. Operating the PORVs through one complete cycle of full travel.

* Only required to be performed in MODES 1 and 2.

04:08:LS34

REACTOR COOLANT SYSTEM

3/4.4.5 STEAM GENERATORS

05:01A

LIMITING CONDITION FOR OPERATION

~~3.4.5 Each steam generator shall be OPERABLE.~~

05:02A

~~APPLICABILITY: MODES 1, 2, 3 and 4.~~

ACTION:

~~With one or more steam generators inoperable, restore the inoperable generator(s) to OPERABLE status prior to increasing T_{avg} above 200°F.~~

SURVEILLANCE REQUIREMENTS

~~4.4.5.0 Each Steam generator tube integrity steam generator shall be demonstrated OPERABLE by performance of the following augmented Inservice inspection program, and the requirement of Specification 4.0.5.~~

05:01A

~~4.4.5.1 Steam Generator Sample Selection and Inspection Each Steam generator tube integrity shall be determined OPERABLE during shutdown by selecting and inspecting at least the minimum number of steam generators specified in Table 4.4.1.~~

05:01A

05:02A

~~4.4.5.2 Steam Generator Tube Sample Selection and Inspection The steam generator tube minimum sample size, inspection result classification, and the corresponding action required shall be as specified in Table 5.5.9.2. The Inservice inspection of steam generator tubes shall be performed at the frequencies specified in Specification 5.5.9.c. 4.4.5.3 and the inspected tubes shall be verified acceptable per the acceptance criteria of Specification 5.5.9d. 4.4.5.4. The tubes selected for each Inservice inspection shall include at least 3% of the total number of tubes in all steam generators; the tubes selected for these inspections shall be selected on a random basis except:~~

05:01A

- ~~a. Where experience in similar plants with similar water chemistry indicates critical areas to be inspected, then at least 50% of the tubes inspected shall be from these critical areas;~~
- ~~b. The first sample of tubes selected for each Inservice inspection (subsequent to the preservice inspection) of each steam generator shall include:
 - ~~1) All nonplugged tubes that previously had detectable wall penetrations (greater than 20%);~~
 - ~~2) Tubes in those areas where experience has indicated potential problems, and~~
 - ~~3) A tube inspection (pursuant to Specification 4.4.5.4a.8) shall be performed on each selected tube. If any selected tube does not permit the passage of the eddy current probe for a tube inspection, this shall be recorded and an adjacent tube shall be selected and subjected to a tube inspection.~~~~

SURVEILLANCE REQUIREMENTS (continued)

~~c. The tubes selected as the second and third samples (if required by Table 4.4-2) during each inservice inspection may be subjected to a partial tube inspection provided:~~

- ~~1) The tubes selected for these samples include the tubes from those areas of the tube sheet array where tubes with imperfections were previously found, and~~
- ~~2) The inspections include those portions of the tubes where imperfections were previously found.~~

~~The results of each sample inspection shall be classified into one of the following three categories:~~

<u>Category</u>	<u>Inspection Results</u>
G-1	Less than 5% of the total tubes inspected are degraded tubes and none of the inspected tubes are defective.
G-2	One or more tubes, but not more than 1% of the total tubes inspected are defective, or between 5% and 10% of the total tubes inspected are degraded tubes.
G-3	More than 10% of the total tubes inspected are degraded tubes or more than 1% of the inspected tubes are defective.
<u>Note:</u>	In all inspections, previously degraded tubes must exhibit significant (greater than 10%) further wall penetrations to be included in the above percentage calculations.

SURVEILLANCE REQUIREMENTS (continued)

~~4.4.5.3 Inspection Frequencies~~ The above required Inservice inspections of steam generator tubes shall be performed at the following frequencies:

- a. ~~The first Inservice inspection shall be performed after 6 Effective Full Power Months but within 24 calendar months of initial criticality. Subsequent Inservice inspections shall be performed at intervals of not less than 12 nor more than 24 calendar months after the previous inspection. If two consecutive inspections not including the preservice inspection, result in all inspection results falling into the C-1 category or if two consecutive inspections demonstrate that previously observed degradation has not continued and no additional degradation has occurred, the inspection interval may be extended to a maximum of once per 40 months;~~
- b. ~~If the results of the Inservice inspection of a steam generator conducted in accordance with Table 4.4-2 at 40 month intervals fall in Category C-3, the inspection frequency shall be increased to at least once per 20 months. The increase in inspection frequency shall apply until the subsequent inspections satisfy the criteria of Specification 4.4.5.3a. The interval may then be extended to a maximum of once per 40 months; and~~
- e. ~~Additional, unscheduled Inservice inspections shall be performed on each steam generator in accordance with the first sample inspection specified in Table 4.4-2 during the shutdown subsequent to any of the following conditions:~~
 - 1) ~~Reactor to secondary tube leaks (not including leaks originating from tube to tube sheet welds) in excess of the limits of Specification 3.4.6.2; or~~
 - 2) ~~A seismic occurrence greater than the Double Design Earthquake, or~~
 - 3) ~~A loss of coolant accident requiring actuation of the Engineered Safety Features, or~~
 - 4) ~~A main steam line or feedwater line break.~~

SURVEILLANCE REQUIREMENTS (continued)4.4.5.4 Acceptance Criteria

a. As used in this Specification:

- 1) ~~Imperfection means an exception to the dimensions, finish or contour of a tube from that required by fabrication drawings or specifications. Eddy current testing indications below 20% of the nominal tube wall thickness, if detectable, may be considered as imperfections;~~
- 2) ~~Degradation means a service induced cracking, wastage, wear or general corrosion occurring on either inside or outside of a tube;~~
- 3) ~~Degraded Tube means a tube containing imperfections greater than or equal to 20% of the nominal wall thickness caused by degradation;~~
- 4) ~~% Degradation means the percentage of the tube wall thickness affected or removed by degradation;~~
- 5) ~~Defect means an imperfection of such severity that it exceeds the plugging limit. A tube containing a defect is defective;~~
- 6) ~~Plugging Limit means the imperfection depth at or beyond which the tube shall be removed from service and is equal to 40% of the nominal tube wall thickness;~~
- 7) ~~Unserviceable describes the condition of a tube if it leaks or contains a defect large enough to affect its structural integrity in the event of a Double Design Earthquake, a loss of coolant accident, or a steam line or feedwater line break as specified in 4.4.5.3c., above;~~
- 8) ~~Tube Inspection means an inspection of the steam generator tube from the point of entry tube end (hot leg side) completely around the U bend to the top support of the cold leg; and~~
- 9) ~~Preservice Inspection means an inspection of the full length of each tube in each steam generator performed by eddy current techniques prior to service to establish a baseline condition of the tubing. This inspection shall be performed after the field hydrostatic test and prior to initial POWER OPERATION using the equipment and techniques expected to be used during subsequent Inservice inspections.~~

05-03A

- b. ~~The steam generator tube integrity shall be determined OPERABLE after completing the corresponding actions (plug all tubes exceeding the plugging limit and all tubes containing through wall cracks) required by Table 4.4 2.~~

05-01A

05-02A

SURVEILLANCE REQUIREMENTS (continued)

4.4.5.5 Reports

- a. ~~Within 15 days following the completion of each Inservice inspection of steam generator tubes, the number of tubes plugged in each steam generator shall be reported to the Commission in a Special Report pursuant to Specification 6.9.2.~~
- b. ~~The complete results of the steam generator tube Inservice inspection shall be submitted to the Commission in a Special Report pursuant to Specification 6.9.2 within 12 months following completion of the inspection. This Special Report shall include:~~
 - 1) ~~Number and extent of tubes inspected,~~
 - 2) ~~Location and percent of wall thickness penetration for each indication of an imperfection, and~~
 - 3) ~~Identification of tubes plugged.~~
- c. ~~Results of steam generator tube inspections, which fall into Category C-3, shall be reported in a Special Report to the Commission pursuant to Specification 6.9.2 within 30 days and prior to resumption of plant operation. This report shall provide a description of investigations conducted to determine cause of the tube degradation and corrective measures taken to prevent recurrence.~~

TABLE 4.4-1

05-017A

MINIMUM NUMBER OF STEAM GENERATORS TO BE
INSPECTED DURING INSERVICE INSPECTION

Preservice Inspection	No			Yes		
	Two	Three	Four	Two	Three	Four
No. of Steam Generators per Unit						
First Inservice Inspection	All			One	Two	Two
Second & Subsequent Inservice Inspections	One ¹			One ¹	One ²	One ³

TABLE NOTATIONS

- ~~1. The Inservice inspection may be limited to one steam generator on a rotating schedule encompassing $3/N$ % of the tubes (where N is the number of steam generators in the plant) if the results of the first or previous inspections indicate that all steam generators are performing in a like manner. Note that under some circumstances, the operating conditions in one or more steam generators may be found to be more severe than those in other steam generators. Under such circumstances the sample sequence shall be modified to inspect the most severe conditions.~~
- ~~2. The other steam generator not inspected during the first Inservice inspection shall be inspected. The third and subsequent inspections should follow the instructions described in 1 above.~~
- ~~3. Each of the other two steam generators not inspected during the first Inservice inspections shall be inspected during the second and third inspections. The fourth and subsequent inspections shall follow the instructions described in 1 above.~~

TABLE 4.4-2

05:01A

STEAM GENERATOR TUBE INSPECTION

1ST SAMPLE INSPECTION			2ND SAMPLE INSPECTION		3RD SAMPLE INSPECTION	
Sample Size	Result	Action Required	Result	Action Required	Result	Action Required
A minimum of S Tubes per S.G.	C-1	None	N.A.	None	N.A.	N.A.
	C-2	Plug defective tubes and inspect additional 2S tubes in this S.G.	C-1	None	N.A.	N.A.
			C-2	Plug defective tubes and inspect additional 4S tubes in this S.G.	C-1	None
			C-3	Perform action for C-3 result of first sample	C-2	Plug defective tubes
	C-3	Inspect all tubes in this S.G., plug defective tubes and inspect 2S tubes in each other S.G. Notification to NRC pursuant to §50.72(b)(2) of 10 CFR Part 50	C-3	Perform action for C-3 result of first sample	C-3	Perform action for C-3 result of first sample
			All other S.G.s are C-1	None	N.A.	N.A.
			Some S.G.s C-2 but no additional S.G. are C-3	Perform action for C-2 result of second sample	N.A.	N.A.
Additional S.G. is C-3	Inspect all tubes in each S.G. and plug defective tubes. Notification to NRC pursuant to §50.72(b)(2) of 10 CFR Part 50	N.A.	N.A.	N.A.	N.A.	

~~S = 3 N % Where N is the number of steam generators in the unit, and n is the number of steam generators inspected during an inspection~~

REACTOR COOLANT SYSTEM

3/4.4.6 REACTOR COOLANT SYSTEM LEAKAGE

LEAKAGE DETECTION SYSTEMS

LIMITING CONDITION FOR OPERATION

3.4.6.1 The following Reactor Coolant System Leakage Detection Systems shall be OPERABLE:

- a. The Containment Atmosphere Particulate Radioactivity Monitoring System.
- b. The Containment Structure Sumps and the Reactor Cavity Sump Level and Flow Monitoring System, and
- c. Either the Containment Fan Cooler Collection Monitoring System or the Containment Atmosphere Gaseous Radioactivity Monitoring System.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

NOTE -
LCO 3.0.4 is not applicable

06-23-LS25

With only two of the above required Leakage Detection Systems OPERABLE, operation may continue for up to 30 days provided a RCS water inventory balance is performed* at least every 24 hours when the containment sump level and flow monitoring system is inoperable and either grab samples of the containment atmosphere are obtained and analyzed OR a RCS water inventory balance is performed* at least once per 24 hours when the required Gaseous and/or Particulate Radioactivity Monitoring System is inoperable; otherwise, be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

06-01-M

06-02-LS8

SURVEILLANCE REQUIREMENTS

4.4.6.1 The required Leakage Detection Systems shall be demonstrated OPERABLE by:

06-03-A

- a. Containment Atmosphere Particulate and Gaseous (if being used) Monitoring System-performance of CHANNEL CHECK, CHANNEL CALIBRATION and CHANNEL FUNCTIONAL TEST at the frequencies specified in Table 4.3-3.
- b. Containment Structure Sumps and the Reactor Cavity Sump Level and Flow Monitoring System-performance of CHANNEL CALIBRATION at least once per 18 months, and
- c. Containment Fan Cooler Collection Monitoring System (if being used) -- performance of CHANNEL FUNCTIONAL TEST at least once per 18 months.

* Not required until 12 hours after establishment of steady state operation

06-26-LS30

REACTOR COOLANT SYSTEM

OPERATIONAL LEAKAGE

LIMITING CONDITION FOR OPERATION

3.4.6.2 Reactor Coolant System leakage shall be limited to:

- a. No PRESSURE BOUNDARY LEAKAGE,
- b. 1 gpm UNIDENTIFIED LEAKAGE,
- c. 1 gpm total reactor-to-secondary leakage through all steam generators and 500 gallons per day through any one steam generator,
- d. 10 gpm IDENTIFIED LEAKAGE from the Reactor Coolant System,
- e. 40 gpm CONTROLLED LEAKAGE at a Reactor Coolant System pressure of 2235 ± 20 psig, and,
- f. ~~1 gpm leakage at a Reactor Coolant System pressure of 2235 ± 20 psig for Reactor Coolant System Pressure Isolation Valves as specified in Table 3.4-1. Leakage from each Reactor Coolant System Pressure Isolation Valve shall be < 0.5 gpm per nominal inch of valve size up to a maximum of 5 gpm at an RCS pressure > 2215 psig and < 2255 psig.~~

06-06-A

06-07-LG

06-25-LS26

APPLICABILITY: MODES 1, 2, 3, and 4#.

06-08-LS9

ACTION:

- a. With any PRESSURE BOUNDARY LEAKAGE, be in at least HOT STANDBY within 6 hours and in COLD SHUTDOWN within the following 30 hours.
- b. With any Reactor Coolant System leakage greater than any one of the above limits, excluding PRESSURE BOUNDARY LEAKAGE, reactor coolant pump (RCP) seal injection flow, and leakage from Reactor Coolant System pressure isolation valves, reduce the leakage rate to within limits within 4 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

06-09-LS10

~~(new) With RCP seal injection flow greater than the above limit, verify >100% flow equivalent to a single OPERABLE ECCS charging train is available within 4 hours and reduce the flow rate to within limits within 72 hours or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours.~~

06-21-LS35

06-09-LS10

- c. With any Reactor Coolant System pressure isolation valve leakage greater than the above limit, isolate the high pressure portion of the affected system from the low pressure portion within 4 hours by use of at least one two closed manual and/or deactivated automatic, or check valve##, and within 72 hours by the use of a second series closed manual, deactivated automatic, or check valve ##, or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

06-11-LS11

06-12-M

REACTOR COOLANT SYSTEM

ACTION: (continued)

1) Pressure isolation valves in the residual heat removal (RHR) flow path when in, or during transition to or from, the RHR mode of operation are excluded in MODE 4.

06-08:LS9

Each valve used to satisfy this action must have been verified to meet surveillance requirement 4.4.6.2.2.

06-09:LS10

06-12:M

SURVEILLANCE REQUIREMENTS

4.4.6.2.1 Reactor Coolant System leakages shall be demonstrated to be within each of the above limits by:

a. ~~Monitoring the containment atmosphere particulate or gaseous radioactivity monitor at least once per 12 hours;~~

06-13:LS12

b. ~~Monitoring the containment structure sump inventory and discharge at least once per 12 hours;~~

06-13:LS12

c. ~~a~~ Measurement of the CONTROLLED LEAKAGE to the reactor coolant pump seals at least once per 31 days when the Reactor Coolant System pressure is 2235 + 20 psig with the modulating valve fully open. The provisions of Specification 4.0.4 are not applicable for entry into MODE 3 or 4.

06-14:A

d. ~~b~~ Performance of a Reactor Coolant System water inventory balance at least once per 72 hours, ~~except when T_{avg} is being changed by greater than 5°F/hour or when diverting reactor coolant to the liquid holdup tank, in which cases the required inventory balance shall be performed within 12 hours after completion of the excepted operation; and not required to be performed until 12 hours after establishment of steady state operation~~

06-17:LG

e. ~~Monitoring the Reactor Head Flange Leakoff System at least once per 24 hours.~~

06-26:LS30

06-16:LS14

4.4.6.2.2 As specified in Table 3.4-1, Reactor Coolant System pressure isolation valves shall be demonstrated OPERABLE pursuant to Specification 4.0.5, except that in lieu of any leakage testing required by Specification 4.0.5, each valve shall be demonstrated OPERABLE by verifying leakage to be within its limit:

06-07:LG

06-20:A

a. Every refueling outage during startup,

b. ~~Prior to returning the valve to service following maintenance, repair or replacement work on the valve, and~~

06-19:TR3

c. ~~b~~ Within 24 hours following valve actuation due to automatic or manual action or flow through the valve. After each disturbance of the valve, in lieu of measuring leak rate, leak-tight integrity may be verified by absence of pressure buildup in the test line downstream of the valve.

The provisions of Specification 4.0.4 are not applicable for entry into MODE 3 or 4.

TABLE 3.4.1

06-07.LG

REACTOR COOLANT SYSTEM PRESSURE ISOLATION VALVES

<u>VALVE NUMBER</u>	<u>FUNCTION</u>
1. 8948 A, B, C, and D	Accumulator, RHR and SIS first off check valves from RCS cold legs
2. 8819 A, B, C, and D	SIS second off check valves from RCS cold legs
3. 8818 A, B, C, and D	RHR second off check valves from RCS cold legs
4. 8956 A, B, C, and D	Accumulator second off check valves from RCS cold legs
5. 8701* and 8702*	RHR suction isolation valves
6. 8949# A, B, C, and D.	RHR and SIS first off check valves from RCS hot legs
7. 8905# A, B, C, and D	SIS second off check valves from RCS hot legs
8. 8740# A and B	RHR second off check valves from RCS hot legs
9. 8802*# A and B	SIS to RCS hot legs isolation valves
10. 8703*#	RHR to RCS hot legs isolation valve

~~* Testing per Specification 4.4.6.2.2c. not required.~~

~~# For flow paths with 3 pressure isolation valves in series, at least 2 of the 3 valves shall meet the requirements of Specification 3.4.6.2f.~~

~~This Page Intentionally Deleted~~

REACTOR COOLANT SYSTEM

3/4.4.8 SPECIFIC ACTIVITY

LIMITING CONDITION FOR OPERATION

3.4.8 The specific activity of the reactor coolant shall be limited to:

- a. Less than or equal to 1 microcurie/gram DOSE EQUIVALENT I-131, and
- b. Less than or equal to $100/\bar{E}$ microcuries/gram of gross radioactivity.

APPLICABILITY: MODES 1, 2, 3*, ~~4, and 5.~~

08-01-LS16

ACTION:

~~MODES 1, 2, and 3*:~~

08-01-LS16

~~ECO 3.0.4 is not applicable for operation in ACTION a.~~

08-02-LS17

- a. With the specific activity of the reactor coolant greater than 1 microcurie/gram DOSE EQUIVALENT I-131 for more than 48 hours during one continuous time interval or exceeding the limit line shown on Figure 3.4-1, be in at least HOT STANDBY with T_{avg} less than 500°F within 6 hours; and
- b. With the specific activity of the reactor coolant greater than $100/\bar{E}$ microcuries/gram of gross radioactivity, be in at least HOT STANDBY ~~within 6 hours and reduce with T_{avg} to less than 500°F within the following 6 hours.~~

04-05-LS31

~~MODES 1, 2, 3, 4, and 5:~~

08-01-LS16

With the specific activity of the reactor coolant greater than 1 microcurie/gram DOSE EQUIVALENT I-131 ~~or greater than $100/\bar{E}$ microcuries/gram of gross radioactivity,~~ perform the sampling and analysis requirements of Item 4.a) of Table 4.4-4 until the specific activity of the reactor coolant is restored to within its limits.

08-01-LS16

SURVEILLANCE REQUIREMENTS

4.4.8 The specific activity of the reactor coolant shall be determined to be within the limits by performance of the sampling and analysis program of Table 4.4-4.

* With T_{avg} greater than or equal to 500°F.

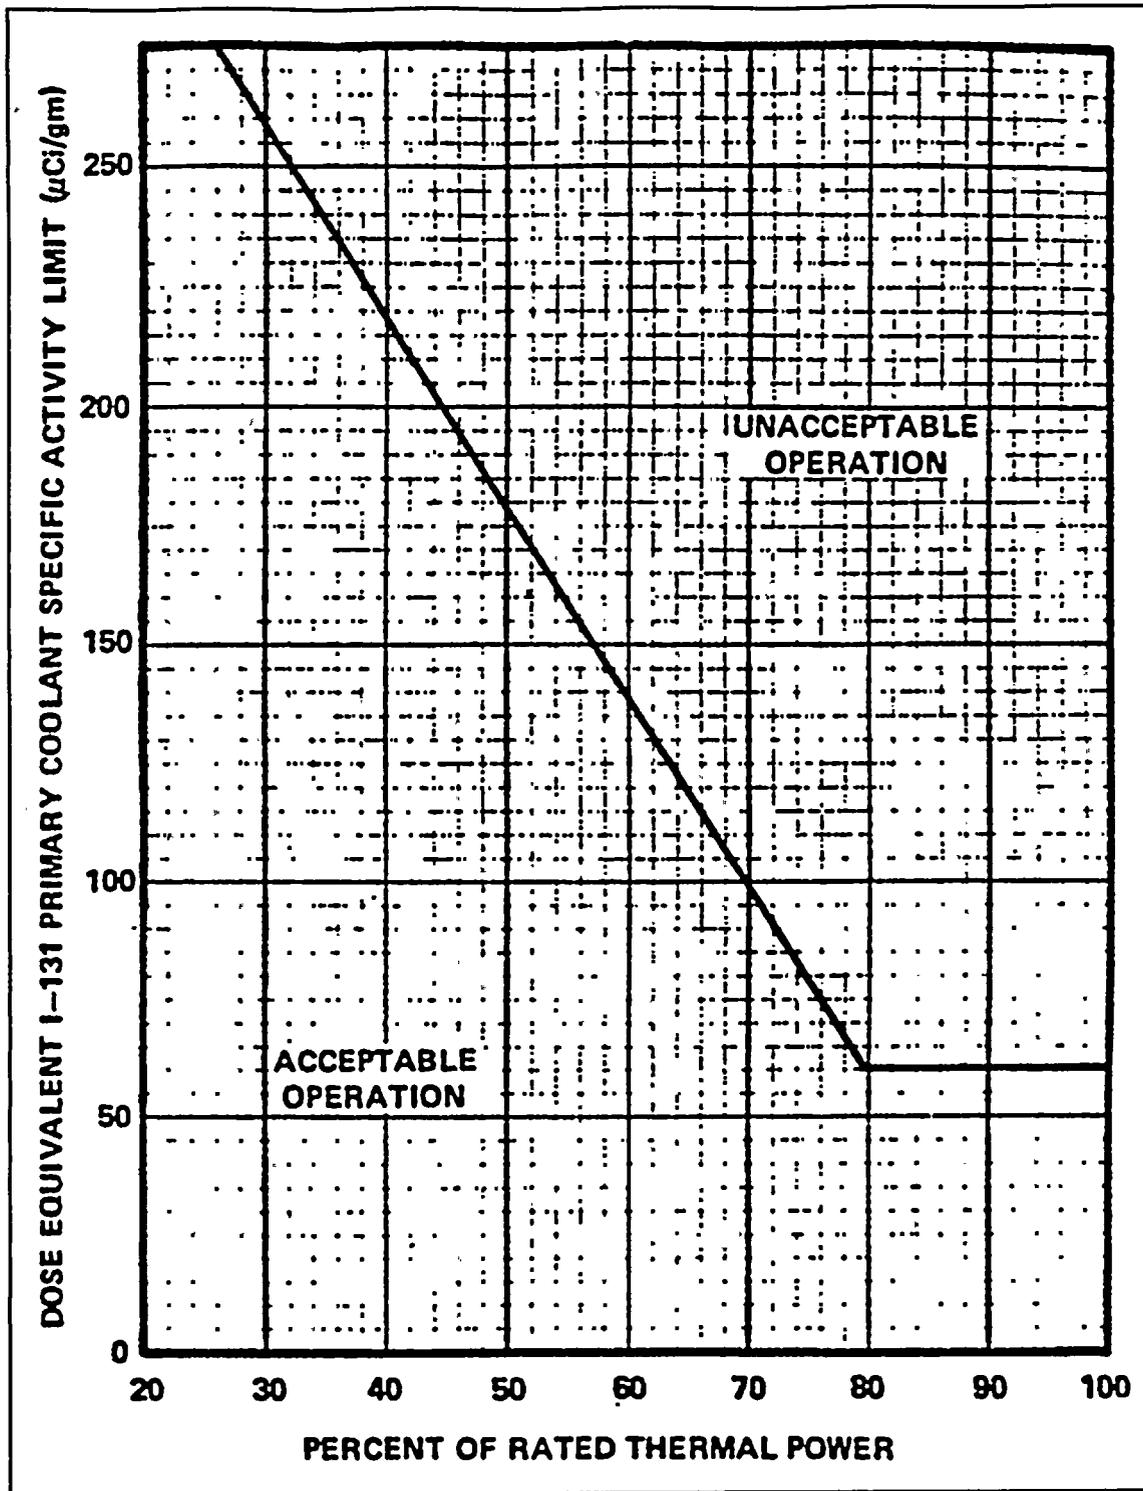

FIGURE 3.4-1

 SPECIFIC ACTIVITY > 1 $\mu\text{CI/GRAM}$ DOSE EQUIVALENT I-131

TABLE 4.4-4

REACTOR COOLANT SPECIFIC ACTIVITY SAMPLE
AND ANALYSIS PROGRAM

TYPE OF MEASUREMENT AND ANALYSIS	SAMPLE AND ANALYSIS FREQUENCY	MODES IN WHICH SAMPLE AND ANALYSIS REQUIRED	
1. Gross Radioactivity Determination**	At least once per 7 days 72 hours	1, 2, 3, with T_{avg} greater than or equal to 500° F. 4	<u>08-03-LS18</u> <u>08-01-LS16</u>
2. Isotopic Analysis for DOSE EQUIVALENT I-131 Concentration	1 per 14 days	1	
3. Radiochemical for E Determination***	1 per 6 months*	1	
4. Isotopic Analysis for DOSE EQUIVALENT I-131, I-133, and I-135	a) Once per 4 hours, whenever the specific activity exceeds 1 μ Ci/gram DOSE EQUIVALENT I-131 or 100/E μ Ci/gram of gross radioactivity, and	1#, 2#, 3# with T_{avg} greater than or equal to 500° F. 4#, 5#	<u>08-04-M</u> <u>08-01-LS16</u>
	b) One sample between 2 and 6 hours following a THERMAL POWER change exceeding 15% of the RATED THERMAL POWER within a 1-hour period.	1, 2, 3	<u>08-05-LS19</u>

TABLE 4.4-4 (Continued)

TABLE NOTATIONS

Until the specific activity of the Reactor Coolant System is restored within its limits.

* Sample to be taken after a minimum of 2 EFPD and 20 days of POWER OPERATION have elapsed since reactor was last subcritical for 48 hours or longer. ~~Not required to be performed until 31 days after a minimum of 2 EFPDs and 20 days of MODE 1 operation have elapsed since the reactor was last subcritical for greater than 48 hours.~~

08-07-A

~~** A gross radioactivity analysis shall consist of the quantitative measurement of the total specific activity of the reactor coolant except for radionuclides with half-lives less than 10 minutes and all radioiodines. The total specific activity shall be the sum of the degassed beta gamma activity and the total of all identified gaseous activities in the sample within 2 hours after the sample is taken and extrapolated back to when the sample was taken. Determination of the contributors to the gross specific activity shall be based upon those energy peaks identifiable with a 95% confidence level. The latest available data may be used for pure beta-emitting radionuclides.~~

08-08-EG

*** A radiochemical analysis for E shall consist of the quantitative measurement of the specific activity for each radionuclide, except for radionuclides with half-lives less than 10 minutes and all radioiodines, which is identified in the reactor coolant. The specific activities for these individual radionuclides shall be used in the determination of E for the reactor coolant sample. Determination of the contributors to E shall be based upon those energy peaks identifiable with a 95% confidence level.

08-06-A

REACTOR COOLANT SYSTEM

3/4.4.9 PRESSURE/TEMPERATURE LIMITS

LIMITING CONDITION FOR OPERATION

3.4.9.1 The Reactor Coolant System (except the pressurizer) temperature and pressure shall be limited in accordance with the limit specified in the PRESSURE AND TEMPERATURE REPORT (PTER) lines shown on Figures 3.4.2 and 3.4.3 during heatup, cooldown, criticality, and Inservice leak and hydrostatic testing with:

09:01:LG

- a. ~~A maximum heatup of 100°F in any 1 hour period.~~
- b. ~~A maximum cooldown of 100°F in any 1 hour period.~~
- c. ~~A maximum temperature change of less than or equal to 10°F in any 1 hour period during Inservice hydrostatic and leak testing operations above the heatup and cooldown limit curves.~~

09:01:LG

APPLICABILITY: At all times.

ACTION:

With any of the above limits exceeded, in MODES 1, 2, 3, or 4, restore the temperature and/or pressure to within the limit within 30 minutes; perform an engineering evaluation to determine the effects of the out-of-limit condition on the structural integrity of the Reactor Coolant System; determine that the Reactor Coolant System remains acceptable for continued operation* within 72 hours, or be in at least HOT STANDBY within the next 6 hours and reduce the RCS Tavg and pressure to less than 200°F and 500 psig, respectively, within the following 30 hours.

09:02:M

09:03:M

~~With any of the above limits exceeded at any time in other than MODES 1, 2, 3, or 4, immediately initiate action to restore parameter(s) within limits and determine the RCS is acceptable for continued operation* prior to entering MODE 4.~~

09:02:M

SURVEILLANCE REQUIREMENTS

4.4.9.1 The Reactor Coolant System temperature and pressure shall be determined to be within the limits at least once per hour 30 minutes during system heatup, cooldown, and Inservice leak and hydrostatic testing operations.

09:16:M

~~*Acceptability for continued operation must be determined whenever the ACTION is entered.~~

09:02:M

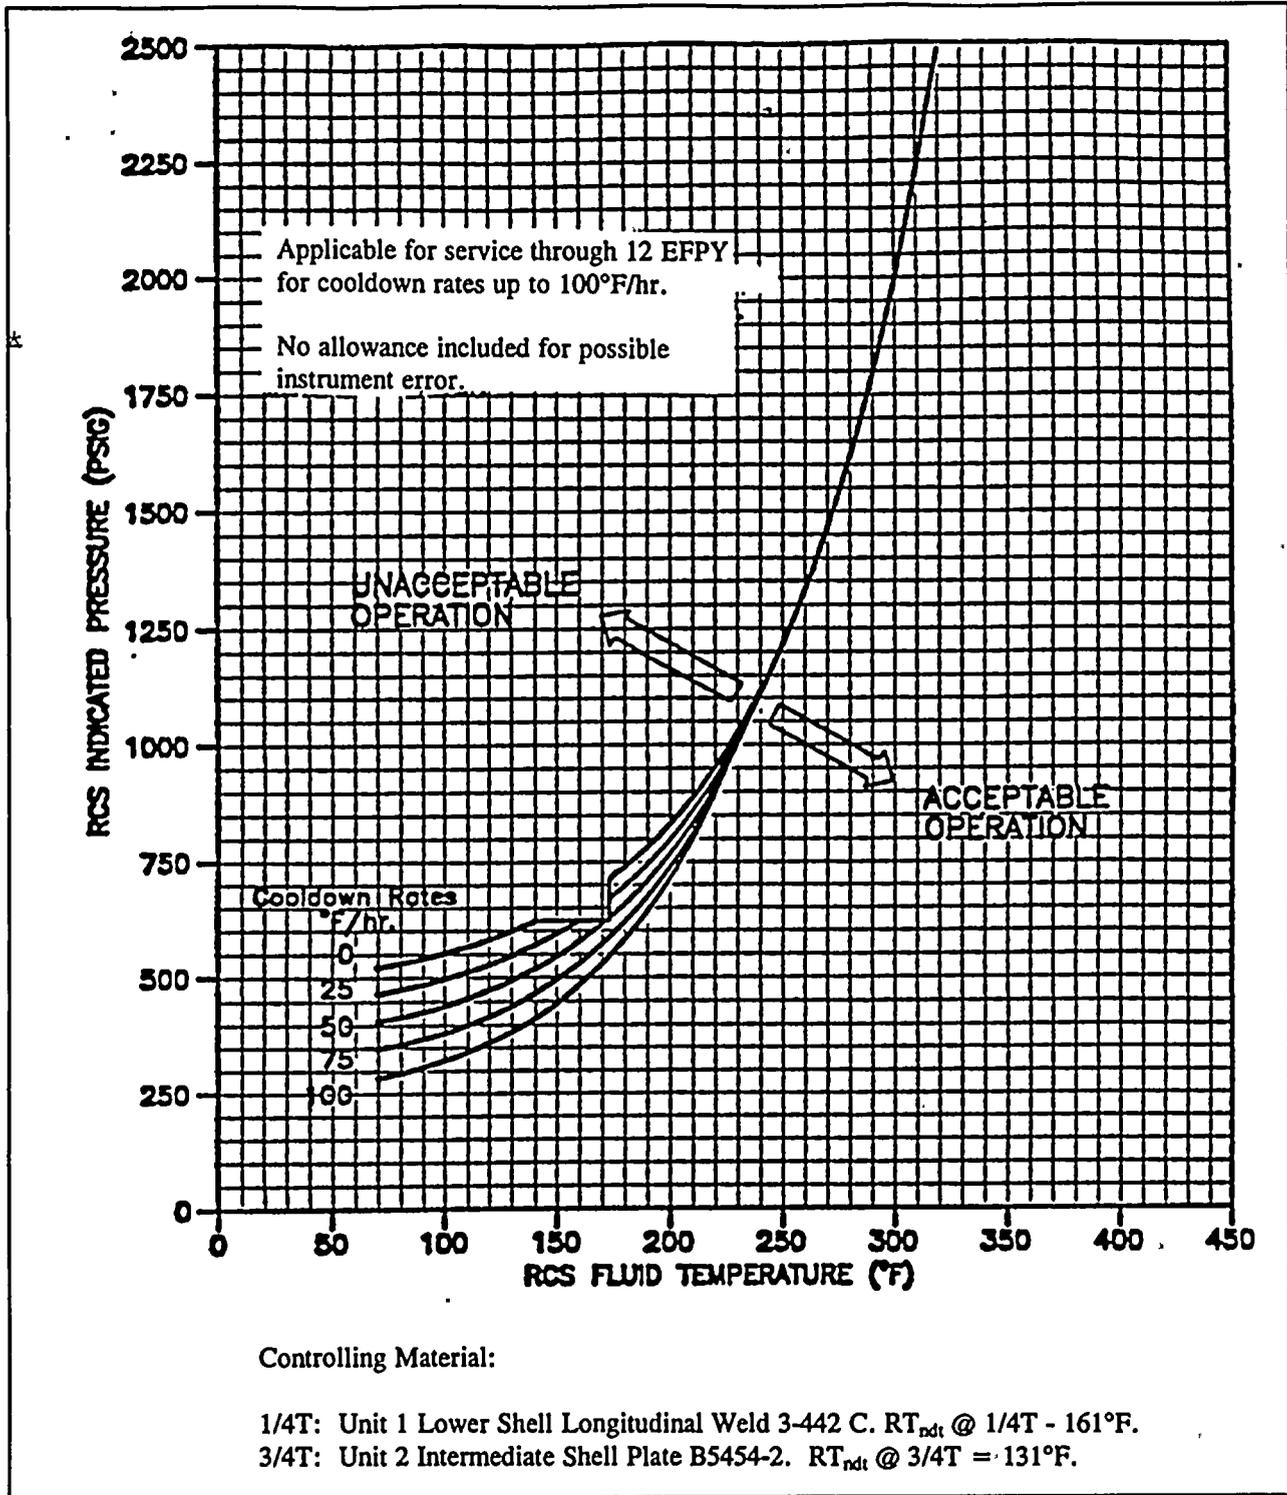

FIGURE 3.4.3
REACTOR COOLANT SYSTEM COOLDOWN LIMITATIONS — APPLICABLE UP TO 12 EFPY

~~THIS PAGE INTENTIONALLY DELETED~~

~~This Page Intentionally Deleted~~

REACTOR COOLANT SYSTEM

OVERPRESSURE PROTECTION SYSTEMS

LIMITING CONDITION FOR OPERATION

3.4.9.3 The following Overpressure Protection Systems shall be OPERABLE with the accumulators isolated or depressurized below allowed RCS pressure per PTLR

09-06:M

- a. Two Class 1 power-operated relief valves (PORVs) with a lift setting of less than or equal to 435 psig, within the limits specified in the PTLR, or
- b. The Reactor Coolant System (RCS) depressurized with an RCS vent of greater than or equal to 2.07 square inches.

09-01:LG

APPLICABILITY: MODE 4 when the temperature of any RCS cold leg is less than or equal to 270°F, the temperature below which LTOP is required as specified in the PTLR; MODE 5 and MODE 6 with the reactor vessel head on and the vessel head closure bolts not fully de-tensioned.

01-17:LG

(new) The limitation for a maximum of one charging pump capable of injecting into the RCS is not required for pump swap operation until 1 hour after completion of pump swap operation.

09-08:LS7

ACTION:

- a. With one Class 1 PORV inoperable in MODE 4, restore the inoperable PORV to OPERABLE status within 7 days or depressurize and vent the RCS through an RCS vent of greater than or equal to 2.07 square inches vent within the next 8 hours.
- b. With one Class 1 PORV inoperable in MODES 5 or 6 with the reactor vessel head on and the vessel head closure bolts not fully de-tensioned, restore the inoperable PORV to operable status within 24 hours or depressurize and vent the RCS through an RCS vent of greater than or equal to 2.07 square inches within the next 8 hours.
- c. With both PORVs inoperable, depressurize and vent the RCS through an RCS vent of greater than or equal to 2.07 square inches vent within 8 hours.
- d. ~~In the event either the PORVs or the RCS vent are used to mitigate an RCS pressure transient, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 30 days. The report shall describe the circumstances initiating the transient, the effect of the PORVs or vent on the transient, and any corrective action necessary to prevent recurrence.~~

09-07:TR2

(new) With two charging pumps capable of injecting into the RCS, immediately initiate action to verify a maximum of one charging pump is capable of injecting into the RCS or within the next 8 hours, depressurize the RCS and establish RCS vent of greater than or equal to 2.07 square inches.

09-09:M

REACTOR COOLANT SYSTEM

OVERPRESSURE PROTECTION SYSTEMS

LIMITING CONDITION FOR OPERATION (continued)

ACTIONS (continued)

(new) The limitation for a maximum of one charging pump is capable of injecting into the RCS is not required for pump swap operation until 1 hour after completion of pump swap operation.	09:08:LS7
(new) With one or more safety injection pumps capable of injecting into the RCS, immediately initiate action to verify that a maximum of zero pumps are capable of injecting into the RCS.	09:15:M
(new) With an accumulator not isolated when the accumulator pressure is greater than or equal to the maximum RCS pressure for existing cold leg temperature allowed by the P/T curves in the PTLR, within 1 hour isolate the affected accumulator or within the next 12 hours either increase all RCS cold leg temperatures to greater than the temperature below which LTOP is required as specified in the PTLR, or depressurize the affected accumulator to less than the maximum RCS pressure for existing cold leg temperature allowed by the P/T curves in the PTLR.	09:10:M 01:17:LG
(new) With the LTOP system inoperable for any other reason, within 8 hours, depressurize the RCS and establish RCS vent of greater than or equal to 2.07 square inches.	09:11:M

SURVEILLANCE REQUIREMENTS

4.4.9.3.1 Each Class 1 PORV shall be demonstrated OPERABLE by:

- a. Performance of a CHANNEL OPERATIONAL TEST on the PORV actuation channel, but excluding valve operation, at least once per 31 days; within 12 hours after entering MODE 4 when the PORV is required OPERABLE and at least once per 31 days thereafter when the PORV is required OPERABLE. 09:12:LS20
- b. Performance of a CHANNEL CALIBRATION on the PORV actuation channel at least once per 18 months; and
- c. Verifying the PORV isolation valve is open at least once per 72 hours when the PORV is being used for overpressure protection.

4.4.9.3.2 The RCS vent shall be verified to be open when the vent is being used for overpressure protection at least once per 31 days when the pathway is provided by a valve(s) that is locked, sealed, or otherwise secured in the open position; otherwise verify the vent pathway every 12 hours.

REACTOR COOLANT SYSTEM

OVERPRESSURE PROTECTION SYSTEMS

LIMITING CONDITION FOR OPERATION (continued)

(new) Verify that each accumulator is isolated at least once per 12 hours when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in the PTLR.

09:14M

~~This Page Intentionally Deleted~~

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. Deletions - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. Additions - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. Modifications - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. Administrative - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

**Methodology For Mark-Up of Current TS
(Continued)**

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant - specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant - specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	LG	The definition of OPERABLE and operating for the Reactor Coolant System (RCS) loops is moved to the Bases. Moving this information to the Bases is consistent with the NUREG-1431 philosophy of moving clarifying information and descriptive details out of the TS to the Bases.
01-02	A	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-03	LS1	This change adds the additional allowance that the Rod Control System is capable of rod withdrawal before the ACTION is applied. This is a relaxation because methods, other than opening the Reactor Trip Breakers (RTBs), are allowed to preclude rod withdrawal. However, as prevention of rod withdrawal is the requirement of concern, the relaxation is justified. This change is in conformance with NUREG-1431. The Limiting Condition for Operation (LCO) is also revised to be based on capability to withdraw rods rather than RTB position.
01-04	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B). This test exception is not in the current TS.
01-05	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-06	M	The Note to allow short term de-energization of Reactor Coolant Pumps (RCPs) and Residual Heat Removal (RHR) pumps in MODES 3, 4, and 5, for 1 hour is clarified as 1 hour per 8 hour period in CTS LCOs 3.4.1.2, 3.4.1.3, and 3.4.1.4.1. This change is in accordance with NUREG-1431 as modified by Industry Traveler TSTF-153 and is more restrictive as no restrictions on use of the Note were required previously.
01-07	M	This change separates the ACTION Statement for one loop OPERABLE from that of no loops OPERABLE. The condition of no loops OPERABLE is now included with the condition of no loops in operation. The additional ACTION of returning a loop to OPERABLE status is added for this change. The effect of this change is more conservative operation as a result of no loops being OPERABLE. This change is consistent with present plant operations. This change is in conformance with NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

01-08	LS2	This change adds a specific relaxation to allow the use of an operating RCS loop in lieu of an operating RHR loop in MODE 5 during planned heatup in preparation to proceed into MODE 4. The primary functions of the operating RHR loop in MODE 5 are to remove decay heat and to prevent boron stratification. These functions can also be performed by an operating RCS loop which is a normal method of accomplishing the same functions when in MODE 4. In addition, at least one RHR loop must remain OPERABLE during the transition to MODE 4. The change is acceptable because there is no reduction in the heat removal/boron stratification capability or system reliability when the RCS loop is performing these functions. This change is in conformance with NUREG-1431.
01-09	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-10	M	The ACTION is changed to include the Required Actions for no required RHR loops OPERABLE. Previously, the specification did not provide specific ACTION for no RHR loops OPERABLE. This change also clarifies that the restored loop must be OPERABLE as well as in operation. This ACTION is consistent with the ACTIONS which are required under this Condition and are in conformance with NUREG-1431.
01-11	M	This change adds a new surveillance for verification of breaker alignment and power availability to the required pump that is not in operation. This change is in conformance with NUREG-1431.
01-12	M	The ACTIONS are changed to delineate the Required Actions for only one required RHR loop OPERABLE. These revised ACTIONS are consistent with the ACTIONS which are required under this LCO in conformance with NUREG-1431 and are more conservative than current Required Actions.
01-13	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-14	LS22	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-15	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-16	A	Consistent with the intent of Industry Traveler TSTF-153, this change revises the Note that permits up to 1 hour "deenergization" of RCP/RHR pumps. The revised wording clarifies the intent of the Note to allow the pumps to be "removed from operation" instead of "deenergized", thus permitting other means of removing the pumps from service. With this change the pumps are not <u>required</u> to be deenergized to use the Note (e.g., the pumps may be isolated, etc.). The change is considered to be administrative because from the standpoint of providing an exception to the LCO requirements (to maintain the operability and operation of the pumps), the revised wording is equivalent.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

01-17	LG	The plant specific minimum temperature specified in degrees below which the RCS must not be subject to overpressure is replaced by the generic statement "the minimum low temperature value specified in the PRESSURE TEMPERATURE LIMITS REPORT (PTLR)". The minimum temperature is a plant specific requirement based on the reactor vessel material characteristics documented in the PTLR and is periodically reviewed and adjusted as required. Referring to the PTLR for the current value is consistent with the relocation of the pressure/temperature limits from improved TS Section 3.4.3 to the PTLR. This is an administrative change. In the CTS, this change involves the footnote for LCO 3.4.1.3, the footnote for Applicability 3.4.1.4.1, the Applicability and ACTION a of 3.4.2.2, the Applicability for 3.4.9.3, and ACTION (new) of 3.4.9.3.
01-18		Not used.
01-19	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-20	LS27	The restriction in the LCO footnote for reactor vessel water level above the reactor flange for the stopping of all RHR pumps is removed . Footnote condition 3) is replaced by the restriction to allow no draining operations that would reduce RCS water inventory. This revised footnote is less restrictive because the water inventory would be less with the level lower than the vessel flange. This change is in conformance with NUREG-1431.
02-01	LS3	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-02	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-03	M	This change in accordance with NUREG-1431 provides a new ACTION for two or more pressurizer safety valves inoperable. Prior to this change, LCO 3.0.3 would have been entered allowing for 1 hour prior to placing the unit in HOT STANDBY within the next 6 hours, etc. This change is more restrictive in that the 1 hour time frame is eliminated. This change is acceptable based on the analysis and commensurate actions required with two or more pressurizer safeties inoperable.
02-04	LG	The footnote about the lift setting being for ambient conditions is moved to the TS Bases. Moving this information to the Bases is consistent with the NUREG-1431 philosophy of moving clarifying information and descriptive details out of the TS to the Bases.
02-05	LS23	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

03-01	LS4	<p>In conformance with NUREG-1431 the ACTION has been changed from the "pressurizer otherwise inoperable" to "water level not within limit." This change is slightly less restrictive because if the pressurizer was declared inoperable for reasons other than those listed in the actions, LCO 3.0.3 would be entered. LCO 3.0.3 entry would provide one additional hour beyond the completion times specified in the LCO. This change is acceptable because a high pressurizer water level is the primary condition in MODES 1, 2, and 3 which could lead to pressurizer inoperability and therefore requires the most immediate actions. High pressurizer level is potentially indicative of a loss of the pressurizer bubble which could adversely effect RCS pressure transients. The actions required for high pressurizer level are unaffected by this change. Any other cause of inoperability is not likely to require immediate action and is adequately protected by LCO 3.0.3.</p>
03-02	LG	<p>The method of verifying heater capacity is moved to the Bases. Moving this information to the Bases is consistent with the NUREG-1431 philosophy of moving clarifying information and descriptive details out of the TS to the Bases.</p>
03-03	LS28	<p>This change relaxes the surveillance requirement for verifying the capacity of the pressurizer backup heaters from 92 days to 18 months. The OPERABILITY of the pressurizer heaters enhances the capability of the plant to control RCS pressure and establish natural circulation. The purpose of the surveillance requirement is to detect potential pressurizer heater degradation. This is done by periodically demonstrating that pressurizer heaters are capable of producing power at their design rating, by testing the power supply output and by performing electrical checks on heater elements. Heating elements are simple resistive devices which are not prone to complex failure modes. Moreover, heater banks are made up of a number of individually powered heater elements such that a common mode failure of the elements is unlikely. The normal power supply to the heaters is in use during normal power operations and a failure of the power supply would be immediately detectable independent of the heater surveillance. The low failure rate experience with pressurizer heater elements is indicative that the surveillance interval may be extended without loss in heater reliability. This change is consistent with Generic Letter 93-05, "Line-Item Technical Specification Improvements to Reduce Surveillance Requirements for Testing During Power Operation" and Industry Traveler TSTF-93, Rev. 1.</p>
03-04	LS29	<p>This ACTION is revised to reflect its LCO. The position of the reactor trip breakers is not an LCO requirement, therefore the ACTION is revised. As currently worded, the ACTION requires the reactor trip breakers to be open. This position could preclude certain testing in MODE 3. A more generic ACTION statement which assures the rods are fully inserted and can not be withdrawn, replaces the specific method of precluding rod withdrawal. The revised ACTION still assures rod withdrawal is precluded, and details of method are not required to be in the TS to provide adequate protection of the public safety. No technical changes result from this revision. This change is based on Industry Traveler TSTF-87, Rev. 1.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

03-05	M	This change adds a requirement to CTS 3.4.3. The change requires the pressurizer heaters to be capable of being powered from an emergency power source. This change, in accordance with NUREG-1431, is not in the CTS, and is more restrictive.
04-01	LS5	In conformance with NUREG-1431, an allowance has been added that separate condition entry is allowed for each valve. This allowance is acceptable because the functionality of each pressurizer power operated relief valve (PORV) is addressed separately within the specification and the allowed Completion Times are based on the discovery of inoperability for each PORV/block valve combination.
04-02	LS6	In conformance with NUREG-1431, the allowance for PORV inoperability has been expanded from previously only allowing block valve isolation when the PORV was inoperable for seat leakage to allowing block valve isolation when the PORV is still capable of manually being cycled. With the PORV still capable of being manually cycled it is available for mitigation of accidents such as the steam generator tube rupture (SGTR) but has lost the functionality of automatic pressure reduction. As loss of the automatic function does not result in a degradation of equipment which is required to operate during an accident, this change is acceptable.
04-03	M	The times to reduce MODE for inoperable PORVs are decreased by one hour. This change is acceptable because it is a more restrictive change.
04-04	LG	The automatic actuation of the PORVs is not credited in MODES 1, 2, or 3. Therefore, performance of the channel calibration is unnecessary as a TS requirement. Consequently, the channel calibration requirement is moved to a licensee controlled document. The portions of the PORV actuation circuitry if required for [LTOP] are calibrated in accordance with ITS SR 3.4.12.9. Moving this information is consistent with the NUREG-1431 philosophy of moving requirements, which are not required to satisfy accident analyses, out of the TS.
04-05	LS31	The shutdown requirement of CTS 3.4.4 would require the plant to reduce T_{avg} to <500°F within 12 hours, rather than go to MODE 4, to address the concern of entering [LTOP] LCO Applicability with inoperable PORVs. For consistency, the shutdown requirements of CTS LCO [3.4.8] would be similarly revised. The proposed change adds a relaxation to the ACTIONS associated with CTS LCO 3.4.4 by keeping the end point of the shutdown action above the LCO [3.4.9.3] Applicability. No credit is taken for the automatic actuation of the PORVs in MODES 1, 2, or 3. Credit is taken for the manual operation of the PORVs during a SGTR. The capability to manually cycle the PORVs will be unaffected by this change. The release of radioactivity in the event of an SGTR with RCS T_{avg} <500°F is unlikely since the saturation pressure of the reactor coolant would be less than the lift pressure of the main steam safety and [SG atmospheric relief] valves. This change is in accordance with Industry Traveler TSTF-113.
04-06	LS32	This change provides a 72 hour completion time to restore an inoperable block valve, with the PORV placed in manual control mode. The CTS requires the block valve to be restored within one hour or remove power from the PORV solenoid. This change is in accordance with NUREG-1431 and is less restrictive.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

04-07	LS33	This change provides a two hour completion time for restoring an inoperable block valve when more than one block valve is inoperable, and 72 hours to restore the remaining valves. The CTS requires the inoperable block valves to be restored within one hour for one or more valves inoperable. This change is in accordance with NUREG-1431 and is less restrictive.
04-08	LS34	Consistent with Industry Traveler WOG-60, the requirement to perform the 92 day surveillance of the pressurizer PORV block valves and the 18 month surveillance of the pressurizer PORVs (i.e., perform one complete cycle of each valve is revised to indicate that the surveillance is only required to be performed in MODES 1 and 2. This footnote allows entry into and operation in MODE 3 prior to performing the SR. This allows the test to be performed in MODE 3 under operating temperature and pressure conditions, prior to entering MODE 1 or 2. This is consistent with the recommendations of Generic Letter 90-06, 'Resolution of Generic Issue 70, 'Power-Operated Relief Valve and Block Valve Reliability,' and Generic Issue 94, 'Additional Low-Temperature Overpressure Protection for Light-Water Reactors,' Pursuant to 10CFR50.54(f), June 25, 1990., which indicates that administrative controls require this test be performed in MODES 3 or 4 to adequately simulate operating temperature and pressure effects on valvePORV operation.
4-09	LS36	The requirement to perform the 92 day surveillance of pressurizer PORV block valves (i.e., perform one complete cycle of each block valve) is revised such that it is not required if the block valve is closed to meet ACTION a of CTS LCO 3.4.4. This change is acceptable because no credit is taken for the automatic actuation of the PORV in MODES 1, 2, or 3. Credit is taken for manual operation of the PORVs during the SGTR accident. However, the capability to manually cycle the PORVs will be unaffected by this change. This change will not affect the ability of the block valve to open; if closed to meet ACTION a, in the mitigation of an SGTR. Deferral of the block valve cycling surveillance will not diminish the design capability of the block valve to open against differential pressures that would be present after an SGTR since the block valves are capable of opening against 2485 psig, the safety valve lift pressure, whereas pressurizer pressure decreases after an SGTR. This change is consistent with traveler WOG-87.
05-01	A	The SG tube surveillance requirements are initiated by ITS SR 3.4.13.2 and the specifics are moved to ITS Administrative Controls Sections 5.5.9, "Steam Generator (SG) Tube Surveillance Program" and 5.6.10, "Steam Generator Tube Inspection Report."
05-02	A	CTS 3.4.5 is deleted for consistency with NUREG-1431. SG operability requirements in MODES 1 through 4 are specified in the RCS loop and operational LEAKAGE specifications.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

05-03	A	<p>CTS SR 4.4.5.4.a.8) is clarified to remove potential interpretation problems related to probe orientation versus entry point. The TS specifies that a SG "tube inspection means an inspection for the steam generator tube from the point of entry (hot leg side) completely around the U-bend to the top support of the cold leg." This statement is interpreted as defining the minimum portion of the tube requiring eddy current testing to meet surveillance requirements, not a particular eddy current probe orientation or entry point. This specification is based on Regulatory Guide 1.83, position c.2.f which requires that "The equipment should be capable of examining the entire length of the tubes." Footnote 3 of position c.2.f specifies for U-bends designed steam generators that an examination from the hot leg side completely around the U-bend to the top support of the cold leg is sufficient for this inspection but contains an inference to probe entry on the hot-leg side. Subsequent to Regulatory Guide 1.83 and development of the Standard Technical Specification provisions, Generic Letter 85-02 recommended that "tube inspections should include an inspection of the entire length of the tube (tube end to tube end) including the hot-leg side, U-bend, and cold-leg side." This recommendation is consistent with the phrasing of CTS SR 4.4.5.4.a.9) for Preservice Inspection and the Technical Specification for non-U-tube Steam Generators (B&W). These requirements do not infer any particular orientation during full length (tube end to tube end) inspections and, as stated in Generic Letter 85-02, should not preclude separate hot leg and cold leg sides of the same tube from being inspected to meet minimum sampling requirements.</p>
06-01	M	<p>Consistent with NUREG-1431, this change adds the requirement to perform an RCS water inventory balance every 24 hours when the [sump level detector] is inoperable. This is a new requirement and is more restrictive than the CTS.</p>
06-02	LS 8	<p>Consistent with NUREG-1431, this change allows the performance of an RCS water inventory balance every 24 hours as an alternative to the requirement to perform 24 hour samples of the containment atmosphere when a required radioactivity monitor is inoperable. The primary function of the leakage detection systems is to detect significant reactor coolant pressure boundary (RCPB) degradation as soon as practical to minimize the potential for propagation to a gross failure. The TS requires multiple diverse systems to ensure that leakage from a variety of locations and leakage rates can be detected in sufficient time to take measures to place the plant in a safe condition. When a required radioactivity monitor is inoperable, the CTS provides compensatory action by requiring containment atmosphere samples be taken and analyzed every 24 hours to supplement indications from detection systems which are still operable [(e.g., sump level and condensate flow rate)]. Another diverse means for determining RCS leakage is the RCS water inventory balance. When performed at the same frequency as the containment atmosphere grab sample, and in conjunction with other leak detection indications, this method provides an equal degree of confidence of the status of RCS leakage.</p>
06-03	A	<p>Consistent with NUREG-1431, this change adds the word "required" to clarify that only those detectors which are being used to satisfy the LCO must be demonstrated to be operable.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
06-04	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
06-05	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
06-06	A	Moves the LCO for CONTROLLED LEAKAGE (seal injection flow) from "Operational Leakage" to LCO 3.5.5 "ECCS" in conformance with NUREG-1431. The reference operating point for surveillance of 40 gpm controlled leakage is unchanged from nominal operating RCS pressure (+/- 20 psig) with the charging flow control valve full open which is moved to SR 3.5.5.1 in the improved TS.
06-07	LG	This change moves the listing of RCS pressure isolation valves (PIVs). This listing is being moved to a licensee controlled document as identified in the Conversion Comparison Table (Enclosure 3B). Moving this information is consistent with the NUREG-1431 philosophy of moving clarifying information and descriptive details out of the TS. The requirement to verify PIV leakage is moved to SR 3.4.14.1 in the ITS.
06-08	LS9	This change, in conformance with NUREG-1431, adds clarification that the valves in the RHR flow path are not required to meet the Pressure Isolation Valve specification "when in, or during the transition to or from the RHR mode of operation" in MODE 4. This change is acceptable because the same allowance was available in the current TS by an exception to Specification 4.0.4. In addition, using RHR through these specific flow paths is the required mode of operation during an accident.
06-09	LS10	The LCO applicability for CONTROLLED LEAKAGE (seal injection flow) is reduced to only MODES 1, 2, and 3 (with the associated change in ACTION b). This change is consistent with NUREG-1431. This change is acceptable because the limitation on this parameter is only required in MODES 1, 2, and 3 to support the LOCA analyses by ensuring sufficient ECCS flow. The limitation does not apply in MODE 4. Thus the shutdown requirement in ACTION b) is revised to require hot shutdown instead of cold shutdown.
06-10	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
06-11	LS11	This change in conformance with NUREG-1431, allows for the flow path to be isolated by one valve within 4 hours and by a second series valve within 72 hours. This change is less restrictive and is acceptable based on the first valve having been surveilled as meeting the same leakage criteria as the inoperable PIV and the small probability of a failure during the 72 hour period. This action additionally allows a check valve to be used for isolation purposes when a PIV is inoperable. This change is less restrictive and is acceptable because the check valve in use has been surveilled in accordance with the same leakage criteria as the PIV.
06-12	M	Any valve(s) used to satisfy the action of isolating the low pressure system from the high pressure system when a RCS PIV is inoperable, must be tested and meet the leakage criteria of the PIV. This change is in conformance with NUREG-1431 and is more restrictive.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

06-13	LS12	This change in conformance with NUREG-1431, removes the specific requirement to monitor the RCS Leakage Detection System once per 12 hours. However, the change is acceptable because ITS SR 3.4.15.1 requires a CHANNEL CHECK be performed on the containment radioactivity monitor channels on the same frequency so there is no change in requirement for those detectors. The [containment sump level detection system] and the [containment fan cooling unit condensate collection monitor] can be monitored from the control room. [].
06-14	A	This change moves the CTS Surveillance for CONTROLLED LEAKAGE (seal injection flow) from "Operational Leakage" to ITS 3.5.5,"ECCS" in conformance with NUREG-1431.
06-15	LS13	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
06-16	LS14	This change in conformance with NUREG-1431, removes the requirement for monitoring the reactor head flange leakoff system. This change is acceptable because reactor head leakage, which is collected in the reactor coolant drain tank, is quantified as identified LEAKAGE. Identified LEAKAGE is determined by performance of a RCS water inventory balance. The initial inventory balance is required within 12 hours following RCS steady state operation and every 72 hours thereafter. Flange leakoff does not provide an indicator of pressure boundary integrity and consequently the removal of the monitoring does not involve the probability of loss of RCS water inventory.
06-17	LG	The definition of steady state is moved to the Bases. Moving this information is consistent with the NUREG-1431 philosophy of moving clarifying information and descriptive details out of the TS.
06-18	LS15	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
06-19	TR3	This change in conformance with NUREG-1431, removes the specific requirement for performing the PIV surveillance prior to returning a valve to service following maintenance, repair or replacement. This requirement is inherent to post maintenance operability requirements and removal from the specifications is not a reduction in testing scope or frequency.
06-20	A	Consistent with NUREG-1431, Inservice Testing (IST) requirements are moved to ITS 5.5.8.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

06-21	LS35	<p>This change increases the RCP seal injection flow Completion Time from 4 to 72 hours, with a new added verification that at least 100% of the assumed charging flow remains available. The Bases for the seal injection flow limit relates to ensuring adequate charging flow during post-LOCA injection. The revised ACTIONS continue to assure this basis is adequately addressed by providing an ECCS-like Required Action. ITS Specification 3.5.2 allows a 72 hour Completion Time for one or more ECCS subsystems inoperable if at least 100% of the assumed ECCS flow is available. The seal injection flow ACTIONS have been modified so that if the remaining charging flow (with some inoperability in the charging system) is greater than or equal to 100% of the assumed post-LOCA charging flow, 72 hours is allowed to restore OPERABILITY. This change is consistent with Industry Traveler WOG-84.</p>
06-22	M	<p>Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).</p>
06-23	LS25	<p>CTS 3.4.6.1, "Leakage Detection Systems", is revised such that the provisions of Specification 3.0.4 are not applicable. This will allow entry into the applicable MODES with only one of the Leakage Detection Systems OPERABLE, subject to the requirements of the ACTION statements. This change is consistent with NUREG-1431 and Industry Traveler TSTF-60 and is acceptable because of the diverse means available to detect RCS leakage.</p>
06-24	M	<p>Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).</p>
06-25	LS26	<p>The Operational Leakage LCO has been modified to change the allowed leakage limit for RCS PIVs for consistency with improved TS SR 3.4.14.1. The RCS PIV LCO permits system operation in the presence of leakage through valves in amounts that do not compromise safety.</p>
06-26	LS30	<p>The CTS surveillance requirement for performing a RCS water inventory balance is modified to allow deferral of the water inventory balance such that it would be performed within 12 hours after achieving steady state conditions. The RCS water inventory balance must be performed with the reactor at steady state conditions as discussed in the ITS Bases. This change is in conformance with Industry Traveler TSTF 116, Rev. 1.</p>
06-27	A	<p>Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).</p>
06-28	LG	<p>Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).</p>
07-01	R	<p>Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

08-01	LS16	<p>This change in conformance with NUREG-1431, revises the Applicability of the specification to MODES 1, 2, or 3 with $(T_{avg}) \geq 500^{\circ}\text{F}$. The change deletes the requirement to perform an isotopic analysis for Iodine every 4 hours in MODES 4 and 5 and in MODE 3 below 500°F, whenever the reactor coolant exceeds its DOSE EQUIVALENT IODINE limit. This change deletes the requirement to perform the once per 4 hour surveillance for DOSE EQUIVALENT I-131 in the event the gross specific activity limit is exceeded, in accordance with Industry Traveler TSTF-28. Further, this is an unnecessary requirement since the ACTION requires the plant to exit the LCO's revised Applicability. This change is acceptable as offsite release of radioactivity in the event of a SGTR is unlikely for operation below 500°F, as the saturation pressure of the reactor coolant is below the lift pressure of the settings of the main steam safety and [relief] valves.</p>
08-02	LS17	<p>This change in conformance with NUREG-1431, adds an exception to LCO 3.0.4 when operating in Condition A. This would allow MODE changes under conditions that the plant is anticipating a return to acceptable activity levels within the allowed Completion Time of Required Action A. 2. This exception is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient specific activity excursions while the plant remains at, or proceeds to power operation.</p>
08-03	LS18	<p>This change in conformance with NUREG-1431, revises the sample frequency from 72 hours to 7 days for performance of a gamma isotopic analysis. The 7 day frequency is acceptable based on the low probability of a gross fuel failure occurring which would significantly alter the analysis results.</p>
08-04	M	<p>Consistent with NUREG-1431, the CTS requirement to measure Iodine including I-131, I-133 and I-135, is replaced with a requirement to measure a DOSE EQUIVALENT I-131. This is more restrictive.</p>
