08-05	LS19	<p>This change in conformance with NUREG-1431, revises the performance of the surveillance of the specific activity of the RCS following a 15% power change to MODE 1 only. Previously the surveillance was also required if the plant was in MODES 2 or 3 which required the plant to perform this surveillance following a Reactor Trip when normal spiking would be anticipated and the results would not be indicative of the operational status of the RCS.</p>
08-06	A	<p>The definition of E-bar is located in the Definition Section of NUREG-1431 and is not duplicated in the corresponding ITS specification (ITS 3.4.16.)</p>
08-07	A	<p>Consistent with NUREG-1431, a Note was added to clarify the time in which the sample is required to be taken upon meeting the minimum conditions to obtain the sample. This is administrative in nature as it is added for clarification.</p>
08-08	LG	<p>The description of gross radioactivity analysis is moved to the ITS Bases in conformance with NUREG-1431.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

09-01	LG	In conformance with NUREG-1431, the CTS figures which contain operational parameters related to the RCS Pressure/Temperature (P/T) Limits are being moved to the RCS PTLR. The PTLR will be in accordance with ITS 5.6.6.
09-02	M	In conformance with NUREG-1431, the ACTIONS are broken into MODES 1, 2, 3, or 4 and a separate ACTION for "at all other times." The MODES 1, 2, 3, or 4 ACTION is essentially the same as the previous ACTIONS. The ACTION which covers other times requires immediate action to restore the parameters and a determination of RCS acceptability prior to entering MODE 4. Both ACTIONS are modified to require a determination of acceptability for continued operation whenever the ACTIONS are entered. These ACTIONS are more restrictive but are acceptable.
09-03	M	In conformance with NUREG-1431, the time allowed for performance of the engineering evaluation following exceeding the P/T limits has been defined as 72 hours. No specific time limit was provided in the current specifications except for the 30 minutes allotted to restore the parameters to within limits. 72 hours is reasonable based on the necessary time for performing the evaluation and the low probability of the RCS structural integrity being unacceptable.
09-04	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
09-05	R	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
09-06	M	In conformance with NUREG-1431, the requirement is included to either isolate the accumulators or depressurize them to a pressure corresponding with the RCS temperature to preclude an RCS overpressure event. This requirement is commensurate with current practice and although addition to the improved TS is more restrictive, the change is necessary to help ensure [LTOP] analysis assumptions are maintained.
09-07	TR 2	This change in accordance with NUREG-1431 removes the requirement for a special report to be generated and submitted to the NRC following the mitigation of an RCS pressure transient. Reporting to the NRC will be done commensurate with the reporting requirements of 10 CFR 50.72 and 50.73.
09-08	LS7	A Note is added to CTS 3.4.9.3 ACTION to allow two centrifugal charging pumps (CCP)s capable of injecting into the RCS during pump swap operation for \leq 1 hour. The [LTOP] system design requires no more than one CCP capable of injection. This change provides flexibility to switch operating pumps without interrupting injection flow. This is in accordance with NUREG-1431 and Industry Traveler WOG-51 and is a less restrictive change.
09-09	M	In conformance with NUREG-1431 an additional ACTION is added for [two] charging pumps capable of injecting into the RCS and subsequent actions for RCS depressurization and venting if necessary.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.4

CHANGE NUMBER

NSHC

DESCRIPTION

09-10	M	In conformance with NUREG-1431 an additional ACTION is added for an accumulator which has not been isolated or depressurized and subsequent actions for RCS depressurization and venting if necessary.
09-11	M	In conformance with NUREG-1431 an additional ACTION is added for the system being inoperable for any other reason to include ACTION for RCS depressurization and venting. The addition of this ACTION is a more restrictive change which is necessary to help ensure [LTOP] analysis assumptions are maintained.
09-12	LS20	In conformance with NUREG-1431 an allowance has been included which provides for performance of the CHANNEL OPERATIONAL TEST (COT) on the PORV actuation channels within 12 hours after entering the applicability. Previously the COT was required to be performed prior to entry and was an unnecessary burden on plant operation. As stated in the improved TS BASES, the 12 hour time frame is an acceptable period for performance of the COT. This change is less restrictive and is acceptable as stated above.
09-13	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
09-14	M	In conformance with NUREG-1431 an additional surveillance is added to verify accumulator isolation when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in the PTLR. This change is consistent with adding the requirement for accumulator isolation to the LCO (see CN 09-06-M). The addition of this surveillance requirement is a more restrictive change which is necessary to help ensure [LTOP] assumptions are maintained.
09-15	M	In conformance with NUREG-1431, an additional ACTION and corresponding SR are added for one or more Safety Injection (SI) pumps or more than one CCP capable of injection into the RCS and subsequent actions for RCS depressurization and venting if necessary. [These items are in the current ECCS TS.]
09-16	M	CTS surveillance 4.4.9.1 determines RCS temperature and pressure are within limits once per hour during RCS heatup, cooldown, or testing. ITS SR 3.4.3.1 requires verification of RCS conditions within limits once per 30 minutes. This is a more restrictive change.
09-17	LS24	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
10-01	LS21	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

(15 pages)

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-01-LG	The definition of OPERABLE and operating for the RCS loops is moved to the Bases.	Yes	Yes	Yes	Yes
01-02-A	Surveillances to verify steam generator OPERABILITY are moved to SR 3.4.13.2 and Section 5.5.9 in the improved TS.	No, DCPD does not have this SR in 3/4.4.1.	Yes	No, WCGS does not have this SR in 3/4.4.1.	No, Callaway does not have this SR in 3/4.4.1.
01-03-LS1	This change replaces the specific requirement that RTBs be open with the more general requirement that the rod control system be not capable of rod withdrawal.	Yes	Yes	No, WCGS did not have the specific requirement that the RTBs be open. See change 1-14-LS.	No, Callaway did not have the specific requirement that the RTBs be open. See change 1-14-LS.
01-04-M	This change removes the special test exception (3.10.4) which allowed for suspending this LCO during the performance of hot rod drop time measurements.	No, not in the DCPD CTS.	Yes	Yes	Yes
01-05-M	Notes are added or revised in current TS LCOs 3.4.1.2, 3.4.1.3, 3.4.1.4.1 to reflect [COMS] analysis requirements restricting conditions for starting an idle RCP.	No, not in CTS	No, not in CTS	Yes	Yes
01-06-M	The allowed short term de-energization of RCPs for 1 hour (with no restrictions) is changed to 1 hour per 8 hour period.	Yes	Yes	Yes	Yes
01-07-M	This change separates the ACTION Statement for one loop OPERABLE from that of no loops OPERABLE. The condition of no loops OPERABLE is now included with the condition of no loops in operation. The additional ACTION of returning a loop to OPERABLE status is added.	Yes	Yes	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-08-LS2	This change adds an allowance to suspend operation of all RHR pumps when proceeding from MODE 5 to MODE 4, if decay heat removal is being provided by an RCS loop. This change is to will provide a smoother transition to MODE 4 operations.	Yes	Yes	Yes	Yes
01-09A	This change replaces the word "or" with "and". The ACTION could have been interpreted to require that the SG level be restored even when the SGs were not being credited for heat removal. The revised wording clarifies that the second part of the LCO (i.e., 'a' or 'b') is met with either one RHR loop OPERABLE or two SGs with required level.	No, DCPD CTS already has an "and."	Yes	No, WCGS CTS already has an "and".	No, Callaway CTS already has an "and".
01-10-M	These ACTIONS are changed to include the required ACTIONS for no required RHR loops OPERABLE. Previously, the specification did not provide specific action for no RHR loops OPERABLE. Also clarifies that the restored loop must be OPERABLE as well as in operation.	Yes	Yes	Yes	Yes
01-11-M	This change adds surveillances to verify breaker alignment and power availability to the required RHR pump not in operation.	Yes	Yes	Yes	Yes
01-12-M	The ACTIONS are changed to separate the required ACTIONS for only one required RHR loop OPERABLE and no required RHR loops OPERABLE.	Yes	Yes	Yes	Yes
01-13-M	An additional restriction is added which prohibits draining of the RCS when the RHR pump is deenergized.	No, see change 01-20-LS 27.	Yes	No, retaining CTS.	Yes
01-14-LS 22	This change modifies the LCO to only require two reactor coolant loops be OPERABLE in MODE 3. Required loops in operation depend on rod control system status.	No, two RCS loops OPERABLE is already part of the CTS.	No, two RCS loops OPERABLE is already part of the CTS.	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.4

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-15-M	A SG level corresponding to 10% of the wide range does not cover all SG tubes. To qualify as a valid heat sink, the tubes must be covered.	No, 15% water level is required for SG OPERABILITY in the CTS.	No, 10% narrow range S/G level is the CTS requirement.	Yes	Yes
01-16-A	This change revises the Note that permits up to 1 hour "deenergization" of RCP/RHR pumps. The revised wording clarifies the intent of the Note to allow the pumps to be "removed from operation" instead of "deenergized", thus permitting other means of removing the pumps from service.	Yes	Yes	Yes	Yes
01-17-LG	The plant specific minimum temperature specified in degrees below which the RCS must not be subject to overpressure is replaced by the generic statement "the minimum low temperature value specified in the PRESSURE TEMPERATURE LIMITS REPORT (PTLR)".	Yes	No, retaining CTS.	No, retaining CTS.	No, retaining CTS.
01-18	Not used	N/A	N/A	N/A	N/A
01-19-M	Changes allowed outage time for "four loops inoperable" from 72 hours to immediate action.	No, "immediate" already in CTS.	Yes	Yes	Yes
01-20-LS 27	The restriction for reactor vessel water level above the vessel flange to the stopping of all RHR pumps is removed.	Yes	No, CPSES does not have this restriction.	No, retaining CTS	No, Callaway does not have this restriction.

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-01-LS 3	The specification for the RCS safety valves in MODES 4 and 5 is deleted.	No, Amendments 98/97 relocated this specification to Equipment Control Guideline (ECG).	Yes	No, Amendment 89 relocated to USAR Chapter 16.	No, Amendment 103 relocated to FSAR Chapter 16.
02-02-M	This change extends the applicability for the required operability of the pressurizer safety valves to include MODE 4 when RCS temperature is above 320°F.	No, MODE 4 requirements are in the CTS.	Yes	No, WCGS has a different LTOP arming temperature.	No, Callaway has a different COMS arming temperature.
02-03-M	This change provides a new ACTION for two or more pressurizer safety valves inoperable. Prior to this change, LCO 3.0.3 would have been entered allowing for 1 hour prior to placing the unit in HOT STANDBY within the next 6 hours, etc.	Yes	Yes	Yes	Yes
02-04-LG	The footnote about the lift setting being for ambient conditions is moved to the Bases.	Yes	Yes	No, see 2-05-LS-23.	No, see 2-05-LS-23.
02-05-LS 23	Safety valve lift settings at ambient (hot conditions) can be deferred for 54 hours following MODE 3 entry.	No, ACTION b. in the CTS already provides 54 hours allowance.	Yes	Yes	Yes
03-01-LS 4	This change revises ACTION from the "pressurizer otherwise inoperable" to "water level not within limit".	Yes	Yes	Yes	Yes
03-02-LG	The method of verifying heater capacity is moved to the Bases.	Yes	Yes	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
03-03-LS 28	This change extends the pressurizer heaters surveillance interval from 92 days to 18 months.	Yes	Yes	Yes	No, already part of CTS per Amendment 105.
03-04-LS 29	The ACTION is modified to reflect generic wording to assure that the rods are fully inserted and cannot be withdrawn. This change is based on Industry Traveler TSTF-87, Rev. 1.	Yes	Yes	Yes	Yes
03-05-M	This change adds a requirement to CTS 3.4.3 LCO. The change requires the pressurizer heaters to be capable of being powered from an emergency power source.	Yes	No, pressurizer heaters normally aligned to emergency power.	No, pressurizer heaters normally aligned to emergency power.	No, pressurizer heaters normally aligned to emergency power.
04-01-LS 5	An allowance has been added that separate condition entry is allowed for each Power Operated Relief Valve (PORV).	Yes	Yes	Yes	Yes
04-02-LS 6	The allowance for PORV inoperability has been expanded from previously only allowing block valve isolation when the PORV was inoperable for seat leakage to allowing block valve isolation when the PORV is still capable of manually being cycled.	Yes	Yes	Yes	Yes
04-03-M	The times to reduce MODE is decreased by one hour.	Yes	Yes	Yes	Yes
04-04-LG	This change moves the requirement to perform channel calibration of PORV actuation instrumentation to a licensee controlled document.	Yes, moved to the FSAR.	Yes, moved to the TRM.	Yes, moved to the USAR.	Yes, moved to the FSAR.
04-05-LS 31	The shutdown requirement of CTS 3.4.4 would require the plant to reduce T_{avg} to <500°F within 12 hours, rather than go to MODE 4, to address the concern of entering [LTOP] LCO Applicability with inoperable PORVs. For consistency the shutdown requirements of CTS LCO [3.4.8] would be similarly revised.	Yes	Yes	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
04-06-LS 32	This change provides a 72 hour completion time to restore an inoperable block valve, with the PORV placed in manual control mode. The CTS requires the block valve to be restored within one hour or remove power from the PORV solenoid	Yes	No, already part of CTS.	No, already part of CTS.	No, already part of CTS.
04-07-LS 33	This change provides a two hour completion time for restoring an inoperable block valve when more than one block valve is inoperable, and 72 hours to restore the remaining valves. The CTS requires the inoperable block valves to be restored within one hour for one or more valves inoperable.	Yes	No, already part of CTS.	No, already part of CTS.	No, already part of CTS.
04-08-LS 34	Consistent with Traveler WOG-60, the requirement to perform the PORV and block valve cycling surveillances is revised such that the surveillances are only required to be performed in MODES 1 and 2.	Yes	Yes	Yes	Yes
4-09-LS-36	Consistent with Industry Traveler WOG-87, the requirement to perform the 92 day surveillance of the pressurizer block valves (i.e., perform one complete cycle of each block valve) is revised such that it is not required if the block valve is closed to meet ACTION a of the CTS LCO 3.4.4.	Yes	Yes	Yes	Yes
05-01-A	This change moves the Steam Generator Surveillances to SR 3.4.13.2 and the Administrative Controls Sections 5.5.9 and 5.6.10.	Yes	No, same as CPSES change 01-14-A for CTS Section 3/4.0.	Yes	Yes
05-02-A	LCO 3.4.5 is deleted. Steam Generator operability requirements in MODES 1-4 are specified in the RCS loop and leakage specifications.	Yes	No, CPSES does not have this specification.	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
05-03-A	The probe orientation is changed to state "tube end" in place of "point of entry" in the tube inspection definition under Acceptance Criteria.	Yes	No, same as CPSES change 01-15 for CTS Section 3/4.0.	Yes	Yes
06-01-M	This change adds the performance of an RCS water inventory balance every 24 hours as a new requirement when the [sump level detector] is inoperable.	Yes	Yes	Yes	Yes
06-02-LS 8	This change allows the performance of an RCS water inventory balance every 24 hours as an alternative to the requirement to perform 24 hour samples of the containment atmosphere when a required radioactivity monitor is inoperable.	Yes	Yes	Yes	Yes
06-03-A	This change adds the word "required" to clarify that only those detectors which are being used to satisfy the LCO must be demonstrated to be OPERABLE.	Yes	Yes	Yes	Yes
06-04-A	The word "Digital" has been deleted to be consistent with the terminology used in NUREG-1431 as it relates to CHANNEL OPERATIONAL TESTS.	No, "Digital" not included in CTS.	Yes	No, "Digital" not included in CTS.	No, "Digital" not included in CTS.
06-05-A	This change deletes the phrase "not isolated from the Reactor Coolant System" when referring to leakage through the SGs.	No, the phrase is not part of the CTS.	Yes	Yes	Yes
06-06-A	This change moves the LCO for CONTROLLED LEAKAGE (seal injection flow) from "Operational Leakage" to ITS LCO 3.5.5 "ECCS."	Yes	Yes	No, see CN 06-28-LG.	No, see CN 06-28-LG.
06-07-LG	This change moves the listing of RCS PIVs to a licensee controlled document.	Yes, moved to the FSAR.	Yes, moved to TRM	Yes, moved to USAR Chapter 16.	Yes, moved to FSAR Table 16.4-1.
06-08-LS 9	Adds clarification that the valves in the RHR flow path are not required to meet the PIV specification "when in, or during the transition to or from the RHR MODE of operation" in MODE 4.	Yes	Yes	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
06-09-LS 10	The LCO Applicability for CONTROLLED LEAKAGE (seal injection flow) is reduced to only MODES 1, 2, and 3 with the associated change in ACTION b.	Yes	Yes	No, see CN 06-28-LG	No, see CN 06-28-LG
06-10-LG	Discussion on how to perform the leak testing is moved to the Bases.	No, valve leak test discussion is not part of CTS.	Yes	Yes	Yes
06-11-LS 11	This change allows for the RCS flow path to be isolated by one valve within 4 hours and a second series valve within 72 hours.	Yes	Yes	Yes	Yes
06-12-M	This change adds a further restriction which requires that any valve(s), used to satisfy the action of isolating the low pressure system from the high pressure system when a RCS PIV is inoperable, must additionally be tested and meet the leakage criteria of the PIV.	Yes	Yes	Yes	Yes
06-13-LS 12	This change removes the specific surveillance requirement to monitor the RCS Leakage Detection System once per 12 hours.	Yes	Yes	Yes, Note - WCGS had 2 TS surveillances for rad monitor and containment sump.	Yes, Note - Callaway had 2 TS surveillances for rad monitor and containment sump.
06-14-A	This change moves the Surveillance for CONTROLLED LEAKAGE (seal injection flow) from "Operational Leakage" to "ECCS".	Yes	Yes	No, see CN 06-28-LG.	No, see CN 06-28-LG.
06-15-LS 13	This change removes the additional criteria that "no more than 96 hours shall elapse between any two successive inventory balances".	No. see CN 06-26-LS 30. DCPD has a different surveillance.	Yes	No, see CN 06-26-LS. WCGS has a different surveillance.	No, see CN 06-26-LS. Callaway has a different surveillance.

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
06-16-LS 14	This change removes the requirement for monitoring the reactor head flange leakoff system.	Yes	Yes	Yes	Yes
06-17-LG	The definition of steady state is moved to the Bases.	Yes	Yes	No, WCGS did not have this definition.	No, Callaway did not have this definition.
06-18-LS 15	This change relaxes the requirement for PIV testing following operation in MODE 5. The previous requirement was testing following 72 hours in MODE 5 which is revised to 7 days in MODE 5.	No, MODE 5 testing requirement is not part of CTS.	Yes	Yes	No, already in CTS per Amendment 105.
06-19-TR 3	This change removes the specific requirement for performing the PIV surveillance prior to returning a valve to service following maintenance, repair or replacement.	Yes	Yes	Yes	Yes
06-20-A	IST requirements are moved to Administrative Controls Section 5.5.8 of the improved ITS.	Yes	Yes	No, WCGS does not have this requirement.	No, Callaway does not have this requirement.
06-21 LS- 35	This change increases the RCP seal injection flow Completion Time from 4 to 72 hours, with a new added verification that at least 100% of the assumed charging flow remains available.	Yes	Yes	No, see CN 06-28-LG	No, see CN 06-28-LG
06-22-M	This change adds a new ACTION to isolate the affected RHR penetration within 4 hours if the RHR suction isolation valve interlock function is inoperable.	No, not part of current DCPPTS.	Yes	Yes	Yes
06-23-LS 25	The leakage detection system specification is revised such that the provisions of 3.0.4 are not applicable.	Yes	No, the non-applicability of 3.0.4 is already part of the CTS.	Yes	Yes
06-24-M	Revises ACTION to require going to COLD SHUTDOWN rather than HOT SHUTDOWN with an RCS pressure less than 600 psig.	No, the 600 psig ACTION is not part of the CTS.	No, the 600 psig ACTION is not part of the CTS.	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
06-25-LS 26	The Operation Leakage LCO has been modified to change allowed limit for RCS PIVs.	Yes	No, leakage limit of ≤ 5 gpm is already part of CTS.	Yes	No, already part of CTS per Amendment 66.
06-26-LS 30	The surveillance requirement for performing an RCS water inventory balance is modified to allow deferral of the water inventory balance such that it would be performed within 12 hours after achieving steady state conditions.	Yes	No, already part of the CPSES CTS.	Yes	Yes
06-27-A	RCS leakage detection system descriptions are revised for consistency with CTS LCO 3.3.3.1 and FSAR Sections 5.2.5.2.2 and 11.5.2.3.2.2.	No, current systems are applicable.	No, current systems are applicable.	Yes	Yes
06-28-LG	The CTS definition of CONTROLLED LEAKAGE would be deleted. RCP seal performance is moved to a licensee controlled document.	No, not in CTS.	No, not in CTS	Yes, moved to USAR.	Yes, moved to FSAR.
07-01-R	This change moves the RCS chemistry specification from the CTS to a licensee controlled document.	No, Amendments 98/97 moved the specification to ECG.	Yes, to be relocated to TRM.	No, Amendment 89 relocated to USAR Chapter 16.	No, Amendment 103 relocated to FSAR Chapter 16.
08-01-LS 16	This change revises the applicability of the specification to MODES 1, 2, or 3 with $(T_{avg}) \geq 500^{\circ}\text{F}$. The change deletes the requirement to perform an isotopic analysis for Iodine every 4 hours in MODES 4 and 5 and in MODE 3 below 500°F , whenever the reactor coolant exceeds its DOSE EQUIVALENT Iodine or Gross Specific Activity limits.	Yes	Yes	Yes	Yes
08-02-LS 17	This change adds an exception to LCO 3.0.4 when operating in ACTION A. This would allow MODE changes under conditions that the plant is anticipating a return to acceptable activity levels within the 48 hour Completion Time.	Yes	Yes	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
08-03-LS 18	This change revises the sample frequency from 72 hours to 7 days for performance of a gamma isotopic analysis.	Yes	Yes	Yes	Yes
08-04-M	This change revises the measurement of I-131, I-133 and I-135 to DOSE EQUIVALENT I-131.	Yes	Yes	Yes	Yes
08-05-LS 19	This change revises the performance of the surveillance of the specific activity of the RCS following a 15% power change to MODE 1 only.	Yes	Yes	Yes	Yes
08-06-A	The definition of E-bar is located in the Definition Section of NUREG-1431 and is not duplicated in this specification.	Yes	Yes	No, WCGS does not have this definition as part of Table 4.4-4.	No, Calloway does not have this definition as part of Table 4.4-4.
08-07-A	This change adds a note to clarify the time in which the sample is required to be taken upon meeting the minimum conditions to obtain the sample.	Yes	Yes	Yes	Yes
08-08-LG	The description of gross radioactivity analysis is moved to the Bases.	Yes	No, not in CTS	No, not in CTS.	No, ot in CTS.
09-01-LG	The TS figures which contain operational parameters related to the RCS P/T limits are moved to the RCS PTLR.	Yes	Yes	Yes	Yes
09-02-M	The ACTIONS for RCS pressure/temperature limits are broken into MODES 1, 2, 3, or 4 and at all other times. The MODES 1, 2, 3, or 4 ACTION is essentially the CTS. The ACTION which covers other times requires immediate action to restore the parameters and a determination of RCS acceptability prior to entering MODE 4.	Yes	Yes	Yes	Yes
09-03-M	The time allowed for performance of the engineering evaluation following exceeding the P/T limits has been defined as 72 hours.	Yes	Yes	Yes	Yes

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
09-04-LG	This change moves the 10 CFR 50 Appendix H, material surveillance program from the CTS to a licensee controlled document.	No, this paragraph is not in the CTS.	Yes, moved to PTLR.	Yes, Note: Table 4.4-5 was deleted by Amendment 57.	Yes, Note: Material surveillance program moved to FSAR Ch. 16. Table 4.4-5 was deleted by Amendment 76.
09-05-R	This change removes the pressurizer specification from the TS. The limits for the pressurizer are relocated to an licensee controlled document.	No, Amendments 98/97 relocated specification to ECG.	Yes, to be relocated to the TRM.	No, Amendment 89 relocated the specification to USAR Chapter 16.	No, Amendment 103 relocated the specification to FSAR Chapter 16.
09-06-M	A requirement is included to either isolate the accumulators or depressurize them to a pressure corresponding with the RCS temperature to preclude an RCS over pressure event.	Yes	Yes	Yes	Yes
09-07-TR 2	This change removes the requirement for a special report to be generated and submitted to the NRC following the mitigation of an RCS pressure transient.	Yes	Yes	Yes	Yes
09-08-LS 7	A Note was added to CTS 3.4.9.3 ACTION to allow two centrifugal charging pumps capable of injection into the RCS during pump swap operation for \leq 1 hour.	Yes, specific to DCPP	No, CTS allows 2 CCPs to be OPERABLE.	No, see change 09-17-LS.	No, see change 09-17-LS.
09-09-M	An additional ACTION is added when more than the allowable number of charging pumps are capable of injecting into the RCS including subsequent actions for RCS depressurization and venting if necessary.	Yes	Yes	No, see change 09-15-M.	No, see change 09-15-M.

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information may be moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3..." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R" (Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The LCO and associated surveillances have been revised to be less restrictive. Prior to the proposed change, the requirement for RCS loops OPERABLE was based on Reactor Trip Breaker (RTB) position. The intent of this requirement was to allow for less stringent operating criteria when rod withdrawal events were precluded via the RTBs being open. The proposed specification allows more freedom in how rod withdrawal is precluded and is thus less restrictive. However, the intent of using physical plant characteristics to prevent inadvertent rod withdrawal is not diminished. The specification now acknowledges that the typical rod control system can be effectively disabled by other means than opening the RTBs.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the requirement to preclude rod withdrawal using physical plant characteristics. The specification does not allow administrative control or other means which could be conceived as less stringent. The specification does allow for alternative means to opening the RTBs for precluding rod withdrawal. These means, such as removing power to the rod control system, would preclude inadvertent rod withdrawal as effectively as opening the RTBs. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

Inadvertent rod withdrawal accidents have been previously evaluated. This change does not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will preclude rod withdrawal with the same level of assurance that opening the RTBs provided. Therefore, this change does not involve a significant reduction in a margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (Continued)

Based on the above safety evaluation, the activities associated with NSHC "LS1" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

Current TS 3.4.7, "MODE 5 Loops Filled", LCO has been modified by a Note which allows the removal of all RHR loops from operation during planned heatup to MODE 4 from MODE 5 when at least one RCS loop is in operation.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This proposed change adds an additional relaxation to allow the use of an operating RCS loop in lieu of an operating RHR loop in MODE 5 during planned heatup in preparation to proceed into MODE 4. The primary functions of RHR loop operation in MODE 5 are to remove decay heat and to prevent boron stratification. These functions can also be performed by an operating RCS loop which is a normal method of accomplishing the same functions when in MODE 4. In addition, at least one RHR loop must remain OPERABLE during the transition to MODE 4. This proposed change does not alter the ability of the RHR and the RCS systems to perform their function to remove heat and provide boron mixing in the RCS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of decay heat removal capability or to boron stratification. Since the use of an RCS loop in lieu of an RHR loop to perform the heat removal/boron stratification functions does not result in any reduction in performance or reliability, the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS2" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

ACTION b. is modified to specifically define "water level not within its limit" as the condition requiring the action instead of the "pressurizer otherwise inoperable." Thus for any other condition which could cause pressurizer inoperability, (except for inoperable heaters which is covered by ACTION a.) LCO 3.0.3 would apply. The net effect is to provide an additional hour (allowed under LCO 3.0.3 to prepare for an orderly shutdown) to correct any condition other than high pressurizer water level before performing the required plant shutdown. This change is acceptable because a high pressurizer water level is the primary condition in MODES 1, 2, and 3 which could lead to pressurizer inoperability and therefore requires the most immediate actions. High pressurizer level is indicative of a reduction in the size of the pressurizer bubble which could adversely effect RCS pressure transients. The actions required for high pressurizer level are unaffected by this change. Any other cause of inoperability is not likely to require immediate action and is adequately protected by LCO 3.0.3.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The pressurizer functions to control RCS pressure and to provide expansion volume for the RCS during normal operating transients and accident conditions. The OPERABILITY of the pressurizer is assumed in the initial conditions of all accident analyses.

The proposed change provides an additional hour to restore the pressurizer to operable (other than for high pressurizer water level) prior to taking required shutdown actions. The primary cause of pressurizer inoperability is high water level or loss of heaters. The actions required by these causes remains unchanged in the improved specifications. Other causes for inoperability are much less likely and adequate protection is provided by LCO 3.0.3. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of pressurizer function which could result in an RCS overpressurization event. This change does not introduce any new overpressure accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 4" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The LCO has been modified to allow separate condition entry for each pressurizer power operated relief valve (PORV). This makes restoration times for each PORV consistent based on the specific condition of a PORV, as long as at least one PORV is capable of being manually cycled.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change adds a relaxation to the LCO by allowing separate condition entry for each PORV. No analysis credit is taken for automatic actuation of the PORVs in MODES 1, 2, or 3. Analysis credit is taken for manual operation of one PORV during the Steam Generator Tube Rupture (SGTR) accident. The specific relaxation allowed by this change could result in having a PORV inoperable and not capable of manual control for a maximum of 144 hours (not the same PORV, i.e., two PORVs becoming inoperable consecutively) as compared to a maximum of 72 hours if separate condition entry were not allowed. However, the capability to manually cycle at least one PORV in response to a SGTR will be maintained during the allowed time. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of pressurizer function which could result in an RCS overpressurization event. This change does not introduce any new overpressure accidents and the existing analyses remain valid. Thus, the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The manual actuation capability of one PORV is credited in the SGTR accident analyses for MODES 1, 2, or 3. At least one PORV will remain capable of being manually cycled during the allowed ACTION time. The margin of safety established by the LCO remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 5" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

The ACTIONS for an inoperable PORV as a result of excess seat leakage associated with the LCO has been changed to specifically address inoperability as a function of whether or not the valve is capable of being manually cycled. This relaxation of the conditions for ACTION entry associated with the PORVs only requires the operability of the manual actuation mode of the pressure reduction function of the PORV. The capability of the PORV to be manually cycled as a criteria in the ACTION requirements continues to maintain the ability of the valve to mitigate a Steam Generator Tube Rupture (SGTR) accident.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change adds a relaxation to the ACTIONS associated with the LCO by expanding the conditions under which an otherwise inoperable PORV may be used to satisfy SGTR accident analyses assumptions. The assumptions require the PORV to be capable of manual operation. No credit is taken for the automatic actuation of the PORV in MODES 1, 2, or 3. Credit is taken for manual operation of the PORVs during the SGTR accident. However, the capability to manually cycle the PORVs will be unaffected by this change. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of pressurizer function which could result in an RCS overpressurization event. This change does not introduce any new overpressure accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. Automatic actuation of the PORVs is not credited in the accident analyses for MODES 1, 2, or 3. The PORVs will remain capable of being manually cycled. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 6" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The proposed change adds a relaxation to CTS 3.4.9.3 ACTION to allow two centrifugal charging pumps (CCP)s to be capable of injecting into the RCS during pump swap operation for ≤ 1 hour. The LTOP system assumes no more than one CCP capable of injection into the RCS. This change to allow two CCPs capable of injection provides smooth transition for switching operating pumps without interrupting charging flow to the RCS. This change, in accordance with NUREG-1431, and Industry Traveler WOG-51 is acceptable based on the close operator attention during this evolution and his understanding of the need to avoid RCS low temperature overpressure.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change allows the capability of two CCPs to inject into the RCS for up to 1 hour during pump swap operation. This allowance provides for pump switching while avoiding a RCS transient associated with stopping and then restarting the injection flow. This proposed change would not affect the initiating events assumed for accidents previously evaluated and would not affect the ability of plant equipment to perform its intended function. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment, does not involve any physical alterations to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The results of analyzed events are not altered. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 7" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

This proposed change revises the ACTION requirements for LCO 3.4.5.1 to provide an alternative (RCS water inventory balance every 24 hours) to the requirement to perform 24 hour samples of containment atmosphere when a required radioactivity monitor is inoperable. The primary function of the leakage detection systems is to detect significant reactor coolant pressure boundary (RCPB) degradation as soon as practical. The detection initiates the investigation to determine the source and to limit the potential for further degradation. The TS requires multiple diverse systems to ensure that leakage from a variety of locations and leakage rates can be detected in sufficient time to take measures to place the plant in a safe condition. When a required radioactivity monitor is inoperable, the CTS provides compensatory action by requiring containment atmosphere samples be taken and analyzed every 24 hours to supplement indications from detection systems which are still operable [(e.g., sump level and containment cooler condensate flow)]. Another diverse means for determining RCS leakage is the RCS water inventory balance. When performed at the same frequency as the containment atmosphere grab sample, and in conjunction with other leak detection indications, this method provides an equal degree of confidence of the status of RCS leakage.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously?

The RCS water inventory balance is a passive method for determining RCS leakage within LCO limits and cannot initiate or increase the consequences of an accident. The daily RCS inventory balance provides as much assurance that leakage will be detected as the daily containment atmosphere samples provide and is only one of several detection indications available. The probability that RCPB leakage will be detected is not reduced by using the RCS water balance instead of the containment atmosphere samples. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of RCPB integrity. This change does not introduce any new mechanisms for causing such RCPB integrity loss or degrade protective measures which mitigate such accidents. The existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 8" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The proposed change allows the delay of Pressure Isolation Valve (PIV) testing in the RHR system during entry into MODE 4 from MODE 5 until RHR operation is completed. The current surveillance allows an exception to required testing within 24 hours following flow through these PIVs, but also allowed exception to the provisions of Specification 4.0.4 for entry into MODES 3 and 4. Otherwise, testing would be required prior to entry into MODE 4. PIVs in the normal RHR flow paths used in MODES 4, 5, and 6 are not required until final RHR operation is terminated during plant heatup. Completion of RHR operation is considered to be one of the required prerequisite conditions necessary for the performance of check valve leakage testing.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change clarifies that the valves in the RHR flow path are not required to meet the PIV specification when in or during the transition to or from the RHR mode of operation in MODE 4. The same allowance was available in the original specification by an exception to Specification 4.0.4. In addition, using RHR through these specific flow paths is the required mode of operation during an accident. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC.LS9 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of RCS inventory. This change does not introduce any new accidents related to a reduction in RCS inventory and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. RHR will remain capable of performing the safety function and the new requirement will continue to provide adequate assurance of that capability. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 9" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The LCO 3.4.5.2 Applicability for CONTROLLED LEAKAGE (RCP seal injection flow) is reduced to only MODES 1, 2, and 3, where previously it had also applied in MODE 4. Associated ACTION b is modified to add requirements to reduce flow within limits within 4 hours or to be in at least HOT STANDBY in the next 6 hours and in HOT SHUTDOWN within the following 6 hours

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The restriction on reactor coolant pump (RCP) seal injection flow limits the amount of ECCS flow that would be diverted from the injection path following an accident. This limit is based on safety analysis assumptions that are required because RCP seal injection flow is not isolated during SI. The seal injection flow limit is not applicable for MODE 4 because high seal injection flow is less critical as a result of the lower initial RCS pressure and decay heat removal requirements. Therefore, RCP seal injection flow need only be limited in MODES 1, 2, and 3 to ensure adequate ECCS performance. Since seal injection restrictions are not required in MODE 4, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accident that could potentially be affected by this proposed change is the LOCA. The LOCA assumptions are continue to be satisfied in MODES 1, 2 and 3 and the LOCA analyses results are not affected by this change. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS10" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

The revised ACTION c would require in the event of a Pressure Isolation Valve (PIV) leakage not within limits that the high pressure portion of the affected system be isolated from the low pressure portion in 4 hours using at least one valve. Then, within 72 hours, [the affected system must be isolated using a second valve or] the leaking PIV must be repaired. Otherwise, the unit must be in HOT STANDBY in 6 hours and COLD SHUTDOWN within the following 30 hours. This requirement is acceptable on the basis that isolation by a single valve for no more than 72 hours provides an acceptable level of safety during the 72 hour interval. The valve used to isolate the inoperable PIV must have been leak tested in accordance with CTS 4.4.6.2.2.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The valve used to isolate the inoperable PIV will be leak tested in accordance with the surveillance requirements. With the successful completion of this leak test requirement, there is sufficient assurance that a single valve can provide adequate isolation for the following 72 hours. [The requirement to employ a second series isolation valve within 72 hours restores the two valve isolation required by the CTS.] The interval during which only single valve isolation of high-to-low pressure isolation is provided is sufficiently short so as to not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change are those related to a loss of RCS inventory. This change does not introduce any new accidents related to a reduction in RCS inventory and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The requirement to use one valve within the first 4 hours followed by [a second valve] within 72 hours provides an acceptable level of safety. Using valves that have been verified to be within limits provides assurance that low pressure piping is protected from RCS pressure. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 11" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

This change in conformance with NUREG-1431, removes the specific requirement to monitor the containment atmosphere particulate and gaseous radioactivity monitor and the containment structure sump inventory and discharge once per 12 hours from current Operational Leakage TS. However, improved SR 3.4.15.1 requires that a CHANNEL CHECK be performed on the containment radioactivity monitor channels on the same frequency so there is no change in requirements for those detectors. The [containment sump level detection system] is continuously monitored from the control room via available alarms and indicators. The condensate from the [containment coolers condensate collection system] can be measured to provide another indicator of RCS leakage.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change deletes the requirement to monitor the RCS Leakage Detection System once per 12 hours. Leak detection provides information that may indicate degradation of the RCS pressure boundary, however, leak detection cannot initiate any accident. The RCS Leakage Detection System is not credited in any safety analyses. The continued operation of the leakage detection function is assured by the diverse means of leakage detection that have been provided within the system and by the requirement that a RCS water inventory balance be performed every 72 hours. The original requirement to "monitor" the system did provide specific details about what constitutes monitoring. Any reduction in performance of the system by the removal of the "monitoring" requirement is not expected to be significant. Since information is available from diverse sources the removal of the surveillance does not negatively impact RCS leak detection. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS-12 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that could potentially be affected by this change are LOCA and MSLB. These accidents have previously been evaluated and remain valid. Thus, the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The leakage detection system is not credited in any accident analyses. The margin of safety established by the LCO remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 12" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS 14 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The current requirement to monitor reactor head flange leakoff at least once per 24 hours would be deleted on the basis that leakage into this system is identified leakage to the reactor coolant drain tank. The RCS water inventory balance is the definitive surveillance for determining leakage as categorized by ITS LCO 3.4.13.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change removes the requirement to monitor reactor head flange leakoff at least once per 24 hours. This leakage is into the reactor coolant drain tank and is classified as identified leakage. Identified leakage is determined by performance of a RCS water inventory balance. The initial inventory balance is required within 12 hours following RCS steady state operation and every 72 hours thereafter. Flange leakoff does not provide an indicator of pressure boundary integrity and consequently, the removal of the monitoring does not involve the probability of loss of RCS water inventory. The flange leakage does not involve any initial assumptions used in the accident analyses. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change, are those related to a loss of RCS inventory. This change does not introduce any new accidents related to a reduction in RCS inventory and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. RCS leakage will continue to be adequately monitored via the RCS water inventory balance. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS14" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS 16
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

CTS [3.4.8.] "Specific Activity," Applicability would be revised to delete MODE 3 with RCS average temperature less than 500°F and MODES 4 and 5 (consistent with NUREG-1431). In addition, this change deletes the requirement to perform the once per 4 hour surveillance for DOSE EQUIVALENT I-131 in the event the gross specific activity limit is exceeded, in accordance with industry traveler TSTF-28. The latter is an unnecessary requirement since the ACTION requires the plant to exit the LCO's revised Applicability. This is acceptable because the offsite release of radioactivity in the event of a Steam Generator Tube Rupture (SGTR) is unlikely since the saturation pressure of the reactor coolant in MODE 3 with RCS temperature less than 500°F, and MODES 4, and 5 is below the lift pressure of the main steam safety and [SG atmospheric relief] valves. This is also consistent with existing ACTIONS a and b which require the unit to be placed in MODE 3 with T_{avg} less than 500°F in the event that specific activity cannot be restored to within limits in the required time.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change in applicable MODES will not affect any of the initiating events assumed for any of the accidents previously evaluated. The release of radioactivity in the event of a SGTR in MODES 3, 4 and 5 is unlikely since the saturation pressure of the reactor coolant is below the lift pressure of the main steam safety and [SG atmospheric dump] valves. The proposed change in applicable MODES for which this specification applies will not affect the ability of plant equipment to perform its intended function to mitigate the consequences of an accident. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment into the plant or alter the manner in which existing equipment will be operated. This change does not introduce new accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The release of radioactivity in the event of a SGTR in MODES 3 (below 500°F), 4 and 5 is unlikely since the saturation pressure of the reactor coolant is below the lift pressure of the main steam safety and [SG atmospheric dump] valves. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS16" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The proposed change revises CTS [3.4.8.] Specific Activity, by adding adds an exception to LCO 3.0.4 when operating within ACTION a. This exception would allow MODE changes under conditions when the plant is anticipating a return to acceptable activity levels within the allowed completion time of required by ACTION a.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change will modify the MODE change restrictions by excluding LCO 3.0.4 as applied to RCS specific activity and will not affect the initiating events assumed for the accidents previously evaluated. This exception is acceptable because of the low risk of an accident during the ACTION allowed time when specific activity may not be within limits. [] Adding the exception to LCO 3.0.4 will not affect the ability of plant equipment to perform its intended function to mitigate consequences of an accident. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment into the plant or alter the manner in which existing equipment will be operated. This change does not introduce new accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS17" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS18 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The proposed change revises the RCS sample frequency of a gamma isotopic analysis from 72 hours to 7 days. The gamma isotopic analysis measures the gross specific activity which includes both the degassed and gaseous gamma activities.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change from 72 hours to 7 days will not affect the initiating events assumed for the accidents previously evaluated. The seven day interval provides sufficient indication of adverse trends to allow appropriate action prior to exceeding the LCO during normal operating conditions. The 7 day frequency is acceptable based on the low probability of a gross fuel failure occurring that would significantly alter the analysis results. Changing the sample frequency from 72 hours to 7 days will not affect the ability of plant equipment to perform its intended function. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment into the plant or alter the manner in which existing equipment will be operated. This change does not introduce new accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS18" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS19 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The proposed change would revise the MODES for which the Iodine analysis surveillance is required to be performed for the RCS following a 15% power change to MODE 1 only. Previously, the surveillance was also required when the plant was in MODES 2 or 3. A 15% power change for MODES 2 and 3 would only occur following a reactor trip from MODE 1. The required surveillance would then only be conducted following a reactor trip when normal spiking would be anticipated, yielding results that would not be indicative of the operational status of the RCS.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or
2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or
3. Involve a significant reduction in a margin of safety."

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change would revise the applicable MODES from 1, 2, and 3 to MODE 1 only. The RCS Iodine analysis surveillance is required to be performed following a 15% power change. The removal of the MODES 2 and 3 requirement for analyzing Iodine in the RCS will not affect the initiating events assumed for the accidents previously evaluated and will not affect the ability of plant equipment to perform its intended function. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment into the plant or alter the manner in which existing equipment will be operated. This change does not introduce new accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS19
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS19" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS20
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

Current overpressure protection TS Surveillance [4.4.9.3.1.a] requires that a CHANNEL OPERATIONAL TEST (COT) be performed on the PORV actuation channel within 31 days prior to entering a condition in which the PORV is required to be operable. This Surveillance would be revised to be required within 12 hours after entering MODE 4 when the PORV is required OPERABLE and at least once per 31 days thereafter. Previously the COT was required to be performed prior to entry. The proposed change is consistent with NUREG-1431 and provides the benefit of not requiring the PORV actuation channel to be tested in MODES 1, 2, or 3 [] as would be required by the CTS.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change only affects the time when a COT has to be performed on the PORV actuation channels. The PORV COT is still required within 12 hours of entering the condition where the PORV LCO is applicable. A 12 hour allowance considers the unlikelihood of a low temperature overpressure event during this time. The time of performing the surveillance is not an input or assumption for the initiating events for the accidents previously evaluated. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce any new equipment into the plant or alter the manner in which existing equipment will be operated. This change does not introduce any new accidents and the existing analyses remain valid. Thus the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. In addition, performing the test under MODE 4 conditions when the PORV setpoint can be reduced is more appropriate than performing the test prior to MODE 4 conditions. The margin of safety established by the LCOs also remains unchanged. Therefore, this change does not involve a significant reduction in a margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NHSC LS20
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS20" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS 25 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The current Leakage Detection System TS ACTION is revised such that the provisions of TS 3.0.4 are not applicable. This revision will allow entry into the Applicable MODES with only one of the Leakage Detection Systems OPERABLE, subject to the requirements of the ACTION statements. This change is consistent with NUREG-1431, and Industry Traveler TSTF-60, and is acceptable because of the diverse means to detect RCS leakage prescribed in the ACTION.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The primary function of the Leakage Detection System is to detect the presence of RCS leakage which may be indicative to degradation of the RCS pressure boundary (RCPB). The TS provides for multiple means of leak detection. Small magnitude leaks can be detected to provide time to determine the RCBP condition before possible progressive degradation can occur. Entry into the applicable MODES while subject to an ACTION statement will not have any effect on the status of the RCPB. The proposed change does not result in degradation in the performance of the leak detection function nor increase the number of challenges imposed on safety-related equipment assumed to function during an accident situation. The proposed change will not affect any event initiators nor will it affect the ability of any safety-related equipment to perform its intended function. The Leakage Detection Systems are passive and cannot initiate or increase the consequences of an accident. No credit is explicitly taken for these systems in the accident analyses.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will not affect the ability of any safety-related equipment to perform its intended function. The proposed change does not introduce any new equipment, does not involve any physical alterations to any plant equipment, and does not involve any change in the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS25
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. No credit is explicitly taken for these systems in the accident analyses. The proposed change does not affect the assumptions used in the safety analyses. The values assumed for the analyses and therefore the results of the analyses remain valid.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 25" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS 26 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

This LCO has been modified to change the allowed leakage limit for reactor coolant system (RCS) pressure isolation valves (PIVs). The LCO permits system operation in the presence of leakage through PIVs in amounts which do not compromise safety.

The RCS is isolated from other systems by valves. During plant life these interfaces can produce varying amounts of reactor coolant leakage through either normal operational wear or through mechanical deterioration. Increasing allowed leakage limits from up to 1 gpm to up to 5 gpm for all PIVs will not challenge the pressure relief capacity of interfacing systems. This amount of leakage is considered negligible when compared with the capacity of the pressure relief valves. PIV leakage limits apply to leakage rates for individual valves.

The basis for this LCO is the 1975 Reactor Safety Study which identifies potential intersystem loss of coolant accidents (LOCAs) as a significant contributor to the risk of core melt. A subsequent study evaluated various PIV configurations to determine the probability of intersystem LOCAs. This study concluded that periodic leak testing of the PIVs can substantially reduce intersystem LOCA probability.

The previous leakage limit of 1 gpm applied to all valve sizes, is considered arbitrary and is not an indicator of imminent accelerated deterioration or potential valve failure. A study concluded allowable leak rates based on valve size was superior to a single allowable value. The single value imposes an unjustified penalty on the larger valves without providing information on potential valve degradation. In addition, enforcing the single value criteria resulted in higher personnel radiation exposures because larger valves must be repaired in place.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This LCO has been modified to change the allowed leakage limit for RCS PIVs. The modification does not compromise the PIV integrity. The operability requirements of the PIVs and their ability to perform their intended functions are not changed and the change will not alter the probability of occurrence of an accident. The allowed leakage rates are not considered to be significant to the analyses and consequences of an accident.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS26 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not increase the possibility of an intersystem LOCA. The proposed change does not introduce any new equipment, does not involve any physical alterations to any plant equipment, and does not involve any change in the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The LCO permits system operation in the presence of leakage through PIVs in amounts which do not compromise safety. The proposed PIV leakage rate change does not affect the acceptance criteria for any analyzed event. The proposed change does not affect the assumptions used in the safety analyses. The values assumed for the analyses and therefore the results of the analyses remain valid.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 26" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS27
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

The CTS LCO footnote for "COLD SHUTDOWN - Loops Not Filled" has been revised in accordance with NUREG-1431. Improved TS Note 1 replaces CTS footnote provision 3) that states a RHR pump may be de-energized for up to one hour provided the reactor vessel water level is above the reactor flange. The replacement states a RHR pump may be de-energized for up to one hour provided there are no RCS draining operations to further reduce the RCS water inventory. The two other provisions, 1) and 2), required to de-energize a RHR pump are not changed. CTS footnote, provision c., maintains vessel water inventory above the flange level to provide a heat sink while the pump is de-energized. This revised footnote is less restrictive because the water inventory would be less with the level lower than the vessel flange. However, condition 2) requires that the core outlet temperature is maintained at least 10°F below saturation temperature. The condition is also present in the ITS. Monitoring core outlet water temperature during de-energization of the RHR pump for up to one hour assures the water temperature will not reach a condition where the cooling characteristics may change.

An increase in RCS temperature would be anticipated due to decay heat when the RHR pumps are de-energized. NUREG-1431 LCO 3.4.8, Note 1, suspends any draining operation during the time the pumps are not operating, but are OPERABLE and specifies that the core outlet must be maintained at least 10°F below saturation temperature. These conditions maintain RCS inventory and temperature to assure adequate cooling. The RHR pumps are OPERABLE and can be put into operation quickly if needed.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change will not affect any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS27 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The proposed change does not introduce new equipment, does not involve any physical alterations to plant equipment, and does not involve any changes in the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the assumptions or the acceptance criteria for any analyzed event. The values used in the analyses and therefore the results of the analyses remain valid.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 27" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS28
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

This change relaxes the surveillance requirement for verifying the capacity of the pressurizer backup heaters from 92 days to 18 months. This change is consistent with Generic Letter 93-05, "Line-Item Technical Specification Improvements to Reduce Surveillance Requirements for Testing During Power Operation" and Industry traveler TSTF-93, Rev. 1. This change is being proposed to reduce the testing burden and to minimize unnecessary operation of RCS pressure control equipment.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The operability of the pressurizer heaters enhance the capability of the plant to control RCS pressure and establish natural circulation. The purpose of the surveillance requirement is to detect potential pressurizer heater degradation. This is done by periodically demonstrating that pressurizer heaters are capable of producing power at their design rating, by testing the power supply output and by performing electrical checks on heater elements.

Heating elements are simple resistive devices which are not prone to complex failure modes. Moreover, heater banks are made up of a number of individually powered heater elements such that a common mode failure of the elements is unlikely. The normal power supply to the heaters is in use during normal power operations and a failure of the power supply would be immediately detectable independent of the heater surveillance. The low failure rate experience with pressurizer heater elements is indicative that the surveillance interval may be extended without loss in heater reliability. The change is consistent with [DCPP] operating experience. In addition, the frequency of capacity testing the pressurizer heaters is not an assumption or input to any of the initiating events for accidents previously evaluated. While the presence of a steam bubble in the pressurizer is an implicit initial assumption for many safety analyses, a natural circulation shutdown can be accomplished without the use of pressurizer heaters. Thus the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS28 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The method of plant operation is unaffected since the change only affects the frequency of testing. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 28" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS29
10 CFR 50.92 EVALUATION FOR SPECIFIC
LESS RESTRICTIVE TECHNICAL CHANGE

The ACTION requirement has been revised to allow alternate methods for precluding rod withdrawal in lieu of requiring that the RTBs be open. The proposed change allows more flexibility in how rod withdrawal is precluded and is considered less restrictive. However, the intent of using physical plant characteristics to prevent rod withdrawal is not diminished. The specification now acknowledges that the rod control system can be effectively disabled by means other than opening the RTBs.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The specification does not allow administrative control or other means which could be conceived as less stringent. The specification does allow for alternative means to opening the RTBs for precluding rod withdrawal. These means if used would be as effective as opening the RTBs, such as removing power to the Rod Control System. Therefore there should be no increase in the probability or consequences of a previously evaluated accident.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

Inadvertent rod withdrawal accidents have been previously evaluated. This change does not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will preclude rod withdrawal with the same level of assurance that opening of the RTBs provided. No reduction in the margin of safety will result from this change.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS29" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS30 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

The function of the RCS water inventory balance is to monitor for unexplained RCS leakage that could be indicative of degradation in the RCS pressure boundary (RCPB). A RCS water inventory balance cannot be meaningfully performed unless the reactor is operating at steady state conditions. The surveillance for current leakage detection would be revised to allow deferring the RCS water inventory balance in the event of a transient until 12 hours after steady state conditions have been established.

Unplanned plant transients can make obtaining a meaningful inventory balance difficult. Other means of leak detection are available during the deferred water inventory balance to provide independent monitoring for RCS leakage. This change is less restrictive, but is practical and acceptable for safe operation and is consistent with Industry Traveler TSTF-116, Rev. 1.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change will not affect any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. A diversity of leak detection monitoring exists independent of the deferral of performing the water inventory balance. The water inventory balance does not initiate any safeguards actuation signals and is not involved with the operation of any safety-related equipment.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS30 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The water inventory balance is performed using input from existing RCS sensors. The proposed change does not introduce any new equipment, does not involve any physical alterations to any plant equipment, and does not involve any change in the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the assumptions or the acceptance criteria for any analyzed event. The values assumed for the analyses and therefore the results of the analyses remain valid.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS30" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS31 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

With inoperable PORVs (inoperable for the overpressure protection function of both CTS LCOs 3.4.4 and [3.4.9.3]), the requirement of LCO 3.4.4 to shutdown to MODE 4 will result in operation in the Applicability for LCO [3.4.9.3], which also requires the PORVs to be OPERABLE. It is undesirable, from a safety perspective, to intentionally enter the LCO [3.4.9.3] Applicability with inoperable overpressure protection. Therefore, a change is proposed that would only require the shutdown to MODE 3 with RCS $T_{avg} < 500^{\circ}\text{F}$ within 12 hours, where the function of the PORVs to mitigate an SGTR is no longer needed. The proposed change would also include a continuing requirement to undertake actions to restore inoperable valve(s). The risks of entering the LCO [3.4.9.3] Applicability with inoperable PORVs is greater than allowing plant shutdown to terminate at MODE 3 with $T_{avg} < 500^{\circ}\text{F}$. The offsite release of radioactivity in the event of an SGTR is unlikely with RCS $T_{avg} < 500^{\circ}\text{F}$ since the saturation pressure of the reactor coolant would be below the lift pressure of the main steam safety and [SG atmospheric dump] valves. The shutdown requirement for CTS [3.4.8] would similarly be revised. This change is consistent with Industry Traveler TSTF-113.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility, involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Overall protection system performance will remain within the bounds of the previously performed accident analyses since no hardware changes are proposed. The proposed change adds a relaxation to the ACTIONS associated with CTS LCO 3.4.4 by keeping the end point of the shutdown action above the LCO [3.4.9.3] Applicability. No credit is taken for the automatic actuation of the PORVs in MODES 1, 2, or 3. Credit is taken for the manual operation of the PORVs during a SGTR. The capability to manually cycle the PORVs will be unaffected by this change. The release of radioactivity in the event of an SGTR with RCS $T_{avg} < 500^{\circ}\text{F}$ is unlikely since the saturation pressure of the reactor coolant would be less than the lift pressure of the main steam safety and [SG atmospheric dump] valves. Since the Bases for CTS [3.4.8] are also associated with the SGTR, shutdown requirements would be revised to require MODE 3 be reached within 6 hours and T_{avg} reduced to $< 500^{\circ}\text{F}$ within 12 hours. The proposed change to the ACTION termination point of CTS 3.4.4 and the increased Completion Time of CTS [3.4.8] will not affect the probability of any event initiators nor will the proposed change affect the ability of any safety-related equipment to perform its intended function. The proposed change in the ACTION statement will not affect any of the analysis assumptions for any of the accidents previously evaluated. There will be no degradation in the performance of nor an increase in the number of challenges imposed on safety-related equipment assumed to function during an accident situation. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS31 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. The change in ACTION termination point will present no undue burden on the normal method of plant operation. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The release of radioactivity in the event of an SGTR with RCS $T_{avg} < 500^{\circ}\text{F}$ is unlikely since the saturation pressure of the reactor coolant would be less than the lift pressure of the main steam safety and [SG atmospheric dump] valves. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS31" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS32 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

CTS ACTION c for an inoperable block valve requires a inoperable PORV block valve to be restored within one hour or close the PORV and remove power from its solenoid. This change, in accordance with NUREG-1431, requires the PORV to be placed in manual control mode and provides a 72 hour completion time to restore an inoperable block valve.

The action to close the PORV and remove power from its solenoid loses the function of the PORV as it can not be cycled in either the automatic or in the manual control mode. CTS ACTION for an inoperable PORV requires the PORV to be restored in 72 hours. Removing the power from the PORV solenoid makes the valve inoperable and consequently the valve would enter the above ACTION statement. Although the 72 hour limit is provided to restore the PORV, it also works for the block valve restoration. The PORV has been administratively disabled and remains so until the block valve is restored. Therefore the block valve must be restored within 72 hours to avoid shutdown under the PORV completion time.

Although the Completion Times can be seen to be equivalent, the ACTION taken on the PORV is different. The CTS removes the capability of the PORV. The valve can not open and there is no potential of a stuck open PORV without an OPERABLE block valve to isolate the PORV flow path. The ITS removes the automatic actuation capability to avoid the valve opening in the automatic actuation mode when the block valve is inoperable. The PORV however can still function in the manual mode to mitigate events such as the steam generator tube rupture. However, the valve being capable of being opened involves the potential for failure to close. Consequently, this change is considered to be less restrictive.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This proposed change provides 72 hours to restore an inoperable block valve with the associated PORV in the manual control mode. This time is considered to be reasonable based on the unlikelihood of a challenge to the PORVs during this time. Manual actuation of the PORV is unlikely due to the availability of the other PORVs. This change will not affect the initiating events assumed for accidents previously evaluated. This proposed change would not affect the ability of plant equipment to perform its intended function. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS32 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment, does not involve any physical alterations to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change provides for placing a PORV under manual control while a block valve is inoperable for up to 72 hours. Automatic valve actuation is not assumed in accident analyses and the analyses results are not affected. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, it is concluded that the activities associated with NSHC "LS32" resulting from the conversion of current TS 3/4.4 to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS33 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

CTS ACTION for one or more PORV block valves inoperable requires the inoperable block valves to be restored within 1 hour or close the associated PORVs and remove power from their solenoids. This change, in accordance with NUREG-1431, requires the associated PORVs to be placed in manual control mode and provides a 2 hour Completion Time to restore one inoperable block valve and a 72 hour Completion Time to restore all block valves.

The CTS requires block valve restoration within 1 hour or close the associated PORVs and remove power from their solenoids. This action loses the function of the affected PORVs as they can not be cycled in either the automatic or in the manual control mode. CTS ACTION for no Class I PORV OPERABLE requires at least one inoperable Class 1 PORV to be restored within 1 hour and the second one within 72 hours. Removing the power from the PORV solenoids makes the PORVs inoperable and consequently the Class 1 valves would enter the appropriate ACTION as a consequence of the required ACTION for an inoperable block valve. The PORVs would be administratively disabled and if not restored within 1 hour, plant shutdown would be initiated.

The CTS removes the ability of the PORV to function. The valve cannot open and there is no potential of a stuck open PORV without an OPERABLE block valve to isolate the PORV flow path. However, the improved TS removes only the automatic actuation capability to avoid the valve opening in that mode when the block valve is inoperable. The PORV however can still function in the manual mode to support SGTR mitigation. The valve being capable of manual operation involves the potential for failure to close. A failure to close can not be isolated due to the associated block valve being inoperable. The time for which this condition exists is 2 hours in accordance with the ITS whereas the CTS requires block valve restoration in 1 hour. Consequently, this change is considered to be less restrictive.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This proposed change provides 2 hours to restore one inoperable block valve with the associated PORV in the manual control mode. During this time the block valve cannot function to isolate the associated PORV if it were actuated manually and failed to close. This time is considered to be reasonable based on the unlikelihood of a challenge to the PORVs during this time. This change will not affect the initiating events assumed for accidents previously evaluated. This proposed change would not affect the ability of plant equipment to perform its intended function. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS33 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment, does not involve any physical alterations to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change provides for placing PORVs under manual control in the event of inoperable block valves. Automatic valve actuation is not assumed in accident analyses and the analyses results are not affected. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS 33" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS34 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

Consistent with Industry Traveler WOG-60, the requirement to perform the 92 day surveillance of the pressurizer PORV block valves and the 18 month surveillance of the pressurizer PORVs (i.e., perform one complete cycle of each valve) is revised to indicate that the surveillance is only required to be performed in MODES 1 and 2. This allows entry into and operation in MODE 3 prior to performing the SR. This allows the test to be performed in MODE 3 under operating temperature and pressure conditions, prior to entering MODES 1 or 2. This is consistent with the recommendations of Generic Letter 90-06, "Resolution of Generic Issue 70, 'Power-Operated Relief Valve and Block Valve Reliability,' and Generic Issue 94, 'Additional Low-Temperature Overpressure Protection for Light-Water Reactors,' Pursuant to 10CFR50.54(f)," June 25, 1990., which indicates that administrative controls require this test be performed in MODES 3 or 4 to adequately simulate operating temperature and pressure effects on valve operation.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The Pressurizer PORV LCO requires the PORVs and block valves to be OPERABLE for manual operation to mitigate the effects associated with a SGTR. The SGTR is primarily a concern during MODES 1 and 2 because the reactor is producing heat, transients are more likely, and the consequences of an accident are more severe. In MODE 3, due to the stable conditions of the plant, a SGTR event is considered to be highly unlikely. Also, the number of PORVs required for heat removal to mitigate a SGTR event is less in MODE 3. More importantly, this surveillance assures that the PORV will operate when called upon under the design basis conditions. These conditions are more appropriately simulated in MODE 3. While the probability of a SGTR event is not affected by this change the consequences may increase slightly if a SGTR occurred in MODE 3 and one or more untested PORVs failed to operate. The slight increase in consequences is not considered significant. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. No new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced as a result of this change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS34
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. By allowing testing in MODE 3, the proposed change provides additional assurance that the PORVs and block valves will be OPERABLE when called upon by allowing testing closer to the design basis conditions. There will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 34" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS35 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

This change increases the seal injection flow Completion Time from 4 to 72 hours, with a new added verification that at least 100% of the assumed charging flow remains available. The Bases for seal injection flow relate the limit to ensuring adequate charging flow during post-LOCA injection. The revised ACTIONS continue to assure this basis is adequately addressed by providing an ECCS-like Required Action. Specification 3.5.2 allows a 72 hour Completion Time for one or more ECCS subsystems inoperable if at least 100% of the assumed ECCS flow is available. The seal injection flow ACTIONS have been modified so that if the remaining charging flow (with some inoperability in the charging system) is greater than or equal to 100% of the assumed post-LOCA charging flow, 72 hours is allowed to restore OPERABILITY. This change is consistent with Industry Traveler WOG-84.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change revises the completion time for restoring seal injection flow from 4 hours to 72 hours. The basis of this completion time is to ensure availability of the assumed post-LOCA charging flow. To compensate for the increased completion time, a new requirement is added to verify, within 4 hours, that at least 100% of the assumed post-LOCA charging flow is available. Since the change continues to ensure 100% of the assumed charging flow is available, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

There are no hardware changes nor are there any changes in the method by which any safety-related plant system performs its safety function. Since the change continues to ensure 100% of the assumed charging flow is available, no new accident scenarios, transient precursors, failure mechanisms, or limiting single failures are introduced. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS35
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. There will be no effect on the manner in which safety limits or limiting safety system settings are determined nor will there be any effect on those plant systems necessary to assure the accomplishment of protection functions. Since the change continues to ensure 100% of the assumed charging flow is available there will be no impact on any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 35" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS36 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

Consistent with Industry Traveler WOG-87, the requirement to perform the 92 day surveillance of pressurizer PORV block valves (i.e., perform one complete cycle of each block valve) is revised such that it is not required if the block valve is closed to meet ACTION a of the CTS LCO 3.4.4.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change adds a relaxation to the surveillance associated with the pressurizer PORV block valves. The quarterly valve cycling will no longer be required if the block valve is closed per any ACTION of the LCO. No credit is taken for the automatic actuation of the PORV in MODES 1, 2, or 3. Credit is taken for manual operation of the PORVs during the SGTR accident. However, the capability to manually cycle the PORVs will be unaffected by this change. This change will not affect the ability of the block valve to open, if closed to meet ACTION a, in the mitigation of an SGTR. Deferral of the block valve cycling surveillance will not diminish the design capability of the block valve to open against differential pressures that would be present after an SGTR since the block valves are capable of opening against 2485 psig, the safety valve lift pressure, whereas pressurizer pressure decreases after an SGTR []. The lack of quarterly block valve cycling, which could extend to a complete cycle since ACTION a allows continued operation with the block valves closed, does not decrease the likelihood of successful pressurizer relief since power remains available to the block valve motor operator(s) and the surveillance frequency for the PORVs can be as long as 18 months (tested during each cold shutdown per the IST plan). Quarterly cycling could make PORV seat leakage worse. If the block valve were to subsequently be unable to close, this surveillance could unnecessarily challenge RCS and Pressurizer Relief Tank (PRT) integrity. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The only accidents that are potentially associated with this proposed change are those related to a loss of pressurizer relief function. This change does not introduce any new overpressure accidents and the existing analyses remain valid. Thus, the proposed change does not create the possibility of a new or different kind of accident from those previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS36
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The automatic actuation of the PORVs is not credited in the accident analyses for MODES 1, 2, or 3. The PORVs will remain capable of being manually cycled. The margin of safety established by the LCOs also remains unchanged. Thus there is no reduction in the margin of safety from that previously established.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS 36" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

V. GENERIC TECHNICAL NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR2 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

This change in accordance with NUREG-1431 removes the requirement for a special report to be generated and submitted to the NRC following the mitigation of a RCS pressure transient. Reporting to the NRC will be done commensurate with the reporting requirements of 10 CFR 50.72 and 50.73.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change is purely an administrative reporting change and cannot affect any accident probability or consequences. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

This change is purely an administrative reporting change and cannot create any new accident or affect any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

This change is purely an administrative reporting change. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "TR2" resulting from the conversion of current TS 3/4.4 to the improved TS format are concluded to satisfy the no significant hazards consideration standards of 10 CFR 50.92(c) and, accordingly, a no significant hazards consideration finding is justified.

V. GENERIC TECHNICAL NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR3 10 CFR 50.92 EVALUATION FOR SPECIFIC LESS RESTRICTIVE TECHNICAL CHANGE

This proposed revision is to remove reference to specific post-maintenance tests from the CTS. Post-maintenance testing programs are controlled via plant administrative procedures in accordance with Licensee Controlled Document (ITS Section 5.4.1, Final Safety Analysis Report and Operating Quality Assurance Program) commitments to NRC Regulatory Guide 1.33, "Quality Assurance Program Requirements (Operation)" and ANS 3.2-ANSI NIB.7. "Administrative Controls and Quality Assurance for the Operational Phase of Nuclear Power Plants". Specific post-maintenance testing requirements are contingent on the type and scope of maintenance actually performed as well as the availability and viability of test equipment, techniques, etc. Removal of specific testing requirements from the CTS and reliance on normal post-maintenance testing programs addressed by Licensee Controlled Documents allow flexibility to modify testing to address the circumstances of the maintenance performed while still assuring OPERABILITY of equipment returned to service,

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This is an administrative change which removes specific post-maintenance test requirements from the CTS. The testing, or equivalent testing, to assure equipment OPERABILITY prior to return to service would still be done as required by normal plant maintenance retest programs. Therefore, this change would not result in any increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

This is an administrative change and does not create a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

This change is an administrative change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "TR 3" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

3.4.9 Pressurizer

LC0 3.4.9 The pressurizer shall be OPERABLE with:

- a. Pressurizer water level \leq ~~[92]~~ 90%; and B-PS
- b. Two groups of pressurizer heaters OPERABLE with the capacity of each group \geq ~~[125]~~ 150 kW ~~±~~ and capable of being powered from an emergency power supply. B-PS

APPLICABILITY: MODES 1, 2, and 3.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME	
A. Pressurizer water level not within limit.	A.1 Be in MODE 3 with reactor trip breakers open.	6 hours	<u>3.4-31</u>
	<u>AND</u>		
	A.2 Fully insert all rods.	6 hours	
	<u>AND</u>		
	A.3 Place Rod Control System in a condition incapable of rod withdrawal.	6 hours	<u>3.4-31</u>
	<u>AND</u>		
	A.4 Be in MODE 4.	12 hours	
B. One required group of pressurizer heaters inoperable.	B.1 Restore required group of pressurizer heaters to OPERABLE status.	72 hours	

(continued)

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
C. Required Action and associated Completion Time of Condition B not met.	C.1 Be in MODE 3.	6 hours
	<u>AND</u> C.2 Be in MODE 4.	12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.4.9.1 Verify pressurizer water level is \leq [92] <u>90%</u> .	12 hour s <u>B:PS</u>
SR 3.4.9.2 Verify capacity of each required group of pressurizer heaters is \geq [125] <u>150</u> kW.	92 days <u>18</u> months <u>B:PS</u> <u>3.4-17</u>
SR 3.4.9.3 [Verify required pressurizer heaters are capable of being powered from an emergency power supply]	18 months <u>B:PS</u> []

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.10 Pressurizer Safety Valves

LCO 3.4.10 ~~Three~~ pressurizer safety valves shall be OPERABLE with lift settings ≥ 2460 psig and ≤ 2510 psig. B

APPLICABILITY: MODES 1, 2, and 3.
MODE 4 with all RCS cold leg temperatures $> 275^{\circ}\text{F}$. the temperature below which LTOP is required as specified in the PIR. 3.4:10

-----NOTE-----
The lift settings are not required to be within the LCO limits during MODES 3 and 4 for the purpose of setting the pressurizer safety valves under ambient (hot) conditions. This exception is allowed for ≤ 54 hours following entry into MODE 3 provided a preliminary cold setting was made prior to heatup. B

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One pressurizer safety valve inoperable.	A.1 Restore valve to OPERABLE status.	15 minutes
B. Required Action and associated Completion Time not met. <u>OR</u> Two or more pressurizer safety valves inoperable.	B.1 Be in MODE 3. <u>AND</u> B.2 Be in MODE 4 with any RCS cold leg temperatures $\leq 275^{\circ}\text{F}$. the temperature below which LTOP is required as specified in the PIR.	6 hours 12 hours <u>3.4:10</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.4.10.1 Verify each pressurizer safety valve is OPERABLE in accordance with the Inservice Testing Program. Following testing, lift settings shall be within $\pm 1\%$.	In accordance with the Inservice Testing Program

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.11 Pressurizer Power Operated Relief Valves (PORVs)

LCO 3.4.11 Each PORV and associated block valve shall be OPERABLE.

APPLICABILITY MODES 1, 2, and 3.

ACTIONS

- NOTES-----
1. Separate Condition entry is allowed for each PORV.
 2. LCO 3.0.4 is not applicable.
-

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME	
A. One or more PORVs inoperable and capable of being manually cycled.	A.1 Close and maintain power to associated block valve.	1 hour	
B. One or two PORV s inoperable and not capable of being manually cycled.	B.1 Close associated block valve s .	1 hour	<u>B-PS</u>
	<u>AND</u>		<u>B</u>
	B.2 Remove power from associated block valve s .	1 hour	<u>B</u>
	<u>AND</u>		<u>3.4.21</u>
	B.3 Restore the Class I PORV s to OPERABLE status.	72 hours	<u>B-PS</u>

(continued)

ACTIONS (continued)

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.4.11.1	<p>-----NOTE----- 1. Not required to be met performed with block valve closed in accordance with the Required Action of Condition A B or E or Required Actions C.3 and F.4. 2. Only required to be performed in MODES 1 and 2. ----- Perform a complete cycle of each block valve.</p>	<p>3:4:47 3:4:21 3:4:35 92 days</p>
SR 3.4.11.2	<p>-----NOTE----- Only required to be performed in MODES 1 and 2 Perform a complete cycle of each PORV.</p>	<p>3:4:35 [18] months <u>B</u></p>
SR 3.4.11.3	<p>Perform a complete cycle of each solenoid air control valve and check valve on the air accumulators in PORV control systems. Demonstrate OPERABILITY of the safety related nitrogen supply for the Class I PORVs.</p>	<p>[18] months B:PS 18 month <u>3:4:26</u> S</p>
SR 3.4.11.4	<p>NOT USED Verify PORVs and block valves are capable of being powered from emergency power sources.</p>	<p>[18] months B</p>

3.4 REACTOR COOLANT SYSTEM (RCS)

3.4.12 Low Temperature Overpressure Protection (LTOP) System

LCO 3.4.12 An LTOP System shall be OPERABLE with ~~no safety injection pumps and a maximum of a maximum of [one] [high pressure injection (HPI)] pump [and one centrifugal charging pump] capable of injecting into the RCS and the accumulators isolated and one of the following pressure relief capabilities~~ either a or b below B:PS
3:4-49

- a. ~~Two RCS relief valves, as follows:~~
 - ~~1. Two Class I power operated relief valves (PORVs) with lift settings within the limits specified in the PTLR,~~ 3:4-21
 - OR
 - ~~[2. Two residual heat removal (RHR) suction relief valves with setpoints > [436.5] psig and < [463.5] psig. or]~~ B:PS
 - ~~[3. One PORV with a lift setting within the limits specified in the PTLR and one RHR suction relief valve with a setpoint > [436.5] psig and < [463.5] psig].~~ B:PS
- b. The RCS depressurized and an RCS vent of \geq [2.07] square inches. B:PS

-----NOTES-----

- 1. Accumulator isolation is only required when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in the PTLR. 3:4-45
- 2. The limitation for a maximum of one charging pump capable of injecting into the RCS is not required for pump swap operation until 1 hour after completion of pump swap operation. 3:4-45

APPLICABILITY: ~~MODE 4 when all any RCS cold leg temperature are \leq [275]°F the temperature below which LTOP is required as specified in the PTLR~~ 3:4-07
~~MODE 5,~~ 3:4-10
~~MODE 6 when the reactor vessel head is on and the vessel head closure bolts are not fully de-tensioned.~~ 3:4-27

(continued)

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>A. Two One or more [HPI] safety injection pumps capable of injecting into the RCS.</p>	<p>A.1 Initiate action to verify a maximum of [one] [HPI] pump is zero safety injection pumps are capable of injecting into the RCS.</p>	<p>Immediately</p> <p><u>3:4:06</u> <u>B-PS</u></p>
<p>B. Two or more centrifugal charging pumps capable of injecting into the RCS.</p>	<p><u>NOTE</u> Two charging pumps may be capable of injecting into the RCS during pump swap operation for < 15 minutes.</p> <p>B.1 Initiate action to verify a maximum of [one] centrifugal charging pump is capable of injecting into the RCS.</p>	<p>Immediately</p> <p><u>3:4:45</u> <u>B</u> <u>B-PS</u> <u>3:4:06</u></p>
<p>C. An accumulator not isolated when the accumulator pressure is greater than or equal to the maximum RCS pressure for existing cold leg temperature allowed in the PTLR.</p>	<p>C.1 Isolate affected accumulator.</p>	<p>1 hour</p>

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

Methodology For Mark-up of NUREG-1431 Specifications
(Continued)

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.1 RCS Pressure, Temperature, and Flow Departure
from Nucleate Boiling (DNB) Limits

BASES

BACKGROUND

These Bases address requirements for maintaining RCS pressure, temperature, and flow rate within limits assumed in the safety analyses. The safety analyses (Ref. 1) of normal operating conditions and anticipated operational occurrences assume initial conditions within the normal steady state envelope. The limits placed on RCS pressure, temperature, and flow rate ensure that the minimum departure from nucleate boiling ratio (DNBR) will be met for each of the transients analyzed.

The RCS pressure limit is consistent with operation within the nominal operational envelope. Pressurizer pressure indications are averaged to come up with a value for comparison to the limit. A lower pressure will cause the reactor core to approach DNB limits.

The RCS coolant average temperature limit is consistent with full power operation within the nominal operational envelope. Indications of temperature are averaged to determine a value for comparison to the limit. A higher average temperature will cause the core to approach DNB limits.

The RCS flow rate normally remains constant during an operational fuel cycle with all pumps running. The minimum RCS flow limit corresponds to that assumed for DNB analyses and is variable with reactor thermal power down to 90% RTP as shown on Tables 3.4.1-1 and 3.4.1-2. Flow rate indications from the plant computer or RCS flow rate indicators are averaged to come up with a value for comparison to the limit. A lower RCS flow will cause the core to approach DNB limits to be approached.

Operation for significant periods of time outside these DNB the limits on RCS flow, pressurizer pressure and average RCS temperature limits increases the likelihood of a fuel cladding failure if a DNB limited event were to occur.

APPLICABLE
SAFETY

The requirements of this LCO represent the initial conditions for DNB limited transients analyzed in the plant safety analyses (Ref. 1). The safety analyses have shown that transients initiated from the limits of this LCO will result in meeting the DNBR criterion correlation limit of $\geq [1.3]$ ≥ 1.17 (Ref. 2 and 3). This is the acceptance limit for the RCS DNB parameters. Changes to the unit that could impact these parameters must be assessed for their impact on the DNBR criterion. The analyzed transients analyzed for include loss of coolant flow events and dropped or stuck rod events. A key assumption for the analysis of these events is that the core power distribution is within the limits of LCO 3.1.7-6.

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

"Control Bank Insertion Limits"; LCO 3.2.3, "AXIAL FLUX DIFFERENCE (AFD)"; and LCO 3.2.4, "QUADRANT POWER TILT RATIO (QPTR)."

The pressurizer pressure limit of [2200 2197.3] psig and the RCS average temperature limit of [581 584.3]°F correspond to nominal analytical limits of [2205] psig 2250 psia and [595] 577.6°F for Unit 2 (the limiting unit) used in the safety analyses, for the DNB calculation in the reload analyses with allowance for measurement analysis initial consideration uncertainty (38 psi and 6.7°F).

The RCS DNB parameters satisfy Criterion 2 of the NRC Policy Statement 10 CFR 50.36 (c) (2) (ii).

LCO

This LCO specifies limits on the monitored process variables--pressurizer pressure, RCS average temperature, and RCS total flow rate to ensure the core operates within the limits assumed in the safety analyses. Operating within these limits will result in meeting the DNBR criterion in the event of a DNB limited transient.

RCS total flow limits are provided for a RTP range of 90% to 100% on Tables 3.4.1-1 and 3.4.1-2 for Unit 1 and Unit 2 respectively.

The RCS total flow rate limit allows for contains a measurement error of [2.34]%, based on performing a precision heat balance and using the result to normalize calibrate the RCS flow rate indicators. Potential fouling of the feedwater venturi, which might not be detected, could bias the result from the precision heat balance in a non-conservative manner. Therefore, a bias error penalty of [0.1]%, for undetected fouling of the feedwater venturi raises the nominal flow is included in the measurement allowance to [2.34]%, for no fouling. error analysis

Any fouling that might significantly bias the flow rate measurement greater than [0.1]%, can be detected by monitoring and trending various plant performance parameters. If detected, either the effect of the fouling shall be quantified and compensated for in the RCS flow rate measurement or the venturi shall be cleaned to eliminate the fouling.

(Continued)

BASES

LCO (continued) The LCO numerical values for pressure, temperature, and flow rate are given for the measurement location but have not been adjusted for instrument error.

APPLICABILITY In MODE 1, the limits on pressurizer pressure, RCS coolant average temperature, and RCS flow rate must be maintained during steady state operation in order to ensure DNBR criteria will be met in the event of an unplanned loss of forced coolant flow or other DNB limited transient. In all other MODES, the power level is low enough that DNB is not a concern.

A Note has been added to indicate the limit on pressurizer pressure is not applicable during short term operational ~~pressure~~ transients such as a THERMAL POWER ramp increase > 5% RTP per minute or a THERMAL POWER step increase > 10% RTP. These conditions represent short term perturbations where actions to control pressure variations might be counterproductive. Also, since they represent transients initiated from power levels < 100% RTP, an increased DNBR margin exists to offset the temporary pressure variations.

Another set of limits on DNB related parameters is provided in SL 2.1.1, "Reactor Core SLs." Those limits are less restrictive than the limits of this LCO, but violation of a Safety Limit (SL) merits a stricter, more severe Required Action. Should a violation of this LCO occur, the operator must check whether or not an SL may have been exceeded.

ACTIONS

A.1

RCS pressure and RCS average temperature are controllable and measurable parameters. With one or both of these parameters not within LCO limits, action must be taken to restore parameter(s).

RCS total flow rate is not a controllable parameter and is not expected to vary during steady state operation. If the indicated RCS total flow rate is below the LCO limit, power must be reduced, as required by Required Action B.1, to restore DNB margin and ~~reduce~~ the potential for violation of the accident analysis ~~limits~~.

The 2 hour Completion Time for restoration of the parameters provides sufficient time to adjust plant parameters, to determine the cause for the off normal

(Continued)

BASES

ACTIONS
(continued)

condition, and to restore the readings within limits, and is based on plant operating experience.

B.1

If Required Action A.1 is not met within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 2 within 6 hours. In MODE 2, the reduced power condition reduces the potential for violation of the accident analysis limits. The Completion Time of 6 hours is reasonable to reach the required plant conditions in an orderly manner.

SURVEILLANCE
REQUIREMENTS

SR 3.4.1.1

Since Required Action A.1 allows a Completion Time of 2 hours to restore parameters that are not within limits, the 12 hour Surveillance Frequency for pressurizer pressure is sufficient to ensure the pressure can be restored to a normal operation, steady state condition following load changes and other expected transient operations. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess for potential degradation and to verify operation is within safety analysis assumptions.

SR 3.4.1.2

Since Required Action A.1 allows a Completion Time of 2 hours to restore parameters that are not within limits, the 12 hour Surveillance Frequency for RCS average temperature is sufficient to ensure the temperature can be restored to a normal operation, steady state condition following load changes and other expected transient operations. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess for potential degradation and to verify operation is within safety analysis assumptions.

SR 3.4.1.3

The 12 hour Surveillance Frequency for the indicated RCS total flow rate is performed using the installed flow instrumentation. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess potential degradation and to verify operation within safety analysis assumptions. The term "indicated RCS total flow" is used to distinguish between the "measured RCS total flow" determined in SR 3.4.1.4.

Sr 3.4.1.4

Measurement of RCS total flow rate by performance of a precision calorimetric heat balance or other acceptable method once every [18] months allows the installed RCS flow instrumentation to be normalized and verifies the actual RCS flow rate is greater than or equal to the minimum required RCS flow rate.

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

The Frequency of ~~[18]~~ months reflects the importance of verifying flow after a refueling outage when the core has been altered, which may have caused an alteration of flow resistance. Flow verification demonstrates that ~~setpoints are relevant and RCS flow resistance is within limits.~~

~~This SR is modified by a Note that allows entry into MODE 1, without having performed the SR, and placement of the unit in the best condition for performing the SR. The Note states that the SR is not required to be performed until 24 hours after > [90%] RTP. This exception is appropriate since the heat balance requires the plant to be at a minimum of [90%] RTP to obtain the stated RCS flow accuracies. The Surveillance shall be performed within 24 hours after reaching [90%] RTP.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.2 RCS Minimum Temperature for Criticality

BASES

BACKGROUND This LCO is based upon meeting several major considerations before the reactor can be made critical and while the reactor is critical.

The first consideration is moderator temperature coefficient (MTC). LCO 3.1.3, "Moderator Temperature Coefficient (MTC)." In the transient and accident analyses, the MTC is assumed to be in a range from slightly positive to negative and the operating temperature is assumed to be within the nominal operating envelope while the reactor is critical. The LCO on minimum temperature for criticality helps ensure the plant is operated consistent with these assumptions.

The second consideration is the protective instrumentation. Because certain protective instrumentation (e.g., excore neutron detectors) can be affected by moderator temperature, a temperature value within the nominal operating envelope is chosen to ensure proper indication and response while the reactor is critical.

The third consideration is the pressurizer operating characteristics. The transient and accident analyses assume that the pressurizer is within its normal startup and operating range (i.e., saturated conditions and steam bubble present). It is also assumed that the RCS temperature is within its normal expected range for startup and power operation. Since the density of the water, and hence the response of the pressurizer to transients, depends upon the initial temperature of the moderator, a minimum value for moderator temperature within the nominal operating envelope is chosen.

The fourth consideration is that the reactor vessel is above its minimum nil ductility reference temperature when the reactor is critical.

**APPLICABLE
SAFETY
ANALYSES**

Although the RCS minimum temperature for criticality is not itself an initial condition assumed in Design Basis Accidents (DBAs), the closely aligned temperature for hot zero power (HZP) is a process variable that is an initial condition of DBAs, such as the rod cluster control assembly (RCCA) withdrawal, RCCA ejection, and main steam line break accidents performed at zero power that either assumes the failure of, or presents a challenge to, the integrity of a fission product barrier.

All low power safety analyses assume initial RCS loop temperatures \geq the HZP temperature of 547°F (Ref. 1). The minimum temperature for criticality limitation provides a small band, 6°F, for critical operation below HZP. This band allows critical operation below HZP during plant startup and does not adversely affect any safety analyses since the MTC is not significantly affected by the small temperature difference between HZP and the minimum temperature for criticality.

(Continued)

BASES

APPLICABLE SAFETY ANALYSES The RCS minimum temperature for criticality satisfies Criterion 2 of the NRC Policy Statement 10 CFR 50.36 (c) (2) (11).

(continued)

LCO Compliance with the LCO ensures that the reactor will not be made or maintained critical ($k_{eff} \geq 1.0$) at a ~~with an operating loop~~ temperature less than a small band below the HZP temperature, which is assumed in the safety analysis. Failure to meet the requirements of this LCO may produce initial conditions inconsistent with the initial conditions assumed in the safety analysis.

APPLICABILITY In MODE 1 and MODE 2 with $k_{eff} \geq 1.0$, LCO 3.4.2 is applicable since the reactor can only be critical ($k_{eff} \geq 1.0$) in these MODES.

The special test exception of LCO 3.1.8, "PHYSICS TESTS, Exceptions, MODE 2" permits PHYSICS TESTS to be performed at $\leq 5\%$ RTP with RCS loop average temperatures slightly lower than normally allowed so that fundamental nuclear characteristics of the core can be verified. In order for nuclear characteristics to be measured, it may be necessary to operate outside the normal restrictions of this LCO. For example, to measure the MTC at beginning of cycle, it is necessary to allow RCS loop average temperatures to fall below $T_{no\ load}$, which may cause RCS loop average temperatures to fall below the temperature limit of this LCO.

ACTIONS A.1

If the parameters that are outside the limit cannot be restored, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE ~~3 2~~ with $k_{eff} < 1.0$ within 30 minutes. Rapid reactor shutdown can be readily and practically achieved within a 30 minute period. The allowed time is reasonable, based on operating experience, to reach MODE ~~3 2~~ with $k_{eff} < 1.0$ in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS SR 3.4.2.1

~~RCS loop average temperature is required to be verified at or above [541]°F every 30 minutes when [T_{avg} - T_{cor} deviation, low low T_{avg}] alarm not reset and any RCS loop T_{avg} < [547]°F.~~

~~The Note modifies the SR. When any RCS loop average temperature is < [547]°F and the [T_{avg} - T_{cor} deviation, low low T_{avg}] alarm is alarming, RCS loop average temperatures could fall below the LCO requirement without additional warning. The SR to verify RCS loop average temperatures every 30 minutes is frequent enough to prevent the inadvertent violation of the LCO.~~

(Continued)

BASES

RCS loop average temperature is required to be verified at or above 541 °F every 12 hours. The SR to verify RCS loop average temperatures every 12 hours is frequent enough to prevent inadvertent violation of the LCO and takes into account indications and alarms that are continuously available to the operator in the control room. If the $T_{avg} - T_{set}$ deviation were to alarm, the specific alarm response procedure would provide an increased frequency of monitoring. Following the clearance of the alarm, the frequency returns to 12 hours to monitor RCS T_{avg} .

REFERENCES 1. FSAR, Section [15.0.3] Chapter 15.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.3 RCS Pressure and Temperature (P/T) Limits

BASES

BACKGROUND All components of the RCS are designed to withstand effects of cyclic loads due to system pressure and temperature changes. These loads are introduced by startup (heatup) and shutdown (cooldown) operations, power transients, and reactor trips. This LCO limits the pressure and temperature changes during RCS heatup and cooldown, within the design assumptions and the stress limits for cyclic operation.

The ~~PRESSURE TEMPERATURE LIMITS REPORT~~ (PTLR) contains ~~pressure/temperature (P/T) limit curves for heatup, cooldown, inservice leak and hydrostatic (ISLH) testing, and data for the maximum rate of change of reactor coolant temperature.~~

Each P/T limit curve defines an acceptable region for normal operation. The usual use of the curves is operational guidance during heatup or cooldown maneuvering, when pressure and temperature indications are monitored and compared to the applicable curve to determine that operation is within the allowable region.

The LCO ~~references the PTLR which~~ establishes operating limits that provide a margin to brittle failure of the reactor vessel and piping of the reactor coolant pressure boundary (RCPB). The vessel is the component most subject to brittle failure, and the ~~LCO-PTLR~~ limits apply mainly to the vessel. The limits do not apply to the pressurizer, which has different design characteristics and operating functions.

10 CFR 50, Appendix G (Ref. 2), requires the establishment of P/T limits for specific material fracture toughness requirements of the RCPB materials: ~~Reference 2 requires an adequate margin to brittle failure during normal operation, anticipated operational occurrences, and system hydrostatic tests. It mandates the use of the American Society of Mechanical Engineers (ASME) Code, Section III, Appendix G (Ref. 3). The NRC reviewed and approved methodology to be applied to determine P/T Limits is documented in the Administrative Controls Section 5.6.6.~~

The neutron embrittlement effect on the material toughness is reflected by increasing the nil ductility reference temperature (RT_{NOT}) as exposure to neutron fluence increases.

The actual shift in the RT_{NOT} of the vessel material will be established periodically by removing and evaluating the irradiated reactor vessel material specimens, in accordance with ~~ASTM E 195 (Ref. 4) and Appendix H of 10 CFR 50 (Ref. 5) with the methodology identified in Section 5.6.6. The operating P/T limit curves will be adjusted, as necessary, based in agreement with the evaluation findings based and the recommendations of Regulatory Guide 1.99 (Ref. 6), on methods used in the PTLR.~~

(Continued)

BASES

BACKGROUND
(continued)

The P/T limit curves are composite curves established by superimposing limits derived from stress analyses of those portions of the reactor vessel and head that are the most restrictive. At any specific pressure, temperature, and temperature rate of change, one location within the reactor vessel will dictate the most restrictive limit. Across the span of the P/T limit curves, different locations are more restrictive, and, thus, the curves are composites of the most restrictive regions.

The heatup curve represents a different set of restrictions than the cooldown curve because the directions of the thermal gradients through the vessel wall are reversed. The thermal gradient reversal alters the location of the tensile stress between the outer and inner walls.

The criticality limit curve includes the Reference 2 requirement that it be $\geq 40^\circ\text{F}$ above the heatup curve or the cooldown curve, and not less than the minimum permissible temperature for ISLH testing. However, the criticality curve is not operationally limiting; a more restrictive limit exists in LCO 3.4.2, "RCS Minimum Temperature for Criticality."

The consequence of violating the LCO limits is that the RCS has been operated under conditions that can result in brittle failure of the RCPB, possibly leading to a nonisolable leak or loss of coolant accident. In the event these limits are exceeded, an evaluation must be performed to determine the effect on the structural integrity of the RCPB components. The ASME Code, Section XI, Appendix E (Ref. 7), provides a recommended methodology for evaluating an operating event that causes an excursion outside the limits.

APPLICABLE
SAFETY
ANALYSES

The P/T limits are not derived from Design Basis Accident (DBA) analyses. They are prescribed during normal operation to avoid encountering pressure, temperature, and temperature rate of change conditions that might cause undetected flaws to propagate and cause nonductile failure of the RCPB, an unanalyzed condition. Administrative Controls Section 5.6.6 establishes identifies the NRC reviewed and approved methodology for determining the P/T limits. Although the P/T limits are not derived from any DBA, the P/T limits are acceptance limits since they preclude operation in an unanalyzed condition.

RCS P/T limits satisfy Criterion 2 of NRC Policy Statement 10 CFR 50.36(c) (2)(ii).

(Continued)

BASES

LCO

The two elements of this LCO are:

- a. The limit curves for heatup, cooldown, and ISLH testing; and
- b. Limits on the rate of change of temperature.

The LCO limits apply to all components of the RCS, except the pressurizer. These limits define allowable operating regions and permit a large number of operating cycles while providing a wide margin to nonductile failure.

The limits for the rate of change of temperature control the thermal gradient through the vessel wall and are used as inputs for calculating the heatup, cooldown, and ISLH testing P/T limit curves. Thus, the LCO for the rate of change of temperature restricts stresses caused by thermal gradients and also ensures the validity of the P/T limit curves.

Violating the LCO limits places the reactor vessel outside of the bounds of the stress analyses and can increase stresses in other RCPB components. The consequences depend on several factors, as follow:

- a. The severity of the departure from the allowable operating P/T regime or the severity of the rate of change of temperature;
- b. The length of time the limits were violated (longer violations allow the temperature gradient in the thick vessel walls to become more pronounced); and
- c. The existences, sizes, and orientations of flaws in the vessel material.

APPLICABILITY

The RCS P/T limits LCO provides a definition of acceptable operation for prevention of nonductile failure in accordance with 10 CFR 50, Appendix G (Ref. 2). Although the P/T limits were developed to provide guidance for operation during heatup or cooldown (MODES 3, 4, and 5) or ISLH testing, their Applicability is at all times in keeping with the concern for nonductile failure. The limits do not apply to the pressurizer.

During MODES 1 and 2, other Technical Specifications provide limits for operation that can be more restrictive than or can supplement these P/T limits. LCO 3.4.1, "RCS Pressure, Temperature, and Flow Departure from Nucleate Boiling (DNB) Limits"; LCO 3.4.2, "RCS Minimum Temperature for Criticality"; and ~~Safety Limit 2.1~~, "Safety Limits," also provide operational restrictions for pressure and temperature and maximum pressure. Furthermore, MODES 1 and 2 are above the temperature range of concern for nonductile failure, and stress analyses have been performed for normal maneuvering profiles, such as power ascension or descent.

(Continued)

BASES

ACTIONS

A.1 and A.2

Operation outside the P/T limits during MODE 1, 2, 3, or 4 must be corrected so that the RCPB is returned to a condition that has been verified by stress analyses.

The 30 minute Completion Time reflects the urgency of restoring the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in this time in a controlled manner.

Besides restoring operation within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify the RCPB integrity remains acceptable and must be completed before continuing operation. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, new analyses, or inspection of the components.

ASME Code, Section XI, Appendix E (Ref. 3), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beltline.

The 72 hour Completion Time is reasonable to accomplish the evaluation. The evaluation for a mild violation is possible within this time, but more severe violations may require special, event specific stress analyses or inspections. A favorable evaluation must be completed before continuing to operate.

Condition A is modified by a Note requiring Required Action A.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action A.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

B.1 and B.2

If a Required Action and associated Completion Time of Condition A are not met, the plant must be placed in a lower MODE because either the RCS remained in an unacceptable P/T region for an extended period of increased stress or a sufficiently severe event caused entry into an unacceptable region. Either possibility indicates a need for more careful examination of the event, best accomplished with the RCS at reduced pressure and temperature. In reduced pressure and temperature conditions, the possibility of propagation with undetected flaws is decreased.

If the required restoration activity cannot be accomplished within 30 minutes, Required Action B.1 and Required Action B.2 must be implemented to reduce pressure and temperature.

(Continued)

BASES

ACTIONS
(continued)

If the required evaluation for continued operation cannot be accomplished within 72 hours or the results are indeterminate or unfavorable, action must proceed to reduce pressure and temperature as specified in Required Action B.1 and Required Action B.2. (Note that Action B.1 is not required when in MODE 4.) A favorable evaluation must be completed and documented before returning to operating pressure and temperature conditions.

Pressure and temperature are reduced by bringing the plant to MODE 3 within 6 hours and to MODE 5 with RCS pressure < 500 psig within 36 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

C.1 and C.2

Actions must be initiated immediately to correct operation outside of the P/T limits at times other than when in MODE 1, 2, 3, or 4, so that the RCPB is returned to a condition that has been verified by stress analysis.

The immediate Completion Time reflects the urgency of initiating action to restore the parameters to within the analyzed range. Most violations will not be severe, and the activity can be accomplished in this time in a controlled manner.

Besides restoring operation within limits, an evaluation is required to determine if RCS operation can continue. The evaluation must verify that the RCPB integrity remains acceptable and must be completed prior to entry into MODE 4. Several methods may be used, including comparison with pre-analyzed transients in the stress analyses, or inspection of the components.

ASME Code, Section XI, Appendix E (Ref. 73), may be used to support the evaluation. However, its use is restricted to evaluation of the vessel beline.

Condition C is modified by a Note requiring Required Action C.2 to be completed whenever the Condition is entered. The Note emphasizes the need to perform the evaluation of the effects of the excursion outside the allowable limits. Restoration alone per Required Action C.1 is insufficient because higher than analyzed stresses may have occurred and may have affected the RCPB integrity.

SURVEILLANCE
REQUIREMENTSSR 3.4.3.1

Verification that operation is within the PTLR limits is required every 30 minutes when RCS pressure and temperature conditions are undergoing planned changes. This Frequency is considered reasonable in view of the control room indication available to monitor RCS status. Also, since temperature rate of

(Continued)

BASES

change limits are specified in hourly increments, 30 minutes permits assessment and correction for minor deviations within a reasonable time.

Surveillance for heatup, cooldown, or ISLH testing may be discontinued when the definition given in the relevant plant procedure for ending the activity is satisfied.

This SR is modified by a Note that only requires this SR to be performed during system heatup, cooldown, and ISLH testing. No SR is given for criticality operations because LCO 3.4.2 contains a more restrictive requirement.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.4 RCS Loops - MODES 1 and 2

BASES

BACKGROUND The primary function of the RCS is removal of the heat generated in the fuel due to the fission process, and transfer of this heat, via the steam generators (SGs), to the secondary plant.

The secondary functions of the RCS include:

- a. Moderating the neutron energy level to the thermal state, to increase the probability of fission;
- b. Improving the neutron economy by acting as a reflector;
- c. Carrying the soluble neutron poison, boric acid;
- d. Providing a second barrier against fission product release to the environment; and
- e. Removing the heat generated in the fuel due to fission product decay following a unit shutdown.

The reactor coolant is circulated through ~~four~~ loops connected in parallel to the reactor vessel, each containing an SG, a reactor coolant pump (RCP), and appropriate flow and temperature instrumentation for both control and protection. The reactor vessel contains the clad fuel. The SGs provide the heat sink to the isolated secondary coolant. The RCPs circulate the coolant through the reactor vessel ~~core~~ and SGs at a sufficient rate to ensure proper heat transfer and prevent fuel damage. This forced circulation of the reactor coolant ensures mixing of the coolant for proper boration and chemistry control.

APPLICABLE
SAFETY
ANALYSES

Safety analyses contain various assumptions for the design bases accident initial conditions including RCS pressure, RCS temperature, reactor power level, core parameters, and safety system setpoints. The important aspect for this LCO is the reactor coolant forced flow rate, which is represented by the number of RCS loops in service.

~~Both transient and steady state analyses have been performed to establish the effect of flow on the departure from nucleate boiling (DNB). The transient and accident analyses for the plant have been performed assuming [four] RCS loops are in operation. The majority of the plant safety analyses are~~

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

~~based on initial conditions at high core power or zero power. The accident analyses that are most important to RCP operation are the [four] pump coastdown, single pump locked rotor, single pump (broken shaft or coastdown), and rod withdrawal events (Ref. 1).~~

~~Steady state DNB analysis has been performed for the [four] RCS loop operation. For [four] RCS loop operation, the steady state DNB analysis, which generates the pressure and temperature Safety Limit (SL) (i.e., the departure from nucleate boiling ratio (DNBR) limit) assumes a maximum power level of 109% RTP. This is the design overpower condition for [four] RCS loop operation. The value for the accident analysis setpoint of the nuclear overpower (high flux) trip is 107% and is based on an analysis assumption that bounds possible instrumentation errors. The DNBR limit defines a locus of pressure and temperature points that result in a minimum DNBR greater than or equal to the critical heat flux correlation limit.~~

~~All of the accident/safety analyses performed at RTP assume that all four RCS loops are in operation as an initial condition. Some accident/safety analyses have been performed at zero power conditions assuming only two RCS loops are in operation to conservatively bound lower modes of operation. The uncontrolled Rod Control Cluster Assembly (RCCA) Bank withdrawal from subcritical event is included in this category. While all accident/safety analyses performed at full rated power assume that all RCS loops are in operation, selected events examine the effects resulting from a loss of RCP operation. These include the complete and partial loss of forced RCS flow, RCP rotor seizure, and RCP shaft break events. For each of these events, it is demonstrated that all the applicable safety criteria are satisfied. For the remaining accident/safety analyses, operation of all four RCS loops during the transient up to the time of reactor trip is assured thereby ensuring that all the applicable acceptance criteria are satisfied. Those transients analyzed beyond the time of reactor trip were examined assuming that a loss of offsite power occurs which results in the RCPs coasting down.~~

The plant is designed to operate with all RCS loops in operation to maintain DNBR above the SL ~~Safety Limit~~ value during all normal operations and anticipated transients. By ensuring heat transfer in the nucleate boiling region, adequate heat transfer is provided between the fuel cladding and the reactor coolant.

RCS Loops - MODES 1 and 2 satisfy Criterion 2 of NRC Policy Statement ~~10 CFR 50.36 (c) (2) (ii)~~.

LCO

The purpose of this LCO is to require an adequate forced flow rate for core heat removal. Flow is represented by the number of RCPs in operation for removal of heat by the SGs. To meet safety analysis acceptance criteria for DNB, ~~four~~ pumps are required at rated power.

(Continued)

BASES

LCO (continued) An OPERABLE RCS loop consists of an ~~one~~ OPERABLE RCP in operation providing forced flow for heat transport and an the associated SG, OPERABLE in accordance with the Steam Generator Tube Surveillance Program, with a water level within the limits specified in SR 3.4.5.2, except for operational transients. A RCP is OPERABLE if it is capable of being powered and is able to provide forced flow if required.

APPLICABILITY In MODES 1 and 2, the reactor is critical and thus has the potential to produce maximum THERMAL POWER. Thus, to ensure that the assumptions of the accident analyses remain valid, all RCS loops are required to be OPERABLE and in operation in these MODES to prevent DNB and core damage.

The decay heat production rate is much lower than the full power heat rate. As such, the forced circulation flow and heat sink requirements are reduced for lower, noncritical MODES as indicated by the LCOs for MODES 3, 4, and 5.

Operation in other MODES is covered by:

LCO 3.4.5, "RCS Loops-MODE 3";
LCO 3.4.6, "RCS Loops-MODE 4";
LCO 3.4.7, "RCS Loops-MODE 5, Loops Filled";
LCO 3.4.8, "RCS Loops-MODE 5, Loops Not Filled";
LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation-High Water Level" (MODE 6); and
LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation-Low Water Level" (MODE 6).

ACTIONS

A.1

If the requirements of the LCO are not met, the Required Action is to reduce power and bring the plant to MODE 3. This lowers power level and thus reduces the core heat removal needs and minimizes the possibility of violating DNB limits.

The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging safety systems.

SURVEILLANCE
REQUIREMENTSSR 3.4.4.1

This SR requires verification every 12 hours that each RCS loop is in operation. Verification may include flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal while maintaining the margin to DNB. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the control room to monitor RCS loop performance.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.5 RCS Loops - MODE 3

BASES

BACKGROUND In MODE 3, the primary function of the reactor coolant is removal of decay heat and transfer of this heat, via the steam generator (SG), to the secondary plant fluid. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

The reactor coolant is circulated through four RCS loops, connected in parallel to the reactor vessel, each containing an SG, a reactor coolant pump (RCP), and appropriate flow, pressure, level, and temperature instrumentation for control, protection, and indication. The reactor vessel contains the clad fuel. The SGs provide the heat sink. The RCPs circulate the water through the reactor vessel core and SGs at a sufficient rate to ensure proper heat transfer and prevent fuel damage.

In MODE 3, RCPs are used to provide forced circulation for heat removal during heatup and cooldown. The MODE 3 decay heat removal requirements are low enough that a single RCS loop with one RCP running is sufficient to remove core decay heat. However, two RCS loops are required to be OPERABLE to ensure redundant capability for decay heat removal.

APPLICABLE SAFETY ANALYSES

~~Whenever the reactor trip breakers (RTBs) are in the closed position and the Control Rod Drive Mechanisms (CRDMs) are energized, an inadvertent rod withdrawal from subcritical, resulting in a power excursion, is possible. Such a transient could be caused by a malfunction of the Rod Control System. In addition, the possibility of a power excursion due to the ejection of an inserted control rod is possible with the breakers closed or open. Such a transient could be caused by the mechanical failure of a CRDM.~~

Therefore, in MODE 3 with RTBs in the closed position and the Rod Control System capable of rod withdrawal, accidental control rod withdrawal from subcritical is postulated and requires at least two RCS loops to be OPERABLE and in operation to ensure that the accident analyses limits are met. For those conditions when the Rod Control System is not capable of rod withdrawal, two RCS loops are required to be OPERABLE, but only one RCS loop is required to be in operation to be consistent with MODE 3 accident analyses.

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

Failure to provide decay heat removal may result in challenges to a fission product barrier. The RCS loops are part of the primary success path that functions or actuates to prevent or mitigate a Design Basis Accident or transient that either assumes the failure of, or presents a challenge to, the integrity of a fission product barrier.

RCS Loops-MODE 3 satisfy Criterion 3 of NRC Policy Statement ~~10 CFR 50.36 (c) (2) (ii)~~

LCO

The purpose of this LCO is to require that at least ~~two~~ RCS loops be OPERABLE. In MODE 3 with the RTBs in the closed position and Rod Control System capable of rod withdrawal, ~~two~~ RCS loops must be in operation. ~~Two~~ RCS loops are required to be in operation in MODE 3 with RTBs closed and the Rod Control System capable of rod withdrawal due to the postulation of a power excursion because of an inadvertent control rod withdrawal. The required number of RCS loops in operation ensures that the Safety Limit criteria will be met for all of the postulated accidents.

~~With the RTBs in the open position, or the CRDMs de-energized, the Rod Control System is not capable of rod withdrawal; therefore, only one RCS loop in operation is necessary to ensure removal of decay heat from the core and homogenous boron concentration throughout the RCS. An additional RCS loop is required to be OPERABLE to ensure that redundancy for heat removal is maintained. safety analyses limits are met.~~

The Note permits all RCPs to be ~~removed from operation~~ de-energized for ≤ 1 hour per 8 hour period. The purpose of the Note is to perform tests that are ~~required to be performed without flow or pump noise, designed to validate various accident analyses values.~~ One of these tests is validation of the pump coastdown curve used as input to a number of accident analyses including a loss of flow accident. This test is generally performed in MODE 3 during the initial startup testing program, and as such should only be performed once. If, however, changes are made to the RCS that would cause a change to the flow characteristics of the RCS, the input values of the coastdown curve must be revalidated by conducting the test again. ~~Another test performed during the startup testing program is the validation of rod drop times during cold conditions, both with and without flow.~~

~~The no flow test may be performed in MODE 3, 4, or 5 and requires that the pumps be stopped for a short period of time. The Note permits the de-energizing of the pumps in order to perform this test and validate the assumed analysis values. As with the validation of the pump coastdown curve, this test should be performed only once unless the flow characteristics of the RCS are changed. The 1 hour time period specified is adequate to perform the desired tests, and operating experience has shown that boron stratification is not a problem during this short period with no forced flow.~~

(Continued)

BASES

LCO (continued) Utilization of the Note is permitted provided the following conditions are met, along with any other conditions imposed by initial-startup test procedures:

- a. No operations are permitted that would dilute the RCS boron concentration, thereby maintaining the margin to criticality. Boron reduction is prohibited because a uniform concentration distribution throughout the RCS cannot be ensured when in natural circulation; and
- b. Core outlet temperature is maintained at least 10°F below saturation temperature, so that no vapor bubble may form and possibly cause a natural circulation flow obstruction.

An OPERABLE RCS loop consists of one OPERABLE RCP and one OPERABLE SG in accordance with the Steam Generator Tube Surveillance Program, which has the minimum water level specified in SR 3.4.5.2. An RCP is OPERABLE if it is capable of being powered and is able to provide forced flow if required.

APPLICABILITY In MODE 3, this LCO ensures forced circulation of the reactor coolant to remove decay heat from the core and to provide proper boron mixing. The most stringent condition of the LCO, that is, two RCS loops OPERABLE and two RCS loops in operation, applies to MODE 3 with RTBs in the closed position, the Rod Control System capable of rod withdrawal. The least stringent condition, that is, two RCS loops OPERABLE and one RCS loop in operation, applies to MODE 3 with the RTBs open the Rod Control System not capable of rod withdrawal.

Operation in other MODES is covered by:

- LCO 3.4.4, "RCS Loops-MODES 1 and 2";
- LCO 3.4.6, "RCS Loops-MODE 4";
- LCO 3.4.7, "RCS Loops-Mode 5, Loops Filled";
- LCO 3.4.8, "RCS Loops-Mode 5, Loops Not Filled";
- LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation-High Water Level" (MODE 6); and
- LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation-Low Water Level" (MODE 6).

ACTIONS

A.1

If one required RCS loop is inoperable, redundancy for heat removal is lost. The Required Action is restoration of the required RCS loop to OPERABLE status within the Completion Time of 72 hours. This time allowance is a justified period to be without the redundant, nonoperating loop because a single loop in operation has a heat transfer capability greater than that needed to remove the decay heat produced in the reactor core and because of the low probability of a failure in the remaining loop occurring during this period.

BASES

ACTIONS
(continued)B.1

If restoration is not possible within 72 hours, the unit must be brought to MODE 4. In MODE 4, the unit may be placed on the Residual Heat Removal System. The additional Completion Time of 12 hours is compatible with required operations to achieve cooldown and depressurization from the existing plant conditions in an orderly manner and without challenging plant systems.

C.1 and C.2

If the required RCS loop is not in operation and the Rod Control System is capable of rod withdrawal, the Required Action is either to restore the required RCS loop to operation or to place the Rod Control System in a condition incapable of rod withdrawal (e.g., de-energize all CRDMs by opening the RTBs or de-energizing the motor generator (MG) sets.) When the Rod Control System is capable of rod withdrawal, it is postulated that a power excursion could occur in the event of an inadvertent control rod withdrawal. This mandates having the heat transfer capacity of two RCS loops in operation. If only one loop is in operation, the Rod Control System must not be capable of rod withdrawal. The Completion Time of 1 hour to restore the required RCS loop to operation or to defeat the Rod Control System is adequate to perform these operations in an orderly manner without exposing the unit to risk for an undue time period.

D.1, D.2, and D.3

If four RCS loops are inoperable or no RCS loop is in operation, except as during conditions permitted by the Note in the LCO section, place the Rod Control System in a condition incapable of rod withdrawal (e.g., all CRDMs must be de-energized by opening the RTBs or de-energizing the MG sets.) All operations involving a reduction of RCS boron concentration must be suspended, and action to restore one of the RCS loops to OPERABLE status and operation must be initiated. Boron dilution requires forced circulation for proper mixing, and opening

(Continued)

BASES

the RTBs or de-energizing the MG sets removes the possibility of an inadvertent rod withdrawal.

ACTIONS
(continued) The immediate Completion Time reflects the importance of maintaining operation for heat removal. The action to restore must be continued until one loop is restored to OPERABLE status and operation.

SURVEILLANCE
REQUIREMENTS

SR 3.4.5.1

This SR requires verification every 12 hours that the required loops are in operation. Verification may include flow rate, temperature, ~~or~~ and pump status monitoring, which help ensure that forced flow is providing heat removal. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the control room to monitor RCS loop performance.

SR 3.4.5.2

SR 3.4.5.2 requires verification of SG OPERABILITY. SG OPERABILITY is verified by ensuring that the secondary side narrow range water level is $\geq 15\%$ for required RCS loops. If the SG secondary side narrow range water level is $< 15\%$, the tubes may become uncovered and the associated loop may not be capable of providing the heat sink for removal of the decay heat. The 12 hour Frequency is considered adequate in view of other indications available in the control room to alert the operator to a loss of SG level.

SR 3.4.5.3

Verification that the required RCPs are OPERABLE ensures that safety analyses limits are met. The requirement also ensures that an additional RCP can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power availability to the required RCPs.

REFERENCES None.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.6 RCS Loops - MODE 4

BASES

BACKGROUND In MODE 4, the primary function of the reactor coolant is the removal of decay heat and the transfer of this heat to either the steam generator (SG) secondary side coolant or the component cooling water via the residual heat removal (RHR) heat exchangers. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

The reactor coolant is circulated through four RCS loops connected in parallel to the reactor vessel; each loop containing an SG, a reactor coolant pump (RCP), and appropriate flow, pressure, level, and temperature instrumentation for control, protection, and indication. The RCPs circulate the coolant through the reactor vessel core and SGs at a sufficient rate to ensure proper heat transfer and to prevent boric acid stratification.

In MODE 4, either RCPs or RHR loops can be used to provide forced circulation. For RHR operation, the reactor coolant is circulated by means of two RHR loops connected to the RCS, each loop containing an RHR heat exchanger, a RHR pump, and appropriate flow and temperature instrumentation for control, protection, and indication. One RHR loop circulates the water through the RCS at a sufficient rate to remove decay heat and to prevent boric acid stratification.

Although NUREG-1431 uses "loop" to define RHR system requirements, past practice is use of "train", consistent with ECCS discussions of train availability and redundancy. Plant procedures are written using "train". The designations of "loop" and "train" are considered synonymous.

In MODE 4, either RCPs or RHR loops can be used to provide forced circulation. The intent of this LCO is to provide forced flow from at least one RCP or one RHR loop for decay heat removal and transport. The flow provided by one RCP loop or RHR loop is adequate for decay heat removal. The other intent of this LCO is to require that two paths be available to provide redundancy for decay heat removal.

APPLICABLE SAFETY ANALYSES In MODE 4, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. The RCS and RHR loops provide this circulation.

RCS Loops - MODE 4 have been identified in NRC Policy Statement 10 CFR 50.36 (c) (2) (iii) as important contributors to risk reduction.

(Continued)

BASES

LCO

The purpose of this LCO is to require that at least two loops be OPERABLE in MODE 4 and that one of these loops be in operation. The LCO allows the two loops that are required to be OPERABLE to consist of any combination of RCS loops and RHR loops. Any one loop in operation provides enough flow to remove the decay heat from the core with forced circulation. An additional loop is required to be OPERABLE to provide redundancy for heat removal.

Note 1 permits all RCPs or RHR pumps to be removed from operation de-energized for ≤ 1 hour per 8 hour period. The purpose of the Note is to permit tests that are required to be performed without flow or pump noise designed to validate various accident analyses values. One of the tests performed during the startup testing program is the validation of rod drop times during cold conditions, both with and without flow. The no flow test may be performed in MODE 3, 4, or 5 and requires that the pumps be stopped for a short period of time. The Note permits the de-energizing of the pumps in order to perform this test and validate the assumed analysis values. If changes are made to the RCS that would cause a change to the flow characteristics of the RCS, the input values must be revalidated by conducting the test again. The 1 hour time period is adequate to perform the test, and operating experience has shown that boron stratification is not a problem during this short period with no forced flow.

Utilization of Note 1 is permitted provided the following conditions are met along with any other conditions imposed by initial startup test procedures:

- a. No operations are permitted that would dilute the RCS boron concentration, therefore maintaining the margin to criticality. Boron reduction is prohibited because a uniform concentration distribution throughout the RCS cannot be ensured when in natural circulation; and
- b. Core outlet temperature is maintained at least 10°F below saturation temperature, so that no vapor bubble may form and possibly cause a natural circulation flow obstruction.

Note 2 requires that the secondary side water temperature of each SG be $\leq 50^{\circ}\text{F}$ above each of the RCS cold leg temperatures before the start of an RCP with any RCS cold leg temperature \leq the temperature below which LTOP is required as specified in the PTLR (the current limiting temperature for DCP is 270°F) 275°F . Note 2 also includes a DCP plant specific alternate condition under which a RCP may be started in MODE 4 and in MODE 5 with the loops filled. Note that RCPs may be "bumped" following a condition of RCS depressurization to establish "loops filled" condition. The Note specifies that a RCP may be started if the pressurizer water level is less than 50%. This option of RCP start with pressurizer water level less than 50% supports plant operational flexibility. The open volume in the pressurizer provides space to sustain reactor coolant thermal swell without incurring a possible excessive pressure transient due to energy additions from the S/G secondary water. The purpose of

(Continued)

BASES

LCO
(continued)

conditions to allow initial RCP start when none is running is to prevent a possible low temperature RCS overpressure event due to a thermal transient when a RCP is started. The condition of SG/RCS temperature difference limits the available relative energy source and the pressurizer level condition provides an expansion volume to accommodate possible reactor coolant thermal swell. ~~This~~ These restraint ~~is~~ conditions are intended to prevent a low temperature overpressure event due to a thermal transient when a RCP is started.

An OPERABLE RCS loop comprises an OPERABLE RCP and an OPERABLE SG in accordance with the Steam Generator Tube Surveillance Program, which has the minimum water level specified in SR 3.4.6.2.

Similarly for the RHR System, an OPERABLE RHR loop comprises an OPERABLE RHR pump capable of providing forced flow to an OPERABLE RHR heat exchanger. RCPs and RHR pumps are OPERABLE if they are capable of being powered and are able to provide forced flow if required. A RHR loop is in operation when the pump is operating and providing forced flow through the loop. Because a loop can be operating without being OPERABLE, the LCO requires at least one loop OPERABLE and in operation.

APPLICABILITY In MODE 4, this LCO ensures forced circulation of the reactor coolant to remove decay heat from the core and to provide proper boron mixing. One loop of either RCS or RHR provides sufficient circulation for these purposes. However, two loops consisting of any combination of RCS and RHR loops are required to be OPERABLE to meet single failure considerations.

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2";
LCO 3.4.5, "RCS Loops - MODE 3";
LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled";
LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled";
LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation - High Water Level" (MODE 6); and
LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation - Low Water Level" (MODE 6).

ACTIONS

A.1 and A.2

If one required RCS loop is inoperable and two RHR loops are inoperable, redundancy for heat removal is lost. Action must be initiated to restore a second RCS loop or RHR loop to OPERABLE status. The immediate Completion Time reflects the importance of maintaining the availability of two paths for heat removal.

(Continued)

BASES

If one required RHR loop is OPERABLE and in operation and there are no RCS loops OPERABLE, an inoperable RCS loop or RHR loop must be restored to OPERABLE status to provide a redundant means for decay heat removal.

If the parameters that are outside the limits cannot be restored, the unit must be brought to MODE 5 within 24 hours. Bringing the unit to MODE 5 is a conservative action with regard to decay heat removal. With only one RHR loop OPERABLE, redundancy for decay heat removal is lost and, in the event of a loss of the remaining RHR loop, it would be safer to initiate that loss from MODE 5 ($\leq 200^{\circ}\text{F}$) rather than MODE 4 ($>200^{\circ}\text{F}$ to $\leq 350^{\circ}\text{F}$). The Completion Time of 24 hours is a reasonable time, based on operating experience, to reach MODE 5 from MODE 4 in an orderly manner and without challenging plant systems.

B.1 and B.2

If no loop is OPERABLE or in operation, except during conditions permitted by Note 1 in the LCO section, all operations involving a reduction of RCS boron concentration must be suspended and action to restore one RCS or RHR loop to OPERABLE status and operation must be initiated.

~~Boron dilution requires forced RCS circulation from at least one RCP for proper mixing, and the margin to so that an inadvertent criticality must not be reduced in this type of operation may be prevented.~~ The immediate Completion Times reflect the importance of maintaining operation for decay heat removal. The action to restore must be continued until one loop is restored to OPERABLE status and operation.

**SURVEILLANCE
REQUIREMENTS****SR 3.4.6.1**

This SR requires verification every 12 hours that one RCS loop or RHR loop is in operation. Verification may include flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the control room to monitor RCS and RHR loop performance.

SR 3.4.6.2

SR 3.4.6.2 requires verification of SG OPERABILITY. SG OPERABILITY is verified by ensuring that the secondary side narrow range water level is $\geq 15\%$. If the SG secondary side narrow range water level is $< 15\%$, the tubes may become

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

uncovered and the associated loop may not be capable of providing the heat sink necessary for removal of decay heat. The 12 hour Frequency is considered adequate in view of other indications available in the control room to alert the operator to the loss of SG level.

SR 3.4.6.3

Verification that the required pump is OPERABLE ensures that an additional RCS or RHR pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to the required pump. The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.

REFERENCES None.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.7 RCS Loops - MODE 5, Loops Filled

BASES

BACKGROUND

In MODE 5 with the RCS loops filled, the primary function of the reactor coolant is the removal of decay heat and transfer of this heat either to the steam generator (SG) secondary side coolant via natural circulation (Ref. 1) or the component cooling water via the residual heat removal (RHR) heat exchangers. While the principal means for decay heat removal is via the RHR System, the SGs are specified as a backup means for redundancy. Even though the SG cannot produce steam in this MODE, they are capable of being a heat sink due to their large contained volume of secondary water. As long as the SG secondary side water is at a lower temperature than the reactor coolant, heat transfer will occur. The rate of heat transfer is directly proportional to the temperature difference. The secondary function of the reactor coolant is to act as a carrier for soluble neutron poison, boric acid.

In MODE 5 with RCS loops filled, the reactor coolant is circulated by means of two RHR loops connected to the RCS, each loop containing an RHR heat exchanger, an RHR pump, and appropriate flow and temperature instrumentation for control, protection, and indication. One RHR pump circulates the water through the RCS at a sufficient rate to prevent boric acid stratification.

The number of loops in operation can vary to suit the operational needs. The intent of this LCO is to provide forced flow from at least one RHR loop for decay heat removal and transport. The flow provided by one RHR loop is adequate for decay heat removal. The other intent of this LCO is to require that a second path be available to provide redundancy for heat removal.

The LCO provides for redundant paths of decay heat removal capability. The first path can be an RHR loop that must be OPERABLE and in operation. The second path can be another OPERABLE RHR loop or two SGs with secondary side water levels above 15% to provide an alternate method for decay heat removal via natural circulation.

APPLICABLE
SAFETY
ANALYSES

In MODE 5, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. The RHR loops provide this circulation.

RCS Loops - MODE 5 (Loops Filled) have been identified in NRC Policy Statement 10 CFR 50.36(c)(2)(ii) as important contributors to risk reduction

LCO

The purpose of this LCO is to require that at least one of the RHR loops be OPERABLE and in operation with an additional RHR loop OPERABLE or two SGs with secondary side water level $\geq 15\%$. One RHR loop provides sufficient

(Continued)

BASES

LCO
(continued)

forced circulation to perform the safety functions of the reactor coolant under these conditions. An additional RHR loop is required to be OPERABLE to meet single failure considerations. However, if the standby RHR loop is not OPERABLE, an acceptable alternate method is two SGs with their secondary side water levels $\geq 15\%$. Should the operating RHR loop fail, the SGs could be used to remove the decay heat via natural circulation.

Note 1 permits all RHR pumps to be removed from operation de-energized ≤ 1 hour per 8 hour period. The purpose of the Note is to permit tests that are required to be performed without flow or pump noise, designed to validate various accident analyses values. One of the tests performed during the startup testing program is the validation of rod drop times during cold conditions, both with and without flow. The no flow test may be performed in MODE 3, 4, or 5 and requires that the pumps be stopped for a short period of time. The Note permits de-energizing of the pumps in order to perform this test and validate the assumed analysis values. If changes are made to the RCS that would cause a change to the flow characteristics of the RCS, the input values must be revalidated by conducting the test again. The 1 hour time period is adequate to perform the test, and operating experience has shown that boron stratification is not likely during this short period with no forced flow.

Utilization of Note 1 is permitted provided the following conditions are met, along with any other conditions imposed by initial startup test procedures:

- a. No operations are permitted that would dilute the RCS boron concentration, therefore maintaining the margin to criticality. Boron reduction is prohibited because a uniform concentration distribution throughout the RCS cannot be ensured when in natural circulation; and
- b. Core outlet temperature is maintained at least 10°F below saturation temperature, so that no vapor bubble may form and possibly cause a natural circulation flow obstruction.

Note 2 allows one RHR loop to be inoperable for a period of up to 2 hours, provided that the other RHR loop is OPERABLE and in operation. This permits periodic surveillance tests to be performed on the inoperable loop during the only time when such testing is safe and possible.

Note 3 requires that the secondary side water temperature of each SG be $\leq 50^{\circ}\text{F}$ above each of the RCS cold leg temperatures before the start of a reactor coolant pump (RCP) with any an RCS cold leg temperature \leq the temperature below which Low Temperature Overpressure Protection (LTOP) is required as specified in the PTLR. Note that RCPs may be "bumped" following a condition of RCS depressurization to establish "loops filled" condition.

(Continued)

BASES

LCO
(continued)

Note 3 also includes an OR condition for starting a RCP. This condition is a DCCP plant specific alternate condition under which a RCP may be started in MODE 4 and in MODE 5 with the loops filled. The Note specifies that a RCP may be started if the pressurizer water level is less than 50%. This option of RCP start with pressurizer water level less than 50% supports plant operational flexibility. The open volume in the pressurizer provides space to sustain reactor coolant thermal swell without incurring a possible excessive pressure transient due to energy additions from the S/G secondary water. The purpose of conditions to allow initial RCP start when none is running is to prevent a possible low temperature RCS overpressure event due to a thermal transient when a RCP is started. The condition of SG/RCS temperature difference limits the available relative energy source and the pressurizer level condition provides an expansion volume to accommodate possible reactor coolant thermal swell. These conditions are intended to prevent a low temperature overpressure event due to a thermal transient when a RCP is started.

Note 4 provides for an orderly transition from MODE 5 to MODE 4 during a planned heatup by permitting removal of RHR loops from operation when at least one RCS loop is in operation. This Note provides for the transition to MODE 4 where an RCS loop is permitted to be in operation and replaces the RCS circulation function provided by the RHR loops.

RHR pumps are OPERABLE if they are capable of being powered and are able to provide flow if required. An OPERABLE SG can perform as a heat sink via natural circulation when it has an adequate water level and is OPERABLE in accordance with the Steam Generator Tube Surveillance Program.

APPLICABILITY In MODE 5 with RCS loops filled, this LCO requires forced circulation of the reactor coolant to remove decay heat from the core and to provide proper boron mixing. One loop of RHR provides sufficient circulation for these purposes. However, one additional RHR loop is required to be OPERABLE, or the secondary side water level of at least two SGs is required to be $\geq 15\%$.

Operation in other MODES is covered by:

LCO 3.4.4, "RCS Loops - MODES 1 and 2";

LCO 3.4.5, "RCS Loops - MODE 3";

LCO 3.4.6, "RCS Loops - MODE 4";

LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled";

(Continued)

BASES

APPLICABILITY LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation - High Water Level" (MODE 6); and

LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation - Low Water Level" (MODE 6).

ACTIONS

A.1 and A.2

If one RHR loop is inoperable and the required SGs have secondary side water levels $< 15\%$, redundancy for heat removal is lost. Action must be initiated immediately to restore a second RHR loop to OPERABLE status or to restore the required SG secondary side water levels. Either Required Action A.1 or Required Action A.2 will restore redundant heat removal paths. The immediate Completion Time reflects the importance of maintaining the availability of two paths for heat removal.

B.1 and B.2

If no RHR loop is in operation, except during conditions permitted by Notes 1 and 4, Note 1, or if no loop is OPERABLE, all operations involving a reduction of RCS boron concentration must be suspended and action to restore one RHR loop to OPERABLE status and operation must be initiated. To prevent inadvertent criticality during a boron dilution, forced circulation from at least one RGP is required to provide proper mixing and preserve the margin to criticality in this type of operation. The immediate Completion Times reflect the importance of maintaining operation for heat removal.

SURVEILLANCE
REQUIREMENTSSR 3.4.7.1

This SR requires verification every 12 hours that the required loop is in operation. Verification may include flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the control room to monitor RHR loop performance.

SR 3.4.7.2

Verifying that at least two SGs are OPERABLE by ensuring their secondary side narrow range water levels are $\geq 15\%$ ensures an alternate decay heat removal method via natural circulation in the event that the second RHR loop is not OPERABLE. If both RHR loops are OPERABLE, this Surveillance is not needed. The 12 hour Frequency is considered adequate in view of other indications available in the control room to alert the operator to the loss of SG level.

(Continued)

BASES

SURVEILLANCE
REQUIREMENT
(continued)

SR 3.4.7.3

Verification that a second RHR pump is OPERABLE ensures that an additional pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to the RHR pump. If secondary side water level is $\geq 15\%$ in at least two SGs, this Surveillance is not needed. The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.8 RCS Loops - MODE 5, Loops Not Filled

BASES

BACKGROUND In MODE 5 with the RCS loops not filled, the primary function of the reactor coolant is the removal of decay heat generated in the fuel, and the transfer of this heat to the component cooling water via the residual heat removal (RHR) heat exchangers. The steam generators (SGs) are not available as a heat sink when the loops are not filled. The secondary function of the reactor coolant is to act as a carrier for the soluble neutron poison, boric acid.

In MODE 5 with loops not filled, only RHR pumps can be used for coolant circulation. The number of pumps in operation can vary to suit the operational needs. The intent of this LCO is to provide forced flow from at least one RHR pump for decay heat removal and transport and to require that two paths be available to provide redundancy for heat removal.

APPLICABLE SAFETY ANALYSES In MODE 5, RCS circulation is considered in the determination of the time available for mitigation of the accidental boron dilution event. The RHR loops provide this circulation. The flow provided by one RHR loop is adequate for heat removal and for boron mixing.

RCS loops in MODE 5 (loops not filled) have been identified in the NRC Policy Statement ~~10 CFR 50.36 (c) (2) (11)~~ as important contributors to risk reduction.

LCO The purpose of this LCO is to require that at least two RHR loops be OPERABLE and one of these loops be in operation. An OPERABLE loop is one that has the capability of transferring heat from the reactor coolant at a controlled rate. Heat cannot be removed via the RHR System unless forced flow is used. A minimum of one running RHR pump meets the LCO requirement for one loop in operation. An additional RHR loop is required to be OPERABLE to meet single failure considerations.

Note 1 permits all RHR pumps to be de-energized for ~~removed from operation for < 1 hour 15 minutes when switching from one loop to another.~~ The circumstances for stopping both RHR pumps are to be limited to situations when the outage time is short and core outlet temperature is maintained at ~~least > 10°F below saturation temperature.~~ The Note prohibits boron dilution or draining operations when RHR forced flow is stopped.

(Continued)

BASES

LCO (continued) Note 2 allows one RHR loop to be inoperable for a period of ≤ 2 hours, provided that the other loop is OPERABLE and in operation. This permits periodic surveillance tests to be performed on the inoperable loop during the only time when these tests are safe and possible.

An OPERABLE RHR loop is comprised of an OPERABLE RHR pump capable of providing forced flow to an OPERABLE RHR heat exchanger. RHR pumps are OPERABLE if they are capable of being powered and are able to provide flow if required.

APPLICABILITY In MODE 5 with loops not filled, this LCO requires core heat removal and coolant circulation by the RHR System. ~~The Applicability is modified by a Note stating that while the LCO is not met, entry into MODE 5, Loops Not Filled, from MODE 5, Loops Filled, is not permitted. This Note specifies an exception to LCO 3.0.4 and would prevent draining the RCS, which would eliminate the possibility of SG heat removal, while the RHR function was degraded~~

Operation in other MODES is covered by:

- LCO 3.4.4, "RCS Loops - MODES 1 and 2";
 - LCO 3.4.5, "RCS Loops - MODE 3";
 - LCO 3.4.6, "RCS Loops - MODE 4";
 - LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled";
 - LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation - High Water Level" (MODE 6); and
 - LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation - Low Water Level" (MODE 6).
-

ACTIONS

A.1

If only one RHR loop is OPERABLE and in operation, redundancy for RHR is lost. Action must be initiated to restore a second loop to OPERABLE status. The immediate Completion Time reflects the importance of maintaining the availability of two paths for heat removal.

B.1 and B.2

If no required RHR loops are OPERABLE or in operation, except during conditions permitted by Note 1, all operations involving a reduction of RCS boron concentration must be suspended and action must be initiated immediately to restore an RHR loop to OPERABLE status and operation. Boron dilution requires forced circulation from at least one RCP for uniform dilution, for proper mixing so that inadvertent ~~and the margin to criticality can be prevented. must not be~~

(Continued)

BASES

ACTIONS (continued) ~~reduced in this type of operation.~~ The immediate Completion Time reflects the importance of maintaining operation for heat removal. The action to restore must continue until one loop is restored to OPERABLE status and operation.

SURVEILLANCE REQUIREMENTS SR 3.4.8.1

This SR requires verification every 12 hours that one loop is in operation. Verification may include flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing heat removal. The Frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the control room to monitor RHR loop performance.

SR 3.4.8.2

Verification that the required number of pumps are OPERABLE ensures that additional pumps can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to the required pumps. The Frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.

REFERENCES None.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.9 Pressurizer

BASES

BACKGROUND The pressurizer provides a point in the RCS where liquid and vapor are maintained in equilibrium under saturated conditions for pressure control purposes to prevent bulk boiling in the remainder of the RCS. Key functions include maintaining required primary system pressure during steady state operation, and limiting the pressure changes caused by reactor coolant thermal expansion and contraction during normal load transients.

The pressure control components addressed by this LCO include the pressurizer water level, the required heaters, and their controls and emergency power supplies. Pressurizer safety valves and pressurizer power operated relief valves are addressed by LCO 3.4.10, "Pressurizer Safety Valves," and LCO 3.4.11, "Pressurizer Power Operated Relief Valves (PORVs)," respectively.

The intent of the LCO is to ensure that a steam bubble exists in the pressurizer prior to power operation to minimize the consequences of potential overpressure transients. The presence of a steam bubble is consistent with analytical assumptions. ~~Relatively small amounts of noncondensable gases can inhibit the condensation heat transfer between the pressurizer spray and the steam, and diminish the spray effectiveness for pressure control.~~

Electrical immersion heaters, located in the lower section of the pressurizer vessel, keep the water in the pressurizer at saturation temperature and maintain a constant operating pressure. A minimum required available capacity of pressurizer heaters ensures that the RCS pressure can be maintained. The capability to maintain and control system pressure is important for maintaining subcooled conditions in the RCS and ensuring the capability to remove core decay heat by either forced or natural circulation of reactor coolant. Unless adequate heater capacity is available, the hot, high pressure condition cannot be maintained indefinitely and still provide the required subcooling margin in the primary system.

Inability to control the system pressure and maintain subcooling under conditions of natural circulation flow in the primary system could lead to a loss of single phase natural circulation and decreased capability to remove core decay heat.

**APPLICABLE
SAFETY
ANALYSES**

In MODES 1, 2, and 3, the LCO requirement for a steam bubble reflected implicitly in the accident analyses. Safety analyses performed for lower MODES are not limiting. All analyses performed from a critical reactor condition assume the existence of a steam bubble and saturated conditions in the pressurizer. In making this assumption, the analyses neglect the small fraction of noncondensable gases normally present.

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

Safety analyses presented in the FSAR (Ref. 1) do not take credit for pressurizer heater operation; however, an implicit initial condition assumption of the safety analyses is that the RCS is operating at normal pressure.

The maximum pressurizer water level limit, which ensures that a steam bubble exists in the pressurizer, satisfies Criterion 2 of the NRC Policy Statement 10 CFR 50.36 (c) (2) (ii). Although the heaters are not specifically used in accident analysis, the need to maintain subcooling in the long term during loss of offsite power, as indicated in NUREG-0737 (Ref. 2), is the reason for providing an LCO.

LCO

The LCO requirement for the pressurizer to be OPERABLE with a water volume ≤ 1600 [1240] cubic feet, which is equivalent to 90% of span ensures that a steam bubble exists. Instrument inaccuracy is not included in this % number. Limiting the LCO maximum operating water level preserves the steam space for pressure control. The LCO has been established to ensure the capability to establish and maintain pressure control for steady state operation and to minimize the consequences of potential overpressure transients. Requiring the presence of a steam bubble is also consistent with analytical assumptions.

The LCO requires two groups of OPERABLE pressurizer heaters, each with a capacity ≥ 150 [125] kW, capable of being powered from either the offsite power source or the emergency power supply. The minimum heater capacity required is sufficient to maintain the RCS near normal operating pressure when accounting for heat losses through the pressurizer insulation. The capability to power the heaters from an emergency power supply using bus cross-tie to an OPERABLE emergency diesel generator, if necessary, provides the means to maintain system pressure control during a loss of normal power. RCS pressure control is necessary to maintain subcooling under conditions of natural circulation flow in the primary system. By maintaining the pressure near the operating conditions, a wide margin to subcooling can be obtained in the loops.

~~The exact design value of [125 kW is derived from the use of seven heaters rated at 17.9 kW each]. The amount needed to maintain pressure is dependent on the heat losses.~~

APPLICABILITY

The need for pressure control is most pertinent when core heat can cause the greatest effect on RCS temperature, resulting in the greatest effect on pressurizer level and RCS pressure control. Thus, applicability has been designated for MODES 1 and 2. The applicability is also provided for MODE 3. The purpose is to prevent solid water RCS operation during heatup and cooldown to avoid rapid pressure rises caused by normal operational perturbation, such as reactor coolant pump startup.

In MODES 1, 2, and 3, there is need to maintain the availability of pressurizer heaters capable of being powered from an emergency power supply, and if

(Continued)

BASES

APPLICABILITY
(continued)

~~necessary, using bus cross-tie to an OPERABLE emergency diesel generator~~ In the event of a loss of offsite power, the initial conditions of these MODES give the greatest demand for maintaining the RCS in a hot pressurized condition with loop subcooling for an extended period. For MODE 4, 5, or 6, it is not necessary to control pressure (by heaters) to ensure loop subcooling for heat transfer when the Residual Heat Removal (RHR) System is in service, and therefore, the LCO is not applicable.

ACTIONS

A.1 and A.2, A.3 and A.4

Pressurizer water level control malfunctions or other plant evolutions may result in a pressurizer water level above the nominal upper limit, even with the plant at steady state conditions. ~~Normally the plant will trip in this event since~~ The upper limit of this LCO is ~~below the same as the~~ Pressurizer Water Level-High Trip at ~~92% of span~~.

If the pressurizer water level is not within the limit, action must be taken ~~to bring the unit to restore the plant to operation within the bounds of the safety analyses, a MODE in which the LCO does not apply.~~ To achieve this status, ~~within 6 hours the unit must be brought to MODE 3, with the reactor trip breakers open with rods fully inserted and the Rod Control System not capable of rod withdrawal, within 6 hours~~ Additionally, the unit must be brought to MODE 4 within 12 hours. This takes the unit out of the Applicable MODES, ~~and restores the unit to operation within the bounds of the safety analyses.~~

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

B.1

If one required group of pressurizer heaters is inoperable, restoration is required within 72 hours. The Completion Time of 72 hours is reasonable considering the anticipation that a demand caused by loss of offsite power would be unlikely in this period. Pressure control may be maintained during this time using normal station powered heaters.

ACTIONS
(continued)

C.1 and C.2

If one ~~required~~ group of pressurizer heaters ~~is~~ are inoperable and cannot be restored in the allowed Completion Time of Required Action B.1, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and to MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating

(Continued)

BASES

ACTIONS (continued) experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE REQUIREMENTS

SR 3.4.9.1

This SR requires that during steady state operation, pressurizer level is maintained below the nominal upper limit to provide a minimum space for a steam bubble. The Surveillance is performed by observing the indicated level. The Frequency of 12 hours corresponds to verifying the parameter each shift. The 12 hour interval has been shown by operating practice to be sufficient to regularly assess level for any deviation and verify that operation is within consistent with the safety analyses assumptions of ensuring that a steam bubble exists in the pressurizer. Alarms are also available for early detection of abnormal level indications.

SR 3.4.9.2

The SR is satisfied when the power supplies are demonstrated to be capable of producing the minimum power and the associated pressurizer heaters are verified to be at their design rating. This may be done by testing the power supply output and by performing an electrical check on heater element continuity and resistance. The Frequency of 92 days 18 months is considered adequate to detect heater degradation and has been shown by operating experience to be acceptable.

SR 3.4.9.3

~~This SR is not applicable if the heaters are permanently powered by Class 1E power supplies.~~

~~This SR demonstrates that the heaters can be manually transferred from the normal to the emergency power supply and energized. The Frequency of 18 months is based on a typical fuel cycle and is consistent with similar verifications of emergency power supplies.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.10 Pressurizer Safety Valves

BASES

BACKGROUND

The pressurizer safety valves provide, in conjunction with the Reactor Protection System, overpressure protection for the RCS. The pressurizer safety valves are totally enclosed pop type, spring loaded, self actuated valves with backpressure compensation. The safety valves are designed to prevent the system pressure from exceeding the system Safety Limit (SL), 2735 psig, which is 110% of the design pressure.

Because the safety valves are totally enclosed and self actuating, they are considered independent components. The relief capacity for each valve, 420,000 lb/hr at 2485 psig plus 3% accumulation [380,000] lb/hr, is based on postulated overpressure transient conditions resulting from a complete loss of steam flow to the turbine. This event results in the maximum surge rate into the pressurizer, which specifies the minimum relief capacity for the safety valves which is divided equally among the three valves. The discharge flow from the pressurizer safety valves is directed to the pressurizer relief tank. This discharge flow is indicated by an increase in temperature downstream of the pressurizer safety valves and an increase in the pressurizer relief tank temperature or level.

Overpressure protection is required in MODES 1, 2, 3, and 4 and 5. However, in MODE 4, with one or more RCS cold leg temperatures \leq the temperature below which LTOP is required as specified in the PTER (the current limiting temperature for DCPP is 270°F) [275]°F, and MODE 5 and MODE 6 with the reactor vessel head on and the reactor vessel head closure bolts not fully de-tensioned, overpressure protection is provided by operating procedures and by meeting the requirements of LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System."

The upper and lower pressure limits are based on the $\pm 1\%$ of nominal pressure tolerance requirement (Ref. 1) for lifting pressures above 1000 psig. The lift setting is for the ambient conditions associated with MODES 1, 2, and 3. This requires either that the valves be set hot (which is the current DCPP practice) or if valves are set cold that a correlation between hot and cold settings be established.

The pressurizer safety valves are part of the primary success path and mitigate the effects of postulated accidents. OPERABILITY of the safety valves ensures that the RCS pressure will be limited to 110% of design pressure.

The consequences of exceeding the American Society of Mechanical Engineers (ASME) pressure limit (Ref. 1) could include damage to RCS components, increased leakage, or a requirement to perform additional stress analyses prior to resumption of reactor operation.

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES

All accident and safety analyses in the FSAR (Ref. 2) that require safety valve actuation assume operation of three pressurizer safety valves to limit increases in RCS pressure. The overpressure protection analysis (Ref. 3) is also based on operation of three safety valves. Accidents that could result in overpressurization if not properly terminated include:

- a. Uncontrolled rod withdrawal from full power;
- b. ~~Feedline break~~ Loss of reactor coolant flow;
- c. Loss of external electrical load;
- d. Loss of normal feedwater;
- e. Loss of all AC power to station auxiliaries; and
- f. Locked ~~Reactor Coolant Pump (RCP)~~ rotor.

Detailed analyses of the above transients are contained in Reference 2. Safety valve actuation is required in events b, c, d, e and f (above) to limit the pressure increase. Compliance with this LCO is consistent with the design bases and accident analyses assumptions.

Pressurizer safety valves satisfy Criterion 3 of ~~the NRC Policy Statement 10~~
~~CFR 50.36 (c)(2)(1)~~.

LCO

The ~~three~~ pressurizer safety valves are set to open at the RCS design pressure ~~(2485 psia) (2500 psia)~~, and within the ASME specified tolerance, to avoid exceeding the maximum design pressure SL, to maintain accident analyses assumptions, and to comply with ASME requirements. The upper and lower pressure tolerance limits are based on the $\pm 1\%$ of ~~nominal~~ pressure tolerance requirements (Ref. 1) for lifting pressures above 1000 psig.

The limit protected by this Specification is the reactor coolant pressure boundary (RCPB) SL of 110% of design pressure. Inoperability of one or more valves could result in exceeding the SL if a transient were to occur. The consequences of exceeding the ASME pressure limit could include damage to one or more RCS components, increased leakage, or additional stress analysis being required prior to resumption of reactor operation.

APPLICABILITY

In MODES 1, 2, and 3, and portions of MODE 4 above the LTOP arming temperature, OPERABILITY of ~~three~~ valves is required because the combined

(Continued)

BASES

APPLICABILITY (continued) capacity is required to keep reactor coolant pressure below 110% of its design value during certain accidents. MODE 3 and portions of MODE 4 are conservatively included, although the listed accidents may not require the safety valves for protection.

The LCO is not applicable in MODE 4 when any all RCS cold leg temperatures are \leq the temperature below which LTOP is required as specified in the PTLR [275] $^{\circ}$ F or in MODE 5 because LTOP is provided. Overpressure protection is not required in MODE 6 with reactor vessel head closure bolts fully de-tensioned.

The Note allows entry into MODES 3 and 4 with the lift settings outside the LCO limits. This permits testing and examination of the safety valves at high pressure and temperature near their normal operating range, but only after the valves have had a preliminary cold setting. The cold setting gives assurance that the valves are OPERABLE near their design condition. Only one valve at a time will be removed from service for testing. The 54 hour exception is based on 18 hour outage time for each of the three valves. The 18 hour period is derived from operating experience that hot testing can be performed in this time frame.

ACTIONS

A.1

With one pressurizer safety valve inoperable, restoration must take place within 15 minutes. The Completion Time of 15 minutes reflects the importance of maintaining the RCS Overpressure Protection System. An inoperable safety valve coincident with an RCS overpressure event could challenge the integrity of the pressure boundary.

B.1 and B.2

If the Required Action of A.1 cannot be met within the required Completion Time or if two or more pressurizer safety valves are inoperable, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 4 with any RCS cold leg temperatures \leq the temperature below which LTOP is required as specified in the PTLR [275] $^{\circ}$ F within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. With any RCS cold leg temperatures at or below the temperature below which LTOP is required as specified in the PTLR [275] $^{\circ}$ F, overpressure protection is provided by the LTOP System. The change from MODE 1, 2, or 3 to MODE 4 reduces the RCS energy (core power and pressure), lowers the potential for large pressurizer insurges, and thereby removes the need for overpressure protection by three pressurizer safety valves.

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.4.10.1

SRs are specified in the Inservice Testing Program. ~~Pressurizer safety valves are to be tested in accordance with the requirements of The ASME Code, Section XI of the ASME Code (Ref. 4), which provides the activities and frequencies necessary to satisfy the SRs, requires that safety and relief tests be performed in accordance with ANSI/ASME OM-a-1988 (Ref. 5). No additional requirements are specified. The surveillance specifies the lift settings to be within $\pm 1\%$ of nominal pressure of 2485 psig.~~

~~The pressurizer safety valve setpoint is $\pm [3]\%$ for OPERABILITY; however, the valves are reset to $\pm 1\%$ during the Surveillance to allow for drift.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.11 Pressurizer Power Operated Relief Valves (PORVs)

BASES

BACKGROUND

The pressurizer is equipped with two types of devices for pressure relief: pressurizer safety valves and PORVs. The PORVs are air operated valves that are controlled to open at a specific set pressure when the pressurizer pressure increases above their actuation setpoint and to close when the pressurizer pressure decreases. The PORVs may also be manually operated from the control room.

DCPP design includes three air operated pressurizer PORVs. Two of these PORVs have been designated as "Class I". These two valves provide the reactor vessel low temperature overpressure protection and they provide the means to depressurize the RCS following a steam generator tube rupture (SGTR). These functions must be accomplished under accident analyses assumptions such as loss of offsite power. Consequently, a Class I nitrogen backup system to the non-safety related air supply is provided for the two Class I PORVs. The identification of Class I is used to make a distinction between these two PORVs that must provide a safety-related function as opposed to the third remaining PORV that is designated as non-Class I. TS 3.4.12 for LTOP applies to the two Class I PORVs but not to the non-Class I PORV.

The non-Class I PORV is an element of the DCPP design for 100% load rejection without reactor trip. This valve is associated with plant transients as compared to accident mitigation. Although mitigation is not its primary purpose, the valve may be used for those functions also, although not credited for operation.

The three PORVs are the same design. The PORV that is not designated as Class I may be used, when instrument air is available, to control RCS pressure similarly to the Class I PORVs. However, two Class I PORVs satisfy the function with redundancy, therefore continued operation with the non-Class I PORV unavailable for RCS pressure control is allowed as long as the block valve or PORV can be closed to maintain the RCS pressure boundary. However, the plant capability to sustain a 100% load rejection without reactor trip would be compromised.

Block valves, which are normally open, are located between the pressurizer and the PORVs. The three MOV block valves are the same design. The block valves are used to isolate the PORVs in case of excessive seat leakage or a stuck open PORV. Block valve closure is accomplished manually using controls in the control room. A stuck open PORV is, in effect, a small break loss of coolant accident (LOCA). As such, block valve closure terminates the RCS depressurization and coolant inventory loss.

(Continued)

BASES

BACKGROUND
(continued)

The PORVs may be manually cycled and are equipped with circuitry for automatic actuation. No credit is taken for PORV automatic actuation in the FSAR analyses for MODE 1, 2 or 3 transients where PORV operation may have a beneficial effect. Therefore the PORVs may be OPERABLE in either manual operation or the automatic mode. The automatic mode is the preferred configuration, as this provides pressure relieving capability without reliance on operator action.

The PORVs and their associated block valves may be used by plant operators to depressurize the RCS to recover from certain transients if normal pressurizer spray is not available. Additionally, the series arrangement of the PORVs and their block valves permits performance of surveillances on the block valves during power operation.

The PORVs may also be used for feed and bleed core cooling in the case of multiple equipment failure events that are not within the design basis, such as a total loss of feedwater.

The PORVs, their block valves, and their controls are powered from the vital buses that normally receive power from offsite power sources, but are also capable of being powered from emergency power sources in the event of a loss of offsite power. Two PORVs and their associated The PORV block valves are all powered from two separate safety trains (Ref. 1) vital busses.

The plant has ~~three~~ two PORVs, each having a relief capacity of 210,000 lb/hr at 2335 psig. The functional design of the PORVs is based on maintaining pressure below the Pressurizer Pressure-High reactor trip setpoint up to and including the design step load decrease following a step reduction of 50% of full load with steam dump. In addition, the PORVs minimize challenges to the pressurizer safety valves and the two Class 1 PORVs are also used for low temperature overpressure protection (LTOP). See LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System."

APPLICABLE
SAFETY
ANALYSES

Plant operators employ the PORVs to depressurize the RCS in response to certain plant transients if normal or auxiliary pressurizer spray is not available. For the Steam Generator Tube Rupture (SGTR) event, the safety analysis assumes that manual operator actions are required to mitigate the event. A loss of offsite power is assumed to accompany the event, and thus, normal pressurizer spray is unavailable to reduce RCS pressure. For the SGTR event, the PORVs are assumed to be used for RCS depressurization, which is one of the steps performed to equalize the primary and secondary pressures in order to terminate the primary to secondary break flow and the radioactive releases from the affected steam generator.

(Continued)

BASES (continued)

APPLICABLE
SAFETY
ANALYSES
(continued)

The PORVs are used in safety analyses for events that result in increasing RCS pressure for which departure from nucleate boiling ratio (DNBR) criteria are critical. By assuming PORV manual actuation, the primary pressure remains below the high pressurizer pressure trip setpoint; thus, the DNBR calculation is more conservative. Automatic actuation of the PORVs is not assumed in any design basis accidents during MODES 1, 2, and 3. Events that assume this condition include a turbine trip and the loss of normal feedwater (Ref. 2).

Pressurizer PORVs satisfy Criterion 3 of NRC Policy Statement 10 CFR 50.36 (c) (2) (ii)

LCO

The LCO requires the PORVs and their associated block valves to be OPERABLE for manual operation to mitigate the effects associated with an SGTR.

By maintaining the two PORVs and their associated block valves OPERABLE, the single failure criterion is satisfied. The block valves are available to isolate the flow path through either a failed open PORV or a PORV with excessive seat leakage. Satisfying the LCO helps minimize challenges to fission product barriers. Note, however, that operability of the PORVs (as indicated by the surveillances) only requires that the PORVs be capable of being manually cycled to perform their safety function and that they need not be capable of automatic actuation since that is not a safety function.

APPLICABILITY

In MODES 1, 2, and 3, the PORVs are required to be OPERABLE to mitigate a SGTR and its block valve. The block valves are required to be OPERABLE to limit the potential for a small break LOCA through the flow path. The most likely cause for a PORV small break LOCA is a result of a pressure increase transient that causes the PORV to open. Imbalances in the energy output of the core and heat removal by the secondary system can cause the RCS pressure to increase to the PORV opening setpoint. The most rapid increases will occur at the higher operating power and pressure conditions of MODES 1 and 2. The PORVs OPERABILITY in are also required to be OPERABLE in MODES 1, 2, and 3 to will also minimize challenges to the pressurizer safety valves.

Pressure increases are less prominent in MODE 3 because the core input energy is reduced, but the RCS pressure is high. Therefore, the LCO is applicable in MODES 1, 2, and 3. OPERABILITY of the PORVs requires them to be capable of manual operation. Automatic operation is not assumed in accident analyses and therefore is not a required safety function. The LCO 3.4.11 is not applicable in MODE 4 when both pressure and core energy are decreased and the pressure surges become much less significant. The PORV setpoint is reduced for LTOP in MODES 4, 5, and 6 with the reactor vessel head in place and the reactor vessel head closure bolts not fully de-tensioned. LCO 3.4.12 addresses the PORV requirements in these MODES

(Continued)

BASES (continued)

ACTIONS

Note 1 has been added to clarify that all pressurizer PORVs are treated as separate entities, each with separate Completion Times (i.e., the Completion Time is on a component basis). The exception for LCO 3.0.4, Note 2, permits ~~MODE changes with inoperable PORVs or block valves as one possible recourse to remaining in the Applicability of LCO 3.4.12. entry into MODES 1, 2, and 3 to perform cycling of the PORVs or block valves to verify their OPERABLE status. Testing is not performed in lower MODES.~~

A.1

~~With the PORVs may be inoperable and capable of being manually cycled, (e.g., excessive seat leakage) In this condition, either the PORVs must be restored or the flow path isolated within 1 hour. The associated block valves should be required to be closed but power must be maintained to the associated block valves, since removal of power would render the block valve inoperable. No credit is given for automatic PORV operation in Reference 2 analyses for MODE 1, 2, and 3 transients. As such, the PORVs are considered OPERABLE in either manual control or in the automatic mode. Although a PORV may be designated inoperable, it may be able to be manually opened and closed, and therefore, able to perform its function. PORV inoperability isolation may be necessary due to seat leakage, instrumentation problems, automatic control problems, or other causes that do not prevent manual use, and do not create a possibility for a small break LOCA. For these reasons, the block valve may be closed but the ACTION requires power be maintained to the valve. This Condition is only intended to permit operation of the plant for a limited period of time not to exceed the next refueling outage (MODE 6) so that maintenance can be performed on the PORVs to eliminate the problem condition. Normally, the PORVs should be available for automatic mitigation of overpressure events and should be returned to OPERABLE and automatic actuation status prior to entering startup (MODE 2).~~

Quick access to the PORV for pressure control can be made when power remains on the closed block valve. The Completion Time of 1 hour is based on plant operating experience that has shown that minor problems can be corrected or closure accomplished in this time period.

B.1, B.2, and B.3

~~If one [or two] PORVs is inoperable and not capable of being manually cycled, it must be either restored or isolated by closing the associated block valve and removing the power to the associated block valve. The Completion Time of~~

(Continued)

BASES (continued)

ACTIONS (continued) 1 hour ~~is~~ are reasonable, based on challenges to the PORVs during this time period, and provides the operator adequate time to correct the situation.

If the inoperable PORV valve cannot be restored to OPERABLE status, it must be isolated within the specified time. Because there is at least one Class I PORV that remains OPERABLE, an additional 72 hours is provided to restore the inoperable PORV to OPERABLE status if it is Class I. If the valve is the non-Class I PORV, there is no required Completion Time. If the Class I PORV cannot be restored within this additional time, the plant must be brought to a MODE in which the LCO does not apply at least MODE 3 with Tavg less than 500°F, as required by Condition D.

C.1, C.2 and C.3

If one PORV block valve is inoperable, then it is necessary to either restore the block valve to OPERABLE status within the Completion Time of 1 hour or place the associated PORV in manual control. The PORV control switch has three positions: open, close, and auto. Placing the PORV in manual control, if required in ACTION C, is accomplished by positioning the switch out of the auto control mode. The prime importance for the capability to close the block valve is to isolate a stuck open PORV. Therefore, if the block valve cannot be restored to OPERABLE status within 1 hour, the Required Action is to place the associated PORV in manual control.

This action is taken to avoid the potential for a stuck open PORV if the valve were to open under automatic control at a time that the block valve is inoperable. The Completion Time of 1 hour is reasonable, based on the small potential for challenges to the system during this time period, and provides the operator time to correct the situation. ~~preclude its automatic opening for an overpressure event and to. Because at least one Class I PORV remains OPERABLE, If the inoperable block valve is associated with a Class I PORV the operator is permitted a Completion Time of 72 hours to restore the inoperable block valve to OPERABLE status. The time allowed to restore the Class I PORV block valve is based upon the Completion Time for restoring an inoperable Class I PORV in Condition B, since the PORVs are not capable of mitigating an overpressure event a SGTR when placed in manual control inoperable and not capable of being manually cycled. If the block valve is restored within the Completion Time of 72 hours, the power will be restored and the PORV restored to OPERABLE status will be transferred to the automatic mode of operation. If the block valve it cannot be restored within this additional time, the plant must be brought to a MODE in which the LCO does not apply, at least MODE 3 with Tavg less than 500°F as required by Condition D.~~

If the inoperable block valve is associated with the non-Class I PORV, the block valve may be closed and the power removed. The 72 hour Completion Time for closing the block valve is the same applied in Required Action C.2. This recognizes that some restoration work may be required since the block valve is inoperable.

(Continued)

BASES (continued)

Restoration of the non-class I PORV block valve to OPERABLE status is not required because the non-Glass I PORV is not required to be available, although having the valve closed impairs the load rejection design capability. Therefore, once the block valve has been closed per Required Action C.3, Completion Time requirements of Condition D do not apply.

If the block valve can not be placed in the closed position, per Required Action C.3, Condition D applies and the unit must be taken to MODE 3 with Tavg less than 500°F until the block valve is restored or closed.

ACTIONS
(continued)

D.1, D.2 and D.3

If the Required Action of Condition A, B, or C is not met, then the plant must be brought to a MODE in which the LCO does not apply, condition below where the function of the PORVs to mitigate a SGTR event is needed. To achieve this status, the plant must be brought to at least MODE 3 with Tavg < 500°F within 6 hours and to MODE 4 within 12 hours. Additional action is required to be initiated immediately to continue efforts to restore the inoperable valve(s) to OPERABLE status. This action will ensure expedient measures are taken to reestablish OPERABLE PORVs and block valves while maintaining plant conditions above MODE 4 but less than 500°F. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. In MODES 4, and 5, and 6 with the reactor vessel head closure bolts not fully de-tensioned, maintaining Class I PORV OPERABILITY may be required by See LCO 3.4.12.

E.1, E.2, E.3, E.4 and E.5

If more than one Class I PORV is inoperable and not capable of being manually cycled, it is necessary to immediately initiate action to restore the valves either restore at least one valve and to, within the Completion Time of 1 hour, or isolate the flow path by closing and removing the power to the associated block valves. The Completion Time of 1 hour is reasonable, based on the small potential for challenges to the system during this time and provides the operator time to correct the situation. If one Class I PORV is restored and one Class I PORV remains inoperable, then the plant will be in Condition B with the time clock started at the original declaration of having two [or three] Class I PORVs inoperable. If no Class I PORVs are restored within the Completion Time, then the plant must be brought to a MODE in which the LCO does not apply, a condition below where the function of the PORVs to mitigate a SGTR event is not needed. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and reduce Tavg to < 500°F to MODE 4 within 12 hours.

Additional action is required to be initiated immediately to continue efforts to restore the inoperable valve(s) to OPERABLE status. This action will ensure expedient measures are taken to reestablish OPERABLE PORVs and block valves while maintaining plant conditions above MODE 4 but less than 500°F. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly

(Continued)

BASES (continued)

ACTIONS
(continued)

manner and without challenging plant systems. In MODES 4, and 5, and 6 with the reactor vessel head closure bolts not fully de-tensioned, maintaining Class I PORV OPERABILITY may be is required by See LCO 3.4.12.

F.1, F.2, F.3 and F.4

If more than one PORV block valve is inoperable, it is necessary to either restore the block valves within the Completion Time of 1 hour, or place the associated PORVs in manual control and restore at least one block valve within 2 hours and restore the remaining block valve within 72 hours. The PORV control switch has three positions, open, close and auto. Placing the PORV in manual control, if required in ACTION F, is accomplished by positioning the switch out of the auto control mode. The Completion Times are reasonable, based on the small potential for challenges to the system during this time and provide the operator time to correct the situation.

If the inoperable block valve is associated with the non-Class I PORV, the block valve may be closed and the power removed. The 72 hour Completion Time for closing the block valve is the same used in Required Action F.3. This recognizes that some restoration work may be required since the block valve is inoperable. Restoration of the non-class I PORV block valve to OPERABLE status is not required because the non-Class I PORV is not required to be available, although having the valve closed impairs the load rejection design capability. Therefore, once the block valve has been closed per Required Action F.4, Completion Time requirements of Condition G do not apply.

If the block valve can not be placed in the closed position per Required Action F.4, Condition G applies and the unit must be taken to MODE 3 with T_{avg} less than 500°F until the block valve is restored or closed.

G.1, G.2 and G.3

If the Required Actions of Condition F are not met, then the plant must be brought to a MODE in which the LCO does not apply condition below where the function of the PORVs to mitigate a SGTR event is not needed. To achieve this status, the plant must be brought to at least MODE 3 with $T_{avg} < 500°F$ within 6 hours and to MODE 4 within 12 hours. Additional action is required to be initiated immediately to continue efforts to restore the inoperable valve(s) to OPERABLE status. This action will ensure expedient measures are taken to reestablish OPERABLE PORVs and block valves while maintaining plant conditions above MODE 4 but less than 500°F. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. In MODES 4, and 5, maintaining PORV OPERABILITY may be required. See LCO 3.4.12, and 6 with the reactor vessel head closure bolts not fully de-tensioned, maintaining Class I PORV OPERABILITY is required by LCO 3.4.12.

SURVEILLANCE
REQUIREMENTS

SR 3.4.11.1

Block valve cycling verifies that the valve(s) can be closed if needed. The basis for the Frequency of 92 days is the ASME Code, Section XI O & M Code Part 10

(Continued)

BASES (continued)

(Ref. 3). If the block valve is closed to isolate a PORV that is capable of being manually cycled, the OPERABILITY of the block valve is of importance, because opening the block valve is necessary to permit the PORV to be used for manual control of reactor pressure. If the block valve is closed to isolate an otherwise inoperable Class I PORV that is incapable of being manually cycled, the maximum Completion Time to restore the Class I PORV and open the block valve is 72 hours, which is well within the allowable limits (25%) to extend the block valve Frequency of 92 days. Furthermore, these test requirements would be completed by the reopening of a recently closed block valve upon restoration of the Class I PORV to OPERABLE status (i.e., completion of the Required Actions fulfills the SR). If the block valve for a non-Class I PORV has been closed by Required Action C 3 or F 4, it can remain closed without further requirements for restoration. The non-Class I PORV is not required for accident mitigation and the closed block valve provides protection against a spurious opening of the PORV.

The Note 1 modifies this SR by stating that it is not required to be performed with the block valve closed, in accordance with the Required Action of Condition A, B and E or Required Actions C 3 and F 4 this LCO.

Note 2 modifies this SR to allow entry into and operation in MODE 3 prior to performing the SR. This allows the test to be performed in any MODE below MODE 2.

SR 3.4.11.2

SR 3.4.11.2 requires a complete cycle of each PORV. Operating a PORV through one complete cycle ensures that the PORV can be manually actuated for mitigation of an SGTR. The Frequency of 18 months is based on a typical refueling cycle and industry accepted practice.

The Note modifies this SR to allow entry into and operation in MODE 3 prior to performing the SR. This allows the surveillance to be performed in any MODE below MODE 2.

SR 3.4.11.3

Verifying OPERABILITY of the safety related nitrogen supply for the Class I PORVs may be accomplished by:

- a. Isolating and venting the normal air supply, and
- b. Verifying that any leakage of the Class I backup nitrogen system is within its limits, and
- c. Operating the Class I PORVs through one complete cycle of full travel.

(Continued)

BASES (continued)

Operating the solenoid nitrogen control valves and check valves on the nitrogen supply system and operating the Class I PORVs through one complete cycle of full travel ensures the nitrogen backup supply for the Class I PORV operates properly when called upon. The Frequency of 18 months is based on a typical refueling cycle and the Frequency of the other Surveillances used to demonstrate Class I PORV OPERABILITY.

SR 3.4.11.4 NOT USED

~~This Surveillance is not required for plants with permanent IE power supplies to the valves.~~

~~The Surveillance demonstrates that emergency power can be provided and is performed by transferring power from normal to emergency supply and cycling the valves. The Frequency of [18] months is based on a typical refueling cycle and industry accepted practice.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.12 Low Temperature Overpressure Protection (LTOP) System

BASES

BACKGROUND The LTOP System controls RCS pressure at low temperatures so the integrity of the reactor coolant pressure boundary (RCPB) is not compromised by violating the pressure and temperature (P/T) limits of 10 CFR 50, Appendix G (Ref. 1). The reactor vessel is the limiting RCPB component for demonstrating such protection. The ~~PRESSURE TEMPERATURE LIMITS REPORT (PTLR)~~ provides the ~~maximum~~ allowable actuation logic setpoints for the power operated relief valves (PORVs) and the maximum RCS pressure for the existing RCS cold leg temperatures during cooldown, shutdown, and heatup to meet the Reference 1 requirements during the LTOP MODES.

The reactor vessel material is less tough at low temperatures than at normal operating temperature. As the vessel neutron exposure accumulates, the material toughness decreases and becomes less resistant to pressure stress at low temperatures (Ref. 2). RCS pressure, therefore, is maintained low at low temperatures and is increased only as ~~after~~ temperature is increased.

The potential for vessel overpressurization is most acute when the RCS is water solid, occurring only while shutdown; a pressure fluctuation can occur more quickly than an operator can react to relieve the condition. Exceeding the RCS P/T limits by a significant amount could cause brittle cracking of the reactor vessel. LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," requires administrative control of RCS pressure and temperature during heatup and cooldown to prevent exceeding the PTLR limits.

This LCO provides RCS overpressure protection by having a minimum coolant input capability and having adequate pressure relief capacity. Limiting coolant input capability requires all ~~SI pumps but [one] [high pressure injection (HPI)] pump and one centrifugal charging pump (CCP)~~ incapable of injection into the RCS and isolating the accumulators.

~~Although not addressed in the LCO, the plant design also includes a positive displacement charging pump (PDP). Operation of a CCP or a PDP or simultaneous operation of both is controlled administratively. The pump operating combinations and limitations are discussed in B 3.4.12 ACTION B.1.~~

The pressure relief capacity requires either two redundant RCS relief valves or a depressurized RCS and an RCS vent of sufficient size. One RCS relief valve or the open RCS vent is the overpressure protection device that acts to terminate an increasing pressure event.

(Continued)

BASES

**BACKGROUND
(continued)**

The pressurizer has three Power Operated Relief Valves (PORVs). Two of the three PORVs are classified as safety related and are designated for LTOP pressure protection. All the PORVs are air operated. These two safety related PORVs have a nitrogen gas backup to the non-safety related air supply.

The three PORVs are the same design. The PORV that is designated as non-Class I may be used, when Instrument air is available, to control RCS pressure similarly to the Class I PORVs although the non-Class I PORV does not receive an automatic open signal like the LTOP designated valves. Therefore, because no credit is taken for its operation for LTOP, continued operation with the non-Class I PORV unavailable for RCS pressure control is allowed as long as the associated block valve or non-Class I PORV can be closed to maintain the RCS pressure boundary.

In MODE 4 with the RHR loops in operation and in MODES 5 and 6, the operating RHR loop, connected to the RCS, can provide pressure relief capability through the RHR suction line relief valve. This capacity for RCS pressure relief is not assumed in the PTLR LTOP considerations and analyses and is not included in the LCO, ACTIONS, or Surveillances.

With minimum coolant input capability, the ability to provide core coolant addition is restricted. The LCO does not require the makeup control system deactivated or the SI actuation circuits blocked. Due to the lower pressures in the LTOP MODES and the expected core decay heat levels, the makeup system can provide adequate flow via the makeup control valve. If conditions require the use of more than one [HPI or] charging pumps CCP for makeup in the event of loss of inventory, then pumps can be made available through manual actions.

Additionally, CCPs in excess of the above limitations can be momentarily capable of injection into the RCS for swapping of inservice CCPs. This condition is acceptable based on the operator's attentiveness to RCS pressure during the pump switch over and the capability of the operator to limit a pressure increase.

The LTOP System for pressure relief consists of two Class I PORVs with reduced lift settings or two residual heat removal (RHR) suction relief valves, or one PORV and one RHR suction relief valve, or a depressurized RCS and an RCS vent of sufficient size. Two RCS relief valves Class I PORVs are required for redundancy. One RCS relief valve Class I PORV has adequate relieving capability to keep from prevent overpressurization for from the required allowable coolant input capability.

PORV Requirements

As designed for the LTOP System, each Class I PORV is signaled to open if the RCS pressure approaches a limit determined by the LTOP actuation logic setpoint. The LTOP actuation logic monitors both RCS temperature and RCS

(Continued)

BASES

BACKGROUND
(continued)

pressure and determines when a condition not acceptable in the PTLR limits is approached. The evolution of RHR cooldown with no RCP forced circulation represents a condition where variation in RCS cold leg temperatures may occur. The RCS loop 2 and 3 wide range cold leg RCS temperature indications are auctioneered to select provide the lowest temperature input signal. Temperature indications from these two loops were selected to constitute a good representation of the overall four loop temperatures. However, in the event that only one RHR loop is in operation, temperature indications from RCS cold legs 2 and 3 will provide indication from a RCS loop into which the cooler water from the RHR discharge is entering. All four cold leg temperature indications are in the control room and provide a loop by loop comparison for the operator.

The LTOP system is placed into service and the block valves verified to be open by procedure at a RCS pressure of about 350 psig. This is an administrative action, not required by TS. However, if LTOP has not been placed into service prior to when the RCS temperature decreases to a temperature of about 323°F, 270°F, the LTOP enable alarm annunciates to alert the operator to place the LTOP system into service. Placing LTOP into service at this point is required to satisfy the LTOP Applicability requirements. Following being placed into service, LTOP will receive RCS temperature and pressure input. The lowest temperature signal is processed through a function generator that calculates a pressure limit for that temperature. The calculated PTLR LTOP pressure limit setpoint is then compared with the indicated RCS pressure from a wide range pressure channel. If the indicated pressure meets or exceeds the calculated LTOP value, and the temperature is lower than the enable temperature, a PORV is signaled to open. The two Class 1 PORVs operate individually with their own setpoints.

The PTLR specifies presents the PORV setpoints for LTOP. The setpoints are normally staggered so only one valve typically opens during a low temperature overpressure transient. Having the setpoints of both valves within the limits in the PTLR ensures that the Reference 1 limits will not be exceeded in any analyzed event.

When a PORV is opened opens in an increasing pressure transient, the release of coolant will cause the pressure increase to slow and reverse. As the PORV releases coolant, the RCS pressure decreases until a reset pressure is reached and the valve is signaled to close. The pressure continues to decrease below the reset pressure as the valve closes.

RHR Suction Relief Valve Requirements

During LTOP MODES, the RHR System is operated for decay heat removal and low pressure letdown control. Therefore, the RHR suction isolation valves are open in the piping from the RCS hot legs to the inlets of the RHR pumps. While these valves are open and the RHR suction valves are open, the RHR suction

(Continued)

BASES

BACKGROUND
(continued)

~~relief valves are exposed to the RCS and are able to relieve pressure transients in the RCS.~~

~~The RHR suction isolation valves and the RHR suction valves must be open to make the RHR suction relief valves OPERABLE for RCS overpressure mitigation. Autoclosure interlocks are not permitted to cause the RHR suction isolation valves to close. The RHR suction relief valves are spring loaded, bellows type water relief valves with pressure tolerances and accumulation limits established by Section III of the American Society of Mechanical Engineers (ASME) Code (Ref. 3) for Class 2 relief valves.~~

RCS Vent Requirements

Once the RCS is depressurized, a vent exposed to the containment atmosphere will maintain the RCS at containment ambient pressure ~~in an~~ during a RCS overpressure transient, if the relieving requirements of the transient do not exceed the capabilities of the vent. Thus, the vent path must be capable of relieving the flow resulting from the limiting LTOP mass or heat input transient, and maintaining pressure below the P/T limits. The required vent capacity may be provided by one or more vent paths.

~~For an RCS vent to meet the flow capacity requirement, it requires removing a pressurizer safety valve, removing a PORV's internals, and disabling its block valve in the open position, or similarly establishing a vent by opening an RCS vent valve. The vent path(s) must be above the level of reactor coolant, so as not to drain the RCS when open.~~

APPLICABLE
SAFETY
ANALYSES

Safety analyses (Ref. 4) demonstrate that the reactor vessel is adequately protected against exceeding the Reference 1 P/T limits. In MODES 1, 2, and 3, and in MODE 4 with RCS cold leg temperatures exceeding ~~above the temperature below which LTOP is required as specified in the PTLR~~ [275]°F, the pressurizer safety valves will prevent RCS pressure from exceeding the Reference 1 limits. ~~At or below the limiting temperature specified in the PTLR At about [275]°F and below,~~ overpressure prevention falls to two OPERABLE RCS relief valves Class I PORVs or to a depressurized RCS and a sufficiently sized RCS vent. Each of these means has a limited overpressure relief capability.

The actual temperature at which the pressure in the P/T limit curve falls below the pressurizer safety valve setpoint increases as the reactor vessel material toughness decreases due to neutron embrittlement. Each time the PTLR curves are revised, the LTOP System must be re-evaluated to ensure its functional requirements can still be met using the RCS relief valve method or the depressurized and vented RCS condition.

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

The PTLR contains the acceptance limits that define the LTOP requirements. Any change to the RCS must be evaluated against the Reference 4 analyses to determine the impact of the change on the LTOP acceptance limits.

Transients that are capable of overpressurizing the RCS are categorized as either mass or heat input transients, examples of which follow:

Mass Input Type Transients

- a. Inadvertent safety injection;
- b. Charging/letdown flow mismatch;
- c. ~~Accumulator discharge~~

Heat Input Type Transients)

- a. Inadvertent actuation of pressurizer heaters;
- b. Loss of RHR cooling; or
- c. Reactor coolant pump (RCP) startup with temperature asymmetry within the RCS or between the RCS and steam generators.

The following are required during the LTOP MODES to ensure that mass and heat input transients do not occur, which either of the LTOP overpressure protection means cannot handle:

- a. Rendering all ~~SI but [one] [HPI] pumps and one CCP~~ incapable of injection;
- b. Deactivating the accumulator discharge isolation valves in their closed positions; and
- c. ~~Disallowing~~ ~~Precluding~~ start of an RCP if secondary temperature is more than 50°F above primary temperature in any one loop and ~~pressurizer water level is not less than 50%. LCO 3.4.6, "RCS Loops - MODE 4," and LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," provide this protection.~~

The Reference 4 analyses demonstrate that either one RCS relief valve or the depressurized RCS and RCS vent can maintain RCS pressure below limits when only ~~one [HPI] pump and one charging pumps CCP~~ is actuated. Thus, the LCO allows only ~~one [HPI] pump [and one charging pumps] CCP~~ OPERABLE during the LTOP MODES. Since neither one RCS relief valve nor the RCS vent can handle the pressure transient ~~resulting~~ need from accumulator injection, when RCS temperature is low the LCO also requires ~~the~~ accumulators isolation when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed in the PTLR.

(Continued)

BASES

APPLICABLE SAFETY ANALYSES (continued) The isolated accumulators must have their discharge valves closed and the valve power supply breakers fixed in their open positions. ~~The analyses show the effect of accumulator discharge is over a narrower RCS temperature range ([175]°F and below) than that of the LCO ([275]°F and below).~~

~~Fracture mechanics analyses established the~~ The current DCCP temperature of LTOP Applicability at of 270 [275]°F was determined in agreement with NRC Branch Technical Position 5-2. ~~This number was added to the current TS by LA 100/99~~

The consequences of a small break loss of coolant accident (LOCA) in LTOP MODE 4 conform to 10 CFR 50.46 and 10 CFR 50, Appendix K (Refs. 5 and 6), requirements by having a maximum of ~~[one] [HPI] pump and one charging pumps]~~ ~~one CCP OPERABLE and SI actuation enabled.~~

PORV Performance

The fracture mechanics analyses show that the vessel is protected when the PORVs are set to open at or below the P/T limit shown in the PTLR. The setpoints are derived by analyses that model the performance of the LTOP System, assuming the limiting LTOP transient of ~~[one] [HPI] pump and one charging pumps]~~ ~~one CCP injecting into the RCS with the positive displacement charging pump (PDP) operating and with RCS letdown isolated.~~ These analyses consider pressure overshoot and undershoot beyond the PORV opening and closing, resulting from signal processing and valve stroke times. The PORV setpoints at or below the derived limit ensures the Reference 1 P/T limits will be met ~~at low temperature operation.~~

The PORV setpoints in the PTLR will be updated when the revised P/T limits conflict with the LTOP analysis limits. The P/T limits are periodically modified as the reactor vessel material toughness decreases due to neutron embrittlement caused by neutron irradiation. Revised limits are determined using neutron fluence projections and the results of examinations of the reactor vessel material irradiation surveillance specimens. ~~The Bases for LCO 3.4.3, "RCS Pressure and Temperature (P/T) Limits," PTLR discusses these examinations.~~

~~The PORVs are considered active components. Thus, the~~ ~~The~~ failure of one ~~Class I~~ PORV is assumed to represent the worst case, single active failure.

RHR Suction Relief Valve Performance]

~~The RHR suction relief valves do not have variable pressure and temperature lift setpoints like the PORVs. Analyses must show that one RHR suction relief valve with a setpoint at or between [436.5] psig and [463.5] psig will pass flow greater than that required for the limiting LTOP transient while maintaining RCS pressure less than the P/T limit curve. Assuming all relief flow requirements during the limiting LTOP event, an RHR suction relief valve will maintain RCS pressure to~~

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

~~within the valve rated lift setpoint, plus an accumulation < 10% of the rated lift setpoint.~~

~~Although each RHR suction relief valve may itself meet single failure criteria, its inclusion and location within the RHR System does not allow it to meet single failure criteria when spurious RHR suction isolation valve closure is postulated. Also, as the RCS P/T limits are decreased to reflect the loss of toughness in the reactor vessel materials due to neutron embrittlement, the RHR suction relief valves must be analyzed to still accommodate the design basis transients for LTOP.~~

~~The RHR suction relief valves are considered active components. Thus, the failure of one valve is assumed to represent the worst case single active failure.~~

RCS Vent Performance

With the RCS depressurized, analyses show a vent size of 2.07 square inches is capable of mitigating the allowed LTOP overpressure transient. The capacity of a vent this size is greater than the flow of the limiting transient for the LTOP configuration, ~~[one] HPI pump [and one charging pump] no SI pumps and one CCP~~ OPERABLE, maintaining RCS pressure less than the maximum pressure on the P/T limit curve.

The RCS vent size will be re-evaluated for compliance each time the P/T limit curves are revised based on the results of the vessel material surveillance.

The RCS vent is passive and is not subject to active failure. ~~The pathway from the RCS to the vent is also considered to be passive. The vent is considered to connect directly to the RCS. If the pathway includes devices with the potential to block the pathway, these devices must be secured to avoid blocking the vent.~~

The LTOP System satisfies Criterion 2 of ~~the NRC Policy Statement~~ 10 CFR 50.36 (c) (2) (ii).

LCO

This LCO requires that the LTOP System is OPERABLE. The LTOP System is OPERABLE when ~~the minimum RCS coolant input and pressure relief capabilities are OPERABLE within limits established in the LCO.~~ Violation of this LCO could lead to the loss of low temperature overpressure mitigation capability and violation of the Reference 1 PTLR limits as a result of an operational transient.

To limit the coolant input capability, the LCO requires ~~that a maximum of [zero SI] [one] [HPI] pumps and [one CCP (except during pump swap operations)] charging pump be capable of injecting into the RCS, and all accumulator discharge isolation valves be closed and immobilized when when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed in the PTLR.~~

(Continued)

BASES

The elements of the LCO that provide low temperature overpressure mitigation through pressure relief are:

a. Two RCS relief valves ~~Class 1 PORVs~~ as follows:

1. A ~~Class 1~~ PORV is OPERABLE for LTOP when its block valve is open, its lift setpoint is set to the limit required by the PTLR and testing proves its ability to open at this setpoint, and motive power is available to the two valves and their control circuits.

~~[2. Two OPERABLE RHR suction relief valves; or]~~

<p>An RHR suction relief valve is OPERABLE for LTOP when its RHR suction isolation valve and its RHR suction valve are open, its setpoint is at or between [436.5] psig and [463.5] psig, and testing has proven its ability to open at this setpoint.</p>	<p>An RHR suction relief valve is OPERABLE for LTOP when its RHR suction isolation valve and its RHR suction valve are open, its setpoint is at or between [436.5] psig and [463.5] psig, and testing has proven its ability to open at this setpoint.</p>
---	---

<p>3- One OPERABLE PORV and one OPERABLE RHR suction relief valve; or</p>	<p>3- One OPERABLE PORV and one OPERABLE RHR suction relief valve; or</p>
--	--

~~OR~~

b. ~~A depressurized RCS and an RCS vent.~~

An RCS vent is OPERABLE when open with an area of \geq ~~2.07~~ square inches.

~~Each~~ ~~Either~~ of these methods of overpressure prevention is capable of mitigating the limiting LTOP transient.

~~the LCO is modified by a Note that permits two LCO capable of injecting into the RCS until 1 hour after completion of pump swap operation~~

APPLICABILITY This LCO is applicable in MODE 4 when any RCS cold leg temperature is \leq the temperature below which LTOP is required as specified in the PTLR [275]°F, in MODE 5, and in MODE 6 when the reactor vessel head is on and the vessel head closure bolts are not fully de-tensioned. RCS overpressure protection is not required in MODE 6 with the reactor vessel head closure bolts fully de-tensioned. The pressurizer safety valves provide overpressure protection that meets the Reference 1 P/T limits above the limiting temperature specified in the PTLR [275]°F. When the reactor vessel head is off, overpressurization cannot occur.

~~LCO 3.4.3~~ The PTLR provides the operational P/T limits for all MODES. LCO 3.4.10, "Pressurizer Safety Valves," requires the OPERABILITY of the pressurizer safety valves that provide overpressure protection during MODES 1, 2, 3, and MODE 4 above the limiting RCS temperature specified in the PTLR [275]°F.

(Continued)

BASES (continued)

APPLICABILITY (continued) Low temperature overpressure prevention is most critical during shutdown when the RCS is water solid, and a mass or heat input transient can cause a very rapid increase in RCS pressure when little or no time allows ~~is available for~~ operator action to mitigate the event.

The Applicability is modified by ~~two Notes~~. ~~Note 1 states~~ stating that accumulator isolation is only required when the accumulator pressure is more than or at the maximum RCS pressure for the existing temperature, as allowed by the P/T limit curves. This Note permits the accumulator discharge isolation valve Surveillance to be performed only under these pressure and temperature conditions. ~~Note 2 states that more than one charging pump may be capable of injection into the RCS during, and up to 1 hour after swapping charging pump operation.~~

ACTIONS

A.1 and B.1

With ~~one two~~ or more ~~SI HPI pumps or two CCPs~~ capable of injecting into the RCS, RCS overpressurization is possible.

To immediately initiate action to restore restricted coolant input capability to the RCS reflects the urgency of removing the RCS from this condition.

~~Required Action B.1 is modified by a Note that permits two charging pumps capable of RCS injection for < 15 minutes to allow for pump swaps.~~

~~The CCP and the PDP are capable of injecting into the RCS both operating alone or simultaneously. Their operation is limited to the conditions specified in the PTLR. The current limitations are based on RCS temperature as follows:~~

<u>RCS Temperature</u>	<u>Allowable Charging Pumps Capable of Injecting into the RCS</u>
<u>Greater than 270°F</u>	<u>Two CCPs AND one PDP</u>
<u>Less than or equal to 270°F but greater than approximately 162°F</u>	<u>One CCP AND one PDP</u>
<u>Less than or equal to approximately 162°F but greater than approximately 134°F</u>	<u>One CCP OR one PDP</u>
<u>Less than or equal to approximately 134°F</u>	<u>One CCP OR one PDP AND ECCS charging injection flow path isolated</u>

(Continued)

BASES

If the RCS reactor vessel head is fully de-tensioned or the RCS is not intact, the above limitation on charging and SI pumps do not apply.

ACTIONS
(continued)

C.1, D.1, and D.2

An unisolated accumulator requires isolation within 1 hour. This is only required when the accumulator pressure is at or more than the maximum RCS pressure for the existing temperature allowed by the P/T limit curves.

If isolation is needed and cannot be accomplished in 1 hour, Required ACTION D.1 and Required ACTION D.2 provide two options, either of which must be performed in the next 12 hours. By increasing the RCS temperature to $>$ the temperature below which LTOP is required as specified in the PTLR [275]^oF, an accumulator pressure of 600 psig cannot exceed the LTOP P/T limits if the accumulators are fully injected. The second option to depressurize the accumulators below the LTOP P/T limits from the PTLR also gives this protection.

The Completion Times are based on operating experience that these activities can be accomplished in these time periods and on engineering evaluations indicating that an event requiring LTOP is not likely in the allowed times.

E.1

In MODE 4 when any RCS cold leg temperature is \leq the temperature below which LTOP is required as specified in the PTLR [275]^oF, with one required RCS Class I PORV relief valve inoperable, the RCS relief valve Class I PORV must be restored to OPERABLE status within a Completion Time of 7 days. Two RCS Class I PORVs relief valves [in any combination of the PORVs and the RHR suction relief valves] are required to provide low temperature overpressure mitigation while withstanding a single failure of an active component.

The Completion Time considers the facts that only one of the RCS relief valves Class I PORVs is required to mitigate an overpressure transient and that the likelihood of an active failure of the remaining valve path during this time period is very low.

F.1

The consequences of operational events that will overpressurize the RCS are more severe at lower temperature (Ref. 7). Thus, with one of the two RCS relief valves Class I PORVs inoperable in MODE 5 or in MODE 6 with the head on and the vessel head closure bolts not fully de-tensioned, the Completion Time to restore two valves to OPERABLE status is 24 hours.

(Continued)

BASES

ACTIONS
 (continued)

The Completion Time represents a reasonable time to investigate and repair several types of relief valve failures without exposure to a lengthy period with only one OPERABLE RCS relief valve Class I PORV to protect against overpressure events.

G.1

The RCS must be depressurized and a vent must be established within 8 hours when:

- a. Both required RCS relief valves Class I PORVs are inoperable; or
- b. A Required Action and associated Completion Time of Condition A, B, D, E, or F is not met; or
- c. The LTOP System is inoperable for any reason other than Condition A, B, C, D, E, or F.

The vent must be sized ≥ 2.07 square inches to ensure that the flow capacity is greater than that required for the worst case mass input transient reasonable during the applicable MODES. This action is needed to protect the RCPB from a low temperature overpressure event and a possible brittle failure of the reactor vessel.

The Completion Time considers the time required to place the plant in this Condition and the relatively low probability of an overpressure event during this time period due to increased operator awareness of administrative control requirements.

SURVEILLANCE
 REQUIREMENTS

SR 3.4.12.1, SR 3.4.12.2 and SR 3.4.12.3

To minimize the potential for a low temperature overpressure event by limiting the mass input capability, a maximum of zero SI [one] [HPI] pumps [and a maximum of one charging pumps] CCP are verified incapable of injecting into the RCS and the accumulator discharge isolation valves are verified closed and locked-out, their breakers open. Verification that each accumulator is isolated is only required when accumulator isolation is required as stated in Note 1 to the Applicability.

The SI [HPI] pumps and one CCP charging pump[s] are rendered incapable of injecting into the RCS for example, through removing the power from the pumps by racking the breakers out under administrative control or by isolating the discharge of the pump by closed isolation valves with power removed from the operators or by a manual isolation valve secured in the closed position.

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

An alternate method of LTOP providing low temperature overpressure protection control may be employed using at least two independent means to prevent a pump start such that a single failure or single action will not that could result in an injection into the RCS. This may be accomplished through the pump control switch being placed in [pull to lock] and at least one valve in the discharge flow path being closed. An inoperable pump may be energized for test or for accumulator fill provided the discharge of the pump is isolated from the RCS by closed isolation valve(s) with power removed from the valve operator(s), or by manual isolation valve(s) sealed in the closed position. The Frequency of 12 hours is sufficient, considering other indications and alarms available to the operator in the control room, to verify the required status of the equipment.

SR 3.4.12.4 NOT USED

~~Each required RHR suction relief valve shall be demonstrated OPERABLE by verifying its RHR suction valve and RHR suction isolation valves are open and by testing it in accordance with the Inservice Testing Program. (Refer to SR 3.4.12.7 for the RHR suction isolation valve Surveillance.) This Surveillance is only required to be performed if the RHR suction relief valve is being used to meet this LCO.~~

~~The RHR suction valve is verified to be opened every 12 hours. The Frequency is considered adequate in view of other administrative controls such as valve status indications available to the operator in the control room that verify the RHR suction valve remains open.~~

~~The ASME Code, Section XI (Ref. 8), test per Inservice Testing Program verifies OPERABILITY by proving proper relief valve mechanical motion and by measuring and, if required, adjusting the lift setpoint.~~

SR 3.4.12.5

The RCS vent of ≥ 207 square inches is proven OPERABLE by verifying its open condition either:

- a. Once every 12 hours for a valve that cannot be is not locked, sealed, or secured in the open position.
- b. Once every 31 days for other vent paths (e.g., a valve that is locked, sealed, or otherwise secured in the open position. A removed pressurizer safety valve or open manway also fits this category.

The Any passive vent path arrangement need must only be open to be OPERABLE. This Surveillance is required to be performed if the vent is being used to satisfy the pressure relief requirements of the LCO 3.4.12.b.

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.4.12.6

The ~~Class I~~ PORV block valve must be verified open every 72 hours to provide the flow path for each required ~~Class I~~ PORV to perform its function when actuated. The valve must be remotely verified open in the main control room. ~~This surveillance is performed if the PORV satisfies the LCO.~~

The block valve is a remotely controlled, motor operated valve. The power to the valve operator is not required removed, and the manual operator is not required locked in the inactive position. Thus, the block valve can be closed in the event the PORV develops excessive leakage or does not close (sticks open) after relieving an overpressure situation.

The 72 hour Frequency is considered adequate in view of other administrative controls available to the operator in the control room, such as valve position indication, that verify that the ~~Class I~~ PORV block valve remains open.

SR 3.4.12.7 ~~NOT USED~~

~~Each required RHR suction relief valve shall be demonstrated OPERABLE by verifying its RHR suction valve and RHR suction isolation valve are open and by testing it in accordance with the Inservice Testing Program. (Refer to SR 3.4.12.4 for the RHR suction valve Surveillance and for a description of the requirements of the Inservice Testing Program.) This Surveillance is only performed if the RHR suction relief valve is being used to satisfy this LCO.~~

~~Every 31 days the RHR suction isolation valve is verified locked open, with power to the valve operator removed, to ensure that accidental closure will not occur. The "locked open" valve must be locally verified in its open position with the manual actuator locked in its inactive position. The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve position.~~

SR 3.4.12.8

~~The Note SR states that the SR is not required to be performed until 12 hours after decreasing any RCS cold leg temperature to $\leq 275^{\circ}\text{F}$ the temperature below which LTOP is required as specified in the PTLR. The test must be performed within 12 hours after entering the LTOP MODES. The 12 hour allowance Frequency considers the unlikelihood of a low temperature overpressure event during this time.~~

~~Following the initial 12 hour SR, while remaining in the Applicable LTOP MODE, the SR will be performed every 31 days thereafter on each required Class I PORV to verify and, as necessary, adjust its lift setpoint. The COT will verify the setpoint is within the PTLR allowed limits in the PTLR. PORV actuation could depressurize the RCS and is not required.~~

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

~~Performance of a COT is required within 12 hours after decreasing RCS temperature to < the temperature below which LTOP is required as specified in the PTLR [275]°F and every 31 days thereafter on each required Class I PORV to verify and, as necessary, adjust its lift setpoint. The COT will verify the setpoint is within the PTLR allowed maximum limits in the PTLR. PORV actuation could depressurize the RCS and is not required.~~

~~A Note has been added indicating that this SR is required to be performed met 12 hours after decreasing RCS cold leg temperature to < the temperature below which LTOP is required as specified by the PTLR [275]°F. The COT cannot be performed until in the LTOP MODES when the PORV lift setpoint can be reduced to the LTOP setting. The test must be performed within 12 hours after entering the LTOP MODES.~~

SR 3.4.12.9

Performance of a CHANNEL CALIBRATION on each required Class I PORV actuation channel is required every 18 months to adjust the whole channel so that it responds and the valve opens within the required range and accuracy to known input.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.13 RCS Operational LEAKAGE

BASES

BACKGROUND Components that contain or transport the coolant to or from the reactor core make up the RCS. Component joints are made by welding, bolting, rolling, or pressure loading, and valves isolate connecting systems from the RCS.

During plant life, the joint and valve interfaces can produce varying amounts of reactor coolant LEAKAGE, through either normal operational wear or mechanical deterioration. The purpose of the RCS Operational LEAKAGE LCO is to limit system operation in the presence of LEAKAGE from these sources to amounts that do not compromise safety. This LCO specifies the types and amounts of LEAKAGE.

10 CFR 50, Appendix A, GDC 30 (Ref. 1), requires means for detecting and, to the extent practical, identifying the source of reactor coolant LEAKAGE. Regulatory Guide 1.45 (Ref. 2) describes acceptable methods for selecting leakage detection systems.

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring reactor coolant LEAKAGE into the containment area is necessary. Quickly separating the identified LEAKAGE from the unidentified LEAKAGE is necessary to provide quantitative information to the operators, allowing them to take corrective action should a leak occur that is detrimental to the safety of the facility and the public.

Possible leakage from a Control Rod Drive Mechanism (CRDM) canopy seal weld may be construed as either identified or unidentified LEAKAGE but not construed as pressure boundary LEAKAGE in accordance with Westinghouse letter PGE-88-622.

A limited amount of leakage inside containment is expected from auxiliary systems that cannot be made 100% leak tight. Leakage from these systems should be detected, located, and isolated from the containment atmosphere, if possible, to not interfere with RCS leakage detection.

This LCO deals with protection of the reactor coolant pressure boundary (RCPB) from degradation and the core from inadequate cooling, in addition to preventing the accident analyses radiation release assumptions from being exceeded. The consequences of violating this LCO include the possibility of a loss of coolant accident (LOCA).

APPLICABLE SAFETY ANALYSES Except for primary to secondary LEAKAGE, the safety analyses do not address operational LEAKAGE. However, other operational LEAKAGE is related to the safety analyses for LOCA; the amount of leakage can affect the probability of such an event. The safety analysis for an event resulting in steam discharge to

(Continued)

BASES

APPLICABLE SAFETY ANALYSES (continued) the atmosphere assumes a 1 gpm primary to secondary LEAKAGE as the initial condition.

Primary to secondary LEAKAGE is a factor in the dose releases outside containment resulting from a steam line break (SLB) accident. To a lesser extent, other accidents or transients involve secondary steam release to the atmosphere, such as a steam generator tube rupture (SGTR). The leakage contaminates the secondary fluid.

~~The FSAR (Ref. 3) analysis for SGTR assumes the contaminated secondary fluid is only briefly released via safety valves and the majority is steamed to the condenser. The 1 gpm primary to secondary LEAKAGE is relatively inconsequential.~~

~~The SLB is more limiting for site radiation releases. The safety analysis for the SLB accident assumes 1 gpm primary to secondary LEAKAGE in one generator as an initial condition. The dose consequences resulting from the SLB accident are well within the limits defined in 10 CFR 100 (Ref. 6) or the staff approved licensing basis (i.e., a small fraction of these limits).~~

~~The SGTR (Ref. 3) is more limiting for radiological releases at the site boundary. The radiological dose analysis assumes loss of off-site power at the time of reactor trip with no subsequent condenser cooling available. The steam generator (SG) PORV for the SG that has sustained the tube rupture is assumed to be open for 30 minutes, at which time the RCS pressure is below the lift setting of the PORV. The dose consequences resulting from the SGTR accident are within the limits defined in 10 CFR 100 (Ref. 6).~~

~~The safety analysis for RCS main loop piping for GDC-4 (Ref. 1) assumes 1 gpm unidentified leakage and monitoring per RG 1.45 (Ref. 2) are maintained (Ref. 4 and 5).~~

The RCS operational LEAKAGE satisfies Criterion 2 of the NRC Policy Statement. ~~10 CFR 50.36 (c) (2) (11).~~

LCO RCS operational LEAKAGE shall be limited to:

a. Pressure Boundary LEAKAGE

No pressure boundary LEAKAGE is allowed, being indicative of material deterioration. LEAKAGE of this type is unacceptable as the leak itself could cause further deterioration, resulting in higher LEAKAGE. Violation of this LCO could result in continued degradation of the RCPB. LEAKAGE past seals and gaskets, or the CRDM canopy seal welds is not pressure boundary LEAKAGE.

Pressure boundary leakage is defined as "non-isolable" leakage. A "non-isolable" RCS leak is one that is not capable of being isolated from the RCS using installed automatic or accessible manual valves.

(Continued)

BASES

LCO
(continued)

b. Unidentified LEAKAGE

One gallon per minute (gpm) of unidentified LEAKAGE is allowed as a reasonable minimum detectable amount that the containment air monitoring and containment sump level monitoring equipment can detect within a reasonable time period. Violation of this LCO could result in continued degradation of the RCPB, if the LEAKAGE is from the pressure boundary.

c. Identified LEAKAGE

Up to 10 gpm of identified LEAKAGE is considered allowable because LEAKAGE is from known sources that do not interfere with detection of unidentified identified LEAKAGE and is well within the capability of the RCS Makeup System. Identified LEAKAGE includes LEAKAGE to the containment from specifically known and located sources, but does not include pressure boundary LEAKAGE or controlled reactor coolant pump (RCP) seal leakoff (a normal function not considered LEAKAGE). Identified LEAKAGE does not include LEAKAGE from portions of the Chemical and Volume Control System outside of containment that can be isolated from the RCS. LEAKAGE of this nature may be reviewed for possible impact on the Primary Coolant Sources Outside Containment Program. Violation of this LCO could result in continued degradation of a component or system.

d. Primary to Secondary LEAKAGE through All Steam Generators (SGs)

Total primary to secondary LEAKAGE amounting to 1 gpm through all SGs produces acceptable offsite doses in the SLB accident analysis. Violation of this LCO could exceed the offsite dose limits for this accident. Primary to secondary LEAKAGE must be included in the total allowable limit for identified LEAKAGE.

e. Primary to Secondary LEAKAGE through Any One SG

The 500 gallons per day limit on one SG is based on the assumption that a single crack leaking this amount would not propagate to a SGTR under the stress conditions of a LOCA or a main steam line rupture. If leaked through many cracks, the cracks are very small, and the above assumption is conservative

APPLICABILITY In MODES 1, 2, 3, and 4, the potential for RCPB LEAKAGE is greatest when the RCS is pressurized.

In MODES 5 and 6, LEAKAGE limits are not required because the reactor coolant pressure is far lower, resulting in lower stresses and reduced potentials for LEAKAGE.

LCO 3.4.14, "RCS Pressure Isolation Valve (PIV) Leakage," measures leakage through each individual PIV and can impact this LCO. Of the two PIVs in series

(Continued)

BASES

APPLICABILITY (continued) in each isolated line, leakage measured through one PIV does not result in RCS LEAKAGE when the other is leak tight. If both valves leak and result in a loss of mass from the RCS, the loss must be included in the allowable identified LEAKAGE.

ACTIONS A.1

Unidentified LEAKAGE, identified LEAKAGE, or primary to secondary LEAKAGE in excess of the LCO limits must be reduced to within limits within 4 hours. This Completion Time allows time to verify leakage rates and either identify unidentified LEAKAGE or reduce LEAKAGE to within limits before the reactor must be shut down. This action is necessary to prevent further deterioration of the RCPB.

B.1 and B.2

If any pressure boundary LEAKAGE exists, or if unidentified LEAKAGE, identified LEAKAGE, or primary to secondary LEAKAGE cannot be reduced to within limits within 4 hours, the reactor must be brought to lower pressure conditions to reduce the severity of the LEAKAGE and its potential consequences. It should be noted that LEAKAGE past seals and gaskets is not pressure boundary LEAKAGE. The reactor must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. This action reduces the LEAKAGE and also reduces the factors that tend to degrade the pressure boundary.

The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems. In MODE 5, the pressure stresses acting on the RCPB are much lower, and further deterioration is much less likely.

SURVEILLANCE REQUIREMENTS SR 3.4.13.1

Verifying RCS LEAKAGE to be within the LCO limits ensures the integrity of the RCPB is maintained. Pressure boundary LEAKAGE would at first appear as unidentified LEAKAGE and can only be positively identified by inspection. It should be noted that LEAKAGE past seals and gaskets is not pressure boundary LEAKAGE. Unidentified LEAKAGE and identified LEAKAGE are determined by performance of an RCS water inventory balance. Primary to secondary LEAKAGE is also measured by performance of an RCS water inventory balance in conjunction with effluent monitoring within the secondary steam and feedwater systems.

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

The RCS water inventory balance must be met with the reactor at steady state operating conditions and near operating pressure. Therefore, a Note is added allowing that this SR is not required to be performed in MODES 3 and 4 until 12 hours of after establishing steady state operation near operating pressure, have been established. The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established.

Steady state operation is required to perform a proper inventory balance since calculations during maneuvering are not useful. and a Note requires the Surveillance to be met when steady state is established. For RCS operational LEAKAGE determination by water inventory balance, steady state is defined as stable RCS pressure, temperature, (avg changes less than 5°F per hour) power level, pressurizer and makeup tank levels, makeup and letdown, and RCP seal injection and return flows.

An early warning of pressure boundary LEAKAGE or unidentified LEAKAGE is provided by the automatic systems that monitor the containment atmosphere radioactivity and by the containment structure sump level and flow monitoring system. It should be noted that LEAKAGE past seals, and gaskets or CRDM canopy seal welds is not pressure boundary LEAKAGE. These leakage detection systems are specified in LCO 3.4.15, "RCS Leakage Detection Instrumentation."

The 72 hour Frequency is a reasonable interval to trend LEAKAGE and recognizes the importance of early leakage detection in the prevention of accidents. A Note under the Frequency column states that this SR is required to be performed during steady state operation. The 12 hour Frequency after steady state operation has been achieved provides for those situations following a transient such that the 72 hours plus extension allowed by SR 3.0.2 would be exceeded. Under these circumstances, the SR would be due within 12 hours after steady state operation has been reestablished and every 72 hours thereafter during steady state operation. Steady state is defined as T_{avg} being changed by less than 5°F/hour.

SR 3.4.13.2

This SR provides the means necessary to determine SG OPERABILITY in an operational MODE. The requirement to demonstrate SG tube integrity in accordance with the Steam Generator Tube Surveillance Program emphasizes the importance of SG tube integrity, even though this Surveillance cannot be performed at normal operating conditions. This surveillance does not tie directly to any of the leakage criteria in the LCO or of the conditions, therefore failure to meet this surveillance is considered failure to meet the integrity goals of the LCO and LCO 3.0.3 applies.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.14 RCS Pressure Isolation Valve (PIV) Leakage

BASES

BACKGROUND 10 CFR 50.2, 10 CFR 50.55a(c), and GDC 55 of 10 CFR 50, Appendix A (Refs. 1, 2, and 3), define RCS PIVs as any two normally closed valves in series within the reactor coolant pressure boundary (RCPB), which separate the high pressure RCS from an attached low pressure system. During their lives, these valves can produce varying amounts of reactor coolant leakage through either normal operational wear or mechanical deterioration. The RCS PIV Leakage LCO allows RCS high pressure operation when leakage through these valves exists in amounts that do not compromise safety.

The PIV leakage limit applies to each individual valve. Leakage through both series PIVs in a line must be included as part of the identified LEAKAGE, governed by LCO 3.4.13, "RCS Operational LEAKAGE." This is true during operation only when the loss of RCS mass through two series valves is determined by a water inventory balance (SR 3.4.13.1). A known component of the identified LEAKAGE before operation begins is the least of the two individual leak rates determined for leaking series PIVs during the required surveillance testing; leakage measured through one PIV in a line is not RCS operational LEAKAGE if the other is leak tight.

Although this specification provides a limit on allowable PIV leakage rate, its main purpose is to prevent overpressure failure of the low pressure portions of connecting systems. The Exceeding the leakage limit is an indication that may indicate the PIVs between the RCS and the connecting systems are degraded or degrading. PIV leakage could lead to overpressure of the low pressure piping or components. Failure consequences could be a loss of coolant accident (LOCA) outside of containment, an unanalyzed accident, that could degrade the ability for low pressure injection.

The basis for this LCO is the 1975 NRC "Reactor Safety Study" (Ref. 4) that identified potential intersystem LOCAs as a significant contributor to the risk of core melt. A subsequent study (Ref. 5) evaluated various PIV configurations to determine the probability of intersystem LOCAs.

PIVs are provided to isolate the RCS from the following typically connected systems:

- a. Residual Heat Removal (RHR) System;
- b. Safety Injection System; and
- c. Chemical and Volume Control System.

(Continued)

BASES

BACKGROUND (continued) Violation of this LCO could result in continued degradation of a PIV, which could leak to overpressurization of a low pressure system and the loss of the integrity of a fission product barrier.

APPLICABLE SAFETY ANALYSES Reference 4 identified potential intersystem LOCAs as a significant contributor to the risk of core melt. The dominant accident sequence in the intersystem LOCA category is the failure of the low pressure portion of the RHR System outside of containment. The accident is the result of a postulated failure of the PIVs, which are part of the RCPB, and the subsequent pressurization of the RHR System downstream of the PIVs from the RCS. Because the low pressure portion of the RHR System is typically designed for 600 psig, overpressurization failure of the RHR low pressure line would result in a LOCA outside containment and subsequent risk of core melt.

Reference 5 evaluated various PIV configurations, leakage testing of the valves, and operational changes to determine the effect on the probability of intersystem LOCAs. This study concluded that periodic leakage testing of the PIVs can substantially reduce the probability of an intersystem LOCA.

RCS PIV leakage satisfies Criterion 2 of the NRC Policy Statement. ~~10 CFR 50.36 (c) (2) (11)~~.

LCO RCS PIV leakage is identified LEAKAGE into closed systems connected to the RCS. Isolation valve leakage is usually on the order of drops per minute. Leakage that increases significantly suggests that something is operationally wrong and corrective action must be taken.

The LCO PIV leakage limit is 0.5 gpm per nominal inch of valve size with a maximum limit of 5 gpm. ~~The previous criterion of 1 gpm for all valve sizes imposed an unjustified penalty on the larger valves without providing information on potential valve degradation and resulted in higher personnel radiation exposures. A study concluded a leakage rate limit based on valve size was superior to a single allowable value.~~

Reference 7 permits leakage testing at a lower pressure differential than between the specified maximum RCS pressure and the normal pressure of the connected system during RCS operation (the maximum pressure differential) in those types of valves in which the higher service pressure will tend to diminish the overall leakage channel opening. In such cases, the observed rate may be adjusted to the maximum pressure differential by assuming leakage is directly proportional to the pressure differential to the one half power.

(Continued)

BASES

APPLICABILITY In MODES 1, 2, 3, and 4, this LCO applies because the PIV leakage potential is greatest when the RCS is pressurized. In MODE 4, valves in the RHR flow path are not required to meet the requirements of this LCO when in, or during the transition to or from, the RHR mode of operation.

In MODES 5 and 6, leakage limits are not provided because the lower reactor coolant pressure results in a reduced potential for leakage and for a LOCA outside the containment

ACTIONS

The ACTIONS are modified by two Notes. Note 1 provides clarification that each flow path allows separate entry into a Condition. This is allowed based upon the functional independence of the flow path. Note 2 requires an evaluation of affected systems if a PIV is inoperable. The leakage may have affected system operability, or isolation of a leaking flow path with an alternate valve may have degraded the ability of the interconnected system to perform its safety function.

A.1, A.2.1 and A.2.2

The flow path must be isolated by two valves. Required ACTIONS A.1 and A.2 are modified by a Note that the valves used for isolation must meet the same leakage requirements as the PIVs and must be within the RCPB or the high pressure portion of the system

Required ACTION A.1 requires that the isolation with one valve must be performed within 4 hours. Four hours provides time to reduce leakage in excess of the allowable limit and to isolate the affected system if leakage cannot be reduced. The 4 hour Completion Time allows the actions and restricts the operation with leaking isolation valves.

Required ACTION A.2 specifies that the double isolation barrier of two valves be restored by closing some other valve qualified for isolation or restoring the RCS PIV to within limits. The 72 hours Completion Time after exceeding the limit allows for the restoration of the leaking PIV to OPERABLE status. This time frame considers the time required to complete the ACTION and the low probability of a second valve failing during this time period

or

~~The 72 hour Completion Time after exceeding the limit allows for the restoration of the leaking PIV to OPERABLE status. This time frame considers the time required to complete this Action and the low probability of a second valve failing during this period. (Reviewer Note: Two options are provided for Required Action A.2. The second option (72 hour restoration) is appropriate if isolation of a second valve would place the unit in an unanalyzed condition.)~~

(Continued)

BASES

ACTIONS
(continued) B.1 and B.2

If leakage cannot be reduced, ~~the system isolated~~ or the other Required Actions accomplished, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. This action may reduce the leakage and also reduces the potential for a LOCA outside containment. The allowed Completion Times are reasonable based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant system.

C-1

~~The inoperability of the RHR autoclosure interlock renders the RHR suction isolation valves incapable of isolating in response to a high pressure condition and preventing inadvertent opening of the valves at RCS pressures in excess of the RHR systems design pressure. If the RHR autoclosure interlock is inoperable, operation may continue as long as the affected RHR suction penetration is closed by at least one closed manual or deactivated automatic valve within 4 hours. This Action accomplishes the purpose of the autoclosure.~~

SURVEILLANCE
REQUIREMENTS SR 3.4.14.1

Performance of leakage testing on each RCS PIV or isolation valve used to satisfy Required Action A.1 and Required Action A.2 is required to verify that leakage is below the specified limit and to identify each leaking valve. The leakage limit of 0.5 gpm per inch of nominal valve diameter up to 5 gpm maximum applies to each valve. Leakage testing requires a stable pressure condition.

For the two PIVs in series, the leakage requirement applies to each valve individually and not to the combined leakage across both valves. ~~This method results in testing each valve separately.~~ If the PIVs are not individually leakage tested, one valve may have failed completely and not be detected if the other valve in series meets the leakage requirement. In this situation, the protection provided by redundant valves would be lost.

Testing is to ~~be~~ performed every ~~18~~ months, a typical refueling cycle, if the plant does not go into MODE 5 for at least 7 days. The ~~18~~ month frequency is consistent with 10 CFR 50.55a(g) (Ref. 8) as contained in the Inservice Testing Program, is within frequency allowed by the American Society of Mechanical Engineers (ASME) QSM Code, Section XI Part 10 (Ref. 7), and is based on the need to perform such surveillances under the conditions that apply during an outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.

(Continued)

BASES

SURVEILLANCE REQUIREMENTS SR 3.4.14.1 (continued)

~~Test pressures less than 2235 psig but greater than 150 psig are allowed for valves where higher pressures would tend to diminish leakage channel opening. Observed leakage shall be adjusted for actual pressure to 2235 psig assuming the leakage to be directly proportional to pressure differential to the one half power.~~

In addition, testing must be performed once after the valve has been opened by flow or exercised to ensure tight reseating. PIVs disturbed in the performance of this Surveillance should also be tested unless documentation shows that an infinite testing loop cannot practically be avoided. Testing must be performed within 24 hours after the valve has been resealed. Within 24 hours is a reasonable and practical time limit for performing this test after opening or reseating a valve.

The leakage limit is to be met at the RCS pressure associated with MODES 1 and 2. This permits leakage testing at high differential pressures with stable conditions not possible in the MODES with lower pressures.

Entry into MODES 3 and 4 is allowed to establish the necessary differential pressures and stable conditions to allow for performance of this Surveillance. ~~The Note that allows this provision is complementary to the Frequency of prior to entry into MODE 2 whenever the unit has been in MODE 5 for 7 days or more, if leakage testing has not been performed in the previous 9 months.~~ In addition, this Surveillance is not required to be performed on the RHR System when the RHR System is aligned to the RCS in the shutdown cooling mode of operation. PIVs contained in the RHR shutdown cooling flow path must be leakage rate tested after RHR is secured and stable unit conditions and the necessary differential pressures are established.

~~Testing is not required for the RHR suction isolation valves more frequently than 18 months as these valves are motor operated with control room position indication, inadvertent opening interlocks and system high pressure alarms.~~

SR 3.4.14.2 and 3.4.14.3 NOT USED

~~Verifying that the RHR system autoclosure interlocks are OPERABLE ensures that RCS pressure will not pressurize the RHR heat exchangers beyond 125% of their design pressure of [600] psig. The interlock setpoint that prevents the valves from being opened is set so the actual RCS pressure must be <[425] psig to open the valves. This setpoint ensures the RHR design pressure will not be exceeded and the RHR relief valves will not lift. The [18] month frequency is also acceptable based on consideration of the design reliability (and confirming operating experience) of the equipment.~~

(Continued)

BASES

~~These SRS are modified by Notes allowing the RHR autoclosure function to be disabled when using the RHR System suction relief valves for cold overpressure protection in accordance with SR 3.4.12.7.~~

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.15 RCS Leakage Detection Instrumentation

BASES

BACKGROUND GDC 30 of Appendix A to 10 CFR 50 (Ref. 1) requires means for detecting and, to the extent practical, identifying the location of the source of RCS LEAKAGE. Regulatory Guide 1.45 (Ref. 2) describes acceptable methods for selecting leakage detection systems.

Leakage detection systems must have the capability to detect significant reactor coolant pressure boundary (RCPB) degradation as soon after occurrence as practical to minimize the potential for propagation to a gross failure. Thus, an early indication or warning signal is necessary to permit proper evaluation of all unidentified LEAKAGE.

Industry practice has shown that water flow changes of 0.5 to 1.0 gpm can be readily detected in contained volumes by monitoring changes in water level, in flow rate, or in the operating frequency of a pump. The containment sumps used to collect unidentified LEAKAGE ~~is (or) and the containment fan cooling unit (CFCU) condensate collection monitor are instrumented to alarm for~~ capable of detecting increases of 0.5 to 1.0 gpm in the normal flow rates. This sensitivity is acceptable for detecting increases in unidentified LEAKAGE.

~~Each CFCU has an individual condensate collection monitor. The condensate from the cooling coils passes out from the CFCU to a containment sump. The condensate collection system design does not use an on-line flow monitor. The condensate drain flow can be collected, measured, and then using the elapsed time of the collection, the average flow rate can be determined. This monitoring can be done from the control room. Although multiple CFCUs may be operating, any individual CFCU condensate monitor may be employed to provide indication of the condensate flow rate.~~

The reactor coolant contains radioactivity that, when released to the containment, can be detected by radiation monitoring instrumentation. Reactor coolant radioactivity levels will be low during initial reactor startup and for a few weeks thereafter, until activated corrosion products have been formed and fission products appear from fuel element cladding contamination or cladding defects. Instrument sensitivities of 10^{-9} $\mu\text{Ci/cc}$ radioactivity for particulate monitoring and of 10^{-6} $\mu\text{Ci/cc}$ radioactivity for gaseous monitoring are practical for these leakage detection systems. Radioactivity detection systems are included for monitoring both particulate and gaseous activities because of their sensitivities and rapid responses to RCS LEAKAGE.

(Continued)

BASES

BACKGROUND
(continued)

An increase in humidity of the containment atmosphere would indicate release of water vapor to the containment. Dew point temperature measurements can thus be used to monitor humidity levels of the containment atmosphere as an indicator of potential RCS LEAKAGE. A 1°F increase in dew point is well within the sensitivity range of available instruments.

Since the humidity level is influenced by several factors, a quantitative evaluation of an indicated leakage rate by this means may be questionable and should be compared to observed increases in liquid flow into or from the containment sump [and condensate flow from air coolers]. Humidity level monitoring is considered most useful as an indirect alarm or indication to alert the operator to a potential problem. Humidity monitors are not required by this LCO.

Air temperature and pressure monitoring methods may also be used to infer unidentified LEAKAGE to the containment. Containment temperature and pressure fluctuate slightly during plant operation, but a rise above the normally indicated range of values may indicate RCS leakage into the containment. The relevance of temperature and pressure measurements are affected by containment free volume and, for temperature, detector location. Alarm signals from these instruments can be valuable in recognizing rapid and sizable leakage to the containment. Temperature and pressure monitors are not required by this LCO

APPLICABLE
SAFETY
ANALYSES

The asymmetric loads produced by postulated breaks are the result of assumed pressure imbalance, both internal and external to the RCS. The internal asymmetric loads result from a rapid decompression that causes large transient pressure differentials across the core barrel and fuel assemblies. The external asymmetric loads result from the rapid depressurization of the annulus regions, such as the annulus between the reactor vessel and the shield wall, and cause large transient pressure differentials to act on the vessel. These differential pressure loads could damage RCS supports, core cooling equipment or core internals. This concern was first identified as Multiplant Action (MPA) D-10 and subsequently as Unresolved Safety Issue (USI) 2, "Asymmetric LOCA Loads" (Ref. 4).

The resolution of USI-2 for Westinghouse PWRs was the use of fracture mechanics technology for RCS piping > 10 inches diameter. (Ref. 5). This technology became known as leak before break (LBB). Included within the LBB methodology was the requirement to have leak detection systems capable of detecting a 10 gpm leak within four hours. This leakage rate is designed to ensure that adequate margins exist to detect leaks in a timely manner during normal operating conditions. The use of the LBB methodology is described in Reference 6.

The need to evaluate the severity of an alarm or an indication is important to the operators, and the ability to compare and verify with indications from other systems is necessary. The system response times and sensitivities are described

(Continued)

BASES

APPLICABLE SAFETY in the FSAR (Ref. 3). ~~Multiple instrument locations are utilized, if needed, to ensure that the transport delay time of the leakage from its~~
ANALYSES (continued) ~~source to an instrument location yields an acceptable overall response time.~~

The safety significance of RCS LEAKAGE varies widely depending on its source, rate, and duration. Therefore, detecting and monitoring RCS LEAKAGE into the containment area is necessary.

Quickly separating the identified LEAKAGE from the unidentified LEAKAGE provides quantitative information to the operators, allowing them to take corrective action should a leakage occur ~~that could be~~ detrimental to the safety of the unit and the public.

RCS leakage detection instrumentation satisfies Criterion 1 of ~~the NRC Policy Statement.~~ ~~10 CFR 50.36 (c) (2) (11)~~

LCO One method of protecting against large RCS LEAKAGE derives from the ability of instruments to rapidly detect extremely small leaks. This LCO requires instruments of diverse monitoring principles to be OPERABLE to provide a high degree of confidence that extremely small leaks are detected in time to allow actions to place the plant in a safe condition when RCS LEAKAGE indicates possible RCPB degradation.

The LCO is satisfied when monitors of diverse measurement means are available. Thus, the containment sump monitoring systems, ~~in combination with a gaseous or the particulate radioactivity monitor and either a CFCU condensate collection monitor or a gaseous radioactivity monitor~~ provides an acceptable minimum

APPLICABILITY Because of elevated RCS temperature and pressure in MODES 1, 2, 3, and 4, RCS leakage detection instrumentation is required to be OPERABLE. In MODE 5 or 6, the temperature is to be $\leq 200^{\circ}\text{F}$ and pressure is maintained low or at atmospheric pressure. Since the temperatures and pressures are far lower than those for MODES 1, 2, 3, and 4, the likelihood of leakage and crack propagation are much smaller. Therefore, the requirements of this LCO are not applicable in MODES 5 and

ACTIONS ~~ACTIONS are modified by a Note that indicates that the provisions of LCO 3.0.4 are not applicable. As a result, a MODE change is allowed when the required containment sump monitor, the required atmospheric particulate monitor, the required atmospheric gaseous monitor or the required CFCU condensate collection monitor are inoperable. This allowance is provided because other instrumentation is available to monitor RCS LEAKAGE.~~

(Continued)

BASES

ACTIONS (continued) A.1 and A.2

With the required containment sump monitors inoperable, ~~no other form of sampling can provide the equivalent information; however,~~ RCS water inventory balance, the containment atmosphere particulate radioactivity monitor, and the CFCU condensate collection monitoring system will provide indications of changes in leakage. Together with the atmosphere monitors, the periodic surveillance for RCS water inventory balance, SR 3.4.13.1, must be performed at an increased frequency of 24 hours to provide information that is adequate to detect leakage. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (near rated operating pressure with stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown, and RCP seal injection and return flows). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established.

Restoration of the required sump monitoring system to OPERABLE status within a Completion Time of 30 days is required to regain the function after the monitoring system failure. This time is acceptable considering the Frequency and adequacy of the RCS water inventory balance required by Required ACTION A.1.

~~Required ACTION A.1 is modified by a Note that indicates that the provisions of LCO 3.0.4 are not applicable. As a result, a MODE change is allowed when the required containment sump monitoring system is inoperable. This allowance is provided because other instrumentation is available to monitor RCS leakage.~~

B.1.1, B.1.2, and B.2.1, and B.2.2

With ~~the~~ both gaseous and particulate containment atmosphere radioactivity monitoring instrumentation channels inoperable, alternative action is required. Either grab samples of the containment atmosphere must be taken and analyzed or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information.

With a sample obtained and analyzed or water inventory balance performed every 24 hours, the reactor may be operated for up to 30 days to allow restoration of the required containment atmosphere particulate radioactivity monitors. ~~Alternatively, continued operation is allowed if the air cooling condensate flow rate monitoring system is OPERABLE, provided grab samples are taken or water inventory balances are performed every 24 hours.~~

The 24 hour interval provides periodic information that is adequate to detect leakage. A Note is added allowing that SR 3.4.13.1 is not required to be performed until 12 hours after establishing steady state operation (with stable RCS pressure, temperature, power level, pressurizer and makeup tank levels, makeup and letdown, and RCP seal injection and return flows). The 12 hour allowance provides sufficient time to collect and process all necessary data after stable plant conditions are established. The 30 day Completion Time recognizes at least one other form of LEAKAGE detection is available.

(Continued)

BASES

ACTIONS
(continued)

~~Required Action B.1 and Required Action B.2 are modified by a Note that indicates that the provisions of LCO 3.0.4 are not applicable. As a result, a MODE change is allowed when the required gaseous and particulate containment atmosphere radioactivity monitor channel is inoperable. This allowance is provided because other instrumentation is available to monitor for RCS LEAKAGE.~~

C.1 and C.2

~~With the required containment air cooling condensate flow rate monitor inoperable, alternative action is again required. Either SR 3.4.15.1 must be performed or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information. Provided a CHANNEL CHECK is performed every 8 hours or a water inventory balance is performed every 24 hours, reactor operation may continue while awaiting restoration of the containment air cooling condensate flow rate monitor to OPERABLE status.~~

~~The 24 hour interval provides periodic information that is adequate to detect RCS LEAKAGE.~~

C.1.1, C.1.2, C.2.1, and C.2.2

~~With the required containment atmosphere gaseous radioactivity monitor and the required CFCU condensate collection monitor inoperable, the means of detecting leakage are the containment sump monitoring system and the containment atmosphere particulate radioactivity monitor. This Condition does not provide all the required diverse means of leakage detection. With both gaseous containment atmosphere radioactivity monitoring and CFCU condensate monitoring instrumentation channels inoperable, alternate action is required. Either grab samples of the containment atmosphere must be taken and analyzed or water inventory balances, in accordance with SR 3.4.13.1, must be performed to provide alternate periodic information.~~

The ~~Follow-up~~ Required Action is to restore either of the inoperable required monitors to OPERABLE status within 30 days to regain the intended leakage detection diversity. The 30 day Completion Time ensures that the plant will not be operated in a reduced configuration for a lengthy time period.

(Continued)

BASES

DE.1 and DE.2

ACTIONS
(continued)

If a Required Action of Condition A, B, or C, or D cannot be met, the plant must be brought to a MODE in which the requirement does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

EF.1

With all required monitors inoperable, (LCO a, b, and c) no automatic means of monitoring leakage are available, and immediate plant shutdown in accordance with LCO 3.0.3 is required. With two of the three groups of leak detection monitoring not operable, the two groups will enter their respective ACTION and Completion statements. The third group provides a continued monitoring function.

SURVEILLANCE REQUIREMENTS SR 3.4.15.1

SR 3.4.15.1 requires the performance of a CHANNEL CHECK of the required containment atmosphere radioactivity monitors. The check gives reasonable confidence that the channels ~~is~~ are operating properly. The Frequency of 12 hours is based on instrument reliability and is reasonable for detecting off-normal conditions.

SR 3.4.15.2

SR 3.4.15.2 requires the performance of a ~~CHANNEL FUNCTIONAL TEST (CFT) CFT~~ on the required containment atmosphere radioactivity monitors. The test ensures that the monitors can perform ~~its~~ their function in the desired manner including alarm functions. ~~The test verifies the alarm setpoint and relative accuracy of the instrument string setting.~~ The Frequency of 92 days considers instrument reliability, and operating experience has shown that it is proper for detecting degradation.

SR 3.4.15.3, SR 3.4.15.4, and SR 3.4.15.5

These SRs require the performance of a CHANNEL CALIBRATION for each of the RCS leakage detection instrumentation channels. The calibration verifies the accuracy of the instrument string, including the instruments located inside containment. The Frequency of 18 months is a typical refueling cycle and considers channel reliability. Again, operating experience has proven that this Frequency is acceptable.

B 3.4 REACTOR COOLANT SYSTEM (RCS)

B 3.4.16 RCS Specific Activity

BASES

BACKGROUND The maximum dose to the whole body and the thyroid that an individual at the site boundary can receive for 2 hours during an accident is specified in 10 CFR 100 (Ref. 1). The limits on specific activity ensure that the doses are held to a small fraction of the 10 CFR 100 limits during analyzed transients and accidents.

The RCS specific activity LCO limits the allowable concentration level of radionuclides in the reactor coolant. The LCO limits are established to minimize the offsite radioactivity dose consequences in the event of a steam generator tube rupture (SGTR) accident.

The LCO contains specific activity limits for both DOSE EQUIVALENT I-131 and gross specific activity. The allowable levels are intended to limit the 2 hour dose at the site boundary to a small fraction of the 10 CFR 100 dose guideline limits. The limits in the LCO are standardized, based on parametric evaluations of offsite radioactivity dose consequences for typical site locations.

The parametric evaluations showed the potential offsite dose levels for a SGTR accident were an appropriately small fraction of the 10 CFR 100 dose guideline limits. Each evaluation assumes a broad range of site applicable atmospheric dispersion factors in a parametric evaluation

**APPLICABLE
SAFETY
ANALYSES**

The LCO limits on the specific activity of the reactor coolant ensures that the resulting 2 hour doses at the site boundary will not exceed a small fraction of the 10 CFR 100 dose guideline limits following a SGTR accident. The SGTR safety analysis (Ref. 2) assumes the specific activity of the reactor coolant at the LCO limit and an existing reactor coolant steam generator (SG) tube leakage rate of 1 gpm. The safety analysis assumes the specific activity of the secondary coolant at its limit of 0.1 $\mu\text{Ci/gm}$ DOSE EQUIVALENT I-131 from LCO 3.7.18.6, "Secondary Specific Activity."

The analysis for the SGTR accident establishes the acceptance limits for RCS specific activity. Reference to this analysis is used to assess changes to the unit that could affect RCS specific activity, as they relate to the acceptance limits.

The analysis is for two cases of reactor coolant specific activity. One case assumes specific activity at 1.0 $\mu\text{Ci/gm}$ DOSE EQUIVALENT I-131 with a concurrent large iodine spike that increases the I-131 activity in the reactor coolant by a factor of about 50 immediately after the accident. The second case assumes the initial reactor coolant iodine activity at 60.0 $\mu\text{Ci/gm}$ DOSE EQUIVALENT I-131 due to a pre-accident iodine spike caused by an RCS transient. In both cases, the noble gas activity in the reactor coolant assumes 1%

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

failed fuel, which closely equals the LCO limit of $100/E$ $\mu\text{Ci/gm}$ for gross specific activity.

The analysis also assumes a loss of offsite power at the same time as the SGTR event. The SGTR causes a reduction in reactor coolant inventory. The reduction initiates a reactor trip from a low pressurizer pressure signal or an RCS overtemperature ΔT signal.

The coincident loss of offsite power causes the steam dump valves to close to protect the condenser. The rise in pressure in the ruptured SG discharges radioactively contaminated steam to the atmosphere through the SG power operated relief valves and the main steam safety valves. The unaffected SGs remove core decay heat by venting steam to the atmosphere until the cooldown ends.

The safety analysis shows the radiological consequences of an SGTR accident are within a small fraction of the Reference 1 dose guideline limits. Operation with iodine specific activity levels greater than the LCO limit is permissible, if the activity levels do not exceed the limits shown in Figure 3.4.16-1, in the applicable specification, for more than 48 hours. The safety analysis has concurrent and pre-accident iodine spiking levels up to $60.0 \mu\text{Ci/gm}$ DOSE EQUIVALENT I-131.

The remainder of the above limit permissible iodine levels shown in Figure 3.4.16-1 are acceptable because of the low probability of a SGTR accident occurring during the established 48 hour time limit. The occurrence of an SGTR accident at these permissible levels could increase the site boundary dose levels, but still be within 10 CFR 100 dose guideline limits.

The limits on RCS specific activity are also used for establishing standardization in radiation shielding and plant personnel radiation protection practices.

RCS specific activity satisfies Criterion 2 of the NRC Policy Statement. ~~10 CFR 50.36 (c) (2) (11)~~

LCO

The specific iodine activity is limited to $1.0 \mu\text{Ci/gm}$ DOSE EQUIVALENT I-131, and the gross specific activity in the reactor coolant is limited to the number of $\mu\text{Ci/gm}$ equal to 100 divided by E (average disintegration energy of the sum of the average beta and gamma energies of the coolant nuclides). The limit on DOSE EQUIVALENT I-131 ensures the 2 hour thyroid dose to an individual at the site boundary during the Design Basis Accident (DBA) will be a small fraction of the allowed thyroid dose. The limit on gross specific activity ensures the 2 hour whole body dose to an individual at the site boundary during the DBA will be a small fraction of the allowed whole body dose.

The SGTR accident analysis (Ref. 2) shows that the 2 hour site boundary dose levels are within acceptable limits. Violation of the LCO may result in reactor coolant radioactivity levels that could, in the event of an SGTR, lead to site boundary doses that exceed the 10 CFR 100 dose guideline limits.

(Continued)

BASES

APPLICABILITY In MODES 1 and 2, and in MODE 3 with RCS average temperature $\geq 500^{\circ}\text{F}$, operation within the LCO limits for DOSE EQUIVALENT I-131 and gross specific activity are necessary to contain the potential consequences of an SGTR to within the acceptable site boundary dose values.

For operation in MODE 3 with RCS average temperature $< 500^{\circ}\text{F}$, and in MODES 4 and 5, the offsite release of radioactivity from the affected SG in the event of a SGTR is unlikely since the saturation pressure of the reactor coolant is below the lift pressure settings of the main steam safety and relief valves

ACTIONS

A.1 and A.2

A Note to these ACTIONS excludes the MODE change restriction of LCO 3.0.4. This exception allows entry into the applicable MODE(S) while relying on the ACTIONS even though the ACTIONS may eventually require plant shutdown. This exception is acceptable due to the significant conservatism incorporated into the specific activity limit, the low probability of an event which is limiting due to exceeding this limit, and the ability to restore transient specific activity excursions while the plant remains at, or proceeds to power operation.

With the DOSE EQUIVALENT I-131 greater than the LCO limit, samples at intervals of 4 hours must be taken to demonstrate that the limits of Figure 3.4.16-1 are not exceeded. The Completion Time of 4 hours is required ~~allowed~~ to obtain and analyze a sample. Sampling is ~~done to~~ continued to provide a trend.

The DOSE EQUIVALENT I-131 must be restored to within limits within 48 hours. The Completion Time of 48 hours is ~~required, allowed to~~ permit recovery, if the limit violation resulted from normal iodine spiking.

B.1 and B.2

With the gross specific activity in excess of the allowed limit, ~~an analysis must be performed within 4 hours to determine DOSE EQUIVALENT I-131. The Completion Time of 4 hours is required to obtain and analyze a sample. The unit must be placed in a MODE in which the requirement does not apply.~~

The change within 6 hours to MODE 3 and RCS average temperature $< 500^{\circ}\text{F}$ lowers the saturation pressure of the reactor coolant below the setpoints of the main steam safety valves and prevents venting the affected SG to the environment in an SGTR event. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 below 500°F from full power conditions in an orderly manner and without challenging plant systems.

(Continued)

BASES

C.1 and C.2

If a Required Action and the associated Completion Time of Condition A is not met or if the DOSE EQUIVALENT I-131 is in the unacceptable region of Figure 3.4.16-1, the reactor must be brought to MODE 3 with RCS average temperature < 500°F within 6 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 below 500°F from full power conditions in an orderly manner and without challenging plant systems

SURVEILLANCE
REQUIREMENTSSR 3.4.16.1

SR 3.4.16.1 requires performing a gamma isotopic analysis as a measure of the gross specific activity of the reactor coolant at least once every 7 days. While basically a quantitative measure of radionuclides with half lives longer than 15 minutes, excluding iodines, this measurement is the sum of the degassed gamma activities and the gaseous gamma activities in the sample taken, beta-gamma activity and the total of all identified gaseous activities in the sample within two hours after the sample is taken and extrapolated back to when the sample was taken. Determination of the contributors to the gross specific activity shall be based upon those energy peaks identifiable with a 95% confidence level. The latest available data may be used for pure beta-emitting radionuclides. This Surveillance provides an indication of any increase in gross specific activity.

Trending the results of this Surveillance allows proper remedial action to be taken before reaching the LCO limit under normal operating conditions. The Surveillance is applicable in MODES 1 and 2, and in MODE 3 with T_{avg} at least 500°F. The 7 day Frequency considers the unlikelihood of a gross fuel failure during the time.

SR 3.4.16.2

This Surveillance is performed in MODE 1 only to ensure iodine remains within limit during normal operation and following fast power changes when fuel failure is more apt to occur. The 14 day Frequency is adequate to trend changes in the iodine activity level, considering gross activity is monitored every 7 days. The Frequency, between 2 and 6 hours after a power change $\geq 15\%$ RTP within a 1 hour period, is established because the iodine levels peak during this time following fuel failure; samples at other times would provide inaccurate less indicative results.

SR 3.4.16.3

A radiochemical analysis for \bar{E} determination is required every 184 days (6 months) with the plant operating in MODE 1 equilibrium (as defined in SR 3.4.16.3 NOTE) conditions. The \bar{E} determination directly relates to the LCO and is required to verify plant operation within the specified gross activity LCO limit. The analysis for \bar{E} is a measurement of the average energies per disintegration

(Continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

~~for isotopes with half lives longer than 15 minutes, excluding iodines. The qualitative measurement of the specific activity for each radionuclide, except for radionuclides with half-lives less than 15 minutes and all radiiodines which are identified in the reactor coolant. The specific activity for these individual radionuclides shall be used in the determination of E for the reactor coolant sample. Determination of the contributors to E shall be based upon those energy peaks identifiable with a 95% confidence level. The Frequency of 184 days recognizes E does not change rapidly.~~

This SR has been modified by a Note that indicates sampling for E determination is required to be performed within 31 days after a minimum of 2 effective full power days and 20 days of MODE 1 operation have elapsed since the reactor was last subcritical for at least 48 hours. This ensures that the radioactive materials are at equilibrium so the analysis for E is representative and not skewed by a crud burst or other similar abnormal event

~~B-3.4 REACTOR COOLANT SYSTEM (RCS)~~

~~B-3.4.17 RCS Loop Isolation Valves~~

~~BASES~~

~~BACKGROUND The RCS may be operated with loops isolated in order to perform maintenance. While operating with a loop isolated, there is potential for inadvertently opening the isolation valves in the isolated loop. In this event, the coolant in the isolated loop would suddenly begin to mix with the coolant in the operating loops. This situation has the potential of causing a positive reactivity addition with a corresponding reduction of SDM if:~~

- ~~a. The temperature in the isolated loop is lower than the temperature in the operating loops (cold water incident); or~~
- ~~b. The boron concentration in the isolated loop is lower than the boron concentration in the operating loops (boron dilution incident).~~

~~As discussed in the FSAR (Ref. 1), the startup of an isolated loop is performed in a controlled manner that virtually eliminates any sudden positive reactivity addition from cold water and/or boron dilution because:~~

- ~~a. LCO 3.4.18, "RCS Isolated Loop Startup," and plant operating procedures require that the boron concentration in the isolated loop be maintained higher than the boron concentration of the operating loops, thus eliminating the potential for introducing coolant from the isolated loop that could dilute the boron concentration in the operating loops;~~
- ~~b. The cold leg loop isolation valve cannot be opened unless the temperatures of both the hot and cold legs of the isolated loop are within 20°F of the temperatures of the hot and cold legs of the operating loops (compliance is ensured by operating procedures and automatic interlocks); and~~
- ~~c. Other automatic interlocks, all of which are part of the Reactor Protection System (RPS), prevent opening the hot leg loop isolation valve unless the cold leg loop isolation valve is fully closed~~

~~APPLICABLE SAFETY ANALYSES During startup of an isolated loop in accordance with LCO 3.4.18, the cold leg loop isolation valve interlocks and operating procedures prevent opening of the valve until the isolated loop and operating loop boron concentrations and temperatures are equalized. This ensures that any undesirable reactivity effect from the isolated loop does not occur.~~

~~The safety analyses assume a minimum SDM as an initial condition for Design Basis Accidents (DBAs) (Ref. 1). Violation of the LCO, combined with mixing of the isolated loop coolant into the operating loops, could result in the SDM being less than that assumed in the safety analyses.~~

(Continued)

BASES

~~The above analyses are for DBAs that establish the acceptance limits for the RCS loop isolation valves. Reference to the analyses for these DBAs is used to assess changes to the RCS loop isolation valves as they relate to the acceptance limits.~~

~~The boron concentration of an isolated loop may affect SDM and therefore RCS loop isolation valves satisfy Criterion 2 of the NRC Policy Statement.~~

LCO

~~This LCO ensures that a loop isolation valve that becomes closed in MODES 1 through 4 is fully isolated and the plant placed in MODE 5. Loop isolation valves are used for performing maintenance when the plant is in MODE 5 or 6, and startup of an isolated loop is covered by LCO 3.4.18.~~

APPLICABILITY

~~In MODES 1 through 4, this LCO is applicable when unisolating an isolated loop with a boron concentration less than that of the operating loops may cause an inadvertent criticality.~~

~~In MODES 5 and 6, the SDM of the operating loops is large enough to permit operation with isolated loops. In these MODES, controlled startup of isolated loops is possible without significant risk of inadvertent criticality.~~

ACTIONS

~~The Actions have been provided with a Note to clarify that all RCS loop isolation valves for this LCO are treated as separate entities, each with separate Completion Times, i.e., the Completion Time is on a component basis.~~

A-1

~~If power is inadvertently restored to one or more loop isolation valve operators, the potential exists for accidental isolation of a loop with a subsequent inadvertent startup of the isolated loop. The loop isolation valves have motor operators. Therefore, these valves will maintain their last position when power is removed from the valve operator. With power applied to the valve operators, only the interlocks prevent the valve from being operated. Although operating procedures and interlocks make the occurrence of this event unlikely, the prudent action is to remove power from the loop isolation valve operators. The Completion Time of 30 minutes to remove power from the loop isolation valve operators is sufficient considering the complexity of the task.~~

(Continued)

BASES

B.1, B.2, and B.3

~~Should a loop isolation valve be closed in MODES 1 through 4, the affected loop must be fully isolated immediately and the plant placed in MODE 5 to preclude inadvertent startup of the loop and the potential inadvertent criticality. The Completion Time of Required Action B.1 allows time for borating the operating loops to a shutdown boration level such that the plant can be brought to MODE 3 within 6 hours and MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.~~

SURVEILLANCE
REQUIREMENTS

SR 3.4.17.1

~~The Surveillance is performed at least once per 31 days to ensure that the RCS loop isolation valves are open, with power removed from the loop isolation valve operators. The primary function of this Surveillance is to ensure that power is removed from the valve operators, since SR 3.4.4.1 of LCO 3.4.4, "RCS Loops MODES 1 and 2," ensures that the loop isolation valves are open by verifying every 12 hours that all loops are operating and circulating reactor coolant. The Frequency of 31 days ensures that the required flow can be made available, is based on engineering judgment, and has proven to be acceptable. Operating experience has shown that the failure rate is so low that the 31 day Frequency is justified.~~

~~B 3.4 REACTOR COOLANT SYSTEM (RCS)~~

~~B 3.4.18 RCS Isolated Loop Startup~~

BASES

~~BACKGROUND The RCS may be operated with loops isolated in MODES 5 and 6 in order to perform maintenance. While operating with a loop isolated, there is potential for inadvertently opening the isolation valves in the isolated loop. In this event, the coolant in the isolated loop would suddenly begin to mix with the coolant in the operating loops. This situation has the potential of causing a positive reactivity addition with a corresponding reduction of SDM if~~

- ~~a. The temperature in the isolated loop is lower than the temperature in the operating loops (cold water incident); or~~
- ~~b. The boron concentration in the isolated loop is lower than the boron concentration in the operating loops (boron dilution incident).~~

~~As discussed in the FSAR (Ref. 1), the startup of an isolated loop is done in a controlled manner that virtually eliminates any sudden reactivity addition from cold water or boron dilution because:~~

- ~~a. This LCO and plant operating procedures require that the boron concentration in the isolated loop be maintained higher than the boron concentration of the operating loops, thus eliminating the potential for introducing coolant from the isolated loop that could dilute the boron concentration in the operating loops.~~
- ~~b. The cold leg loop isolation valve cannot be opened unless the temperatures of both the hot leg and cold leg of the isolated loop are within 20°F of the operating loops. Compliance with the temperature requirement is ensured by operating procedures and automatic interlocks.~~
- ~~c. Other automatic interlocks prevent opening the hot leg loop isolation valve unless the cold leg loop isolation valve is fully closed. All of the interlocks are part of the Reactor Protection System~~

~~APPLICABLE SAFETY ANALYSES During startup of an isolated loop, the cold leg loop isolation valve interlocks and operating procedures prevent opening the valve until the isolated loop and operating loop boron concentrations and temperatures are equalized. This ensures that any undesirable reactivity effect from the isolated loop does not occur.~~

~~The safety analyses assume a minimum SDM as an initial condition for Design Basis Accidents. Violation of this LCO could result in the SDM being reduced in the operating loops to less than that assumed in the safety analyses.~~

(Continued)

BASES

~~The boron concentration of an isolated loop may affect SDM and therefore RCS isolated loop startup satisfies Criterion 2 of the NRC Policy Statement~~

LCO ~~Loop isolation valves are used for performing maintenance when the plant is in MODE 5 or 6. This LCO ensures that the loop isolation valves remain closed until the differentials of temperature and boron concentration between the operating loops and the isolated loops are within acceptable limits.~~

APPLICABILITY ~~In MODES 5 and 6, the SDM of the operating loops is large enough to permit operation with isolated loops. Controlled startup of isolated loops is possible without significant risk of inadvertent criticality. This LCO is applicable under these conditions.~~

ACTIONS ~~A.1 and A.2~~

~~Required Action A.1 and Required Action A.2 assume that the prerequisites of the LCO are not met and a loop isolation valve has been inadvertently opened. Therefore, the Actions require immediate closure of isolation valves to preclude a boron dilution event or a cold water event. However, each Required Action is preceded by a Note that states that Action is required only when a specific concentration or temperature requirement is not met~~

SURVEILLANCE REQUIREMENTS ~~SR 3.4.18.1~~

~~This Surveillance is performed to ensure that the temperature differential between the isolated loop and the operating loops is $\leq [20]^{\circ}\text{F}$. Performing the Surveillance 30 minutes prior to opening the cold leg isolation valve in the isolated loop provides reasonable assurance, based on engineering judgment, that the temperature differential will stay within limits until the cold leg isolation valve is opened. This Frequency has been shown to be acceptable through operating experience.~~

~~SR 3.4.18.2~~

~~To ensure that the boron concentration of the isolated loop is greater than or equal to the boron concentration of the operating loops, a Surveillance is performed 2 hours prior to opening either the hot or cold leg isolation valve. Performing the Surveillance 2 hours prior to opening either the hot or cold leg isolation valve provides reasonable assurance the boron concentration difference will stay within acceptable limits until the loop is unisolated. This Frequency has been shown to be acceptable through operating experience.~~

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.

Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.

Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.

Methodology For Mark-up of NUREG-1431 Specifications

Bracket Inserts -

The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(7 Pages)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE NUMBER

JUSTIFICATION

- 3.4-01 This change clarifies intent of wording for the allowance to remove pumps from operation by changing "de-energized" to "removed from operation" consistent with Industry Traveler TSTF-153.
- 3.4-02 This change revises Condition A of ITS 3.4.6 to cover any required loop's inoperability and adds Required Action A.2 indicating that cooldown to MODE 5 is only required if an RHR loop is OPERABLE. Consistent with the CTS, this change addresses all possible configurations under the LCO and clarifies potentially confusing ISTS language with regard to the number of loops that are required. Condition B is deleted.
- 3.4-03 The CTS allows 1 hour for all RHR pumps to be removed from operation. One hour is the time allowed in the version of the Westinghouse STS from which the plant-specific TS was prepared. The change and its basis are not discussed in the documentation for the improved STS. Plant-specific experience has not indicated that the one hour allowance is unsafe or unacceptable. This is the current licensing basis.
- 3.4-04 The symbol ">" in LCO 3.4.8, NOTES 1.a. is replaced with the words "at least". This is consistent with the use of "at least" in CTS 3.4.1.2 footnote *, 3.4.1.3 footnote *, 3.4.1.4.1 footnote *), and in ITS 3.4.6 LCO, and 3.4.7 LCO. The change makes the ITS consistent with the CTS.
- 3.4-05 Not applicable to Diablo Canyon Power Plant (DCPP.) See Conversion Comparison Table (Enclosure 6B).
- 3.4-06 These changes are consistent with the current plant specific analysis and are reflective of the CTS. The plant-specific analysis does not allow injection from any safety injection pumps and does allow injection from [one] centrifugal charging pumps. The changes are made consistently in the LCO, ACTIONS, and Surveillance Requirements.
- 3.4-07 The word "all" in the improved TS 3.4.12 Applicability is replaced by the word "any". Use of "any" makes the Applicability consistent with the Bases. The intention is to enter LTOP Applicability if one or more of the cold legs have a temperature below the limit specified in the PTLR. Similar statements appear in ITS 3.5.2, 3.4.6, 3.4.7, and 3.4.10, all of which are consistent in that all cold legs must be above the PTLR specified temperature to conduct various evolutions whereas any cold leg below that temperature initiates the need for vessel low temperature overpressure protection. The change makes the ITS consistent with the CTS.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.4-08	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.4-09	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.4-10	The minimum temperature specified in degrees below which the RCS must not be subject to low temperature overpressurization is replaced by the statement "the temperature below which LTOP is required as specified in the PTLR," per Industry Traveler WOG-67, Rev 1. The pressure temperature limits report (PTLR) provides the limiting temperature that is a plant-specific requirement based on the reactor vessel material characteristics documented in the PTLR and is periodically reviewed and revised. Referring to the PTLR for the current value is consistent with the relocation of the pressure temperature limits from improved TS Section 3.4.3 to the PTLR. This is an administrative change.
3.4-11	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.4-12	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.4-13	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
3.4-14	This change revises grouping of required detectors to be consistent with the CTS and with Reg. Guide 1.45, Regulatory Position C.3.
3.4-15	LCO 3.0.4 is applicable to Condition [D] of ITS 3.4.15 (required containment atmosphere gaseous radioactivity monitor and containment cooler condensate monitoring system inoperable) because other mechanisms (i.e., grab samples, RCS inventory balance, containment sump monitor, etc.) exist which are capable of adequately detecting RCS leakage and because a 30 day AOT is usually accompanied by a LCO 3.0.4 exception (e.g., PAM and Remote Shutdown Technical Specifications). Therefore, an exception to LCO 3.0.4 was added to Condition [D]. As there is already an LCO 3.0.4 exception to Conditions A and B [and LCO 3.0.4 is not applicable to ACTION C (which allows indefinite operation),] the LCO 3.0.4 exception was moved to apply to all ACTIONS and the specific exceptions for Conditions A and B were deleted. The change is made per Industry Traveler TSTF-60.
3.4-16	Consistent with CTS requirements [and with Condition B,] a requirement to perform 24 hour containment atmosphere samples is added when a gaseous monitor is inoperable []. Also, consistent with Conditions A and B, the performance of SR 3.4.13.1 every 24 hours as an alternative to analyzing a containment atmosphere sample is allowed. Both of these 24 hour surveillances provide a compensatory diverse method for detecting RCS leakage to compliment the remaining operable systems (i.e., sump level and particulate detection).

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.4-17	This change extends the surveillance interval for pressurizer heaters from 92 days to 18 months. The operability of the pressurizer heaters enhance the capability of the plant to control RCS pressure and establish natural circulation. The purpose of the surveillance requirement is to detect potential pressurizer heater degradation. This is done by periodically demonstrating that pressurizer heaters are capable of producing power at their design rating by testing the power supply output and by performing electrical checks on heater elements. Heating elements are simple resistive devices which are not prone to complex failure modes. Moreover, heater banks are made up of a number of individually powered heater elements such that a common mode failure of the elements is unlikely. The normal power supply to the heaters is in use during normal power operations and a failure of the power supply would be immediately detectable independent of the heater surveillance. The low failure rate experienced with pressurizer heater elements is indicative that the surveillance interval may be extended without loss in heater reliability. This surveillance interval extension is consistent with the guidance of GL 93-05, "Line-Item Technical Specification Improvements to Reduce Surveillance Requirements for Testing During Power Operation." This proposed change is consistent with Industry Traveler TSTF-93, Rev. 1.
3.4-18	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
3.4-19	CTS LCO 3.4.6.2 states required conditions for the start of a RCP when none have been operating. Another condition for starting an RCP is added that is not specified in NUREG-1431. This added condition provides an <u>OR</u> restraint for the option of a RCP start if the pressurizer water level is less than 50%. The option of pressurizer water level being less than 50% provides plant operational flexibility because it allows a RCP start in the event the primary/secondary temperature difference was not satisfied. The volume in the pressurizer provides space to sustain possible reactor coolant thermal swell without incurring an excessive pressure transient. Consequently the intent to protect the RCS from cold overpressure transients is maintained. The vessel water level method is not present in NUREG-1431 and has been incorporated in the reformatted LCO note. This proposed change meets the intent of NUREG-1431 and is consistent with the DCP licensing basis.
3.4-20	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
3.4-21	DCP design includes three air operated pressurizer PORVs. Two of these PORVs have been designated as "Class I". These two valves provide the reactor vessel low temperature overpressure protection and they provide the means to depressurize the RCS following a SGTR. The identification of Class I has been added to the ITS to make a distinction between these two PORVs that must provide a safety-related function as opposed to the third remaining PORV that is designated as non-Class I. TS 3.4.12 for LTOP applies to the two Class I PORVs but not to the non-Class I PORV.
3.4-22	This change deletes Required Action B.1 consistent with Industry Traveler TSTF-28. The deleted ACTION required that SR 3.4.16.2 be performed within 4 hours. This SR must be performed in order to verify "restoration" of the specific activity to within limits, and does not need to be otherwise required. Further, if the Condition is entered and the plant is in MODE 2 in 4 hours or less, the NUREG Required Action is in conflict with the Note of SR 3.4.16.2 that states that this SR is only required in MODE 1. In addition, this ACTION is an unnecessary burden as the plant is required to be in MODE 3 with $T_{avg} < 500^{\circ}\text{F}$ within 12 hours, exiting the MODE of Applicability.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.4-23	ITS SR 3.4.12.3 is revised to be consistent with the requirements denoted in LCO 3.4.12 and Industry Traveler WOG-51, Rev. 1. This change clarifies that the SR (to verify the accumulators isolated) is only applicable when accumulator pressure is greater than or equal to the maximum RCS pressure for the existing RCS cold leg temperature allowed by the P/T limit curves provided in the PTLR.
3.4-24	Improved SR 3.4.14.1 requires testing of PIVs prior to entering MODE 2 whenever the unit has been in MODE 5 for seven days or longer. This surveillance frequency is not in the DCPD CTS. DCPD tests the valves on an 18 month Frequency which is acceptable based on valve type, interlocks, position indication and system alarm functions. These valves meet the criteria for testing at least every 18 months but do not require additional testing based on when the unit is in cold shutdown. None of these valves change position during normal plant operation. There is little reason to anticipate leakage to initiate in mid cycle when they have not changed position. In conformance with the CTS, DCPD has chosen not to include this surveillance frequency of retesting the valves following an extended period of operation in MODE 5.
3.4-25	Consistent with the CTS, the gross activity limit is added to LCO 3.4.16 Condition B rather than its first reference being in SR 3.4.16.1. This change is also consistent with the treatment of DOSE EQUIVALENT I-131.
3.4-26	DCPD design designates two pressurizer PORVs to provide the function for low temperature overpressure protection. The valves have been designated as a Class I system. The PORVs are air operated. The air supply is not a Class I system, consequently, the design includes a back-up nitrogen Class I system to power the valves in the event the air supply is not available. The surveillance for the nitrogen back-up system is in the DCPD CTS but not present in NUREG-1431. Improved TS SR 3.4.11.3 has been added to provide assurance of the operation of the nitrogen gas supply to the PORVs. Methodology of verifying operability has been moved to the Bases.
3.4-27	TS 3.4.12 Applicability for MODE 6 has an additional qualification if the head closure bolts are not fully de-tensioned. With the bolts fully de-tensioned this TS is not Applicable because the lack of tension provides a pressure relief path across the vessel flange. This Applicability is in the current licensing basis.
3.4-28	This change has added the description of a secured open valve. This description is in use in the DCPD CTS and in plant procedures. This description is also consistent with that used in NUREG-1431 SR 3.5.2.2 and SR 3.5.2.5.
3.4-29	The definition for CHANNEL FUNCTIONAL TEST (CFT) would be retained from the current DCPD TS to the improved TS. CFT is in active use in numerous procedures in the plant. The CFT is used in applications for which the CHANNEL FUNCTIONAL TEST (COT) is not fully suitable. Although CFT and COT definitions appear similar, there is one important difference. Strict adherence to COT requirements includes quantitative adjustments as appropriate to bring setpoints into the desired range. This requirement for quantitative adjustment can not be satisfied in a reasonable manner on some components/sensors/channels due to their design. CFT however, is a qualitative test to determine functionality. A loss of function indicated by the CFT results in a notification to, following existing procedures, restore the functional performance. The CFT is in the current licensing basis.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

CHANGE NUMBER

JUSTIFICATION

- 3.4-30 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.4-31 These ACTIONS in ITS 3.4.5 and 3.4.9 are modified to reflect their LCO. The position of the reactor trip breakers and their power supply status of the CRDMs are not LCO requirements; therefore Conditions and ACTIONS are revised. As worded in NUREG-1431, these ACTIONS could preclude certain testing in MODE 3. A more generic ACTION, which assures the rods cannot be withdrawn, replaces the specific method of precluding rod withdrawal. The specific methods are added to the Bases as examples. The revised ACTIONS still assure rod withdrawal is precluded and this detail is not required to be in the TS to provide adequate protection to the public health and safety. No technical changes result from this change. These changes are consistent with Industry Traveler TSTF-87, Rev. 1.
- 3.4-32 In accordance with Industry Traveler TSTF-26, the ACTION would be changed to specify taking the plant to a MODE for which the LCO is not applicable. This change maintains the consistency between the MODE of Applicability and the Required Action which requires the MODE of Applicability to be exited.
- 3.4-33 The Frequency of SR 3.4.2.1 to verify operating RCS loop average temperature at or above [541] °F is changed to 12 hours from the current surveillance Frequency of 30 minutes. The SR to verify operating RCS loop average temperatures every 12 hours is sufficiently frequent to prevent inadvertent violation of the LCO and considers indications and alarms that are continuously available to the operator in the control room. This change is based on Industry Traveler TSTF-27, Rev. 2.
- 3.4-34 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).
- 3.4-35 This change adds a Note to SR 3.4.11.1 and SR 3.4.11.2 stating that the SRs are only required to be performed in MODES 1 and 2. The ACTIONS Note "LCO 3.0.4 is not applicable" is intended to allow MODE changes for testing purposes (per Bases). This allowance is properly presented as an SR Note. A properly placed exception (i.e., an SR Note exception) would not allow the SR to be considered to be met until the appropriate conditions were available for it to be performed without entering the ACTIONS. The Note to these SRs would allow startup in MODE 3 if the SR had not been performed during the required Frequency, but would limit the exception to prior to entering MODE 2. The change is consistent with Industry Traveler WOG-60.
- 3.4-36 SR 3.4.13.1 and ACTIONS for LCO 3.4.15 are revised with the addition of a Note per Industry Traveler TSTF-116, Rev. 1. The Note addresses the concern that RCS water inventory balance cannot be meaningfully performed unless the unit is operating at or near steady state conditions. The Note added to the surveillance provides an exception for operation at less than steady state conditions. The RCS water inventory balance will only be allowed to be deferred for 12 hours after re-establishing steady state conditions.
- 3.4-37 Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B).

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.4-38	Consistent with Industry Traveler TSTF-105, the details on the method by which the RCS flow rate is verified are moved from SR 3.4.1.4 to the Bases. Moving this information to the Bases allows the use of precision heat balances, elbow taps, and other acceptable methods in order to perform this verification and is consistent with the NUREG-1431 philosophy of moving clarifying information and descriptive details out of the TS to the Bases.
3.4-39	The shutdown requirements of ITS 3.4.11 would require the plant to reduce T_{avg} to $<500^{\circ}\text{F}$ within 12 hours, rather than be in MODE 4, to address the concern of entering [LTOP] LCO 3.4.12 Applicability with inoperable PORVs. For consistency, the shutdown requirements of ITS 3.4.16 are also revised to allow 12 hours to reduce T_{avg} to $<500^{\circ}\text{F}$. This change is consistent with Industry Traveler TSTF-113, Rev. 3.
3.4-40	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
3.4-41	Consistent with the current licensing basis in CTS 3.2.3, LCO 3.4.1 would be revised to reference Tables 3.4.1-1 and 3.4.1-2 for RCS total flow rate limits for Unit 1 and Unit 2 respectively. These tables show allowed reduction in reactor thermal power to account for reduced RCS total flow. DCP LA 60/59 added this allowance to the CTS.
3.4-42	An exception to SR 3.4.14.1 Frequency to leak test PIVs within 24 hours of actuation or flow through the valves has been added for valves 8802A, 8802B and 8703. Testing of these valves under this Frequency is not required as stated in the footnote to current Surveillance 4.4.6.2.1, Table 3.4-1. This change is consistent with the CTS.
3.4-43	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
3.4-44	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
3.4-45	ITS 3.4.12 has been revised to move the Note for Required ACTION B.1 regarding CCP pump swap operations and the Applicability Note for accumulator isolation to the LCO, as discussed in Industry Traveler WOG-51, Rev 1. Plant-specific time allowances for exceeding LCO's number of [Centrifugal Charging] pumps capable of injecting into the RCS are incorporated. [] These Notes detail situations where exceptions to the LCO are permitted and are more appropriately annotated under the LCO.
3.4-46	Consistent with CTS 3/4.1.1.4, "Minimum Temperature for Criticality," ITS LCO 3.4.2 and its Condition A and SR 3.4.2.1 are modified to refer to "operating" RCS loops. Adopting the CTS wording is acceptable since valid T_{avg} measurements are not obtainable for a non-operating loop.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.4

<u>CHANGE NUMBER</u>	<u>JUSTIFICATION</u>
3.4-47	ITS SR 3.4.11.1 contains a Note which exempts the cycling of the block valve when it is closed in accordance with Required Actions of Conditions B or E of LCO 3.4.11. However, Required Action A.1 also directs closure of the block valve when one or more PORVs are inoperable and capable of being manually cycled. The SR Note should also exempt performance when the block valve is closed in accordance with Required Action A.1 as the block valve should not be opened when the PORV is inoperable. This change is consistent with NUREG-1430 and NUREG-1432 in as much as the block valve cycling is exempted under Conditions A, B, and E. Since power to the block valve(s) is maintained in Required Action A.1, the Note to SR 3.4.11.1 will be revised to not require the surveillance performance if the block valve(s) is closed per Condition A. Since power to the block valve(s) is removed in Required ACTIONS B.2 and E.3, the surveillance cannot be met. Given the wording change "met" to "performed" in the Note, the wording of SR 3.4.11.1 is revised to accommodate the Condition B and E exception. This change is consistent with Industry-Traveler WOG-87.
3.4-48	A Note is added to ITS 3.4.8 ACTIONS, indicating that entry into MODE 5, Loops Not Filled, from MODE 5, Loops Filled, is not permitted while LCO 3.4.8 is not met. The addition of this Note is based on the performance of a plant specific LCO 3.0.4 matrix (see CN 01-02-LS1 of the CTS 3/4.0 package).
3.4-49	LCO 3.4.12 [LTOP] System, provides four different methods for pressure relief. Any of the four methods may be used. However, SR 3.4.12.5 requires testing whether or not the equipment is being credited to meet the LCO. The proposed change adds the words "required" to the SR to exempt its performance if the equipment to be tested is not being used to meet the LCO. In addition, two editorial changes were made. The LCO requirement presentation was clarified. Also, the Note to SR 3.4.12.8 was revised to replace "required to be met" with "required to be performed" since the "performed" nomenclature is appropriate here, consistent with the CTS. This change is consistent with Industry Traveler WOG-100.
3.4-50	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
3.4-51	The Note for SR 3.4.1.4 is removed. This is consistent with DCP CTS 4.2.3.5. DCP conducts a measured RCS total flow rate verification on the 18 month frequency in accordance with NUREG-1431.
3.4-52	Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).

ENCLOSURE 6B

CONVERSION COMPARISON TABLE - NUREG-1431

Conversion Comparison Table

(8 Pages)

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.4

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-01	Clarifies intent of wording for the allowance to remove pumps from operation by changing "de-energized" to "removed from operation" consistent with Industry Traveler TSTF-153.	Yes	Yes	Yes	Yes
3.4-02	This change revises Condition A of ITS 3.4.6 to cover any required loop's inoperability and adds Required ACTION A.2 indicating that cooldown to MODE 5 is only required if an RHR loop is OPERABLE. Condition B is deleted.	Yes	Yes	Yes	Yes
3.4-03	The current TS allows 1 hour for all RHR pumps to be removed from operation [].	Yes	Yes	Yes	Yes
3.4-04	The symbol ">" in DCPD LCO 3.4.8, NOTES 1.a., is replaced with the words "at least" to make this LCO Note wording consistent with LCOs 3.4.6 and 3.4.7 Note wording.	Yes	No	No	No
3.4-05	This change is being made consistent with the current assumptions used in the analysis. The analysis credits three operational restrictions below 350°F, to ensure that the reactor vessel is protected.	No, these operational restrictions are not in the CTS.	Yes	No, similar analysis not contained in CTS.	No, similar analysis not contained in CTS.
3.4-06	Plant specific safety analyses do not allow injection from safety injection pumps but do allow centrifugal charging pumps (CCPs) injection.	Yes, DCPD analysis assumes one CCP only.	Yes, CPSES analysis assumes two CCPs.	Yes, WCNOG analysis assumes one CCP only.	Yes, Callaway analysis assumes one CCP only.
3.4-07	The word "all" in the DCPD LCO 3.4.12 LTOP Applicability is replaced by the word "any" to make the Applicability wording consistent with the Bases.	Yes	No	No	No
3.4-08	The current licensing basis as contained in the Technical Specifications requires performance of this surveillance on a frequency of 72 hours.	No, DCPD LTOP design does not use RHR relief valves.	Yes	Yes, see Amendment No. 49.	Yes, see OL Amendment No. 42.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.4

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-09	The plant does not have manual RHR suction isolation valves. The motor-operated suction isolation valves (2 per relief valve line) are surveilled in accordance with SR 3.4.12.4.	No, DCPD LTOP design does not use RHR relief valves.	Yes	Yes	Yes
3.4-10	The DCPD plant-specific limiting temperature specified in degrees, below which the RCS must not be subject to low temperature overpressure is replaced by the generic statement "the temperature below which LTOP is required as specified in the PTLR."	Yes	No	No	No
3.4-11	The plant does not have the RHR autoclosure portion of the RHR System interlock as the system was deleted from the design. However, the portion of the interlock which prevents the valves from opening when system pressure is in excess of the setpoint has been retained.	No, the valve interlock is not in the CTS.	Yes	Yes, see Amendment No. 49	Yes, see OL Amendment No. 42.
3.4-12	In conformance with the CTS, the RHR Isolation Valves which are RCS PIVs are excluded from being retested following an extended period of operation in MODE 5.	No, RHR valve testing after MODE 5 operation is not in the CTS.	Yes	No, WCNOG does not have this exclusion.	No, Callaway does not have this exclusion.
3.4-13	The RHR Isolation Valves which are RCS PIVs are excluded from being retested following flow through the valves.	No, not in CTS.	Yes	Yes	Yes
3.4-14	This change revises the grouping of required detectors to be consistent with the CTS and with Reg. Guide 1.45 Regulatory Position C.3.	Yes	Yes	Yes	Yes
3.4-15	LCO 3.0.4 is applied to Condition [D] (required containment atmosphere gaseous radioactivity monitor and containment cooler condensate monitoring system inoperable).	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.4

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-16	Consistent with CTS requirements [and with Condition B,] a requirement to perform 24 hour containment atmosphere samples is added when a gaseous monitor is inoperable. [] Also, consistent with Conditions A and B, the performance of SR 3.4.13.1 every 24 hours as an alternative to analyzing a containment atmosphere sample is allowed.	Yes	Yes	Yes	Yes
3.4-17	This change revises the pressurizer heater capacity surveillance requirement frequency from 92 days to 18 months.	Yes	Yes	Yes	Yes, part of CTS per Amendment 105.
3.4-18	The Applicability for ITS LCOs 3.4.10 and 3.4.11, LCO 3.4.12 and LCO Note 2 for ITS 3.4.5, are modified to be consistent with current [LTOP] analyses requirements.	No, DCPD has different LTOP requirements.	No, 2 CCPs are allowed per CTS.	Yes	Yes
3.4-19	For DCPD, this change adds an LCO condition to allow RCP start with pressurizer water level less than 50%, per CTS.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
3.4-20	This change adds a provision to allow one or more SI pumps to be capable of injecting into RCS in MODES 5 and 6 when RCS water level is below the top of the reactor vessel flange for the purpose of protecting the decay heat removal function, per CTS.	No, not part of CTS.	No, not part of CTS.	Yes	Yes
3.4-21	Two DCPD pressurizer PORVs have been identified as Class I to make the distinction between these and the third PORV that is designated non-Class I.	Yes	No	No	No
3.4-22	This change deletes ISTS 3.4.16 ACTION B.1 per Industry Traveler TSTF-28.	Yes	Yes	Yes	Yes
3.4-23	ITS SR 3.4.12.3 is revised to be consistent with the requirements denoted in LCO 3.4.12.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.4

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-24	Improved SR 3.4.14.1 requires testing of PIVs prior to entering MODE 2 whenever the unit has been in MODE 5 for seven days or longer. This surveillance Frequency is not in the DCPD CTS. In conformance with the CTS, DCPD has chosen not to include this surveillance Frequency.	Yes	No	No	No
3.4-25	The gross specific activity limit is added to LCO 3.4.16, Condition B, rather than having its first reference occurring in SR 3.4.16.1.	Yes	Yes	Yes	Yes
3.4-26	This change adds surveillance for PORV safety related nitrogen supply, per DCPD CTS.	Yes	No	No	No
3.4-27	Applicability for LCO 3.4.12, MODE 6, is revised to include an additional qualification if the head closure bolts are not fully de-tensioned, per DCPD CTS.	Yes	No	No	No
3.4-28	This change adds a DCPD-specific description of a secured open valve.	Yes	No	No	No
3.4-29	The use of CHANNEL FUNCTIONAL TEST (CFT) would be retained from the current DCPD TS to the improved TS.	Yes	No	No	No
3.4-30	An LCO 3.0.4 exception is added to the ACTIONS LCO 3.4.12.	No, not in CTS	Yes	Yes	Yes
3.4-31	Condition C and Required ACTION D.1 of ITS 3.4.5 and Condition A of ITS 3.4.9 are modified to reflect generic wording to assure that the rods are fully inserted and cannot be withdrawn. This change is consistent with Industry Traveler TSTF-87, Rev. 1.	Yes	Yes	Yes	Yes
3.4-32	In accordance with Industry Traveler TSTF-26, 3.4.2 ACTION would be changed to specify taking the plant to a MODE for which the LCO is not applicable.	Yes	Yes	Yes	Yes

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-33	The Frequency of SR 3.4.2.1 is changed to "12 hours". This change is based on Industry Traveler TSTF-27, Rev. 2.	Yes	Yes	Yes	Yes
3.4-34	Retains CPSES current TS which requires that the precision RCS flow measurement be performed prior to exceeding 85% RTP.	No	Yes	No	No
3.4-35	Adds a Note to SR 3.4.11.1 and SR 3.4.11.2 stating that the SRs are only required to be performed in MODES 1 and 2, per Industry Traveler WOG-60.	Yes	Yes	Yes	Yes
3.4-36	SR 3.4.13.1 and LCO 3.4.15 ACTIONS are revised with the addition of a Note requiring steady state conditions per Industry Traveler TSTF-116, Rev. 1.	Yes	Yes	Yes	Yes
3.4-37	The primary to secondary leakage limits are revised per Callaway OL Amendment No. 116 dated October 1, 1996.	No	No	No	Yes
3.4-38	Consistent with Industry Traveler TSTF-105, the details on the method by which the RCS flow rate is verified are moved from SR 3.4.1.4 to the Bases.	Yes	Yes	Yes	Yes
3.4-39	The shutdown requirements of ITS 3.4.11 would require the plant to reduce T_{avg} to <500°F within 12 hours, rather than MODE 4, to address the concern of entering [LTOP] LCO 3.4.12 Applicability with inoperable PORVs. For consistency, the shutdown requirements of ITS 3.4.16 are also revised to allow 12 hours to reduce T_{avg} to <500°F. This change is consistent with Industry Traveler TSTF-113, Rev. 3.	Yes	Yes	Yes	Yes
3.4-40	Consistent with Industry Traveler WOG-99, the Note to SR 3.4.1.4 would be modified to specify a plant-specific power and to provide additional time to perform an RCS precision flow rate measurement.	No, see CN 3.4-51.	No, see CN 3.4-34.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.4

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-41	LCO 3.4.1 is revised to reference Tables 3.4.1-1 and 3.4.1-2 for RCS total flow rate limits for DCPD Unit 1 and Unit 2 respectively.	Yes, allowance added per Amendments 60/59	No	No	No
3.4-42	An exception to SR 3.4.14.1 Frequency to leak test PIVs 8802A, 8802B and 8703 has been added. This change is consistent with the DCPD CTS.	Yes	No	No	No
3.4-43	A new Condition C is added to LCO 3.4.1 to reflect the CTS of Wolf Creek for RCS flow rate.	No	No	Yes	No
3.4-44	Steam generator levels for MODES 3, 4, and 5 are specified to ensure SG tubes are covered. The Callaway CTS did not ensure tube coverage.	No	No	No	Yes
3.4-45	ITS 3.4.12 has been revised to move the Note for Required ACTION B.1 regarding CCP pump swap operations and the Applicability Note for accumulator isolation to the LCO, as discussed in Industry Traveler WOG-51, Rev 1. Plant-specific time allowances for exceeding LCO's number of [RHR] pumps capable of injecting into the RCS are incorporated, [].	Yes	No, operation of 2 CCPs are allowed per CTS; also see CN 3.4-52.	Yes	Yes
3.4-46	ITS LCO 3.4.2 and its Condition A and SR 3.4.2.1 are modified to refer to "operating" RCS loops.	Yes	Yes	Yes	Yes

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-47	ITS SR 3.4.11.1 contains a Note which exempts the cycling of the block valve when it is closed in accordance with Required Actions of Condition B or E of LCO 3.4.11. However, Required ACTION A.1 also directs closure of the block valve when one or more PORVs are inoperable and capable of being manually cycled. The SR Note should also exempt performance when the block valve is closed in accordance with Required ACTION A.1 as the block valve should not be opened when the PORV is inoperable, per Industry Traveler WOG-87.	Yes	Yes	Yes	Yes
3.4-48	A Note is added to ITS 3.4.8 ACTIONS, indicating that entry into MODE 5, Loops Not Filled, from MODE 5, Loops Filled, is not permitted while LCO 3.4.8 is not met.	Yes	Yes	Yes	Yes
3.4-49	This change reorganizes the presentation of ITS LCO 3.4.12, adds the word "required" to ITS SR 3.4.12.5, and changes the word "met" to "performed" in ITS SR 3.4.12.8, per Industry Traveler WOG-100.	Yes	Yes	Yes	Yes
3.4-50	This change is consistent with CTS SR 4.4.9.3.3. The 12 hour Frequency applies to vent pathway(s) that are "not locked, sealed, or otherwise secured in the open position". The wording added to ITS SR 3.4.12.5 is also consistent with the format used in similar ITS 3.6 SRs. The 31 day Frequency is also revised to be consistent with CTS SR 4.4.9.3.3.	No, adopting ITS format.	No, adopting ITS format.	Yes	Yes
3.4-51	The Note for SR 3.4.1.4 is removed. This is consistent with DCPD CTS 4.2.3.5. DCPD conducts a measured RCS total flow rate verification on the 18 month frequency in accordance with NUREG-1431.	Yes	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.4

DIFFERENCE FROM NUREG-1431		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.4-52	Consistent with Industry Traveler WOG-51, Rev 1, the Note concerning accumulator isolation is moved from the Applicability to the LCO.	No, see CN 3.4-45.	Yes	No, see CN 3.4-45.	No, see CN 3.4-45.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-115	Not used.	N/A	N/A	N/A	N/A
3.3-116	ACTION J of ITS 3.3.2 is not used since DCPD does not rely on motor-driven AFW pump start with loss of both main FW pumps.	Yes	No	No	No
3.3-117	This change to ITS 3.3.1 Condition R reflects CTS Table [3.3-1, ACTION Statement 12] which was based on NRC Generic Letter 85-09.	Yes	No, not in CTS.	Yes	Yes
3.3-118	This change is for consistency with ITS 3.7.10 Condition [G].	Yes	Yes	Yes	Yes
3.3-119	This change reflects Callaway-specific BDMS analysis restrictions associated with RCS mixing volume and dilution flow rate. These are administratively controlled under the CTS, as approved in OL Amendment No. 94 dated March 7, 1995. However, with the conversion to ITS 3.3.9, these analysis assumptions should be included in the body of the TS.	No	No	No	Yes
3.3-120	ITS 3.3.1 Condition D is revised to reflect ITS SR 3.2.4.2 and CN 3.2-15 in the 3/4.2 package.	Yes	Yes	Yes	Yes
3.3-121	For Callaway, ITS 3.3.9 is revised to reflect that only one BDMS train is required OPERABLE in MODE 5 and that the suspension of positive reactivity additions and accelerated SDM verifications are required only if no source range neutron flux indicator is OPERABLE.	No	No	No	Yes
3.3-122	ITS 3.3.1 APPLICABILITY Note (b) for Functions 1, 5, 19-21 and Conditions C and K are revised to replace ACTIONS requiring the RTBs to be opened with ACTIONS that ensure subcriticality is maintained (i.e., by fully inserting all rods and ensuring the Rod Control System is incapable of rod withdrawal) yet do not initiate a feedwater isolation (P-4 and low T_{avg}) in MODE 3, consistent with Traveler TSTF-135.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-123	This change deletes ACTION L.2 and renumbers L.3 since the requirement to close the unborated water source valves is not in the CTS.	Yes; refer to LA 28/27.	No, see CN 3.3-41.	No, see CN 3.3-41.	No, see CN 3.3-41.
3.3-124	Consistent with the CTS Table 4.3-1, Note [15], the notes for ITS SR 3.3.1.4 and Table 3.3.1-1, Function 20 are modified to clarify that the SR is required for the reactor trip bypass breaker local manual shunt trip only. The Bases for SR 3.3.1.14 clearly state that SR 3.3.1.14 includes the automatic undervoltage trip of the reactor trip bypass breakers. The Note (k) added to Table 3.3.1-1, Function 20 clarifies the Applicability of the undervoltage and shunt trip mechanisms to include those functions of the reactor trip bypass breakers when in use.	Yes	Yes	Yes	Yes
3.3-125	ITS SR 3.3.1.11 is modified by a Note that requires verification that the time constants are adjusted to the prescribed values. The addition of this Note is consistent with SR 3.3.1.10 and is required because SR 3.3.1.11 is used for the Power Range Neutron Flux - High Positive Rate [and High Negative Rate] trip functions which have time constants associated with their calibration.	Yes	Yes	Yes	Yes
3.3-126	The surveillance frequency associated with the RWST Level - Low-Low ESFAS function is restricted to 9 months by the drift allowance in the CPSES-specific setpoint study. Therefore, a new surveillance requirement (SR 3.3.2.12) is specified that replaces SR 3.3.2.9 used for those ESFAS functions with 18 month surveillance frequencies. This modification is consistent with the CPSES CTS.	No, not in CTS.	Yes	No, not in CTS.	No, not in CTS.

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-127	The MODE 2 applicability for the undervoltage RCP start of the steam-driven AFW pump is deleted and the surveillance frequency is revised per the DCPD CTS. Thus, the Required Actions of ACTION I are revised to include entering MODE 2 for function 6.g and MODE 3 for function 5.b, and the required surveillance is changed from SR 3.3.2.7 to SR 3.3.2.8.	Yes	No	No	No
3.3-128	This change revises ITS Table 3.3.4-1 to be consistent with DCPD CTS 3.3.3.5.	Yes	No	No	No
3.3-129	Consistent with the CPSES CTS, the ITS requirement to have the Loss of Power Diesel Generator Start Instrumentation (ITS 3.3.5) applicable in Modes 5 and 6 when the associated DG is required to OPERABLE by ITS LCO 3.8.2 "AC Sources - Shutdown" is deleted. In these modes, the Reactor Coolant System or Reactor Vessel cavity temperatures are low enough that the time available for the reactor operators to manually start the diesel generators is adequate. Thus, there is no need to require the automatic loss of power DG start instrumentation to be operable in these modes.	No	Yes	No	No
3.3-130	Consistent with the CTS and the CPSES design, the Conditions, Required Actions and Surveillances are not applicable to the 6.9 kV Preferred Offsite Source Undervoltage function if the associated source breaker is open. When the associated source breaker is open, credit is not being taken for the immediate availability of the 6.9 kV Preferred Offsite AC power source.	No	Yes	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3.3

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.3-131	ITS 3.3.5 Condition B is replaced with new Conditions B, C, D, and E. Condition C in the ISTS is changed to Condition F. The CPSES CTS have specific actions for the various bus undervoltage and degraded voltage function. These actions allow an appropriate amount of time to restore an inoperable channel or declare the associated power source or bus inoperable and take action to isolate an inoperable power source. These actions are a proper way to respond to the inoperable channels because the actions result in taking the Required Actions in ITS 3.8 associated with the affected power source or bus. The new Conditions match the Actions of the CTS.	No	Yes	No	No
3.3-132	The trip setpoints for the loss of power diesel generator start instrumentation are relocated to a licensee controlled document. This approach is consistent with a format allowed by a reviewer's note for the RTS and ESFAS instrumentation.	No -adopted ITS format.	Yes	No, adopted ITS format.	No, adopted ITS format.
3.3-133	This change revises ITS LCO 3.3.5 and SR 3.3.5.3 to include the DG start sequence delay timers from DCPP CTS Table 3.3-4.	Yes	No	No	No
3.3-134	This change is Wolf Creek specific to revise the NOTE in Condition K of ITS 3.3.2 consistent with CTS Table 3.3-3 Action 16 for Function 7b and Amendment 43 to provide 4 hours foran additional channel to be placed in bypass for surveillance testing of other channels.	No	No	Yes	No
3.3-135	A MODE change restriction has been added per the matrix discussed in CN 1-02-LS-1 of the ITS 3.0 package.	Yes	Yes	Yes	Yes
3.3-136	The TADOT perfomed under ITS SR 3.3.2.7 includes verification of relay setpoints since the trip actuating devices being tested are the same circuits tested under ITS SR 3.3.5.2.	No, adopted ISTS format.	No, adopted ISTS format.	Yes	Yes
{3.3-137	The Condition for Function 4.c is changed from Condition D to E consistant with the DCPP CTS.	Yes	No	No	No}

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Methodology for Cross-Reference Tables
(Continued)

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).
Note:	The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

**Methodology for Cross-Reference Tables
(Continued)**

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

Methodology (2 Pages)

3/4.5 EMERGENCY CORE COOLING SYSTEMS

3/4.5.1 ACCUMULATORS

LIMITING CONDITION FOR OPERATION

3.5.1 Each Reactor Coolant accumulator shall be OPERABLE with:

- a. The isolation valve open and power removed.
- b. A contained borated water volume of between 836 and 864 cubic feet ~~±50.8% and ±72.6%~~ of borated water. 01-08-A
- c. A boron concentration of between 2200 and 2500 ppm, and
- d. A nitrogen cover-pressure of between 595.5 and 647.5 psig.

APPLICABILITY: MODES 1, 2 and 3.*

ACTION:

- a. With ~~three accumulators OPERABLE and with one accumulator inoperable - except as a result of a closed isolation valve, due to boron concentration not within limits - restore the inoperable accumulator to OPERABLE status within 1 hour - 72 hours - or be in at least HOT STANDBY within the next 6 hours and in at least HOT SHUTDOWN reduce RCS pressure to ≤1000 psig within the following 6 hours.~~ 01-06-A
01-04-LS8
01-03-A
- b. With ~~three accumulators OPERABLE and one accumulator inoperable due to the isolation valve being closed, for reasons other than boron concentration not within limits, either immediately open the isolation valve or restore accumulator to OPERABLE status within 1 hour or be in HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours, and reduce pressurizer RCS pressure to 1000 psig within the following 6 hours.~~ 01-06-A
01-05-LS9
01-03-A

*Pressurizer RCS pressure above 1000 psig. 01-03-A

EMERGENCY CORE COOLING SYSTEMS

SURVEILLANCE REQUIREMENTS

4.5.1.1 Each accumulator shall be demonstrated OPERABLE:

- a. At least once per 12 hours by:
 - 1) Verifying that the contained b^{or}ated water volume and nitrogen cover-pressure in the tanks are within their limits, and
 - 2) Verifying that each accumulator isolation valve is open ~~and power is removed.~~

- b. At least once per 31 days and within 6 hours after each solution volume increase of greater than or equal to ~~1% of tank volume~~ ~~5.6%~~ ~~of narrow range indicated level~~ by verifying the boron concentration of the accumulator solution. This surveillance is not required when the volume increase makeup source is the RWST and the RWST has not been diluted since verifying that the RWST boron concentration is equal to or greater than the accumulator boron concentration limit. and: 01-08-A

- c. At least once per 31 days when the RCS pressure is above 1000 psig by verifying that power to the isolation valve operator is disconnected by sealing the breaker in the open position. 01-07-LG

EMERGENCY CORE COOLING SYSTEMS

3/4.5.2 ECCS SUBSYSTEMS - T_{avg} GREATER THAN OR EQUAL TO 350°F

LIMITING CONDITION FOR OPERATION

3.5.2 Two Emergency Core Cooling System (ECCS) ~~trains~~ subsystems shall be OPERABLE. ~~with each subsystem comprised of:~~

02-01-LG

- a. ~~One OPERABLE centrifugal charging pump.~~
- b. ~~One OPERABLE Safety Injection pump.~~
- c. ~~One OPERABLE Residual Heat Removal heat exchanger.~~
- d. ~~One OPERABLE Residual Heat Removal pump, and~~
- e. ~~An OPERABLE flow path capable of taking suction from the Refueling Water Storage Tank on a Safety Injection signal and manually transferring suction to the containment sump during the recirculation phase of operation.~~

APPLICABILITY: MODES 1, 2, and 3. #

02-02-LS1

ACTION:

a. ~~With one or more ECCS trains subsystem inoperable, and at least 100% of the ECCS flow equivalent to a single OPERABLE ECCS train available, restore the inoperable subsystem train(s) to OPERABLE status within 72* hours or be in at least HOT STANDBY within the next 6 hours and in at least HOT SHUTDOWN within the following 6 hours.~~

02-01-LG

02-03-LS2

b. ~~In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date. The current value of the usage factor for each affected safety injection nozzle shall be provided in this Special Report whenever its value exceeds 0.70.~~

02-04-TR2

~~In MODE 3, both SI injection pump flow paths may be isolated by closing the isolation valve(s) for up to 2 hours to perform pressure isolation valve testing per SR ([4.4.6.2.2.1])~~

02-02-LS1

EMERGENCY CORE COOLING SYSTEMS

SURVEILLANCE REQUIREMENTS

4.5.2 Each ~~two~~ ECCS subsystem ~~trains~~ shall be demonstrated OPERABLE:

- a. At least once each 12 hours by verifying that the following valves are in the indicated ~~listed~~ positions with power to the valve operators removed:

02-07-A

<u>Valve Number</u>	<u>Valve Function</u>	<u>Valve Position</u>
8703	RHR to RCS Hot Legs	Closed
8802A	Safety Injection to RCS Hot Legs	Closed
8802B	Safety Injection to RCS Hot Legs	Closed
8809A	RHR to RCS Cold Legs	Open
8809B	RHR to RCS Cold Legs	Open
8835	Safety Injection to RCS Cold Legs	Open
8974A	Safety Injection Pump Recir. to RWST	Open
8974B	Safety Injection Pump Recir. to RWST	Open
8976	RWST to Safety Injection Pumps	Open
8980	RWST to RHR Pumps	Open
8982A	Containment Sump to RHR	Closed
8982B	Containment Sump to RHR	Closed
8992	Spray Additive Tank to Eductor	Open
8701	RHR Suction	Closed
8702	RHR Suction	Closed

EMERGENCY CORE COOLING SYSTEMS

SURVEILLANCE REQUIREMENTS (continued)

- b. At least once per 31 days by:
- 1) Verifying that the ECCS piping is full of water by ~~venting the ECCS pump casings and accessible discharge piping high points, and~~ 02-16-LG
 - 2) Verifying that each ~~ECCS~~ valve (manual, power-operated, or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position.
- c. ~~By a visual inspection which verifies that no loose debris (rags, trash, clothing, etc.) is present in the containment which could be transported to the containment sump and cause restriction of the pump suction during LOCA conditions. This visual inspection shall be performed:~~ 02-09-LG
- ~~1) For all accessible areas of the containment prior to establishing CONTAINMENT INTEGRITY, and~~
 - ~~2) At least once daily of the areas affected within containment by containment entry and during the final entry when CONTAINMENT INTEGRITY is established.~~
- d. At least once per 18 months by: a visual inspection of the containment sump and verifying that the subsystem suction inlets are not restricted by debris and that the sump components (trash racks, screens, etc.) show no evidence of structural distress or corrosion:
- e. At least once per 18 months by:
- 1) Verifying that each automatic valve in the flow path ~~that is not locked, sealed, or otherwise secured in position, actuates to its correct position on an actual or simulated Safety Injection actuation test signal.~~ 02-17-A
02-11-TR1
 - 2) Verifying that each of the following ~~ECCS~~ pumps starts automatically upon receipt of a ~~Safety Injection an actual or simulated actuation test signal.~~ 02-11-TR1
 - a) Centrifugal charging pump.
 - b) Safety Injection pump, and
 - c) Residual Heat Removal pump.
- f. ~~By verifying that each of the following pumps develops the indicated differential pressure on recirculation flow when tested pursuant to Specification 4.0.5:~~ 02-12-LG

EMERGENCY CORE COOLING SYSTEMS

SURVEILLANCE REQUIREMENTS (continued)

- 1) ~~Centrifugal charging pump \geq 2400 psid.~~
- 2) ~~Safety Injection pump \geq 1455 psid. and~~
- 3) ~~Residual Heat Removal pump \geq 165 psid.~~

~~Verifying, in accordance with the Inservice Testing Program, that each ECCS pump's developed head at the test flow point is greater than or equal to the required developed head.~~

02-12-LG

g. By verifying the correct position of each electrical and/or mechanical position stop for the following ECCS throttle valves:

- 1) ~~Within 4 hours following completion of each valve stroking operation or maintenance on the valve when the ECCS subsystems are required to be OPERABLE, and~~
- 2) At least once per 18 months.

02-13-TR3

Charging Injection
Throttle Valves

8822A
8822B
8822C
8822D

~~h. By performing a flow balance test, during shutdown, following completion of modifications to the ECCS subsystems that alter the subsystem flow characteristics and verifying that:~~

02-15-LG

- 1) ~~For centrifugal charging pumps, with a single pump running:~~
 - a) ~~The sum of injection line flow rates, excluding the highest flow rate, is greater than or equal to 299 gpm, and~~
 - b) ~~The total flow rate through all four injection lines is less than or equal to 461 gpm, and~~
 - e) ~~The difference between the maximum and minimum injection line flow rates is less than or equal to 15.5 gpm, and~~

SURVEILLANCE REQUIREMENTS (continued)

- d) ~~The total pump flow rate is less than or equal to 560 gpm.~~
- 2) ~~For safety injection pumps, with a single pump running:~~
 - a) ~~The sum of the injection line flow rates, excluding the highest flow rate, is greater than or equal to 427 gpm, and~~
 - b) ~~The total flow through all four injection lines is less than or equal to 650 gpm, and~~
 - c) ~~The difference between the maximum and minimum injection line flow rates is less than or equal to 20.0 gpm, and~~
 - d) ~~The total pump flow rate is less than or equal to 675 gpm.~~
- i. ~~By performing a flow test, during shutdown, following completion of modifications to the RHR system that alter the system flow characteristics, and verifying that with a single pump running, and delivering to all four cold legs, a total flow rate greater than or equal to 3976 gpm.~~

02-15-LG

EMERGENCY CORE COOLING SYSTEMS

3/4.5.3 ECCS SUBSYSTEMS - T_{avg} LESS THAN 350°F

LIMITING CONDITION FOR OPERATION

3.5.3 As a minimum, one ~~One~~ ECCS subsystem comprised of the following ~~train~~ shall be OPERABLE.*#

~~03-01-LG~~

~~03-06-A~~

~~03-02-LS4~~

- a. ~~One OPERABLE centrifugal charging pump.*~~
- b. ~~One OPERABLE Residual Heat Removal heat exchanger.~~
- c. ~~One OPERABLE Residual Heat Removal pump, and~~
- d. ~~An OPERABLE flow path capable of taking suction from the Refueling Water Storage Tank upon being manually realigned and transferring suction to the containment sump during the recirculation phase of operation.~~

APPLICABILITY: MODE 4.

ACTION:

- a. ~~With no the required ECCS centrifugal charging pump (CCP) subsystem OPERABLE inoperable because of the inoperability of either the centrifugal charging pump or the flow path from the Refueling Water Storage Tank, restore at least one required ECCS CCP subsystem to OPERABLE status within 1 hour or be in COLD SHUTDOWN within the next 20 24 hours.~~
- b. ~~With no the required ECCS Residual Heat Removal (RHR) subsystem OPERABLE because of the inoperability of either the residual heat removal heat exchanger or residual heat removal pump, inoperable, restore at least one required ECCS RHR subsystem to OPERABLE status immediately, or maintain the Reactor Coolant System T_{avg} less than 350°F by use of alternate heat removal methods.~~
- c. ~~In the event the ECCS is actuated and injects water into the Reactor Coolant System, a Special Report shall be prepared and submitted to the Commission pursuant to Specification 6.9.2 within 90 days describing the circumstances of the actuation and the total accumulated actuation cycles to date. The current value of the usage factor for each affected safety injection nozzle shall be provided in this Special Report whenever its value exceeds 0.70.~~

~~03-03-LS5~~

~~03-04-LG~~

~~03-05-TR2~~

*A maximum of one centrifugal charging pump shall be OPERABLE capable of injecting into the RCS whenever the temperature of one or more of the RCS cold legs is less than or equal to 270°F, below the temperature where LTOP is required

~~03-02-LS4~~

~~03-11-LG~~

EMERGENCY CORE COOLING SYSTEMS

ACTION (continued)

as specified in the Pressure Temperature Limits Report.

~~#An RHR train may be considered OPERABLE during alignment and operation for decay heat removal, if capable of being manually realigned to the ECCS mode of operation.~~

03-06-A

SURVEILLANCE REQUIREMENTS

4.5.3.1 ~~The each ECCS subsystem train shall be demonstrated OPERABLE per the applicable Surveillance Requirements of Specifications 4.5.2., 4.5.2a, 4.5.2b 1), 4.5.2d, 4.5.2f, and 4.5.2g 2).~~

03-10-LS6

4.5.3.2 All centrifugal charging pumps and Safety Injection pumps, except the above allowed OPERABLE pumps, shall be demonstrated ~~inoperable not capable of injection into the RCS~~ at least once per 12 hours whenever the temperature of one or more of the RCS cold legs is ~~less than or equal to 270°F, below the temperature where LTOP is required as specified in the PTLR, by verifying that the motor circuit breakers D.C. control power is de-energized.~~

03-02-LS4

03-11-LG

~~*An inoperable pump may be made OPERABLE for testing or for filling accumulators provided the discharge of the pump has been isolated from the RCS by an isolation valve with power removed from the valve operator, or by a sealed closed manual isolation valve.~~

03-02-LS4

~~THIS PAGE WAS INTENTIONALLY DELETED.~~

~~THIS PAGE WAS INTENTIONALLY DELETED.~~

EMERGENCY CORE COOLING SYSTEMS

3/4.5.5 REFUELING WATER STORAGE TANK

LIMITING CONDITION FOR OPERATION

3.5.5 The Refueling Water Storage Tank (RWST) shall be OPERABLE ~~with:~~

- a. A minimum contained borated water volume of 400,000 gallons. 05-03-A
(~~≥81.5% indicated level~~)
- b. A boron concentration of between 2300 and 2500 ppm, and
- c. A minimum solution temperature of 35°F.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

- a. With the RWST inoperable ~~due to boron concentration not within limits or RWST borated water temperature less than the minimum required temperature~~, restore the tank to OPERABLE status within 8 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. 05-04-LS12
- b. With the RWST inoperable for reasons other than boron concentration ~~not within limits~~, ~~ACTION a~~ restore the tank to OPERABLE status within 1 hour or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. 05-04-LS12

SURVEILLANCE REQUIREMENTS

4.5.5 The RWST shall be demonstrated OPERABLE:

- a. At least once per 7 days by:
 - 1) Verifying the contained borated water volume in the tank and
 - 2) Verifying the boron of the water.
- b. At least once per 24 hours by verifying the RWST temperature when the outside ambient air temperature is less than 35°F.

Note...RCP seal water requirements are part of current DCPD Technical Specification 3.4.6.2. Operational Leakage. NUREG-1431, Rev. 1 has a specific T.S. 3.5.5 to address RCP seal requirements. ITS 3.5.5 replaces the CTS.

--	----------------

Methodology For Mark-Up of Current TS

This enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (CTS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The CTS are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. **Deletions** - Material is no longer in the specifications. (this includes material which is moved to the BASES of the TS).
2. **Additions** - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the CTS.
3. **Modifications** - This includes requirements which exist in the CTS but are being revised in the improved TS.
4. **Administrative** - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is :

Deletions -

The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.

Additions -

The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.

Modifications -

The information being revised is annotated in the CTS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.

Administrative -

The text of the CTS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the CTS, a change number is provided in the markup of the CTS and an explanation is provided in

Methodology For Mark-up of Current TS
(continued)

Enclosure 3A which explains where that requirement has been located in the improved TS.

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 04-13-LS. The first number (i.e., 04 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS markup. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO CURRENT TS (CTS) SECTION 3/4.5

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	M	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-02	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-03	A	Replaces reference to the "pressurizer pressure" with a reference to the "RCS pressure." ACTIONS A. and B. require reducing pressurizer pressure to less than 1000 psig. However, pressurizer pressure instrumentation does not have the range to read that pressure. Consequently, reactor coolant system (RCS) pressure instrumentation is used. For the purposes of this limiting condition of operation (LCO), the use of RCS pressure is equivalent.
01-04	LS 8	The ACTION statement is restructured in agreement with NUREG-1431. The CTS ACTION time (within 1 hour) for restoration of accumulator OPERABILITY for conditions other than a closed isolation valve has been replaced. The replacement ACTION requires that an accumulator inoperable due to boron concentration not within limits must be restored within 72 hours. Also, the requirement to go to HOT SHUTDOWN within the following 6 hours is replaced by the ACTION to reduce RCS pressure to less than or equal to 1000 psig within the following 6 hours. These changes are considered to be relaxations.
01-05	LS 9	The ACTION statement is restructured in agreement with NUREG-1431. The CTS ACTION time (immediately) for restoration of accumulator OPERABILITY due to the isolation valve closed is replaced. The replacement ACTION requires that for reasons other than boron concentration, the accumulator must be restored within 1 hour. Also, the requirement to go to HOT SHUTDOWN within the following 6 hours is replaced by the ACTION to reduce RCS pressure to less than or equal to 1000 psig. These changes are considered to be relaxations.
01-06	A	The words "with three accumulators OPERABLE and" are added to both ACTION statements to make entry into LCO 3.0.3 mandatory with two or more accumulators inoperable. This change is consistent with NUREG-1431 and is considered administrative in nature since it reflects current plant practice, i.e., current ACTION Statements A. and B. are not entered at the same time on different accumulators.

CHANGE NUMBER

NSHC

DESCRIPTION

01-07	LG	The Surveillance Requirement (SR) currently requires a 6 hour surveillance if the makeup source is the refueling water storage tank (RWST) and the RWST has not been diluted since verifying its boron concentration per the RWST LCO. The proposed change would move the statement "and the RWST has not been diluted since verifying ..." from the accumulator SR to the ITS SR 3.5.1.4 Bases. This level of detail is not included in the ISTS and is consistent with the kind of information contained in the Bases.
01-08	A	In accordance with NUREG-1431, the LCO accumulator contained solution volume expressed in cubic feet is replaced by percent (%). Also, the surveillance solution volume increase is revised from 1 percent tank volume (101 gallons) to 5.6 percent of narrow range indicated level, equivalent of 1 percent tank volume. This value can be read from control room indicators. This change in terms is administrative and does not result in a change in the measured volume.
02-01	LG	Consistent with NUREG-1431, the LCO and ACTION a. are revised to replace the word "subsystem" with the word "train." The descriptive information in the LCO is moved to the Bases. Whereas there is no technical change associated with the replacement of the term "subsystem," "train" better describes that all parts of the required system (e.g., piping, instruments, controls, etc.) must be OPERABLE to support the required safety function.
02-02	LS 1	Consistent with NUREG-1431, a Note with respect to RCS pressure isolation valve (PIV) testing is added to the LCO. Plant design requires closure of certain valves in the safety injection (SI) paths to perform PIV testing. Isolation of the injection paths in MODE 3 is currently prohibited as it would constitute entering TS 3.0.3 since both SI trains would be made administratively inoperable. The flow paths are readily restorable from the control room and a single active failure is not likely in the short term (2 hours). The new Note will allow closing these valves for testing without declaring either SI train inoperable. This change is consistent with Industry Traveler TSTF-153.
02-03	LS 2	This change revises ACTION a. to allow for increased flexibility in plant operations under circumstances where components in opposite trains are inoperable, but at least 100 percent of the emergency core cooling system (ECCS) flow equivalent to a single OPERABLE ECCS train is available. Due to the design of the ECCS subsystems, the inoperable condition of one or more components in each train does not necessarily render the ECCS inoperable for performing its safety function. The allowed outage time (AOT) of 72 hours is unchanged; but it is to be contingent on being capable of providing 100 percent of the ECCS flow equivalent to a single OPERABLE ECCS train. This change is consistent with NUREG-1431.

CHANGE NUMBER

NSHC

DESCRIPTION

02-04	TR 2	Consistent with NUREG-1431, the requirement to submit a special report within 90 days of an ECCS actuation and injection event is deleted. This change is acceptable because the requirement to submit a report is sufficiently addressed by the reporting requirements contained in 10 CFR 50.73.
02-05	LS 3	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-06		Not used.
02-07	A	Consistent with NUREG-1431, this change revises the surveillance to make it clear that "listed" valve position is the concern and not indicated position in the control room. The surveillance can be satisfied using indicated position in the control room but may also be satisfied using local observation. This is an administrative change since the surveillance acceptance criteria are not changed.
02-08	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-09	LG	The visual inspection surveillance performed when establishing containment integrity is moved to a licensee controlled document, consistent with NUREG-1431.
02-10	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-11	TR 1	Consistent with NUREG-1431, the ECCS pump and valve actuation SR is changed to allow the use of an actual signal, if and when one occurs, to satisfy SRs. The specific signals used to actuate the pumps and valves have been moved to the Bases.
02-12	LG	The ECCS pump performance is revised to be consistent with NUREG-1431. The test method and specific data required to verify pump performance is relocated to the Bases. CTS 4.0.5 no longer exists in the ITS. However, the requirement for an Inservice Testing (IST) Program is moved to Section 5.5.8 of the ITS. The IST Program is referenced directly for the frequency of testing.
02-13	TR 3	The CTS allowance, which permits the ECCS throttle valves to be declared OPERABLE without verifying ECCS throttle valve position for four hours following stroke valve testing or maintenance is deleted from the CTS consistent with NUREG-1431. The ECCS throttle valves are manual valves and plant procedures governing the restoration of equipment after maintenance specify verification of correct throttle position prior to declaring the valves OPERABLE. This requirement is inherent to post-maintenance OPERABILITY requirements and removal from the specifications does not affect TS requirements for testing scope or frequency.

CHANGE NUMBER

NSHC

DESCRIPTION

02-14

A

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

02-15

LG

The SR for the flow balance test following ECCS modifications is moved to a licensee controlled document. This requirement is not included in NUREG-1431.

02-16

LG

The specific means by which the ECCS piping is assured to be full of water is moved to the Bases. This level of detail is not included in the ISTS and is consistent with the kind of information contained in the Bases.

02-17

A

This change adds the phrase "that is not locked, sealed, or otherwise secured in position" with regard to which valves require actuation testing. This change is merely a clarification. Valves that are secured in place, are secured in the position required to meet their safety function. The actuation testing ensures that valves can move to the position that meets their safety function. If the valves are secured in the position that meets their safety function, no testing is necessary.

02-18

LG

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

02-19

LG

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

03-01

LG

Consistent with NUREG-1431, the LCO is revised to replace the word "subsystem" with the word "train" and the descriptive information in the LCO is moved to the Bases. Whereas, there is no technical change associated with the replacement of the term "subsystem," "train" better describes that all parts of the required system (e.g., piping, instruments, controls, etc.) must be OPERABLE to support the required safety functions.

03-02

LS 4

Consistent with NUREG-1431, the LTOP limitation on ECCS pumps and related surveillances are moved to ITS 3.4.12. The prescriptive wording related to pump OPERABILITY is changed to wording specifically addressing the pump's capability to inject into the RCS. This change is less restrictive on the configuration of the centrifugal charging pump (CPP) and SI pumps but is acceptable because it is consistent with the cold overpressure analysis requirements and still precludes flow to the RCS.

03-03

LS 5

Consistent with NUREG-1431, CTS 3.5.3 ACTION a. terminology is revised and the descriptive information moved to the Bases. The ACTION a. Completion Time for COLD SHUTDOWN due to CCP inoperability is increased by 4 hours, from 20 hours to 24 hours. This time is reasonable based on operating experience to reach MODE 5 in an orderly manner, without challenging plant systems or operators, and is consistent with other shutdown ACTION Completion Times to reach MODE 5 from MODE 4.

CHANGE NUMBER

NSHC

DESCRIPTION

03-04

LG

Consistent with NUREG-1431, the ACTION b terminology is revised. The requirement to restore at least one ECCS subsystem is revised to "immediately initiate action to restore" a residual heat removal (RHR) subsystem. With both RHR pumps and heat exchangers inoperable, it would be unwise to require the plant to go to MODE 5, when the only available heat removal system is the RHR. Therefore, the appropriate ACTION is to initiate measures to restore one ECCS RHR subsystem and to continue the ACTIONS until the subsystem is restored to OPERABLE status.

Also, the alternate requirement (if RHR cannot be restored) to maintain $T_{avg} < 350^{\circ}F$ by use of alternate heat removal methods is descriptive information and is moved to the Bases. The transition to MODE 3 is already prohibited in this scenario by the ECCS specification for MODES 1, 2, and 3.

03-05

TR 2

Consistent with NUREG-1431, the requirement to submit a special report within 90 days of an ECCS actuation and injection event is deleted. This change is acceptable because the requirement to submit a report is sufficiently addressed by the reporting requirements contained in 10 CFR 50.73.

03-06

A

Consistent with TSTF-90, a Note is added to the LCO that clarifies an RHR train's ECCS function is operable if it is capable of being manually realigned to the ECCS mode of operation. This is an administrative change to provide clarification.

03-07

M

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

03-08

A

Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

03-09

M

This change is not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

03-10

LS 6

Consistent with NUREG-1431, the requirement to demonstrate ECCS train OPERABILITY in MODE 4 in SR [4.5.3.1] has been revised to delete the 31 day surveillance to verify the correct position of each valve in the ECCS flow path which is not already locked in place, and the 18 month surveillance to verify automatic actuation of ECCS pumps and automatic valves.

03-11

LG

The minimum RCS temperature limit below which the CCP and SI pumps must be demonstrated not capable of injecting into the RCS is replaced by the statement "below the temperature where LTOP is required as specified in the pressure temperature limits report (PTLR)." The minimum temperature is a plant specific requirement based on the reactor vessel material characteristics documented in the PTLR and is periodically reviewed and adjusted as required. Referring to the PTLR for the current value is consistent with the relocation of the pressure temperature limits from ITS Section 3.4.3 to

the PTLR.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
03-12	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
04-01	LS 4	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
04-02	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
04-03	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
04-04	A	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
04-05	M	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
04-06	A	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-01	LS 7	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-02	LS 10	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
05-03	A	This change converts the RWST volume requirement from gallons to the equivalent percent of tank water level, in accordance with NUREG-1431. This change in method of indicating tank volume is administrative and does not result in a change in volume of the tank contents.
05-04	LS 12	This change modifies 3.5.5 ACTION a. to include the requirement for RWST borated water temperature to be above the minimum required temperature and ACTION b. to reference ACTION a. The ACTION for water temperature was in ACTION b with a Completion Time of 1 hour. With the water temperature included in ACTION a. the Completion Time is 8 hours. This change is consistent with NUREG-1431. This change from 1 to 8 hours is a relaxation.

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3..." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION
BASES, FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?
The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:
- a) Increasing the analytical or safety limit,
 - b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
 - c) Increasing the applicability of the specification,
 - d) Providing additional actions,
 - e) Decreasing restoration times,
 - f) Imposing new surveillances, or
 - g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The LCO Applicability is revised to provide a Note with respect to RCS PIV testing in MODE 3. The design requires closure of the PIVs in both SI flow paths to perform PIV testing. Isolation of the injection paths in MODE 3 is currently prohibited as it would constitute entering TS 3.0.3 since both trains of SI would be made administratively inoperable. The revision provides for closing the valves for up to two hours to allow PIV testing. The CCP injection flow paths are available, the SI flow paths are readily restorable from the control room and a single active failure is highly unlikely in the short term. Operating and testing experience has shown that 2 hours is a reasonable period of time required to perform the PIV testing. The low decay heat and non-critical condition of the core allow ample time to take operator action in the event of a loss-of-coolant accident (LOCA) in MODE 3 on startup. The new Note will allow closing these valves without declaring either SI train inoperable. The new Note will allow closing these valves for testing without declaring either ECCS train inoperable.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change does not result in any hardware changes. The ECCS components covered by this TS are not assumed to be initiators of any analyzed event. The proposed change allows both SI flow paths to be isolated for up to 2 hours.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

The proposed Completion Time of 2 hours is a reasonable time to allow both SI trains to be isolated because of the unlikelihood of a design basis accident (DBA) which would require ECCS during that time period. The ECCS components are not altered by this change, and following the test period, retain their full capability to mitigate the consequences of an accident once correctly aligned. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will allow both SI trains to be isolated for up to 2 hours. This change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Following the completion of the testing, full SI capability continues. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS 1" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The ACTION statement is revised to provide an AOT for 1 or both ECCS trains inoperable. Due to the design of the ECCS subsystems, the inoperable condition of 1 or more components in each train does not necessarily render the ECCS inoperable for performing its safety function. The AOT of 72 hours is unchanged, but it is to be contingent on being capable of providing 100 percent of the ECCS flow equivalent to a single operable ECCS train assuming no single failure. This change is consistent with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change does not result in any hardware changes. Providing an AOT for one or both ECCS trains inoperable is not assumed to be an initiator of any analyzed event. The proposed change allows both ECCS trains to be inoperable for up to 72 hours provided the remaining operable ECCS components can provide the flow equivalent to a single operable train which will ensure 100 percent of the flow assumed in the safety analyses, assuming no single failure. The ECCS system function, equivalent of 1 full train, remains available to mitigate the consequences of an unlikely DBA event during this time. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will allow both ECCS trains to be inoperable for up to 72 hours provided the remaining OPERABLE ECCS components can provide the flow equivalent to a single OPERABLE train. The proposed change does not, introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (continued)

safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The allowance to have both ECCS trains inoperable for up to 72 hours, provided the remaining OPERABLE ECCS components can provide the flow equivalent to a single OPERABLE train, does not have any effect on accident or transient analysis. The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS2" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The Completion Time to achieve COLD SHUTDOWN due to failure to restore the OPERABILITY of an ECCS CCP subsystem within 1 hour is extended from 20 to 24 hours. This is consistent with NUREG-1431 and is a reasonable time, based on operating experience, to reach MODE 5 in an orderly manner and without challenging plant systems or operators.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Due to the low energy, stable conditions associated with operation in MODE 4, the occurrence of a DBA is unlikely. In recognition, the ECCS operational requirements are reduced, with only 1 train of the ECCS CCP subsystem required to be OPERABLE. The CTS has an ACTION Completion Time of 1 hour to restore required ECCS CCP OPERABILITY. The 1 hour restoration Completion Time is in accordance with NUREG-1431, and is not affected by this proposed change, and does not alter the probability of an accident during the ACTION Completion Time. The allowed time to reach MODE 5 is increased from 20 hours to 24 hours by this proposed change. This additional time allows for an orderly MODE transition. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 (continued)

related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS5" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6

10 CFR 50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, the requirement to demonstrate ECCS train OPERABILITY in MODE 4 has been revised to delete the 31 day surveillance to verify the correct position of each valve in the ECCS flow path which is not already locked in place, and the 18 month surveillance to verify automatic actuation of ECCS pumps and automatic valves. This change is acceptable because the ECCS operational requirements are reduced due to the stable reactivity conditions and limited core cooling requirements associated with operation in MODE 4 and the unlikelihood of occurrence of a DBA in MODE 4. It is understood these surveillance reductions increase the possibility that automatic positioning of ECCS valves and actuation of ECCS pumps may not occur on a SI actuation signal. In MODE 4, sufficient time exists for manual actuation of the required ECCS to mitigate the consequences of a DBA.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Due to the stable conditions associated with operation in MODE 4, the probability of occurrence of a DBA is lower than in MODES 1, 2, and 3. Because of the reduced core cooling requirements, sufficient time is available for manual actuation/alignment of required ECCS equipment. Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will delete certain surveillances for MODE 4 OPERABILITY of an ECCS train. However, the proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS6" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The ACTION statement is revised in accordance with NUREG-1431 to extend the time required to restore accumulator water boron concentration to within limits from 1 to 72 hours. A 1 hour ACTION to initiate plant shutdown compromises the opportunity for verification, diagnosis, and restoration of the condition of the accumulator to within limits. Changes in boron concentration are slow and the ACTION change provides a more reasonable time in which to restore limits. Increasing the AOT from 1 hour to 72 hours could avoid unnecessary plant transients and plant shutdowns if OPERABILITY cannot be restored within 1 hour but could be restored within 72 hours, thus improving plant safety and increasing plant availability.

The boron in the accumulator water contributes to the analyses assumption that the combined ECCS water in the partially recovered core during the early reflood phase of a large break LOCA is sufficient to keep that portion of the core subcritical. Core cooling during the ECCS injection mode is not affected by the accumulator water boron concentration being outside limits because the accumulator water remains available for injection throughout the duration of the AOT.

The condition of 1 accumulator not within the boron concentration limits does not affect the other 3 accumulators as the accumulators are mutually isolated. One accumulator below the minimum boron concentration will have no effect on available ECCS water and an insignificant effect on core subcriticality during reflood. Consequently, although the accumulator may be inoperable in accordance with TS requirements due to boron concentration outside of limits, it still retains capability to contribute in satisfying its safety function. If 2 or more accumulators are inoperable for any reason, ITS 3.5.1, ACTION D requires immediate entry into TS 3.0.3.

Increasing the AOT is consistent with recommendations of NUREG-1024, "Technical Specification -- Enhancing the Safety Impact." NUREG 1024 states:

"Allowable outage times that are too short will subject the plant to unnecessary trips, transients and fatigue cycling. Outage times that are too short also may result in less thorough repair and post-repair testing before equipment is returned to service."

Replacing the ACTION requirement to go to HOT SHUTDOWN within the following 6 hours with the requirement to reduce RCS pressure to less than or equal to 1000 psig within the following 6 hours makes the ACTION consistent with the Applicability. Reducing the RCS pressure to less than or equal to 1000 psig results in the accumulators no longer being required, and TS Applicability can be exited. At pressures less than or equal to 1000 psig, the rate of RCS blowdown is reduced and the ECCS pumps can provide adequate injection to ensure the peak clad temperature remains below the acceptance limit of 10 CFR 50.46.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
(continued)

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change does not result in any hardware or operating procedure changes. The ECCS conditions covered by this TS are not assumed to be initiators of any analyzed event. The potential for the accumulator water boron concentration to be outside limits is small because the accumulators and contents are not involved with normal plant operation and are not subject to process variations associated with plant operation. The proposed change allows a longer time to restore conditions to within limits. The reactor will be in MODES 1, 2, 3 (with RCS pressure >1000 psig) during this condition.

The effect of a departure from boron concentration is insignificant to core criticality, whereas the effect of the water to mitigate consequences is not decreased. Consequently, although the likelihood of an event occurrence during the additional 71 hours is small, the consequences of an event occurring during the period are not significantly different.

The replacement of the requirement to go to HOT SHUTDOWN with the requirement to go to a RCS pressure less than or equal to 1000 psig reduces the plant transients. Reducing the RCS pressure to less than or equal to 1000 psig results in the accumulators no longer being required for TS Applicability. However the peak clad temperature remains below the acceptance limit of 10 CFR 50.46 using ECCS pump injection without the contribution from the accumulators. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will allow additional time to restore boron concentration to within limits. The change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed), does not change the method by which any safety-related system performs its function, and does not change parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The additional time to restore boron concentration to within limits prior to requiring a unit shutdown is based on the fact that the contents of the affected accumulator are still available for injection in agreement with the analyses assumptions. Consequently, any change in a margin of safety will be insignificant and offset by the benefit of avoiding an unnecessary plant transient.

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS8" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The ACTION statement is revised in agreement with NUREG-1431 to extend the time required to restore accumulator OPERABILITY for reasons other than boron concentration not within limits from immediately to 1 hour. Accumulator OPERABILITY is important to satisfy the analyses assumption that the contents of 3 of the 4 accumulators reach the core following a LOCA. However, an immediate ACTION to initiate plant shutdown denies the opportunity for verification, diagnosis, and restoration of the condition of the accumulator to within limits. The additional time proposed will reduce the probability of unnecessary plant transients and plant shutdowns, thus improving plant safety and increasing plant availability. If 2 or more accumulators are inoperable for any reason, ITS 3.5.1 ACTION D requires immediate entry into TS 3.0.3.

Increasing the AOT is consistent with recommendations of NUREG-1024, "Technical Specification -- Enhancing the Safety Impact." NUREG 1024 states:

"Allowable outage times that are too short will subject the plant to unnecessary trips, transients and fatigue cycling. Outage times that are too short also may result in less thorough repair and post-repair testing before equipment is returned to service."

Replacing the ACTION requirement to go to HOT SHUTDOWN within the following 6 hours with the requirement to reduce RCS pressure to less than or equal to 1000 psig within the following 6 hours makes the ACTION consistent with the Applicability. Reducing the RCS pressure to less than or equal to 1000 psig results in the accumulators no longer being required for TS Applicability. At pressures less than or equal to 1000 psig, the rate of RCS blowdown is reduced and the ECCS pumps can provide adequate injection to ensure the peak clad temperature remains below the acceptance limit of 10 CFR 50.46.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 (continued)

This change does not result in any hardware or operating procedure changes. The ECCS conditions covered by this TS are not assumed to be initiators of any analyzed event. The 1 hour Completion Time ensures that prompt action will be taken to return the inoperable accumulator to OPERABLE status. The likelihood of an event occurrence during 1 hour is low.

The replacement of the requirement to go to HOT SHUTDOWN with the requirement to go to a RCS pressure less than or equal to 1000 psig reduces plant transients. Reducing the RCS pressure to less than or equal to 1000 psig results in the accumulators no longer being required for TS Applicability. However, the peak clad temperature remains below the acceptance limit of 10 CFR 50.46 using ECCS pump injection without the contribution from the accumulators. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will allow 1 hour to restore an accumulator to OPERABLE status. The change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed), does not change the method by which any safety-related system performs its function, and does not change parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The occurrence of an event during the 1 hour AOT is extremely unlikely, whereas allowing some time to restore the accumulator may avoid unnecessary plant transients associated with a required shutdown. As such, any change in a margin of safety will be insignificant and offset by the benefit of reducing the possibility of an unnecessary plant transient. The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS9" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12

10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The ACTION statement is revised to extend the time required to restore RWST borated water temperature to within limits from 1 to 8 hours. Changes in water temperature are slow and the change provides a more reasonable time in which to restore limits. The increase in allowed time to restore conditions to within limits prior to requiring a unit shutdown recognizes that the deviation from the analysis temperature assumption would probably be minor due to the moderate site temperature and that the contents of the tank are still available for injection. Also, the occurrence of an event requiring injection of the RWST contents during the increased Completion Time is extremely unlikely. The additional time proposed will reduce the possibility of unnecessary plant transients and plant shutdowns, thus improving plant safety and increasing plant availability.

Increasing the AOT is consistent with recommendations of NUREG-1024, "Technical Specification - Enhancing the Safety Impact." NUREG 1024 states:

"Allowable outage times that are too short will subject the plant to unnecessary trips, transients and fatigue cycling. Outages times that are too short also may result in less thorough repair and post-repair testing before equipment is returned to service."

The contents of the tank are still available for injection during the Completion Time and the extent of temperature outside the limit is not likely to be significant to safety. This change is consistent with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12 (continued)

This change does not result in any hardware or operating procedure changes. The RWST conditions covered by this TS are not assumed to be initiators of any analyzed event. The likelihood of an event occurrence during the additional 7 hours is very small, and the analysis effect of small departures from temperature is judged to be slight. The consequences of an event occurring during the increased Completion Time period are not significantly different. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will allow additional time to restore conditions to within limits; but it does not alter the activity. The change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed), does not change the method by which any safety-related system performs its function, and does not change parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not significantly changed. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "LS12" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR1

10 CFR 50.92 EVALUATION FOR RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision modifies the CTS to additionally allow the use of actual actuation signals for surveillances that currently call for testing using simulated test signals only. This change achieves consistency with the STS (NUREG-1431).

In several specifications throughout the CTS, OPERABILITY of certain equipment is demonstrated by ensuring that the equipment performs its safety function upon receipt of a simulated test signal. The intent of a 'simulated' signal was to be able to perform the required testing without the occurrence (or without causing) an actual signal generating event. However, the unintended effect was to require the performance of the surveillance (using a test signal) even if an actual signal had previously verified the operation of the equipment. This change allows credit to be taken for actual events when the required equipment actuates successfully.

While the occurrence of events that cause actuation of accident mitigation equipment is undesirable, the actuation of mitigation equipment on an actual signal is a better demonstration of its OPERABILITY than an actuation using a test signal. Thus, the change does not reduce the reliability of the equipment tested. The change also improves plant safety by reducing the amount of time the equipment is taken out of service for testing, and thereby increasing its availability during an actual event, and by reducing the wear of the equipment caused by unnecessary testing.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change allows the use of an actual actuation signal (when/if it occurs) to satisfy SRs currently requiring simulated test signals to demonstrate equipment OPERABILITY. While the change takes advantage of events that may have occurred, it has no adverse effect on any accident initiators or accident consequences.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR1 (continued)

It may also reduce accident consequences by increasing the equipment availability (i.e., less time in test). Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The use of an actual actuation signal to satisfy a SR has either no impact on, or increases the margin of plant safety by:

- a) Increasing mitigation equipment availability, and
- b) Improving mitigation equipment reliability by potentially reducing wear caused by unnecessary testing.

The proposed change does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "TR1" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR2

10 CFR 50.92 EVALUATION FOR RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change in accordance with NUREG-1431, removes the requirement for a special report to be prepared and submitted to the NRC within 90 days of an ECCS actuation and injection event. Reporting to the NRC will be done commensurate with the reporting requirements of 10 CFR 50.72 and 50.73.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This proposed change is an administrative reporting change and cannot affect any accident probability or consequences or the method by which the plant is operated. Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change is administrative and does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change is administrative and does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

**NSHC TR2
(continued)**

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "TR 2" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR3

10 CFR 50.92 EVALUATION FOR RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed change removes references to specific post-maintenance tests from the CTS. Post-maintenance testing programs are controlled via plant administrative procedures in accordance with licensee controlled document (ITS Section 5.4.1, Final Safety Analysis Report and Operating Quality Assurance Program) commitments to NRC Regulatory Guide 1.33, "Quality Assurance Program Requirements (Operation)," and ANS 3.2-ANSI N18.7, "Administrative Controls and Quality Assurance for the Operational Phase of Nuclear Power Plants." Specific post-maintenance testing requirements are contingent on the type and scope of maintenance actually performed as well as the availability and viability of test equipment, techniques, etc. Removal of specific testing requirements from the CTS and reliance on normal post-maintenance testing programs addressed by licensee controlled documents allow flexibility to modify testing to address the circumstances of the maintenance performed while still assuring OPERABILITY of equipment returned to service.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This proposed change is an administrative change which removes specific post-maintenance test requirements from the CTS. The testing, or equivalent testing, to assure equipment OPERABILITY prior to return to service would still be done as required by normal plant maintenance retest programs. Therefore, this proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR3 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change is administrative and does not introduce new equipment, does not involve any physical alteration to any plant equipment, and does not involve any changes in the method by which any safety-related system performs its function. Therefore, this proposed change does not create the possibility of a new or different accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change is administrative and does not alter the basic regulatory requirements and does not change any assumptions, conditions, or acceptance criteria of any analyzed event. The analyses remain valid and the margin of safety is not changed. Therefore, this proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, the activities associated with NSHC "TR 3" resulting from the conversion to the ITS format are seen to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exists in NUREG-1431, Rev. 1, but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is :

Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.

Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.

Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.

Editorial Changes- Changes/corrections which are obviously editorial are annotated using the redline/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.

Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "redline" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line", "strike-out" and margin codes are as follows:

1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is

Methodology For Mark-up of NUREG-1431 Specifications
(continued)

used as the margin code.

2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out", the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.
3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is redlined. The text included within the brackets is not redlined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are struck-out, redlined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note, NUREG-1431, Rev. 1 is used for all markups. Industry Travelers which are incorporated are indicated using the "redlines", "strike-outs" and margin codes discussed above.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.1 Accumulators

BASES

BACKGROUND

The functions of the ECCS accumulators are to supply borated water to replace inventory in the reactor vessel during the blowdown refill phase of a loss of coolant accident (LOCA), to provide inventory to help accomplish the refill phase that follows thereafter, and to provide Reactor Coolant System (RCS) makeup for a small break LOCA.

The blowdown phase of a large break LOCA is the initial period of the transient during which the RCS departs from equilibrium conditions, and heat from fission product decay, hot internals, and the vessel continues to be transferred to the reactor coolant. The blowdown phase of the transient ends when the RCS pressure falls to a value approaching that of the containment atmosphere.

In the refill phase of a LOCA, which immediately follows the blowdown phase, reactor coolant inventory has vacated the core through steam flashing and ejection spill out through the break. The core is essentially in adiabatic heatup. The balance of accumulator inventory is then available to help fill voids in the lower plenum and reactor vessel downcomer so as to establish a recovery level at the bottom of the core and ongoing reflood of the core with the addition of safety injection (SI) water.

The accumulators are pressure vessels partially filled with borated water and pressurized with nitrogen gas. The accumulators are passive components, since no operator or control actions are required in order for them to perform their function. Internal accumulator tank pressure is sufficient to discharge the accumulator contents to the RCS, if RCS pressure decreases below the accumulator pressure.

Each accumulator is piped into an RCS cold leg via an accumulator line and is isolated from the RCS by two check valves in series and by an open motor operated isolation valve (8808A, B, C, and D). The motor operated isolation valves are interlocked by P-11 with the pressurizer pressure measurement channels to ensure that the valves will automatically open as RCS pressure increases to above permissive circuit P-11 setpoint. to receive an "open" signal when permissive circuit P-11 is cleared. However, before permissive circuit P-11 is reached, these valves are manually opened and their motor operator breakers are sealed open to satisfy SR 3.5.1.5. Therefore, in the event of a LOCA, accumulator actuation is passive. (Ref [6.1])

BASES

BACKGROUND
(continued)

This interlock also prevents inadvertent closure of the valves during normal operation prior to an accident. However, if these valves were closed, they would be automatically opened as a result of an SI signal. These features ensure that the valves meet the requirements of the Institute of Electrical and Electronic Engineers (IEEE) Standard 279-1971 (Ref. 1) for "operating bypasses" and that the accumulators will be available for injection without reliance on operator action.

The accumulator size, water volume, and nitrogen cover pressure are selected so that three of the four accumulators are sufficient to partially cover the core before significant clad melting or zirconium water reaction can occur following a LOCA. The need to ensure that three accumulators are adequate for this function is consistent with the LOCA assumption that the entire contents of one accumulator will be lost via the RCS pipe break during the blowdown phase of the LOCA.

APPLICABLE
SAFETY ANALYSES

The accumulators are assumed OPERABLE in both the large and small break LOCA analyses at full power (Ref. 2 and 4). These are the Design Basis Accidents (DBAs) that establish the acceptance limits for the accumulators. Reference to the analyses for these DBAs is used to assess changes in the accumulators as they relate to the acceptance limits.

The limiting large break LOCA is a double ended guillotine break at the discharge of the reactor coolant pump. During this event, the accumulators discharge to the RCS as soon as RCS pressure decreases to below accumulator pressure.

In performing the LOCA calculations, conservative assumptions are made concerning the availability of ECCS flow with no credit taken for ECCS pump flow until an effective delay has elapsed. In the early stages of a LOCA, with or without a loss of offsite power, the accumulators provide the sole source of makeup water to the RCS. The assumption of loss of offsite power is required by regulations and conservatively imposes a delay wherein the ECCS pumps cannot deliver flow until the emergency diesel generators start, come to rated speed, and go through their timed loading sequence. The delay time is conservatively set with an additional 2 seconds to account for SI signal generation. In cold leg break scenarios, the entire contents of one accumulator are assumed to be lost through the break. No operator action is assumed during the blowdown stage of a large break LOCA.

BASES

APPLICABLE SAFETY
ANALYSES (continued)

~~As a conservative estimate, no credit is taken for ECCS pump flow until an effective delay has elapsed. This delay accounts for the diesels starting and the pumps being loaded and delivering full flow. The delay time is conservatively set with an additional 2 seconds to account for SI signal generation. During this time, the accumulators are analyzed as providing the sole source of emergency core cooling. No operator action is assumed during the blowdown stage of a large break LOCA.~~

The worst case small break LOCA analyses also assume a time delay before pumped flow reaches the core. For the larger range of small breaks, the rate of blowdown is such that the SI pumps begin RCS injection, however, the increase in fuel clad temperature is terminated solely primarily by the accumulators, with pumped flow then providing continued cooling. As break size decreases, the accumulators and the ECCS centrifugal charging and SI pumps both play a part in terminating the rise in clad temperature. As break size continues to decrease, the role of the accumulators continues to decrease. The accumulators do not discharge above the pressure of their nitrogen cover gas (595.5 to 647.5 psig). At higher pressures the ECCS centrifugal charging pumps and SI pumps injection becomes solely responsible for terminating the temperature increase.

This LCO helps to ensure that the following acceptance criteria established for the ECCS by 10 CFR 50.46 (Ref. 3) that are applicable for the accumulators will be met following a LOCA:

- a. Maximum fuel element cladding temperature is $\leq 2200^{\circ}\text{F}$;
- b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation;
- c. Maximum hydrogen generation from a zirconium-water reaction is ≤ 0.01 times the hypothetical amount that would be generated if all of the metal in the cladding cylinders surrounding the fuel, excluding cladding surrounding the plenum volume, were to react; and
- d. Core is maintained in a coolable geometry.

Since the accumulators discharge during the blowdown phase of a LOCA, they do not contribute to the long term cooling requirements of 10 CFR 50.46.

For both the large and small break LOCA analyses, a nominal contained accumulator water volume is used. The contained water volume is the same as the deliverable volume for the accumulators, since the accumulators are emptied, once discharged. For small breaks, an increase

BASES

APPLICABLE SAFETY
ANALYSES (continued)

in water volume is a peak clad temperature penalty. For large breaks depending on the NRC-approved methodology used to analyze large breaks, an increase in water volume can result in either a peak clad temperature penalty or benefit, depending on downcomer filling and subsequent spill through the break during the core reflooding portion of the transient. The analysis makes a conservative assumption with respect to ignoring or taking credit for line water volume from the accumulator to the check valve. The safety analysis assumes values of \geq [6468] 60.8% (836 cubic feet) gallons and \leq [6879] 72.6% (864 cubic feet) gallons as read on narrow range level instruments not including instrument uncertainty. To allow for instrument inaccuracy values of [6520] gallons and [6820] gallons are specified.

The minimum boron concentration setpoint is used in the post LOCA boron concentration calculation. The calculation is performed to assure reactor subcriticality in a post LOCA environment. Of particular interest is the large break LOCA, since no credit is taken for control rod assembly insertion. A reduction in below the accumulator LCO minimum boron concentration would produce a subsequent reduction in the available containment recirculation sump boron concentration for post LOCA shutdown and an increase in the maximum sump pH. The maximum boron concentration is used in determining the cold leg to hot leg recirculation injection switchover time and minimum sump pH.

The large and small break LOCA analyses are performed at the minimum nitrogen cover pressure (603 psia) (595.5 psig), since sensitivity analyses have demonstrated that higher nitrogen cover pressure results in a computed peak clad temperature benefit. The maximum nitrogen cover pressure limit (693 psia) (647.5 psig) prevents accumulator relief valve actuation and ultimately preserves accumulator integrity, provides margin to assure inadvertent relief valve actuation does not occur.

These analysis-assumed pressures are specified in the SRs. Volumes are shown on the control board indicators as % readings on accumulator narrow range level instruments. Adjustments to the analysis parameters for instrument inaccuracies or other reasons are applied to determine the acceptance criteria used in the plant surveillance procedures. These adjustments assure the assumed analyses parameters are maintained.

The effects on containment mass and energy releases from the accumulators are accounted for in the appropriate analyses (Refs. 2 and 4).

The accumulators satisfy Criterion 3 of the NRC Policy Statement. 10 CFR 50.36(c)(2)(ii)

BASES

LCO

The LCO establishes the minimum conditions required to ensure that the accumulators are available to accomplish their core cooling safety function following a LOCA. Four accumulators are required to ensure that 100% of the contents of three of the accumulators will reach the core during a LOCA. This is consistent with the assumption that the contents of one accumulator spill through the break. If less than three accumulators are injected during the blowdown phase of a LOCA, the ECCS acceptance criteria of 10 CFR 50.46 (Ref. 3) could be violated.

For an accumulator to be considered OPERABLE, the isolation valve must be fully open, power removed above [2000] a nominal RCS pressure of 1000 psig, and the limits established in the SRs for contained volume, boron concentration, and nitrogen cover pressure must be met.

APPLICABILITY

In MODES 1 and 2, and in MODE 3 with RCS pressure > 1000 psig, the accumulator OPERABILITY requirements are based on full power operation. Although cooling requirements decrease as power decreases, the accumulators are still required to provide core cooling as long as elevated RCS pressures and temperatures exist.

This LCO is only applicable at RCS pressures > 1000 psig. At pressures ≤ 1000 psig, the rate of RCS blowdown is such that the ECCS pumps can provide adequate injection to ensure that peak clad temperature remains below the 10 CFR 50.46 (Ref. 3) limit of 2200°F.

In MODE 3, with RCS pressure ≤ 1000 psig, and in MODES 4, 5, and 6, the accumulator motor operated isolation valves are normally closed to isolate the accumulators from the RCS. This allows RCS cooldown and depressurization without discharging the accumulators into the RCS or requiring depressurization of the accumulators.

ACTIONS

A.1

If the boron concentration of one accumulator is not within limits, it must be returned to within the limits within 72 hours. In this Condition, the ability to maintain subcriticality or minimum boron precipitation time may be reduced. The boron in the accumulators contributes to the assumption that the combined ECCS water in the partially recovered core during the early reflooding phase of a large break LOCA is sufficient to keep that portion of the core subcritical. One accumulator below the minimum boron concentration limit, however, will have no effect on available ECCS water and an insignificant effect on core subcriticality during reflood. Boiling of ECCS water in the core during reflood concentrates boron in the saturated liquid that remains in

BASES

the core. In addition, current analysis techniques demonstrate that the accumulators will do not discharge following a large main steam line break for the majority of plants. Even if they do discharge, their impact of their discharge is minor and not a design limiting event. Thus, 72 hours is allowed to return the boron concentration to within limits.

B.1

If one accumulator is inoperable for a reason other than boron concentration, the accumulator must be returned to OPERABLE status within 1 hour. In this Condition, the required contents of three accumulators cannot be assumed to reach the core during a LOCA. Due to the severity of the consequences should a LOCA occur in these conditions, the 1 hour Completion Time to open the valve, remove power to the valve, or restore the proper water volume or nitrogen cover pressure ensures that prompt action will be taken to return the inoperable accumulator to OPERABLE status. The Completion Time minimizes the potential for exposure of the plant to a LOCA under these conditions.

C.1 and C.2

If the accumulator cannot be returned to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and pressurizer RCS pressure reduced to ≤ 1000 psig within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

D.1

If more than one accumulator is inoperable, the plant is in a condition outside the accident analyses; therefore, LCO 3.0.3 must be entered immediately.

SURVEILLANCE
REQUIREMENTSSR 3.5.1.1

Each accumulator motor operated isolation valve (8808A, B, C, and D) should be verified to be fully open every 12 hours. This verification ensures that the accumulators are available for injection and ensures timely discovery if a valve should be less than fully open. If an isolation valve is not fully open, the rate of injection to the RCS would be reduced. Although a motor operated valve position should not change with power removed, a closed valve could result in not meeting accident

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

analyses assumptions. This Frequency is considered reasonable in view of other administrative controls that ensure a mispositioned isolation valve is unlikely.

SR 3.5.1.2 and SR 3.5.1.3

Every 12 hours, borated water volume and nitrogen cover pressure are verified for each accumulator. This Frequency is sufficient to ensure adequate injection during a LOCA. Because of the static design of the accumulator, a 12 hour Frequency usually allows the operator to identify changes before limits are reached. Operating experience has shown this Frequency to be appropriate for early detection and correction of off normal trends.

SR 3.5.1.4

The boron concentration should be verified to be within required limits for each accumulator every 31 days since the static design of the accumulators limits the ways in which the concentration can be changed. The 31 day Frequency is adequate to identify changes that could occur from mechanisms such as stratification or in-leakage. Sampling the affected accumulator within 6 hours after a solution volume increase of 5.6-1% (101 gallon) narrow range indicated level will identify whether in-leakage has caused a reduction in boron concentration to below the required limit. It is not necessary to verify boron concentration if the added water inventory is from the refueling water storage tank (RWST), and the RWST has not been diluted since verifying that its boron concentration satisfies SR 3.5.4.3, because the water contained in the RWST is within the accumulator boron concentration requirements as verified by SR 3.5.4.3. This is consistent with the recommendation of GL 93-05 (Ref. 5).

SR 3.5.1.5

Verification every 31 days that power is removed from each accumulator isolation valve operator (8808A, B, C, and D) when the pressurizer RCS pressure is ≥ 2000 greater than 1000 psig ensures that an active failure could not result in the undetected closure of an accumulator motor operated isolation valve. If this were to occur, only two accumulators would be available for injection given a single failure coincident with a LOCA. Since power is removed under administrative control, the 31 day Frequency will provide adequate assurance that power is removed.

This SR allows power to be supplied to the motor operated isolation valves when pressurizer RCS pressure is < 2000

BASES

~~less than or equal to 1000 psig, thus allowing operational flexibility by avoiding unnecessary delays to manipulate the breakers during plant startups or shutdowns. The valves to be closed to enable plant shutdown without discharging the accumulators into the RCS. Even with power supplied to the valves, inadvertent closure is~~

SURVEILLANCE
REQUIREMENTS (continued)

prevented by the RCS pressure interlock (P-11) associated with the valves.

Should closure of a valve occur in spite of the interlock, the SI signal provided to the valves would open a closed valve in the event of a LOCA.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.2 ECCS - Operating

BASES

BACKGROUND

The function of the ECCS is to provide core cooling and negative reactivity to ensure that the reactor core is protected after any of the following accidents:

- a. Loss of coolant accident (LOCA), non-isolable coolant leakage greater than the capability of the normal charging system;
- b. Rod ejection accident;
- c. Loss of secondary coolant accident, including uncontrolled steam release or loss of feedwater; and
- d. Steam generator tube rupture (SGTR).

The addition of negative reactivity is designed primarily for the loss of secondary coolant accident where primary cooldown could add enough positive reactivity to achieve criticality and return to significant power.

The ECCS consists of three separate subsystems: centrifugal charging (high head), safety injection (SI) (intermediate head) and residual heat removal (RHR) (low head). Each subsystem consists of two redundant, 100% capacity trains. The ECCS accumulators and the Refueling Water Storage Tank (RWST) are also part of the ECCS, but are not considered part of an ECCS flow path as described by this LCO.

The ECCS components are divided into two trains, A and B. The following are the train assignments for the ECCS pumps:

Train A:	RHR Pump 2	Train B:	RHR Pump 1
	SI Pump 1		SI Pump 2
	Centrifugal Charging Pump (CCP) 1		Centrifugal Charging Pump (CCP) 2

The ECCS flow paths consist of piping, valves, heat exchangers, and pumps such that water from the RWST can be injected into the RCS following the accidents described in this LCO. The major components of each subsystem are the centrifugal charging pumps, CCPs, the RHR pumps, heat exchangers, and the SI pumps. Each of the three subsystems consists of two 100% capacity trains that are interconnected and redundant such that either train is capable of supplying 100% of the flow required to mitigate the accident consequences. This interconnecting and redundant subsystem design provides the operators with the

BASES

BACKGROUND
(continued)

ability to utilize components from opposite trains to achieve the required 100% flow to the core.

There are three phases of ECCS operation following a LOCA: injection, cold leg recirculation, and hot leg recirculation. In the injection phase, water is taken from the RWST and injected into the Reactor Coolant System (RCS) through the cold legs. When sufficient water is removed from the RWST to ensure that enough boron has been added to maintain the reactor subcritical and the containment recirculation sump has enough water to supply the required net positive suction head to the ECCS RHR pumps, suction is switched to the containment recirculation sump for cold leg recirculation. After several hours, the ECCS flow operation is shifted to the hot leg recirculation phase to provide a backflush, which would reduce the boiling in the top of the core and any resulting boron precipitation, reverse flow through the core to backflush out the high boron concentration that could result from core boiling after a cold leg break.

During the injection phase of LOCA recovery, a suction header supplies water from the RWST to the ECCS pumps. The RWST header supplies separate piping supplies for each subsystem, and each train within the subsystem. The discharge from the CCPS centrifugal charging pumps combines in a common header and then divides again into four supply lines, each of which feeds the injection line to one RCS cold leg. The discharge from the SI and RHR pumps divides and feeds an injection line to each of the RCS cold legs. Control Throttle/runout valves are set to balance the flow to the RCS. The throttle/runout valves also protect the SI and CCPS from exceeding their runout flow limits. This balance ensures sufficient flow to the core to meet the analysis assumptions following a LOCA in one of the RCS cold legs.

For LOCAs that are too small to depressurize the RCS below the shutoff head of the SI pumps, the CCPS centrifugal charging pumps supply water until the RCS pressure decreases below the SI pump shutoff head. During this period, the steam generators are used to provide part of the core cooling function.

During the recirculation phase of LOCA recovery, RHR pump suction is transferred to the containment recirculation sump. The RHR pumps then supply the other ECCS pumps. Initially, recirculation discharge is through the same paths as the injection phase to the cold legs. Subsequently, recirculation alternates provides injection between both the hot and cold legs.

The centrifugal charging subsystem of the ECCS also functions to supply borated water to the reactor core following increased heat removal events, such as a main steam line break (MSLB). The limiting design conditions

BASES

BACKGROUND
(continued)

occur when the negative moderator temperature coefficient is highly negative, such as at the end of each cycle.

(continued)

During low temperature conditions in the RCS, limitations are placed on the maximum number of ECCS pumps that may be OPERABLE. Refer to the Bases for LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," for the basis of these requirements.

The ECCS subsystems are actuated upon receipt of an SI signal. The actuation of safeguard loads is accomplished in a programmed time sequence. If offsite power is available, the safeguard loads start after a one second sequencer delay in the programmed time sequence. If offsite power is not available, the Engineered Safety Feature (ESF) buses shed normal operating loads and are connected to the emergency diesel generators (EDGs). Safeguard loads are then actuated in the programmed time sequence. The time delay associated with diesel starting, sequenced loading, and pump starting determines the time required before pumped flow is available to the core following a LOCA.

Each ECCS pump is provided with normally open miniflow lines for pump protection. The RHR miniflow isolation valves close on flow to the RCS and have a time delay to prevent them from closing until the RHR pumps are up to speed and capable of delivering fluid to the RCS. The SI pump miniflow isolation valves are closed manually from the control room prior to transfer from injection to recirculation. The CCP miniflow isolation valves are also closed manually from the control room prior to transfer from injection to recirculation.

The active ECCS components, along with the passive accumulators and the RWST covered in LCO 3.5.1, "Accumulators," and LCO 3.5.4, "Refueling Water Storage Tank (RWST)," provide the cooling water necessary to meet GDC 35 (Ref. 1).

APPLICABLE
SAFETY ANALYSIS

The LCO helps to ensure that the following acceptance criteria for the ECCS, established by 10 CFR 50.46 (Ref. 2), will be met following a LOCA:

- a. Maximum fuel element cladding temperature is $\leq 2200^{\circ}\text{F}$;
- b. Maximum cladding oxidation is ≤ 0.17 times the total cladding thickness before oxidation;
- c. Maximum hydrogen generation from a zirconium water reaction is ≤ 0.01 times the hypothetical amount generated if all of the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react;
- d. Core is maintained in a coolable geometry; and

BASES

APPLICABLE SAFETY
SAFETY ANALYSES
(continued)

- e. Adequate long term core cooling capability is maintained.

The LCO also limits the potential for a post-trip return to power following an MSLB event and ensures that containment temperature limits are met.

Each ECCS subsystem is taken credit for in a large break LOCA event at full power (Refs. 3 and 4). This event establishes the requirement to limit runoff flow for the ECCS pumps, as well as the maximum response time for their actuation. The centrifugal charging pumps and SI pumps are credited in the injection phase for mitigation of a small break LOCA event. This event establishes the flow and discharge head for the design point of the CCPs centrifugal charging pumps. The SGTR and MSLB events also credit the CCPs centrifugal charging pumps. The OPERABILITY requirements for the ECCS are based on the following LOCA analysis assumptions:

- a. A large break LOCA event, with loss of offsite power and a single failure disabling one RHR pump (all EDG trains are assumed to operate due to requirements for modeling full active containment heat removal system operation); and
- b. A small break LOCA event, with a loss of offsite power and a single failure disabling one ECCS train.

During the blowdown stage of a LOCA, the RCS depressurizes as primary coolant is ejected through the break into the containment. The nuclear reaction is terminated either by moderator voiding during large breaks or control rod insertion for small breaks. Following depressurization, emergency cooling water is injected into the cold legs, flows into the downcomer, fills the lower plenum, and refloods the core.

The effects on containment mass and energy releases are accounted for in appropriate analyses (Refs. 3 and 4). The LCO ensures that an ECCS train will deliver sufficient water to match boiloff rates soon enough to minimize the consequences of the core being uncovered following a large break LOCA. It also ensures that the centrifugal charging and SI pumps will deliver sufficient water and boron during a small break LOCA to maintain core subcriticality. For smaller break LOCAs, the centrifugal charging pump delivers sufficient fluid to maintain RCS inventory. For a small break LOCA, the steam generators continue to serve as the heat sink, providing part of the required core cooling.

The ECCS trains satisfy Criterion 3 of the NRC Policy Statement. 10 CFR 50.36(c)(2)(iii)

BASES

LCO

In MODES 1, 2, and 3, two independent (and redundant) ECCS trains are required to ensure that sufficient ECCS flow is available, assuming a single failure affecting either train. Additionally, individual components within the ECCS trains may be called upon to mitigate the consequences of other transients and accidents.

In MODES 1, 2, and 3, an ECCS train consists of a centrifugal charging subsystem, an SI subsystem, and an RHR subsystem.

Each train includes the piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWST upon an SI signal, and initiating semi-automatic switchover of suction having its. During an event requiring ECCS actuation, a flow path is required to provide an abundant supply of water from the RWST to the RCS via the ECCS pumps and their respective supply headers to each of the four cold legs. The ECCS suction is manually transferred to the containment recirculation sump to place the system in the recirculation mode of operation to supply its flow to the RCS hot and cold legs. During the recirculation operation, the RHR pumps provide suction to the charging and SI pumps.

~~During an event requiring ECCS actuation, a flow path is required to provide an abundant supply of water from the RWST to the RCS via the ECCS pumps and their respective supply headers to each of the four cold leg injection nozzles. In the long term, this flow path may be switched to take its supply from the containment recirculation sump and to supply its flow to the RCS hot and cold legs.~~

During recirculation operation, the flow path for each train must maintain its designed independence to ensure that no single failure can disable both ECCS trains.

~~As indicated in Note 1, the SI flow paths may be isolated for 2 hours in MODE 3, under controlled conditions, to perform pressure isolation valve testing per SR 3.4.14.1. The flow path is readily restorable from the control room and a single active failure (Ref. 7) is not assumed coincident with this testing. Therefore the ECCS trains are considered OPERABLE during this isolation.~~

APPLICABILITY

In MODES 1, 2, and 3, the ECCS OPERABILITY requirements for the limiting Design Basis Accident, a large break LOCA, are based on full power operation. Although reduced power would not require the same level of performance, the accident analysis does not provide for reduced cooling requirements in the lower MODES. The centrifugal charging pump performance is based on a small break LOCA, which establishes the pump performance curve and has less dependence on power. The SI pump performance requirements are based on a small break LOCA. MODE 2 and MODE 3 requirements are bounded by the MODE 1 analysis.

BASES

APPLICABILITY
(continued)

This LCO is only applicable in MODE 3 and above. Below MODE 3, the SI signal setpoint is manually bypassed by operator control, and system functional requirements are relaxed as described in LCO 3.5.3, "ECCS - Shutdown."

~~As indicated in Note 1, the flow path may be isolated for 2 hours in MODE 3, under controlled conditions, to perform pressure isolation valve testing per SR 3.4.14.1. The flow path is readily restorable from the control room. As indicated in Note 2, operation in MODE 3 with ECCS trains declared inoperable pursuant to LCO 3.4.12, "Low Temperature Overpressure Protection (LTOP) System," is necessary for plants with an LTOP arming temperature at or near the MODE 3 boundary temperature of 350°F. LCO 3.4.12 requires that certain pumps be rendered inoperable at and below the LTOP arming temperature. When this temperature is at or near the MODE 3 boundary temperature, time is needed to restore the inoperable pumps to OPERABLE status.~~

In MODES 5 and 6, plant conditions are such that the probability of an event requiring ECCS injection is extremely low. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation - High Water Level," and LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation - Low Water Level."

ACTIONS

A.1

With one or more trains inoperable and at least 100% of the ECCS flow equivalent to a single OPERABLE ECCS train available (capable of injection into the RCS if actuated) the inoperable components must be returned to OPERABLE status within 72 hours. The 72 hour Completion Time is based on an NRC reliability evaluation (Ref. 5) and is a reasonable time for repair of many ECCS components.

An ECCS train is inoperable if it is not capable of delivering design flow to the RCS. Individual components are inoperable if they are not capable of performing their design safety function or supporting systems are not available.

The LCO requires the OPERABILITY of a number of independent subsystems. Due to the redundancy of trains and the diversity of subsystems, the inoperability of one component in a train does not render the ECCS incapable of performing its function. Neither does the inoperability of two different components, each in a different train, necessarily result in a loss of function for the ECCS. The intent of this Condition is to maintain a combination of equipment such that 100% of the ECCS flow equivalent to

BASES

a single OPERABLE ECCS train remains available. (i.e. minimum of one OPERABLE CCP, SI, and RHR pump and applicable flow paths capable of drawing from the RWST and injecting into the RCS cold legs). This allows increased flexibility in plant operations under circumstances when components in opposite trains are inoperable.

The intent of this Condition to maintain a combination of equipment such that 100% of the ECCS flow equivalent to a single OPERABLE ECCS train remains available applies to both the injection mode and the recirculation mode.

ACTIONS
(continued)

An event accompanied by a loss of offsite power and the failure of an EDG can disable one ECCS train until power is restored. A reliability analysis (Ref. 5) has shown that the impact of having one full ECCS train inoperable is sufficiently small to justify continued operation for 72 hours.

Reference 6 describes situations in which one component, such as an RHR crossover cross tie valve can disable both ECCS trains. With one or more component(s) inoperable such that 100% of the flow equivalent to a single OPERABLE ECCS train is not available, the facility is in a condition outside the accident analysis. Therefore, LCO 3.0.3 must be immediately entered.

Opening the containment recirculation sump access hatch in MODES 1 through 4 is considered to be a condition which is outside the accident analysis. Therefore, LCO 3.0.3 must be immediately entered. (Ref. 9)

B.1 and B.2

If the inoperable trains cannot be returned to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to MODE 3 within 6 hours and MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTSSR 3.5.2.1

Verification of proper valve position ensures that the flow path from the ECCS pumps to the RCS is maintained. Valve position is the concern and not indicated position in the control room. Misalignment of these valves could render both ECCS trains inoperable. Securing these valves in position by removal of power by a control board switch in the correct position ensures that they cannot change position as a result of an active failure or be

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

inadvertently misaligned. The surveillance can be satisfied using indicated position in the control room but may also be satisfied using local observation. These valves are of the type, described in References 6 and 7, that can disable the function of both ECCS trains and invalidate the accident analyses. A 12 hour Frequency is considered reasonable in view of other administrative controls that will ensure a mispositioned valve is unlikely. As noted in LCO Note 1, both SI pump flow paths may each be isolated for two hours in MODE 3 by closure of one or more of these valves to perform pressure isolation valve testing.

In addition to the valves listed in SR 3.5.2.1, there are other ECCS related valves that must be appropriately positioned. Improper valve position can affect the ECCS performance required to meet the analysis assumptions. These valves are identified in plant documents and are listed in the following table.

ECCS Valve Position Table

Valve Number	Valve Function	Required Valve Position	MODES
8105	CCP 1 and 2 Recirc Line Isolation	Open	1, 2, 3
8106	CCP 1 and 2 Recirc Line Isolation	Open	1, 2, 3
8716A	RHR Cross-tie Line	Open	1, 2, 3
8716B	RHR Cross-tie Line	Open	1, 2, 3
9003A	RHR to Containment Spray	Closed	1, 2, 3
9003B	RHR to Containment Spray	Closed	1, 2, 3
8804A	RHR to CCP	Closed	1, 2, 3
8804B	RHR to SI Pump	Closed	1, 2, 3
8741	RHR to RWST - Manual Valve	Closed	1, 2, 3
SI-1	RWST to ECCS - Manual Valve	Open	1, 2, 3, 4
8923A*	Train "A" SI Pump Suction Valve	Open	1, 2, 3

* Valve can be closed, but not when RHR Train "A" (containing RHR pump 2) is out of service. Closing this valve with RHR Train "A" out of service would result in both trains of ECCS being inoperable due to the ECCS piping configuration.

SR 3.5.2.2

Verifying the correct alignment for manual, power operated, and automatic valves in the ECCS flow paths provides assurance that the proper flow paths will exist

SURVEILLANCE

BASES

REQUIREMENTS
(continued)

for ECCS operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these were verified to be in the correct position prior to locking, sealing, or securing. A valve that receives an actuation signal is allowed to be in a non-accident position provided the valve will automatically reposition within the proper stroke time. This Surveillance does not require any testing or valve manipulation. Rather, it involves verification that those valves capable of being mispositioned are in the correct position. The 31 day Frequency is appropriate because the valves are operated under administrative control, and an improper valve position would only affect a single train. This Frequency has been shown to be acceptable through operating experience.

SR 3.5.2.3

With the exception of the operating ~~CCP centrifugal charging pump~~, the ECCS pumps are normally in a standby, nonoperating mode. As such, flow path piping has the potential to develop voids and pockets of entrained gases. Maintaining the piping from the ECCS pumps to the RCS full of water ensures that the system will perform properly, injecting its full capacity into the RCS upon demand. This will also prevent water hammer, pump cavitation, and pumping of non-condensable gas (e.g., air, nitrogen, or hydrogen) into the reactor vessel following an SI signal or during shutdown cooling. The 31 day Frequency takes into consideration the gradual nature of gas accumulation in the ECCS piping and the procedural controls governing system operation.

~~The intent of the SR is to assure the ECCS piping is full of water. Different means of verification, as alternates to venting the accessible system high points, can be employed to provide this assurance.~~

~~Venting of the accessible ECCS high points prior to entering MODE 3 ensures the system is full of water and will perform properly, injecting its full capacity into the RCS on demand.~~

~~The CCP design and attached piping configuration allow the CCP to vent the accumulated gases via the attached suction and discharge piping. Continuous venting of the suction piping to the Volume Control tank (VCT) and manual venting of the discharge piping high points satisfies the pump casing venting requirements for the CCPs.~~

SR 3.5.2.4

Periodic surveillance testing of ECCS pumps to detect gross degradation caused by impeller structural damage or other hydraulic component problems is required by

SURVEILLANCE

BASES

REQUIREMENTS
(continued)

~~Section XI of the ASME Code. (Ref. B) This type of testing may be accomplished by measuring the pump developed head at only one point of the pump characteristic curve. This verifies both that the measured performance is within an acceptable tolerance of the original pump baseline performance and that the performance at the test flow is greater than or equal to within the performance assumed in the plant safety analysis. SRS are specified in Technical Requirements Manual and in the applicable portions of the Inservice Testing Program, which encompasses Section XI Part 6 of the ASME Code for Operation and Maintenance of Nuclear Power Plants. (Ref. 8). Section XI this section of the ASME Code provides the activities and frequencies necessary to satisfy the requirements.~~

SR 3.5.2.5 and SR 3.5.2.6

These Surveillances demonstrate that each automatic ECCS valve actuates to the required position on an actual or simulated SI signal and that each ECCS pump starts on receipt of an actual or simulated SI signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The 18 month Frequency is based on the need to perform these Surveillances under the conditions that apply during a plant outage and the potential for unplanned plant transients if the Surveillances were performed with the reactor at power. The 18 month Frequency is also acceptable based on consideration of the design reliability (and confirming operating experience) of the equipment. The actuation logic is tested as part of ESF Actuation System testing, and equipment performance is monitored as part of the Inservice Testing Program.

SR 3.5.2.7

~~The correct Realignment position of throttle/runout valves in the ECCS flow paths on an SI signal is necessary for proper ECCS performance. These manual throttle/runout valves are positioned during flow balancing and have mechanical locks and seals -steps to allow ensure that the proper positioning for restricted flow to a ruptured cold leg -ensuring is maintained. The verification of proper position of a throttle/runout valve can be accomplished by confirming the seals and lock have not been altered since the last performance of the flow balance test. Restricting the flow to a ruptured cold leg ensures and that the other cold legs receive at least the required minimum flow. This Surveillance is not required for-~~

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

~~plants with flow limiting orifices.~~ The 18 month Frequency is based on the same reasons as those stated in SR 3.5.2.5 and SR 3.5.2.6.

SR 3.5.2.8

Periodic inspections of the containment recirculation sump suction inlet ensure that it is unrestricted and stays in proper operating condition. The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage, on the need to have access to the location, and because of the potential for an unplanned transient if the Surveillance were performed with the reactor at power. This Frequency has been found to be sufficient to detect abnormal degradation and is confirmed by operating experience.

Opening the containment recirculation sump access hatch in MODES 1 through 4 is considered to be a condition which is outside the accident analysis. Therefore, LCO 3.0.3 must be immediately entered. (Ref. 9)

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.3 ECCS - Shutdown

BASES

BACKGROUND

The Background section for Bases 3.5.2, "ECCS - Operating," is applicable to these Bases, with the following modifications.

In MODE 4, the required ECCS train consists of two separate subsystems: centrifugal charging (high head) and residual heat removal (RHR) (low head).

The ECCS flow paths consist of piping, valves, heat exchangers, and pumps such that water from the refueling water storage tank (RWST) can be injected into the Reactor Coolant System (RCS) following the accidents described in Bases 3.5.2, and subsequently transferring RHR pump suction to the containment recirculation sump.

APPLICABLE
SAFETY ANALYSES

The Applicable Safety Analyses section of Bases 3.5.2 also applies to this Bases section.

Due to the stable core reactivity and the lower heat removal conditions associated with operation in MODE 4 and the reduced probability of occurrence of a Design Basis Accident (DBA), the ECCS operational requirements are reduced. It is understood in these reductions that certain automatic safety injection (SI) actuations are not available. In this MODE, sufficient time exists for manual actuation of the required ECCS to mitigate the consequences of a DBA. (Ref 1)

Only one train of ECCS is required for MODE 4. This requirement dictates that single failures are not considered during this MODE of operation.

The ECCS trains satisfy Criterion 3 of the NRC Policy Statement. 10 CFR 50.36(c)(2)(ii)

LCO

In MODE 4, one of the two independent (and redundant) ECCS trains (as defined for MODE 4) is required to be OPERABLE to ensure that sufficient ECCS flow is available to the core following a DBA.

The LCO is modified by a Note that allows a RHR train to be considered OPERABLE during alignment and operation for decay heat removal, if capable of being manually realigned.

BASES

LCO (continued)

(remote or local) to the ECCS mode of operation and not otherwise inoperable. This allows operation in the RHR mode during MODE 4.

In MODE 4, an ECCS train consists of a centrifugal charging subsystem and an RHR subsystem. Each train includes the piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWST and transferring suction to the containment recirculation sump.

During an event requiring ECCS actuation, a flow path is required to provide an abundant supply of water from the RWST to the RCS via the ECCS charging and RHR pumps and their respective supply headers to each of the four cold legs. injection nozzles. In the long term, this flow path may be switched to take its supply from the containment recirculation sump and to deliver its flow to the RCS hot and cold legs.

This LCO is modified by a Note that allows an RHR train to be considered OPERABLE during system alignment and operation for decay heat removal, if capable of being manually realigned (remote or local) to the ECCS mode of operation and not otherwise inoperable. This allows operation in the RHR mode during MODE 4.

APPLICABILITY

In MODES 1, 2, and 3, the OPERABILITY requirements for ECCS are covered by LCO 3.5.2.

In MODE 4 with RCS temperature below 350°F, one OPERABLE ECCS high head and low head train is acceptable without single failure consideration, on the basis of the stable reactivity of the reactor and the limited core cooling requirements.

In MODES 5 and 6, plant conditions are such that the probability of an event requiring ECCS injection is extremely low. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation - High Water Level," and LCO 3.9.6, "Residual Heat Removal (RHR) and Coolant Circulation - Low Water Level."

ACTIONS

A.1

ACTIONS (continued)

With no ECCS RHR subsystem OPERABLE, the plant is not prepared to respond to a loss of coolant accident or to continue a cooldown using the RHR pumps and heat

BASES

exchangers. The Completion Time of "immediately" to initiate actions that would restore at least one ECCS RHR subsystem to OPERABLE status ensures that prompt action is taken to restore the required cooling capacity. Normally, in MODE 4, reactor decay heat is removed from the RCS by an RHR loop. If no RHR loop is OPERABLE for this function, reactor decay heat must be removed by some alternate method, such as use of the steam generators. The alternate means of heat removal must continue until the inoperable RHR loop components can be restored to operation so that decay heat removal is continuous.

With both RHR pumps and heat exchangers inoperable, it would be unwise to require the plant to go to MODE 5, where the only available heat removal system is the RHR. Therefore, the appropriate action is to initiate measures to restore one ECCS RHR subsystem and to continue the actions until the subsystem is restored to OPERABLE status.

Opening the containment recirculation sump access hatch in MODES 1 through 4 is considered to be a condition which is outside the accident analysis. Therefore, LCO 3.0.3 must be immediately entered. (Ref. 9)

B.1

With no ECCS centrifugal charging high-head subsystem OPERABLE, due to the inoperability of the centrifugal charging pump or flow path from the RWST, the plant is not prepared to provide high pressure response to Design Basis Events requiring SI. The 1 hour Completion Time to restore at least one ECCS centrifugal charging high-head subsystem to OPERABLE status ensures that prompt action is taken to provide the required cooling capacity or to initiate actions to place the plant in MODE 5, where an ECCS train is not required.

C.1

When the Required Actions of Condition B cannot be completed within the required Completion Time, a controlled shutdown should be initiated. Twenty-four hours is a reasonable time, based on operating experience, to reach MODE 5 in an orderly manner and without challenging plant systems or operators.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.4 Refueling Water Storage Tank (RWST)

BASES

BACKGROUND

~~The RWST supplies borated water to the Chemical and Volume Control System (CVCS) during abnormal operating conditions, to the refueling pool during refueling, and to the ECCS and the Containment Spray System during accident conditions.~~

~~The RWST supplies both trains of the ECCS and the Containment Spray System through separate, redundant supply headers during the injection phase of a loss of coolant accident (LOCA) recovery. A motor operated isolation valve is provided in each header to isolate the RWST from the ECCS once the system has been transferred to the recirculation mode. The recirculation mode is entered when pump suction is transferred to the containment recirculation sump following receipt of the RWST Low Low (Level 1) signal. Use of a single RWST to supply both trains of the ECCS and Containment Spray System is acceptable since the RWST is a passive component, and passive failures are not required to be assumed to occur coincidentally with Design Basis Events.~~

~~The switchover from normal operation to the injection phase of ECCS operation requires changing centrifugal charging pump suction from the CVCS volume control tank (VCT) to the RWST through the use of isolation valves. Each set of isolation valves is interlocked so that the VCT isolation valves will begin to close once the RWST isolation valves are fully open. Since the VCT is under pressure, the preferred pump suction will be from the VCT until the tank is isolated. This will result in a delay in obtaining the RWST borated water. The effects of this delay are discussed in the Applicable Safety Analyses section of these Bases.~~

~~During normal operation in MODES 1, 2, and 3, the safety injection (SI) and residual heat removal (RHR) pumps are aligned to take suction from the RWST.~~

~~The ECCS and Containment Spray System pumps are provided with recirculation lines that ensure each pump can maintain minimum flow requirements when operating at or near shutoff head conditions.~~

~~When the suction for the ECCS and Containment Spray System pumps is transferred to the containment recirculation sump, the RWST flow paths must be isolated to prevent a release of the containment recirculation sump contents to the RWST, which could result in a release of contaminants to the atmosphere and the eventual loss of suction head for the~~

BASES

~~ECCS pumps.~~

~~This LCO ensures that:~~

- ~~a. The RWST contains sufficient borated water to support the ECCS during the injection phase;-~~
- ~~b. Sufficient water volume exists in the containment recirculation sump to support continued operation of the ECCS and Containment Spray System pumps at the time of transfer to the recirculation mode of cooling; and~~
- ~~c. The reactor remains subcritical following a LOCA.~~

~~Insufficient water in the RWST could result in insufficient cooling capacity when the transfer to the recirculation mode occurs. Improper boron concentrations could result in a reduction of SDM or excessive boric acid precipitation in the core following the LOCA, as well as excessive caustic stress corrosion of mechanical components and systems inside the containment.~~

~~The RWST supplies borated water to the Chemical and Volume Control System (CVCS) during abnormal operating conditions (boration flow path); to the refueling cavity during refueling, and to the ECCS and the Containment Spray (CS) System during accident conditions.~~

~~The RWST supplies both trains of the ECCS through one header and both trains of the CS System through a separate supply header during the injection phase of a loss of coolant accident (LOCA) recovery. Motor-operated isolation valves in each sub-system header isolate the RWST from the ECCS and from the CS System once the RWST is no longer supplying flow to these systems.~~

~~Use of a single RWST to supply both trains of the ECCS and CS Systems is acceptable since the RWST is a passive component, and a passive failure is not assumed to occur coincidentally with a Design Basis Accident (DBA).~~

~~During normal plant operation in MODES 1, 2, and 3, the Safety Injection (SI) and Residual Heat Removal (RHR) pumps are aligned to take suction from the RWST. The Centrifugal Charging Pumps (CCPs) operate during normal plant operation with their suction aligned to the Volume~~

BASES

BACKGROUND (continued)

Control Tank (VCT). The switchover from normal operation to the injection phase of ECCS operation requires auto-transfer of the CCP suction from the CVCS VCT to the RWST. The CS pumps suction is aligned to the RWST with closed motor operated discharge valves which open on a CS signal. When the suction for the RHR pumps is transferred to the containment recirculation sump, the RWST must be isolated from ECCS and CS system. The isolation prevents flow of containment recirculation sump water into the RWST. Flow of containment water into the RWST could result in a release of contaminants to the atmosphere and the eventual loss of suction head for the RHR pumps due to loss of containment recirculation sump inventory.

The reactivity control systems are available to the operators to ensure that negative reactivity is available during each mode of plant operation. This system is not an automatic accident mitigation system, but is used under operator control if needed to increase the Reactor Coolant System (RCS) boration concentration. The sources of borated water are the boric acid storage tanks in the CVCS and the RWST. The RWST source of borated water is available as an alternate source to the boric acid storage tanks. RWST water can be used in the event of abnormal conditions, including single active failure events that may impair the function of the boric acid storage tank source of borated water of the CVCS. The boration subsystem provides the means to meet one of the functional requirements of the CVCS, i.e., to control the neutron absorber (boron) concentration in the RCS and to help maintain the SHUTDOWN MARGIN (SDM).

The LCO ensures that:

- a. The RWST contains a sufficient volume at an acceptable boron concentration and temperature to support the ECCS and CS systems during the injection phase;
- b. Sufficient water volume exists in the containment recirculation sump to support continued operation of the ECCS System pumps at the time of transfer to the recirculation mode of cooling;
- c. The reactor remains subcritical following a LOCA

APPLICABLE
SAFETY ANALYSES

During accident conditions, the RWST provides a source of borated water to the ECCS and CS Containment Spray System pumps. As such, it provides containment cooling and depressurization, core cooling, and replacement inventory and is a source of negative reactivity for reactor shutdown (Ref. 1). The design basis transients and

BASES

APPLICABLE SAFETY
ANALYSES (continued)

applicable safety analyses concerning each of these systems are discussed in the Applicable Safety Analyses section of B 3.5.2, "ECCS - Operating"; B 3.5.3, "ECCS - Shutdown"; and B 3.6.6, "Containment Spray and Cooling Systems." These analyses are used to assess changes to the RWST in order to evaluate their effects in relation to the acceptance limits in the analyses.

~~The RWST must also meet volume, boron concentration, and temperature requirements for non-LOCA events. The volume is not an explicit assumption in non-LOCA events since the required volume is a small fraction of the available volume.~~

~~The deliverable volume limit is set by the LOCA and containment analyses. For the RWST, the deliverable volume is different from the total volume contained since, due to the design of the tank, more water can be contained than can be delivered.~~

~~The minimum boron concentration is an explicit assumption in the main steam line break (MSLB) analysis to ensure the required shutdown capability. The importance of its value is small for units with a boron injection tank (BIT) with a high boron concentration. For units with no BIT or reduced BIT boron requirements, the minimum boron concentration limit is an important assumption in ensuring the required shutdown capability. The maximum boron concentration is an explicit assumption in the inadvertent ECCS actuation analysis, although it is typically a non-limiting event and the results are very insensitive to boron concentrations. The maximum temperature ensures that the amount of cooling provided from the RWST during the heatup phase of a feedline break is consistent with safety analysis assumptions; the minimum is an assumption in both the MSLB and inadvertent ECCS actuation analyses, although the inadvertent ECCS actuation event is typically non-limiting.~~

~~The MSLB analysis has considered a delay associated with the interlock between the VCT and RWST isolation valves, and the results show that the departure from nucleate boiling design basis is met. The delay has been established as [27] seconds, with offsite power available, or [37] seconds without offsite power. This response time includes [2] seconds for electronics delay, a [15] second stroke time for the RWST valves, and a [10] second stroke time for the VCT valves. Plants with a BIT need not be concerned with the delay since the BIT will supply highly borated water prior to RWST switchover, provided the BIT is between the pumps and the core.~~

BASES

APPLICABLE SAFETY
ANALYSES (continued)

For a large break LOCA analysis, the minimum water volume limit [~~466,200~~] ~~428,237~~ ~~400,000~~ gallons (~~91%~~) (~~81.5%~~) and the lower boron concentration limit of [~~2000~~] ~~2400~~ ~~2300~~ ppm are used to compute the post LOCA sump boron concentration necessary to assure subcriticality. The large break LOCA is the limiting case since the safety analysis assumes that all control rods are out of the core.

The upper limit on boron concentration of [~~2200~~] ~~2600~~ (2500) ppm is used to determine the maximum allowable time to switch to hot leg recirculation following a LOCA. The purpose of switching from cold leg to hot leg injection is to avoid boron precipitation in the core following the accident.

In the ECCS analysis, the containment spray temperature is assumed to be equal to the RWST lower temperature limit of [~~35~~] ~~35~~°F. If the lower temperature limit is violated, the containment spray further reduces containment pressure, which decreases the rate at which steam can be vented out the break and increases peak clad temperature. The upper temperature limit of [~~100~~] ~~120~~°F is used in the small break LOCA analysis and containment OPERABILITY analysis. Exceeding this temperature will result in a higher peak clad temperature, because there is less heat transfer from the core to the injected water for the small break LOCA and higher containment pressures due to reduced containment spray cooling capacity. For the containment response following an MSLB, the lower limit on boron concentration and the upper limit on RWST water temperature are used to maximize the total energy release to containment.

Any event that results in SI initiation, including inadvertent ECCS actuation, results in delivery of RWST water to the RCS. However, the events for which the RWST parameters provide mitigation or are limiting are large break LOCA and steam line break. Feedwater line break and steam generator tube rupture (SGTR) also involve SI but the RWST parameters are less significant to the analysis results. RWST boron concentration is an explicit assumption in the inadvertent ECCS actuation analysis, although it is typically a non-limiting event and the results are very insensitive to boron concentrations. The effect of these RWST parameters on large break LOCA, main steam line break, feedwater line break, and SGTR are discussed below:

LOCAVolume

Insufficient water in the RWST could result in insufficient borated water inventory in the containment

BASES

APPLICABLE SAFETY
ANALYSES (continued)

recirculation sump when the transfer to the recirculation phase occurs. The deliverable volume limit is set by the LOCA and containment analyses. For the RWST, the deliverable volume is less than the total volume contained since, due to the design of the tank, the ECCS suction nozzle elevation is above the bottom of the tank, so more water can be contained than can be delivered. The contained water volume limit includes an allowance for water not usable because of tank discharge location or other physical characteristics.

Boration

During accident conditions, the RWST provides a source of borated water to the ECCS and CS System pumps. Improper boron concentrations could result in a reduction of SDM or excessive boric acid precipitation in the core following a LOCA, as well as excessive caustic stress corrosion of mechanical components and systems inside the containment. The minimum boron concentration limit ensures that the spray and the containment recirculation sump solutions, after mixing with the sodium hydroxide from the spray additive tank, will not exceed the maximum pH values. The maximum boron concentration limit ensures that the containment recirculation sump solution will not be less than the minimum pH requirement. The design basis transients and applicable safety analyses concerning each of these systems are discussed in the Diablo Canyon FSAR Update. These analyses are used to assess changes to the RWST in order to evaluate their effects in relation to the acceptance limits in the analyses.

For a large-break LOCA analysis, the RWST minimum contained water volume of 400,000 gallons (81.5% indicated level, uncorrected for uncertainty) and the lower boron concentration limit of 2300 ppm are used to compute the post-LOCA sump boron concentration necessary to assure subcriticality. The large-break LOCA is the limiting case since the safety analysis assumes that all control rods are out of the core.

The upper limit on boron concentration of 2500 ppm is used to determine the maximum allowable time to initiate hot leg recirculation following a LOCA. The purpose of initiating hot leg recirculation is to avoid boron precipitation in the core following the accident when the break is in the cold leg.

The use of minimum containment backpressure in the LOCA analysis results in a conservative calculation of Peak Clad Temperature (PCT). The basis for this conclusion is the effect that the containment pressure has on the core reflood rate. A lower containment pressure has the effect of reducing the density of the steam exiting the break.

BASES

APPLICABLE SAFETY
ANALYSES (continued)

which increases the differential pressure provided by the downcomer head (this phenomena is sometimes referred to as steam binding). Thus, a higher downcomer mixture level is required to maintain the same reflood rate as before. The additional time required to establish the downcomer head translates into a reduction in the reflood rate in the core. When the downcomer has completely filled, the equilibrium reflood rate for the low containment pressure case would be less than that calculated for a high containment pressure case. This reduction in reflood rate results in a reduction in heat transfer and ultimately an increase in the calculated POT. Thus, the regulations require that a low containment pressure be calculated in the large-break LOCA analysis.

In the ECCS analysis, the CS temperature is assumed to be equal to the RWST minimum temperature limit of 35°F. If the minimum temperature limit is violated, the CS containment spray further reduces containment pressure, which decreases the core reflood as explained in the preceding paragraph. For the containment response following a MSLB, the lower limit on boron concentration is used to maximize the total energy release to containment.

Steam Line and Feedwater Line BreaksVolume

RWST volume is not an explicit assumption in other than LOCA events since the required volume for those events is much less than that required by LOCA.

Boration

The minimum RWST solution boron concentration is an explicit assumption in the MSLB analysis to ensure the required shutdown capability. Since DCPD no longer uses the boron injection tank, the minimum boron concentration limit is an important assumption in ensuring the required shutdown capability. For the containment response following an MSLB, the lower limit on boron concentration is used to maximize the total energy release to containment.

Feedwater line break results in high temperature/high pressure in the RCS. There is very little RWST water injected due to the high pressure. Also, the analysis results are not affected by the negative reactivity provided by RWST water. Therefore, RWST boron concentration is not a consideration for the feedwater line break.

BASES

APPLICABLE SAFETY

ANALYSES ~~Steam Generator Tube Rupture (SGTR)~~

(continued)

Volume

The RWST volume needed in response to a SGTR is not an explicit assumption since the required volume is much less than that required by a LOCA.

Boration

Borated RWST water will be injected into the RCS for a SGTR event. The insertion of the control rods and the negative reactivity provided by the injected RWST solution provides sufficient SDM during the initial recovery operations. One of the initial operator recovery actions for this event is to equalize the RCS pressure and the faulted steam generator pressure to minimize or stop the primary-to-secondary tube rupture flow and terminate safety injection. Further RCS boration will be initiated by the operator by manual makeup to the RCS.

The RWST satisfies Criterion 3 of the NRC Policy Statement 10 CFR 50.36(c)(2)(ii).

LCO

The RWST ensures that an adequate supply of borated water is available to cool and depressurize the containment in the event of a Design Basis Accident (DBA), to cool and cover the core in the event of a LOCA, to maintain the reactor subcritical following a DBA, and to ensure adequate level in the containment recirculation sump to support ECCS and ~~Containment Spray System~~ pump operation in the recirculation mode.

To be considered OPERABLE, the RWST must meet the water volume, boron concentration, and temperature limits established in the SRs.

APPLICABILITY

In MODES 1, 2, 3, and 4, RWST OPERABILITY requirements are dictated by ECCS and ~~CS Containment Spray System~~ OPERABILITY requirements. Since both the ECCS and the ~~CS Containment Spray System~~ must be OPERABLE in MODES 1, 2, 3, and 4, the RWST must also be OPERABLE to support their operation. Core cooling requirements in MODE 5 are addressed by LCO 3.4.7, "RCS Loops - MODE 5, Loops Filled," and LCO 3.4.8, "RCS Loops - MODE 5, Loops Not Filled." MODE 6 core cooling requirements are addressed by LCO 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation - High Water Level," and LCO 3.9.6, "Residual

BASES

APPLICABILITY
(continued)

Heat Removal (RHR) and Coolant Circulation—Low Water Level."

ACTIONS

A.1

With RWST boron concentration or borated water temperature* not within limits, they must be returned to within limits within 8 hours. Under these conditions neither the ECCS nor the ~~CS~~ Containment Spray System can perform its design function. Therefore, prompt action must be taken to restore the tank to OPERABLE condition. The 8 hour limit to restore the RWST temperature or boron concentration to within limits was developed considering the time required to change either the boron concentration or temperature and the fact that the contents of the tank are still available for injection.

DGPP GTS does not have an upper limit for RWST borated water temperature. An upper limit would typically be about 100°F. The coastal weather at the DGPP site is moderated by the Pacific Ocean and historically does not exceed 100°F. A requirement for a high temperature limit would therefore not be of value.

*
§

The requirement for RWST temperature is to be greater than or equal to the minimum required temperature. The expression "within the required limits" applied to RWST temperature is satisfied when the temperature is greater than or equal to the minimum.

B.1

With the RWST inoperable for reasons other than Condition A (e.g., water volume), it must be restored to OPERABLE status within 1 hour.

In this Condition, neither the ECCS nor the ~~CS~~ Containment Spray System can perform its design function. Therefore, prompt action must be taken to restore the tank to OPERABLE status or to place the plant in a MODE in which

BASES

ACTIONS (continued)

the RWST is not required. The short time limit of 1 hour to restore the RWST to OPERABLE status is based on this condition simultaneously affecting redundant trains and that borated water volume can be restored more rapidly than boron concentration or temperature.

C.1 and C.2

If the RWST cannot be returned to OPERABLE status within the associated Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTSSR 3.5.4.1

The RWST borated water temperature should be verified every 24 hours to be within the limits above the minimum assumed in the accident analyses band. This Frequency is sufficient to identify a temperature change that would approach either the limit and has been shown to be acceptable through operating experience.

The SR is modified by a Note that eliminates the requirement to perform this Surveillance when ambient air temperatures are within the operating limits of or above the minimum temperature for the RWST. With ambient air temperature within the band, above the minimum temperature the RWST temperature should not exceed the limit.

SR 3.5.4.2

The RWST water volume should be verified every 7 days to be above the required minimum level in order to ensure that a sufficient initial supply is available for ECCS injection and CS pump operation and to support continued ECCS on recirculation. Since the RWST volume is normally stable and the contained volume required is protected by an alarm, a 7 day Frequency is appropriate and has been shown to be acceptable through operating experience.

The required RWST water volume of 95% (428,237 gallons, 91% plus 4% measurement uncertainty) is surveilled by the control board indication.

BASES

SURVEILLANCE
REQUIREMENTS (continued)

The analysis assumed 400,000 gallons (81.5% of indicated range) is used in the TS Surveillance and is shown on the control board indicators. Adjustments to the analysis parameters for instrument inaccuracies or other reasons are applied to determine the acceptance criteria used in the plant surveillance procedures. These adjustments assure the assumed analyses parameters are maintained.

SR 3.5.4.3

The boron concentration of the RWST should be verified every 7 days to be within the required limits. This SR ensures that the reactor will remain subcritical following a LOCA. Further, it assures that the resulting sump pH will be maintained in an acceptable range so that boron precipitation in the core will not occur and the effect of chloride and caustic stress corrosion on mechanical systems and components will be minimized. Since the RWST volume is normally stable, a 7 day sampling Frequency to verify boron concentration is appropriate and has been shown to be acceptable through operating experience.

B 3.5 EMERGENCY CORE COOLING SYSTEMS (ECCS)

B 3.5.5 Seal Injection Flow

BASES

BACKGROUND

This LCO is applicable because only to those units that utilize the centrifugal charging pumps CCPs are utilized for high head safety injection (SI). The function of the seal injection throttle valves during an accident is similar to the function of the ECCS throttle valves in that each restricts flow from the CCP pump header to the Reactor Coolant System (RCS).

The restriction on reactor coolant pump (RCP) seal injection flow limits the amount of ECCS flow that would be diverted from the injection path following an accident. This limit is based on safety analysis assumptions that are required because RCP seal injection flow is not isolated during SI.

APPLICABLE
SAFETY ANALYSES

All ECCS subsystems are taken credit for in the large break loss of coolant accident (LOCA) at full power (Ref. 1). The LOCA analysis establishes the minimum flow for the ECCS pumps while the inadvertent SI and the SGTR analyses establish the maximum flow for the ECCS pumps. The centrifugal charging pumps CCPs are also credited in the small break LOCA analysis. This analysis establishes the flow and discharge head at the design point for the CCPs. The steam generator tube rupture and main steam line break event analyses also credit the CCPs but are not limiting in their design requirements. Reference to these analyses is made in assessing changes to the Seal Injection System for evaluation of their effects in relation to the acceptance limits in these analyses.

The ECCS flow balance assumes RCP seal injection is limited to 40 gpm with the flow control valve fully open.

This LCO ensures that total seal injection flow of ≤ 40 gpm, with CCP discharge header RCS pressure $\geq [2480]$ 2215 psig and ≥ 2255 psig and charging flow control valve full open, will be sufficient for RCP seal integrity but limited so that the ECCS trains will be capable of delivering sufficient water to match boiloff rates soon enough to minimize uncovering of the core following a large LOCA. It also ensures that the CCPs will deliver sufficient water for a small LOCA and sufficient boron to maintain the core subcritical. For smaller LOCAs, the charging pumps alone deliver sufficient fluid to overcome the loss and maintain RCS inventory.

Seal injection flow satisfies Criterion 2 of the NRC Policy Statement 10 CFR 50.36(c)(2)(ii)

(continued)

BASES

LCO

The intent of the LCO limit on seal injection flow is to make sure that flow through the RCP seal water injection line is low enough to ensure that sufficient centrifugal charging pump injection flow is directed to the RCS via the injection points cold legs (Ref. 2 1). This is accomplished by limiting the line resistance in the RCP seal injection lines to a value consistent with the assumptions in the accident analysis.

The 40 gpm identified in the LCO is not strictly an absolute flow limit, but rather a flow limit through the RCP seal injection line that is assumed in the accident analyses initial conditions when the ECCS systems are aligned in the injection mode following a LOCA. This flow value correlates to a line resistance in the seal injection flow path that is used in the accident analyses ECCS performance. Thus, the line resistance is the parameter which is controlled to ensure that the ECCS alignment is maintained consistent with the accident analysis assumptions. Charging flow control valve, FCV-128 full open is a test condition and is not indicative of normal operation. Consequently, during normal plant operation, it is possible to have the indicated total seal injection flow greater than 40 gpm while still being within the LCO because during normal plant operation, the ECCS system is not in post accident alignment. Based on flow line resistance with the CCPs aligned for safety injection.

In order to establish the proper flow line resistance, the seal injection flow path differential pressure and flow are measured. The line resistance is then determined with the RCS pressure within normal limits and the CCP flow control valve fully open, a pressure and flow must be known. The flow line resistance is determined by assuming that the RCS pressure is at normal operating pressure and that the CCP discharge pressure is in this LCO. The CCP discharge header pressure remains essentially constant through all the applicable MODES of this LCO. A reduction in RCS pressure, with no concurrent decrease in CCP discharge header pressure, would result in more flow being diverted to discharged through the RCP seal injection line than at normal RCS operating pressure. The RCP seal injection valve settings established at the prescribed CCP discharge header RCS pressure result in a conservative valve position should RCS pressure decrease. The additional modifier of this LCO, the charging flow control valve (charging flow for four loop units and air operated seal injection for three loop units) being full open, is required since consistent with the air operated valve is designed assumed to fail open for the accident condition.

(continued)

BASES

LCO
(continued)

With the discharge RCS pressure and control valve position as specified by the LCO, a flow limit is established which assures that the seal injection line resistance is consistent with the analysis assumptions. ~~a limit is established. It is this line limit resistance that is used in the accident analyses. This limit assures that when the RCS depressurizes following a LOCA and the flow to the pump seals increases, the resulting flow to the seals will be less than the limit assumed in the accident analysis.~~

~~The limit on seal injection flow, combined with the CCP discharge header pressure limits and an open wide condition of the charging flow control valve, must be met to render the ECCS OPERABLE. If these conditions are not met, the ECCS flow will not be as assumed in the accident analyses.~~

APPLICABILITY

In MODES 1, 2, and 3, the seal injection flow limit is dictated by ECCS flow requirements, which are specified for MODES 1, 2, 3, and 4. The seal injection flow limit is not applicable for MODE 4 and lower, however, because high seal injection flow is less critical as a result of the lower initial RCS pressure and decay heat removal requirements in ~~this MODE 4~~. Therefore, RCP seal injection flow must be limited in MODES 1, 2, and 3 to ensure adequate ECCS performance.

ACTIONS

A.1 and A.2

With the seal injection flow exceeding its limit, the amount of charging flow available for ECCS injection to the RCS may be reduced. Under this Condition, action must be taken to restore the seal injection flow to below its limit. Required Action A.1 ensures that within 4 hours the remaining available ECCS charging flow (without assuming an additional failure) is $\geq 100\%$ of the assumed post-LOCA charging flow. 100% flow capability may be verified by assuring both CCPs are OPERABLE. Required Action A.2 then allows the operator has 4 72 hours from the time the flow is known to be above the limit but still allowing 100% of the assumed post-LOCA ECCS charging flow, to correctly position the manual valves and thus be in compliance with the accident analysis. The Completion Time minimizes the potential exposure of the plant to a LOCA with insufficient injection flow and provides a reasonable time to restore seal injection flow within limits. This time is conservative consistent with respect to the Completion Times for ECCS in 3.5.2 ACTION A.1 of other ECCS LCOs; it is based on operating experience and is sufficient for taking corrective actions by operations personnel.

(continued)

BASES

ACTIONS
(continued)

B.1 and B.2

When the Required Actions cannot be completed within the required Completion Time, a controlled shutdown must be initiated. The Completion Time of 6 hours for reaching MODE 3 from MODE 1 is a reasonable time for a controlled shutdown, based on operating experience and normal cooldown rates, and does not challenge plant safety systems or operators. Continuing the plant shutdown begun in Required Action B.1, an additional 6 hours is a reasonable time, based on operating experience and normal cooldown rates, to reach MODE 4, where this LCO is no longer applicable.

SURVEILLANCE
REQUIREMENTS

SR 3.5.5.1

Verification every 31 days that the manual seal injection throttle valves are adjusted to give a flow ~~within~~ below the limit ensures ~~that~~ proper manual seal injection throttle valve position, and hence, proper seal injection flow, is maintained. The Frequency of 31 days is based on engineering judgment and is consistent with other ECCS valve Surveillance Frequencies. The Frequency has proven to be acceptable through operating experience.

As noted, the Surveillance is ~~not required to be performed until completed within 4 hours~~ after the RCS pressure has stabilized within a ~~± 20 psig range of normal operating the specified pressure limits~~. The RCS pressure requirement is specified since this configuration will produce the required pressure conditions necessary to assure that the manual valves are set correctly. The exception is limited to 4 hours to ensure that the Surveillance is timely.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

ENCLOSURE 6A

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(2 Pages)

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431
NUREG-1431 Section 3.5

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE
NUMBER

JUSTIFICATION

- | | |
|-------|---|
| 3.5-1 | This change replaces reference to the "pressurizer pressure" with a reference to the "RCS pressure" in the APPLICABILITY, Required Action C.2, and SR 3.5.1.5. Required ACTION C.2 requires reducing pressurizer pressure to less than 1000 psig. However, pressurizer pressure instrumentation does not have the range to read that pressure. Consequently, RCS pressure instrumentation is used. For the purposes of this LCO, the use of RCS pressure is equivalent. This is consistent with Industry Traveler 117. |
| 3.5-2 | Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 6B). |
| 3.5-3 | This change adds the word "mechanical" with regard to throttle valve position stop, consistent with the CTS. These valves have mechanical stops that maintain the valves in position for proper ECCS performance. |
| 3.5-4 | This change increases the RCP seal injection flow Completion Time from 4 to 72 hours, with a new added verification that at least 100 percent of the assumed charging flow remains available. The Bases for seal injection flow relate the limit to ensuring adequate charging flow during post-LOCA injection. The revised ACTIONS continue to assure this basis is adequately addressed by providing an ECCS-like Required Action. ITS 3.5.2 allows a 72 hour Completion Time for 1 or more ECCS subsystems inoperable if at least 100 percent of the assumed ECCS flow is available. The seal injection flow ACTIONS have been modified so that if the remaining charging flow (with some inoperability in the charging system) is greater than or equal to 100 percent of the assumed post-LOCA charging flow, 72 hours is allowed to restore OPERABILITY. This change is consistent with industry Traveler WOG-84. |
| 3.5-5 | This change deleted reference to CCP discharge header pressure from the LCO and ACTION A to reflect CTS [3.4.6.2.]. A description is added to the Bases which provides the methodology for adjusting the seal injection throttle valves consistent with plant-specific analyses. |

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431
NUREG-1431 Section 3.5

**CHANGE
NUMBER**

JUSTIFICATION

- | | |
|-------|---|
| 3.5-6 | SR 3.5.3.1 Note (An RHR train may be considered OPERABLE during alignment and operation for decay heat removal, if capable of being realigned to the ECCS mode of operation) is moved to the LCO per industry Traveler TSTF-90, Rev. 1.

The Note is more appropriately placed in the LCO because it defines the intended capability of the ECCS equipment. |
| 3.5-7 | Not used. |
| 3.5-8 | Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B). |
| 3.5-9 | Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B). |

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-01	ACTION A.1 is revised [new ACTION A.2 is added , and Table 3.7.1-1 is revised] to account for operation with inoperable MSSVs and resetting the power range neutron flux high trip setpoints with inopreable MSSVs. The Compelction Time to reset the power range neutron flux high trip setpoints is extended to 72 hours. [The table is revised based on NSAL 94-001 and deletes the reference to five OPERABLE MSSVs.]	Yes	Yes	Yes	YES
3.7-02	The CTS Applicability of MODES 1, 2, and 3 is being retained in ITS 3.7.2, MSIVs, and ITS 3.7.3, MFIVs.	No, DCPD is adopting ITS.	No, CPSES is adopting ITS.	Yes	YES
3.7-03	SR 3.7.3.1 is divided into two surveillances since both the stroke time and the Frequency requirements are different at DCPD for the feedwater regulation/bypass valves and the feedwater isolation valve.	Yes, per LA 77/76	No	No	No
3.7-04	Requirements involving reliance on the SG heat removal system for heat removal in MODE 4 would be deleted.	No, DCPD is adopting ITS.	Yes	Yes	Yes
3.7-05	Required Action B.1 and new C.1 are revised to state that restoration of "all but one" and "all but two" [ADV] lines is required which will effectively exit the respective Required Action.	Yes	Yes	No, refer to 3.7-19.	No, refer to 3.7-19.
3.7-06	The Condition and Required Action for two or more inoperable [ADV] lines is limited to two [ADV] lines and the Completion Time is revised from 24 to 72 hours per the current licensing basis. A new Condition C is added.	Yes	Yes	No, not part of CTS.	No, not part of CTS.
3.7-07	Revised Conditions A and C to be consistent with CTS. The ITS as written would have allowed the OPERABLE EES train to remain in standby during movement of irradiated fuel.	No, not part of CTS.	No, not part of CTS.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-08	SR 3.7.5.1 is revised to add a Note consistent with the CTS and the plant specific design. The verification of flow control valve position is deferred until conditions are appropriate.	No, AFW valves have a correct position.	Yes	Yes	Yes
3.7-09	New Conditions F, G, and H and the surveillance requirement associated with the FWST AFW pump supply are relocated from the CTS on AFW supply and included in the DCPD AFW specification for completeness.	Yes	No	No	No
3.7-10	The specification description, the LCO, the ACTION requirements and the Surveillance are revised to incorporate the DCPD plant specific requirement for OPERABLE AFW supply sources via the CST and the FWST per the current licensing basis.	Yes	No	No	No
3.7-11	The Required Actions for CPSES feedwater isolation and associated bypass valves inoperable are revised consistent with the current licensing basis for a Completion Time of 4 hours and to credit the MFRVs (feedwater control valves (FCVs)) and associated bypass valves for a Completion Time of 72 hours. A new SR is added for the FCVs and associated bypass valves.	No	Yes	No	No
3.7-12	WOG-83 revised Condition A and Table 3.7-1 to account for plants that credit the Power Range High Neutron Flux trip function when MTC is positive (See 3.7-01 above). The wording of the traveler has been modified for CPSES to account for plant specific differences.	No	Yes	No	No
3.7-13	Note 1. under Action Required A.1 is deleted. The DCPD emergency diesel generators have self contained cooling systems that do not rely upon an external source of cooling water.	Yes	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-14	The Note for SR 3.7.8.1 is deleted since the DCPD ASW system supplies only the CCW heat exchanger and no other individual components.	Yes	No	No	No
3.7-15	SR 3.7.8.1 is revised to include a DCPD specific requirement to verify the availability of power and air so that the valves can be placed in their correct positions as described in the Bases.	Yes	No	No	No
3.7-16	SR 3.7.8.2 is revised to include only power operated valves since there are no automatically operated valves in the DCPD ASW system. The surveillance is revised to require movement of power operated valves to demonstrate the ability to reconfigure the ASW system as described in the FSAR and the ITS Bases.	Yes	No	No	No
3.7-17	The DCPD UHS specification is revised to reflect the fact that for the system to perform its intended function, it is temperature limited. The LCO is revised to note that the specification limits the temperature to less than or equal to 64°F. SR numbers are revised accordingly and the remaining surveillances are deleted as being not applicable.	Yes	No	No	No
3.7-18	The DCPD specific CTS surveillance for leakage testing of ABVS dampers M2A and M2B is retained.	Yes	No	No	No
3.7-19	Required Action B.1 is revised to state that restoration of "all but" one [ASD] line is required, which will effectively exit Required Action B.1 and re-enter Required Action A.1.	No, refer to change 3.7-5 and 3.7-6.	No, refer to change 3.7-5 and 3.7-6.	Yes	Yes
3.7-20	A Callaway specific Condition is added to address the inoperability of one of the Essential Service Water (ESW) supplies to the turbine-driven AFW pump.	No	No	No	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-21	The ACTIONS and SR 3.7.12.1 are revised to include the DCPD specific CTS ACTION requirement for an inoperable HEPA filter and/or charcoal absorber and to provide the appropriate charcoal absorber monthly drying time for the single common charcoal absorber.	Yes	No	No	No
3.7-22	SR 3.7.12.3 is revised for DCPD to describe the expected actions upon an actuation of the ABVS.	Yes	No	No	No
3.7-23	ACTION C and SR 3.7.12.4 are deleted since the DCPD ABVS was not designed to maintain a specific negative pressure.	Yes	No	No	No
3.7-24	SR 3.7.12.5 is deleted since there are no DCPD ABVS bypass dampers and the system automatic dampers are tested by SR 3.7.12.3.	Yes	No	No	No
3.7-25	Based on the CTS, a Note is added to [SR 3.7.3.1, 3.7.3.2, 3.7.4.1 and 3.7.4.2] to indicate that demonstration of valve OPERABILITY is only required to be performed for entry into (and continued operation in) MODES 1 and 2. This Note states that the SR is only required to be performed in MODES 1 and 2. This would allow entry into MODE 3 for the purpose of testing the valves.	No, note is not part of CTS.	No, note is not part of CTS.	Yes	Yes
3.7-26	Condition D is deleted to reflect the CPSES plant specific design of primary FIVs and associated bypass valves and isolation backup via the in series FCVs and associated bypass valves.	No	Yes	No	No
3.7-27	A Note is added to DCPD Table 3.7.1-2 under Lift Setting that specifies that the lift point of the lowest set safety is +3% and -2%.	Yes (per LA 108/107)	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-28	Revise [ADV] Frequency from 18 months to "in accordance with Inservice Test Program."	No, CTS is 18 months.	Yes	Yes	Yes
3.7-29	Revise AFW pump testing to be "In accordance with Inservice Test Program."	Yes	Yes	Yes	Yes
3.7-30	LCO 3.7.8 and ACTIONs are revised for CPSES to incorporate requirements for two units with station service water system cross connections.	No, covered by ECG per GL 91-13 response.	Yes	No, single unit plant.	No, single unit plant.
3.7-31	SR 3.7.8.2 is replaced with the current CPSES specific surveillance of the cross connections between units. The CPSES design has no automatic valves as per this SR in the ITS.	No, refer to 3.7-15 and 3.7-16.	Yes	No	No
3.7-32	CONDITION A for CPSES is changed to "SSI level less than required" and SR 3.7.9.3 and 3.7.9.4 are deleted.	No	Yes	No	No
3.7-33	The requirement to verify a make-up flow rate during the tests demonstrating the capability to maintain control room differential pressure above atmospheric pressure would be deleted.	Yes, per CTS.	No, retained CTS requirement.	Yes	Yes
3.7-34	In accordance with Traveler WOG-64, the Completion Time for closing one inoperable MSIV is extended to 72 hours; and separate Required Actions are included for either one MSIV inoperable or two or more MSIVs inoperable in MODES 2 and 3.	No, adopting 8 hour AOT from STS.	Yes	Yes	Yes
3.7-35	SR 3.7.10.3 is revised to reflect DCPD specific plant configuration and CTS required testing.	Yes	No	No	No
3.7-36	Required Actions D and E are revised for CPSES for two trains inoperable where at least 100% of the required heat removal capacity is available.	No	Yes	No	No

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-37	Modifies LCO 3.7.2 Condition A and adds new Condition B and C to be consistent with the CPSES CTS.	No	Yes	No	No
3.7-38	This proposed change deletes reference to a specific flowrate for conducting the negative pressure test per the CPSES CTS.	No, see CN 3.7-49.	Yes	No, see CN 3.7-49.	No, see CN 3.7-49.
3.7-39	SR 3.7.12.6 is added to verify the shutdown of the non-ESF fans to prevent bypass of the ESF Filtration units (CPSES specific).	No	Yes	No	No
3.7-40	Not used.	N/A	N/A	N/A	N/A
3.7-41	The Main Feedwater Regulating and associated Bypass Valves are deleted from the ITS per current licensing basis.	No, CTS includes MFRVs.	No, refer to 3.7-11.	Yes	Yes
3.7-42	Add DCPD specific note that states that 3.0.3 is not applicable to the fuel handling building ventilation system during fuel movement since fuel movement is independent of reactor operation.	Yes	No	No	No
3.7-43	ACTION A of ITS 3.7.13 is revised and ACTIONS C, E and F.1 of ITS 3.7.13 are not used per the DCPD CTS.	Yes	No	No	No
3.7-44	This change would revise ITS 3.7.13 to add a new Note to the Applicability and change the Conditions, Required Actions, and SRs to conform to the design of the Emergency Exhaust System.	No, fuel building ventilation not required for post LOCA leakage.	No, CTS does not require this specification.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-45	ITS 3.7.15 is revised to be CPSES specific to address the two spent fuel pools and the in-containment storage racks.	No	Yes	No	No
3.7-46	Revised to delete "irradiated fuel assemblies seated in" since accident analysis assumes fuel assembly lying on top of the fuel storage racks.	No, ITS is consistent with CTS.	Yes	No, ITS is consistent with CTS.	Yes
3.7-47	This change adds TS 3.7.19, a safety chilled water system which is in the CPSES CTS.	No	Yes	No	No
3.7-48	This change adds TS 3.7.20, an UPS HVAC system which is in the CPSES CTS.	No	Yes	No	No
3.7-49	The requirement to verify a make-up flow rate during the tests demonstrating the capability to maintain [fuel handling] building differential pressure below atmospheric pressure would be deleted. The current licensing basis of the plant is to be able to maintain a negative pressure [in the fuel handling building] with respect to the outside atmosphere.	Yes	No, see CN 3.7-38.	Yes	Yes
3.7-50	The CTS DCPD specific ADV surveillance that verifies the back-up air bottle pressure once per 24 hours is retained.	Yes	No	No	No
3.7-51	A new spent fuel pool storage specification is created for Region 1 fuel storage due to unique storage requirements at DCPD.	Yes	No	No	No
3.7-52	ITS 3.7.14 is not used due to the mild coastal environment in which the plant is located.	Yes	No	No	No
3.7-53	ITS 3.7.16 for DCPD is revised to be consistent with the current licensing basis and CTS.	Yes	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-54	The LCO, Required Actions, and Surveillances are revised per the DCPD specific CTS to incorporate Region 2 fuel storage requirements.	Yes, per LA 116/114.	No	No	No
3.7-55	NUREG-1431 Specification 3.7.14 is not used since an equivalent safety grade system does not exist. Therefore, the deletion is per the current licensing basis.	Yes	No	No	No
3.7-56	This change creates a new SR for the MSIVs [and MFIVs] to distinguish between the IST and the automatic actuation testing of these isolation valves. The SR allows credit for an actual actuation, if one occurs, to satisfy the surveillance requirements. Although SRs 3.7.2.2 and 3.7.3.2 are new SRs, they may be performed in conjunction with SRs 3.7.2.1 and 3.7.3.1. Therefore, the Note allowing testing to be performed on MODE 3 is also needed for these new SRs.	Yes	Yes	Yes	Yes
3.7-57	This change establishes appropriate Required Actions and Completion Times for ventilation system pressure envelope degradation.	{No, retained CTS.}	Yes	Yes	Yes

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Methodology for Cross-Reference Tables
(Continued)

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).

Note: The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note: . When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

3/4.6 CONTAINMENT SYSTEMS

3/4.6.1 CONTAINMENT

CONTAINMENT INTEGRITY

LIMITING CONDITION FOR OPERATION

3.6.1.1 CONTAINMENT INTEGRITY shall be maintained OPERABLE.

01-01-LG

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

Without CONTAINMENT INTEGRITY inoperable, restore CONTAINMENT INTEGRITY to OPERABLE within 1 hour or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

01-01-LG

SURVEILLANCE REQUIREMENTS

4.6.1.1 CONTAINMENT INTEGRITY shall be demonstrated OPERABLE

01-02-A

a. At least once per 31 days by verifying that all penetrations*# not capable of being closed by OPERABLE containment automatic isolation valves and required to be closed during accident conditions are closed by valves, blind flanges, or deactivated automatic valves secured in their positions, or check valve with flow through the valve secured except for valves that are open under administrative control as permitted by Specification 3.6.3. Isolation devices in high radiation areas may be verified by administrative means.

01-06-LS19

1-03-A

01-04-LS1

b. By verifying that each containment air lock is in compliance with the requirements of Specification 3.6.1.3.

01-05-A

*Except valves, blind flanges, and deactivated automatic valves which are located inside the containment and are locked, sealed, or otherwise secured in the closed position. These penetrations# shall be verified closed during each COLD SHUTDOWN except such verification need not be performed more often than once per 92 days.

01-06-LS19

Except when closed by manual valves that are locked, sealed, or otherwise secured and blind flanges. If locked, sealed, or otherwise secured manual valves, blind flanges, and deactivated automatic valves are closed to satisfy an ACTION (e.g. 3.6.3) the position must be verified but may be verified by administrative means.

01-06-LS19

CONTAINMENT SYSTEMS

CONTAINMENT LEAKAGE

02-01-A

LIMITING CONDITION FOR OPERATION

3.6.1.2 Containment leakage rates shall be limited in accordance with the Containment Leakage Rate Testing Program.

APPLICABILITY: MODES 1, 2, 3 and 4.

ACTION:

With the measured overall integrated containment leakage rate exceeding 1.0 L_a , within 1 hour initiate action to be in HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. Restore the overall integrated leakage rate to less than or equal to 0.75 L_a , and the combined leakage rate for all penetrations subject to Type B and C tests to less than or equal to 0.60 L_a prior to increasing the Reactor Coolant System temperature above 200°F the first unit startup following testing performed in accordance with the Containment Leakage Rate Testing Program.

02-06-A

02-02-A

SURVEILLANCE REQUIREMENTS

4.6.1.2 The containment leakage rates shall be demonstrated at the test schedule and shall be determined in conformance with the criteria specified in the Containment Leakage Rate Testing Program.

CONTAINMENT SYSTEMS

CONTAINMENT AIR LOCKS

LIMITING CONDITION FOR OPERATION

3.6.1.3 Each ~~the two~~ containment air locks shall be OPERABLE with both doors closed except when the air lock is being used for normal transit entry and exit through the containment, then at least one air lock door shall be closed.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION: * ** ***

a. With one or more containment air locks with one containment airlock door or the interlock mechanism inoperable:

1. Maintain at least Verify the OPERABLE air lock door closed within 1 hour and either restore the inoperable air lock door to OPERABLE status within 24 hours or lock the OPERABLE air lock door closed, and

2. Operation may then continue until performance of the next required overall air lock leakage test provided that Verify the OPERABLE air lock door is verified to be locked closed at least once per 31 days.

3. Otherwise, be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours, and

4. The provisions of Specification 3.0.4 are not applicable.

b. With the one or more containment air locks inoperable for reasons other than a, initiate Action to evaluate overall containment leakage rate per LCO 3.6.1, except as the result of an inoperable air lock door, or an interlock mechanism maintain Verify at least one air lock door closed within 1 hour, restore the inoperable air lock to OPERABLE status within 24 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 36 hours.

* Entry and exit is permissible to perform repairs on the affected airlock components.

** Separate condition entry is allowed for each airlock

*** Enter applicable Conditions and Required Actions of LCO 3.6.1 "Containment" when airlock leakage results in exceeding the overall containment leakage rate.

**** Entry and exit is permissible for 7 days under Administrative controls if both airlocks are inoperable.

***** Airlock doors in high radiation areas may be verified locked by Administrative means.

++ Entry and exit of containment is permissible under the control of a dedicated individual.

CONTAINMENT SYSTEMS

SURVEILLANCE REQUIREMENTS

4.6.1.3 Each containment air lock shall be demonstrated OPERABLE:

- a. By verifying leakage rates in accordance with the Containment Leakage Rate Testing Program.
- b. At least once per 6 ~~24~~ months by verifying that only one door in each air lock can be opened at a time.

03-10-LS8

CONTAINMENT SYSTEMS

INTERNAL PRESSURE

LIMITING CONDITION FOR OPERATION

3.6.1.4 Containment internal pressure shall be maintained between -1.0 and +1.2 psig.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

With the containment internal pressure outside of the limits above, restore the internal pressure to within the limits within 4 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.6.1.4 The containment internal pressure shall be determined to be within the limits at least once per 12 hours.

CONTAINMENT SYSTEMS

AIR TEMPERATURE

LIMITING CONDITION FOR OPERATION

3.6.1.5 Containment average air temperature shall not exceed 120°F.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

With the containment average air temperature greater than 120°F, reduce the average air temperature to within the limit within 8 hours, or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.6.1.5 The containment average air temperature shall be the arithmetical average of the temperatures at the following locations and shall be determined at least once per 24 hours.

05-01-LG

Element and Location

- a. ~~TE 85 or TE 86, approximately 100 ft elevation between crane wall and containment wall.~~
- b. ~~TE 87 or TE 88, approximately 100 ft elevation between steam generators.~~
- c. ~~TE 89 or TE 90, approximately 140 ft elevation near equipment hatch or stairs at 270°, respectively, and~~
- d. ~~TE 91 or TE 92, approximately 184 ft elevation on top of steam generator missile barriers away from steam generators.~~

CONTAINMENT SYSTEMS

CONTAINMENT STRUCTURAL INTEGRITY

LIMITING CONDITION FOR OPERATION

3.6.1.6 The structural integrity of the containment shall be maintained at a level consistent with the acceptance criteria in Specification 4.6.1.6.

06-02-A

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

With the structural integrity of the containment not conforming to the above requirements, restore the structural integrity to within the limits within 24 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

06-04-M

SURVEILLANCE REQUIREMENTS

4.6.1.6.1 Containment Surfaces The structural integrity of the exposed accessible interior and exterior surfaces of the containment, including the liner plate, shall be determined during shutdown by a visual inspection of these surfaces. This inspection shall be performed in accordance with the Containment Leakage Rate Testing Program to verify no apparent changes in appearance or other abnormal degradation.

06-02-A

~~4.6.1.6.2 Reports Any abnormal degradation of the containment structure detected during the above required inspections shall be reported to the Commission in a Special Report pursuant to Specification 6.9.2 within 15 days. This report shall include a description of the condition of the concrete, the inspection procedure, the tolerances on cracking, and the corrective actions taken.~~

06-03-TR2

CONTAINMENT SYSTEMS

CONTAINMENT VENTILATION SYSTEM

07-01-A

LIMITING CONDITION FOR OPERATION

3.6.1.7 One purge supply line and/or one purge exhaust line of the Containment Purge System may be open or the vacuum/pressure relief line may be open. ~~The vacuum/pressure relief line may be open provided the vacuum/pressure relief isolation valves are blocked to prevent opening beyond 50° (90° is fully open). Operation with any two of these three lines open is permitted. Operation with the purge supply and/or exhaust isolation valves open or with the vacuum/pressure relief isolation valves open up to 50° shall be limited to less than or equal to 200 hours during a calendar year.~~

07-04-R

APPLICABILITY: MODES 1, 2, 3, and 4.

11-02-A

ACTION: ~~***~~

03-13-A

~~With a containment purge supply and/or exhaust isolation valve open or the vacuum/pressure relief isolation valves open up to 50° for more than 200 hours during a calendar year or the Containment Purge System open and the vacuum/pressure relief lines open, or with the vacuum/pressure relief isolation valves open beyond 50° With two containment purge supply or exhaust valves or two vacuum/pressure relief valves on the same penetration inoperable for reasons other than leakage, close the open isolation valve(s) or isolate the penetration(s) flowpath(s) within 1 hour; otherwise, be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.~~

07-04-R

07-05-A

11-12-A

~~(new) One or more penetration flow paths with one or more containment purge or vacuum/pressure relief valves not within purge valve leakage limits. Within 24 hours isolate the affected penetration flow path by use of at least one closed and de-activated automatic valve, closed manual valve, or blind flange. Verify the affected penetration flow path is isolated once per 31 days for isolation devices outside containment and prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days for isolation devices inside containment* and perform Surveillance 4.6.3.4 for the resilient seal purge valves closed to comply with this Required Action E-1D 1, once per 92 days.~~

07-02-LS9

01-04-LS1

SURVEILLANCE REQUIREMENTS

4.6.1.7.1 The position of the containment purge supply and exhaust isolation valves and the vacuum/pressure relief isolation valves shall be determined closed at least once per 31 days except for one valve in a penetration flow path while in action 3.6.1.7 for excessive leakage.

07-03-A

4.6.1.7.2 The cumulative time that the purge supply and/or exhaust isolation valves or the vacuum/pressure relief isolation valves have been open during a calendar year shall be determined at least once per 7 days.

07-04-R

4.6.1.7.3 The 12-inch vacuum/pressure relief isolation valves shall be verified to be blocked to prevent opening beyond 50° at least once per 18 months.

ED

* Isolation devices in high radiation areas may be verified by use of administrative means.

01-04-LS1

** Separate Condition entry is allowed for each penetration flow path.

11-02-A

*** Enter applicable Conditions and Required Actions of the Containment EGO when leakage results in exceeding the overall containment leakage rate.

03-13-A

CONTAINMENT SYSTEMS

3/4.6.2 DEPRESSURIZATION AND COOLING SYSTEMS

08-04-A

CONTAINMENT SPRAY SYSTEM

LIMITING CONDITION FOR OPERATION

8-01-LG

3.6.2.1 Two Containment Spray Systems shall be OPERABLE with each Spray System capable of taking suction from the RWST and transferring spray function to a RHR System taking suction from the containment sump.

APPLICABILITY: MODES 1, 2, 3 and 4.

08-11-LS2

ACTION: *

With one Containment Spray System inoperable, restore the inoperable Spray System to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours; restore the inoperable Spray System to OPERABLE status within the next 48 hours or ~~and~~ be in COLD SHUTDOWN within the following ~~30~~ 78 hours.

08-02-A

SURVEILLANCE REQUIREMENTS

4.6.2.1 Each Containment Spray System shall be demonstrated OPERABLE:

- a. At least once per 31 days by verifying that each valve (manual, power operated or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position;
- b. By verifying that ~~on recirculation flow, each pump's developed head at the flow test point is a differential pressure of greater than or equal to 205 psid the required developed head when tested pursuant to Specification 4.0.5 the Inservice Test Program;~~ 08-08-LG
- c. At least once per 18 months by:
 - 1) Verifying that each automatic valve in the flow path actuates to its correct position on an actual or simulated actuation signal, and
 - 2) Verifying that each spray pump starts automatically on an actual or simulated actuation signal.
- d. At least once per 10 years by ~~performing an air or smoke flow test through each spray header and verifying each spray nozzle is unobstructed.~~ 08-06-LG

* ~~Additionally, a completion time of 10 days from discovery of failure to meet the conditions of 3.6.2.1 and 3.6.2.3.~~ 08-11-LS2

CONTAINMENT SYSTEMS

SPRAY ADDITIVE SYSTEM

LIMITING CONDITION FOR OPERATION

3.6.2.2 The Spray Additive System shall be OPERABLE with:

- a. A spray additive tank with a contained volume of between ~~2025 and 4000 gallons~~ 46.2% and 91.9% of between 30 and 32% by weight NaOH solution, and 09-01-A
- b. ~~Two spray additive eductors each capable of adding NaOH solution from the chemical additive tank to a Containment Spray System pump flow.~~ 09-02-LG

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

With the Spray Additive System inoperable, restore the system to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours; restore the Spray Additive System to OPERABLE status within the next 48 hours or be in COLD SHUTDOWN within the following 30 hours. 09-03-A

SURVEILLANCE REQUIREMENTS

4.6.2.2 The Spray Additive System shall be demonstrated OPERABLE:

- a. At least once per 31 days by verifying that each valve (manual, power-operated, or automatic) in the flow path that is not locked, sealed, or otherwise secured in position, is in its correct position;
- b. At least once per 6 months by:
 - 1) Verifying the contained solution volume in the tank, and
 - 2) Verifying the concentration of the NaOH solution by chemical analysis.
- c. At least once per 18 months by verifying that each automatic valve in the flow path ~~that is not locked, sealed, or otherwise secured in position~~ actuates to its correct position on a ~~an actual or simulated~~ Containment Spray actuation test signal; and 09-04-A
09-05-TR1
- d. At least once per 5 years by verifying both spray additive and RWST full flow from the test valve 8993 ~~through each solution flow path in~~ the Spray Additive System. 09-07-M

CONTAINMENT SYSTEMS

CONTAINMENT COOLING SYSTEM

08-04-A

LIMITING CONDITION FOR OPERATION

3.6.2.3 The Containment Cooling System shall be OPERABLE with either:

- a. At least four containment fan cooler units (CFCUs), or
- b. At least three CFCUs, each of the three supplied from a different vital bus.

APPLICABILITY: MODES 1, 2, 3, and 4.

08-11-LS2

ACTION: *

- a. With the requirements of the above specification not satisfied, but at least two CFCUs OPERABLE and both Containment Spray Systems OPERABLE, restore the Containment Cooling System to OPERABLE status within 7 days, otherwise be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.
- b. With the requirements of the above specification not satisfied and one Containment Spray System inoperable, but at least two CFCUs OPERABLE, restore the inoperable Containment Spray System to OPERABLE status within 72 hours otherwise be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. Restore the Containment Cooling System to OPERABLE status within 7 days of initial loss or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

~~(new) With one Containment Spray System and one or less CFCUs operable or two Containment Spray Systems inoperable enter LCO 3.0.3.~~

08-10-A

SURVEILLANCE REQUIREMENTS

4.6.2.3 Each containment fan cooler unit shall be demonstrated OPERABLE:

- a. At least once per 31 days by:
 - 1) Starting each containment fan cooler unit and verifying that each containment fan cooler unit operates for at least 15 minutes.

~~* Additionally, a completion time of 10 days from discovery of failure to meet the conditions of 3.6.2.1 and 3.6.2.3.~~

08-11-LS2

CONTAINMENT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- 2) Verifying a cooling water flow rate of greater than or equal to 1650* gpm to each cooler, and 10-03-LG
- 3) Verifying that each containment fan cooler unit starts on low speed.
- b. At least once per 18 months by verifying that each containment fan cooler unit starts automatically on a Safety Injection test an actual or simulated actuation signal. 09-05-TR1

~~* The CFCU cooling water flow rate requirement of IS 4.6.2.3a.2) may not be met during Section XI testing and in Mode 4 during residual heat removal heat exchanger operation.~~

10-03-LG

CONTAINMENT SYSTEMS

3/4.6.3 CONTAINMENT ISOLATION VALVES

LIMITING CONDITION FOR OPERATION

3.6.3 Each containment isolation valve shall be OPERABLE.* #

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION: **; ***; ****

With one or more of the penetration flow paths with one isolation valve(s) inoperable, maintain at least one isolation valve OPERABLE in each affected penetration that is open and:

11-12-A

a. ~~Restore the inoperable valve(s) to OPERABLE status within 4 hours, or~~

11-16-A

b. Isolate each affected penetration flow path within 4 hours by use of at least one deactivated automatic valve secured in the isolation position, or

11-12-A

c. Isolate each affected penetration flow path within 4 hours by use of at least one closed manual valve or blind flange or check valve with flow secured; or

11-12-A

01-03-A

d. Be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

Not applicable to Main Steam Safety Valves (MSSVs), Main Steam Isolation Valves (MSIVs), Main Feedwater Isolation Valves (MFIVs), Main Feedwater Regulating Valves (MFRVs) and Associated Bypass Valves, and Atmospheric Dump Valves (ADVs)

11-11-A

NOTE 1 * ~~Locked or sealed closed valves~~ Penetration flow paths may be opened on an intermittent basis under administrative control.

11-01-LS13

(new) With one or more penetration flow paths with two containment isolation valves inoperable, isolate the affected penetration flow path within 1 hour by use of at least one closed and deactivated automatic valve, closed manual valve, or blind flange, or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

11-04-A

(new) With one or more penetration flow paths of the type configured with only one containment isolation valve and a closed system, with one containment isolation valve inoperable, isolate the affected penetration flow path within 72 hours by use of at least one closed and deactivated automatic valve, closed manual valve, or blind flange, or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

11-05-LS14

SURVEILLANCE REQUIREMENTS

4.6.3.1 ~~Each containment isolation valve shall be demonstrated OPERABLE prior to returning the valve to service after maintenance, repair or replacement work is performed on the valve or its associated actuator, control or power circuit by performance of a cycling test, and verification of isolation time.~~

11-06-TR3

11-09-A

CONTAINMENT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

4.6.3.2 Each automatic containment isolation valve that is not locked, sealed or otherwise secured in position shall be demonstrated OPERABLE at least once per 18 months by:

11-14-A

11-07-LG

- a. Verifying that on a Phase "A" Isolation test an actual or simulated signal, each Phase "A" isolation valve actuates to its isolation position.
- b. Verifying that on a Phase "B" Isolation test signal, each Phase "B" isolation valve actuates to its isolation position; and
- c. Verifying that on a Containment Ventilation Isolation test signal, each containment ventilation isolation valve actuates to its isolation position.

11-08-TR1

11-07-LG

11-07-LG

Note 2: ** Separate Condition entry is allowed for each penetration flow path.

11-02-A

*** Enter applicable Conditions and Required Actions for systems made inoperable by containment isolation valves.

11-03-A

**** Enter applicable Conditions and Required Actions of Specification 3.6.1.1, "Containment," when isolation valve leakage results in exceeding the overall containment leakage rate acceptance criteria.

03-13-A

CONTAINMENT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

4.6.3.3 The isolation time of each testable power operated or automatic containment isolation valve that is not locked, sealed, or otherwise secured shall be determined to be within its limit when tested pursuant to Specification 4.0.5 the Inservice Testing Program.

11-07-LG

11-09-A

4.6.3.4 Each containment ventilation isolation valve, except the air sample supply and return valves, shall be demonstrated OPERABLE every 184 days and within 24 hours 92 days after each closing of opening the valve, except when the valve is being used for multiple cycling, then at least once per 72 hours, by verifying leakage rates in accordance with the Containment Leakage Rate Testing Program. This surveillance is not required when the penetration flow path is isolated by a leak tested blank flange.

11-13-LS22

07-10-LS9

CONTAINMENT SYSTEMS

3/4.6.4 COMBUSTIBLE GAS CONTROL

12-01-A

HYDROGEN ANALYZERS/MONITORS

LIMITING CONDITION FOR OPERATION

3.6.4.1 Two independent containment hydrogen analyzers/monitors shall be OPERABLE.

APPLICABILITY: MODES 1, and 2 and 3.

12-02-M

ACTION: ECO 3.0.4 is not applicable

13-05-LS23

- a. With one hydrogen analyzer/monitor inoperable, restore the inoperable analyzer/monitor to OPERABLE status within 30 days or be in at least HOT STANDBY within the next 6 hours submit a Special Report in accordance with 10 CFR 50.4 within the following 14 days outlining the preplanned alternate method of monitoring, the cause of the inoperability and the plans and schedule for restoring the hydrogen analyzer/monitor to OPERABLE status.
- b. With both hydrogen analyzer/monitors inoperable, restore at least one analyzer/monitor to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and be in HOT SHUTDOWN within the next 6 hours.

12-03-LS15

12-04-M

SURVEILLANCE REQUIREMENTS

4.6.4.1 Each hydrogen analyzer/monitor shall be demonstrated OPERABLE at least once per 92 days 18 months by performing a CHANNEL CALIBRATION using a zero and span gas.

12-05-LS16

12-06-LG

(new) Perform CHANNEL CHECK at least once per 31 days to verify hydrogen analyzer/monitor OPERABLE.

12-07-M

CONTAINMENT SYSTEMS

ELECTRIC HYDROGEN RECOMBINERS

LIMITING CONDITION FOR OPERATION

3.6.4.2 Two independent Hydrogen Recombiner Systems shall be OPERABLE.

APPLICABILITY: MODES 1 and 2.

ACTION:

With one Hydrogen Recombiner System inoperable, restore the inoperable system to OPERABLE status within 30 days or be in at least HOT STANDBY within the next 6 hours.

13-05-LS23

~~(new) With two hydrogen recombers inoperable, verify within 1 hour and once per 12 hours thereafter, by administrative means, that the hydrogen control function is maintained, and restore one hydrogen recombiner to OPERABLE status within 7 days or be in at least HOT STANDBY within the next 6 hours.~~

13-01-LS17

SURVEILLANCE REQUIREMENTS

4.6.4.2 Each Hydrogen Recombiner System shall be demonstrated OPERABLE:

- a. ~~At least once each refueling interval 18 months by verifying, during performing a Recombiner System functional test, that the minimum heater sheath temperature increases to greater than or equal to 700°F within 90 minutes. Upon reaching 700°F, increase the power setting to maximum power for 2 minutes and verify that the power meter reads greater than or equal to 60 kW; and~~
 - 13-02-LS18
 - 13-03-LG
- b. ~~At least once each refueling interval 18 month by:~~
 - 1) ~~Performing a CHANNEL CALIBRATION of all recombiner instrumentation and control circuits,~~
 - 13-02-LS18
 - 13-04-LG
 - 2) ~~Verifying through a visual examination that there is no evidence of abnormal conditions within the recombiner enclosure (i.e., loose wiring or structural connections, deposits of foreign materials, etc.), and~~
 - 13-03-LG
 - 3) ~~Verifying the integrity of all heater electrical circuits by performing a resistance to ground test following the above required functional test. The resistance to ground for any heater phase shall be greater than or equal to 10,000 ohms.~~
 - 13-03-LG

~~* 3.0.4 is not applicable.~~

13-05-LS23

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. **Deletions** - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. **Additions** - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. **Modifications** - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. **Administrative** - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions** - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions** - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications** - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative** - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

Methodology For Mark-Up of Current TS (Continued)

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	LG	CONTAINMENT INTEGRITY is no longer a defined term in NUREG-1431. The requirements for containment OPERABILITY, including the requirements previously found in the CONTAINMENT INTEGRITY definition, are discussed in the expanded Bases of the containment limiting condition for operation (LCO). This change is consistent with NUREG-1431.
01-02	A	Consistent with NUREG-1431, this requirement to verify the penetration flow path is isolated is now addressed by improved Technical Specification (ITS) 3.6.3, Containment Isolation Valves, Condition A, C, and [D] and Surveillance Requirements (SR) 3.6.3.3 and SR 3.6.3.4.
01-03	A	The ACTION statements are revised to incorporate the NUREG-1431 alternative isolation method of a "check valve with the flow through the valve secured." This isolation method is provided in NUREG-1431 and is considered an acceptable variation of a de-activated automatic valve.
01-04	LS1	A Note is added to valve and blind flange SRs consistent with NUREG-1431. The Note allows verification of valves, flanges, and isolation devices located in high radiation areas to be verified by use of administrative means. This change is less restrictive in that the CTS SR 4.6.1.1 has an exception to valves, blind flanges, and deactivated automatic valves which are located inside containment and are locked, sealed, or otherwise secured in the closed position. These valves shall be verified closed during each COLD SHUTDOWN. However, under CTS, if an area outside of containment becomes a high radiation area, we would still be required to enter the area to verify the closed positions. The ITS would allow verification of all areas that are high radiation areas or become high radiation areas to be verified by administrative means once they have been verified to be in the proper position. This is considered acceptable, since access to these areas is restricted for ALARA reasons. Therefore, the probability of misalignment of these devices, once they have been initially verified in the proper position, is small.
01-05	A	Consistent with NUREG-1431, this requirement is addressed by SR 3.6.2.1 in ITS 3.6.2, Containment Air Locks Required Actions.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-06	LS19	<p>The CTS requires all penetrations not capable of being closed by an OPERABLE containment automatic isolation valve (and required to be closed for accident conditions) be verified closed on a 31 day frequency, except for valves, blind flanges, and deactivated automatic valves which are located inside containment and locked closed, sealed, or otherwise secured in a closed position. These excepted penetrations were to be verified closed during each cold shutdown but not more often than once per 92 days. Consistent with Traveler TSTF-45, Rev. 1 only containment isolation valves that are not locked, sealed, or otherwise secured are required to be verified closed at the once per COLD SHUTDOWN frequency. Penetrations (inside or outside containment) which are isolated by manual valves and blind flanges that are locked, sealed or otherwise secured are not required to be verified closed, since they are verified to be in the correct position prior to locking/securing.</p> <p>CTS Surveillance 4.6.1.1 is incorporated into ITS SR 3.6.3.3 and SR 3.6.3.4 and into the redundant requirements of ITS 3.6.3, Required Action A.2, C.2, and [D.2]. As discussed above, the ITS surveillances were modified consistent with TSTF-45. The redundant Required Actions were also modified in a subsequent Traveler (WOG-91). The TSTF-45 modifications to the ITS surveillances and the WOG-91 modifications to Required Actions, while similar, differed in that the Required Actions still require some verification of position of valves that are locked closed, sealed or otherwise secured, although this verification may be performed via administrative means. The surveillances require no additional verification.</p>
02-01	A	Consistent with NUREG-1431, the Containment Leakage LCO is now included in ITS 3.6.1, Containment LCO.
02-02	A	The wording "prior to increasing the Reactor Coolant System temperature above 200°F" is replaced by the equivalent requirement of "prior to the first unit startup following testing performed in accordance with the Containment Leakage Rate Testing Program." The fact that the Applicability of the new Containment LCO is MODE 1-4, and that SR 3.0.4 requires surveillances to be performed before entering the MODE of Applicability, ensures that the required leakage rate testing is performed and that the as-left test acceptance criteria are met before entry into MODE 4. This change is consistent with NUREG-1431. This requirement is now included in ITS 5.5.16, the Containment Leak Rate Test Program.
02-03	A	This change is not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
02-04	A	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
02-05	LG	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
02-06	A	Consistent with industry Traveler TSTF-52, the leakage rate acceptance criteria is revised to $<0.60 L_a$ for Type B and Type C tests rather than $\leq 0.60 L_a$. There is no significant difference between the two expressions.
03-01	LG	The descriptive information in the LCO regarding OPERABILITY of the air locks is moved to the Bases 3.6.2. This change is consistent with NUREG-1431 and the approach of discussing OPERABILITY in the TS Bases.
03-02	A	This Note revises ACTIONS to permit separate Condition entry for each airlock consistent with NUREG-1431. The Note provides guidance and clarification for use of the TS and is considered administrative in nature.
03-03	LS3	Consistent with NUREG-1431, this Note allows entry and exit into containment via the air locks for up to 7 days if both air locks are inoperable and administrative controls are provided. With both air locks inoperable containment entry may be required on a periodic basis to perform TS surveillances and Required Actions, as well as other activities on equipment inside containment. This Note provides allowance for these activities to be performed.
03-04	M	The CTS ACTIONS [] are revised to be consistent with NUREG-1431, LCO 3.6.2, ACTIONS A.1. and A.2. The NUREG-1431 ACTIONS establish a one hour time limit for verifying the OPERABLE air lock door closed. The current requirement does not specify a time for verifying an air lock door closed.
03-05	LS4	The allowance to continue operation with one air lock door inoperable has been modified to remove the restriction which limits this Condition until the next required overall air lock leakage test. This restriction was removed because the air lock remains capable of performing its safety functions with the remaining OPERABLE door. Therefore, continued operations may proceed indefinitely subject to the other restrictions of the TS (continuing to meet the ACTIONS and applicable surveillances). This change is consistent with NUREG-1431.
03-06	LS5	Consistent with NUREG-1431, this Note modifies the requirement to verify an air lock door locked closed every 31 days. The Note allows the verification of locked closed air lock doors located in high radiation areas to be performed by use of administrative means. This change is less restrictive in that the CTS does not require this exception due to current design and capability to verify inner door locked from outside of the containment airlock. Under CTS, if the area outside of the airlock and containment became a high radiation area, we would still be required to enter the area to verify the closed positions. The ITS would allow verification of all areas that are high radiation areas or become high radiation areas by administrative means once they have been verified to be in the proper position. This is considered acceptable, since access to these areas is restricted for ALARA reasons. Therefore, the probability of misalignment of the air lock doors once they have been initially verified in the proper position, is small.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

CHANGE NUMBER

NSHC

DESCRIPTION

03-07

M

Consistent with NUREG-1431, this ACTION addresses any air lock inoperability other than an inoperable air lock door or air lock interlock mechanism. This includes two air lock doors in the same air lock. A new TS requirement, that is current operating practice conducted under the Containment Leakage Rate Testing Program, is included to immediately initiate ACTION to evaluate the overall containment leakage rate per the containment OPERABILITY LCO if the air lock limit has been exceeded. In addition, this change establishes a one hour time limit to verify one air lock door is closed in the affected air lock. The CTS does not specify a time.

03-08

LS6

Consistent with the ACTIONS and modifying Notes provided for an inoperable airlock door, ACTIONS are added which allow continued operation when the personnel airlock is inoperable due to an inoperable interlock mechanism. Use of the airlock is permissible under the control of a dedicated individual since an equivalent level of assurance that only one door will be open at a time is provided. The ACTIONS and modifying Notes provided for the interlock mechanism are consistent with the ACTIONS and Notes for an inoperable airlock door. These ACTIONS ensure that an OPERABLE door is closed and locked and entry or exit is controlled by a dedicated individual. While this change provides a slightly less restrictive TS requirement, the overall impact on plant safety is negligible due to the Required Actions implemented.

03-09

LS7

Consistent with NUREG-1431, a Note is added to allow access (entry and exit) to repair airlock components in an inoperable airlock. The ACTION requirement to close and lock an airlock door remains applicable with the exception of the brief entry and exit of the airlock to perform necessary repairs. The allowance to enter and exit through the airlock door required closed by the ACTIONS is acceptable based on the low probability of an event occurring that could challenge the containment boundary during the short time the door is open for entry and exit. In addition, this allowance reduces the potential risk incurred during a plant transient that may result from a shutdown required by TS due to the inoperable airlock.

03-10

LS8

Consistent with industry Traveler TSTF-17, Rev. 1, the surveillance Frequency on containment airlock interlock mechanisms is extended from 6 months to 24 months. The 24 month Frequency is based on engineering judgement and is considered adequate given that the interlock mechanism is not normally challenged when the containment air lock door is used for entry and exit. The 24 month Frequency is needed to allow the surveillance to be performed under conditions that apply during a plant outage due to the potential for loss of containment OPERABILITY if the surveillance were performed with the reactor at power.

03-11

Not Used.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6

(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
03-12	A	The statement that Specification 3.0.4 does not apply is no longer needed as revised ACTIONS consistent with NUREG-1431 permit continued operation for an unlimited period of time.
03-13	A	Consistent with NUREG-1431, a Note is added to the ACTIONS to enter applicable Conditions and Required ACTIONS of the "Containment" LCO when leakage results in exceeding the overall containment leakage rate. This is current operating practice per TS requirement CTS 3.6.1.1. Therefore, this change is considered an administrative change in format.
05-01	LG	The method for calculating containment average temperature and the locations where measurements are taken are moved to the Bases. This level of detail in the TS is not consistent with NUREG-1431. The improved STS Bases is licensee controlled under the Bases Control Program in the Administrative Controls section of the improved STS.
06-01		Not Used.
06-02	A	The structural integrity requirements of containment are contained in ITS 3.6.1. The inspection requirements associated with structural integrity of the exposed accessible interior and exterior containment surfaces, are contained in Appendix J, Option B and in Regulatory Guide (RG) 1.163. The requirement to perform visual inspections is in ITS Surveillance Requirement (SR) 3.6.1.1 which refers to the containment Leakage Rate Testing Program as controlled by ITS 5.5.16.
06-03	TR2	Consistent with NUREG-1431, the reporting requirement is being deleted. 10 CFR 50.72 and 10 CFR 50.73 establish the reporting requirements.
06-04	M	The ACTION is moved to ITS 3.6.1, Condition A and B. The ITS requirements are more severe in that only 1 hour allowed outage time (AOT) is provided while the CTS provides a 24 hour AOT. The shorter AOT is acceptable because a containment which may not be able to act as a boundary as designed could have a significant adverse impact on the consequences of an accident.
07-01	A	Consistent with NUREG-1431, the LCO and SRs for containment ventilation/purge valves are now included in ITS 3.6.3 for Containment Isolation Valves.
07-02	LS9	Consistent with NUREG-1431, the Required Action for a containment ventilation/purge valve with a leakage rate which exceeds the acceptance criteria is revised to allow continued operation if the penetration flow path is isolated within 24 hours. This action is in lieu of requiring a shutdown if the valve leakage rate is not restored to an acceptable value within 24 hours. This is considered acceptable because with the associated penetrations isolated per the proposed ACTION requirement, no accident is credible as a result of the leaking valve.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
07-03	A	A change [] consistent with NUREG-1431, SR 3.6.3.1, is added to provide an allowance for one isolation valve in a penetration flow path to be open when performing the Required Actions for leakage not within limits. This is actually a consistency change which goes with the revised Required Actions (see 07-02-LS9 above). The Required Action allows continued operation with leakage not in limits and this change to the SR allows a valve to be opened to repair the excessive leakage.
07-04	R	The time limit restrictions on opening the [containment purge supply and exhaust and pressure/vacuum relief flow paths] and the requirements to periodically accumulate the time that the valves have been open would be relocated to licensee controlled documents.
07-05	A	Consistent with NUREG-1431, an ACTION is added for two valves inoperable in one penetration flow path. The change is administrative since the CTS would have relied on LCO 3.0.3 which has essentially the same requirements.
07-06	LS11	This change is not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-07	LG	This change is not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-08	M	This change is not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-09	LG	This change is not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-10	LS9	A Note is added to clarify that leakage rate testing is not required for containment purge valves with resilient seals when the penetration flow path is isolated by a leak tested blank flange. The purpose of the leak testing requirement is to ensure containment leakage integrity during an accident, and thereby limit accident consequences. Isolation of the flow path with a leak tested blind flange accomplishes this safety function and additional leak testing of the valves in the flow path is redundant and unnecessary.
07-11	LS25	This change is not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
08-01	LG	Consistent with NUREG-1431, the LCO references to suction flowpath and manual transfer of suction to containment sump have been deleted. These details are included within the OPERABILITY requirements of the containment spray system (CSS) (as required by CTS 4.6.2.1 and as further described in the Bases). There is no technical change resulting from this deletion.

**DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)**

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
08-02	A	Consistent with NUREG-1431, the ACTION statement is revised by replacing the reference to restoring the CSS to OPERABLE status within 48 hours or be in COLD SHUTDOWN within the following 30 hours, with the requirement to be in COLD SHUTDOWN within 78 hours. The time allowed to be in cold shutdown has not changed. The requirements of the action statement have also not changed, since as discussed in the Bases, the extended interval to reach COLD SHUTDOWN allows 48 hours for restoration of the system OPERABILITY and an additional 36 hours to achieve COLD SHUTDOWN.
08-03	TR1	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
08-04	A	The LCOs for containment spray system and containment coolers are combined into one LCO per NUREG-1431.
08-05	LS12	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
08-06	LG	The details on flow testing for nozzle obstructions and specific actuation signals that apply for automatic actuations are moved to the Bases. This is acceptable as the requirement to test remains in the Technical Specification and this level of detail is not contained in NUREG-1431.
08-07		Not Used.
08-08	LG	The specific pump discharge pressure value would be moved to the Inservice Testing Program.
08-09	LG	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
08-10	A	ITS Condition F. specifies two containment spray trains or any combination of three or more trains inoperable to enter 3.0.3. Even though this condition is not specified in the CTS, 3.0.3 would be entered.
08-11	LS2	A "from discovery of failure to meet the LCO provision" has been added to the Completion Time for one train of containment spray/cooling systems inoperable. This change is considered less restrictive in that the 10 days allowed in the ITS not to meet the LCO is greater than the CTS would allow.
09-01	A	The DCPP units for the spray additive tank volume limits are changed from gallons to percent.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
09-02	LG	The descriptive information in LCO 3.6.2.2 regarding OPERABILITY of the spray additive system is contained within the definition of OPERABILITY as described in the ITS 3.6.7 Bases. This is consistent with NUREG-1431 and is acceptable because while the descriptive detail has been moved to the Bases, the basic requirement is retained in the LCO.
09-03	A	Consistent with NUREG-1431, the ACTION statement is revised by deleting the reference to restoring the spray additive system to OPERABILITY within 48 hours or be in COLD SHUTDOWN within the following 30 hours. The revised ACTION statement contains a requirement to be in COLD SHUTDOWN within 78 hours. The time allowed to be in COLD SHUTDOWN has not changed. As discussed in the Bases, the interval to reach COLD SHUTDOWN allows 48 hours for restoration of the system OPERABILITY and an additional 36 hours to achieve COLD SHUTDOWN.
09-04	A	Consistent with NUREG-1431, adds the phrase "that is not locked, sealed, or otherwise secured in position with regard to which valves require actuation testing. This change is merely a clarification. Valves that are secured in place, are secured in the position required to meet their safety function. The actuation testing ensures that valves can move to the position that meets their safety function. If the valves are secured in the position that meets their safety function, no testing is necessary.
09-05	TR1	The specific actuation signal (a safety injection test signal) for the surveillance was replaced with a generic words that allow credit for an actual or simulated actuation. Identification of the signal is moved to the Bases.
09-06	LG	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
09-07	M	Consistent with NUREG-1431, the surveillance is modified to require demonstration of flow through each solution flow path. This assures that all spray additive flow paths are clear.
10-01	LG	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
10-02	LG	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
10-03	LG	The DCPP specific Note cautioning that containment fan cooling unit (CFCU) flow rate may not be achieved during Section XI testing and residual heat removal (RHR) operation is relocated to the Bases. This level of detail is not required in the TS.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
11-01	LS13	Consistent with NUREG-1431, LCO 3.6.3, a Note is added to the ACTIONS that apply to all containment isolation valves. The first Note allows containment isolation valves that are required to be closed [] to be opened under administrative controls. This is acceptable based on the administrative controls consisting of a dedicated operator at the valve in continuous communication with the control room. This control provides protection equivalent to the automatic isolation system. [] Opening on an intermittent basis under administrative controls is allowed for certain valves by references made from CTS 1.8 and 4.6.1.1 of the CTS.
11-02	A	Consistent with NUREG-1431 LCO 3.6.3, a Note is added to the ACTIONS to allow separate Condition entry for each penetration flow path. The Note provides guidance and clarification for the use of TS and is consider administrative in nature.
11-03	A	This Note is added to the ACTIONS to enter applicable Conditions and Required ACTIONS for systems made inoperable by containment isolation valves.
11-04	A	NUREG-1431 adds a new Condition to the current Containment Isolation Valve TS to cover the case where two containment isolation valves in a penetration flow path are inoperable. The CTS addresses only the condition of one valve inoperable in a penetration flow path. If two valves were inoperable on the same penetration, LCO 3.0.3 would be entered. Consistent with NUREG-1431, a completion time of 1 hour is provided to isolate the penetration flow path. This is the same amount of time allowed by LCO 3.0.3 before a power reduction ACTION is specified and is administratively similar to the existing requirements.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6

(Continued)

CHANGE NUMBER

NSHC

DESCRIPTION

11-05

LS14

A new Condition is added to the current Containment Isolation Valve TS to cover the case where one containment isolation valve is inoperable in a penetration flow path of the type configured with only one containment isolation valve and a closed system. General Design Criteria (GDC) 57 allows the use of a closed system in combination with a containment isolation valve to provide the two containment barriers against the release of radioactive material following an accident. Traveler TSTF-30, Rev. 1, provides the basis for extending the Completion Time for this Condition to allow 72 hours to isolate an inoperable isolation valve associated with a closed system. The CTS, LCO 3.6.3, does not allow the use of a closed system to isolate a failed containment isolation valve even though the closed system is subjected to a Type A containment leakage test, is missile protected, and is seismic Category I piping. Also, a closed system typically has flow through it during normal operation such that any loss of integrity could be observed through leakage detection systems within containment and system walkdowns for closed systems outside containment. As such, the use of a closed system is equivalent to isolating a failed containment isolation valve by use of a single valve as specified in NUREG-1431, Required ACTION A.1. The 72 hours provides the necessary time to perform repairs on a failed containment isolation valve when relying on an intact closed system. A Completion Time of 72 hours is considered appropriate given the reliability of the closed system and that 72 hours is typically provided for losing one train of redundancy throughout the NUREG. If the closed system and associated containment isolation valve were both inoperable, the plant would be in LCO 3.0.3 since there is no specific Condition specified.

11-06

TR3

Consistent with NUREG-1431, the CTS SR to demonstrate the OPERABILITY of each containment isolation valve by performance of a cycling and isolation time test prior to returning the valve to service after maintenance, repair, or replacement work on the valve or its associated actuator, control or power circuit has been deleted. Any time repairs, maintenance or modifications have affected the OPERABILITY of a system or component, post-maintenance testing is required to demonstrate operability of the system or component. Particular SRs needed to demonstrate OPERABILITY of the system must be evaluated for each maintenance or modification performed. Explicit post-maintenance and modification TS SRs have therefore been deleted from the ITS because these requirements are inherent in the LCO OPERABILITY requirements.

11-07

LG

Consistent with the NUREG-1431 level of detail, the descriptive material regarding the required containment isolation valve actuation signals in the CTS surveillance requirement is moved to the revised expanded Bases. This is acceptable as the requirement to verify actuation of the valves is retained in the TSs while the identification of the applicable actuation signal is moved to the Bases.

11-08

TR1

The actuation surveillance is revised consistent with NUREG-1431 to clarify that an actual signal as well as a test signal may be used to verify actuation. The actuation signal is moved to the Bases.

**DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)**

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
11-09	A	Consistent with NUREG-1431 and industry Traveler TSTF-46, Rev. 1, the isolation time surveillance is revised to delete the reference to verifying "each power operated" containment isolation valve and only require verification of each "automatic isolation valve." Containment isolation valves which are power operated but do not receive a containment isolation signal (i.e. can be remotely operated), do not have an isolation time assumed in the accident analysis since they require operator action. Therefore, deleting the reference to power operated isolation valve time testing is a clarification that reduces the potential for misinterpreting the requirements of this SR while maintaining the assumptions of the accident analysis.
11-10	A	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
11-11	A	A Note is added to the containment isolation specification that the LCO is not applicable to main steam safety valves (MSSVs), main steam isolation valves (MSIVs), feedwater isolation valves (FIVs), [] and atmospheric dump valve (ADVs). License Amendment (LA) 73/72 (LAR 91-08, 12/26/91) removed the listing of containment isolation valves (Table 3.6-1) and authorized revision of the list under the control of the Administrative section of the TS (e.g., under 10 CFR 50.59). These valves are currently not considered to have a containment isolation function. This note is consistent with current licensing bases.
11-12	A	The phrase "flow path" is added for clarification and constancy with NUREG-1431. This specification is based on GDC 55, 56, and 57 which address the proper isolation for each "line" that penetrates containment. Licensees have always been required to assure that proper protection is provided for each line or flow path that passes through containment even if multiple flow paths share the same penetration. In this specification, the term "penetration" has always meant each flow path that penetrates containment. Adding the words "flow path" to the specification clarifies this meaning.
11-13	LS22	This change revises the DCPP containment ventilation isolation valve leak rate surveillance frequency from 30 months to every 184 days and from 24 hours to 92 days after opening a valve. This change is consistent with NUREG-1431 and NRC resolution of Multi-Plant Action No. B-20, "Containment Leakage Due to Seal Deterioration." These valves have a good service record and have consistently met leakage rate requirements. The revised 92 day frequency still reflects conservative margin to compensate for degradation of the resilient seats in these valves.

**DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)**

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
11-14	A	Consistent with NUREG-1431, the phrase "that is not locked, sealed, or otherwise secured in position" is added for clarification in regard to which valves require isolation time testing. Valves that are secured in place, are secured in the position required to meet their safety function. The isolation time testing ensures that valves can respond to the position that meets their safety function in the time assumed in the safety analysis. If the valves are secured in the position that meets their safety function, no testing is necessary.
11-15	A	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
11-16	A	Even though it is not specified in ITS 3.6.3 Required Actions, the ACTION to restore the inoperable valve stated in CTS 3.6.3.a is understood as always the primary objective and a continuous option to be performed during any Completion Time.
11-17		Not Used.
11-18	LG	This change is not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-01	A	Consistent with NUREG-1431, the hydrogen monitoring specification is moved to improved STS Section 3.3.3 concerning Post Accident Monitoring (PAM) Instrumentation.
12-02	M	Consistent with the MODE of Applicability for PAM instrumentation in NUREG-1431, the MODE of Applicability for the hydrogen monitors is extended to MODE 3.
12-03	LS15	Consistent with NUREG-1431 the ACTION is revised to require a special report be submitted within 14 days in lieu of being in HOT STANDBY within 6 hours, if one train of hydrogen monitoring cannot be restored to operable within 30 days. This is acceptable because the report is required to identify alternative methods for monitoring and plans and schedule for restoring the instrumentation before a loss of functional capability occurs. (See ITS LCO 3.3.3 and 5.6.8)
12-04	M	Adds the requirement to be in HOT SHUTDOWN within 12 hours if both trains of hydrogen monitoring are inoperable and one train was not restored within 72 hours. This is a more restrictive requirement than is currently applied and is being done to be consistent with the PAM requirements in NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
12-05	LS16	Revises the Frequency of the hydrogen monitor surveillance to perform CHANNEL CALIBRATION from 92 days on a staggered test basis to once per 18 months consistent with NUREG-1431. The hydrogen monitors are part of the PAM instrumentation and their primary function is to detect high hydrogen concentration conditions that may occur during accident situations. This change is acceptable because the primary means of reducing hydrogen concentration during accidents is via the independent hydrogen recombiners [and hydrogen purge systems]. Failure of the monitors would not affect the capabilities of [these systems]. Further changing the CHANNEL CALIBRATION surveillance interval from 92 days (on a staggered test basis) to every [18 months] is not expected to effect the reliability or performance of the hydrogen monitors based on industry operating experience.
12-06	LG	The details provided for performing the CHANNEL CALIBRATION are moved out of the SR. This information is procedural in nature and is not consistent with the level of detail in NUREG-1431. The information is moved to the Bases for ITS SR 3.3.3.2.
12-07	M	A new SR is added for DCPD requiring a CHANNEL CHECK every 31 days (if energized) for the hydrogen analyzer/ monitors. This change is consistent with NUREG-1431.
13-01	LS17	A new Condition has been added to this specification. This Condition describes the Required Action for two hydrogen recombiners inoperable. Whereas in the current specification LCO 3.0.3 applied, this change allows up to 7 days to restore one hydrogen recombiner to OPERABLE status, based on the availability of the containment hydrogen purge system to provide the required safety function. In order to use this ACTION time, the Required Actions require that the hydrogen control function be verified available within 1 hour and once every 12 hours thereafter. This administrative verification will assure that the hydrogen purge system is capable of performing the safety function if an event occurs. Also, the Bases for operation of the recombiners indicates that if a design basis event occurs, 8 days or more would elapse before the containment atmosphere approached the lower flammability limit for hydrogen. Therefore, it is reasonable to assume that the inoperability of two hydrogen recombiners will not significantly jeopardize the capability of the facility to respond to a design basis event. This change is consistent with NUREG-1431.
13-02	LS18	The current SR to perform a hydrogen recombiner functional test every 6 months is revised to every 18 months consistent with NUREG-1431. This change is considered acceptable due to the redundancy and proven high reliability of the system. Hydrogen recombiner operating experience has shown that functional test failures are rare. In addition, the fully redundant and independent hydrogen purge system provides an alternate, and equally effective, method of controlling hydrogen. The proposed change is in accordance with NUREG-1366, "Improvement to Technical Specification Requirements" and NUREG-1431.
13-03	LG	Descriptive information regarding the current hydrogen recombiner surveillances is moved into the Bases. The proposed changes to the surveillances are consistent with the wording and detail present in the NUREG-1431 surveillance requirements.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.6
(Continued)

CHANGE NUMBER

NSHC

DESCRIPTION

13-04

LG

The SR to perform a CHANNEL CALIBRATION on all the hydrogen recombiner instrumentation is moved to a Licensee controlled document in accordance with NUREG-1431. These calibrations and any necessary compensatory measures (i.e., substitute test instrumentation) will be controlled administratively by the plant preventive maintenance and operational procedures. This change is acceptable based on the system redundancy, available alternate means of controlling hydrogen, the fact the recombiners are controlled manually, and the instrumentation does not provide essential control or interlock function. In addition, the functional test required by the TS every 18 months verifies the operation of the hydrogen recombiner instrumentation. This change is consistent with NUREG-1431.

13-05

LS23

Added statement that LCO 3.0.4 is not applicable to ACTION. This allowance is based upon the pressure of another 100% hydrogen recombiner, the hydrogen purge system and the time available for operator action after a LOCA.

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR1, 2, 3...." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1

10CFR50.92 EVALUATION
FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A Note is added to valve and blind flange SRs consistent with NUREG-1431. The note allows verification of valves, flanges, and isolation devices located in high radiation areas to be verified by use of administrative means. This change is less restrictive in that the CTS SR 4.6.1.1 has an exception to valves, blind flanges, and deactivated automatic valves which are located inside containment and are locked, sealed, or otherwise secured in the closed position. These valves shall be verified closed during each COLD SHUTDOWN. However, under the CTS, if an area outside of containment became a high radiation area, entry into the area would still be required to verify the closed positions. The ITS would allow verification of all areas that are high radiation areas or become high radiation areas by administrative means once they had been verified to be in the proper position. This is considered acceptable, since access to these areas is restricted for ALARA reasons. Therefore, the probability of misalignment of these devices, once they have been initially verified in the proper position, is small.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves upgrading the Containment Isolation Valve TS to more closely agree with the Westinghouse Standard ITS (NUREG-1431) and does not result in any hardware changes. The isolation devices affected are not assumed to be an initiator of any analyzed event. The isolation devices are passive and serve to limit the consequences of accidents. The proposed change ensures the isolation devices remain positioned to limit the consequences of design basis events as described in the Final Safety Analysis Report (FSAR) and that the results of the analyses in the FSAR remain bounding. Additionally, the proposed change does not impose any new safety analyses limits or alter the plant's ability to detect and mitigate events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves upgrading the Containment Isolation Valve TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change, which upgrades the Containment Isolation Valve TS to be consistent with the Westinghouse Standard TS (NUREG-1431), does not involve a significant reduction in a margin of safety. The proposed change has been developed considering the importance of the isolation devices in limiting the consequences of a design basis event and ALARA concerns for the plant personnel. The proposed change and ALARA access restrictions still ensure the isolation devices are properly positioned to limit the consequences of a design basis event. In addition, the proposed change eliminates unnecessary exposure of plant personnel to high radiation areas.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS1" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A provision, "within 10 days from discovery of failure to meet the LCO," has been added to the Completion Time for the ACTIONS with the "Containment Cooling System" inoperable. The CTS, "Containment Spray," and "Containment Cooling," systems require restoring the inoperable system to OPERABLE status within 72 hours. The CTS limits the inoperability of any combination of these two systems to 72 hours or it provides a maximum of 7 days for restoring one group of cooling fans to OPERABLE status when everything else is OPERABLE. NUREG-1431 provides a maximum of 10 days for not meeting the LCO. The 10 day provision in the Completion Time is considered appropriate based upon engineering judgment considering the low probability of coincident entry into two Conditions in this specification coupled with the low probability of an accident occurring during this time.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves a provision, "within 10 days from discovery of failure to meet the LCO," being added to the Completion Time for the ACTIONS with the "Containment Cooling System" inoperable. The CTS, "Containment Spray," and "Containment Cooling," systems require restoring the inoperable system to OPERABLE status within 72 hours. The CTS limits the inoperability of any combination of these two systems to 72 hours or it provides a maximum of 7 days for restoring one group of cooling fans to OPERABLE status when everything else is OPERABLE. NUREG-1431 provides a maximum of 10 days for not meeting the LCO. The 10 day provision in the Completion Time is considered appropriate based upon engineering judgment considering the low probability of coincident entry into two Conditions in this specification coupled with the low probability of an accident occurring during this time. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation.

The proposed change will make a provision for a maximum 10 day allowance for not meeting the LCO. The provision takes into account the capability of the remaining systems based upon the applicable Conditions entered. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (continued)

3. Does this change involve a significant reduction in a margin of safety?

Analysis shows that [one train of the containment cooling together with one train of containment spray] can provide 100 percent of the required peak cooling capacity during the post accident Conditions. The provision to allow 10 days not meeting the LCO for one containment spray train inoperable, or one train of the required containment cooling trains inoperable, is acceptable taking into account the low probability of coincident entry into two Conditions coupled with the low probability of an accident occurring during this time. The provision also takes into account the capability of the remaining systems based upon the applicable Conditions entered. Thus, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS2" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, a Note has been added to the Containment Airlock TS to allow entry and exit into containment via the air locks if both air locks are inoperable and administrative controls are provided. This is permitted for up to 7 days. With both air locks inoperable, containment entry may be required on a periodic basis to perform TS surveillances and Required ACTIONS, as well as other activities on equipment inside containment. This Note provides allowance for these activities to be performed.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves changing the Containment Air Lock TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not result in any hardware changes. The containment air lock is not assumed to be the initiator of any analyzed event. The role of the containment air lock is in containing releases to the containment during a design basis accident (DBA), and thereby limiting consequences. The requested change does not allow continuous operation such that a single failure could allow a release from containment during a DBA. The proposed allowance would only apply for 7 days. Therefore, the likelihood of the door being open when an accident occurs is very small. Additionally, during the period when this allowance applies, entry and exit is supervised by personnel such that in the event of an incident or unusual condition the operable air lock door could be quickly closed, thereby reestablishing the containment boundary. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves changing the Containment Air Lock TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will still ensure the containment boundary is capable of being maintained. Since air lock malfunction is not the initiator of any event, having the air lock open for a brief period during plant operation could not result in the occurrence of a new or different type of accident. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change, which revises the Containment Air Lock TS to be consistent with the Westinghouse Standard TS (NUREG-1431), does not involve a significant reduction in a margin of safety. The allowance to permit entry and exit under administrative controls is acceptable based on the small probability of an event requiring the containment air lock to mitigate consequences of DBAs occurring while the air lock is open. The requested change provides the ability to repair an inoperable air lock door or enter containment to perform surveillances with both air locks inoperable. The exposure of the plant to the small probability of an event requiring the operable containment air lock to be closed during the short time period it is opened to permit entry and exit under administrative controls is insignificant. Additionally, this change provides the benefit of avoiding an unnecessary plant shutdown transient by allowing entry and exit to perform surveillances or Required Actions.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS3" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The allowance to continue operation with one air lock door inoperable has been modified to remove the restriction which limits this condition until the next overall air lock leakage test. This restriction was removed because the air lock remains capable of performing its safety function with the remaining operable door. Therefore, continued operation may proceed indefinitely subject to the other restrictions of the TS (continuing to meet the ACTIONS and applicable surveillances). This change is consistent with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes. An inoperable air lock door is not assumed to be an initiator of any accident previously evaluated. The change allows operation to continue if the overall air lock leakage test passes since the containment boundary is maintained intact in this Condition by the remaining operable door. Administrative controls are implemented to provide an interlock function such that containment integrity is not jeopardized. As such, no increase in the probability or consequences of an accident is involved with this change.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will provide an allowance to continue operations indefinitely with one air lock door inoperable subject to the other restrictions of the specification. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

No reduction in a margin of safety is involved since the containment boundary remains intact and compensatory administrative controls are invoked such that there is no adverse impact created by this change. In addition, this change provides the benefit of avoiding an unnecessary plant transient required by TS when overall leakage is still within limits.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4
(continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS4" resulting from the conversion to the ITS format satisfy the NSCH standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, this note modifies the requirement to verify an air lock door locked closed every 31 days. The note allows the verification of locked closed air lock doors located in high radiation areas to be performed by use of administrative means. This change is less restrictive in that the CTS does not allow this exception due to current design and capability to verify the inner door locked from outside the containment airlock. Under the CTS, if an area outside of the airlock became a high radiation area, entry into the area would still be required to verify the closed positions. The ITS would allow verification of all areas that are high radiation areas or become high radiation areas by administrative means once they had been verified to be in the proper position. This is considered acceptable, since access to these areas is restricted for ALARA reasons. Therefore, the probability of misalignment of the air lock doors once they have been initially verified in the proper position, is small.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves changing the Containment Air Lock TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not result in any hardware changes. The air locks are not assumed to be an initiator of any analyzed event. The air locks are passive and serve to limit the consequences of accidents. The proposed change still ensures the air locks remain closed to limit the consequences of design basis events as described in the FSAR and that the results of the analyses in the FSAR remain bounding. Additionally, the proposed change does not impose any new safety analyses limits or alter the plant's ability to detect and mitigate events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves changing the Containment Air Lock TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The air locks are not the initiators of any event. Allowing verification of the position of the operable air lock door by administrative means if the door is located in a high radiation area could not result in the occurrence of a new or different kind of accident. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change, which revises the Containment Air Lock TS to be consistent with the Westinghouse Standard TS (NUREG-1431), does not involve a significant reduction in a margin of safety. The proposed change has been developed considering the importance of the air locks in limiting the consequences of a design basis event and ALARA concerns for the plant personnel. The proposed change and ALARA access restrictions still ensure the isolation devices are properly positioned to limit the consequences of a design basis event. In addition, the proposed change eliminates unnecessary exposure of plant personnel to high radiation areas.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS5" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, a Condition and associated Required Actions have been added which allows continued operation when the personnel air lock is inoperable due to an inoperable interlock mechanism. Use of the air lock is permissible under the control of a dedicated individual since an equivalent level of assurance that only one door will be open at a time is provided. The ACTIONS and modifying notes provided for the interlock mechanism are consistent with the ACTIONS and notes for an inoperable air lock door. These ACTIONS ensure that an operable door is closed and locked and entry or exit is controlled by a dedicated individual. While this change provides a slightly less restrictive TS requirement, the overall impact on plant safety is negligible due to the Required Actions implemented.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes. The air lock door interlock mechanism is not assumed to be an initiator of any accident previously evaluated. The function of the air lock door mechanism is to prevent simultaneous opening of both doors in a single air lock, thus providing a release path from containment to the environment. Both the inner and outer doors of an air lock are designed to withstand the maximum expected post-accident containment pressure. During the time when the air lock door interlock mechanism is inoperable, and ingress and egress of containment is necessary, the use of a dedicated individual is provided to ensure only one air lock door is opened at a time. This method of control is reasonable since an equivalent level of assurance is provided that one door in a single air lock will remain closed, thereby ensuring that containment remains operable. The consequences of an event occurring during the indefinite operation with the air lock door interlock mechanisms inoperable are the same as the consequences of an event occurring during the current allowance of 24 hours. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Since the air locks are not the initiators of any event and serve only to mitigate the consequences of events, this change could not result in the occurrence of a new or different kind of accident. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed allowance to use a dedicated individual to ensure one air lock door in a single air lock is maintained closed when the air lock door interlock mechanism is inoperable does not have any effect on accident or transient analyses. As a result, the proposed change deletes the requirement to place the plant in MODE 3 when the air lock door interlock mechanism is inoperable. This is considered acceptable since the dedicated individual serves the function of the interlock mechanism to ensure one air lock door is always maintained closed. The closed single air lock door is designed to withstand the maximum expected post-accident containment pressure, and thereby ensures the assumptions of the applicable safety analysis are maintained. As such, any reduction in a margin of safety created by allowing the air lock door interlock mechanism to be inoperable for an indefinite time will be offset by the benefits gained by avoiding an unnecessary plant transient when an adequate compensatory measure exists.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS6" resulting from the conversion to the ITS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, a Note is added to allow unrestricted access (entry and exit) to repair air lock components in an inoperable air lock. The ACTION requirement to close and lock an air lock door remains applicable with the exception of the brief entry and exit of the air lock to perform necessary repairs. The allowance to enter and exit through the air lock door required closed by the ACTIONS is acceptable based on the low probability of an event occurring that could challenge the containment boundary during the short time the door is open for entry and exit. In addition, this allowance reduces the potential risk incurred during a plant transient that may result from a shutdown required by TS due to the inoperable air lock.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves changing the Containment Air Lock TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not result in any hardware changes. The containment air locks are not assumed to be the initiator of any analyzed event. The containment air locks are assumed closed in the safety analyses to limit the consequences of accidents. The proposed change allows the locked closed door to be opened briefly to facilitate entry and exit for repairs. The brief time the door is open for entry or exit is acceptable based on the extremely low probability of an event occurring that would challenge the containment boundary in the brief time it takes to enter or exit through the air lock door. The proposed change does not alter the intent of the TS requirement which, in effect, still ensures that the containment air locks will remain closed to limit the consequences of design basis events as described in the FSAR and that the results of the analyses in the FSAR remain bounding. Additionally, the proposed change does not impose any new safety analyses limits or alter the plant's ability to detect and mitigate events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves changing the Containment Air Lock TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change, which revises the Containment Air Lock TS to be consistent with the Westinghouse Standard TS (NUREG-1431), does not involve a significant reduction in a margin of safety. The proposed change allows the locked closed air lock door to be opened briefly to facilitate entry and exit for repairs. The brief time the door is open for entry or exit is acceptable based on the extremely low probability of an event occurring that would challenge the containment boundary in the brief time it takes to enter or exit through the air lock door. Therefore, the proposed change does not alter the intent of the TS requirement, which in effect, still ensures that the containment air locks will remain closed to limit the consequences of design basis events as described in the FSAR and that the results of the analyses in the FSAR remain bounding. In addition, the proposed change reduces the potential risk incurred during a plant transient that may result from a shutdown required by TS due to the inoperable air lock. Therefore, any reduction in the margin of safety is insignificant and offset by the reduction in potential plant transients.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS7" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with industry Traveler TSTF-17, Rev. 1, this change would extend the testing frequency for the containment airlock interlock mechanisms from 6 months to 24 months.

Air lock interlock mechanisms are typically enabled after each refueling outage, then verified OPERABLE with this surveillance, and not disturbed until the next refueling outage. Should the need for maintenance on an interlock mechanism arise while the interlock is required, performance of this surveillance would be required following the interlock maintenance. In addition, when an air lock is opened during the time the interlock is required, the operator first verifies that one door is completely shut before attempting to open the other door. Therefore, the interlock is not normally challenged except during actual testing of the interlock. Consequently, testing of the interlock on a 24 month interval is sufficient to ensure its proper operation.

Testing of the air lock mechanism is accomplished through having one door open, then attempting to open the second door. Failure of the interlock as a result of this surveillance would effectively result in a momentary loss of containment integrity until one door could be reclosed. The air lock interlock mechanism is not challenged during ingress and egress based on training, procedures, and conservative operating practices. One door is opened, all personnel and equipment as necessary are placed into the air lock, and then the door is completely closed prior to attempting to open the second door. Performance of this surveillance when the interlock function is required is contrary to conservative operating practices and training. In addition, failure rates of the interlock mechanisms are very low due to their design. Also, the door interlock mechanisms cannot be readily bypassed and are under the control of station administrative processes. By adopting a 24 month interval for the required testing frequency, the number of challenges to containment integrity due to interlock testing would be reduced.

Historically, the interlock verification frequency has coincided with the frequency of the overall air lock leakage test, which in accordance with 10 CFR 50, Appendix J, Option A, is once per 6 months. With the adoption of Appendix J, Option B, the overall air lock leakage test frequency requirement is 30 months. By changing the required interlock test surveillance frequency to 24 months the interlock testing frequency would correspond to the overall air lock leakage test frequency allowable under Option B.

The 24 month interlock frequency is based on engineering judgement and is considered adequate given that the interlock mechanism is not normally challenged when the containment air lock door is used for entry and exit.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8 (Continued)

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change extends the testing frequency of containment interlock mechanisms from 6 months to 24 months. This change is consistent with the change proposed to the Westinghouse TS (NUREG-1431) by industry traveler TSTF-17, Rev. 1. The air lock does not serve as an initiator of an accident nor does this change result in any hardware changes. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change extends the testing frequency of containment air lock interlock mechanisms from 6 months to 24 months. The change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Since the air locks are not the initiators of any event and serve only to mitigate the consequences of events, this change could not result in the occurrence of a new or different kind of accident. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not affect the acceptance criteria for any analyzed event. The interlock mechanism is not normally challenged when the containment air lock door is used for entry and exit, nor is it challenged during an accident. By adopting a 24 month interval for the required frequency the number of challenges to containment integrity due to interlock testing would be reduced. None of these changes impact the margin of safety in any way. Thus there is no reduction in the margin of safety from that previously established.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS8" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The required ACTION for a containment ventilation isolation valve not within its leakage limit is revised to allow the penetration to be isolated using a closed and deactivated automatic valve, a closed manual valve or a blind flange and does not require the isolation valve to be restored to OPERABLE status. This is an option not explicitly available in the CTS. The Completion Time of 24 hours remains the same as in the CTS. If valves with resilient seals are used to isolate the flow path, the leakrate of these valves must be verified at least every 92 days. If a blind flange is used to isolate the penetration flow path, the valves with resilient seals whose flow is isolated by the blind flange are not required to be leakrate tested. Isolation of the flow path with a leak tested blind flange provides the required leak barrier and additional leak testing of the valves in the flow path is redundant and unnecessary.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes. The role of these valves during an accident is to isolate containment, and thereby limit accident consequences. The proposed ACTIONS will not allow continuous operation such that containment leakage after an accident will exceed assumed values. With the associated penetrations isolated per the proposed ACTION requirements, no accident as a result of the leaking valve is credible. Further, with the line isolated it cannot contribute to the consequences of a previously evaluated accident. Therefore, this change will not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change is acceptable since the isolated penetration provides protection equivalent to restoring the valve to OPERABLE status. Providing the option to isolate the penetration will minimize the potential for plant transients that could occur during a shutdown required by TS if the isolation valve could not be restored to OPERABLE status. In addition, the isolation of the line (in accordance with the proposed Required Action) ensures that leakage through the associated penetration is within limits. As such, any reduction in a margin of safety will be insignificant and offset by the benefit gained through avoiding an unnecessary plant transient.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS9" resulting from the conversion to the ITS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS13
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A Note is added to the ACTIONS in accordance with the NUREG-1431, LCO 3.6.3, Containment Isolation Valves which provides an allowance to open, under administrative controls, containment isolation valves required to be closed []. This is acceptable based on administrative controls consisting of a dedicated operator at the valve in continuous communication with the control room. These controls provide for the capability to manually close the isolation valve should an automatic isolation be required. []

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves changing the Containment Isolation Valve TS to more closely agree with the Westinghouse Standard TS (NUREG-1431). The change does not result in any hardware changes. The isolation valves act to isolate the containment penetrations in the event of a DBA and serve to limit the consequences of accidents. The proposed change continues to ensure that the isolation valves will perform their required function and limit the consequences of design basis events as described in the FSAR and that the results of the analyses in the FSAR remain bounding. The proposed change does not impose any new safety analyses limits or alter the plant's ability to detect and mitigate events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves changing the Containment Isolation Valve TS to more closely agree with the Westinghouse Standard TS (NUREG-1431) and does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS13 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change revises the Containment Isolation Valve TS to be consistent with the Westinghouse Standard TS (NUREG-1431) and does not involve a significant reduction in a margin of safety. The proposed change has been developed considering the importance of the containment isolation valves in limiting the consequences of a design basis event and the concerns for the plant's ability to perform required operational support functions with necessary systems isolated. The proposed change allows for protection commensurate with that provided by an automatic isolation system. Considering the probability of an event that would challenge the containment boundary, the alternative protection provided by this change and the operational requirements to occasionally open these valves, the proposed change is acceptable and any reduction in the margin of safety insignificant.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS13" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14
10 CFR 50.92 EVALUATION
FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A new Condition and Required Actions consistent with NUREG-1431 and modified in accordance with TSTF-30, Rev. 1, is added to the current Containment Isolation Valve TS to cover the case where one containment isolation valve is inoperable in a penetration flow path of the type configured with only one containment isolation valve and a closed system. GDC 57 allows the use of a closed system in combination with a containment isolation valve to provide the two containment barriers against the release of radioactive material following an accident. The CTS LCO 3.6.3 does not allow the use of a closed system to isolate a failed containment isolation valve even though the closed system is subjected to a Type A containment leakage test, is missile protected, and is seismic Category I piping. A closed system also typically has flow through it during normal operation such that any loss of integrity could be continually observed through leakage detection systems within containment and system walkdowns for closed systems outside containment. As such, the use of a closed system is no different from isolating a failed containment isolation valve by use of a single valve as specified in NUREG-1431 Required Action A.1. Therefore, in accordance with NUREG-1431 and Traveler TSTF-30, Rev. 1, the Required Action for this condition allows 72 hours to isolate a failed valve associated with a closed system. 72 hours provides the necessary time to perform repairs on a failed containment isolation valve when relying on an intact closed system. A Completion Time of 72 hours is considered appropriate given that certain valves may be located inside containment, the reliability of the closed system, and that 72 hours is typically provided for losing one train of redundancy throughout NUREG-1431. If the closed system and associated containment isolation valve were both inoperable, the plant would be in LCO 3.0.3 since there is no specific Condition specified.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

Consistent with NUREG-1431 as modified in accordance with industry Traveler TSTF-30, Rev. 1, the proposed change adds a new Condition and Required Actions to the Containment Isolation Valves specification for the case where one containment isolation valves is inoperable in a penetration flow path of the type configured with only one containment isolation valve and a closed system. GDC 57 allows the use of a closed system in combination with a containment isolation valve to provide two containment barriers. This change does not result in any hardware changes or alter the plant's ability to detect and mitigate events. Since containment isolation is an accident mitigating function and not an initiator of an accident, it can not increase the probability of an accident. The use of a closed system is no different from isolating a failed containment isolation valve by use of a single valve. A completion time of 72 hours is appropriate given that certain valves may be located inside containment, the reliability of the closed system, and that 72 hours is typically provided for losing one train of redundancy throughout the NUREGs. Therefore, this change will not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation, and does not impose any new safety analyses limits. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change adds a new Condition and Required Actions to the Containment Isolation Valves specification to be consistent with the Westinghouse Standard TS (NUREG-1431) and does not involve a significant reduction in a margin of safety. The proposed change has been developed considering the importance of the containment isolation valves in limiting the consequence of a design basis event and the reasonable time to perform repairs on a failed containment isolation valve when relying on an intact closed system. Considering the probability of an event that would challenge the containment boundary and the reliability of the closed system, the proposed change is acceptable and any reduction in the margin of safety would be insignificant. As such any reduction in margin of safety will be insignificant and offset by the benefit gained through avoiding an unnecessary plant transient.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS14" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly, a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The requirements for the hydrogen monitors are combined into the new PAM TS and revised to be consistent with other PAM instrumentation. The current containment hydrogen monitor ACTION statements are replaced by the specified NUREG-1431 Conditions. These Conditions are based on the required channels operable column. The 30 day Completion Time allowed by the NUREG-1431 is based on operating experience and takes into account the remaining OPERABLE channel and the function of the instrument (no critical automatic action is initiated from this instrumentation). The requirement to submit a special report in lieu of a plant shutdown is appropriate since alternative ACTIONS are identified before a loss of functional capability occurs and given the likelihood of unit conditions that would require information provided by this instrumentation. These changes are consistent with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated. The proposed changes affect instrumentation that would be used to assess the condition of the plant during and following an accident. As such, the changes can have no effect on the probability of any accident previously evaluated since the hydrogen monitors have no bearing on initiating events. The proposed changes will continue to ensure the capability to monitor plant conditions during and following an accident by requiring redundancy or diversity and timely corrective action in the event of inoperable instrumentation. Therefore, the proposed changes will not significantly increase the consequences of any accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed changes affect the operability and action requirements for the PAM instrumentation system. Accordingly, the proposed changes do not involve any change to the configuration or method of operation of any plant equipment, and no new failure modes have been defined for any plant system or component nor has any new limiting failure been identified as a result of the proposed changes. Therefore, the proposed changes do not create the possibility of a new or different kind of accident from any previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed changes do not involve a significant reduction in a margin of safety. The intent of the existing TS requirements is to ensure the capability to monitor the plant condition during and following an accident so that the operators will have the information necessary to monitor and evaluate the course of the event and take any necessary action. Under the proposed changes this capability will be maintained by ensuring redundancy or diversity and by requiring timely corrective action in the event of inoperable instrumentation. In addition, the proposed changes would avoid unnecessary plant shutdowns by specifying an appropriate level of action in response to inoperable instrumentation. Therefore, the proposed changes do not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS15" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Revises the frequency of the hydrogen monitor surveillance to perform CHANNEL CALIBRATION from 92 days on a staggered basis to once per 18 months consistent with NUREG-1431. The hydrogen monitors are part of the PAM instrumentation and their primary function is to provide information required by the control room operator during accident situations. The hydrogen monitors are provided to detect high hydrogen concentration conditions that represent a potential for containment breach from a hydrogen explosion.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The hydrogen monitors provide information required by the control room operator during accident situations and their failure would not increase the probability of an accident previously evaluated.

The failure of the hydrogen monitors could potentially increase the consequences of an accident previously evaluated if hydrogen were allowed to accumulate during an accident situation. However, the primary means of reducing hydrogen concentration during accidents is via the independent hydrogen recombiners []. Failure of the monitors would not affect the capabilities of that system. Further, the extension of the CHANNEL CALIBRATION surveillance interval from 92 days (on a staggered test basis) to every 18 months is not expected to effect the reliability or performance of the hydrogen monitors based on industry operating experience. Also, this surveillance interval is consistent with frequency of other PAM instrumentation. Therefore the extension of the surveillance interval would not involve a significant increase in the consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change affects the frequency of a SR for the PAM instrumentation system. It does not involve any change to the configuration or method of operation of any plant equipment, and no new failure MODES have been defined for any plant system or component, nor has any new limiting failure been identified as a result of the proposed change. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16 (continued)

3. Does this change involve a significant reduction in a margin of safety?

The accident analyses are assumed to be initiated from Conditions which are consistent with the TS LCO. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Further, the proposed change has no effect on any actual or regulated failure point which is protected by an event acceptance criterion. Because there is no change in any failure point nor in any event acceptance criteria, there is no reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS16" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A new Condition and Required Action have been added to this specification. This Condition describes the Required Action for two hydrogen recombiners inoperable. This change allows up to 7 days to restore one hydrogen recombiner to OPERABLE status, based on the availability of the containment hydrogen purge system to provide the required safety function. In order to utilize this action time, the Required Actions require that the hydrogen control function be verified available within 1 hour and once every 12 hours thereafter. This administrative verification will assure that other means of controlling hydrogen, e.g., hydrogen purge, are capable of performing the safety function if an event occurs. Also, the Bases for operation of the recombiners indicates that if a design basis event occurs, 8 or more days would elapse before the containment atmosphere approached the lower flammability limit for hydrogen. It is, therefore reasonable to assume that the inoperability of two hydrogen recombiners will not significantly jeopardize the capability of the facility to respond to a design basis event. This change is consistent with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change does not result in any hardware changes. The hydrogen recombiners are not assumed to be initiators of any analyzed event. The proposed change allows two hydrogen recombiners to be inoperable for up to 7 days provided an alternate hydrogen control function is available. The alternate hydrogen control capability is provided by the containment hydrogen purge system. This method of hydrogen control is acceptable since the hydrogen purge system is capable of maintaining the hydrogen concentration in containment below flammability limit, thus ensuring the pressure and temperature assumed in the applicable safety analysis are not exceeded. A 1 hour Completion Time to initially verify the availability of the alternate hydrogen control function and additional verification once per 12 hours thereafter, is an acceptable frequency to ensure the alternate hydrogen control function is maintained. The proposed Completion Time of 7 days is a reasonable time to allow two hydrogen recombiners to be inoperable because the hydrogen control function is maintained and because of the low probability of a DBA, which would generate hydrogen in the amount capable of exceeding the flammability limit. While the hydrogen purge system maintains the hydrogen concentration below the lower flammability limit during a loss-of-coolant accident (LOCA), its operation is fundamentally different than the operation of the hydrogen recombiners. The hydrogen recombiners process containment atmosphere entirely within the containment (i.e., suction and discharge remain in the containment), whereas the hydrogen purge system takes suction on the containment atmosphere, processes it outside containment via atmospheric cleanup units (particulates, iodine absorbers, and HEPA filters), and exhausts the cleansed air through the vent stacks.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17 (continued)

Vent stack radiation monitors help to ensure the exhaust remains within discharge limits. Outside air replaces the exhaust air to maintain containment pressure. The operation of the hydrogen purge system allows some gaseous radioactive products to escape the containment (e.g., noble gases), and may increase the potential of an inadvertent radioactive release. However, the design of the hydrogen purge system and testing requirements, as well as the vent stack monitoring ensure that operation of the system does not significantly increase the potential for releases in excess of accidents previously evaluated. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change will allow two hydrogen recombiners to be inoperable for up to 7 days provided an alternate hydrogen control function is maintained. The change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The allowance to have two hydrogen recombiners inoperable for up to 7 days, provided an alternate hydrogen control function is available, does not have any effect on accident or transient analysis. Use of the hydrogen purge system as the alternate means of hydrogen control ensures the temperature and pressure assumptions in the applicable safety analysis are maintained. The 1 hour Completion Time to initially verify the availability of the alternate hydrogen control function, and the additional verification once per 12 hours thereafter, is an acceptable frequency to ensure availability of the hydrogen purge system is maintained. The 7 day Completion Time to restore the inoperable hydrogen recombiners prior to requiring a plant shutdown is acceptable based on the small probability of an event requiring the hydrogen recombiners to function during this time period and the availability of the hydrogen purge system to control hydrogen concentration in containment. Providing the 7 day Completion Time when two hydrogen recombiners are inoperable will minimize the potential for plant transients that can occur while shutting down the plant by providing an adequate time to restore an inoperable hydrogen recombiner to operable status. As such, any reduction in a margin of safety by allowing two hydrogen recombiners to be inoperable for 7 days will be offset by the benefits gained by avoiding an unnecessary plant transient by providing adequate time to restore a hydrogen recombiner to OPERABLE status when the hydrogen control function can still be satisfied.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS17" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS18
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The current surveillance requirement to perform a hydrogen recombiner functional test every 6 months is revised to every 18 months consistent with NUREG-1431. This change is considered acceptable due to the redundancy and proven high reliability of the system. Hydrogen recombiner operating experience has shown that functional test failures are rare. In addition, the fully redundant and independent hydrogen purge system provides an alternate, and equally effective, method of controlling hydrogen. The proposed change is in accordance with NUREG-1366, "Improvement to Technical Specification Requirements," and NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change, to extend the surveillance interval for the hydrogen recombiner functional tests, does not result in any hardware changes. The hydrogen recombiners are not assumed in the initiation of any analyzed event. Their role is in reducing hydrogen concentration in containment, and thereby limiting potential accident consequences. Hydrogen recombiner operating experience has shown that functional test failures are rare. Thus, the extended surveillance interval will not result a loss in the capability to reduce hydrogen concentration in containment. Additionally, in the unlikely event both recombiners fail, a diverse method of reducing hydrogen concentration is available utilizing the containment purge system.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will still ensure the recombiners are maintained operable. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The increased interval between hydrogen recombiner functional tests is acceptable based on the relative simplicity of the recombiner system and industry experience which indicates that the recombiner availability can be assured with reduced testing. As a result, any reduction in a margin of safety will be insignificant.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS18
(continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS18" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS19
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change would specify that containment isolation valves which are locked, sealed, or otherwise secured are not required to be verified closed during periodic surveillances since these were verified to be in the correct position prior to locking, sealing, or securing. If locked, sealed, or otherwise secured manual valves, blind flanges, and deactivated automatic valves are closed to satisfy an ACTION (e.g., 3.6.3) the position must be verified but may be verified by administrative means. This change is consistent with NUREG-1431 requirements for other valves required to be in the correct position prior to an accident, i.e. emergency core cooling system (SR 3.5.2.2), auxiliary feedwater (SR 3.7.5.1), and SW (SR 3.7.8.1) and is in accordance with industry Traveler TSTF-45 and WOG-91. The probability of misalignment of these devices, once they have been initially verified in the proper position, is small.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change, to not require that containment isolation valves which are locked, sealed, or otherwise secured be verified closed during periodic surveillance (or to verify their closure was required by a required action), involves upgrading the Containment Isolation Valve TS to more closely agree with the Westinghouse Standard ITS (NUREG-1431) and does not result in any hardware changes. The isolation devices affected are not assumed to be an initiator of any analyzed event. The isolation devices are passive and serve to limit the consequences of accidents. The proposed change would still ensure that the isolation devices remain positioned to limit the consequences of design basis events as described in the FSAR and that the results of the analyses in the FSAR remain bounding. Additionally, the proposed change does not impose any new safety analyses limits or alter the plant's ability to detect and mitigate events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration to the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change would still ensure that the isolation devices remain positioned to limit the consequences of design basis events as described in the FSAR and that the results of the analyses in the FSAR remain bounding. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS19 (Continued)

3. Does this change involve a significant reduction in a margin of safety?

This change would specify that containment isolation valves which are locked, sealed, or otherwise secured are not required to be verified closed during periodic surveillance since these were verified to be in the correct position prior to locking, sealing, or securing. The proposed change still ensures that the isolation devices are properly positioned to limit the consequences of a design basis event. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS19" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS22
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change revises the containment ventilation isolation valve leakage surveillance frequency after opening a valve from 24 hours to 92 days. This change is consistent with NUREG-1431. These valves have a good service record and have consistently met leakage rate requirements. The revised 92 day frequency still reflects conservative margin to compensate for degradation of the resilient seats in these valves. This change also adds the more restrictive change that the valves be leak tested every 184 days (CTS states 18 months) even if they have not been used.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92 (c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

These valves fully meet the requirement of the Branch Technical Position CSB 6-4 (except for their larger size). The ten year service records for these valves show that they consistently meet their leakage rate limits. The revised surveillance frequency still retains the NRC recommended adequate margin to compensate for the fact that these valves are resilient seated valves. Therefore, the proposed change to surveillance frequency does not effect the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change to the surveillance frequency does not involve a physical alteration to any plant equipment, causes no change in the method by which any safety related system performs its function, and does not alter the manner in which any safety system is operated. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

These valves fully meet the requirement of the Branch Technical Position CSB 6-4 (except for their larger size). The [nine] year service records for these valves show that they consistently meet their leakage rate limits. The revised surveillance frequency still retains the NRC recommended adequate margin to compensate for the fact that these valves are resilient seated valves. Therefore, there is no significant reduction in the margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS22
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based upon the preceding information, it has been determined that the proposed changes associated with NSHC "LS22" do not involve a significant increase in the probability or consequences of an accident previously evaluated, create the possibility of a new or different kind of accident from any accident previously evaluated, or involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed change meets the requirements of 10 CFR 50.92 (c), and does not involve a significant hazards consideration.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS23
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The current ACTION statement, "with one of the two Hydrogen Recombiner Systems inoperable, restore the inoperable Hydrogen Recombiner System to OPERABLE status within 30 days or be in at least HOT STANDBY within the next 6 hours," is being modified by a note that states the provisions of LCO 3.0.4 are not applicable consistent with NUREG-1431, Rev. 1. This allowance is based on the availability of the other hydrogen recombiner, the small probability of a LOCA or SLB occurring (that would generate an amount of hydrogen that exceeds the flammability limit), and the amount of time available after a LOCA or SLB (should one occur) for operator action to prevent hydrogen accumulation from exceeding the flammability limit.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes. The hydrogen recombiners are not assumed in the initiation of any analyzed event. In the condition that is being revised, one containment hydrogen recombiner inoperable, the inoperable recombiner must be restored to OPERABLE status. However, the remaining OPERABLE hydrogen recombiner is adequate to perform the hydrogen control function. The overall reliability is reduced because a single failure in the OPERABLE recombiner could result in reduced hydrogen control capability. The added note, "the provisions of 3.0.4 not applicable," allows a MODE change when one recombiner is inoperable. Exceptions to the requirements of 3.0.4 allow entry into MODES or other specified Conditions in the Applicability when the associated ACTIONS to be entered allow unit operation in the MODE or other specified Condition in the Applicability only for a limited period of time. Additionally, in the unlikely event both recombiners fail, a diverse method of reducing hydrogen concentration is available utilizing the containment purge system. Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS23 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will still ensure the recombiners are maintained operable. This change is being made consistent with NUREG-1431 that allows entry into MODES or other specified Conditions in the Applicability when the associated ACTIONS to be entered allow unit operation in the MODE or other specified Condition in the Applicability only for a limited period of time. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

In the Condition that is being revised, one containment hydrogen recombiner inoperable, the inoperable recombiner must be restored to OPERABLE status. However, the remaining OPERABLE hydrogen recombiner is adequate to perform the hydrogen control function. The overall reliability is reduced because a single failure in the OPERABLE recombiner could result in reduced hydrogen control capability. However, in the unlikely event both recombiners fail, a diverse method of reducing hydrogen concentration is available utilizing the containment purge system. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS23" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c) and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR1 10 CFR 50.92 EVALUATION FOR RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the existing TS to additionally allow the use of actual actuation signals for surveillances that currently call for testing using simulated test signals only. This change achieves consistency with the proposed ISTS (NUREG-1431).

In several specifications throughout the TS, OPERABILITY of certain equipment is demonstrated by ensuring that the equipment performs its safety function upon receipt of a simulated test signal. The intent of a 'simulated' signal was to be able to perform the required testing without the occurrence (or without causing) an actual signal generating event. However, the unintended effect was to require the performance of the surveillance (using a test signal) even if an actual signal had previously verified the operation of the equipment. This change allows credit to be taken for actual events when the required equipment actuates successfully.

While the occurrence of events that cause actuation of accident mitigation equipment is undesirable, the actuation of mitigation equipment on an actual signal is a better demonstration of its OPERABILITY than an actuation using a test signal. Thus the change does not reduce the reliability of the equipment tested. The change also improves plant safety by reducing the amount of time the equipment is taken out of service for testing and thereby increasing its availability during an actual event and by reducing the wear of the equipment caused by unnecessary testing.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or
2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or
3. Involve a significant reduction in a margin of safety."

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change allows the use of an actual actuation signals (when/if it occurs) to satisfy SRs currently requiring simulated test signals to demonstrate equipment OPERABILITY. While the change takes advantage of events that may have occurred, it has no adverse effect on any accident initiators or accident consequences. In fact, by potentially reducing unnecessary testing, it may reduce the probability of an accident because the testing itself can increase the probability of an accident. It may also reduce accident consequences by increasing the equipment availability (i.e., less time in test). Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR1 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The use of an actual actuation signal to satisfy a SR has either no impact on, or increases the margin of plant safety by:

- a) Increasing mitigation equipment availability, and,
- b) Improving mitigation equipment reliability by potentially reducing wear caused by unnecessary testing.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "TR1" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR2
10 CFR 50.92 EVALUATION
FOR
RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change in accordance with NUREG-1431, Rev. 1, removes the requirement for a special report to be generated and submitted to the NRC. Reporting to the NRC will be done commensurate with the reporting requirements of 10CFR 50.72 and 50.73.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This change is purely an administrative reporting change and cannot affect any accident probability or consequences.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

This change is purely an administrative reporting change and cannot create any new accident or affect any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

This change is purely an administrative reporting change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "TR2" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR3
10 CFR 50.92 EVALUATION
FOR
RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision is to remove reference to specific post-maintenance tests from the ITS. Post-maintenance testing programs are controlled via plant administrative procedures in accordance with licensee controlled document (ITS Section 5.4.1, Procedures) commitments to NRC RG 1.33, "Quality Assurance Program Requirements (Operation)" and ANS 3.2-ANSI N 18.7, "Administrative Controls and Quality Assurance for the Operational Phase of Nuclear Power Plants." Specific post-maintenance testing requirements are contingent on the type and scope of maintenance actually performed as well as the availability and viability of test equipment, techniques, etc. Removal of specific testing requirements from the ITS and reliance on normal post-maintenance testing programs addressed by licensee controlled documents allow flexibility to modify testing to address the circumstances of the maintenance performed while still assuring OPERABILITY of equipment returned to service,

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated;*
or
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated;*
or
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

This is an administrative change which removes specific post-maintenance test requirements from TS. The testing, or equivalent testing, to assure equipment OPERABILITY prior to return to service would still be done as required by normal plant maintenance retest programs. Therefore, this change would not result in any increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

This is an administrative change and does not create a new or different kind of accident from any previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

This change is an administrative change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "TR3" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.1 Containment (Atmospheric)

BASES

BACKGROUND The containment consists of the concrete reactor building, its steel liner, and the penetrations through this structure. The structure is designed to contain radioactive material that may be released from the reactor core following a Design Basis Accident (DBA). Additionally, this structure provides shielding from the fission products that may be present in the containment atmosphere following accident conditions.

The containment is a reinforced concrete structure with a cylindrical wall, a flat foundation mat with a reactor cavity pit projection, and a shallow hemispherical dome roof. The inside surface of the containment is lined with a carbon steel liner to ensure a high degree of leak tightness during operating and accident conditions.

~~For containments with ungrouted tendons, the cylinder wall is prestressed with a post tensioning system in the vertical and horizontal directions, and the dome roof is prestressed utilizing a three way post tensioning system.~~

~~The exterior shell and concrete reactor building structure around the reactor vessel (crane wall and bio-shield wall) is required for structural integrity of the containment under DBA conditions. The steel liner and its penetrations establish the leakage limiting boundary of the containment. The steel liner additionally provides support and anchorage for safety related piping and electrical raceway. Maintaining the containment OPERABLE limits the leakage of fission product radioactivity from the containment to the environment. SR 3.6.1.1 leakage rate requirements comply with 10 CFR 50, Appendix J, Option B (Ref. 1), as modified by approved exemptions. The isolation devices for the penetrations in the containment boundary are a part of the containment leak tight barrier. To maintain this leak tight barrier:~~

- a. All penetrations required to be closed during accident conditions are either:
 1. capable of being closed by an OPERABLE automatic containment isolation system, or
 2. closed by manual valves, blind flanges, or de-activated automatic valves secured in their closed positions, except as provided in LCO 3.6.3, "Containment Isolation Valves"
- b. Each air lock is OPERABLE, except as provided in LCO 3.6.2, "Containment Air Locks";
- c. All equipment hatches are closed; and
- d. ~~The pressurized sealing mechanism associated with a penetration (e.g. welds, bellows or O-rings) is OPERABLE, except as provided in LCO 3.6.[-].~~

APPLICABLE
SAFETY
ANALYSIS

The safety design basis for the containment is that the containment must withstand the pressures and temperatures of the limiting DBA without exceeding the design leakage rate.

The DBAs that result in a challenge to containment OPERABILITY from high pressures and temperatures are a loss of coolant accident (LOCA) and a steam line break and a red

(Continued)

BASES

ejection accident (REA) (Ref. 2). In addition, release of significant fission product radioactivity within containment can occur from a LOCA or REA or a fuel handling accident. In the DBA analyses, it is assumed that the containment is OPERABLE such that, for the DBAs involving release of fission product radioactivity, release to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of 0.1% of containment air weight per day (Ref. 3). This leakage rate, used to evaluate offsite doses resulting from accidents, is defined in 10 CFR 50, Appendix J, Option B (Ref. 1), as L_3 : the maximum allowable containment leakage rate at the calculated peak containment internal pressure (P_3) resulting from the limiting DBA LOCA. The allowable leakage rate represented by L_3 forms the basis for the acceptance criteria imposed on all containment leakage rate testing. L_3 is assumed to be 0.10% of containment air weight per day in the safety analysis at $P_3 = 47$ psig (Ref. 3).

Satisfactory leakage rate test results are a requirement for the establishment of containment OPERABILITY.

The containment satisfies Criterion 3 of the NRC Policy Statement 10CFR50.36(c)(2)(ii).

LCO

Containment OPERABILITY is maintained by limiting leakage to $\leq 1.0 L_3$, except prior to the first startup after performing a required 10 CFR 50, Appendix J, Containment Leakage Rate Testing Program leakage test. At this time, the combined Type B and C leakage must be $< 0.6 L_3$, and the overall Type A leakage must be $< 0.75 L_3$, applicable Containment Leakage Rate Testing Program leakage limits must be met.

Compliance with this LCO will ensure a containment configuration, including equipment hatch, that is structurally sound and that will limit leakage to those leakage rates assumed in the safety analysis.

Individual leakage rates specified for the containment air lock (LCO 3.6.2) and containment purge supply and exhaust, hydrogen purge, and containment pressure/vacuum relief valves with resilient seals (LCO 3.6.3) are not specifically part of the acceptance criteria of 10 CFR 50, Appendix J. Therefore, leakage rates exceeding

(Continued)

BASES

~~these individual limits only~~ result in the containment being inoperable when the leakage results in exceeding the Overall acceptance criteria of Appendix J 1.0 L_a.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material into containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, containment is not required to be OPERABLE in MODE 5 to prevent leakage of radioactive material from containment. The requirements for containment during MODE 6 are addressed in LCO 3.9.4, "Containment Penetrations."

ACTIONS A.1

In the event containment is inoperable, containment must be restored to OPERABLE status within 1 hour. The 1 hour Completion Time provides a period of time to correct the problem commensurate with the importance of maintaining containment during MODES 1, 2, 3, and 4. This time period also ensures that the probability of an accident (requiring containment OPERABILITY) occurring during periods when containment is inoperable is minimal.

B.1 and B.2

If containment cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTSSR 3.6.1.1

Maintaining the containment OPERABLE requires compliance with the visual examinations and leakage rate test requirements as specified in the Containment Leakage Rate Testing Program which is consistent with Reg Guide 1.163, 1995, and the requirements of 10 CFR 50, Appendix J, Option B (Ref. 1), as modified by approved exemptions. Failure to meet air lock and purge valve with resilient seal leakage limits specified in the Containment Leakage Rate Test Program LCO 3.6.2 and LCO 3.6.3 does not invalidate the acceptability of these overall leakage determinations unless their contribution to overall Type A, B, and C leakage causes that to exceed limits. As left leakage prior to the first startup after performing a required 10 CFR 50, Appendix J, Containment Leakage Rate Testing Program leakage test is required to be $< 0.6 L_a$ for combined Type B and C leakage following an outage or shutdown that included Type B and C testing only, and $\leq 0.75 L_a$ for overall Type A leakage following an outage or shutdown that included Type A testing. At all other times between required leakage rate tests, the acceptance criteria is based on an overall Type A leakage limit of $\leq 1.0 L_a$. At $\leq 1.0 L_a$, the offsite dose consequences are bounded by the assumptions of the safety analysis. SR Frequencies are as required by Appendix J, as modified by approved exemptions 10CFR50 App J Option B. These periodic testing requirements verify that the containment leakage rate does not exceed the leakage rate assumed in the safety analysis.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.2 Containment Air Locks (~~Atmospheric, Subatmospheric, Ice Condenser, and Dual~~)

BASES

BACKGROUND

Containment air locks form part of the containment pressure boundary and provide a means for personnel access during all MODES of operation.

~~There are two containment airlocks. Each [the personnel] air lock is nominally a right circular cylinder, approximately 9 ft in diameter, with a door at each end. The emergency air lock is approximately 5 ft 9 in inside diameter with a 2 ft 6 in door at each end. The On both air locks, doors are interlocked to prevent simultaneous opening. During periods when containment is not required to be OPERABLE, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. Each air lock door has been designed and tested to certify its ability to withstand a pressure in excess of the maximum expected pressure following a Design Basis Accident (DBA) in containment. As such, closure of a single door supports containment OPERABILITY. Each of the doors contains double gasketed seals and local leakage rate testing capability to ensure pressure integrity. To effect a leak tight seal, the air lock design uses pressure seated doors (i.e., an increase in containment internal pressure results in increased sealing force on each door).~~

~~Each personnel air lock is provided with limit switches on both doors that provide control room indication of door position. Additionally, control room indication is provided to alert the operator whenever an air lock door interlock mechanism is defeated.~~

The containment air locks form part of the containment pressure boundary. As such, air lock integrity and leak tightness is essential for maintaining the containment leakage rate within limit in the event of a DBA. Not maintaining air lock integrity or leak tightness may result in a leakage rate in excess of that assumed in the unit safety analyses.

APPLICABLE
SAFETY
ANALYSIS

~~In MODE 1, 2, 3, and 4, the DBAs that results in a release of radioactive material within containment are as a loss of coolant accident and a rod ejection accident (Ref. 2). In the analysis of each of these this accidents, it is assumed that containment is OPERABLE such that release of fission products to the environment is controlled by the rate of containment leakage. The containment was designed with an allowable leakage rate of 0.1% of containment air weight per day (Ref. 2). This leakage rate is defined in 10 CFR 50, Appendix J, Option B (Ref. 1), as $L_a = 0.1\%$ of containment air weight per day, the maximum allowable containment leakage rate at the calculated peak containment internal pressure $P_a = 48.3-47.0$ psig following a DBA LOCA. This allowable leakage rate forms the basis for the acceptance criteria imposed on the SRs associated with the air locks.~~

~~The containment air locks satisfy Criterion 3 of the NRC Policy Statement 10CFR50.36(c)(2)(ii).~~

LCO Each containment air lock forms part of the containment pressure boundary. As part of containment pressure boundary, the air lock safety function is related to control of the containment leakage rate resulting from a DBA. Thus, each air lock's structural integrity and leak tightness are essential to the successful mitigation of such an event.

(Continued)

BASES

Each air lock is required to be OPERABLE. For the air lock to be considered OPERABLE, the air lock interlock mechanism must be OPERABLE, the air lock must be in compliance with the Type B air lock leakage test, and both air lock doors must be OPERABLE. The interlock allows only one air lock door of an air lock to be opened at one time. This provision ensures that a gross breach of containment does not exist when containment is required to be OPERABLE. Closure of a single door in each air lock is sufficient to provide a leak tight barrier following postulated events. Nevertheless, both doors are kept closed when the air lock is not being used for normal entry into or exit from containment.

APPLICABILITY In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, the containment air locks are not required in MODE 5 to prevent leakage of radioactive material from containment. The requirements for the containment air locks during MODE 6 are addressed in LCO 3.9.34, "Containment Penetrations."

ACTIONS The ACTIONS are modified by a Note that allows entry and exit to perform repairs on the affected air lock component. If the outer door is inoperable, then it may be easily accessed for most repairs. It is preferred that the air lock be accessed from inside primary containment by entering through the other OPERABLE air lock. However, if this is not practicable, or if repairs on either door must be performed from the barrel side of the door then it is permissible to enter the air lock through the OPERABLE door, which means there is a short time during which the containment boundary is not intact (during access through the OPERABLE door). The ability to open the OPERABLE door, even if it means the containment boundary is temporarily not intact, is acceptable due to the low probability of an event that could pressurize the containment during the short time in which the OPERABLE door is expected to be open. After each entry and exit, the OPERABLE door must be immediately closed. If ALARA conditions permit, entry and exit should be via an OPERABLE air lock.

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each air lock. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable air lock. Complying with the Required Actions may allow for continued operation, and a subsequent inoperable air lock is governed by subsequent Condition entry and application of associated Required Actions.

In the event the air lock leakage results in exceeding the ~~limit for the air lock~~ then the leakage must be evaluated for its effect on the overall containment leakage rate. Note 3 directs entry into the applicable Conditions and Required Actions of LCO 3.6.1, "Containment" if the overall containment leakage limits are exceeded.

A.1, A.2, and A.3

With one air lock door in one or more containment air locks inoperable, the OPERABLE door must be verified closed (Required Action A.1) in each affected containment air lock. This ensures that a leak tight containment barrier is maintained by the use of an OPERABLE air lock door. This action must be completed within 1 hour. This specified time period is consistent with the ACTION of LCO 3.6.1, which requires containment be restored to OPERABLE status within 1 hour.

In addition, the affected air lock penetration must be isolated by locking closed the OPERABLE air lock door within the 24 hour Completion Time. The 24 hour Completion

(Continued)

BASES

Time is reasonable for locking the OPERABLE air lock door, considering the OPERABLE door of the affected air lock is being maintained closed.

Required Action A.3 verifies that an air lock with an inoperable door has been isolated by the use of a locked and closed OPERABLE air lock door. This ensures that an acceptable containment leakage boundary is maintained. The Completion Time of once per 31 days is based on engineering judgment and is considered adequate in view of the low likelihood of a locked door being mispositioned and other administrative controls. Required Action A.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified locked closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable. With both doors in the same air lock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. The exception of Note 1 does not affect tracking the Completion Time from the initial entry into Condition A; only the requirement to comply with the Required Actions. Note 2 allows use of the air lock for entry and exit for 7 days under administrative controls if both air locks have an inoperable door. This 7 day restriction begins when the second air lock is discovered inoperable. Containment entry may be required on a periodic basis to perform Technical Specifications (TS) Surveillances and Required Actions, as well as other activities on equipment inside containment that are required by TS or activities on equipment that support TS-required equipment. This Note is not intended to preclude performing other activities (i.e., non-TS-required activities) if the containment is entered, using the inoperable air lock, to perform an allowed activity listed above. This allowance is acceptable due to the low probability of an event that could pressurize the containment during the short time that the OPERABLE door is expected to be open.

B.1, B.2, and B.3

With an air lock interlock mechanism inoperable in one or more air locks, the Required Actions and associated Completion Times are consistent with those specified in Condition A.

The Required Actions have been modified by two Notes. Note 1 ensures that only the Required Actions and associated Completion Times of Condition C are required if both doors in the same air lock are inoperable. With both doors in the same air lock inoperable, an OPERABLE door is not available to be closed. Required Actions C.1 and C.2 are the appropriate remedial actions. Note 2 allows entry into and exit from containment under the control of a dedicated individual stationed at the air lock to ensure that only one door is opened at a time (i.e., the individual performs the function of the interlock).

Required Action B.3 is modified by a Note that applies to air lock doors located in high radiation areas and allows these doors to be verified locked closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of the door, once it has been verified to be in the proper position, is small.

C.1, C.2, and C.3

With one or more air locks inoperable for reasons other than those described in Condition A or B, Required Action C.1 requires action to be initiated immediately to

(Continued)

BASES

evaluate previous combined leakage rates using current air lock test results. The air lock operability leakage limit is 0.05 L, and is considered part of the type B and C leakage and therefore subject to the containment inoperability limit of >1.0 L, under LCO 3.6.1. An evaluation is acceptable, since it is overly conservative to immediately declare the containment inoperable if both doors in an air lock have failed a seal test or if the overall air lock leakage is not within limits. In many instances (e.g., only one seal per door has failed), containment remains OPERABLE, yet only 1 hour (per LCO 3.6.1) would be provided to restore the air lock door to OPERABLE status prior to requiring a plant shutdown. In addition, even with both doors failing the seal test, the overall containment leakage rate can still be within limits.

Required Action C.2 requires that one door in the affected containment air lock must be verified to be closed within the 1 hour Completion Time. This specified time period is consistent with the ACTIONS of LCO 3.6.1, which requires that containment be restored to OPERABLE status within 1 hour.

Additionally, the affected air lock(s) must be restored to OPERABLE status within the 24 hour Completion Time. The specified time period is considered reasonable for restoring an inoperable air lock to OPERABLE status, assuming that at least one door is maintained closed in each affected air lock.

D.1 and D.2

If the inoperable containment air lock cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3.6.2.1

Maintaining containment air locks OPERABLE requires compliance with the leakage rate test requirements of 10 CFR 50, Appendix J (Ref. 1), as modified by approved exemptions the Containment Leakage Rate Testing Program. This SR reflects the leakage rate testing requirements with regard to air lock leakage (Type B leakage tests). The acceptance criteria were established within the Containment Leakage Rate Testing Program during initial air lock and containment OPERABILITY testing under 10CFR50, Appendix J, Option B. The periodic testing requirements verify that the air lock leakage does not exceed the allowed fraction of the overall containment leakage rate. The Frequency is also required by Appendix J (Ref. 1), as modified by approved exemptions.

(Continued)

BASES (Continued)

SURVEILLANCE
REQUIREMENTS
(Continued)

~~Thus, SR 3.0.2 (which allows Frequency extensions) does not apply the
Containment Leakage Rate Testing Program~~

The SR has been modified by two Notes. Note 1 states that an inoperable air lock door does not invalidate the previous successful performance of the overall air lock leakage test. This is considered reasonable since either air lock door is capable of providing a fission product barrier in the event of a DBA. Note 2 has been added to this SR requiring the results to be evaluated against the acceptance criteria of the ~~Containment Leakage Rate Testing Program~~, which is applicable to SR 3.6.1.1. This ensures that air lock leakage is properly accounted for in determining the overall ~~combined Type B and C~~ containment leakage rate.

SR 3.6.2.2

The air lock interlock is designed to prevent simultaneous opening of both doors in a single air lock. Since both the inner and outer doors of an air lock are designed to withstand the maximum expected post accident containment pressure, closure of either door will support containment OPERABILITY. Thus, the door interlock feature supports containment OPERABILITY while the air lock is being used for personnel transit in and out of the

(Continued)

BASES (Continued)

SURVEILLANCE
REQUIREMENTS

containment. Periodic testing of this interlock demonstrates that the interlock will function as designed and that simultaneous opening of the inner and outer doors will not inadvertently occur. Due to the purely mechanical nature of this interlock, and given that the interlock mechanism is only not normally challenged when the containment air lock door is opened used for entry and exit (procedures require strict adherence to single door opening). This test is only required to be performed upon entering or exiting a containment air lock but is not required more frequently than every 184 days every 24 months. The 24 month Frequency is based on avoiding the loss of containment OPERABILITY if the Surveillance were performed with the reactor at power. Operating experience has shown these components usually pass the Surveillance when performed at the 24 month Frequency. The 184 day 24 month Frequency is based and on engineering judgement and is considered adequate in view of other indications of door and interlock mechanism status available to operations personnel given that the interlock is not challenged during use of the airlock.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.3 Containment Isolation Valves (~~Atmospheric, Subatmospheric, Ice Condenser, and Dual~~)

BASES

BACKGROUND

The containment isolation valves form part of the containment pressure boundary and provide a means for fluid penetrations not serving accident consequence limiting systems to be provided with two isolation barriers that are closed on a containment isolation signal. These isolation devices are either passive or active (automatic). Manual valves, de-activated automatic valves secured in their closed position (including check valves with flow through the valve secured), blind flanges, and closed systems are considered passive devices. Check valves, or other automatic valves designed to close without operator action following an accident, are considered active devices. Two barriers in series are provided for each penetration so that no single credible failure or malfunction of an active component can result in a loss of isolation or leakage that exceeds limits assumed in the safety analyses. One of these barriers may be a closed system. These barriers (~~typically containment isolation valves (A listing of containment isolation valves is provided in Technical Requirements Manual Table 2.1.1.)~~) make up the Containment Isolation System.

Automatic isolation signals are produced during accident conditions. Containment Phase "A" isolation occurs upon receipt of a safety injection signal. The Phase "A" isolation signal isolates nonessential process lines in order to minimize leakage of fission product radioactivity. Containment Phase "B" isolation occurs upon receipt of a containment pressure High-High signal and isolates the remaining process lines, except systems required for accident mitigation. In addition to the isolation signals listed above, the ~~containment purge supply and exhaust valves, Hydrogen Purge and containment pressure/vacuum relief isolation purge and exhaust valves receive an a Containment Ventilation Isolation (CVI) signal on a containment high radiation condition. In addition to these large valves, the containment gas and particulate radiation monitor penetrations also isolate upon receipt of a CVI signal.~~ As a result, the containment isolation valves (and blind flanges) help ensure that the containment atmosphere will be isolated from the environment in the event of a release of fission product radioactivity to the containment atmosphere as a result of a Design Basis Accident (DBA).

The OPERABILITY requirements for containment isolation valves help ensure that containment is isolated within the time limits assumed in the safety analyses. Therefore, the OPERABILITY requirements provide assurance that the containment function assumed in the safety analyses will be maintained.

Shutdown Containment Purge System (48 inch purge valves)

The ~~Shutdown Containment Purge System~~ operates to supply outside air into the containment for ventilation and cooling or heating needed for ~~prolonged containment access following a shutdown and during refueling and~~ The system may also be used to reduce the concentration of noble gases within containment prior to and during

(Continued)

BASES

BACKGROUND
(Continued)

personnel access. The supply and exhaust lines each contain two isolation valves. Because of their large size, the 48 inch Containment Purge valves in some units are not qualified for automatic closure from their open position under DBA conditions. Therefore, the 48 inch Containment Purge supply and exhaust isolation valves are normally maintained closed must be blocked to prevent opening more than 80% in MODES 1, 2, 3, and 4 to ensure closure within 2 seconds under DBA conditions (in order to support the required containment ventilation isolation time) and to ensure that the containment boundary is maintained. These valves may be opened as necessary to:

a. Reduce noble gases within containment prior to and during personnel access, and

b. Mitigate the effects of controller leakage and other sources which may effect the habitability of the containment for personnel entry.

Operation in MODES 1, 2, 3, or 4 with the 48 inch purge valves or the 12-inch vacuum/pressure relief valves open providing a flow path is limited to no more than 200 hours per calendar year.

Hydrogen Purge System (12-4 inch purge valves)

The Hydrogen Purge System is a supplementary system for the internal electric hydrogen recombiners and operated for hydrogen dilution or external hydrogen recombiners in for the containment following a LOCA. Because the 12-4 inch Containment Hydrogen Purge supply and exhaust valves are remote manually operated not qualified for automatic closure from their open position under DBA conditions they are normally maintained closed with power removed in MODES 1, 2, 3, and 4 to ensure the containment boundary is maintained.

Minipurge System Containment Pressure/Vacuum Relief (12 inch purge discharge isolation valves)

The Minipurge System Containment Pressure/Vacuum Relief valves are operated as necessary to:

a. Reduce the concentration of noble gases within containment prior to and during personnel access, and

b. Equalize containment internal and external pressures.

Since the 12 inch Containment Pressure/Vacuum Relief valves used in the Minipurge System are designed to meet the requirements for automatic containment isolation valves within 5 seconds if mechanical blocks are installed to prevent opening more than 50%, these valves may be opened as needed in MODES 1, 2, 3, and 4.

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES

The containment isolation valve LCO was derived from the assumptions related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during major accidents. As part of the containment boundary, containment isolation valve OPERABILITY supports leak tightness of the containment. Therefore, the safety analyses of any event requiring isolation of containment is applicable to this LCO.

The DBAs that result in a release of radioactive material within containment are in ~~MODES 1, 2, 3, or 4~~ is a loss of coolant accident (LOCA) and a ~~rod ejection accident~~ (Ref. 1). In the analyses for each of these ~~this~~ accidents, it is assumed that containment isolation valves are either closed or function to close within the required isolation time following event initiation. This ensures that potential paths to the environment through containment isolation valves (including ~~containment purge the Containment Purge, Hydrogen Purge, and Containment Vacuum/Pressure Relief valves~~) are minimized. ~~The safety analyses assume that if the 48 inch Containment Purge supply and exhaust valves close within 2 seconds and the 12 inch Hydrogen Purge pressure/vacuum relief valves are closed close within 5 seconds after the DBA at event initiation, the safety analysis shows that offsite dose release will be less than 10CFR100 guidelines.~~

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSES
(continued)

~~The DBA analysis assumes that, within 60 seconds after the accident, isolation of the containment is complete and leakage terminated except for the design leakage rate, L_d . The containment isolation total response time of 60 seconds includes signal delay, diesel generator startup (for loss of offsite power), and containment isolation valve stroke times.~~

~~The LOCA offsite dose analysis assumes leakage from the containment at a maximum leak rate of 0.10 percent of the containment volume per day for the first 24 hours, and at 0.05 percent of the containment volume per day for the duration of the accident. The Containment Purge supply and exhaust and the Containment Pressure Relief penetration are the only flow paths explicitly addressed in the dose analysis since it provides a direct activity release path from the containment to the environment. It is assumed to isolate within 5 seconds of receiving a containment isolation signal.~~

~~The single failure criterion required to be imposed in the conduct of plant safety analyses was considered in the original design of the 48 inch Containment Purge supply and exhaust and the 18 1/2 inch containment purge Containment Pressure/Vacuum Relief valves. Two valves in series on each purge line provide assurance that both the supply and exhaust line's could flow paths can be isolated even if a single failure occurred. The inboard and outboard isolation valves on each line are provided with diverse power sources, motor operated and are pneumatically operated spring closed, respectively valves that will fail closed on the loss of power or air. This arrangement was designed to preclude common mode failures from disabling both valves on a purge line.~~

~~The 48 inch Containment Purge supply and exhaust and 12 inch Hydrogen Purge Containment Pressure/Vacuum Relief valves may be unable to close in the environment following a LOCA. Therefore, each of the Containment Purge supply and exhaust and Hydrogen Purge Containment Vacuum/Pressure Relief valves is required to remain sealed closed may be opened to provide a flow path. The 48 inch Containment Purge supply and exhaust valves and/or 12-inch vacuum/pressure relief valves may be open no more than 200 hours per calendar year while in during MODES 1, 2, 3, and 4. In this case, the single failure criterion remains applicable to the containment purge valves due to failure in the control circuit associated with each valve. Again, The Purge Additionally, only two of the three flow paths (containment purge supply and exhaust, and containment vacuum/pressure relief) may be open at one time. The system valve design is designed to preclude a single failure from compromising the containment boundary as long as the system is operated in accordance with the subject LCO.~~

~~The containment isolation valves satisfy Criterion 3 of the NRC Policy Statement 10CFR50.36(c)(2)(ii).~~

(Continued)

BASES (Continued)

LCO

Containment isolation valves form a part of the containment boundary. The containment isolation valves' safety function is related to minimizing the loss of reactor coolant inventory and establishing the containment boundary during a DBA. The automatic power operated isolation valves are required to have isolation times within limits and to actuate on an automatic isolation signal. The 48 inch Containment Purge supply and exhaust and 12 inch Hydrogen Purge valves and the Pressure/Vacuum Relief valves must be maintained sealed closed or have blocks installed to prevent full opening. These blocked purge valves also actuate on an automatic isolation signal. The valves covered by this LCO are listed along with their associated stroke times in the FSAR Technical Requirements Manual Plant Procedure AD13 DC1 Attachment 7.10 (Ref. 2 5).

The Normally closed passive containment isolation valves/devices are considered OPERABLE when manual valves are closed, automatic valves are de-activated and secured in their closed position, blind flanges are in place, and closed systems are intact. These passive isolation valves/devices are those listed in Reference 1.

Containment Purge supply and exhaust valves, Hydrogen Purge, and Containment Pressure/Vacuum Relief valves with resilient seals (and secondary containment bypass valves) must meet additional leakage rate surveillance frequency requirements. The other containment isolation valve leakage rates are addressed by LCO 3.6.1, "Containment," as Type C testing.

This LCO provides assurance that the containment isolation valves and the Containment Purge supply and exhaust, Hydrogen Purge, and Containment Pressure/Vacuum Relief purge valves will perform their designed safety function to minimize the loss of reactor coolant inventory and establish the containment boundary during accidents.

The LCO is modified by a Note stating that the Main Steam Safety Valves, Main Steam Isolation Valves, Feedwater Isolation Valves, and Atmospheric Dump Valves are not addressed in this LCO. These penetration flow paths credit the steam generators and piping inside containment as a containment isolation barrier (i.e., closed system). These valves are addressed by LCO 3.7.1 "Main Steam Safety Valves (MSSVs)", LCO 3.7.2 "Main Steam Isolation Valves (MSIVs)", LCO 3.7.3 "Main Feedwater Isolation Valves (MFIVs)", Main Feedwater Regulating Valves (MFRVs), and Associated Bypass Valves, and LCO 3.7.4 "Atmospheric Dump Valves (ADVs)" which provide the appropriate Required Actions in the event these valves are inoperable.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES.

(Continued)

APPLICABILITY (continued) Therefore, the containment isolation valves are not required to be OPERABLE in MODE 5. The requirements for containment isolation valves during MODE 6 are addressed in LCO 3.9.4, "Containment Penetrations."

ACTIONS The ACTIONS are modified by a Note allowing penetration flow paths that are normally isolated by locked or sealed closed valves or valves that do not receive a containment isolation signal, except for 48-inch Containment Purge and 12-inch Hydrogen Purge valve penetration flow paths, to be unisolated intermittently under administrative controls. These administrative controls consist of stationing a dedicated operator at the valve controls, who is in continuous communication with the control room. In this way, the penetration can be rapidly isolated when a need for containment isolation is indicated. Due to the size of the containment purge line penetration and the fact that the 48-inch Containment Purge and the 12-inch Hydrogen Purge supply and exhaust valves are not qualified for automatic closure from their open position under DBA conditions and that these penetrations exhaust directly from the containment atmosphere to the environment, the penetration flow path containing these valves may not be opened under administrative controls. A single valve in either the 48-inch Containment Purge or the 12-inch Hydrogen Purge a penetration flow path may be opened to effect repairs to an inoperable valve, as allowed by SR 3.6.3.1. This Note also limits operation of the normally isolated Containment Supply and Exhaust valves (2 penetration flow paths) and the Vacuum/Pressure Relief valves (1 penetration flow path) no more than 2 of 3 penetration flow paths open at one time.

A second Note has been added to provide clarification that, for this LCO, separate Condition entry is allowed for each penetration flow path. This is acceptable, since the Required Actions for each Condition provide appropriate compensatory actions for each inoperable containment isolation valve. Complying with the Required Actions may allow for continued operation, and subsequent inoperable containment isolation valves are governed by subsequent Condition entry and application of associated Required Actions.

The ACTIONS are further modified by a third Note, which ensures appropriate remedial actions are taken, if necessary, if the affected systems are rendered inoperable by an inoperable containment isolation valve.

In the event the air lock containment isolation valve leakage results in exceeding the overall containment leakage rate acceptance criteria, Note 4 directs entry into the applicable Conditions and Required Actions of LCO 3.6.1.

A.1 and A.2

(Continued)

BASES (Continued)

In the event one containment isolation valve in one or more penetration flow paths requiring isolation following a DBA is inoperable [~~except for purge Containment Purge supply and exhaust, Hydrogen Purge and Containment Pressure/Vacuum Relief isolation valve or shield building bypass leakage not within limit~~], the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic containment isolation valve, a closed manual valve (this includes power operated valves with power removed), a blind flange, and a check valve with flow through the valve secured. For a penetration flow path isolated in accordance with Required Action A.1, the device used to isolate the penetration should be the closest available one to containment. Required Action A.1 must be completed within 4 hours. The 4 hour Completion Time is reasonable, considering the time required to isolate the penetration and the relative importance of supporting containment OPERABILITY during MODES 1, 2, 3, and 4.

For affected penetration flow paths that cannot be restored to OPERABLE status within the 4 hour Completion Time and that have been isolated in accordance with Required Action A.1, the affected penetration flow paths must be verified to be isolated on a periodic basis. This is necessary to ensure that containment penetrations required to be isolated following an accident and no longer capable of being automatically isolated will be in the isolation position should an event occur. This Required Action does not require any testing or device manipulation. Rather, it involves verification, ~~through a system walkdown,~~ that those isolation devices outside containment and capable of being mispositioned are in the correct position. The Completion Time of "once per 31 days for isolation devices outside containment" is appropriate considering the fact that the devices are operated under administrative controls and the probability of their misalignment is low. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.

Condition A has been modified by a Note indicating that this Condition is only applicable to those penetration flow paths with two containment isolation valves. For penetration flow paths with only one containment isolation valve and a closed system, Condition C provides the appropriate actions.

Required Action A.2 is modified by a Note that applies to isolation devices located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of these devices once they have been verified to be in the proper position, is small.

(Continued)

BASES (Continued)

A second Note has been added to Required Action A.2 to provide clarification that the action to periodically verify the affected penetration flow path is isolated does not apply to manual valves and blind flanges that are locked, sealed, or otherwise secured. This is acceptable since these were verified to be in the correct position prior to locking, sealing, or securing.

ACTIONS
(continued)

B.1

With two containment isolation valves in one or more penetration flow paths requiring isolation following a DBA inoperable, the affected penetration flow path must be isolated within 1 hour. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic valve, a closed manual valve (this includes power operated valves with power removed), and a blind flange. The 1 hour Completion Time is consistent with the ACTIONS of LCO 3.6.1. In the event the affected penetration is isolated in accordance with Required Action B.1, the affected penetration must be verified to be isolated on a periodic basis per Required Action A.2, which remains in effect. This periodic verification is necessary to assure leak tightness of containment and that penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days for verifying each affected penetration flow path is isolated is appropriate considering the fact that the valves are operated under administrative control and the probability of their misalignment is low.

Condition B is modified by a Note indicating this Condition is only applicable to penetration flow paths with two containment isolation valves. Condition A of this LCO addresses the condition of one containment isolation valve inoperable in this type of penetration flow path.

C.1 and C.2

With one or more penetration flow paths requiring isolation following a DBA with one containment isolation valve inoperable, the inoperable valve flow path must be restored to OPERABLE status or the affected penetration flow path must be isolated. The method of isolation must include the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a closed and de-activated automatic valve, a closed manual valve (this includes power operated valves with power removed), and a blind flange. A check valve may not be used to isolate the affected penetration flow path. Required Action C.1 must be completed within the [4] 72 hour Completion Time. The specified time period is reasonable considering the relative stability of the closed system (hence, reliability) to act as a penetration isolation boundary and the relative importance of maintaining containment integrity during MODES 1, 2, 3, and 4 (See FSAR Table 6.2-39 GDC-57 valves). In the event the affected penetration flow path

(Continued)

BASES (Continued)

is isolated in accordance with Required Action C.1, the affected penetration flow path must be verified to be isolated on a periodic basis. This periodic verification is necessary to assure leak tightness of containment and that containment penetrations requiring isolation following an accident are isolated. The Completion Time of once per 31 days for verifying that each affected penetration flow path is isolated is appropriate because the valves are operated under administrative controls and the probability of their misalignment is low.

Condition C is modified by a Note indicating that this Condition is only applicable to those penetration flow paths with only one containment isolation valve and a closed system. ~~The closed system must meet the requirements of Reference 3.~~ This Note is necessary since this Condition is written to specifically address those penetration flow paths in a closed system.

ACTIONS
(continued)

Required Action C.2 is modified by a Note that applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted. Therefore, the probability of misalignment of these valves, once they have been verified to be in the proper position, is small.

~~A second Note has been added to Required Action C.2 to provide clarification that the action to periodically verify the affected penetration flow path is isolated does not apply to manual valves and blind flanges that are locked, sealed, or otherwise secured. This is acceptable since these were verified to be in the correct position prior to locking, sealing, or securing.~~

D-1

~~With the shield building bypass leakage rate not within limit, the assumptions of the safety analyses are not met. Therefore, the leakage must be restored to within limit caused the limit to be exceeded by use of one closed and de-activated automatic valve, closed manual valve, or blind flange. When a penetration is isolated the leakage rate for the isolated penetration is assumed to be the actual pathway leakage through the isolation device. If two isolation devices are used to isolate the penetration, the leakage rate is assumed to be the lesser actual pathway leakage of the two devices. The 4 hour Completion Time is reasonable considering the time required to restore the leakage by isolating the penetration(s) and the relative importance of secondary containment bypass leakage to the overall containment function.~~

ED.1, ED.2, and ED.3

~~In the event one or more Containment Purge supply and exhaust, Hydrogen Purge, or Containment Pressure/Vacuum Relief isolation valves in one or more penetration flow paths are not within the purge valve leakage limits, purge valve leakage must be~~

(Continued)

BASES (Continued)

restored reduced to within limits, or the affected penetration flow path must be isolated. For this ACTION, the leakage limit is as specified under the Containment Leakage Rate Testing Program and exceeding this limit would require evaluation per Note 4 under LCO 3.6.3. The method of isolation must be by the use of at least one isolation barrier that cannot be adversely affected by a single active failure. Isolation barriers that meet this criterion are a ~~FE~~ closed and de-activated automatic valve, closed manual valve (this includes power operated valves with power removed), or blind flange. A purge Containment Purge supply and exhaust, ~~Hydrogen Purge, or Containment Pressure/Vacuum Relief~~ Isolation valve with resilient seals utilized to satisfy Required Action ED.1 must have been demonstrated to meet the leakage requirements of SR 3.6.3.7. The specified Completion Time is reasonable, considering that one containment purge valve remains closed so that a gross breach of containment does not exist.

ACTIONS
(continued)

In accordance with Required Action ED.2, this penetration flow path must be verified to be isolated on a periodic basis. The periodic verification is necessary to ensure that containment penetrations required to be isolated leak rate following an accident, which are no longer capable of being automatically isolated, will be in the isolation position should an event occur will not exceed the limit assumed in the offsite dose analysis. This Required Action does not require any testing or valve manipulation. Rather, it involves verification, through a system walkdown, that those isolation devices outside containment capable of being mispositioned are in the correct position. For the isolation devices inside containment, the time period specified as "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is based on engineering judgment and is considered reasonable in view of the inaccessibility of the isolation devices and other administrative controls that will ensure that isolation device misalignment is an unlikely possibility.

For the ~~Containment Purge supply and exhaust, Hydrogen Purge, or Containment Pressure/Vacuum Relief~~ Isolation valve with resilient seal that is isolated in accordance with Required Action ED.1, SR 3.6.3.7 must be performed at least once every 92 days. This assures that degradation of the resilient seal is detected and confirms that the leakage rate of the containment purge valve does not increase beyond the limits during the time the penetration is isolated. The normal Frequency for SR 3.6.3.7, 184 days, is based on an NRC initiative, Generic Issue B-20 (Ref. 3 4). Since more reliance is placed on a single valve while in this Condition, it is prudent to perform the SR more often. Therefore, a Frequency of once per 92 days was chosen and has been shown to be acceptable based on operating experience.

FE.1 and FE.2

If the Required Actions and associated Completion Times are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5

(Continued)

BASES (Continued)

within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

(Continued)

SURVEILLANCE
REQUIREMENTS

SR 3.6.3.1 Not Used

~~Each 18 inch Containment Purge and 12 inch Hydrogen Purge valve is required to be verified sealed closed at 31 day intervals. This Surveillance is designed to ensure that a gross breach of containment is not caused by an inadvertent or spurious opening of a Containment Purge or Hydrogen Purge valve. Detailed analysis of the purge these valves failed to conclusively demonstrate their ability to close during a LOCA in time to limit offsite doses. Therefore, these valves are required to be in the sealed closed position during MODES 1, 2, 3, and 4. A Containment Purge or Hydrogen Purge valve that is sealed closed must have motive power to the valve operator removed. This can be accomplished by de energizing the source of electric power or by removing the air supply to the valve operator. In this application, the term "sealed" has no connotation of leak tightness. The Frequency is a result of an NRC initiative, Generic Issue B 24 (Ref. 4 5), related to containment purge valve use during plant operations. In the event Containment Purge or Hydrogen Purge valve leakage requires entry into Condition E, the Surveillance permits opening one purge valve in a penetration flow path to perform repairs.~~

SR 3.6.3.2

This SR ensures that the minipurge 18 inch Containment Pressure Relief 48 inch Containment Purge supply and exhaust and the 12 inch Containment Pressure/Vacuum Relief valves are closed as required or, if open, open for an allowable reason. If a purge or pressure relief valve is open in violation of this SR, the valve is considered inoperable. If the inoperable valve is not otherwise known to have excessive leakage when closed, it is not considered to have leakage outside of limits. The SR is not required to be met when the minipurge Containment Purge supply and exhaust or Containment Pressure Relief valves are open for the reasons stated. The valves may be opened for pressure control, ALARA or air quality considerations for personnel entry, or for Surveillances that require the valves to be open. The minipurge Containment Purge supply and exhaust or Containment Pressure/Vacuum Relief valves are capable of closing in the environment following a LOCA. Therefore, these valves are allowed to be open for limited periods of time. The 31 day Frequency is consistent with other containment isolation valve requirements discussed in SR 3.6.3.3.

SR 3.6.3.3

This SR requires verification that each containment isolation manual valve and blind flange located outside containment and not locked sealed, or otherwise secured and required to be closed during accident conditions is closed. The SR helps to ensure

(Continued)

BASES

that post accident leakage of radioactive fluids or gases outside of the containment boundary is within design limits. This SR does not require any testing or valve manipulation. Rather, it involves verification, ~~through a system walkdown,~~ that those containment isolation valves outside containment and capable of being mispositioned are in the correct position. Since verification of valve position for containment isolation valves outside containment is relatively easy, the 31 day Frequency is based on engineering judgment and was chosen to provide added assurance of the correct positions. The SR specifies that containment isolation valves that are open under administrative controls are not required to meet the SR during the time the valves are open.

The Note applies to valves and blind flanges located in high radiation areas and allows these devices to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, 3 and 4 for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in the proper position, is small.

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.6.3.4

This SR requires verification that each containment isolation manual valve and blind flange located inside containment ~~and not locked sealed, or otherwise secured~~ and required to be closed during accident conditions is closed. The SR helps to ensure that post accident leakage of radioactive fluids or gases outside of the containment boundary is within design limits. For containment isolation valves inside containment, the Frequency of "prior to entering MODE 4 from MODE 5 if not performed within the previous 92 days" is appropriate since these containment isolation valves are operated under administrative controls and the probability of their misalignment is low. The SR specifies that containment isolation valves that are open under administrative controls are not required to meet the SR during the time they are open.

This Note allows valves and blind flanges located in high radiation areas to be verified closed by use of administrative means. Allowing verification by administrative means is considered acceptable, since access to these areas is typically restricted during MODES 1, 2, 3, and 4, for ALARA reasons. Therefore, the probability of misalignment of these containment isolation valves, once they have been verified to be in their proper position, is small.

~~Note 2 modifies the requirement to verify the blind flange on the fuel transfer canal. The refueling cavity areas in containment are flooded only during plant shutdown for refueling. The flange is only removed to support refueling operations and replaced after drainage of the canal when no more fuel transfers between the fuel handling building and the containment will occur. Once replaced, the flange is not removed again until the next refueling. Since the removal of this flange is limited to refueling operations and access to it is restricted during MODES 1, 2, 3, and 4, the probability~~

(Continued)

BASES

~~of it being mispositioned between refuelings is small. Therefore, it is reasonable that it is only required to be verified closed after each drainage of the canal.~~

SR 3.6.3.5

Verifying that the isolation time of each power operated and automatic containment isolation valve is within limits is required to demonstrate OPERABILITY. The isolation time test ensures the valve will isolate in a time period less than or equal to that assumed in the safety analyses. ~~[- The isolation time and Frequency of this SR are in accordance with the Inservice Testing Program. or 92 days.]~~

SR 3.6.3.6 Not Used

SURVEILLANCE
REQUIREMENTS
(Continued)

~~In subatmospheric containments, the check valves that serve a containment isolation function are weight or spring loaded to provide positive closure in the direction of flow. This ensures that these check valves will remain closed when the inside containment atmosphere returns to subatmospheric conditions following a DBA. SR 3.6.3.6 requires verification of the operation of the check valves that are testable during unit operation. The Frequency of 92 days is consistent with the Inservice Testing Program requirement for valve testing on a 92 day Frequency.~~

SR 3.6.3.7

~~For Containment Purge supply and exhaust, Hydrogen Purge, and Containment Pressure/Vacuum Relief valves with resilient seals, additional leakage rate testing beyond the test requirements of 10 CFR 50, Appendix J, Option B is required to ensure OPERABILITY. Operating experience has demonstrated that this type of seal has the potential to degrade in a shorter time period than do other seal types. Based on this observation and the importance of maintaining this these penetrations leak tight (due to the direct path between containment and the environment), a Frequency of 184 days was established as part of the NRC resolution of Generic Issue B-20, "Containment Leakage Due to Seal Deterioration" (Ref. 3 4).~~

Additionally, this SR must be performed within 92 days after opening the valve. The 92 day Frequency was chosen recognizing that cycling the valve could introduce additional seal degradation (beyond that occurring to a valve that has not been opened). Thus, decreasing the interval (from 184 days) is a prudent measure after a valve has been opened.

~~The leak rate acceptance criteria for the containment purge supply and exhaust, hydrogen purge, and containment pressure/vacuum relief valves are in accordance with the Containment Leakage Rate Testing Program.~~

(Continued)

BASES

SR 3.6.3.8

Automatic containment isolation valves close on a ~~Phase A, Phase B, or CVI~~ signal to prevent leakage of radioactive material from containment following a DBA. This SR ensures that each automatic containment isolation valve will actuate to its isolation position on a containment isolation signal. This surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The ~~18~~ month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass this Surveillance when performed at the ~~18~~ month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

SR 3.6.3.9 ~~Not Used~~

~~In subatmospheric containments, the check valves that serve a containment isolation function are weight or spring loaded to provide positive closure in the direction of flow. This ensures that these check valves will remain closed when the inside containment atmosphere returns to subatmospheric conditions following a DBA. SR 3.6.3.9 verifies the operation of the check valves that are not testable during unit operation. The Frequency of 18 months is based on such factors as the inaccessibility of these valves, the fact that the unit must be shut down to perform the tests, and the successful results of the tests on an 18 month basis during past unit operation.~~

SR 3.6.3.10

~~Reviewer's Note: This SR is only required for those units with resilient seal purge valves allowed to be open during [MODE 1, 2, 3, or 4] and having blocking devices on the valves that are not permanently installed.~~

Verifying that each ~~[42]~~ ~~12~~ inch containment purge ~~pressure/vacuum relief~~ valve is blocked to restrict opening to ~~≤ [50]%~~ ~~50%~~ is required to ensure that the valves can close under DBA conditions within the times assumed in the analyses of References 1 and 2. If a LOCA occurs, the ~~purge containment pressure/vacuum relief~~ valves must close to maintain containment leakage within the values assumed in the accident analysis. ~~At other times when purge valves are required to be capable of closing (e.g., during movement of recently irradiated fuel assemblies), pressurization concerns are not present, thus the purge valves can be fully open. The 18 month Frequency is appropriate because the blocking devices are not typically removed only during a refueling outage except during maintenance.~~

(Continued)

SR 3.6.3.11 Not Used

~~This SR ensures that the combined leakage rate of all shield building bypass leakage paths is less than or equal to the specified leakage rate. This provides assurance that the assumptions in the safety analysis are met. The leakage rate of each bypass leakage path is assumed to be the maximum pathway leakage (leakage through the worse of the two isolation valves) unless the penetration is isolated by use of one closed and de activated automatic valve, closed manual valve, or blind flange. In this case, the leakage rate of the isolated bypass leakage path is assumed to be the actual pathway leakage through the isolation device. If both isolation valves in the penetration are closed, the actual leakage rate is the lesser leakage rate of the two valves. This method of quantifying maximum pathway leakage is only to be used for this SR (i.e., Appendix J maximum pathway leakage limits are to be quantified in accordance with Appendix J). The Frequency is required by 10 CFR 50, Appendix J, as modified by approved exemptions (and therefore, the Frequency extensions of SR 3.0.2 may not be applied), since the testing is an Appendix J, Type C test. This SR simply imposes additional acceptance criteria.~~

~~[By pass leakage is considered part of L₁. [Reviewer's Note: Unless specifically exempted].]~~

B 3.6 CONTAINMENT SYSTEMS

B 3.6.4A Containment Pressure (Atmospheric, Dual, and Ice Condenser)

BASES

BACKGROUND The containment pressure is limited during normal operation to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or steam line break (SLB). These limits also prevent the containment pressure from exceeding the containment design negative pressure differential with respect to the outside atmosphere in the event of inadvertent actuation of the Containment Spray System.

Containment pressure is a process variable that is monitored and controlled. The containment pressure limits are derived from the input conditions used in the containment functional analyses and the containment structure external pressure analysis. Should operation occur outside these limits coincident with a Design Basis Accident (DBA), post accident containment pressures could exceed calculated values.

APPLICABLE SAFETY ANALYSES

Containment internal pressure is an initial condition used in the DBA analyses to establish the maximum peak containment internal pressure. The limiting DBAs considered, relative to containment pressure, are the LOCA and SLB, which are analyzed using computer modeled pressure transients. The worst case LOCA generates larger mass and energy release than the worst case SLB (SLB at 30% power) generates the greatest mass and energy release rate. Thus, the LOCA SLB event bounds the SLB LOCA event from the containment peak pressure standpoint (Ref. 1).

The initial pressure condition used in the containment analysis was 17.716 psia (3.013 psig). This resulted in a maximum peak pressure from a LOCA of 53.9 SLB of 42.25 psig. The containment analysis (Ref. 1) shows that the maximum peak calculated containment pressure, P_a , results from the limiting LOCA SLB at 30% power. The maximum containment pressure resulting from the worst case LOCA, 44.1 SLB, 42.25 psig, does not exceed the containment design pressure, 55.47 psig.

The containment was also designed for an external pressure load equivalent to 3.52.5 psig. The inadvertent actuation of the Containment Spray System was

(Continued)

BASES

analyzed to determine the resulting reduction in containment pressure (sudden cooling of -1.8 psid). The initial pressure condition used in this analysis was -0.3 -1.7 psig. EOC 3.6.4 limits the operation of containment to equal to or less than -1.0 psig. This resulted in a minimum pressure inside containment of -2.8 -2.0 psig, which is less than the design load.

(Continued)

BASES

APPLICABLE
SAFETY
ANALYSIS
(continued)

For certain aspects of transient accident analyses, maximizing the calculated containment pressure is not conservative. In particular, the cooling effectiveness of the Emergency Core Cooling System during the core reflood phase of a LOCA analysis increases with increasing containment backpressure. Therefore, for the reflood phase, the containment backpressure is calculated in a manner designed to conservatively minimize, rather than maximize, the containment pressure response in accordance with 10 CFR 50, Appendix K (Ref. 2).

Containment pressure satisfies Criterion 2 of the NRC Policy Statement ~~10CFR50.36(c)(2)(ii)~~.

LCO

Maintaining containment pressure at less than or equal to the LCO upper pressure limit ensures that, in the event of a DBA, the resultant peak containment accident pressure will remain below the containment design pressure. Maintaining containment pressure at greater than or equal to the LCO lower pressure limit ensures that the containment will not exceed the design negative differential pressure following the inadvertent actuation of the Containment Spray System.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. Since maintaining containment pressure within limits is essential to ensure initial conditions assumed in the accident analyses are maintained, the LCO is applicable in MODES 1, 2, 3 and 4.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, maintaining containment pressure within the limits of the LCO is not required in MODE 5 or 6.

ACTIONS

A.1

When containment pressure is not within the limits of the LCO, it must be restored to within these limits within ~~1 1/4~~ hours. The Required Action is necessary to return operation to within the bounds of the containment analysis. ~~The 1 1/4 hour Completion Time is reasonable to return pressure to normal. Consistent with the ACTIONS of LCO 3.6.1, "Containment," which requires that containment be restored to OPERABLE status within 1 hour.~~

B.1 and B.2

(Continued)

BASES

If containment pressure cannot be restored to within limits within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within

(Continued)

BASES

ACTIONS
(continued)

6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3.6.4A.1

Verifying that containment pressure is within limits ensures that unit operation remains within the limits assumed in the containment analysis. The 12 hour Frequency of this SR was developed based on operating experience related to trending of containment pressure variations during the applicable MODES. Furthermore, the 12 hour Frequency is considered adequate in view of other indications available in the control room, including alarms, to alert the operator to an abnormal containment pressure condition.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.5A Containment Air Temperature (Atmospheric and Dual)

BASES

BACKGROUND

The containment structure serves to contain radioactive material that may be released from the reactor core following a Design Basis Accident (DBA). The containment average air temperature is limited during normal operation to preserve the initial conditions assumed in the accident analyses for a loss of coolant accident (LOCA) or steam line break (SLB).

The containment average air temperature limit is derived from the input conditions used in the containment functional analyses and the containment structure external pressure analyses. This LCO ensures that initial conditions assumed in the analysis of containment response to a DBA are not violated during unit operations. The total amount of energy to be removed from containment by the Containment Spray and Cooling systems during post accident conditions is dependent upon the energy released to the containment due to the event, as well as the initial containment temperature and pressure. The higher the initial temperature, the more energy that must be removed resulting in higher to avoid exceeding peak containment pressure and temperature. Exceeding containment design pressure may result in leakage greater than that assumed in the accident analysis. Operation with containment temperature in excess of the LCO limit violates an initial condition assumed in the accident analysis.

APPLICABLE
SAFETY
ANALYSES

Containment average air temperature is an initial condition used in the DBA analyses that establishes the containment environmental qualification operating envelope for both pressure and temperature. The limit for containment average air temperature ensures that operation is maintained within the assumptions used in the DBA analyses for containment (Ref. 1).

The limiting DBAs considered relative to containment OPERABILITY are the LOCA and SLB. The DBA LOCA and SLB are analyzed using computer codes designed to predict the resultant containment pressure transients. No two DBAs are assumed to occur simultaneously or consecutively. The postulated DBAs are analyzed with regard to Engineered Safety Feature (ESF) systems, assuming the loss of one ESF bus, which is the worst case single active failure, resulting in one train each of the Containment Spray System, Residual Heat Removal System, and Containment Cooling System being rendered inoperable. A spectrum of SLBs were analyzed assuming the worst single active failure. The failure to close of one Main Steam Isolation Valve (MSIV) is the worst case single active failure for the SLB which results in the highest containment air temperature.

The limiting DBA for the maximum peak containment air temperature is an SLB. The initial containment average air temperature assumed in the design basis analyses

(Continued)

BASES (Continued)

(Ref. 1) is 120°F. This resulted in a maximum containment air temperature of [340.9]°F. The design temperature is [320]°F.

The containment design temperature is 271°F. The containment structure was analyzed to withstand the maximum peak temperature for the limiting DBA LOCA to ensure that it can contain the release of radioactive materials resulting from the accident. The containment structure was not analyzed for SLBs since it is a less limiting event structurally which were not considered design basis for containment structural design.

The spectrum of SLBs cases are temperature limit is used to establish the environmental qualification operating envelope for inside containment. The analysis shows that the peak containment temperature is 326°F (experienced during the MSLB at 70 % power). The performance of required safety-related equipment including the containment structure itself, is evaluated against this operating envelope to ensure the equipment can perform its safety function (Ref. 2). The maximum peak containment air temperature was calculated to exceed the containment design temperature for only a few seconds during the transient. The basis of the containment design temperature, however, is to ensure the performance of safety related equipment inside containment (Ref. 2). Thermal analyses showed that the time interval during which the containment air temperature exceeded the containment design temperature was short enough that the equipment surface temperatures remained below the design temperature. Therefore, it is concluded that the calculated transient containment air temperature is acceptable for the DBA SLB.

The temperature limit is also used in the depressurization Containment external pressure analyses to ensure that the minimum pressure limit is maintained following an inadvertent actuation of the Containment Spray System (Ref. 1).

The containment pressure transient is sensitive to the initial air mass in containment and, therefore, to the initial containment air temperature. The limiting DBA for establishing the maximum peak containment internal pressure is a LOCA. The temperature limit is used in this analysis to ensure that in the event of an accident the maximum containment internal pressure will not be exceeded. Containment average air temperature satisfies Criterion 2 of the NRC Policy Statement 10CFR50.36(c)(11).

LCO

During a DBA, with an initial Maintaining the containment average air temperature less than or equal to the LCO temperature limit, the resultant peak accident temperature is maintained below the containment design temperature. As a result, the ability of containment to perform its design function is ensured ensures that the initial containment temperature assumed in the DBA analysis will not be violated.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment. In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Therefore, maintaining containment average air temperature within the limit is not required in MODE 5 or 6.

(Continued)

BASES (Continued)

ACTIONS

A.1

When containment average air temperature is not within the limit of the LCO, it must be restored to within limit within 8 hours. This Required Action is necessary to return operation to within the bounds of the containment analysis. The 8 hour Completion Time is acceptable considering the sensitivity of the analysis to variations in this parameter and provides sufficient time to correct minor problems.

B.1 and B.2

If the containment average air temperature cannot be restored to within its limit within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3.6.5A.1

Verifying that containment average air temperature is within the LCO limit ensures that containment operation remains within the limit assumed for the containment analyses. In order to determine the containment average air temperature, an arithmetic average is calculated using four temperature measurements. The four temperature measurement locations are per-selected from:

a. TE-85 or TE-86, approximately 100 ft elevation between crane wall and containment wall.

b. TE-87 or TE-88, approximately 100 ft elevation between steam generators.

c. TE-89 or TE-90, approximately 140 ft elevation near equipment hatch or stairs at 270°, respectively.

d. TE-91 or TE-92, approximately 184 ft elevation on top of steam generator missile barriers away from steam generators.

~~taken at locations within the containment selected to provide a representative sample of the overall containment atmosphere.~~ The 24 hour Frequency of this SR is considered acceptable based on observed slow rates of temperature increase within containment as a result of environmental heat sources (due to the large volume of containment). Furthermore, the 24 hour Frequency is considered adequate in view of other indications available in the control room, including alarms, to alert the operator to an abnormal containment temperature condition.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.6A Containment Spray and Cooling Systems (~~Atmospheric and Dual~~) (~~Credit taken for iodine removal by the Containment Spray System~~)

BASES

BACKGROUND

The Containment Spray and Containment Cooling systems provide containment atmosphere cooling to limit post accident pressure and temperature in containment to less than the design values. Reduction of containment pressure and the iodine removal capability of the spray reduces the release of fission product radioactivity from containment to the environment, in the event of a Design Basis Accident (DBA), to within limits. The Containment Spray and Containment Cooling systems are designed to meet the requirements of 10 CFR 50, Appendix A, GDC 38, "Containment Heat Removal," GDC 39, "Inspection of Containment Heat Removal Systems," GDC 40, "Testing of Containment Heat Removal Systems," GDC 41, "~~Containment Atmosphere Cleanup,~~" GDC 42, "Inspection of Containment Atmosphere Cleanup Systems," and GDC 43, "Testing of Containment Atmosphere Cleanup Systems" (Ref. 1), ~~or other documents that were appropriate at the time of licensing (identified on a unit specific basis).~~

The Containment Cooling System and Containment Spray System are ~~is an~~ Engineered Safety Feature (ESF) systems. They are ~~it is~~ designed to ensure that the heat removal capability required during the post accident period can be attained. The Containment Spray System and the Containment Cooling System provide ~~redundant~~ diverse methods to limit and maintain post accident conditions to less than the containment design values.

Containment Spray System

The Containment Spray System consists of two separate trains of equal capacity, each capable of meeting the design bases. Each train includes a containment spray pump, spray headers, nozzles, valves, and piping. Each train is powered from a separate ESF bus. The refueling water storage tank (RWST) supplies borated water to the Containment Spray System during the injection phase of operation. In the recirculation mode of operation, ~~containment spray pump suction is transferred from the RWST to the containment sumps is supplied by manual realignment of the residual heat removal (RHR) pumps after the RWST is empty.~~

The Containment Spray System provides a spray of cold borated water mixed with sodium hydroxide (NaOH) from the spray additive tank into the upper regions of containment to reduce the containment pressure and temperature, and to reduce fission products from the containment atmosphere during a DBA. The RWST solution temperature is an important factor in determining the heat removal capability of the Containment Spray System during the injection phase. In the recirculation mode of operation, heat is removed from the containment sump water by the ~~residual heat~~

(Continued)

BASES (Continued)

BACKGROUND
(continued)

~~removal RHR heat exchangers and containment spray heat exchangers, coolers.~~ Each train of the Containment Spray System provides adequate spray coverage to meet the system design requirements for containment atmospheric heat removal.

The Spray Additive System injects an NaOH solution into the spray. The resulting alkaline pH of the spray enhances the ability of the spray to scavenge fission products from the containment atmosphere. The NaOH added in the spray also ensures an alkaline pH for the solution recirculated in the containment sump. The alkaline pH of the containment sump water ~~minimizes the evolution~~ maximizes the retention of iodine and minimizes the occurrence of chloride and caustic stress corrosion on mechanical systems and components exposed to the fluid.

The Containment Spray System is actuated either automatically by a containment High-3 High pressure signal or manually. ~~If an "S" signal is present, the high- high pressure signal automatically actuation opens the containment spray pump discharge valves, starts the two containment spray pumps. If containment pressure continues to increase, a "P" signal (Containment Pressure Hi-3-Hi-) generates a pump signal, opens the containment spray pump discharge valves, opens the spray additive tank outlet valves, initiates a phase "B" isolation signal, and begins the injection phase. A manual actuation of the Containment Spray System will begin the same sequence and can be initiated by requires the operator to actuate two separate switches on action from the main control board to begin the same sequence. The injection phase of containment spray continues until an RWST empty Low-Low level alarm is received. The Low-Low empty level alarm for the RWST actuates valves to align the Containment Spray System pump suction with the containment sump and/or signals the operator to manually align secure the system to the recirculation mode. The Containment Spray System in the recirculation mode maintains an equilibrium temperature between the containment atmosphere and the recirculated sump water. Operation of the Containment Spray System in the recirculation mode is controlled by the operator in accordance with the emergency operating procedures. After re-alignment of the RHR system to the containment recirculation sump, the associated RHR spray header isolation valve may be opened to allow continued spray operation of one train of spray utilizing the RHR pump to supply flow~~

Containment Cooling System

Two trains of containment fan cooling, ~~each consisting of two CFCUs with one shared CFCU for a total of five, each of sufficient capacity to supply 100% of the design cooling requirement, are provided. The five CFCUs are powered from three separate vital buses, with two CFCUs on each of two vital buses and the remaining CFCU from the third vital bus. Each train of two fan units CFCU is supplied with cooling water from a one of two separate trains of essential service water (ESW) loops of component cooling water (CCW). Air is drawn into the coolers through the fan and discharged to the annulus ring which supplies the steam generator compartments.~~

(Continued)

BASES (Continued)

pressurizer compartment, and instrument tunnel reactor coolant pumps, and outside the secondary shield in the lower areas of containment.

BACKGROUND
(continued)

During normal operation, all four fan units three CFCUS are operating. The fans are normally operated at high speed with ESW CCW supplied to the cooling coils. The Containment Cooling System, operating in conjunction with the Containment Ventilation and Air Conditioning systems, is CFCUS are designed to limit the ambient containment air temperature during normal unit operation to less than the limit specified in LCO 3.6.5, "Containment Air Temperature." This temperature limitation ensures that the containment temperature does not exceed the initial temperature conditions assumed for the DBAs.

In post accident operation following an actuation signal, the Containment Cooling System fans CFCUS are designed to start automatically in slow speed if not already running. If running in high (normal) speed, the fans automatically shift to slow speed. The fans are operated at the lower speed during accident conditions to prevent motor overload from the higher mass atmosphere. The temperature of the ESW CCW is an important factor in the heat removal capability of the fan units.

APPLICABLE
SAFETY
ANALYSES

The Containment Spray System and Containment Cooling System limits the temperature and pressure that could be experienced following a DBA. The limiting DBAs considered are the loss of coolant accident (LOCA) and the main steam line break (MSLB). The LOCA and MSLB are analyzed using computer codes designed to predict the resultant containment pressure and temperature transients. No DBAs are assumed to occur simultaneously or consecutively. The postulated DBAs are analyzed with regard to containment ESF systems, assuming the loss of one worst case single failure, containment spray train for LOCA and the failure to close of one MSIV for the SLB ESF bus, which are is the worst case single active failure for the respective DBAs. [Ref. 3] and results in one train of the Containment Spray System and Containment Cooling System being rendered inoperable. For the LOCA case, the worst single failure is the failure of one SSPS train, which results in only one CSP and two CFCUS available. For SLB case, the worst single failure is the failure of one MSIV to close with two CSP and three CFCUS operating.

The analysis and evaluation show that under the worst case scenario, the highest peak containment pressure is 46-12 42.25 psig (experienced during an MSLB at 30% power) compared to an allowable 47 psig. The analysis shows that the peak containment temperature is 340-85 326°F (experienced during an MSLB at 70% power) and is compared to the environmental qualifications of plant equipment. Both results meet the intent of the design basis. (See the Bases for LCO 3.6.4, "Containment Pressure," and LCO 3.6.5 for a detailed discussion.) The analyses and evaluations assume a unit specific power level of 100 102% for the LOCA with one containment spray train and two CFCUS operating. The limiting case MSLB analyses and evaluations

(Continued)

BASES (Continued)

APPLICABLE
SAFETY
ANALYSIS
(continued)

are based upon a unit specific power level of 30% or 70% with two one containment spray trains and one containment cooling train three CFCUS operating, and failure of one MSIV to close. Initial (pre-accident) containment conditions of 120°F and 4-5.13 psig are assumed. The analyses also assume a response time delayed initiation to provide conservative peak calculated containment pressure and temperature responses.

For certain aspects of transient accident analyses, maximizing the calculated containment pressure is not conservative. In particular, the effectiveness of the Emergency Core Cooling System during the core reflood phase of a LOCA analysis increases with increasing containment backpressure. For these calculations, the containment backpressure is calculated in a manner designed to conservatively minimize, rather than maximize, the calculated transient containment pressures in accordance with 10 CFR 50, Appendix K (Ref. 2).

The effect of an inadvertent containment spray actuation has been analyzed. An inadvertent spray actuation results in a - 2-9 2-0 1-80 psid containment pressure decrease and is associated with the based on a sudden cooling effect of 70°F in the interior of the leak tight containment. Additional discussion is provided in the Bases for LCO 3.6.4A.

The modeled Containment Spray System actuation from the containment analysis is based on a response time associated with exceeding the containment "P" signal (High-3 High-High) pressure setpoint to achieving full flow through the containment spray nozzles. The Containment Spray System total response time of [60] seconds includes diesel generator (DG) startup (for loss of offsite power), block sequenced loading of equipment, containment spray pump startup, and spray line filling (Ref. 4 3).

~~Containment cooling train~~The CFCUS performance for post accident conditions is given in Reference 4. The result of the analysis is that each train (two CFCUS) combined with one train of containment spray can provide 100% of the required peak cooling capacity during the post accident condition. ~~The train post accident cooling capacity under varying containment ambient conditions, required to perform the accident analyses, is also shown in Reference 5 4.~~

The modeled Containment Cooling System actuation from the containment analysis is based upon a response time associated with exceeding the containment High-3 High-High pressure setpoint to achieving full Containment Cooling System air and safety grade cooling water flow. The Containment Cooling System total response time of [60] seconds, includes signal delay, DG startup (for loss of offsite power), and service water component cooling water pump startup times (Ref. 6).

The Containment Spray System and the Containment Cooling System satisfies Criterion 3 of the NRC Policy Statement (10CFR50.36(c)(2)(ii)).

BASES (Continued)

LCO

During a DBA LOCA, a minimum of one containment cooling train ~~two CFCUs~~ and one containment spray train are required to maintain the containment peak pressure and temperature below the design limits (Refs. 7.4). Additionally, one containment spray train is also required to remove iodine from the containment atmosphere and maintain concentrations below those assumed in the safety analysis. To ensure that these requirements are met, two containment spray trains and two containment cooling CFCU trains consisting of ~~four CFCUs or three CFCUs~~ each supplied by a different vital bus must be OPERABLE. Therefore, in the event of an accident, at least one train in each system of containment spray and one train of CFCUs (two CFCUs) operate, assuming the worst case single active failure occurs. Each Containment Spray System train typically includes a spray pump, spray headers, nozzles, valves, piping, instruments, and controls to ensure an OPERABLE flow path capable of taking suction from the RWST upon an ESF actuation signal and automatically transferring. Upon actuation of the RWST empty alarm, the suction flowpath must be capable of being manually transferred to the containment sump.

Each Containment Cooling System CFCU typically includes demisters, cooling coils, dampers, fans, instruments, and controls to ensure an OPERABLE flow path.

APPLICABILITY

In MODES 1, 2, 3, and 4, a DBA could cause a release of radioactive material to containment and an increase in containment pressure and temperature requiring the operation of the containment spray trains and containment cooling trains CFCUs.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations of these MODES. Thus, the Containment Spray System and the Containment Cooling System are ~~is~~ not required to be OPERABLE in MODES 5 and 6.

ACTIONS

A.1

With one containment spray train inoperable, the inoperable containment spray train must be restored to OPERABLE status within 72 hours. In this Condition, the remaining OPERABLE spray and cooling trains are ~~is~~ adequate to perform the iodine removal and containment cooling functions. The 72 hour Completion Time takes into account the redundant heat removal capability afforded by the Containment Spray System, reasonable time for repairs, and low probability of a DBA occurring during this period.

(Continued)

BASES (Continued)

The 10 day portion of the Completion Time for Required Action A.1 is based upon engineering judgment. It takes into account the low probability of coincident entry into two Conditions in this Specification coupled with the low probability of an accident occurring during this time. Refer to Section 1.3, "Completion Times," for a more detailed discussion of the purpose of the "from discovery of failure to meet the LCO" portion of the Completion Time.

ACTIONS
(continued)B.1 and B.2

If the inoperable containment spray train cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 84 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging plant systems. The extended interval to reach MODE 5 allows additional time for attempting restoration of the containment spray train and is reasonable when considering the driving force for a release of radioactive material from the Reactor Coolant System is reduced in MODE 3.

C.1

~~With one of the required containment cooling trains inoperable, the inoperable required containment cooling train must be restored to OPERABLE status within 7 days. With one CFCU train inoperable such that a minimum of two CFCUs remain operable, restore the required CFCUs to OPERABLE status within 7 days. The components in this degraded condition provide the heat removal capabilities and are capable of providing at least 100% of the heat removal needs. The 7 day Completion Time was developed taking into account the redundant heat removal capabilities afforded by combinations of the Containment Spray System and Containment Cooling System and the low probability of DBA occurring during this period.~~

The 10 day portion of the Completion Time for Required Action C.1 is based upon engineering judgment. It takes into account the low probability of coincident entry into two Conditions in this Specification coupled with the low probability of an accident occurring during this time. Refer to Section 1.3 for a more detailed discussion of the purpose of the "from discovery of failure to meet the LCO" portion of the Completion Time.

D.1 and D.2

BASES (Continued)

~~With two required containment cooling trains inoperable, one of these required containment cooling trains must be restored to OPERABLE status within 72 hours. With one train of containment spray inoperable and one train of CFCUs inoperable such that a minimum of two CFCUs remain OPERABLE, restore one required train to OPERABLE status within 72 hours. The components remaining in OPERABLE status in this degraded condition provide iodine removal capabilities and are capable of providing at least 100% of the heat removal needs after an accident. The 72 hour Completion Time was developed taking into account the redundant heat removal capabilities afforded by combinations of the Containment Spray System and Containment Cooling System, the iodine removal function of the Containment Spray System, and the low probability of DBA occurring during this period.~~

ACTIONS
(continued)

E.1 and E.2

If the Required Action and associated Completion Time of Condition C or D of this LCO are not met, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

F.1

~~With two containment spray trains or any combination of three or more containment spray and cooling trains inoperable one containment spray train inoperable and two CFCU trains inoperable such that one or less CFCUs remain OPERABLE, the unit is in a condition outside the accident analysis. Therefore, LCO 3.0.3 must be entered immediately.~~

SURVEILLANCE
REQUIREMENTS

SR 3.6.6A.1

Verifying the correct alignment for manual, power operated, and automatic valves in the containment spray flow path provides assurance that the proper flow paths will exist for Containment Spray System operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these were verified to be in the correct position prior to locking, sealing, or securing. This SR does not require any testing or valve manipulation. Rather, it involves verification, ~~through a system walkdown,~~ that those valves outside containment (only check valves are inside containment) and capable of potentially being mispositioned are in the correct position.

(Continued)

BASES (Continued)

SR 3.6.6A.2

Operating each ~~required~~ containment cooling train fan unit CFCU for ≥ 15 minutes ensures that all trains are OPERABLE and that all associated controls are functioning properly. It also ensures that blockage, fan or motor failure, or excessive vibration can be detected for corrective action. The 31 day Frequency was developed considering the known reliability of the fan units and controls, the two train redundancy available, and the low probability of significant degradation of the ~~containment cooling train~~ CFCUS occurring between surveillances. It has also been shown to be acceptable through operating experience.

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.6.6A.3

Verifying that each required ~~containment cooling train~~ ESW cooling flow rate to each cooling unit is CFCU is receiving the required component cooling water flow of \geq ~~700~~ 1650 gpm provides assurance that the design flow rate assumed in the safety analyses will be achieved (Ref. 3 4). The component cooling water (CCW) system is hydraulically balanced during normal operation to ensure that at least 1650 gpm is delivered to each CFCU during a design bases event (DBA). The hydraulic system balance considers normal system alignments and the potential for any single active failure.

Operation of the CFCUS is permitted with lower CCW flow to the CFCUS during ASME Section XI testing or decay heat removal in MODE 4 with the residual heat removal heat exchangers in service. To support this conclusion a calculation was performed to evaluate containment heat removal with one train of containment spray OPERABLE and reduced CCW flow to three CFCUS. The calculation concluded that this configuration would provide adequate heat removal to ensure that the maximum design pressure of containment was not exceeded during a DBA in MODE 1. This analysis also determined that a single failure could not be tolerated during this condition and still assure that the maximum design pressure of containment would not be exceeded (Ref. 6).

The Frequency was developed considering the known reliability of the Cooling Water System, the two train redundancy available, and the low probability of a significant degradation of flow occurring between surveillances.

SR 3.6.6A.4

Verifying each containment spray pump's developed head at the flow test point is greater than or equal to the required developed head ensures that spray pump performance has not degraded during the cycle. Flow and differential pressure are

(Continued)

BASES (Continued)

normal tests of centrifugal pump performance required by Section XI Part 6 of the ASME O&M Code (Ref. 8 5). Since the containment spray pumps cannot be tested with flow through the spray headers, they are tested on recirculation flow. This test confirms one point on the pump design curve and is indicative of overall performance. Such inservice tests confirm component OPERABILITY, trend performance, and detect incipient failures by abnormal performance. The Frequency of the SR is in accordance with the Inservice Testing Program.

SR 3.6.6A.5 and SR 3.6.6A.6

These SRs require verification that each automatic containment spray valve actuates to its correct position and that each containment spray pump starts upon receipt of an actual or simulated actuation of a containment ~~"S"~~ ~~(High 1) 3 high-high~~ pressure signal with a coincident ~~"S"~~ signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. ~~The 18 month Frequency is based on the need to perform these Surveillances under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillances were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillances when performed at the 18 month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.~~

~~The surveillance of containment sump isolation valves is also required by SR 3.5.2.5. A single surveillance may be used to satisfy both requirements.~~

SURVEILLANCE
 REQUIREMENTS
 (continued)

SR 3.6.6A.7

This SR requires verification that each ~~[required] containment cooling train~~ ~~(FCU)~~ actuates upon receipt of an actual or simulated safety injection signal. The [18] month Frequency is based on engineering judgment and has been shown to be acceptable through operating experience. See SR 3.6.6.5 and SR 3.6.6.6, above, for further discussion of the basis for the 18 month Frequency.

SR 3.6.6A.8

With the containment spray inlet valves closed and the spray header drained of any solution, low pressure air or smoke can be blown through test connections. This SR ensures that each spray nozzle is unobstructed and provides assurance that spray coverage of the containment during an accident is not degraded. Due to the passive design of the nozzle, a test at ~~[the first refueling and at]~~ 10 year intervals is considered adequate to detect obstruction of the nozzles.

SR 3.6.6.9

(Continued)

BASES (Continued)

The CFCUs are designed to start or restart in low speed upon receipt of an SI signal. This limits the starting current and resultant load on the Emergency Diesel Generators. This allow optimum load sequencing of ESF equipment immediately following a DBA. This SR ensures that this feature is functioning properly. The 31 day frequency is selected based upon the normal operation of the CFCUs in high speed during power operation.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.7 Spray Additive System (~~Atmospheric, Subatmospheric, Ice Condenser, and Dual~~)

BASES

BACKGROUND The Spray Additive System is a subsystem of the Containment Spray System that assists in reducing the iodine fission product inventory in the containment atmosphere resulting from a Design Basis Accident (DBA ~~LOCA~~).

Radioiodine in its various forms is the fission product of primary concern in the evaluation of a DBA. It is absorbed by the spray droplets from the containment atmosphere. To enhance the iodine absorption capacity of the spray, the spray solution is adjusted to an alkaline pH that promotes iodine hydrolysis, in which iodine is converted to nonvolatile forms. Because of its stability when exposed to radiation and elevated temperature, sodium hydroxide (NaOH) is the preferred spray additive. The NaOH added to the spray also ensures a pH value of between ~~8.0~~ 8.5 and ~~10-11.0~~ 10.0 of the solution recirculated from the containment sump. This pH band minimizes the evolution of iodine as well as the occurrence of chloride and caustic stress corrosion on mechanical systems and components.

Eductor Feed Systems Only

The Spray Additive System consists of one spray additive tank that is shared by the two trains of spray additive equipment. Each train of equipment provides a flow path from the spray additive tank to a containment spray pump and consists of an eductor for each containment spray pump, valves, instrumentation, and connecting piping. Each eductor draws the NaOH spray solution from the common tank using a portion of the borated water discharged by the containment spray pump as the motive flow. The eductor mixes the NaOH solution and the borated water and discharges the mixture into the spray pump suction line. ~~The eductors are designed to ensure that the pH of the spray mixture is between 8.5 and 11.0.~~

BACKGROUND
(continued)

Gravity Feed Systems Only

~~The Spray Additive System consists of one spray additive tank, two parallel redundant motor operated valves in the line between the additive tank and the refueling water storage tank (RWST), instrumentation, and recirculation pumps. The NaOH solution is added to the spray water by a balanced gravity feed from the additive tank through the connecting piping into a weir within the RWST. There, it mixes with the borated water flowing to the spray pump suction. Because of the hydrostatic balance between the two tanks, the flow rate of the NaOH is controlled by the volume per foot of height ratio of the two tanks. This ensures a spray mixture pH that is ≥ 8.5 and ≤ 11.0 .~~

(Continued)

BASES

The Containment Spray System actuation signal opens the valves from the spray additive tank to the spray pump suction or the containment spray pump start a manual containment spray initiation signal also opens the valves from the spray additive tank after a 5 minute delay. The 28 30% to 31 32% NaOH by weight solution is drawn into the spray pump eductor suction which inject it into the spray pump suction. The spray additive tank capacity provides for the addition of NaOH solution to all of the water sprayed from the RWST into containment. The percent solution and volume of solution sprayed into containment ensures a long term containment sump pH of ≥ 9.0 8.0 and ≤ 9.5 10.0. This ensures the continued iodine retention effectiveness of the sump water during the recirculation phase of spray operation and also minimizes the occurrence of chloride induced stress corrosion cracking of the stainless steel recirculation piping.

APPLICABLE
SAFETY
ANALYSES

The Spray Additive System is essential to the removal of airborne iodine within containment following a DBA LOCA.

Following the assumed release of radioactive materials into containment, the containment is assumed to leak at its design value volume following the accident. The analysis assumes that 100% 56.3 a minimum 83% of the containment free volume is covered by the spray (Ref. 1).

The DBA response time assumed for the Spray Additive System is the same as for the Containment Spray System and is discussed in the Bases for LCO 3.6.6. "Containment Spray and Cooling Systems."

The DBA analyses assume that one train of the Containment Spray System/Spray Additive tank volume solution is added to the remaining Containment Spray System flow path to achieve the minimum required containment recirculation sump solution pH of 8.0 prior to reaching RWST low-low level.

The Spray Additive System satisfies Criterion 3 of the NRC Policy Statement 10CFR50.36(c)(2)(ii).

LCO

The Spray Additive System is necessary to reduce the release of radioactive material to the environment in the event of a DBA LOCA. To be considered OPERABLE, the volume and concentration of the spray additive solution must be sufficient to provide NaOH injection into the spray flow until the Containment Spray System suction path is switched from the RWST to the containment sump, and to raise the average long term containment sump spray solution pH to a level conducive to iodine removal retention in the liquid phase, namely, to between 8.5 8.0 and 11.0 10.5 10.0. This pH range maximizes the effectiveness of the iodine removal mechanism (from the containment atmosphere) without introducing

(Continued)

BASES

conditions that may induce caustic stress corrosion cracking of mechanical system components. In addition, it is essential that valves in the Spray Additive System flow paths are properly positioned and that automatic valves are capable of activating to their correct positions.

APPLICABILITY In MODES 1, 2, 3, and 4, a DBA ~~LOCA~~ could cause a release of radioactive material to containment requiring the operation of the Spray Additive System. The Spray Additive System assists in reducing the ~~containment atmosphere~~ iodine fission product inventory prior to release to the environment.

In MODES 5 and 6, the probability and consequences of these events are reduced due to the pressure and temperature limitations in these MODES. Thus, the Spray Additive System is not required to be OPERABLE in MODE 5 or 6.

ACTIONS

A.1

If the Spray Additive System is inoperable, it must be restored to OPERABLE within 72 hours. The pH adjustment of the Containment Spray System flow for corrosion protection and iodine removal enhancement is reduced in this condition. The Containment Spray System would still be available and would remove some iodine from the containment atmosphere in the event of a DBA. The 72 hour Completion Time takes into account the redundant flow path capabilities and the low probability of the worst case DBA occurring during this period.

B.1 and B.2

If the Spray Additive System cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 84 hours. The allowed Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging plant systems. The extended interval to reach MODE 5 allows 48 hours for restoration of the Spray Additive System in MODE 3 and 36 hours to reach MODE 5. This is reasonable when considering the reduced pressure and temperature conditions in MODE 3 for the release of radioactive material from the Reactor Coolant System.

SURVEILLANCE REQUIREMENTS

SR 3.6.7.1

Verifying the correct alignment of Spray Additive System manual, power operated, and automatic valves in the spray additive flow path provides

(Continued)

BASES

assurance that the system is able to provide additive to the Containment Spray System in the event of a DBA. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves were verified to be in the correct position prior to locking, sealing, or securing. This SR does not require any testing or valve manipulation. Rather, it involves verification, ~~through a system walkdown~~, that those valves outside containment and capable of potentially being mispositioned are in the correct position.

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.6.7.2

To provide effective iodine removal, the containment spray must be an alkaline solution. Since the RWST contents are normally acidic, the volume of the spray additive tank must provide a sufficient volume of spray additive to adjust pH for all water injected. This SR is performed to verify the availability of sufficient NaOH solution in the Spray Additive System. ~~The required volume may be surveilled using an indicated level band of 50 to 88% for the Spray Additive Tank which corresponds to the LCO 3.6.7 minimum and maximum limits adjusted conservatively for instrument accuracy of $\pm 0.3\%$. The 184 day Frequency was developed based on the low probability of an undetected change in tank volume occurring during the SR interval (the tank is isolated during normal unit operations). Tank level is also indicated and equipped with a low level alarm in the control room, so that there is high confidence that a substantial change in level below an acceptable value would be detected.~~

SR 3.6.7.3

This SR provides verification of the NaOH concentration in the spray additive tank and is sufficient to ensure that the spray solution being injected into containment is at the correct pH level. The 184 day Frequency is sufficient to ensure that the concentration level of NaOH in the spray additive tank remains within the established limits. This is based on the low likelihood of an uncontrolled change in concentration (the tank is normally isolated) and the probability that any substantial variance in tank volume will be detected.

SR 3.6.7.4

This SR provides verification that each automatic valve in the Spray Additive System flow path actuates to its correct position. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

(Continued)

BASES (Continued)

SR 3.6.7.5

To ensure that the correct operation of the Spray Additive System pH level is established in the borated water solution provided by the Containment Spray System, the flow rate in to the Spray Additive System eductors is verified once every 5 years by verifying that the solution flow path is not blocked from the RWST through test valve 8993 for each of the two flow paths. Flow of between 50 and 100 gpm through the eductor test loops (supplied from the RWST) simulates flow from the Chemical Additive Tank. The flow rate through the eductors is not critical because the entire Chemical Additive Tank contents is injected prior to isolation. This SR provides assurance that the correct amount of NaOH will be metered into the flow path upon Containment Spray System initiation. Due to the passive nature of the spray additive flow controls, the 5 year Frequency is sufficient to identify component degradation that may affect flow rate.

REFERENCES 1. FSAR, Chapter 6.2.

B 3.6 CONTAINMENT SYSTEMS

B 3.6.8 Hydrogen Recombiners (~~Atmospheric, Subatmospheric, Ice Condenser, and Dual~~) (~~if permanently installed~~)

BASES

BACKGROUND . The function of the hydrogen recombiners is to eliminate the potential breach of containment due to a hydrogen-oxygen reaction.

Per 10 CFR 50.44, "Standards for Combustible Gas Control Systems in Light-Water-Cooled Reactors" (Ref. 1), and GDC 41, "Containment Atmosphere Cleanup" (Ref. 2), hydrogen recombiners are required to reduce the hydrogen concentration in the containment following a loss of coolant accident (LOCA) or steam line break (SLB). The recombiners accomplish this by recombining hydrogen and oxygen to form water vapor. The vapor remains in containment, thus eliminating any discharge to the environment. The hydrogen recombiners are manually initiated since flammable limits would not be reached until several days after a Design Basis Accident (DBA).

Two 100% capacity independent hydrogen recombiner systems are provided. Each consists of controls located in the control room, a power supply and a recombiner. Recombination is accomplished by heating a hydrogen-air mixture above 1150°F. ~~The resulting water vapor and discharge gases are cooled prior to discharge from the recombiner.~~ A single recombiner is capable of maintaining the hydrogen concentration in containment below the 4.1 volume percent (v/o) flammability limit. Two recombiners are provided to meet the requirement for redundancy and independence. Each recombiner is powered from a separate Engineered Safety Features bus, and is provided with a separate power panel and control panel.

APPLICABLE SAFETY ANALYSES

The hydrogen recombiners provide for the capability of controlling the bulk hydrogen concentration in containment to less than the lower flammable concentration of 4.1 v/o following a DBA. This control would prevent a containment wide hydrogen burn, thus ensuring the pressure and temperature assumed in the analyses are not exceeded. The limiting DBA relative to hydrogen generation is a LOCA. Hydrogen may accumulate in containment following a LOCA as a result of:

- a. A metal steam reaction between the zirconium fuel rod cladding and the reactor coolant;
- b. Radiolytic decomposition of water in the Reactor Coolant System (RCS) and the containment sump;
- c. Hydrogen in the RCS at the time of the LOCA (i.e., hydrogen dissolved in the reactor coolant and hydrogen gas in the pressurizer vapor space); or

(Continued)

BASES (Continued)

- d. Corrosion of metals exposed to containment spray and Emergency Core Cooling System solutions.

To evaluate the potential for hydrogen accumulation in containment following a LOCA, the hydrogen generation as a function of time following the initiation of the accident is calculated. Conservative assumptions recommended by Reference 3 are used to maximize the amount of hydrogen calculated.

Based on the conservative assumptions used to calculate the hydrogen concentration versus time after a LOCA, the hydrogen concentration in the primary containment would reach 3.5 v/o about 616 days after the LOCA and 4.0 v/o about 2 days later if no recombiner was functioning (Ref. 3). Initiating the hydrogen recombiners when the primary containment hydrogen concentration reaches 3.5 v/o will maintain the hydrogen concentration in the primary containment below flammability limits.

The hydrogen recombiners are designed such that, with the conservatively calculated hydrogen generation rates discussed above, a single recombiner is capable of limiting the peak hydrogen concentration in containment to less than 4.0 v/o (Ref. 4). The Hydrogen Purge System is similarly designed and constructed such that one of two redundant trains is Design Class I (for Quality and electrical power) but not redundant. As such, it is an adequate backup to the redundant hydrogen recombiners since it would be relied upon only in the event of a non-design basis condition.

The hydrogen recombiners satisfy Criterion 3 of the NRC Policy Statement 10CFR50.36(c)(2)(11).

LCO

Two hydrogen recombiners must be OPERABLE. This ensures operation of at least one hydrogen recombiner in the event of a worst case single active failure.

Operation with at least one hydrogen recombiner ensures that the post LOCA hydrogen concentration can be prevented from exceeding the flammability limit.

APPLICABILITY

In MODES 1 and 2, two hydrogen recombiners are required to control the hydrogen concentration within containment below its flammability limit of 4.1 v/o following a LOCA, assuming a worst case single failure.

In MODES 3 and 4, both the hydrogen production rate and the total hydrogen produced after a LOCA would be less than that calculated for the DBA LOCA. Also, because of the limited time in these MODES, the probability of an accident requiring the hydrogen recombiners is low. Therefore, the hydrogen recombiners are not required in MODE 3 or 4.

(Continued)

BASES

In MODES 5 and 6, the probability and consequences of a LOCA are low, due to the pressure and temperature limitations in these MODES. Therefore, hydrogen recombiners are not required in these MODES.

ACTIONS

A.1

With one containment hydrogen recombiner inoperable, the inoperable recombiner must be restored to OPERABLE status within 30 days. In this condition, the remaining OPERABLE hydrogen recombiner is adequate to perform the hydrogen control function. However, the overall reliability is reduced because a single failure in the OPERABLE recombiner could result in reduced hydrogen control capability. The 30 day Completion Time is based on the availability of the other hydrogen recombiner, the small probability of a LOCA or SLB occurring (that would generate an amount of hydrogen that exceeds the flammability limit), and the amount of time available after a LOCA or SLB (should one occur) for operator action to prevent hydrogen accumulation from exceeding the flammability limit.

Required Action A.1 has been modified by a Note that states the provisions of LCO 3.0.4 are not applicable. As a result, a MODE change is allowed when one recombiner is inoperable. This allowance is based on the availability of the other hydrogen recombiner, the small probability of a LOCA or SLB occurring (that would generate an amount of hydrogen that exceeds the flammability limit), and the amount of time available after a LOCA or SLB (should one occur) for operator action to prevent hydrogen accumulation from exceeding the flammability limit.

B.1 and B.2

With two hydrogen recombiners inoperable, the ability to perform the hydrogen control function via alternate capabilities must be verified by administrative means within 1 hour. The alternate hydrogen control capabilities are provided by the containment Hydrogen Purge System. The 1 hour Completion Time allows a reasonable period of time to verify that a loss of hydrogen control function does not exist. In addition, the alternate hydrogen control system capability must be verified once per 12 hours thereafter to ensure its continued availability. Both the initial verification and all subsequent verifications may be performed as an administrative check by examining logs or other information to determine the availability of the ~~key locked~~ alternate hydrogen control system. It does not mean to perform the surveillances are needed to demonstrate OPERABILITY of the alternate hydrogen control system. If the ability to perform the hydrogen control function is maintained, continued operation is permitted with two hydrogen recombiners inoperable for up to 7 days. Seven days is a reasonable time to allow two hydrogen recombiners to be inoperable because the hydrogen control function is maintained and because of the low probability of the occurrence of a LOCA that would generate hydrogen in the amounts capable of exceeding the flammability limit.

(Continued)

BASES (Continued)

C.1

If the inoperable hydrogen recombiner(s) cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours. The Completion Time of 6 hours is reasonable, based on operating experience, to reach MODE 3 from full power conditions in an orderly manner and without challenging plant systems.

SURVEILLANCE
REQUIREMENTS

SR 3.6.8.1

Performance of a system functional test for each hydrogen recombinder ensures the recombiners are operational and can attain and sustain the temperature necessary for hydrogen recombination. In particular, this SR verifies that the minimum heater sheath temperature increases to $\geq 700^{\circ}\text{F}$ in ≤ 90 minutes. After reaching 700°F , the power is increased to maximum power for approximately 2 minutes and power is verified to be ≥ 60 kW.

Operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. Therefore, the Frequency was concluded to be acceptable from a reliability standpoint.

SR 3.6.8.2

This SR ensures there are no physical problems that could affect recombinder operation. Since the recombiners are mechanically passive, they are not subject to mechanical failure. The only credible failure involves loss of power, blockage of the internal flow, missile impact, etc.

A visual inspection is sufficient to determine abnormal conditions that could cause such failures. The 18 month Frequency for this SR was developed considering the incidence of hydrogen recombiners failing the SR in the past is low.

SR 3.6.8.3

This SR, which is performed following the functional test of SR 3.6.8.1 requires performance of a resistance to ground test for each heater phase to ensure that there are no detectable grounds in any heater phase. This is accomplished by verifying that the resistance to ground for any heater phase is $\geq 10,000$ ohms.

The 18 month Frequency for this Surveillance was developed considering the incidence of hydrogen recombiners failing the SR in the past is low.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.6

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431, to make them plant-specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE NUMBER

JUSTIFICATION

- 3.6-1 This change supports implementation of the 10 CFR 50, Appendix J, Option B, for performance based leakage rate testing Option B by referencing the Containment Leakage Rate Testing Program described in the Administrative Controls section. This change is consistent with the CTS and Traveler TSTF-52.
- 3.6-2 Consistent with Traveler TSTF-17, Rev. 1, this change would extend the testing frequency of containment air lock interlock mechanisms from 184 days to 24 months and delete the SR note per implementation of Appendix J, Option B. SR 3.6.2.2 would be revised to require testing of the air lock door interlocks at an interval of 24 months. Typically, the interlock is installed after each refueling outage, verified OPERABLE with this surveillance and not disturbed until the next refueling outage. If the need for maintenance arises when the interlock is required, the performance of the interlock surveillance would be required following the maintenance. In addition, when an air lock is opened during times the interlock is required, the operator first verifies that one door is completely shut and the door seals pressurized before attempting to open the other door. Therefore, the interlock is not challenged except during actual testing of the interlock. Consequently, it should be sufficient to ensure proper operation of the interlock by testing the interlock on a 24 month interval.
- 3.6-3 Consistent with the CTS, a Note has been added to clarify that the valves listed are not addressed in LCO 3.6.3. These valves utilize the steam generators and associated piping as a closed system inside of containment. These valves have separate LCOs that provide the appropriate Required Actions in the event these valves are inoperable.
- 3.6-4 Consistent with traveler TSTF-30, Rev. 1, this change takes credit for a closed system for isolating a failed containment isolation valve. The change would extend the Completion Time for a closed system flow path with an inoperable isolation valve to 72 hours. General Design Criteria 57 allows the use of a closed system in combination with a containment isolation valve to provide two containment barriers against the release of radioactive material following an accident. Currently, LCO 3.6.3 does not allow the use of a closed system to isolate a failed containment isolation valve even though the closed system is subjected to Type A containment leakage testing, is missile protected, and is seismic Category I piping. A closed system also typically has flow through it during normal operation such that any loss of integrity could be continually observed through a leakage detection system within containment and during routine system walkdowns for closed systems outside containment. As such, the use of a closed system is no different from isolating a failed containment isolation valve by use of a single valve as specified in Required ACTION A.1. Therefore, LCO 3.6.3, Required ACTION C.1 is revised to allow 72 hours to isolate a failed valve associated with a closed system. This 72 hour period provides the necessary time to perform repairs on a failed containment isolation valve when relying on an intact closed system. A Completion Time of 72 hours is considered appropriate given that certain valves may be located inside containment, the reliability of the closed system, and that 72 hours is typically provided for losing one train of redundancy throughout the NUREG-1431. If the closed system and associated containment isolation valve were both inoperable, the plant would be in LCO 3.0.3 since there is no specific Condition specified.

JUSTIFICATION FOR DIFFERENCES FROM NUREG-1431

NUREG-1431 Section 3.6

CHANGE NUMBER

JUSTIFICATION

- 3.6-5 This change is in accordance with TSTF-45, Rev. 1 and revises SR 3.6.3.3 and SR 3.6.3.4 to specify that only containment isolation valves that are not locked, sealed, or otherwise secured are required to be verified closed. The position of the locked, sealed, or otherwise secured valves was verified before the valves were locked, sealed, or otherwise secured.
- 3.6-6 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.6-7 This change is in accordance with TSTF-46, Rev. 1 and revises SR 3.6.3.5 to delete the reference to verifying the isolation time of "each power operated" containment isolation valve and only require verification of each "automatic isolation valve." Valves credited as containment isolation valves which are power operated (i.e., can be remotely operated) that do not receive a containment isolation signal do not have as isolation time as assumed in the accident analyses since they require operator action. Therefore, deleting reference to power operated isolation valve time testing reduces the potential for misinterpreting the requirements of this SR while maintaining the assumptions of the accident analyses.
- 3.6-8 Revises the Completion Time for the restoration of containment pressure from 1 hour to [4] hours. The [4] hour Completion Time is consistent with the CTS. The [4] hours [] allows the adequate time to take all Required Actions in a controlled manner.
- 3.6-9 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.6-10 Replaces the chemical additive tank volume limits in gallons with a tank level limits in percent [].
- 3.6-11 A new Note is added to ITS 3.6.3, Condition A.2 [and C.2] in accordance with Traveler WOG-91. The additional Note applies to isolation devices that are locked, sealed or otherwise secured in position and allows these devices to be verified closed by use of administrative means. It is sufficient to assume that initial establishment of component status (e.g., isolation valves closed) was performed correctly. Subsequently, verification is intended to ensure the component has not been inadvertently repositioned. Given that the function of locking, sealing, or securing components is to ensure the same avoidance of inadvertent repositioning, the periodic reverification should only be a verification of the administrative control that ensures that the component remains in the required state. It would be inappropriate to remove the lock, seal, or other means of securing the component solely to perform an active verification of the required state.
- 3.6-12 Consistent with SR 3.6.3.8, which provides that actuation position testing is not required for valves locked, sealed, or otherwise secured in their required position under administrative control, this change would provide that isolation time testing is not required for automatic containment isolation valves that are locked, sealed, or otherwise secured in their required position under administrative control. This change is consistent with WOG-91.
- 3.6-13 A clarifying note is added to SR 3.6.3.7 that would allow that leakage rate testing for containment purge valves with resilient seals is not required when the penetration flow path is isolated by a leak tested blind flange.
- 3.6-14 This change would incorporate plant specific operability criteria for containment fan cooler units required to meet design functional requirements. These requirements are contained in the CTS.
- 3.6-15 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.6-16 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.6-17 The ACTIONS and SRs of ITS 3.6.3 are modified to reflect DCP current license bases allowance to open at one time any 2 of 3 the DBA qualified 48 inch purge supply and/or exhaust flow paths and 12 inch vacuum/pressure relief flow paths.

(3 Pages)

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.6-1	This change supports implementation of 10 CFR 50, Appendix J, Option B, approved in November 1995. Testing is performed in accordance with the Containment Leakage Rate Testing Program as described in the Administrative Controls section. This change is consistent with CTS and is in accordance with Traveler TSTF-52.	Yes	Yes, in CTS	Yes	Yes, approved as Amendment 111
3.6-2	This change would extend the testing frequency of containment air lock interlock mechanisms from 184 days to 24 months. This change is in accordance with TSTF-17, Rev. 1.	Yes	Yes	Yes	Yes
3.6-3	Consistent with the CTS, a Note has been added to clarify that the valves listed are not addressed in LCO 3.6.3. These valves utilize the steam generators and associated piping as a closed system inside of containment. These valves also have separate LCOs that provide the appropriate Required Actions in the event these valves are inoperable.	Yes	Yes	Yes	Yes
3.6-4	This change would extend the Completion Time for a closed system flow path with an inoperable isolation valve to 72 hours. This change is in accordance with TSTF-30, Rev. 1.	Yes	Yes	No, WC does not have GDC 57 valves	No, Callaway does not have GDC 57 valves
3.6-5	This change would revise SR 3.6.3.3 and SR 3.6.3.4 to specify that only containment isolation valves that are not locked, sealed, or otherwise secured are required to be verified closed. This change is in accordance with TSTF-45, Rev. 1.	Yes	Yes	Yes	Yes
3.6-6	Consistent with the current CPSES TS, a note is added to SR 3.6.3.4 to clarify that the blind flange on the fuel transfer canal need not be verified closed except after each drainage of the canal.	No	Yes	No	No
3.6-7	This change would revise SR 3.6.3.5 to delete the reference to verifying the isolation time of "each power operated" containment isolation valve and only require verification of each "automatic isolation valve." This change is in accordance with TSTF-46, Rev. 1.	Yes	Yes	Yes	Yes

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.6-8	This change would revise the Completion Time for the restoration of containment pressure from 1 hour to [4] hours. The [4] hour Completion Time is consistent with the CTS.	Yes	Yes	No, CTS has 1 hour completion time.	No, CTS has 1 hour completion time.
3.6-9	These portions of the specification do not apply since a containment cooling system is not part of the CPSES plant design.	No	Yes	No	No
3.6-10	This change would replace the chemical additive tank volume limits in gallons with tank level limits in percent [].	Yes	Yes	No -CTS in gallons	No - Callaway does not have this system.
3.6-11	This change would provide that the Required Action to periodically verify the affected penetration flow path is isolated does not apply to manual valves and blind flanges that are locked, sealed, or otherwise secured since these were verified to be in the correct position prior to locking, sealing, or securing.	Yes	Yes	Yes	Yes
3.6-12	Consistent with SR 3.6.3.8 which provides that actuation position testing is not required for valves locked, sealed, or otherwise secured in their required position under administrative control, this change would provide that isolation time testing is not required for automatic containment isolation valves that are locked, sealed, or otherwise secured in their required position under administrative control.	Yes	Yes	Yes	Yes
3.6-13	A clarifying note is added to SR 3.6.3.7 that would allow that leakage rate testing for containment purge valves with resilient seals is not required when the penetration flow path is isolated by a leak tested blind flange.	Yes	Yes	Yes	Yes
3.6-14	This change would incorporate DCPD specific OPERABILITY criteria for CFCU required to meet design functional requirements.	Yes	No	No	No
3.6-15	SR 3.6.6.7 would be modified to reflect Callaway plant specific requirements for cooling water automatic functions as well as containment cooler functions	No	No	No	Yes

TECH SPEC CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.6-16	Consistent with the CTS, this specification has been modified to reflect the Callaway recirculation fluid pH control system.	No	No	No	Yes
3.6-17	The ACTIONS and SRs of ITS 3.6.3 are modified to reflect DCPD current licensing bases allowance to open at one time any 2 of 3 the DBA qualified 48 inch purge supply and/or exhaust valves and 12 inch vacuum/pressure relief valves.	Yes	No	No	No
3.6-18	Consistent with CTS 4.6.1.7.2.a, a new SR is being added to perform leakage rate testing for the 36 inch containment purge valves and associated blank flange once per 24 months and following each re-installation of the blank flange.	No, CTS does not contain 24 month requirement	No, CTS does not contain 24 month requirement.	Yes	Yes
3.6-19	Consistent with CTS 4.6.1.7.4, SR 3.6.3.7 is being revised to cover the leak rate testing of the mini-purge valves with resilient seals after opening for testing once each 184 days and within 92 days after opening the valve.	No, DCPD does not have Mini-purge system	No, not in CTS	Yes	Yes
3.6-20	Not Used	N/A	N/A	N/A	N/A
3.6-21	Consistent with Wolf Creek CTS 4.6.2.3.b, SR 3.6.6.3 is being deleted and included as part of SR 3.6.6.7. The current licensing basis only requires for the flow rate to be tested as part of the actuation test every 18 months not the 31 days frequency required in the ITS 3.6.6.3.	No	No	Yes	No
3.6-22	This change deletes the Note to ITS 3.6.3, Condition A and B. deleted.	No, retain ITS wording	No, retain ITS wording	Yes	Yes
3.6-23	This change deletes the Note to ITS 3.6.3, Condition C.	No, retain ITS wording	No, retain ITS wording	Yes	Yes

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple

Methodology for Cross-Reference Tables
(Continued)

paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).

Methodology for Cross-Reference Tables
(Continued)

- Note: The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."
- Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

3/4.7 PLANT SYSTEMS

3/4.7.1 ~~TURBINE CYCLE MAIN STEAM SAFETY VALVES (MSSVs)~~

SAFETY VALVES

LIMITING CONDITION FOR OPERATION

3.7.1.1 All main steam line Code safety valves associated with each steam generator shall be OPERABLE with lift settings as specified in Table 3.7-2.

01-01-A

APPLICABILITY: MODES 1, 2 and 3.

ACTION*:

- a. With one or more main steam line Code safety valves inoperable, operation in MODES 1, 2 and 3 may proceed provided, that within 4 hours, either the inoperable valve is restored to OPERABLE status or the Power Range Neutron Flux High Trip Setpoint is reduced reduce power per Table 3.7-1; otherwise, be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 hours.

01-02-LS1

01-04-LS3

(new) Reduce the Power Range High Neutron Flux reactor trip set points to less than or equal to the Maximum Allowable % RTP specified in Table 3.7-1 for the number of OPERABLE MSSVs within 72 hours. Otherwise, be in at least MODE 3 within 6 hours and in MODE 4 within 12 hours.

01-04-LS3

- b. The provisions of Specification 3.0.4 are not applicable.

01-05-M

(new) With one or more steam generators with less than two MSSVs OPERABLE, be in at least MODE 3 within the next 6 hours and in MODE 4 within 12 hours.

01-06-M

SURVEILLANCE REQUIREMENTS

4.7.1.1** No additional requirements other than those required by Specification 4.0.6. Verify each required MSSV lift setpoint per Table 3.7-2 in accordance with the Inservice Testing Program. Following testing, lift setting shall be within ± 1%.

01-07-A

* Separate Condition entry is allowed for each MSSV.

01-02-LS1

** Only required to be performed in MODES 1 and 2.

01-05-M

~~* The lift setting pressure shall correspond to ambient conditions of the valve at nominal operating temperature and pressure.~~

01-10-EG

~~** Within +1% following main steam line Code Safety Valve testing.~~

01-07-A

PLANT SYSTEMS

AUXILIARY FEEDWATER (AFW) SYSTEM

LIMITING CONDITION FOR OPERATION

3.7.1.2 At least three ~~three~~ steam generator auxiliary feedwater pumps and ~~trains~~ associated flow paths shall be OPERABLE with:

02-01-LG

- a. ~~Two motor driven auxiliary feedwater pumps, each capable of being powered from separate vital busses, and~~
- b. ~~One steam turbine driven auxiliary feedwater pump capable of being powered from two OPERABLE and redundant steam supply sources.~~

APPLICABILITY: MODES 1, 2 and 3-

02-04-M

~~MODE 4* when steam generator is relied upon for heat removal~~

ACTIONS:

02-02-LS5

~~(new) With one steam supply to turbine driven AFW inoperable, restore the inoperable steam supply to OPERABLE status within 7 days and 10 days from discovery of failure to meet the LCO~~

02-03-M

a. ~~With one auxiliary feedwater pump inoperable in MODE 1, 2 or 3, restore the required auxiliary feedwater pumps train to OPERABLE status within 72 hours and within 10 days of discovery of failure to meet the LCO or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 12 hours.~~ or

02-03-M

02-10-LS21

b. ~~With two auxiliary feedwater pumps trains inoperable in MODE 1, 2 or 3, be in at least HOT STANDBY within 6 hours and in HOT SHUTDOWN within the following 6 12 hours.~~

02-10-LS21

c. ~~With three auxiliary feedwater pumps trains inoperable in MODE 1, 2 or 3, immediately initiate corrective action to restore at least one auxiliary feedwater pump train to OPERABLE status as soon as possible. NOTE: LCO 3.0.3 and all other LCO Required Actions requiring MODE changes are suspended until one AFW train is restored to OPERABLE status.~~

02-05-A

~~(new) With the required AFW train inoperable in MODE 4 immediately initiate action to restore the AFW train to OPERABLE status~~

02-04-M

~~*Only one AFW train, which includes a motor driven pump, is required to be OPERABLE in MODE 4~~

02-04-M

SURVEILLANCE REQUIREMENTS

4.7.1.2.1 Each auxiliary feedwater pump train shall be demonstrated OPERABLE:

a. At least once per 31 days by-

- 1) Deleted.

SURVEILLANCE REQUIREMENTS

- (2) Verifying that each ~~non-automatic manual power operated and automatic valve in the pump water flow path and both steam supplies to the steam turbine driven pump that is not locked, sealed, or otherwise secured in position, is in its correct position.~~ 02-07-M
02-09-A

- (3) ~~Verifying that each non automatic valve in both steam supplies to the steam turbine driven pump that is not locked, sealed, or otherwise secured in position, is in its correct position.~~ 02-09-A

- b. * ~~At least once per 92 days on a STAGGERED TEST BASIS by: Testing the steam turbine-driven pump and motor-driven pumps pursuant to in accordance with the frequency specified in Specification 4.0.5* the Inservice Testing Program. The provisions of Specification 4.0.4 are not applicable for entry into MODE 3 for the steam turbine-driven pump.~~ 02-08-LS6
02-04-M

- c. ** ~~At least once per 18 months by verifying that each auxiliary feedwater pump starts and valve opens* as designed automatically upon receipt of an a simulated or actual Auxiliary Feedwater Actuation test signal.~~ 02-11-A
02-12-TRI

- (new)
* ** ~~At least once per 18 months by verifying each AFW pump starts automatically on an actual or simulated actuation signal.~~ 02-11-A
02-12-TRI
02-04-M

- * ~~Not required to be performed for the steam turbine-driven pump, when until 24 hours after the secondary steam supply pressure is greater than 650 psig.~~ 02-14-M

- ** ~~Not applicable in MODE 4 when steam generator is relied upon for heat removal.~~ 02-04-M

PLANT SYSTEMS

AUXILIARY FEEDWATER SOURCES - CONDENSATE STORAGE TANK (CST) AND FIRE WATER STORAGE TANK (FWST)

LIMITING CONDITION FOR OPERATION

3.7.1.3 The Condensate Storage Tank (CST) ~~level~~ shall have a usable volume of ~~be at least 164,678 gallons of water 41.3%~~ with an open flow path to the Auxiliary 03-01-LG Feedwater (AFW) pump suction, and the Fire Water Storage Tank (FWST) ~~level~~ shall have a usable volume of ~~be at least 57,922 gallons of water 22.2%~~ for one Unit operation and ~~115,844 gallons of water 41.7%~~ for two Unit operation with a flow path capable of being aligned to the AFW pump suction.

APPLICABILITY: MODES 1, 2 and 3-~~4~~

~~MODE 4 when steam generator is relied upon for heat removal~~

02-04-M

ACTION:

- a. With the CST usable volume less than 164,678 gallons ~~level not within limits~~, or with the CST flow path not open to the AFW pumps suction, within four hours restore the required CST conditions; or, be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN ~~without reliance upon steam generator for heat removal~~ within the following ~~6~~12 hours. 02-04-M
02-10-LS21
- b. With an FWST usable volume less than 57,922 gallons for one Unit operation and 115,844 gallons for two Unit operation ~~level not within limits~~, or with the FWST flow path not capable of being aligned to the AFW pump suction, within seven days restore the required FWST conditions; or, be in at least HOT STANDBY, within the next 6 hours and in HOT SHUTDOWN ~~without reliance upon steam generator for heat removal~~ within the following ~~6~~12 hours. 02-10-LS21
02-04-M

SURVEILLANCE REQUIREMENTS

- 4.7.1.3.1 The CST volume shall be demonstrated at least once per 12 hours by verifying the usable volume ~~level~~ is within its limits.
- 4.7.1.3.2 The FWST volume shall be demonstrated at least once per 12 hours by verifying the usable volume ~~level~~ is within its limits.
- 4.7.1.3.3 Verify the FWST is capable of being aligned to the Auxiliary Feedwater System by cycling each FWST valve in the flow path necessary for realignment through at least one full cycle once per quarter. 02-13-A

PLANT SYSTEMS

SECONDARY SPECIFIC ACTIVITY

LIMITING CONDITION FOR OPERATION

3.7.1.4 The specific activity of the Secondary Coolant System shall be less than or equal to 0.1 microcurie/gram DOSE EQUIVALENT I-131.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

With the specific activity of the Secondary Coolant System greater than 0.1 microcurie/gram DOSE EQUIVALENT I-131, be in at least HOT STANDBY within 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.7.1.4 ~~Verify that~~ The specific activity of the Secondary Coolant System shall be determined to be within the limit by performance of the sampling and analysis program of Table 4.7-1 ~~is~~ $\leq 0.10 \mu\text{Ci/gm}$ DOSE EQUIVALENT I-131 once per 31 days.

04-01-M

TABLE 4.7-1

SECONDARY COOLANT SYSTEM SPECIFIC ACTIVITY
SAMPLE AND ANALYSIS PROGRAM

<u>TYPE OF MEASUREMENT</u> <u>AND ANALYSIS</u>	<u>SAMPLE AND ANALYSIS</u> <u>FREQUENCY</u>	
1. Gross Radioactivity Determination hours.	At least once per 72	<u>04-02-LS8</u>
2. Isotopic Analysis for DOSE ¹³¹I Concentration	a) Once per 31 days, EQUIVALENT I whenever the gross radioactivity determination indicates concentrations greater than 10% of the allowable limit for radioiodines.	
	b) Once per 6 months, whenever the gross radioactivity determination indicates concentrations less than or equal to 10% of the allowable limit for radioiodines.	<u>04-01-M</u>

PLANT SYSTEMS

MAIN STEAM LINE ISOLATION VALVES (MSIVs)

LIMITING CONDITION FOR OPERATION

3.7.1.5 Each main steam line isolation valve ~~Four~~ (MSIV) shall be OPERABLE.

05-04-A

APPLICABILITY: MODES 1, ~~MODES~~ 2 and 3 ~~except when all MSIVs are closed and de-activated.~~

05-01-LS9

ACTION:

MODE 1:

With one MSIV inoperable but open, POWER OPERATION may continue provided the inoperable valve is restored to OPERABLE status within 48 hours; otherwise be in ~~HOT STANDBY~~ ~~MODE 2~~ within the next 6 hours and in ~~HOT SHUTDOWN~~ within the following 6 hours.

05-02-LS11

MODES 2 and 3*:

With one ~~or more~~ MSIVs inoperable, subsequent operation in MODE 2 or 3 may proceed provided the isolation valve is maintained closed within 8 hours and verified closed once per 7 days. Otherwise, be in at least HOT STANDBY within the next 6 hours and in at least HOT SHUTDOWN within the following 6 hours.

05-02-LS11

05-05-M

SURVEILLANCE REQUIREMENTS

4.7.1.5 Each MSIV shall be demonstrated OPERABLE** by verifying full closure within 5 seconds when tested pursuant to Specification 4.0.5. ~~The provisions of Specification 4.0.4 are not applicable for entry into MODE 3.~~

05-07-LS23

~~(new) Verify each MSIV actuates to the isolation position on an actual or simulated actuation signal once every 18 months.~~

05-08-M

~~* Separate condition entry is allowed for each MSIV~~

05-02-LS11

~~** Only required to be performed in MODES 1 and 2~~

05-07-LS23

PLANT SYSTEMS

STEAM GENERATOR 10% ATMOSPHERIC DUMP VALVES (ADV'S)

LIMITING CONDITION FOR OPERATION

3.7.1.6 Four steam generator 10% atmospheric dump valves (ADV's) with the associated block valves open and associated remote manual controls, including the backup air bottles, ~~lines~~ shall be OPERABLE.

06-01-LG

06-09-A

APPLICABILITY: MODES 1, 2, and 3-

~~MODE 4 when steam generator is relied upon for heat removal~~

02-04-M

ACTION:

06-02-LS14

a. With one less than the required number of 10% ADV's ~~lines~~ OPERABLE, restore the inoperable steam generator 10% ADV ~~line~~ to OPERABLE status within 7 days ~~(304 is not applicable)~~; or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN ~~without reliance upon steam generator for heat removal~~ within the following ~~612~~ hours.

02-10-LS21

02-04-M

b. With two less than the required number of 10% ADV's ~~lines~~ OPERABLE, restore at least one of the inoperable steam generator 10% ADV's to OPERABLE status within 72 hours; or be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN ~~without reliance upon steam generator for heat removal~~ within the following ~~612~~ hours.

02-10-LS21

02-04-M

~~(new) With three or more ADV lines inoperable, restore at least two to an OPERABLE status within 24 hours or be in MODE 3 in 6 hours and be in MODE 4 without reliance upon steam generators for heat removal within 18 hours~~

06-05-LS24

02-10-LS21

02-04-M

SURVEILLANCE REQUIREMENTS

4.7.1.6 Each steam generator 10% ADV ~~lines~~, associated block valve and associated remote manual controls including the backup air bottles shall be demonstrated OPERABLE:

06-01-LG

a. At least once per 24 hours by verifying that the backup air bottle for each steam generator 10% ADV has a pressure greater than or equal to 260 psig, and

b. ~~At least once per 31 days by verifying that the steam generator 10% ADV block valves are open, and~~

06-06-LG

c. At least once per 18 months by verifying that all steam generator 10% ADVs will operate using the remote manual controls and the backup air bottles.

06-06-LG

~~(new) Verify one complete cycle of each 10% ADV block valve once per 18 months~~

06-04-M

PLANT SYSTEMS

MAIN FEEDWATER ISOLATION (MFIVS), REGULATING (MFRVS) AND ASSOCIATED BYPASS AND ISOLATION VALVES

LIMITING CONDITION FOR OPERATION

3.7.1.7 ~~Four~~ In each feedwater line, each Main Feedwater Isolation Valve (MFIV)s shall be OPERABLE or closed. Each Main Feedwater Regulating Valve (MFRV)s, and ~~four~~ MFRV bypass valves shall be OPERABLE, closed or isolated.

07-01-A

APPLICABILITY: MODES 1, 2, and 3 except when MFIV, MFRV, or associated bypass valve is closed and de-activated or isolated by a closed manual valve.

07-02-LS37

ACTION:*

07-03-LS15

With one or more MFIVs, one or more MFRVs, or one or more MFRV bypass valves inoperable either:

07-06-LS33

- a. Restore the inoperable valve to OPERABLE status within 4 hours, or
- b. Close the inoperable valve within 4 hours, or
- c. If the inoperable valve is a MFRV or MFRV bypass valve, isolate the inoperable valve with at least one closed valve within 4 hours, or

07-04-LS16

07-04-LS16

07-04-LS16

(new) With two valves in the same flowpath inoperable, isolate the affected flowpath within 8 hours, or

07-04-LS16

- d. Be in at least HOT STANDBY within the next 6 hours and in HOT SHUTDOWN within the following 6 hours.

(new) Verify the inoperable MFIV, MFRV, or MFRV bypass valve(s) closed or isolated once per 7 days.

07-11-M

SURVEILLANCE REQUIREMENTS

4.7.1.7.1 Each MFRV and MFRV bypass valve shall be demonstrated OPERABLE by determining the isolation time of each valve to be less than or equal to 7 seconds (not including instrument delays) at least each COLD SHUTDOWN but not more frequently than once per 92 days.

4.7.1.7.2 Each MFIV shall be demonstrated OPERABLE by determining the isolation time of each valve to be less than or equal to 60 seconds (not including instrument delays) when tested pursuant to Specification 4.0.5.

(new) Verify each feedwater isolation valve actuates to the isolation position on an actual or simulated actuation signal once every 18 months.

05-08-M

* Separate condition entry is allowed for each valve.

07-03-LS15

~~THIS PAGE INTENTIONALLY DELETED~~

PLANT SYSTEMS

3/4.7.3 VITAL COMPONENT COOLING WATER (CCW) SYSTEM

LIMITING CONDITION FOR OPERATION

3.7.3.1 At least two vital component cooling water loops shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:*

08-02-A

With only one vital component cooling water loop OPERABLE, restore at least two loops to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.7.3.1 At least two vital component cooling water loops shall be demonstrated OPERABLE:

- a. ** At least once per 31 days by verifying that each CCW valve (manual, power-operated, or automatic) in the flow path servicing safety-related equipment that is not locked, sealed, or otherwise secured in position, is in its correct position; and 08-04-A
08-08-A
- b. At least once per 18 months, by verifying that each automatic valve in the flow path that is not locked, sealed or otherwise secured in position servicing safety-related equipment actuates to its correct position on a Safety Injection or Phase "B" Isolation test an actual or simulated actuation signal, as appropriate. 08-08-A
08-05-A

(new) Verify each CCW pump starts automatically on an actual or simulated actuation signal at least once per 18 months. 08-06-TRI
08-07-M

* Enter applicable conditions and required actions of LCO 3, 4, 6, "RCS Loops" MODE 4, for residual heat removal loops made inoperable by CCW. 08-02-A

** Isolation of CCW flow to individual components does not render the CCW system inoperable. 08-04-A

PLANT SYSTEMS

3/4.7.4 AUXILIARY SALTWATER SYSTEM (ASW)

LIMITING CONDITION FOR OPERATION

3.7.4.1 At least two auxiliary saltwater trains shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION: ~~XXXX~~

08-02-A

With only one auxiliary saltwater train OPERABLE, restore at least two trains to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

SURVEILLANCE REQUIREMENTS

4.7.4.1 At least two auxiliary saltwater trains shall be demonstrated OPERABLE at least once per 31 days by verifying that each valve (manual, ~~or power-operated, or automatic~~) in the flow path servicing safety-related equipment that is not locked, sealed, or otherwise secured in position, is in its correct position or that power and/or air supplies are available such that the valve would be capable of being placed in its correct position.

09-03-A

09-01-M

(new) Verify each ASW pump starts automatically on an actual or simulated actuation signal at least once per 18 months.

09-04-M

(new) Verify each ASW power operated valve in the flow path that is not locked, sealed or otherwise secured in position is capable of being placed in the correct position in accordance with the Inservice Testing Program.

09-06-M

Enter applicable conditions and required actions of LCD 3.4.6, RCS Loops, MODE 4, for residual heat removal loops made inoperable by ASW/CCW.

08-02-A

PLANT SYSTEMS

3/4.7.5 CONTROL ROOM VENTILATION SYSTEM (CRVS)

LIMITING CONDITION FOR OPERATION

~~3.7.5.1 The two Control Room Ventilation System* trains shall be OPERABLE** with two separate trains with each train consisting of one main supply fan, one filter booster fan, one pressurization supply fan and one HEPA Filter and Charcoal Adsorber System.~~

10-01-LG

10-13-LG

APPLICABILITY: All MODES.

~~During movement of irradiated fuel assemblies~~

10-02-M

ACTION:

MODES 1, 2, 3, and 4:

With one Control Room Ventilation System train inoperable, restore the inoperable train to OPERABLE status within 7 days or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

~~With two trains of CRVS trains inoperable in MODES 1, 2, 3 or 4 immediately enter 3.0.3.~~

10-04-A

MODES 5 and 6 ~~or during movement of irradiated fuel assemblies:~~

10-02-M

a. With one Control Room Ventilation System train inoperable, restore the inoperable train to OPERABLE status within 7 days or immediately initiate and maintain operation of the OPERABLE Control Room Ventilation System train in the recirculation mode or immediately suspend CORE ALTERATIONS and suspend movement of irradiated fuel assemblies.

10-05-LS18

b. With both Control Room Ventilation System trains inoperable, or with the OPERABLE Control Room Ventilation System required to be in the recirculation mode by ACTION a. not capable of being powered by an OPERABLE emergency power source, immediately suspend all operations involving CORE ALTERATIONS or positive reactivity changes or movement of irradiated fuel assemblies.

10-06-LG

10-16-LG

10-21-LS38

SURVEILLANCE REQUIREMENTS

4.7.5.1 Each Control Room Ventilation System train shall be demonstrated OPERABLE:-

a- ~~At least once per 12 hours by verifying that the control room air temperature is less than or equal to 120°F;~~

10-07-R

~~*The Control Room Ventilation System is common to both units.~~

10-02-M

~~**The system may be considered OPERABLE with no chlorine monitors, provided no bulk chlorine gas is stored within the SITE BOUNDARY.~~

10-13-LG

PLANT SYSTEMS

SURVEILLANCE REQUIREMENTS (continued)

b. At least once per 31 days by:

- 1) ~~Initiating flow through the HEPA Filter And Charcoal Adsorber System and verifying that either redundant set of booster and pressurization supply fans the system operates for at least 10 continuous hours with the heaters operating.~~ 10-06-LG
- 2) ~~Verifying that each Ventilation System redundant fan is aligned to receive electrical power from a separate OPERABLE vital bus, and~~ 10-16-LG
- 3) ~~Starting (unless already operating) each main supply fan, booster fan, and pressurization supply fan, and verifying that it operates for 1 hour.~~ 10-06-LG

~~(new) Perform required CRVS FILTER TESTING in accordance with the Ventilation Filter Testing Program (VFIP).~~ 10-08-A

c. At least once per 18 months or (1) after any structural maintenance on the HEPA filter or charcoal adsorber housings, or (2) following painting, fire, or chemical release in any ventilation zone communicating with the system by:

- 1) Verifying that the cleanup system satisfies the in-place penetration and bypass leakage testing acceptance criteria of less than 1% and uses the test procedure guidance in ANSI N510-1980, and the system flow rate is 2100 cfm \pm 10%; 10-08-A
- 2) ~~Verifying within 31 days after removal, that a laboratory analysis of a representative carbon sample obtained in accordance with Regulatory Position C.6.b of Regulatory Guide 1.52, Revision 2, March 1978, meets the laboratory testing criteria of ASTM D 3803-1989 at a temperature of 30°C and at 70% R.H. for a methyl iodide penetration of less than 1%; and~~ 10-23-LS13
10-24-A
- 3) ~~Verifying a system flow rate of 2100 cfm \pm 10% during system operation when tested in accordance with ANSI N510-1980.~~ 10-17-A

d. After 720 hours of charcoal adsorber operation, by verifying, ~~within 31 days after removal, that a laboratory analysis of a representative carbon sample obtained in accordance with Regulatory Position C.6.b of Regulatory Guide 1.52, Revision 2, March 1978, meets the laboratory testing criteria of ASTM D 3803-1989 at a temperature of 30°C and at 70% R.H. for a methyl iodide penetration of less than 1%;~~ 10-08-A
10-23-LS13
10-24-A

PLANT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- e. At least once per 18 months by: 10-08-A
- 1) Verifying that the pressure drop across the combined HEPA filters and charcoal adsorber banks is less than 3.5 inches Water Gauge while operating the system at a flow rate of 2100 cfm \pm 10%;
 - ~~2) Verifying that on an actual or simulated actuation a Phase "A" Isolation test signal, the system automatically switches into the pressurization mode of operation with approximately 27% (determined by damper position) of the flow through the HEPA filters and charcoal adsorber banks;~~ 10-10-IR1
10-08-A
 - ~~3) Verifying on a STAGGERED TEST BASIS that the system maintains the control room at a positive pressure of greater than or equal to 1/8 inch Water Gauge relative to the outside atmosphere during the pressurization mode of system operation; and~~ 10-11-LS19
 - 4) Verifying that the heaters dissipate 5 ± 1 kW when tested in accordance with ANSI N510-1980. 10-08-A
- f. After each complete or partial replacement of a HEPA filter bank, by verifying that the cleanup system satisfies the in-place penetration and bypass leakage testing acceptance criteria of less than 1% in accordance with ANSI N510-1980 or a DOP test aerosol while operating the system at a flow rate of 2100 cfm \pm 10%; and 10-08-A
- g. After each complete or partial replacement of a charcoal adsorber bank, by verifying that the cleanup system satisfies the in-place penetration and bypass leakage testing acceptance criteria of less than 1% in accordance with ANSI N510-1980 for a halogenated hydrocarbon test gas while operating the system at a flow rate of 2100 cfm \pm 10%. 10-08-A

PLANT SYSTEMS

3/4.7.6 AUXILIARY BUILDING SAFEGUARDS AIR FILTRATION VENTILATION SYSTEM (ABVS)

LIMITING CONDITION FOR OPERATION

3.7.6.1 Two Auxiliary Building Safeguards Air Filtration Ventilation System exhaust trains with one common HEPA filter and charcoal adsorber bank and at least two supply and exhaust fans shall be OPERABLE.

12-10-M

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

- a. With the HEPA filter and charcoal adsorber bank inoperable, restore the HEPA filter and charcoal adsorber bank to OPERABLE status within 24 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.
- b. With only one supply and one exhaust fan OPERABLE, restore at least two supply and two exhaust fans to OPERABLE status within 7 days or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

12-10-M

SURVEILLANCE REQUIREMENTS

4.7.6.1 Each Auxiliary Building Safeguards Air Filtration Ventilation System train shall be demonstrated OPERABLE:

- a. At least once per 31 days by:
 - 1) ~~Initiating flow through the HEPA filter and charcoal adsorber bank and verifying that the train operates for at least 10 continuous hours with the heaters operating, and~~
 - 2) ~~Verifying that each exhaust fan is aligned to receive electrical power from a separate OPERABLE vital bus.~~

12-06-LG

12-06-LG

~~(new) Perform required ABVS filter system testing in accordance with the Ventilation Filter Testing Program (VFETP).~~

10-08-A

- b. At least once per 18 months or (1) after any structural maintenance on the HEPA filter or charcoal adsorber housings, or (2) following painting, fire, or chemical release in any ventilation zone communicating with the system, by:

10-08-A

PLANT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- 1) Verifying that the cleanup system satisfies the in-place penetration and bypass leakage testing acceptance criteria of less than 1% and uses the test procedure guidance in ANSI N510-1980, and the system flow rate is 73,500 cfm \pm 10%;
- 2) Verifying, ~~within 31 days after removal,~~ that a laboratory analysis of a representative carbon sample obtained in accordance with Regulatory Position C.6.b of Regulatory Guide 1.52, Revision 2, March 1978, meets the laboratory testing criteria of ASTM D 3803-1989 at a ~~temperature of 30 °C and at~~ 70% R.H. for a methyl iodide penetration of less than 6%; and 10-23-LS13
10-24-A
- 3) Verifying a system flow rate of 73,500 cfm \pm 10% during system operation when tested in accordance with ANSI N510-1980. 10-17-A
10-08-A
- c. After every 720 hours of charcoal adsorber operation, by verifying, ~~within 31 days after removal,~~ that a laboratory analysis of a representative carbon sample obtained in accordance with Regulatory Position C.6.b of Regulatory Guide 1.52, Revision 2, March 1978, meets the laboratory testing criteria of ASTM-D-3803-1989 at a ~~temperature of 30 °C and at~~ 70% R.H. for a methyl iodide penetration of less than 6%. 10-23-LS13
- d. At least once per 18 months by:
 - 1) Verifying that the pressure drop across the combined HEPA filters and charcoal adsorber banks is less than 3.7 inches Water Gauge while operating the system at a flow rate of 73,500 cfm \pm 10%. 10-08-A
 - 2) Verifying that ~~each train actuates and that flow is established through the HEPA filter and charcoal adsorber bank on a Safety Injection test~~ ~~an actual or simulated actuation~~ signal, and 12-10-M
12-04-IR1
 - 3) Verifying that the heaters dissipate 50 \pm 5 kW when tested in accordance with ANSI N510-1980. 10-08-A
 - 4) Verifying that leakage through the Auxiliary Building Safeguards Air Filtration System Dampers M2A and M2B is less than or equal to 5 cfm when subjected to a Constant Pressure or Pressure Decay Leak Rate Test in accordance with ASME N510-1989. The test pressure for the leak rate test shall be based on a maximum operating pressure as defined in ASME N510-1989, of 8 inches water gauge.

PLANT SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- e. After each complete or partial replacement of a HEPA filter bank, by verifying that the cleanup system satisfies the in-place penetration and bypass leakage testing acceptance criteria of less than 1% in accordance with ANSI N510-1980 for a DOP test aerosol while operating the system at a flow rate of 73,500 cfm \pm 10%; and 10-08-A
- f. After each complete or partial replacement of a charcoal adsorber bank, by verifying that the cleanup system satisfies the in-place penetration and bypass leakage testing acceptance criteria of less than 1% in accordance with ANSI N510-1980 for a halogenated hydrocarbon test gas while operating the system at a flow rate of 73,500 cfm \pm 10%. 10-08-A

PLANT SYSTEMS

PLANT SYSTEMS

3/4.7.12 ULTIMATE HEAT SINK (UHS)

LIMITING CONDITION FOR OPERATION

3.7.12 The ultimate heat sink (UHS)* shall be OPERABLE with an inlet water temperature of less than or equal to 64°F.

13-01-LG

APPLICABILITY: MODES 1, 2, and 3 and 4.

13-08-M

ACTION:

With the requirements of the above specification not satisfied, place a second vital component cooling water heat exchanger in service within 8 hours or be in at least HOT STANDBY within the next 6 hours and in at least HOT/COLD SHUTDOWN within the following 636 hours. ~~The provisions of Specification 3.0.4 are not applicable.~~

13-08-M

13-09-A

SURVEILLANCE REQUIREMENTS

4.7.12 The UHS shall be determined OPERABLE by verifying the inlet water temperature to be within its limit:

- a. At least once per 24 hours when the inlet water temperature is equal to or less than 60°F, or
- b. At least once per 12 hours when the inlet water temperature is greater than 60°F but less than 62°F, or
- c. At least once per 2 hours when the inlet water temperature is equal to or greater than 62°F but less than or equal to 64°F.

~~*The UHS is common to both units.~~

13-01-LG

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. Deletions - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. Additions - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. Modifications - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. Administrative - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

**Methodology For Mark-Up of Current TS
(Continued)**

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.7

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	A reference to Table 3.7-2 is deleted from the limiting condition of operation (LCO) and moved to the surveillance requirement (SR) (refer to change 01-07-A). This change is consistent with NUREG-1431.
01-02	LS1	A Note is added to allow separate entry for each main steam safety valve (MSSV). The current specification requires that all MSSVs discovered to be inoperable be returned to OPERABLE within the initial four hours provided for the first inoperable MSSV. For example, if a second inoperable MSSV were discovered three hours into the ACTION statement of the first inoperable MSSV, both MSSVs would have to be returned to OPERABLE within the following one hour or the plant power level would have to be reduced to that specified in Table 3.7-1. The addition of the Note allowing separate entry for each inoperable MSSV provides the full four hours for each inoperable MSSV.
01-03	LS2	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-04	LS3	The CTS allows continued operation with inoperable MSSVs if the power range neutron flux high trips are reduced. [] Industry traveler WOG-83, Rev. 0 and draft Rev. 1, provided revised ACTIONS to require that: 1) the reactor power be reduced to compensate for the loss of pressure relief capacity to a maximum allowable power determined in accordance with Westinghouse NSAL 94-001 and NRC Information Notice 94-60, 2) the power range neutron flux high trip setpoint be reduced for inoperable MSSVs if a positive moderator temperature coefficient (MTC) exists at the allowed percent rated thermal power in MODE 1, and 3) the power range neutron flux high trip setpoints be reduced to account for a control rod withdrawal at partial power with more than one MSSV inoperable. In addition, the Completion Time for resetting the high flux trips is revised from four hours to 72 hours and the ACTION is revised to specifically require an appropriate power reduction within four hours. This is a relaxation since the CTS require the high neutron flux trip setpoint to be reduced as required within four hours for inoperable MSSVs regardless of the MTC value. Pending approval of draft Rev. 1 of WOG-83, the changes proposed in the traveler have been modified to retain

CHANGE
NUMBER

NSHC

DESCRIPTION

the CTS requirement to reset the power range neutron flux-high trip setpoints based on the number of MSSVs inoperable to a maximum allowable power determined in accordance with calculations or analysis to account for Westinghouse NSAL 94-001 and NRC Information Notice 94-60. However, the Completion Time of 72 hours proposed by WOG-83 has been retained and is justified based on the low probability of an event occurring during this time and the need to provide sufficient time to reset the channels in an orderly manner without inducing a transient due to human error. Retention of the CTS requirement for resetting the reactor trip setpoints is acceptable because this requirement is more conservative than the ACTIONS specified by either the ISTS or WOG-83, as revised. []

01-05

M

The exception to TS 3.0.4 is no longer needed due to the note associated with the revised surveillance. The exception was allowed to TS 3.0.4 due to the fact that the applicable MODES must be entered in order to perform the required surveillance (if the MSSVs are tested in place) and to allow Mode changes to be made if the applicable action was met. In the CTS, MODE 1, 2, or 3 could be entered. In NUREG-1431, the surveillance is modified by a more restrictive note that specifies that the surveillance need only be current prior to reaching MODE 2. The surveillance note still allows MODE changes into the MODE of Applicability of the LCO, i.e., MODE 3 for testing purposes.

01-06

M

The new ACTION adds an explicit requirement to be in MODE 3 in 6 hours and MODE 4 in 12 hours if any steam generator (SG) loop has less than two MSSVs OPERABLE. NUREG-1431 requires that the plant only be placed in a MODE where the specification is no longer applicable, which in this case would be MODE 4. The CTS would require the plant to enter TS 3.0.3 because operation with less than two MSSVs OPERABLE per SG is an undefined condition, and thus not permitted. Therefore, the new ACTION eliminates the one hour allowed for action via TS 3.0.3. This requirement is more restrictive with the loss of the one hour for ACTIONS required by TS 3.0.3.

01-07

A

The CTS SR is revised to specifically reference the In-service Testing (IST) Program developed per TS 4.0.5 and contained in the Administrative Section of the ISTS. The surveillance directly references Table 3.7-2 for lift points and incorporates the requirement that the MSSV as-left liftpoints to be within +/- 1 percent of the nominal setpoint.

01-08

Not Used.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

01-09	LS31	The maximum power range neutron high flux trip setpoints required for one or more inoperable MSSVs are revised in accordance with the recommendations of Westinghouse NSAL 94-001, dated January 20, 1994, and a specific calculation and analysis to support the proposed revision. Since the issuance of NSAL 94-001, administrative controls have been in place to require a reactor power and high neutron flux trip setpoint reduction to be consistent with those values determined by NSAL 94-001 or as required by the CTS if they were more conservative. Since the trip setting of the CTS Table 3.7-1 is revised upward for one inoperable MSSV for incorporation into the ITS, this change has been classified as less restrictive. The settings for two or three inoperable MSSVs are more restrictive than the CTS or NUREG-1431 as modified by WOG-83.
01-10	LG	The note on Table 3.7-2 stating that the set pressures of the MSSVs shall correspond to the ambient conditions of the valve at normal operating temperatures is moved to the Bases of ITS SR 3.7.1.1. This change is acceptable because it removes details from the TS that are not required to protect the health and safety of the public while retaining the basic limiting condition for operation.
01-11	LG	The MSSV line orifice size is moved from Table 3.7-2 to a licensee-controlled document. This is design information that is not required in the ITS for operating or OPERABILITY concerns.
01-12	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
02-01	LG	The descriptive material related to the definition of an auxiliary feedwater (AFW) train is deleted from the LCO and moved to the Bases. This change is acceptable because it removes details from the TS that are not required to protect the health and safety of the public while retaining the basic limiting condition for operation.
02-02	LS5	The ACTION specifies the requirements for allowed outage time (AOT) should one of the steam supplies to the turbine driven auxiliary feedwater (TDAFW) pump become inoperable. A previous interpretation required that the TDAFW pump be declared inoperable and the ACTION statement for one inoperable pump be entered. This revision is a relaxation of the CTS requirements.
02-03	M	The ACTIONS are modified to require restoration of the systems to meet the LCO within 10 days of discovery of failure to meet the LCO. This new requirement is intended to prevent multiple overlapping ACTION entries such that the intended AOT is exceeded. This proposed change is acceptable because it results in more stringent TS requirements that are both appropriate and consistent with NUREG-1431.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

02-04	M	The LCO Applicability and ACTION are revised to include a requirement that an AFW train with a motor driven pump, the appropriate atmospheric dump valves (ADV) and the condensate storage tank (CST) be operable in MODE 4 when the SG is relied upon for heat removal. This reflects the situation where credit is taken for a reactor coolant system (RCS) loop for heat removal in MODE 4 in lieu of a residual heat removal (RHR) train. (Refer to RCS HOT SHUTDOWN CTS.) This change clarifies the Applicability of AFW, CST and ADVs to the RCS loops - MODE 4 TS.
02-05	A	Although previously implied, the addition of the footnote for three inoperable AFW trains assures that TS 3.0.3 will not be entered and that no other ACTION statement for other inoperable components will be applied that might force the unit into an unsafe condition.
02-06	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-07	M	The surveillance to verify valve alignments is revised to include automatic valves. This proposed change is acceptable because it results in more stringent TS requirements that are both appropriate and consistent with NUREG-1431.
02-08	LS6	The surveillance interval for the AFW pump performance is changed from once per 92 days on a STAGGERED TEST BASIS (STB) to "in accordance with the IST Program." This proposed change will eliminate any potential ambiguity associated with AFW pump testing as a result of ASME changes and results in consistent presentation of pump testing throughout the TS.
02-09	A	The surveillance is revised to combine the water flow and steam flowpaths into one SR. This proposed change is acceptable because it is administrative in nature; no change to technical requirements would result.
02-10	LS21	The time to achieve HOT SHUTDOWN conditions if ACTIONS are not completed is changed from 6 to 12 hours. This time is reasonable to reach the required conditions under the circumstances, since the SG heat removal system is degraded, but is the system performing the cooldown to MODE 4.
02-11	A	The testing requirements for pumps and valves are separated into two SRs in accordance with NUREG-1431.
02-12	TR1	The respective valve and pump SRs are revised to allow credit for an actual actuation, if one occurs, to satisfy the SRs. The identification of the initiating signal is moved to the Bases.
02-13	A	The requirement to verify that the fire water storage tank is capable of realignment as an AFW backup supply is moved to the AFW ITS from the CTS describing the AFW sources and volume requirements. Both the flow path verification and the frequency are moved to make the AFW ITS complete.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

02-14	M	The Note for testing of the steam TDAFW pump is revised to explicitly define when the testing must be performed. Previously, the time period was unspecified.
02-15	LG	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
02-16	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
02-17	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
02-18	M	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
02-19	LG	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
02-20	LS35	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
02-21	LG	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
03-01	LG	The description of the AFW supply pathway is deleted due to its relocation to AFW ITS 3.7.5 and associated Bases. The revised specification deals only with the required volumes of the AFW pump supply sources.
03-02	LS22	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
03-03	LG	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
04-01	M	The revision requires isotopic analysis for DOSE EQUIVALENT I-131 concentration to be performed on a 31-day frequency. The conditional performance requirements in the current surveillance (i.e., based on 10 percent of the allowable limit for radionuclides contained in Table 4.7-1) are deleted. This results in a more restrictive requirement for the isotopic analysis.
04-02	LS8	The SR of Table 4.7-1 to determine gross radioactivity is deleted. The change is acceptable because radioiodines and the resulting thyroid dose are limiting, not noble gases and whole-body dose. The primary to secondary leakage limits and DOSE EQUIVALENT I-131 limits ensure the dose analyses in the [Final Safety Analysis Report] remain valid.
05-01	LS9	The MODE of Applicability for the main steam isolation valves (MSIVs) is revised to clarify that in MODES 2 and 3 with all MSIVs closed [and deactivated], the safety function of the MSIVs is already met. Thus, OPERABILITY of the MSIVs in this condition is not required.

**CHANGE
NUMBER**

NSHC

DESCRIPTION

05-02	LS11	This change revises the AOT/Completion Time for an inoperable MSIV from four hours to eight hours in MODE 1, 2, and 3. This is a relaxation from the AOT of the CTS which requires that the valve be returned to an OPERABLE condition within four hours and implies that the valve must be immediately closed in MODES 2 and 3. The revised completion time is acceptable due to the low probability of an accident occurring that would require the closing of the MSIVs. In addition, from a containment isolation standpoint, the completion time can be greater for these valves as opposed to other containment isolation valves because these valves isolate a closed system that penetrates containment and do not act directly as the containment boundary. This revision deletes the MODE 1 ACTION to place the plant in MODE 3, and then MODE 4 due to an inoperable MSIV and only requires entry into MODE 2 since the ACTIONS for MODE 2 or 3 operation would then be applicable. Operation in MODES 2 and 3 is revised to allow more than one MSIV to be inoperable and by a note to allow a separate condition entry for each inoperable MSIV.
05-03	LS12	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
05-04	A	The LCO is changed from the OPERABILITY of each MSIV to the OPERABILITY of four MSIVs.
05-05	M	A new requirement for a 7 day periodic verification of the closure [or isolation] of inoperable isolation valves is added to be consistent with NUREG-1431.
05-06		Not used.
05-07	LS23	A footnote is added to the SR to indicate that demonstration of MSIV OPERABILITY is only required to be performed for entry into (and continued operation in) MODES 1 and 2. The footnote is added in lieu of the current exception to CTS 4.0.4. While the footnote is intended to establish the same exemption, it is in fact less restrictive because the footnote permits an indefinite stay in MODE 3 while the exception to CTS 4.0.4 requires testing within 24 hours of establishing the necessary plant conditions per TS 4.0.3 as described in Generic Letter (GL) 87-09.
05-08	M	This change creates a new SR for the MSIVs and [main feedwater isolation valves (MFIVs)] to distinguish between the IST and the automatic actuation testing of these isolation valves. The surveillance allows credit for an actual actuation, if one occurs, to satisfy the SRs. This change is consistent with WOG-98. This proposed change is acceptable because it results in more stringent TS requirements that are both appropriate and consistent with NUREG-1431.
06-01	LG	This change revises the CTS to delete the descriptive material from the CTS LCO and moves this material to the Bases.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
06-02	LS14	This change adds an exception to LCO 3.0.4 for the 7 day ACTION to restore the atmospheric [dump] valve OPERABILITY. This change allows the plant to change MODES if one atmospheric [dump] valve is found inoperable while in MODE 2 or 3. Allowing MODE transition with an inoperable atmospheric [dump] valve does not significantly increase the risk since the remaining valves are OPERABLE.
06-03	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B)
06-04	M	A surveillance is added that requires the manual cycling of the atmospheric [dump] valve [block] valves [every 18 months]. This proposed change is acceptable because it results in more stringent TS requirements that are both appropriate and consistent with NUREG-1431.
06-05	LS24	This change adds a new ACTION for three or more inoperable atmospheric [dump] valves that requires action within 24 hours. The CTS would require entry into TS 3.0.3 for three inoperable atmospheric [dump] valves. However, NUREG-1431 recognizes the low probability of an accident requiring the atmospheric [dump] valves, thus permitting this configuration.
06-06	LG	This change moves the requirements for the surveillances to the Bases. The details of the specific test requirements such as those dealing with the "remote manual controls" are not included in the STS, but are included in the Bases section for the SR. [Verification that the block valves to the 10% ADVs are open is moved to the Bases as a procedural surveillance.] This change is acceptable because it removes details from the TS that are not required to protect the health and safety of the public while retaining the basic limiting condition for operation.
06-07	LS25	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
06-08	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
06-09	A	This change revises the LCO to refer to the atmospheric [dump] valve lines versus atmospheric [dump] valves.
06-10	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
07-01	A	The LCO is changed from the OPERABILITY of each main feedwater line to the OPERABILITY of four feedwater flow path isolation valves [and associated bypasses] [and the requirement to have the valves closed or isolated if not OPERABLE is moved to Applicability. The ACTIONS are also revised to compensate for the line requirement deletion].
07-02	LS37	The LCO Applicability is revised to exclude [MFIVs or FRVs] that are closed [and de-activated or isolated by a closed manual valve]. NUREG-1431 recognizes that if one or more [MFIVs or FRVs] or associated bypass valves are closed [and de-activated] and verified closed, their safety function is being fulfilled and there is no need to enter the ACTION statement.

DCPP Description of Changes to Current TS

**CHANGE
NUMBER**

NSHC

DESCRIPTION

07-03	LS15	The CTS are written on a per feedwater line basis and NUREG-1431 is written for four lines. A Note is added to the ACTION statement that allows separate condition entry for each inoperable valve. The addition of the Note allowing separate entry for each valve inoperable in a flow path provides the full AOT for each of the inoperable flow paths.
07-04	LS16	The AOT is revised for an individual inoperable valve from 4 hours to 72 hours. With one valve inoperable in the flow path, flow path isolation is still available. The extended AOT is based upon the ability to isolate the flow path and the low probability of the occurrence of a main steam line break accident. The ACTIONS are further revised to add a new ACTION for two inoperable valves in the same flowpath to address the loss of isolation capability. This new ACTION requires that the inoperable flow path be isolated within eight hours. The CTS require entry into TS 3.0.3 if two valves in a flow path are inoperable since the condition is undefined.
07-05	LS17	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-06	LS33	This change revises the ACTION to apply to one "or more" [MFIVs] inoperable, consistent with NUREG-1431. This is less restrictive than the CTS which applied to only one inoperable valve. The proposed change is acceptable due to the low probability of an event for which the [MFIVs] are required to be OPERABLE and the availability of alternate methods of performing the required function.
07-07	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-08	LS26	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-09	LS10	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-10	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-11	M	A new requirement for a 7 day periodic verification of the closure [or isolation] of inoperable isolation valves is added. This proposed change is acceptable because it results in more stringent TS requirements that are both appropriate and consistent with NUREG-1431.
07-12	LS4	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-13		Not used.
07-14		Not used.
07-15		Not used.
07-16	LS34	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
07-17	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
08-01	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

DCPP Description of Changes to Current TS

**CHANGE
NUMBER**

NSHC

DESCRIPTION

08-02	A	A Note is added to the ACTION that references a potential interaction with ITS 3.4.6 dealing with OPERABILITY of the RHR system in MODE 4. The Note requires that the applicable TS be entered for the RHR train made inoperable by the inoperable [component cooling water (CCW) or auxiliary saltwater (ASW)] system. The ACTIONS of the referenced TS (RCS Loops-MODE 4) require more immediate action than are required by the [CCW or ASW] ACTIONS.
08-03	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
08-04	A	A Note is added to the [CCW] surveillance that clarifies that the system is not made inoperable by the isolation of individual components. This change is in accordance with NUREG-1431, and provides clarification only.
08-05	A	The surveillance is modified to clarify that valves that are locked, sealed, or otherwise secured in their correct position are not required to be tested. This change is in accordance with NUREG-1431, and provides clarification only.
08-06	TR1	The SR is revised to allow credit for an actual actuation, if one occurs, to satisfy the SRs. The identification of the signal is moved to the Bases.
08-07	M	A new surveillance is added that requires verifying that each CCW pump starts automatically on an actual or simulated signal actuation at least once per 18 months.
08-08	A	The surveillances are revised to clarify that only verification of the correct position of valves in the flow path is required.
08-09		Not used.
08-10	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
09-01	M	This change revises the existing surveillance to verify that a motive source is available that would permit the required ASW valves to be repositioned. This change is consistent with the intent of NUREG-1431.
09-02	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
09-03	A	The surveillance is reworded and the requirement to verify the position of automatic valves is deleted since the ASW system has no automatic valves.
09-04	M	A new surveillance is added that requires verifying that each ASW pump starts automatically on an actual or simulated actuation signal at least once per 18 months.
09-05	TR1	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
09-06	M	A new surveillance is added that requires verifying that each valve in the flow path that is not locked, sealed, or otherwise secured in position is capable of being placed in the correct position in accordance with the Inservice Testing (IST) Program.

DCPP Description of Changes to Current TS

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
09-07	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
10-01	LG	The descriptive material, related to the definition of a ventilation train, is deleted from the LCO and moved to the Bases.
10-02	M	The Applicability and applicable ACTIONS are revised to incorporate "during movement of irradiated fuel assemblies" in addition to all MODES (i.e., MODES 1-6).
10-03	LS7	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
10-04	A	A new ACTION statement is added by NUREG-1431 to require entering TS 3.0.3 immediately if two trains of the CR ventilation system are inoperable in MODES 1, 2, 3, or 4. The CTS requires entry into TS 3.0.3, since the condition of two trains inoperable is undefined; therefore, the revision has been classified as administrative.
10-05	LS18	A new option is added to the ACTION by NUREG-1431 that allows the suspension of CORE ALTERATIONS or movement of irradiated fuel versus placing the CR ventilation system in the recirculation mode.
10-06	LG	The details and description of the required ACTIONS and the monthly SRs for train operability are moved to the Bases. This is an example of removing details that are not required to be in the TS and is consistent with NUREG-1431.
10-07	LG	The surveillance that verifies CR temperature once per 12 hours is moved to a licensee controlled document.
10-08	A	The description of the ventilation filter specific testing requirements and the required surveillances are moved to the Ventilation Filter Testing Program (VFTP) as defined in the Administrative Controls of the ITS. No technical changes to requirements or test specifics except as noted in separate change numbers are made. A new SR is added that requires [CR and Auxiliary Building ventilation] system filter testing in accordance with the VFTP. The requirements of this specification are: 1) moved to Section 5.5.11 of the ITS, or 2) deleted since they are duplicated in Regulatory Guide (RG) 1.52, Revision 2, [ANSI N510-1980, or ASTM D 3803-1989].
10-09	LS27	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
10-10	TR1	The SR is revised to allow credit for an actual actuation, if one occurs, to satisfy the SRs. The identification of the initiating signal is moved to the Bases.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
10-11	LS19	The Frequency of the surveillance requiring verification of the CR ventilation system capability to maintain a positive pressure is relaxed to 18 months on a STB, consistent with NUREG-1431. The new Frequency requires one of the two trains to be tested every 18 months instead of both trains every 18 months. The most likely cause of a failure to achieve the required pressure is a failure of the ventilation pressure boundary. Thus, when one train successfully demonstrates the ability to maintain the pressure, in all likelihood the other train will also. This results in less testing of the CR ventilation system than is required by the CTS.
10-12	LS32	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
10-13	LG	The footnotes indicating that CR ventilation system is common to both units, and that the system may be considered OPERABLE with no chlorine monitors if no bulk chlorine gas is stored within the SITE BOUNDARY, are moved to the Bases.
10-14	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
10-15	LG	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
10-16	LG	The requirement to have an available emergency power source for the CR ventilation system is moved to the Bases. This change is consistent with the Bases of NUREG-1431 for ventilation systems required during fuel movement.
10-17	A	The SR to measure ventilation system flow rate is not identified as a separate SR in the ITS because it is verified during the other in-place filter tests (see ITS 5.5.11).
10-18	LS36	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
10-19	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
10-20	LS39	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
10-21	LS38	The ACTION to immediately suspend all operations involving CORE ALTERATIONS and movement of irradiated fuel assemblies when both trains of CR ventilation are inoperable in MODES 5 and 6 and during movement of irradiated fuel assemblies is deleted consistent with NUREG-1431. This change is acceptable because the immediate suspension of CORE ALTERATIONS and movement of irradiated fuel provides adequate protection from a release of radioactivity. Boron dilution events leading to criticality are not postulated as these events are prevented from occurring.
10-22	M	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).

NSHC

DESCRIPTION

10-23	LS13	The "within 31 days after removal" requirement for completion of laboratory analyses is deleted. This requirement is not contained in the ITS nor is it contained in the RG 1.52 or the applicable ANSI standards. Failure to complete an analysis within 31 days has insignificant safety consequences because the results would be available within approximately the same time period and it is very unlikely that the charcoal would be degraded to the extent that there would be a complete loss of a safety function.
10-24	A	The 30°C temperature specified for laboratory testing of filter carbon samples is added to be consistent with NUREG-1431. [This temperature is also specified in ASTM D 3803-1989.] This proposed change is acceptable because it adds a requirement already required to be performed when testing in accordance with the standard already specified in the TS; no change to technical requirements would result.
11-01	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
11-02	LS28	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-01	LS29	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-02	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-03		Not used.
12-04	TR1	The SR is revised to allow credit for an actual actuation, if one occurs, to satisfy the SRs. The identification of the specific signals that initiate the change in state of the equipment is moved to the Bases.
12-05	LS32	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-06	LG	The descriptive material and details of the retained ventilation surveillance testing are moved to the Bases. The change is acceptable because it removes detail no longer required in the TS to protect the health and safety of the public while retaining the basis limiting condition for operation.
12-07	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-08	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-09	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
12-10	M	The CTS ABVS LCO is extended to the supply fans. The ABVS "train" is defined in the ITS Bases to include the supply fans.
13-01	LG	The Note stating that the ultimate heat sink (UHS) is common to both units is moved to the Bases, consistent with NUREG-1431.
13-02	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
13-03	R	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).

DCPP Description of Changes to Current TS

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
13-04	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B)
13-05	LS30	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
13-06	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
13-07	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
13-08	M	The Applicability is extended to MODE 4 to be consistent with NUREG-1431 and the MODE 4 OPERABILITY requirements associated with CCW and ASW. The ACTION is revised to require entering COLD SHUTDOWN within 36 hours which is consistent with CTS 3.0.3 and NUREG-1431. This proposed change is acceptable because it results in more stringent TS requirements that are both appropriate and consistent with NUREG-1431.
13-09	A	The exemption to TS 3.0.4 is deleted as it is no longer needed. The revised LCO 3.0.4 of NUREG-1431 is not Applicable if entry into a Required Action allows indefinite operation in that ACTION. Placing the second CCW heat exchanger in service allows operation to continue indefinitely.
14-01	R	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
15-01	R	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
16-01	R	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
17-01	R	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
18-01	A	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
18-02	LG	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
18-03	TR1	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
19-01	R	Not applicable to DCPD. See Conversion Comparison Table (Enclosure 3B).
20-01	LG	Not applicable to DCPD - see Conversion Comparison Table (Enclosure 3B).
20-02	TR1	Not applicable to DCPD - see Conversion Comparison Table (Enclosure 3B).

CONVERSION COMPARISON TABLE - CURRENT TS

Conversion Comparison Table

(21 pages)

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-01 A	Reference to Table 3.7-2 is deleted from the LCO and moved to the SR (refer to 01-07-A).	Yes	Yes	Yes	Yes
01-02 LS1	A Note is added to allow separate condition entry for each MSSV which allows the full four hours for each inoperable MSSV.	Yes	Yes	Yes	Yes
01-03 LS2	This CPSES specific revision relaxes the as-found MSSV lift tolerances from +/- 1% to +/- 3%.	No, LA 108/107 issued 10/1/95 to relax setpoint (refer also to 01-13-LS20).	Yes	No	No
01-04 LS3	Revised ACTIONS for inoperable MSSVs: 1) specifically requires a power reduction within four hours and 2) requires the reactor power neutron flux high trip set point to be reduced within 72 hours.	Yes	Yes	Yes	Yes
01-05 M	The ACTION of the CTS which allowed an exception to TS 3.0.4 is deleted due to the Note associated with revised SR 4.7.1.1, which allows a MODE change into MODE 3, one of the MODES of Applicability of the LCO.	Yes	Yes	Yes	Yes
01-06 M	The new ACTION adds an explicit requirement to be in MODE 3 in 6 hours and MODE 4 in 12 hours if any SG loop has less than two MSSVs operable. This is one hour less than allowed by LCO 3.0.3.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
01-07 A	The CTS SR is revised to specifically reference the IST Program. The surveillance directly references Table 3.7-2 for lift points and incorporates the footnote from the table requiring the MSSV as left liftpoints to be within +/- 1% of the nominal setpoint.	Yes	Yes	Yes	Yes
01-08	Not used.	NA	NA	NA	NA
01-09 LS31	This DCPP specific change revises the maximum power range neutron high flux trip setpoints required for one or more inoperable MSSVs in accordance with the recommendations of Westinghouse NSAL 94-001, dated January 20, 1994, and specific analysis and calculations performed to confirm the conclusions of the Westinghouse NSAL.	Yes; LAR 97-06 submitted justifying revised high flux trip set points for inoperable MSSVs.	No; refer to 01-04-LS3.	No; refer to 01-04-LS3.	No; refer to 01-04-LS3.
01-10 LG	The Note on Table 3.7-2 stating that the set pressures shall correspond to the ambient conditions of the valve at normal operating temperatures is moved to the Bases of ITS SR 3.7.1.1.	Yes	Yes	Yes	Yes
01-11 LG	The MSSV line orifice size is moved to a licensee-controlled document.	Yes; moved to FSAR.	Yes; moved to FSAR.	Yes; moved to USAR.	Yes; moved to FSAR.
01-12 A	The proposed change would require that the plant be placed in HOT SHUTDOWN within 12 hours instead of COLD SHUTDOWN within 36 hours.	No; already part of CTS.	No; part of CTS.	Yes	Yes
02-01 LG	The descriptive material, definition of an AFW train, in the LCO is moved to the Bases.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-02 LS5	The ACTION specifies the requirements for AOT should one of the steam supplies to the TDAFW pump become inoperable.	Yes	No; part of CTS.	Yes	Yes
02-03 M	ACTIONS are modified to require restoration of the systems to meet the LCO within 10 days of discovery of failure to meet the LCO.	Yes	Yes	Yes	Yes
02-04 M	In this DCPD specific revision, the Applicability and ACTIONS are revised to include MODE 4 when the SGs are relied upon for heat removal.	Yes	No	No	No
02-05 A	The addition of the Note for three inoperable AFW trains assures that TS 3.0.3 will not be entered and that no other ACTION statement for other inoperable components will be applied that might force the unit into an unsafe condition.	Yes	Yes	Yes	Yes
02-06 LG	The change would move details regarding AFW motor operated discharge valves and ESW supply valve descriptions to the Bases.	No; descriptive material not part of CTS.	No; descriptive material not part of CTS.	Yes	Yes
02-07 M	The verification of valve alignments is revised to include automatic valves.	Yes	Yes	Yes	Yes
02-08 LS6	The surveillance interval for the AFW pump performance is changed from 92 days on a STB to "in accordance with the IST Program."	Yes	Yes	Yes	Yes
02-09 A	This DCPD specific surveillance is revised to combine the water and steam flow paths.	Yes	No	No	No

DCPD Conversion Comparison Table - Current TS

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-10 LS21	The time to achieve HOT SHUTDOWN if ACTIONS are not completed is changed from 6 to 12 hours. This time is reasonable to reach the required conditions under the circumstances since the SG heat removal system is the system performing the cooldown to MODE 4.	Yes; also refer to 02-04-M.	No; refer to 02-20-LS35.	No; refer to 02-20-LS35.	No; refer to 02-20-LS35.
02-11 A	In this DCPD specific revision, the testing requirements for pumps and valves are separated into two SRs.	Yes	No	No	No
02-12 TR1	The SR is revised to allow credit for an actual actuation and moves signal specifics to the Bases.	Yes	Yes	Yes	Yes
02-13 A	In this DCPD specific revision, the verification that the fire water storage tank is capable of realignment as an AFW water source is moved to the AFW ITS.	Yes	No	No	No
02-14 M	The Note for testing of the steam TDAFW pump is revised to explicitly define when testing must be performed.	Yes	Yes	Yes	No; part of CTS.
02-15 LG	The pump performance testing is revised to move the acceptance criteria to the Bases.	No; acceptance criteria not specified in CTS.	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
02-16 A	ACTION a. is clarified to note that ACTION [d.] conditions are not included.	No; CTS does not contain an Action for TDAFW pump supplies.	Yes	Yes	Yes
02-17 A	The CPSES specific note with respect to Unit 2 Train A is deleted since 2RFO2 is complete.	No	Yes	No	No
02-18 M	The surveillance is revised to be consistent with NUREG-1431 which requires verification of flow from the CST to each SG.	No; flow path verified at each startup.	No; SR not in CTS.	Yes	Yes
02-19 LG	The Callaway specific ACTIONS b and d are deleted since the LCO now refers to AFW trains versus pumps.	No	No	No	Yes
02-20 LS35	The time from failure to meet the ACTION requirements to shut the plant down would be revised from achieving HOT STANDBY within the next 6 hours and HOT SHUTDOWN within the following 6 hours to achieving HOT STANDBY within the next 6 hours and HOT SHUTDOWN within the following 12 hours.	No; refer to CN 02-10-LS21	Yes	Yes	Yes
02-21 LG	The Callaway specific requirement to perform the 18 month surveillance "during shutdown" would be moved to the Bases.	No	No	No	Yes
03-01 LG	The DCPD specific description of the AFW supply pathway and the required surveillances are moved to the AFW ITS and Bases.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
03-02 LS22	The requirement to verify the OPERABILITY of the ESW system when acting as backup to the CST for AFW supply by verifying the system is in operation is deleted. The surveillance will now require that the OPERABILITY of the backup system be verified "by administrative means."	No, the service water system is not a credited AFW backup supply	No, refer to 03-03-LG.	Yes	Yes
03-03 LG	The CPSES specific description of how to verify the OPERABILITY of the service water system when acting as backup to the CST for AFW supply is moved to the Bases. The surveillance will now require that the OPERABILITY of the backup system be verified "by administrative means."	No, the service water system is not a credited AFW backup supply	Yes	No, refer to 03-02-LS22.	No, refer to 03-02-LS22.
04-01 M	Isotopic analysis for DOSE EQUIVALENT I-131 concentration is to be performed on a 31 day frequency. The conditional performance requirements in the CTS are deleted.	Yes	Yes	Yes	Yes
04-02 LS8	The SR of Table 4.7-1 to determine gross radioactivity is deleted.	Yes	Yes	Yes	Yes
05-01 LS9	The MODE of Applicability for MSIVs is revised to clarify that in MODES 2 and 3 with all MSIVs closed [and de-activated], the safety function of the MSIVs is met.	Yes	Yes	No, maintaining CTS.	No, maintaining CTS.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
05-02 LS11	This DCPD specific change revises the AOT/completion time for an inoperable MSIV from four hours to eight hours in MODE 1 and in MODES 2 and 3. This change also deletes the MODE 1 requirement to place the plant in MODE 3, and then MODE 4 due to an inoperable MSIV and only requires entry into MODE 2 since the ACTIONS for MODE 2 or 3 operation would then be applicable. Operation in MODES 2 and 3 is revised to allow more than one MSIV to be inoperable and by a note to allow a separate condition entry for each inoperable MSIV.	Yes	No	No	No
05-03 LS12	The completion time for closing one inoperable MSIV is extended to 72 hours and separate required ACTIONS are included for either one MSIV inoperable or two or more MSIVs inoperable in MODES 2 or 3.	No, refer to 05-02-LS11.	Yes	Yes	Yes
05-04 A	The LCO is changed from the OPERABILITY of each MSIV to the OPERABILITY of four MSIVs.	Yes	No, already in CTS	Yes	Yes
05-05 M	A new requirement for a 7 day periodic verification of the closure [or isolation] of inoperable isolation valves is added.	Yes	No, already in CTS	Yes	Yes
05-06	Not used.	NA	NA	NA	NA
05-07 LS23	A footnote is added to the SR (in lieu of the current exception to TS 4.0.4) to indicate that demonstration of isolation valve operability is only required to be performed for entry into (and continued operation in) MODES 1 and 2.	Yes	Yes	No, part of CTS.	No, part of CTS.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
05-08 M	This change creates a new SR for the MSIVs and MFIVs to distinguish between the IST and the automatic actuation testing of these isolation valves. The surveillance allows credit for an actual actuation, if one occurs, to satisfy the SRs.	Yes	Yes	Yes	Yes
06-01 LG	This DCPP specific change revises the LCO to move the descriptive material to the Bases.	Yes	No	No	No
06-02 LS14	Adds an exception to LCO 3.0.4 for the 7 day action statement to restore the [ADV] operability.	Yes	Yes	No; part of CTS.	No; part of CTS.
06-03 M	Revises the specification to be applicable to the [ADV] lines, rather than only to the [ADV]. This includes the [block] valves.	No; CTS includes the block valves.	Yes	Yes	Yes
06-04 M	Surveillance is added that requires the manual cycling of the [block] valves [every 18 months.]	Yes	Yes	Yes	Yes
06-05 LS24	Adds a new ACTION for three or more inoperable [ADV] that requires action within 24 hours.	Yes	Yes	No; similar requirement in CTS.	No; similar requirement in CTS.
06-06 LG	Moves the requirements for the surveillances to the Bases and the testing specifics to licensee controlled documents.	Yes; testing specifics moved to FSAR.	Yes; testing specifics moved to TRM.	No; not in CTS.	No; not in CTS.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
06-07 LS25	The ACTION for [ADV] inoperable due to seat leakage is deleted. Seat leakage is no longer a condition of OPERABILITY.	No; CTS do not include seat leakage as operability criteria.	No; CTS do not include seat leakage as operability criteria.	Yes	Yes
06-08 M	Removes the exemption to TS 3.0.4 from the ACTION dealing with more than one inoperable [ADV].	No; TS 3.0.4 exemption not in CTS.	No; TS 3.0.4 exemption not in CTS.	Yes	Yes
06-09 A	This DCPD specific change revises the LCO to refer to the [ADV] lines versus [ADVs].	Yes	No	No	No
06-10 A	The CPSES specific action to place the RCS/RHR in operation is included in ITS 3.4.6.	No	Yes	No	No
07-01 A	The LCO and ACTIONS are changed from the OPERABILITY of each main feedwater line to the OPERABILITY of four [MFIVs and associated bypass valves] [and the requirement to have the valves closed or isolated if inoperable, is moved to APPLICABILITY].	Yes	Yes	Yes	Yes
07-02 LS37	The LCO Applicability is revised to exclude valves that are closed [and de-activated or isolated by a closed manual valve].	Yes	Yes	No, maintaining CTS.	No, maintaining CTS.
07-03 LS15	A Note is added to the ACTION statement that allows a separate condition entry for each inoperable valve.	Yes	Yes	No, refer to 07-16-LS34.	No, refer to 07-16-LS34.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
07-04 LS16	The DCPD specific AOT is revised for an individual inoperable valve from 4 hours to 72 hours. The ACTIONS are revised to add a new ACTION and eight hour AOT for two inoperable valves in the same flowpath to address the loss of isolation capability.	Yes	No	No	No
07-05 LS17	The CPSES specific action for inoperable feedwater isolation valves in MODE 1 is revised to include the option to isolate or close the inoperable valve and the restriction of the action to an inoperable "but open" valve is deleted. The ACTION for inoperable feedwater isolation valves in MODES 2 and 3 is revised to include the option to isolate the inoperable valve. The ACTIONS for inoperable feedwater isolation bypass valves in MODES 1, 2, and 3 are revised to include the option to isolate the inoperable valve.	No	Yes	No	No
07-06 LS33	This change revises the ACTION to apply to one "or more" feedwater valves inoperable.	Yes	Yes	Yes	Yes
07-07 A	The ACTIONS were revised that require achieving MODE 4 within 12 hours when the ACTIONS or Completion Times are not met.	No, part of CTS.	No, part of CTS.	Yes	Yes
07-08 LS26	The CPSES specific allowed Completion Time for an inoperable feedwater isolation valve is revised from 4 to 72 hours when credit for the feedwater control and associated bypass valves may be taken and is verified within four hours.	No, refer to 07-04-LS16	Yes	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
07-09 LS10	A new CPSES specific ACTION is added that retains the ACTION requirement which was modified by CN 07-08-LS26 and revises the Completion Time from four to eight hours.	No	Yes	No	No
07-10 M	A new CPSES specific surveillance for each feedwater control and associated bypass valve is added.	No, surveillance already in CTS	Yes	No	No
07-11 M	Verification of valve [isolation or] closure once every 7 days is added.	Yes	Yes	Yes	Yes
07-12 LS4	The ACTIONS associated with inoperable [MFIVs] would be revised to provide the alternative of closing [or isolating] an inoperable valve.	No, part of CTS.	No, refer to 07-05-LS17.	Yes	Yes
07-13	Not used.	NA	NA	NA	NA
07-14	Not used.	NA	NA	NA	NA
07-15	Not used.	NA	NA	NA	NA
07-16 LS34	CTS are revised to add a Note to allow separate condition entry for each inoperable [MFIV].	No, refer to change 07-03-LS15.	No, refer to change 07-03-LS15.	Yes	Yes
07-17 A	The CPSES specific allowance to open a valve closed per an ACTION in this specification is enveloped by ITS SR 3.0.5.	No	Yes	No	No
08-01 LG	The requirement to perform ACOTs and CHANNEL CALIBRATIONS would be moved to licensee controlled documents.	No, not in CTS.	No, not in CTS.	Yes, moved to USAR.	Yes, moved to FSAR.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
08-02 A	A Note is added to ACTION that references potential interaction with ITS 3.4.6 for RHR MODE 4 operability.	Yes	Yes	Yes	Yes
08-03 LG	The requirement to perform the 18 month surveillance "during shutdown" would be moved to the Bases.	No, not in CTS.	No, not in CTS.	Yes	Yes
08-04 A	A Note is added that clarifies [CCW] operability.	Yes	Yes	Yes	Yes
08-05 A	Surveillance is modified to exclude valves that are locked, sealed, or otherwise secured in their correct position.	Yes	Yes	Yes	Yes
08-06 TR1	The SR is revised to allow credit for an actual actuation and moves signal specifics to the Bases.	Yes	Yes	Yes	Yes
08-07 M	A new surveillance specific to DCPD is added that requires verifying that each CCW pump starts automatically on an actual or simulated signal actuation at least once per 18 months.	Yes	No	No	No
08-08 A	Surveillance is modified to only be applicable to flow path valves.	Yes	Yes	Yes	Yes
08-09	Not Used.	NA	NA	NA	NA
08-10 A	The Callaway specific Note applicable to cycle 1 surveillance requirements is no longer needed.	No	No	No	Yes
09-01 M	A DCPD existing surveillance is revised that requires verifying that a motive source is available that would allow the required valves to be repositioned.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
09-02 A	A Note is added that requires entry into applicable LCOs if an inoperable [ASW] system makes the affected equipment inoperable.	No, ASW only supplies CCW heat exchangers.	Yes	Yes	Yes
09-03 A	The DCPD specific surveillance is reworded and the requirement to verify the position of automatic valves is deleted since the ASW system has no automatic valves.	Yes	No	No	No
09-04 M	A new surveillance specific to DCPD is added that requires verifying that each ASW pump starts automatically on an actual or simulated actuation signal at least once per 18 months.	Yes	No	No	No
09-05 TR1	The SR is revised to allow credit for an actual actuation and moves signal specifics to the Bases.	No, refer to 09-04-M. This requirement did not previously exist.	Yes	Yes	Yes
09-06 M	A new surveillance specific to DCPD is added that requires verifying that each valve in the flow path that is not locked, sealed, or otherwise secured in position is capable of being placed in the correct position in accordance with the IST Program.	Yes, also refer to change 09-01-M.	No	No	No
09-07 A	A Note is added to the [ASW] surveillance that clarifies system OPERABILITY requirements. Isolation of [ASW] flow to individual components does not render the system inoperable.	No, ASW only supplies CCW heat exchangers.	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
10-01 LG	The DCPD specific text description, definition of a ventilation train, is deleted from the LCO and moved to the Bases.	Yes	No	No	No
10-02 M	The Applicability and ACTIONS are revised to include "during movement of irradiated fuel assemblies."	Yes	No, part of CTS.	Yes	Yes
10-03 LS7	The SR for control room ventilation system is revised to require the filtration units without electric heaters to be tested for only 15 minutes instead of 10 hours.	No, plant configuration includes heaters.	Yes	No, refer to 10-22-M.	No, refer to 10-22-M.
10-04 A	An ACTION statement is added to require entering 3.0.3 if two trains of the control room (CR) ventilation filter system are inoperable in MODES 1, 2, 3, or 4.	Yes	Yes	Yes	Yes
10-05 LS18	A new option is added to the ACTIONS by NUREG 1431 that allows the suspension of CORE ALTERATIONS or movement of irradiated fuel versus placing the ventilation system in the recirculation mode.	Yes	No, part of CTS.	Yes	Yes
10-06 LG	The details and description of the Required Actions and the monthly SRs for train operability are moved to the Bases.	Yes	No, not in CTS.	Yes	Yes
10-07 LG	The surveillance that verifies CR temperature once per 12 hours is moved to a licensee-controlled document.	Yes, moved to ECGs.	No, not in CTS.	Yes, moved to USAR.	Yes, moved to FSAR.

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
10-08 A	The description of the ventilation filter specific testing requirements are moved to the VFTP, as defined in the Administrative Controls of the ITS, or deleted as being duplicated in the applicable RGs or Standards. A SR is added that requires [CR and Auxiliary Building ventilation system] filter testing in accordance with the VFTP.	Yes	Yes	Yes	Yes
10-09 LS27	The ACTION for an OPERABLE ventilation train not being capable of being supplied from an emergency power source is deleted.	No, refer to change 10-16-LG.	No, not in CTS.	Yes	Yes
10-10 TR1	The SR is revised to allow credit for an actual actuation and moves signal specifics to the Bases.	Yes	Yes	Yes	Yes
10-11 LS19	Frequency of the surveillance requiring verification of the control room ventilation system capability to maintain a positive pressure in the CR is relaxed to 18 months on a STB.	Yes	Yes	Yes	Yes
10-12 LS32	Deletes the STB for the 31 day testing.	No, CTS surveillance is not STB.	No, not in CTS.	Yes	Yes
10-13 LG	The DCPD specific footnotes indicating the control room ventilation system is common to both units and that the system may be considered OPERABLE with no chlorine monitors if no bulk chlorine gas is stored within the SITE BOUNDARY, are moved to the Bases.	Yes	No	No	No

CONVERSION COMPARISON TABLE - CURRENT TS 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
10-14 A	The statement that LCO 3.0.4 is not applicable is deleted based upon the new ITS definition of LCO 3.0.4 which does not apply in MODES 5 and 6.	No, TS 3.0.4 exemption is not in CTS.	No, TS 3.0.4 exemption is not in CTS.	Yes	Yes
10-15 LG	The ventilation system flow rates would be moved to licensee controlled documents. These flow rates are established in conjunction with flow balancing of the ventilation systems.	No, retained in CTS.	No, retained in CTS.	Yes, to USAR.	Yes, to FSAR.
10-16 LG	The DCPD specific requirement to have an available emergency power source for the control room ventilation system is moved to the Bases. This change is consistent with the Bases of NUREG-1431 for ventilation systems required during fuel movement.	Yes	No	No	No
10-17 A	The SR to measure ventilation system flow rate is not identified as a separate SR in the ITS because it is verified during the other in place filter tests (see ITS 5.5.11).	Yes	Yes	Yes	Yes
10-18 LS36	The CPSES specific action shutdown requirement is revised from MODE 3 in the next 6 hours and MODE 5 in the following 30 hours to enter LCO 3.0.3. This effectively adds up to one hour to the completion time.	No	Yes	No	No
10-19 A	Clarifies that for CPSES, the "pressurization" mode is called the "emergency recirculation" mode.	No	Yes	No	No
10-20 LS39	This change establishes appropriate Required Actions and Completion Times for ventilation system pressure envelope degradation.	No	Yes	Yes	Yes

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

DCPP No Significant Hazards Evaluations

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS.

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3..." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"

10CFR50.92 EVALUATION FOR ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

DCPP No Significant Hazards Evaluations

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

DCPP No Significant Hazards Evaluations

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications.

DCPP No Significant Hazards Evaluations

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION
BASES, FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

DCPP No Significant Hazards Evaluations

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?
The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident

DCPP No Significant Hazards Evaluations

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

10 CFR 50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A Note is added to allow separate condition entry and completion times for each inoperable main steam safety valve (MSSV). In the event of an inoperable MSSV, the CTS require that any MSSVs discovered to be inoperable, be returned to an OPERABLE condition or that the power range neutron flux high trip setpoint be appropriately reduced within the four hours provided. The most probable cause for an inoperable MSSV is the failure to meet the surveillance required as-found lift pressure. The intent of the four hours is to allow time to reset the valve lift point to within required tolerances or reduce power and the power range neutron flux high trip setpoints. The NUREG-1431 ACTION statement and the CTS inferred ACTION for the required power reduction is based on an inoperable MSSV per steam generator (SG).

The CTS requires that all MSSVs discovered to be inoperable be returned to an OPERABLE status within the four hours provided for the first inoperable valve. For example, if a second inoperable MSSV was discovered three hours into the ACTION statement of the first inoperable MSSV, both MSSVs would have to be returned to OPERABLE within the following one hour or the unit power level would have to be reduced in accordance with the CTS. The addition of the Note allowing separate entry for each inoperable MSSV provides the full four hours for each inoperable MSSV. This is acceptable based upon the assumptions used to analyze the unit with inoperable MSSVs (highest flow MSSV fails to open and the other three MSSVs with similar lift points on the other SGs also fail).

The accident scenarios of concern involve a loss of load (LOL) or turbine trip (TT) without a direct, or with a delayed, reactor trip. However, although it is not credited in the accident analysis (because the analysis was meant to evaluate a LOL as well as a turbine trip), the reactor protection system will cause a reactor trip on a turbine trip. This would avoid excessive heat input into the secondary side and provide further protection to prevent overpressurization.

The lift pressures of the MSSVs were determined assuming that the [atmospheric steam dump] valve [(ADV)] on each steam line was non-safety class and conservatively were not assumed to function in the licensing basis analyses. However, the [ADVs] themselves are safety grade and are expected to function to provide overpressure control [even though the automatic pressure control portion of the control circuitry is not Design Class I. However, the control circuitry for manual operation is Design Class I; thus manual operation of the ADVs would be able to relieve pressure in the long term.] The non safety grade condenser steam dumps would also be expected to provide overpressure control in the event of a turbine trip. With a loss of offsite power, the condenser steam dumps will not function due to the loss of condenser vacuum.

[The inoperability of the lowest set MSSV can potentially affect auxiliary feedwater (AFW) flow to the SGs following the above transients. However, if the lowest set MSSV is inoperable the lift point of the next higher set MSSV establishes the back pressure that the AFW pump must pump against. Adequate AFW flow has been verified as being available.]

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. This change is bounded by the analysis performed for an inoperable MSSV on each SG, which assumed that all of the valves at the lowest lift point fail to open. Thus, the multiple conditional entry for one valve inoperable on each SG is enveloped. The allowed multiple condition entry for inoperable valves on the same SG is predicated on the low probability of an event that would require the MSSVs to function and recognizes the availability of the other OPERABLE MSSVs, the [ADV(s)], the reactor trip from turbine trip, and the availability of the condenser steam dumps for transient pressure mitigation.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. The existing analysis for inoperable MSSVs envelopes the multiple entries since it assumes that one MSSV on each SG is inoperable. The allowed multiple condition entry for inoperable valves on the same SG is predicated on the low probability of an event that would require the MSSVs to function and recognizes the availability of the other OPERABLE MSSVs, the [ADVs], the reactor trip from turbine trip, and the availability of the condenser steam dumps for transient pressure mitigation.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1 (continued)

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions, or results. Consequently, it does not have an effect on a margin of safety. Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS1" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS allow continued operation with inoperable MSSVs if the power range neutron flux high reactor trip setpoints are reduced. The amount of reduction in the trip setpoint is dependent on the total number of inoperable MSSVs per SG and is intended to compensate for the lost relief capacity (heat removal capability and thus overpressure protection) should a transient requiring their operation occur. In the proposed specification, the CTS requirement to reduce the power range high neutron flux reactor trip setpoint is retained; however, the time to complete resetting the trip setpoints would be changed from four to 72 hours.

The CTS require that, if the MSSV cannot be restored to an OPERABLE status within four hours, the power range high neutron flux reactor trip setpoints must be reset in the same 4-hour period. NUREG-1431 requires that the reactor power be reduced in four hours if the MSSV cannot be returned to an OPERABLE status; however, NUREG-1431 would not require resetting the power range neutron flux high setpoints. The Westinghouse Owners Group (WOG) has proposed changes to NUREG-1431 (traveler WOG-83, as revised through draft Rev. 1) that: 1) propose that the completion time for resetting the power range neutron flux high trip setpoint to compensate for a positive MTC or a control rod withdrawal event at partial reactor power to be 72 hours, 2) specifies that power level reductions be per the Westinghouse Nuclear Safety Advisory Letter, NSAL 94-01 and 3) deletes the Maximum Allowable % RTP for 5 MSSVs OPERABLE. However, pending approval of draft Rev. 1 of WOG-83, the changes proposed in the traveler have been modified to retain the current TS requirement to reset the power range neutron flux-high trip setpoints based on the number of MSSVs inoperable to a maximum allowable power determined in accordance with calculations or analysis to account for Westinghouse NSAL 94-001. The allowed Completion Time to reduce the Power Range Neutron Flux trip setpoints is reasonable based on operating experience to accomplish the required ACTIONS in an orderly manner. The power levels specified per NSAL 94-001 are based on a conservative algorithm developed by Westinghouse to bound the required relief capacity.

The above changes are consistent with NUREG-1431 as revised by WOG-83 and NSAL-94-001. This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3 (continued)

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. The proposed change is based on recognition that: 1) Reactor power must be limited to compensate for lost pressure relief (heat removal capability) with inoperable MSSVs; and 2) that there is a need to prevent a reactor power increase via a reduced power range neutron flux high trip setting, for transients that would cause added heat transfer to the secondary system. The proposed change also allows for an appropriate amount of time to: 1) restore the MSSV to OPERABLE or reduce power; and 2) reduce the power range neutron flux high reactor trip setpoints. The probability of an accident occurring and requiring MSSV operation during the 72-hour Completion Time would be very small. The time extension allows the reactor trip setpoint reduction to be performed in a more deliberate manner, thereby reducing the potential for inadvertent reactor trips introduced during the setpoint reduction. However, because the accident analyses are unaffected by the proposed change, the consequences of the accident analyses are not affected by this change.

Therefore, the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not require physical alteration to any plant system or change the method by which any safety-related system performs its function. No changes in plant operation result from the changes, and no new event initiators are introduced.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions or results. The required reduction in power level and the required reduction in power range neutron flux high reactor trip setpoints both restore the assumed margin of safety. The extension of time to reset the reactor trip setpoints does not have a significant effect on a margin of safety because the likelihood of the initial conditions and the occurrence of the sequence of events that would be required to challenge the MSSVs during the time period is very small. In addition, the Completion Time for reducing reactor power remains unchanged. Furthermore, the accident analyses are assumed to be initiated from conditions which are consistent with the TS LCOs. The proposed change does not affect any LCO. Therefore, there is no change in the accident analyses and all relevant event acceptance criteria remain valid. Consequently, this change does not have a significant effect on a margin of safety.

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

**NSHC LS3
(continued)**

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS-3" resulting from the conversion to the improved TS format satisfy the no significant hazards consideration standards of 10 CFR 50.92(c); and accordingly, a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS define the steam turbine-driven (TDAFW) pump as OPERABLE if it has two OPERABLE and redundant steam supplies. Since no ACTIONS are specified for an inoperable steam supply, the TDAFW pump must be declared inoperable if one of the two redundant steam supplies becomes inoperable. The requirement for two supplies is based upon the SG tube rupture (SGTR) and main steam line break (MSLB) accidents to assure that a 100 percent redundant steam supply to the TDAFW pump is available.

NUREG-1431 provides a Required Action if one of the steam supplies becomes inoperable, thus avoiding inoperability of the pump. NUREG-1431 recognizes that the TDAFW pump can continue to perform its intended function with only one steam supply since the supplies are redundant. NUREG-1431 requires that with only a single steam supply OPERABLE that a Required Action be entered. The time to return the inoperable steam supply to an OPERABLE condition is seven days. This time is reasonable considering that: 1) there is an OPERABLE 100 percent redundant steam supply; 2) there are two OPERABLE motor-driven AFW pumps; and 3) there is a low probability of an SGTR or MSLB event occurring that would require the use of the inoperable steam supply.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident since the TDAFW pump steam supply only provides power to equipment required to mitigate the consequences of an accident.

The revision recognizes the low probability of an accident requiring the use of the inoperable steam supply for the TDAFW pump coincident with the failure of the motor-driven AFW pumps.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 (continued)

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions, or results. Consequently, it does not have an effect on margin of safety.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS5" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The surveillance interval for the AFW pump performance test is revised from a Frequency of 92 days on a STAGGERED TEST BASIS to the Frequency specified by the IST Program. This change will result in all TS pump performance surveillance tests referencing the IST Program for frequency and test requirements. This change will eliminate any potential ambiguity associated with AFW pump testing as a result of ASME changes and results in consistent presentation of pump testing throughout the TS. The inservice tests confirm component operability, trend performance, and detect incipient failures by indicating abnormal performance. This change is classified as a relaxation since the frequency is no longer specified in the TS. The pump testing frequency will now be controlled by the IST Program which may be changed within the limits of the ASME code without prior NRC written approval per Generic Letter (GL) 89-04, Supplement 1. This change has been proposed as a change to NUREG-1431 via TSTF-101.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the unit configuration or operation or the function of any safety system. Consequently, the changes do not increase the probability of an accident as defined in the FSAR Update. Revising the testing frequency or the reference for the testing frequency for an accident mitigating system consistent with NRC guidance does not effect the analyzed accident, its probability, or its consequences.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system is tested or performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions or results. Consequently, the proposed change does not involve a significant reduction in margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS6" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS require that the gross radioactivity of the secondary system coolant be determined every 72 hours. This surveillance is basically only an indicator of the potential offsite whole body dose. Since the radioiodines and the resulting thyroid dose are limiting, not noble gases and whole body dose, NUREG-1431 has deleted the 72 hour gross radioactivity surveillance requirement. Since the limits on primary to secondary leakage and DOSE EQUIVALENT I-131 assure that the dose analyses in the FSAR remain valid, the revised surveillance is more appropriate. NUREG-1431 also requires that the surveillance for verification of I-131 activity be performed every 31 days on an unconditional basis, which is more restrictive than the CTS.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. This change only deletes gross radioactivity sampling where results are bounded by the primary to secondary leakage and DOSE EQUIVALENT I-131 limits. The consequences of secondary system releases are limited by radioiodines and their resultant thyroid exposures, not the whole-body exposures received from the noble gases. In addition, the surveillance Frequency for verification of I-131 activity has been increased to 31 days unconditionally, which is more restrictive than the CTS.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8 (continued)

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. The change only deletes a surveillance function utilized for trending.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions, or results. Consequently, it does not have an effect on margins of safety.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS8" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS require that if one main steam isolation valve (MSIV) is inoperable in MODES 2 or 3, operation may continue if that valve is maintained closed. The CTS do not recognize additional MSIVs being closed as meeting the LCO. Thus, if multiple MSIVs are closed, the unit is required to enter the ACTION statement.

NUREG-1431 recognizes that if all MSIVs are closed [and de-activated] and verified closed, their safety function is being fulfilled and there is no need to enter the ACTION. If the valves cannot be closed, then NUREG-1431 requires that the unit be taken to MODE 4 in 12 hours, which is consistent with the CTS ACTION for one MSIV that cannot be closed. Going to MODE 4 places the unit in a condition such that the LCO is no longer applicable.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. This change recognizes that since the MSIVs are closed, they are performing their intended function. Consequently, there is no need to place the unit in a MODE where the LCO is not applicable.

Therefore, the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9 (continued)

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. The MSIVs would be in their accident mitigating position, thus fulfilling their required function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions, or results. Consequently, it does not have an effect on margins of safety.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS9" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS ACTION statement requires that with one MSIV inoperable and open in MODE 1, OPERABILITY be restored within four hours, or the unit be placed in at least HOT STANDBY within the next six hours and in HOT SHUTDOWN within the following six hours. The CTS MODES 2 and 3 ACTION statement specifies that subsequent operation in MODE 2 or MODE 3 may proceed provided the one inoperable MSIV is closed and maintained closed. The CTS and NUREG-1431, LCO 3.0.3, state that where corrective measures are completed that permit operation under the ACTION requirements, the ACTION may be taken in accordance with the specified time limits as measured from the time of failure to meet the LCO. This logic can also be applied to specific ACTIONS requiring MODE transitions. In this case, if an MSIV could not be returned to an OPERABLE condition in four hours, the unit would be required to transition to MODE 4 as long as the MSIV remained open. If during the transition, the inoperable valve was closed, the ACTION requirements for operation in MODES 2 or 3 would be met and the transition to MODE 4 would not be required. Some repairs to an MSIV can be made during operation in MODE 1; however, it may not be possible to restore OPERABILITY within the AOT of four hours.

NUREG-1431 increases the AOT from four hours to eight hours for an inoperable and open MSIV. This revised AOT provides a more reasonable time to diagnose the problem, mobilize corrective ACTIONS, obtain administrative clearances, complete the maintenance, restore the valve to an OPERABLE condition, and where appropriate, perform a post-maintenance verification. The additional time reduces the probability of unnecessary unit transients and unit shutdowns, thus improving unit safety and increasing unit availability.

The CTS MODE 1 requirement to take the unit to HOT SHUTDOWN if the valve cannot be closed within four hours is overly restrictive. Once the transition to MODE 2 occurs, the ACTIONS of MODE 2 should apply. The ACTIONS of MODE 2 require the inoperable valve to be closed in 4 hours or the unit must be taken to HOT SHUTDOWN. To eliminate potential confusion, NUREG-1431 revises the MODE 1 ACTION to clarify the stages of unit shutdown required for an inoperable MSIV. The ACTION is revised to specify that if an inoperable MSIV is not restored to OPERABLE status within the proposed 8 hour AOT, the unit must be in MODE 2 within the next 6 hours and the MODE 2 requirements would apply. The Completion Time can be greater for these valves as opposed to other containment isolation valves because these valves are isolating a closed system that penetrates containment.

The safety function of the MSIVs is to close. Therefore, a closed MSIV will perform its safety function even if it is not OPERABLE. However, an MSIV cannot be closed with the unit operating in MODE 1 without initiating a unit shutdown. To provide the option to close the MSIV, the unit must be in at least MODE 2. The CTS MODES 2 and 3 ACTION specifies that subsequent operation with an inoperable MSIV may proceed provided that the MSIV is maintained closed. However, the frequency at which the valve is to be verified "maintained closed" is not specified, nor is the AOT to return the valve to an OPERABLE condition or the time to close an inoperable MSIV. NUREG-1431 recognizes that if the MSIV is closed, it is performing its safety function and that if other MSIVs become inoperable their closure will allow them to perform their safety function. The addition of the note allowing separate entry for each inoperable MSIV provides the full AOT for each inoperable MSIV. This is acceptable based upon the fact that the ACTION is to close the valve and also based on the low probability of a condition requiring the closure of the MSIVs in MODES 2 and 3 while in the proposed eight hour ACTION.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11 (continued)

NUREG-1431 revises the MODES 2 and 3 ACTION to allow up to eight hours to restore the valve to an OPERABLE condition or close an inoperable MSIV. Additionally, NUREG-1431 MODES 2 and 3 ACTION requires an inoperable and closed MSIV to be verified closed at least once every 31 days. Verifying the position of a closed MSIV every 31 days is reasonable because MSIV status indications are available in the CR to verify the valve is closed and this frequency is consistent with the CIV STS 3.6.3. From a containment isolation consideration, these valves can have a longer completion time since the valves are isolating a closed system that penetrates containment.

The proposed changes to increase the MSIV AOTs are consistent with the recommendations from NUREG-1024, "Technical Specifications - Enhancing the Safety Impact." NUREG-1024 states in part:

Allowable outage times that are too short will subject the unit to unnecessary trips, transients and fatigue cycling. Outage times that are too short also may result in less thorough repair and post repair testing before equipment is returned to service.

Safety Function of MSIVs

The MSIVs must be open during power operation. The valves have a safety function to close to mitigate the consequences for the following:

1. The steam discharged into containment from a MSLB inside containment is limited by MSIV closure. After MSIV closure, only steam from the affected SG and from the residual steam in the main steam header downstream of the closed MSIVs in the unaffected loops is discharged into containment. For this accident scenario, steam is discharged into containment from all SGs until the unaffected are isolated by closure of their respective MSIVs. Closure of the MSIVs for the unaffected (SG) isolates them from the break.
2. A break outside of containment and upstream from the MSIVs is not a containment pressurization concern. However, the uncontrolled blowdown of more than one SG loop must be prevented to limit the extent of uncontrolled RCS cooldown and core positive reactivity addition. Closure of the MSIVs isolates the break and limits the blowdown to a single SG loop in the same manner as a break within the containment.
3. A break downstream of the MSIVs will be isolated by the closure of the MSIVs. A single failure of one MSIV will not result in uncontrolled blowdown of more than one SG loop.
4. Following a SGTR, closure of the MSIV for the affected SG isolates that SG from the intact SGs. In addition to minimizing radiological releases, this enables the operator to maintain the pressure of the SG with the ruptured tube independent of the other SGs, a necessary step toward equalizing the pressure difference across the tube rupture and terminating flow through the ruptured tube.
5. The MSIVs are also utilized during other events such as a feedwater line break. This event is less limiting than a steam line break for MSIV operability, since the uncontrolled blowdown transient and resulting containment pressurization associated with a feedwater break is slightly less severe.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11
(continued)

Summary and Conclusions

The effect on unit safety of an increase in the MSIV MODE 1 AOT from four hours to eight hours, the addition of a MODE 2 and 3 eight hour AOT to restore or close inoperable valves, and the allowance of multiple condition entries has been evaluated. The increase in AOT does result in a slight increase in risk; however, the risk associated with a unit shutdown due to the shorter AOT is reduced. In conclusion, there is reasonable assurance the health and safety of the public will not be adversely affected by the proposed TS changes.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change to the MSIV TS does not alter the unit configuration or operating methodologies or the function of any safety-related systems. Even though there is a slight risk increase associated with an increase in AOT, the risk is small and not significant. The proposed changes do not significantly increase the probability of an accident as defined in the FSAR Update.

Closure of inoperable MSIVs in MODES 2 or 3 and the allowed multiple condition entries that would eventually result in their closure places them in the position that fulfills their safety function. Therefore, continued unit operation in MODES 2 or 3 with inoperable MSIVs in separate condition entries or closed does not effect the consequences of an accident.

The 31 day surveillance frequency to verify the closure of an isolated valve is reasonable considering there is valve position indication in the CR, and since the valve is in its safeguard position, there are no safety concerns.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

LS11 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. Closure of inoperable MSIVs places them in the position that fulfills their safety function, and consequently is not a physical alteration to the unit.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions, or results. Consequently, there is no significant effect on margins of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS11" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS13
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

To assure charcoal adsorber OPERABILITY, the SR requires that a laboratory analysis be performed and the results obtained within 31 days of removing the charcoal sample. The sample must be sent to an offsite laboratory for this analysis. It is proposed that the time requirement of "within 31 days after removal" for completion of laboratory analyses be deleted. This requirement is intended to avoid extended plant operation with degraded charcoal filters. This requirement is not contained in the ITS nor is it contained in the RG 1.52 or the applicable ANSI standards. There is no safety significant basis for maintaining this time limit as a TS requirement. Laboratory analyses are performed under contract with a laboratory on a prompt basis, and it is not necessary to prescribe a time limit within TS for completing the analysis. Failure to complete an analysis within 31 days has insignificant safety consequences because the results would be available within approximately the same time period and it is very unlikely that the charcoal would be degraded to the extent that there would be a complete loss of a safety function.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. The revision recognizes that the timely completion of this surveillance will not affect the probability or consequences of any accident.

In addition, the results of charcoal filter testing would be available on approximately the same schedule as before. Thus, the proposed change would not have a significant effect on the availability of the filters to perform as assumed following an accident.

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

LS13 (continued)

Therefore, the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any plant system or change the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change would continue to assure that the charcoal filters perform as required although the time period for obtaining test results would be removed from TS. However, the results would be available on approximately the same schedule as before. Consequently, it does not have significant effect on a margin of safety.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS13" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14
10 CFR 50.92 EVALUATION
FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

An exemption to TS 3.0.4 is added that allows MODE transition to occur with a single inoperable [ADV]. The CTS does not permit a MODE transition with an inoperable valve. The valve must be returned to an OPERABLE condition within seven days of becoming inoperable before the MODE transition is permitted. The CTS allow an [ADV] to be inoperable in MODES 1, 2, or 3, because the risk of an accident requiring [ADV] valve operation has been evaluated and found to be low. Allowing MODE transition with an inoperable [ADV] does not significantly increase that risk since the remaining valves are operable.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies or affect the function of any safety-related system. This revision does not affect an accident initiator of any analyzed accident. This change recognizes that the probability of an accident requiring the single inoperable valve to function is low and is unlikely to occur during the AOT even with the permitted MODE transition.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14
(continued)

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions, or results. Consequently, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS14" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS are revised to apply to all four feedwater lines as a group. A Note is added to the CTS to allow separate condition entry time for each inoperable valve. NUREG-1431 recognizes that with one valve inoperable and open in the flow path, that feedwater isolation, within the assumptions used for accident analysis, is still functional via the safety grade MFIVs, [the safety grade main feedwater (MFW) regulating and bypass valves (that are located in non safety grade piping), or via the MFW pump non safety grade pump trip.]

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or alter the function of any safety-related system. This revision does not affect an accident initiator of any analyzed accident. This change recognizes that the probability of an accident requiring isolation of the flow is low and recognizes the availability of the feedwater pump trip upon a feedwater isolation signal to maintain the consequences of the assumed accident within the analyzed conditions.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15 (continued)

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions, or results. Consequently, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS15" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS EVALUATION

NSHC LS16
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

With one feedwater isolation/regulating/bypass valve inoperable and open in MODE 1, 2, or 3, the CTS ACTION statement requires that OPERABILITY be restored within four hours. If OPERABILITY cannot be restored or valve closure accomplished, the MFIV must be closed or for the main feedwater regulating (MFRV)/bypass valves, the valve must be closed or isolated, or the unit must be placed in at least HOT STANDBY within the next six hours and in HOT SHUTDOWN within the following six hours. The CTS applies to each feedwater line individually. Some repairs to a valve can be made during operation in MODE 1, 2, or 3; however, it may not be possible to restore OPERABILITY within the AOT of four hours.

NUREG-1431 increases the MODE 1, 2, and 3 AOT from 4 hours to 72 hours for an inoperable and open valve. The increased AOT provides a more reasonable time to diagnose the problem, mobilize corrective ACTIONS, obtain administrative clearances, complete the maintenance, restore the valve to an OPERABLE condition, and where appropriate, perform a post-maintenance verification. The additional time reduces the probability of unnecessary unit transients and unit shutdowns, thus improving unit safety. NUREG-1431 recognizes that the inoperability of one valve in the flow path does not render the feedwater isolation function inoperable. This conclusion is based on the isolation redundancy provided by the MFIV and MFRV and associated bypass valves that are assumed to close in less than or equal to seven seconds by NUREG-1431.

An argument and a similar conclusion can be made for MFIVs that have closure times greater than that of the MFRVs and associated bypass valves. In addition, a containment pressure analysis has been performed for the large secondary line break with an assumed failure of one MSIV, assuming other MFIVs close (which the CTS require to be less than or equal to 60 seconds) and the peak containment pressure remains below the design limit. The containment isolation function is still available via the main feedwater isolation check valve if a MFIV is assumed to be inoperable. The feedwater isolation function is effectively present via the MFW pump trip (which is Class II but receives a Class I signal) which acts to stop feedwater flow in less than 10 seconds if the MFRV or associated bypass valve are inoperable. If the MFIV is inoperable, feedwater isolation automatically occurs via the MFRV/bypass valve closure and the MFW pump trip. The MFIV can be closed manually if required.

The CTS as written would permit a single valve in each line to be inoperable and open for the AOT, but would not permit a second valve in the flow path to be inoperable and open, and thus would require entry into 3.0.3. NUREG-1431 revises the MODES 1, 2, and 3 ACTION to include two valves in the flow path inoperable and allows up to eight hours to restore one valve to an OPERABLE condition or isolate the affected flow path. NUREG-1431 recognizes that the feedwater pump trip will effectively stop feedwater flow under these conditions. The eight hour AOT allowed by NUREG-1431 assumes that the isolation function is lost since the two valves inoperable could be in series.

As noted above, the existing plant design would still provide for containment isolation via the Class I MFW isolation check valve and provides effective feedwater isolation via the MFW pump trip even with two valves in the flow path inoperable.

IV. SPECIFIC NO SIGNIFICANT HAZARDS EVALUATION

NSHC LS16 (continued)

The proposed changes to increase the valve AOTs are consistent with recommendations from NUREG-1024, "Technical Specifications - Enhancing the Safety Impact." NUREG-1024 states in part:

Allowable outage times that are too short will subject the unit to unnecessary trips, transients and fatigue cycling. Outage times that are too short also may result in less thorough repair and post repair testing before equipment is returned to service.

Safety Function of MFIV/MFRV/Bypass Valves

The MFIV/MFRVs must be open during power operation. The valves including the bypass valves have a safety function to close to mitigate the consequences for the following:

1. The safety-related function of the MFRVs and the associated bypass valves is to provide the initial isolation of MFW flow to the secondary side of the SGs following a high energy line break (HELB) (either a feedwater (FWLB) or a MSLB line break). Since the MFRVs and associated bypass valves are located in non safety grade piping, the MFIVs ultimately provide (in less than or equal to 60 seconds) the safety-related isolation function of the MFW flow to the secondary side of the SGs following an HELB. Closure of the MFIVs or MFRVs and associated bypass valves or the automatic trip of the MFW pumps effectively terminates flow to the SGs, terminating the event for FWLBs occurring upstream of the MFIVs or MFRVs. The consequences of events occurring in the main steam lines or in the MFW lines downstream from the MFIVs will be mitigated by the termination of feedwater flow. The termination of feedwater to an affected SG limits the mass and energy release for steam line breaks (SLBs) or FWLBs inside containment, and reduces the cooldown effects for SLBs.
2. The MFIVs isolate the non safety-related portions of the piping system from the safety-related portions of the system. In the event of a secondary side pipe rupture inside containment, the valves limit the quantity of high energy fluid that enters containment through the break, and provide a pressure boundary for the controlled addition of AFW to the intact loops. The MFW isolation check valves also function to provide a pressure boundary for the controlled addition of AFW to the intact loops.

One MFIV, one MFW isolation check valve, and one MFRV and its associated bypass valve, are located on each MFW line, outside but close to containment. The MFIVs, MFW check valves, and MFRVs are located upstream of the AFW injection point so that AFW may be supplied to the SGs following MFIV or MFRV closure.

The MFIVs and MFRVs and associated bypass valves, close on receipt of any safety injection signal (SIS), a T_{avg} low coincident with reactor trip (P-4) or SG water level high high signal. They may also be actuated manually. The MFW pumps trip on any SIS or on a SG water level high high signal. As noted above, a check valve located upstream of the MFIV is available. The check valve isolates the feedwater line, penetrating containment, and ensures that the intact SGs do not continue to feed the FWLB in the non safety-related piping upstream of the feedwater isolation check valves and that the AFW input will be forward to the SGs.

IV. SPECIFIC NO SIGNIFICANT HAZARDS EVALUATION

NSHC LS16 (continued)

3. The design basis of the MFIVs and MFRVs is established by the analyses for the large SLB and the resulting containment pressure. It is also influenced by the accident analysis for the large FWLB. Closure of the MFIVs or MFRVs and associated bypass valves, are relied on to terminate an SLB for core response analysis and excess feedwater event upon the receipt of a SG water level high high signal or a feedwater isolation signal on high SG level. Failure of an MFIV, MFRV, or the associated bypass valves to close following an SLB or FWLB, can result in additional mass and energy being delivered to the SGs, contributing to cooldown. This failure also results in additional mass and energy releases following an SLB or FWLB event. However, as noted above, the MFV pump trip, even though Class II, is also available to effectively terminate feedwater flow into containment.

Summary and Conclusions

The affect on unit safety of an increase in the MFIV/MFRV/Bypass valve MODE 1, 2, and 3 AOT/completion time from 4 hours to 72 hours and the addition of an eight hour AOT/completion time for two valves inoperable in a flow path to restore or close the valve(s) has been evaluated. The isolation functions are intended to protect against Condition IV events and the increase in AOT and the new ACTION related to two valves in the flowpath have minimal impact since the probabilities of these events is low. In conclusion, there is reasonable assurance the health and safety of the public will not be adversely affected by the proposed TS changes.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed changes to the MFIV AOT/completion times do not alter the unit configuration or operation, and consequently do not significantly increase the probability of an accident as defined in the FSAR Update. While the consequences of an accident may possibly be increased with the subject valves inoperable, the chances of an accident occurring during the AOT is very small, so the potential increase in consequences is not significant.

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS EVALUATION

NSHC LS16 (continued)

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter any basic regulatory requirements or affect any safety analyses. Consequently, the proposed changes do not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS16" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS18
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

In MODES 5 and 6, the CTS require that the remaining CR [emergency filtration (ventilation) system (CREFS)] train be placed in the recirculation MODE if the inoperable train cannot be returned to an OPERABLE condition in seven days. NUREG-1431 recognizes the primary function of the [CREFS] in MODES 5 and 6 is to protect CR personnel from a fuel handling accident. Therefore, NUREG-1431 permits the inoperable train to remain inoperable if CORE ALTERATIONS and/or movement of irradiated fuel assemblies are suspended, thus eliminating the potential for a fuel handling accident. This is a relaxation from the CTS.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the unit configuration or operation or the function of any safety system. Consequently, the change does not increase the probability of an accident as defined in the FSAR Update. Allowing the unit to comply with an ACTION REQUIREMENT by eliminating the potential for an analyzed accident places the unit in a safe condition.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS18 (continued)

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements and change any accident analysis assumptions, initial conditions, or results. Consequently, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS18" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS19
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS require that the CR [emergency filtration (ventilation) system (CREFS)] trains be tested at least once every 18 months by verifying that the system maintains the control room at a positive pressure of greater than or equal to [1/8 inches] of water gauge relative to the outside atmosphere during the pressurization MODE of operation. This testing is currently performed on both [CREFS] trains as required by the CTS. NUREG-1431 would revise the Frequency to at least once every 18 months on a STB, which would require testing only one train every 18 months. This revised testing Frequency is consistent with NUREG-0800, Section 6.4 for proving the [CR] pressure boundary integrity. The test will still evaluate the integrity of the CR structure and the ability of the [CR ventilation system] to maintain a positive pressure with respect to the outside atmosphere and adjacent areas every 18 months. The [CR ventilation system] OPERABILITY verification conducted every 31 days is not revised and will verify OPERABILITY of the system components.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC. -

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the unit configuration or operation or the function of any safety system. Consequently, the change does not increase the probability of an accident as defined in the FSAR Update. Revising the testing Frequency to verify the CR pressure boundary consistent with NRC guidance does not effect the analyzed accident, its probability, or its consequences.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS19 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions, or results. Consequently, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS19" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS21
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The time to achieve HOT SHUTDOWN (MODE 4) if ACTIONS are not complete for the SG heat removal system is changed from 6 hours to 12 hours. The CTS have been revised per NUREG-1431 to require a SG to be OPERABLE if used for heat removal in MODE 4. The Required Action if the SG becomes inoperable due to inoperable ADV or condensate storage tank (CST), or AFW pump is to be in MODE 4 without reliance upon the SG for heat removal. Since the inoperable conditions may affect the normal cooldown capability, NUREG-1431 allows an additional six hours to reach residual heat removal (RHR) system entry conditions. The added six hours provides additional time to perform an orderly transfer from the SG method of heat removal to the RHR system to maintain the heat removal function.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the unit configuration or operation or the function of any safety system. Consequently, the change does not increase the probability of an accident as defined in the FSAR Update. The proposed change permits a longer time to cooldown to RHR entry conditions; however, this is appropriate due to the reduced temperatures and pressures present and the reduced probability of an accident during these conditions.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS21 (continued)

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. As discussed above, the change does allow additional time to complete the transfer from the SG as the method for heat removal to the RHR system, but does not alter the basic methodology.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions, or results.

Consequently, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS21" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS23
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A footnote is added to the SR that demonstrates that the MSIV close within five seconds to indicate that the demonstration of MSIV operability is only required to be performed for entry into (and continued operation in) MODES 1 and 2. The footnote is added in lieu of the current exception to specification 4.0.4. Exceptions to the corresponding specification in NUREG-1431 (SR 3.0.4) do not exist. While the footnote is intended to accomplish the same thing, it is in fact less restrictive because the footnote permits an indefinite stay in MODE 3 while the exception to specification 4.0.4 requires testing within 24 hours of establishing unit conditions by applying the requirements of specification 4.0.3 as discussed in GL 87-09.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes. The MSIVs are not assumed to be the initiators of any analyzed event. The deletion of the 24-hour time limit required by 4.0.4 to perform the surveillance in MODE 3 is justified on the basis of the performance of the valves during testing. Because of the high reliability of the valves and their consistent performance during testing, it is highly unlikely that one of the valves would fail to close when required even if testing were to be delayed as allowed by this revision. Therefore, this change will not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the unit (no new or different type of equipment will be installed) or changes in parameters governing normal unit operation.

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

**NSHC LS23
(continued)**

Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change is trivial and does not alter the bases for allowing entry into MODE 3 to perform the surveillance. Any reduction in a margin of safety will be insignificant and offset by the benefit gained through avoiding an unnecessary unit transient.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS23" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS24
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change adds a new Required Action for three or more [ADV] lines inoperable and specifies a Completion Time of 24 hours to return all but two [ADV] lines to an OPERABLE status. NUREG-1431 permits two or more [ADV] lines to be inoperable with a Required Action of returning all but one to an OPERABLE status within a Completion Time of 24 hours. The 24-hour Completion Time is based upon the low probability of an event occurring that would require the [ADV] lines to function. The CTS do not specify an ACTION for three or more [ADV] lines inoperable. Therefore, the unit is required to enter (LCO) 3.0.3. The requirement to enter LCO 3.0.3 is overly restrictive based upon the NUREG-1431 allowance of 24 hours, and would subject the unit to unnecessary down-power transients.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- (1) Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- (2) Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- (3) Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the NSHC.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not alter the unit configuration or operation or the function of any safety system. Consequently, the change does not increase the probability of an accident as defined in the FSAR Update. Revising the conditions associated with an accident mitigating system consistent with NRC guidance does not effect the analyzed accident, its probability, or its consequences. The revision simply recognizes the low probability of an event that would require the [ADV] lines to function, and that the condenser steam dump valves would likely be available.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS24 (continued)

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not alter the basic regulatory requirements or change any accident analysis assumptions, initial conditions, or results. Consequently, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS24" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS31
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS allow continued operation with inoperable MSSVs if the power range neutron flux high trip setpoints are reduced. The amount of reduction in the trip setpoint is dependent on the total number of inoperable MSSVs and is intended to compensate for the lost relieving capacity (heat removal capability) should a transient requiring their operation occur. On January 20, 1994, Westinghouse issued NSAL 94-001, which stated that the reductions in the power range neutron flux high trip setpoint required by TS Table 3.7-1 may not be bounding for the LOL/TT event since the power range neutron flux high trip setpoint specified may not be low enough to preclude secondary system overpressurization. In the proposed specification, the requirement to reduce the power range neutron flux high trip setpoint is revised such that the required setpoints satisfy the requirements of NSAL 94-001 or specific unit safety analyses. The reduction in trip setting prevents a power increase above those settings should the unit be operating with a positive MTC. The MSSVs are set to protect the secondary system against overpressurization in accordance with ASME codes and mitigate the consequences of anticipated operational transients. This change has been identified as less restrictive since the applicable set points have been revised consistent with NSAL 94-001 as opposed to NUREG-1431.

A unit may continue to operate with up to three MSSVs inoperable per steam line provided the power range neutron flux high trip setpoint is reduced as specified. Currently administrative controls are used to assure that the neutron high flux trip settings are reduced to appropriate levels per NSAL 94-001 should entry into the be required.

Upon receipt of Westinghouse NSAL 94-001, reanalysis of the LOL/TT event was performed. An analysis was performed for one MSSV inoperable on each SG that verified the plant could continue to operate at 100 percent rated thermal power. The analysis assumed worst case assumptions and that the lowest set MSSVs (the first to open during a pressure transient) were all inoperable. The analysis verified that the SG pressure would not reach 110 percent of design following a LOL/turbine trip transient. For two or three MSSVs inoperable on any SG, the algorithm recommended in Westinghouse NSAL 94-001, was used to calculate the power range neutron flux high trip setpoints. The algorithm recommended by Westinghouse is based on extremely conservative assumptions to determine the power level/steam flow that can be handled by the remaining OPERABLE MSSVs, i.e., that a reactor trip does not occur and that feedwater is unavailable. The calculation is documented and verified and specifies where the power range neutron flux high trip setpoints must be set to meet the required analysis. The required setpoints specified in Table 3.7-1 incorporate the uncertainties of the neutron flux measurement and the heat balance measurements as recommended by Westinghouse.

The NSHCs involved with the proposed amendment have been evaluated, focusing on the three standards set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in paragraph 50.91, that a proposed amendment to an operating license for a facility licensed under paragraph 50.21(b) or paragraph 50.22 or a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

(1) Involve a significant increase in the probability or consequences of an accident previously evaluated; or

DCPP No Significant Hazards Evaluations

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS31 (continued)

(2) Create the possibility of a new or different kind of accident from any accident previously evaluated; or

(3) Involve a significant reduction in a margin of safety."

The following evaluation is provided for the no significant hazards consideration.

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. The proposed change revises the required power level versus number of OPERABLE MSSVs to be consistent with the recommendation of, or per analyses performed in support of NSAL 94-001, which was attached to IEN 94-60.

Therefore, the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any unit system or change the method by which any safety-related system performs its function. The increased power level and high flux trip setpoint have been evaluated for the LOL/turbine trip, which is the most significantly effected transient. The evaluation indicates that the results are within limits even with the conservative assumptions used.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does the change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions or results. Consequently, it does not have an effect on a margin of safety.

Therefore, the proposed change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS31" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS33
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed change would revise the ACTION for MODES 1 and 2, which currently apply to one inoperable [main feedwater isolation valve (MFIV)] to apply to one or more [MFIVs]. This is less restrictive than the current requirements which apply to only one inoperable valve.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change would have an insignificant effect on the probability of occurrence of an accident because the number of inoperable [MFIVs] would not affect any accident initiators. Therefore, the probability of an accident would not be significantly increased.

The operability of [MFIVs] could have an effect on the consequences of accidents that take credit for [MFIV] closure. However, these accidents are very low probability events that are not expected to occur during the lifetime of the unit. Nevertheless, should one of these low probability events occur, the accident analyses assume that various failures of equipment occur, and the failure of an [MFIV] is considered in these failure assumptions. Furthermore, other equipment would be expected to function to backup the [MFIV] function. These include feedwater check valves that prevent backflow through the feedwater lines, flow control valves that direct AFW flow away from a broken feedwater line, and feedwater control valves and feedwater pump trip circuits that can terminate feedwater flow. Effective decay heat removal from the unit can be accomplished with only one SG. These factors tend to mitigate the consequences of having more than one [MFIV] inoperable if an accident should occur.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS33 (continued)

Therefore, the proposed change would have no significant effect on the probability or consequences of any previously analyzed accidents.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change involves the number of inoperable [MFIVs]. As noted above, there is other equipment available to backup the [MFIVs] should an accident occur. This equipment assures that an accident sequence would proceed as expected and analyzed in the unit safety analysis. Although some of the backup components are not in TS, they are designed to high standards and are periodically tested to assure operability. Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The change involves the operability of equipment used to mitigate postulated accidents. As noted in the evaluation of Criterion 1 above, there is backup equipment available in the design to assist in performing the [MFIV] function. This equipment is expected to operate and would perform the [MFIV] functions in sufficient time to avoid a significant reduction in any margin of safety. Therefore, the proposed change would have no significant adverse effect on margins of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS33" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS37
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change exempts from the Applicability of the [MFIVs] LCO the condition where one or more [MFIV] is inoperable in MODES 1, 2, or 3, but the [MFIV, feedwater regulating (FRVs) or its associated bypass valve] is closed [and deactivated or isolated by a closed manual valve].

NUREG-1431 recognizes that if one or more [MFIVs or FRVs] or associated bypass valves are closed [and de-activated] and verified closed [], their safety function is being fulfilled and there is no need to enter the ACTION statement. If the valves cannot be closed or isolated, then NUREG-1431 requires that the unit be taken to MODE 4, which is consistent with the CTS ACTION for one [MFIV or FRV valve or associated bypass valve] that cannot be closed. Going to MODE 4 places the unit in a condition such that the LCO is no longer applicable.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This revision does not affect an accident initiator of any analyzed accident. This change recognizes that since the [MFIVs or FRVs] or associated bypass valves are closed they are performing their intended safety function; consequently, there is no need to place the plant in a MODE where the LCO is not applicable.

Therefore, the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS37 (continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not require physical alteration to any plant system or change the method by which any safety-related system performs its function. The [MFIVs, FRVs] and associated bypass valves would be in their accident mitigating position, thus fulfilling their required safety function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions, or results. Consequently, it does not have an effect on margins of safety. Therefore, the proposed change would have no significant adverse effect on margins of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS37" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS38
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change deletes the CTS ACTION "immediately suspend all operations involving ...positive reactivity changes..." associated with both CR ventilation trains being inoperable in MODES 5 and 6. The CR isolation on high radiation is designed for rapid isolation following an immediate release of radioactivity. CORE ALTERATIONS, positive reactivity additions via deboration and movement of irradiated fuel are processes that could lead to the release of radioactivity. However, CORE ALTERATIONS and movement of irradiated fuel are the only processes that could lead to an immediate release of radioactivity. Positive reactivity addition via deboration is a slow process and does not represent a potential for an immediate release of radioactivity. The deletion of this ACTION is consistent with NUREG-1431.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not result in any hardware changes or changes to operating methodologies. This change recognizes that since a positive reactivity addition via deboration is a slow change that the immediate suspension of such a positive reactivity change is beyond the basis of the LCO.

Therefore, the proposed changes do not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS38 (continued)

The proposed change does not require physical alteration to any plant system or change the method by which any safety-related system performs its function.

Therefore, the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change does not change any accident analysis assumptions, initial conditions, or results. Consequently, it does not have an effect on margins of safety. Therefore, the proposed change would have no significant adverse effect on margins of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS38" resulting from the conversion to the ISTS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC TR1 10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the CTS to allow the use of actual actuation signals for SRs that currently require testing using simulated test signals only. This change is consistent with NUREG-1431.

In several SRs in the CTS, operability of certain equipment is demonstrated by ensuring that the equipment performs its safety function upon receipt of a simulated test signal. The intent of a "simulated" signal was to be able to perform the required testing without the occurrence (or without causing) an actual signal generating event. However, the unintended effect was to require the performance of the SR (using a test signal) even if an actual signal had previously verified the operation of the equipment. This change allows credit to be taken for actual events when the required equipment actuates successfully.

While the occurrence of events that cause actuation of accident mitigation equipment is undesirable, the actuation of mitigation equipment on an actual signal is a better demonstration of its operability than an actuation using a test signal. Thus, the change does not reduce the reliability of the equipment tested. The change also improves unit safety by reducing the amount of time the equipment is taken out of service for testing, and thereby increasing its availability during an actual event, and by reducing the wear of the equipment caused by unnecessary testing.

This proposed TS change has been evaluated and it has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change allows the use of an actual actuation signal (when/if it occurs) to satisfy SRs currently requiring simulated test signals to demonstrate equipment operability. While the change credits events that may have occurred, it has no adverse effect on any accident initiators

V. RECURRING NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC TR1
(continued)

or accident consequences. In fact, by potentially reducing unnecessary testing, it may reduce the probability of an accident because the testing itself can increase the probability of an accident. It may also reduce accident consequences by increasing the equipment availability (i.e., less time in test).

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not involve a physical alteration of the unit (no new or different type of equipment will be installed) or changes in parameters governing normal unit operation.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The use of an actual actuation signal to satisfy a SR either has no impact on, or increases the margin of unit safety by:

- a) Increasing mitigation equipment availability, and,
- b) Improving mitigation equipment reliability by potentially reducing wear caused by unnecessary testing.

The change is consistent with the safety analysis and licensing basis.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Therefore, it is concluded that, based on the above safety evaluation, the activities associated with NSHC "TR1" satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

<p>B. Required Action and associated Completion Time not met.</p> <p><u>OR</u></p> <p>One or more steam generators with less than two MSSVs OPERABLE.</p>	<p>B.1 Be in MODE 3.</p> <p><u>AND</u></p> <p>B.2 Be in MODE 4.</p>	<p>6 hours</p> <p>12 hours</p> <p><u>B.</u></p>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>SR 3.7.1.1</p> <p>-----NOTE----- Only required to be performed in MODES 1 and 2. -----</p> <p>Verify each required MSSV lift setpoint per Table 3.7.1-2 in accordance with the Inservice Testing Program. Following testing, lift setting shall be within $\pm 1\%$.</p>	<p>In accordance with the Inservice Testing Program</p>

Table 3.7.1-1 (page 1 of 1)
 OPERABLE Main Steam Safety Valves versus
 Applicable ~~Maximum Allowable~~ Power in Percent of RATED THERMAL POWER

MINIMUM NUMBER OF OPERABLE MSSVs PER STEAM GENERATOR REQUIRED OPERABLE	MAXIMUM ALLOWABLE (RTP)
5	100
4	65 87
3	46 47
2	29 29

~~B=PS~~

3.7 PLANT SYSTEMS

3.7.2 Main Steam Isolation Valves (MSIVs)

LCO 3.7.2 ~~Four~~ MSIVs shall be OPERABLE.

B

APPLICABILITY: MODE 1,
MODES 2 and 3 except when all MSIVs are closed and ~~de-activated~~.

B

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One MSIV inoperable in MODE 1.	A.1 Restore MSIV to OPERABLE status.	8 hours <u>B</u>
B. Required Action and associated Completion Time of Condition A not met.	B.1 Be in MODE 2.	6 hours
C. -----NOTE----- Separate Condition entry is allowed for each MSIV. ----- One or more MSIVs inoperable in MODE 2 or 3.	C.1 Close MSIV. <u>AND</u> C.2 Verify MSIV is closed.	8 hours <u>B</u> Once per 7 days
D. Required Action and associated Completion Time of Condition C not met.	D.1 Be in MODE 3. <u>AND</u> D.2 Be in MODE 4.	6 hours 12 hours

(continued)

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>SR 3.7.2.1 -----NOTE----- Only required to be performed in MODES 1 and 2. ----- Verify closure time of each MSIV is \leq [4.6] seconds on an actual or simulated actuation signal.</p>	<p>B-PS B-PS 3.7-56 In accordance with the [Inservice Testing Program or 18 months]</p>
<p>SR 3.7.2.2 -----NOTE----- Only required to be performed in MODES 1 and 2. ----- Verify each MSIV actuates to the isolation position on an actual or simulated actuation signal.</p>	<p>3.7-56 18 months</p>

3.7 PLANT SYSTEMS

3.7.3 Main Feedwater Isolation Valves (MFIVs) and Main Feedwater Regulation Valves (MFRVs) and Associated Bypass Valves B

LCO 3.7.3 Four MFIVs, four MFRVs, and associated bypass valves shall be OPERABLE. B

APPLICABILITY: MODES 1, 2, and 3 except when MFIV, MFRV, or associated bypass valve is closed and deactivated or isolated by a closed manual valve. B

ACTIONS

-----NOTE-----
Separate Condition entry is allowed for each valve.

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more MFIVs inoperable.	A.1 Close or isolate MFIV. <u>AND</u> A.2 Verify MFIV is closed or isolated.	72 hours <u>B</u> Once per 7 days
B. One or more MFRVs inoperable.	B.1 Close or isolate MFRV. <u>AND</u> B.2 Verify MFRV is closed or isolated.	72 hours <u>B</u> Once per 7 days
C. One or more MFRV or preheater bypass valves inoperable.	C.1 Close or isolate bypass valve. <u>AND</u> C.2 Verify bypass valve is closed or isolated.	72 hours B-PS <u>B</u> Once per 7 days

CONDITION	REQUIRED ACTION	COMPLETION TIME
D. Two valves in the same flow path inoperable.	D.1 Isolate affected flow path.	8 hours
E. Required Action and associated Completion Time not met.	E.1 Be in MODE 3.	6 hours <u>B</u>
	E.2 Be in MODE 4.	12 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>SR 3.7.3.1 Verify the closure time of each MFIV is is 60 seconds. MFRV [and associated bypass valve] is is [7] seconds on an actual or simulated actuation signal.</p>	<p><u>3.7-3</u></p> <p>In accordance with the [Inservice Testing Program or [18] months] B-PS <u>3.7-56</u></p>
<p>SR 3.7.3.2 Verify the closure time of each MFRV and associated bypass valve is is 7 seconds.</p>	<p>At each COLD SHUTDOWN but not more frequently than once per 92 days <u>3.7-3</u></p>
<p>SR 3.7.3.3 Verify each MFIV actuates to the isolation position on an actual or simulated actuation signal.</p>	<p><u>18 months</u> <u>3.7-56</u></p>

3.7 PLANT SYSTEMS

3.7.4 ~~10%~~ Atmospheric Dump Valves (ADVs)

PS

LCO 3.7.4 ~~Three~~ ~~Four~~ ADV lines shall be OPERABLE.

B-PS

APPLICABILITY: MODES 1, 2, and 3,
MODE 4 when steam generator is relied upon for heat removal.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One required ADV line inoperable.	A.1 -----NOTE----- LCO 3.0.4 is not applicable. ----- Restore required ADV line to OPERABLE status.	7 days
B. Two or more required ADV lines inoperable.	B.1 Restore all but one ADV line to OPERABLE status.	24 72 hours <u>3.7-5</u> <u>3.7-6</u>
C. Three or more required ADV lines inoperable	C.1 Restore all but two ADV lines to OPERABLE status	24 hours <u>3.7-5</u> <u>3.7-6</u>
C D. Required Action and associated Completion Time not met.	C D. 1 Be in MODE 3. <u>AND</u> C D. 2 Be in MODE 4 without reliance upon steam generator for heat removal.	6 hours <u>3.7-6</u> 18 hours <u>B</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.7.4.1 Verify one complete cycle of each ADV.	18 months <u> B </u>
SR 3.7.4.2 Verify one complete cycle of each ADV block valve.	18 months <u> B </u>
SR 3.7.4.3 Verify that the backup air bottle for each ADV has a pressure ≥ 260 psig.	24 hours <u> 3.7-50 </u>

3.7 PLANT SYSTEMS

3.7.5 Auxiliary Feedwater (AFW) System

B

LCO 3.7.5 ~~Three~~ AFW trains shall be OPERABLE.

~~NOTE~~
~~Only one AFW train, which includes a motor driven pump, is required to be OPERABLE in MODE 4.~~

B

APPLICABILITY: MODES 1, 2, and 3,
 MODE 4 when steam generator is relied upon for heat removal.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One steam supply to turbine driven AFW pump inoperable.	A.1 Restore steam supply to OPERABLE status.	7 days <u>B</u> AND 10 days from discovery of failure to meet the LCO
B. One AFW train inoperable in MODE 1, 2 or 3 for reasons other than Condition A.	B.1 Restore AFW train to OPERABLE status.	72 hours <u>B</u> AND <u>B</u> 10 days from discovery of failure to meet the LCO

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>C. Required Action and associated Completion Time for Condition A or B not met.</p> <p><u>OR</u></p> <p>Two AFW trains inoperable in MODE 1, 2, or 3.</p>	<p>C.1 Be in MODE 3.</p> <p><u>AND</u></p> <p>C.2 Be in MODE 4.</p>	<p>6 hours</p> <p><u>B</u></p> <p><u>B</u></p> <p>18 hours</p>
<p>D. Three AFW trains inoperable in MODE 1, 2, or 3.</p>	<p>D.1 <u>NOTE</u></p> <p>LCO 3.0.3 and all other LCO Required Actions requiring MODE changes are suspended until one AFW train is restored to OPERABLE status.</p> <p>Initiate action to restore one AFW train to OPERABLE status.</p>	<p><u>B</u></p> <p><u>B</u></p> <p>Immediately</p>
<p>E. Required AFW train inoperable in MODE 4.</p>	<p>E.1 Initiate action to restore AFW train to OPERABLE status.</p>	<p>Immediately</p>
<p>F. With the GST flow path not open to the AFW pump suction.</p>	<p>F.1 Restore the GST flow path.</p>	<p>4 hours</p> <p><u>3.7-9</u></p>
<p>G. With the FWST flow path not capable of being aligned to the AFW pump suction.</p>	<p>G.1 Restore the capability of FWST alignment.</p>	<p>7 days</p> <p><u>3.7-9</u></p>

CONDITION	REQUIRED ACTION	COMPLETION TIME
Required Action and associated Completion Time for Condition F or G not met	H.1 Be in MODE 3	6 hours
	AND H.2 Be in MODE 4 without reliance upon steam generator for heat removal.	3-7-9 18 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.7.5.1 Verify each AFW manual, power operated, and automatic valve in each water flow path, [and in both steam supply flow paths to the steam turbine driven pump,] that is not locked, sealed, or otherwise secured in position, is in the correct position.	31 days <u>B</u>
SR 3.7.5.2 NOTE Not required to be performed for the turbine driven AFW pump until 24 hours after ≥ [1000] 650 psig in the steam generator Verify the developed head of each AFW pump at the flow test point is greater than or equal to the required developed head.	In accordance with the Inservice Test Program 3-7-29 <u>B</u> [31] days on a STAGGERED TEST BASIS <u>B-PS</u>
SR 3.7.5.3 NOTE Not applicable in MODE 4 when steam generator is relied upon for heat removal. Verify each AFW automatic valve that is not locked, sealed, or otherwise secured in position, actuates to the correct position on an actual or simulated actuation signal.	<u>B</u> 18 months

Surveillance Requirements (continued)

SURVEILLANCE	FREQUENCY
<p>SR 3.7.5.4</p> <p>-----NOTES-----</p> <p>1. Not required to be performed for the turbine driven AFW pump until 24 hours after \geq [1000] 650 psig in the steam generator.</p> <p>2. Not applicable in MODE 4 when generator is relied upon for heat removal.</p> <p>-----</p> <p>Verify each AFW pump starts automatically on an actual or simulated actuation signal.</p>	<p><u>B</u></p> <p><u>B-PS</u></p> <p>18 months <u>B</u></p>
<p>SR 3.7.5.5 Not Used</p> <p>Verify proper alignment of the required AFW flow paths by verifying flow from the condensate storage tank to each steam generator.</p>	<p><u>B-PS</u></p> <p>Prior to entering MODE 2, whenever unit has been in MODE 5 or 6 for > 30 days</p>
<p>SR 3.7.5.6 Verify the FWST is capable of being aligned to the AFW system by cycling each FWST valve in the flow path necessary for realignment through at least one full cycle.</p>	<p>92 days</p> <p><u>3.7-9</u></p>

3.7 PLANT SYSTEMS

3.7.6 Condensate Storage Tank (CST) and Fire Water Storage Tank (FWST)

3.7-10

LC0 3.7.6 The CST level shall be \geq ~~[110,000 gal]~~ 41.3% and the FWST level shall be \geq 22.2% for one unit operation and \geq 41.7% for two unit operation.

3.7-10

APPLICABILITY: MODES 1, 2, and 3,
MODE 4 when steam generator is relied upon for heat removal.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. CST level not within limit.	A.1 Verify by administrative means OPERABILITY of backup water supply. Restore CST level to within limit.	4 hours <u>AND</u> <u>3.7-10</u> Once per 12 hours thereafter
B. FWST level not within limit.	<u>AND</u> A.2B.1 Restore CST FWST level to within limit.	<u>3.7-10</u> 7 d ays
B.C. Required Action and associated Completion Time not met.	B.C.1 Be in MODE 3. <u>AND</u> B.C.2 Be in MODE 4, without reliance on steam generator for heat removal.	6 hours 18 hours <u>B.C.</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.6.1	Verify the CST level is \geq [110,000 gal] 41.3 %.	12 hours <u>3.7-10</u>
SR 3.7.6.2	Verify the FWST level is \geq 22.2 % for one unit operation and \geq 41.7 % for two unit operation.	12 hours <u>3.7-10</u>

3.7 PLANT SYSTEMS

3.7.7 ~~Vital~~ Component Cooling Water (CCW) System

PS

LCO 3.7.7 Two ~~vital~~ CCW trains ~~loops~~ shall be OPERABLE.

PS

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One vital CCW train loop inoperable.	A.1 -----NOTE----- Enter applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," for residual heat removal loops made inoperable by CCW. ----- Restore vital CCW train loop to OPERABLE status.	<u>PS</u> 72 hours
B. Required Action and associated Completion Time of Condition A not met.	B.1 Be in MODE 3. <u>AND</u> B.2 Be in MODE 5.	6 hours 36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>SR 3.7.7.1 -----NOTE----- Isolation of CCW flow to individual components does not render the CCW System inoperable -----</p> <p>Verify each CCW manual, power operated, and automatic valve in the flow path servicing safety related equipment, that is not locked, sealed, or otherwise secured in position, is in the correct position.</p>	<p>31 days</p>
<p>SR 3.7.7.2 Verify each CCW automatic valve in the flow path that is not locked, sealed, or otherwise secured in position, actuates to the correct position on an actual or simulated actuation signal.</p>	<p>18 months <u>B</u></p>
<p>SR 3.7.7.3 Verify each CCW pump starts automatically on an actual or simulated actuation signal.</p>	<p>18 months <u>B</u></p>

3.7 PLANT SYSTEMS

3.7.8 Service Water ~~Auxiliary Saltwater (ASW)~~ System (SWS)

PS

LCO 3.7.8 Two SWS ~~ASW~~ trains shall be OPERABLE.

PS

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>A. One SWS ASW train inoperable.</p>	<p>A.1 -----NOTES----- 1. Enter applicable Conditions and Required Actions of LCO 3.8.1, "AG Sources - Operating," for emergency diesel generator made inoperable by SWS.</p> <p>Enter applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," for residual heat removal loops made inoperable by SWS ASW.</p> <p>-----</p> <p>Restore SWS ASW train to OPERABLE status.</p>	<p><u>3.7-13</u></p> <p><u>PS</u></p> <p>72 hours</p>

Surveillance Requirements (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time of Condition A not met.	B.1 Be in MODE 3.	6 hours
	<u>AND</u> B.2 Be in MODE 5.	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>SR 3.7.8.1</p> <p style="text-align: center;"><u>NOTE</u></p> <p>Isolation of SWS flow to individual components does not render the SWS inoperable.</p> <p>Verify each SWS ASW manual- and power operated, and automatic valve in the flow path servicing safety related equipment, that is not locked, sealed, or otherwise secured in position, is in the correct position or that a motive force is available such that the valve would be capable of being placed in the correct position.</p>	<p>3.7-14</p> <p>PS</p> <p>31 days</p> <p>3.7-15</p>
<p>SR 3.7.8.2</p> <p>Verify each SWS automatic ASW power operated valve in the flow path that is not locked, sealed, or otherwise secured in position, actuates to can be moved to the correct position. on an actual or simulated actuation signal</p>	<p>18 months</p> <p>B-PS</p> <p>PS</p> <p>3.7-16</p> <p>In accordance with the Inservice Test Program.</p>
<p>SR 3.7.8.3</p> <p>Verify each SWS ASW pump starts automatically on an actual or simulated actuation signal.</p>	<p>18 months</p> <p>B</p> <p>PS</p>

3.7 PLANT SYSTEMS

3.7.9 Ultimate Heat Sink (UHS)

LCO 3.7.9 The UHS shall be OPERABLE

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more cooling towers with one cooling tower fan with the UHS inoperable	A.1 Restore cooling tower fan(s) to OPERABLE status. Place a second CCW heat exchanger in service	7 days 8 hours <u>B</u> <u>3.7-17</u>
B. Required Action and associated Completion Time of Condition A not met. <u>OR</u> UHS inoperable [for reasons other than Condition A].	B.1 Be in MODE 3. <u>AND</u> B.2 Be in MODE 5.	6 hours <u>B</u> 36 hours <u>3.7-17</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.7.9.1 NOT USED Verify water temperature level of UHS is $\leq 60^{\circ}\text{F}$ [] $> [562]$ ft [mean sea level]	[24] hours <u>3.7-17</u>
SR 3.7.9.2 If water temperature is $> 60^{\circ}\text{F}$ but $\leq 62^{\circ}\text{F}$ [] Verify average water temperature of UHS is $\leq [90]^{\circ}\text{F}$ within limits.	24 hours <u>B</u> if UHS temperature is $\leq 60^{\circ}\text{F}$ AND <u>B-PS</u> 12 hours if UHS temperature $> 60^{\circ}\text{F}$ but $\leq 62^{\circ}\text{F}$ AND 2 hours if UHS temperature $> 62^{\circ}\text{F}$ but $\leq 64^{\circ}\text{F}$ <u>3.7-17</u>
SR 3.7.9.3 Operate each cooling tower fan for $\geq [15]$ minutes.	31 days <u>B-PS</u>
SR 3.7.9.4 Verify each cooling tower fan starts automatically on an actual or simulated actuation signal.	18 months <u>B-PS</u>

3.7 PLANT SYSTEMS

3.7.10 Control Room Emergency Filtration ~~Ventilation~~ System (GREFS
CRVS)

PS

LCO 3.7.10 Two GREFS ~~CRVS~~ trains shall be OPERABLE.

PS

APPLICABILITY: MODES 1, 2, 3, 4, ~~5~~ and ~~6~~
During movement of irradiated fuel assemblies,
~~[During CORE ALTERATIONS].~~

B

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One GREFS CRVS train inoperable.	A.1 Restore GREFS CRVS train to OPERABLE status.	7 days <u>PS</u>
B. Required Action and associated Completion Time of Condition A not met in MODE 1, 2, 3, or 4.	B.1 Be in MODE 3. <u>AND</u> B.2 Be in MODE 5.	6 hours 36 hours
C. Required Action and associated Completion Time of Condition A not met in MODE 5 or 6 or during movement of irradiated fuel assemblies [or during CORE ALTERATIONS].	C.1 <u>NOTE</u> Place in toxic gas protection mode if automatic transfer to toxic gas protection mode is inoperable. Place OPERABLE GREFS CRVS train in emergency recirculation mode. <u>OR</u>	<u>B-PS</u> <u>B</u> Immediately <u>PS</u>

ACTIONS (continued)

CRVS
3.7.10

CONDITION	REQUIRED ACTION	COMPLETION TIME
C. (continued)	C.2.1 Suspend CORE ALTERATIONS	Immediately <u>B</u>
	AND C.2.2 Suspend movement of irradiated fuel assemblies.	Immediately <u>B</u>
D. Two GREFS CRVS trains inoperable for reasons other than Condition D in MODE 5 or 6, or during movement of irradiated fuel assemblies [or during CORE ALTERATIONS].	D.1 Suspend CORE ALTERATIONS	Immediately <u>B</u>
	AND D.2 Suspend movement of irradiated fuel assemblies.	Immediately <u>B-PS</u> <u>PS</u>
E. Two GREFS CRVS trains inoperable for reasons other than Condition D in MODE 1, 2, 3, or 4.	E.1 Enter LCO 3.0.3.	Immediately <u>PS</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.7.10.1 Operate each GREFS CRVS train for ≥ 10 continuous hours with the heaters operating or (for systems without heaters) ≥ 15 minutes].	31 days <u>B-PS</u> <u>PS</u>
SR 3.7.10.2 Perform required GREFS CRVS filter testing in accordance with the Ventilation Filter Testing Program (VFTP).	In accordance with VFTP <u>PS</u> <u>B</u>

3.7 PLANT SYSTEMS

3.7.11 Control Room Emergency Air Temperature Control System (CREATCS)

3.7-52

LCO 3.7.11 ~~Two CREATCS trains shall be OPERABLE. Not Used~~

APPLICABILITY: ~~MODES 1, 2, 3, 4, [5, and 6,]
During movement of irradiated fuel assemblies,
[During CORE ALTERATIONS].~~

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One CREATCS train inoperable.	A.1 Restore CREATCS train to OPERABLE status.	30 days
B. Required Action and associated Completion Time of Condition A not met in MODE 1, 2, 3, or 4.	B.1 Be in MODE 3. AND B.2 Be in MODE 5.	6 hours 36 hours
C. Required Action and associated Completion Time of Condition A not met [in MODE 5 or 6, or] during movement of irradiated fuel assemblies [, or during CORE ALTERATIONS].	C.1 Place OPERABLE CREATCS train in operation. OR [C.2.1] Suspend CORE ALTERATIONS. AND C.2.[2] Suspend movement of irradiated fuel assemblies.	Immediately Immediately Immediately
D. Two CREATCS trains inoperable [in MODE 5 or 6, or] during movement of irradiated fuel assemblies [, or during CORE ALTERATIONS].	D.1 Suspend CORE ALTERATIONS. AND D.[2] Suspend movement of irradiated fuel assemblies.	Immediately Immediately

ACTIONS (continued) CONDITION	REQUIRED ACTION	COMPLETION TIME
E. Two CREATCS trains inoperable in MODE 1, 2, 3, or 4.	E.1 Enter LCO 3.0.3.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.7.11.1 Verify each CREATCS train has the capability to remove the assumed heat load.	[18] months

3.7 PLANT SYSTEMS

3.7.12 ~~Emergency Core Cooling System (ECCS) Pump Room Exhaust
Air Cleanup System (PREACS) Auxiliary Building
Ventilation System (ABVS)~~ PS PS
PS

LCO 3.7.12 Two ~~ECCS PREACS~~ ABVS trains shall be OPERABLE.
PS

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. The common HEPA filter and/or charcoal adsorber inoperable.	A.1 Restore the common HEPA filter and charcoal adsorber to OPERABLE status.	24 hours 3.7-21
A B. One ECCS PREACS <u>ABVS</u> train inoperable.	A B.1 Restore ECCS PREACS <u>ABVS</u> train to OPERABLE status.	7 days <u>PS</u>
C. ECCS Pump Room Pressure not capable of being maintained \leq [0.125] inches water gauge in the [post accident] mode of operation.	C.1 Restore capability to maintain pressure in the penetration room within limit.	24 hours 3.7-23
B C. Required Action and associated Completion Time not met.	B C.1 Be in MODE 3. <u>AND</u> B C.2 Be in MODE 5.	6 hours 36 hours <u>B</u>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE		FREQUENCY
SR 3.7.12.1	Operate each EGCS PREACS ABVS train for ≥ 15 minutes, and one train for ≥ 10 continuous hours with the heaters operating or (for systems without heaters) ≥ 15 minutes].	31 days <u>PS</u> <u>3.7-21</u>
SR 3.7.12.2	Perform required EGCS PREACS ABVS filter testing in accordance with the Ventilation Filter Testing Program (VFETP).	In accordance with the VFETP <u>PS</u> <u>B</u>
SR 3.7.12.3	Verify each EGCS PREACS ABVS train actuates on an actual or simulated actuation signal and the system realigns to exhaust through the common HEPA filter and charcoal adsorber.	18 months <u>PS</u> <u>B</u> <u>3.7-22</u>
SR 3.7.12.4	NOT USED Verify one EGCS PREACS train can maintain a pressure $\leq [0.125]$ inches water gauge relative to atmospheric pressure during the [post accident] mode of operation at a flow rate of $\leq [3000]$ cfm.	[18] months on a STAGGERED TEST BASIS <u>3.7-23</u>
SR 3.7.12.5	NOT USED Verify each EGCS PREACS filter bypass damper can be closed.	[18] months <u>3.7-24</u>
SR 3.7.12.6	Verifying that leakage through the ABVS Dampers M2A and M2B is less than or equal to 5 cfm when subjected to a Constant Pressure or Pressure Decay Leak Rate Test in accordance with ASME N510-1989. The test pressure for the leak rate test shall be based on a maximum operating pressure as defined in ASME N510-1989, of 8 inches water gauge.	18 months <u>3.7-18</u> <u>PS</u>

3.7 PLANT SYSTEMS

3.7.13 Fuel Handling Building Air Cleanup Ventilation System (FBACS FHBVS) PS

LC0 3.7.13 Two FBACS FHBVS trains shall be OPERABLE. PS

APPLICABILITY: ~~[MODES 1, 2, 3, and 4.]~~
During movement of irradiated fuel assemblies in the fuel handling building. B-PS

NOTE
LC0 3.0.3 is not applicable

PS
3.7-42

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One FBACS FHBVS train inoperable.	A.1 Restore FBACS FHBVS train to OPERABLE status. <u>OR</u>	7 days <u>Immediately</u> <u>PS</u>
	A.2 Place the OPERABLE FHBV train in operation. <u>OR</u>	Immediately <u>3.7-43</u>

Methodology For Mark-up of NUREG-1431 Specifications

Enclosure 5A contains an electronic (or hand written) mark-up of NUREG-1431 Revision 1. The purpose of the mark-up is to identify those changes necessary to create a plant specific improved TS (by incorporating plant specific values in bracketed areas) and to identify any other changes with a cross-reference to a justification or explanation for the change. Descriptions/justifications for changes are contained in Enclosure 6A.

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS into a bracketed portion of NUREG-1431, Rev. 1.

The methodology of identifying the changes is:

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number or a change code in the adjacent right margin. A change code of "PS" indicates an obvious plant specific change and is usually reserved for plant specific names of systems and components.
- Editorial Changes- Changes/corrections which are obviously editorial are annotated using the red-line/strike-out feature of WordPerfect and identified by a change code of "Ed" in the adjacent margin. All such changes will be submitted for incorporation into the generic traveler for editorial changes.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct for this plant, the "generic" information is "struck-out" and the correct information inserted using the "red-line" feature. The brackets provided in NUREG-1431, Rev. 1 are deleted. "Red-line," "strike-out" and margin codes are as follows:
1. If the bracketed wording or parameter values remain unchanged, the bracketed information is "red-lined" and 'B' (for bracketed information) is used as the margin code.
 2. If the bracketed wording or parameter values are changed to the plant specific wording/values in the current specifications, the old bracketed information is "struck-out," the new information is "red-lined" and 'B-PS' (for plant specific bracketed information) is used as a margin code.

**Methodology For Mark-up of NUREG-1431 Specifications
(Continued)**

3. If the entire Condition, Action, or Surveillance is bracketed and is applicable, the letter/number designator for the item is red-lined. The text included within the brackets is not red-lined unless plant specific changes are made. The 'B' or 'B-PS' margin code is used depending on whether plant specific changes were made.

If the entirely bracketed Condition/Action/Surveillance is not applicable, the entire contents are "struck-out," red-lined words "Not Used" are inserted, and a 'B-PS' margin code is used.

Changes which have margin identifiers of letters instead of numbers (i.e., B, B-PS, Ed or PS) do not have descriptions/justifications in Enclosure 6A.

Note: All brackets are removed as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred.

In summary, in the non-bracketed portions of NUREG-1431, Rev. 1, "red-line" is used to annotate new material, "strike-out" is used to annotate deleted material, and change numbers or change codes are used in the right margin to identify these changes. All changes (i.e., "red-line" or "strike-out" items) have a change number or a change code.

Note: NUREG-1431, Rev. 1 is used for all mark-ups. Industry Travelers which are incorporated are indicated using the "red-lines," "strike-outs" and margin codes discussed above.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

BASES

BACKGROUND

The primary purpose of the MSSVs is to provide overpressure protection for the secondary system. The MSSVs also provide protection against overpressurizing the reactor coolant pressure boundary (RCPB) by providing a heat sink for the removal of energy from the Reactor Coolant System (RCS) if the preferred heat sink, provided by the Condenser and Circulating Water System, is not available.

Five MSSVs are located on each main steam header, outside containment, upstream of the main steam isolation valves, as described in the FSAR, Section [10.3.1] (Ref. 1). The MSSV capacity criteria is 110% of rated steam flow at must have sufficient capacity to limit the secondary system pressure to $\leq 110\%$ of the steam generator design pressure. This meets the requirements of the ASME Code, Section III (Ref. 2). The MSSV design includes staggered setpoints, according to Table 3.7.1-2 in the accompanying LCO, so that only the needed valves will actuate. Staggered setpoints reduce the potential for valve chattering that is due to steam pressure insufficient to fully open all valves following a turbine reactor trip during an overpressure event.

APPLICABLE
SAFETY ANALYSES

The design basis for the MSSVs comes from Reference 2 and its purpose is to limit the secondary system pressure to $\leq 110\%$ of design pressure when passing 100% of design steam flow. This design basis is sufficient to cope with for any anticipated operational occurrence (AOO) or accident considered in the Design Basis Accident (DBA) and transient analysis.

The events that challenge the relieving capacity of the MSSVs, and thus RCS pressure, are those characterized as decreased heat removal events, which are presented in the FSAR, Section [15.2] and [15.3] (Ref. 3). Of these, the full power turbine trip without steam dump is the limiting AOO with respect to secondary system pressure. This event also terminates normal feedwater flow to the steam generators.

The safety analysis demonstrates that the transient response for turbine trip occurring from full power without a direct reactor trip presents no hazard to the integrity of the RCS or the Main Steam System. If a minimum reactivity feedback is assumed, the reactor is tripped on high pressurizer pressure. In this case, the pressurizer safety valves open, and RCS pressure remains below 110% of the design value. The MSSVs also open to limit the secondary steam pressure.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

One turbine trip analysis is performed assuming primary system pressure control via operation of the pressurizer relief valves and sprays. The analysis demonstrates that the DNB design basis is met. Another analysis is performed assuming no primary system pressure control, but crediting reactor trip on high pressurizer pressure and operation of the pressurizer safety valves. This analysis demonstrates that the maximum RCS pressure does not exceed 110% of the design pressure. All cases analyzed demonstrate that the MSSVs maintain Main Steam System integrity by limiting the maximum steam pressure to less than 110% of the steam generator design pressure.

~~If maximum reactivity feedback is assumed, the reactor is tripped on overtemperature ΔT . The departure from nucleate boiling ratio increases throughout the transient, and never drops below its initial value. Pressurizer relief valves and MSSVs are activated and prevent overpressurization in the primary and secondary systems. The MSSVs are assumed to have two active and one passive failure modes. The active failure modes are spurious opening, and failure to reclose once opened. The passive failure mode is failure to open upon demand.~~

The MSSVs satisfy Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

The accident analysis requires ~~four~~ ~~that~~ ~~five~~ MSSVs per steam generator be OPERABLE to provide overpressure protection for design basis transients occurring at 102% RTP. An MSSV will be considered inoperable if it fails to open on demand. The LCO requires that ~~five~~ MSSVs per steam generator be OPERABLE in compliance with Reference 2, even though this is not a requirement of the DBA analysis. This is because operation with less than the full number of MSSVs requires limitations on allowable THERMAL POWER (to meet ASME Code requirements). These limitations are according to Table 3.7.1.1 in the accompanying LCO, and Required Action A.2.

The OPERABILITY of the MSSVs is defined as the ability to open upon demand within the setpoint tolerances, to relieve steam generator overpressure, and reseal when pressure has been reduced. The OPERABILITY of the MSSVs is determined/verified by periodic surveillance testing in accordance with the Inservice Testing Program.

This LCO provides assurance that the MSSVs will perform their designed safety functions to mitigate the consequences of accidents that could result in a challenge to the RCPB, or Main Steam System integrity.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

APPLICABILITY In MODE 1 above [40] % RTP, the number of MSSVs per steam generator required to be OPERABLE must be according to Table 3.7.1-1 in the accompanying LCO. Below [40%] in MODES 1, 2, and 3, only two [five] MSSVs per steam generator are required to be OPERABLE to limit secondary pressure.

In MODES 4 and 5, there are no credible transients requiring the MSSVs. The steam generators are not normally used for heat removal in MODES 5 and 6, and thus cannot be overpressurized; there is no requirement for the MSSVs to be OPERABLE in these MODES.

ACTIONS The ACTIONS table is modified by a Note indicating that separate Condition entry is allowed for each MSSV.

A.1 [and A.2]

With one or more MSSVs inoperable, reduce power action must be taken so that the available MSSV relieving capacity meets Reference 2 requirements for the applicable THERMAL POWER.

Continued operation with less than all [five] MSSVs OPERABLE for each steam generator is permissible, if THERMAL POWER is proportionally limited to the relief capacity of the remaining MSSVs. This is accomplished by restricting THERMAL POWER [and the Power Range Neutron Flux trip setpoint] so that the energy transfer to the most limiting steam generator is not greater than the available relief capacity in that steam generator. For example, if one MSSV is inoperable in one steam generator, the relief capacity of that steam generator is reduced by approximately 20%. To offset this reduction in relief capacity, energy transfer to that steam generator must be similarly reduced by at least 20%. This is accomplished by reducing THERMAL POWER by at least 20%, which conservatively limits the energy transfer to all steam generators to approximately 80% of total capacity, consistent with the relief capacity of the most limiting steam generator. If one MSSV is inoperable on a SG, calculation N-114 (Ref 8) demonstrates via RETRAN analysis that the secondary system pressure peak resulting from the limiting AOO is < 110% of design. The transient is terminated by a reactor trip, either high pressurizer pressure or OTDT, and the MSSVs maintain steam pressure below 110% at design

When a MSSV(s) is inoperable, the power must be reduced in 4 hours (required action A.1) to a value less than or equal to the value specified in table 3.7.1-1, corresponding to the number of OPERABLE MSSVs regardless of the value of the MTC.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

The Power Range Neutron Flux-high trip setpoint must also be reduced in 72 hours (Required by Action A-2), to less than or equal to the value specified in Table 3.7.1-1, corresponding to the number of OPERABLE MSSVs regardless of the value of the MIT. Required Action A-2 is modified by a Note. The Note indicates that the Power Range Neutron Flux-high trip setpoint reduction is only required in MODE 1. In MODE 1, a reduced Power Range Neutron Flux-high trip setpoint provides the required protection. In MODES 2 and 3, the reactor protection system trips specified in LCO 3.3.1, "Reactor Trip System Instrumentation" provide sufficient protection. Thus, reduction of the Power Range Neutron Flux-high trip setpoint is not necessary in MODE 2 or 3.

The algorithm and the RETRAN analysis used for References 7 and 9 are conservative since they both assume that the relief capacity is accordingly reduced on each SG and that the flow capacity for all inoperable MSSVs is that of the highest capacity valve.

The calculated power level is further reduced to account for instrument and channel and heat balance uncertainties and is the value specified as the MAXIMUM ALLOWABLE % RTP in Table 3.7.1-1. Per Reference 7, the calculated instrument and channel uncertainties for the power range neutron flux measurement requires a further reduction of 6% RTP to assure that the maximum RTP is not exceeded with inoperable MSSVs. Therefore, when reducing the Power Range Neutron Flux-high trip setpoint, the setpoint must be reduced to less than or equal to the % RTP value shown on Table 3.7.1-1.

The allowed Completion Times are reasonable base on operating experience to complete the Required Action(s) in an orderly manner without challenging unit systems.

For each steam generator, at a specified pressure, the fractional relief capacity (FRC) of each MSSV is determined as follows:

$$FRC = \frac{A}{B}$$

where:

A—the relief capacity of the MSSV; and

B—the total relief capacity of all the MSSVs of the steam generator.

The FRC is the relief capacity necessary to address operation with reduced THERMAL POWER.

The reduced THERMAL POWER levels in the LCO prevent operation at power levels greater than the relief capacity of the remaining MSSVs. The reduced THERMAL POWER is determined as follows:

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

$$RP = 1 - \frac{(N_1 \times FRC_1 + N_2 \times FRC_2 + \dots + N_5 \times FRC_5)}{5} \times 100\%$$

where:

~~RP~~ - Reduced THERMAL POWER for the most limiting steam generator expressed as a percent of RTP;

~~N₁, N₂, ..., N₅~~ represent the status of the MSSV 1, 2, ..., 5, respectively;

~~=0~~ if the MSSV is OPERABLE;

~~=1~~ if the MSSV is inoperable;

~~FRC₁, FRC₂, ..., FRC₅~~ - the relief capacity of the MSSV 1, 2, ..., 5, respectively, as defined above.

B.1 and B.2

If the MSSVs cannot be restored to OPERABLE status, THERMAL POWER for the Power Range Neutron Flux Trip is not reduced as required by Table 3.7-1 within the associated Completion Time, or if one or more steam generators have less than two MSSVs OPERABLE, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTSSR 3.7.1.1

This SR verifies the OPERABILITY of the MSSVs by the verification of each MSSV lift setpoint in accordance with the Inservice Testing Program. The ASME Code, Section XI (Ref. 4 5), requires that safety and relief valve tests be performed in accordance with ANSI/ASME OM-1-1987 (Ref. 5 6). According to Reference 5 6, the following tests are required:

- a. Visual examination;
- b. Seat tightness determination;
- c. Setpoint pressure determination (lift setting);
- d. Compliance with owner's seat tightness criteria; and
- e. Verification of the balancing device integrity on balanced valves.

B 3.7 PLANT SYSTEMS

B 3.7.1 Main Steam Safety Valves (MSSVs)

The ANSI/ASME Standard requires that all valves be tested every 5 years, and a minimum of 20% of the valves be tested every 24 months. The ASME Code specifies the activities and frequencies necessary to satisfy the requirements. Table 3.7.1-2 allows a $\pm 3\%$ setpoint (as found lift point) tolerance on the valves for OPERABILITY (with the exception of the lowest set MSSV setpoint which is $(+3\%/-2\%)$; however, the valves are reset to $+1\%$ during the surveillance to allow for drift. The lift settings, according to Table 3.7.1-2 in the accompanying LCO, correspond to ambient conditions of the valve at nominal operating temperature and pressure.

This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. The MSSVs may be either bench tested or tested in situ at hot conditions using an assist device to simulate lift pressure. If the MSSVs are not tested at hot conditions, the lift setting pressure shall be corrected to ambient conditions of the valve at operating temperature and pressure.

B 3.7 PLANT SYSTEMS

B 3.7.2 Main Steam Isolation Valves (MSIVs)

BASES

BACKGROUND

The MSIVs isolate steam flow from the secondary side of the steam generators following a high energy line break (HELB). MSIV closure terminates flow from the unaffected (intact) steam generators.

One MSIV is located in each main steam line outside, but close to, containment. The MSIVs are installed back to back with the MS reverse flow check valves. The MSIVs are downstream from the main steam safety valves (MSSVs) and auxiliary feedwater (AFW) pump turbine steam supply, to prevent MSSV and AFW isolation from the steam generators by MSIV closure. Closing the MSIVs isolates each steam generator from the others, and isolates the turbine, Steam Bypass System, and other auxiliary steam supplies from the steam generators.

The MSIVs close on a main steam isolation signal generated by either high negative steam line pressure rate or low steam line generator pressure or high-high containment pressure. The MSIVs are held in the open position and will fail in the closed direction on loss of control air or fail open on loss of actuation power.

Each MSIV has an MSIV bypass valve. Although these bypass valves are normally closed, they receive the same emergency closure signal as do their associated MSIVs. The MSIVs may also be actuated manually.

A description of the MSIVs is found in the FSAR, Section [10.3] (Ref. 1).

APPLICABLE
SAFETY ANALYSES

The design basis of the MSIVs is established by the containment analysis for the large steam line break (SLB) inside containment, discussed in the FSAR, Section [6.2] 6, Appendix 6.2 (Ref. 2). It is also affected by the accident analysis of the SLB events presented in the FSAR, Section [15.1.5] 15.4.2 (Ref. 3). The design precludes the blowdown of more than one steam generator, assuming a single active component failure (e.g., the failure of one MSIV to close on demand).

The limiting case for the containment pressure analysis is the SLB inside containment, with initial reactor power at 30% with a no loss of offsite power, following turbine trip, and failure of the MSIV on the affected steam generator to close. At lower powers, the steam generator inventory and temperature are

(continued)

BASES

at their maximum, maximizing the analyzed mass and energy release to the containment. Due to the assumed reverse flow (the MSIV reverse flow check valves are not credited to function even though they are Design Class I) and failure of the MSIV to close, the additional mass and energy in the steam headers downstream from the other MSIV contribute to the total release. With the most reactive rod cluster control assembly assumed stuck in the fully withdrawn position, there is an increased possibility that the core will become critical and return to power. The core is ultimately shut down by the boric acid injection delivered by the Emergency Core Cooling System.

The accident analysis compares several different SLB events against different acceptance criteria. The large SLB outside containment upstream of the MSIV is limiting for offsite dose, although a break in this short section of main steam header has a very low probability. The large SLB inside containment at hot zero power is the limiting case for a post trip return to power. The analysis includes scenarios with offsite power available, and with a loss of offsite power following turbine trip. With offsite power available, the reactor coolant pumps continue to circulate coolant through the steam generators, maximizing the Reactor Coolant System cooldown. With a loss of offsite power, the response of mitigating systems is delayed. Significant single failures considered include failure of an MSIV to close.

The MSIVs serve only a safety function and remain open during power operation. These valves operate under the following situations:

- a. An HELB inside containment. In order to maximize the mass and energy release into containment, the analysis assumes that the MSIV in the affected steam generator remains open. For this accident scenario, steam is assumed to be discharged into containment from all steam generators, as no credit is taken for the MSIV reverse flow check valves until the remaining MSIVs close. After MSIV closure, steam is discharged into containment only from the affected steam generator and from the residual steam in the main steam header downstream of the closed MSIVs in the unaffected loops. Closure of the MSIVs isolates the break from the unaffected steam generators.
- b. A break outside of containment and upstream from the MSIVs is not a containment pressurization concern. The uncontrolled blowdown of more than one steam generator must be prevented to limit the potential for uncontrolled RCS cooldown and positive reactivity addition. Closure of the MSIVs isolates the break and limits the blowdown to a single steam generator.

(continued)

BASES

- c. A break downstream of the MSIVs will be isolated by the closure of the MSIVs.
- d. Following a steam generator tube rupture, closure of the MSIVs isolates the ruptured steam generator from the intact steam generators to minimize radiological releases.
- e. The MSIVs are also utilized during other events such as a feedwater line break. This event is less limiting so far as MSIV OPERABILITY is concerned.

The MSIVs satisfy Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

This LCO requires that ~~four~~ MSIVs in the steam lines be OPERABLE. The MSIVs are considered OPERABLE when the isolation times are within limits, and they close on an isolation actuation signal.

This LCO provides assurance that the MSIVs will perform their design safety function to mitigate the consequences of accidents that could result in offsite exposures comparable to the 10 CFR 100 (Ref. 4) limits or the NRC staff approved licensing basis.

APPLICABILITY

The MSIVs must be OPERABLE in MODE 1, and in MODES 2 and 3 except when closed and de-activated (~~vented or prevented from opening~~), when there is significant mass and energy in the RCS and steam generators. When the MSIVs are closed, they are already performing the safety function.

~~In MODE 4, normally most of the MSIVs are closed, and the steam generator energy is low, thus OPERABILITY in MODE 4 is not required.~~

In MODE 5 or 6, the steam generators do not contain much energy because their temperature is below the boiling point of water; therefore, the MSIVs are not required for isolation of potential high energy secondary system pipe breaks in these MODES.

ACTIONS

A.1

With one MSIV inoperable in MODE 1, action must be taken to restore OPERABLE status within 8 hours. Some repairs to the MSIV can be made with the unit hot. The 8 hour Completion Time is reasonable, considering the low probability of an accident

(continued)

BASES

occurring during this time period that would require a closure of the MSIVs.

The 8 hour Completion Time is greater than that normally allowed for containment isolation valves because the MSIVs are valves that isolate a closed system penetrating containment. These valves differ from other containment isolation valves in that the closed system provides an additional means for containment isolation.

B.1

If the MSIV cannot be restored to OPERABLE status within 8 hours, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 2 within 6 hours and Condition C would be entered. The Completion Times are reasonable, based on operating experience, to reach MODE 2 and to close the MSIVs in an orderly manner and without challenging unit systems.

C.1 and C.2

Condition C is modified by a Note indicating that separate Condition entry is allowed for each MSIV.

Since the MSIVs are required to be OPERABLE in MODES 2 and 3, the inoperable MSIVs may either be restored to OPERABLE status or closed. When closed, the MSIVs are already in the position required by the assumptions in the safety analysis. MSIV closure is indicated by the control room valve indicating lights or monitor light box lights.

The 8 hour Completion Time is consistent with that allowed in Condition A.

For inoperable MSIVs that cannot be restored to OPERABLE status within the specified Completion Time, but are closed, the inoperable MSIVs must be verified on a periodic basis to be closed. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of MSIV status indications available in the control room, and other administrative controls, to ensure that these valves are in the closed position.

D.1 and D.2

If the MSIVs cannot be restored to OPERABLE status or are not closed within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed at least in MODE 3 within

(continued)

BASES

6 hours, and in MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from MODE 2 conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTSSR 3.7.2.1

This SR verifies that MSIV closure time is \leq [4-6] 5.0 seconds on an actual or simulated actuation signal. ~~The remote manual hand switch may be used as the actuation signal for this SR. The MSIV closure time is assumed in the accident and containment analyses. This Surveillance is normally performed upon returning the unit to operation following a refueling outage. The MSIVs should not be tested at power, since even a part stroke exercise increases the risk of a valve closure when the unit is generating power. As the MSIVs are not tested at power, they are exempt from the ASME Code, Section XI (Ref. 5), requirements during operation in MODE 1 or 2.~~

~~The Frequency is in accordance with the [Inservice Testing Program or [18] months]. The [18] month Frequency for valve closure time is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~

~~This test is may be conducted in MODE 3 with the unit at operating temperature and pressure, as discussed in Reference 5 exercising requirements. This SR is modified by a Note that allows entry into and operation in MODE 3 prior to performing the SR. This allows a delay of testing until MODE 3, to establish conditions consistent with those under which the acceptance criterion was generated. However, the test is normally conducted in MODE 5 as permitted by the cold shutdown frequency justification provided in the Inservice Testing Program (IST) and as permitted by Reference 6, Part 10, paragraph 4.2.1.2(c).~~

SR 3.7.2.2

~~This SR verifies that each MSIV can close on an actual or simulated actuation signal. This Surveillance is normally performed upon returning the plant to operation following a refueling outage. The frequency of MSIV testing is every 18 months. The 18 month Frequency is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.~~

B 3.7 PLANT SYSTEMS

B 3.7.3 Main Feedwater Isolation Valves (MFIVs) and Main Feedwater Regulation Valves (MFRVs) and Associated Bypass Valves

BASES

BACKGROUND

The safety related function of the MFRVs and the associated bypass valves is to provide the initial isolation of main feedwater (MFW) flow to the secondary side of the steam generators following a high energy line break (HELB). Since the MFRVs and associated bypass valves are located in non-safety related piping, the MFIVs also provide safety related isolation of the isolate main feedwater (MFW) flow to the secondary side of the steam generators following a high energy line break (HELB) a short time later. The safety related function of the MFRVs is to provide the second isolation of MFW flow to the secondary side of the steam generators following an HELB. Closure of the MFIVs and associated bypass valves or MFRVs and associated bypass valves terminates flow to the steam generators, terminating the event for feedwater line breaks (FWLBs) occurring upstream of the MFIVs or MFRVs. The consequences of events occurring in the main steam lines or in the MFW lines downstream from the MFIVs will be mitigated by their closure. Closure of the MFIVs and associated bypass valves, or MFRVs and associated bypass valves, effectively terminates the addition of feedwater to an affected steam generator, limiting the mass and energy release for steam line breaks (SLBs) or FWLBs inside containment, and reducing the cooldown effects for SLBs.

The MFIVs and associated bypass valves, or MFRVs and associated bypass valves, isolate the non-safety related portions from the safety related portions of the system. In the event of a secondary side pipe rupture inside containment, the valves limit the quantity of high energy fluid that enters containment through the break, and provide a pressure boundary for the controlled addition of auxiliary feedwater (AFW) to the intact loops.

One MFIV and associated bypass valve, and one MFRV and its associated bypass valve, are located on each MFW line, outside but close to containment. The MFIVs and MFRVs are located upstream of the AFW injection point so that AFW may be supplied to the steam generators following MFIV or MFRV closure. The piping volume from these valves to the steam generators must be accounted for in calculating mass and energy releases, and refilled prior to AFW reaching the steam generator following either an SLB or FWLB.

The MFIVs and associated bypass valves, and MFRVs and associated bypass valves, close on receipt of any safety injection (SI) signal a T - Low coincident with reactor trip (P-4) or steam generator (S76) water level-high high signal. They may also be actuated manually. The Main Feedwater Pump Turbine is also

(continued)

BASES

tripped upon receipt of an SI or S/G water level- high high signal (as well as other pump related trips), however these are Class II trips and are only credited as a backup to the single failure of a MFRV and associated bypass valve trip. The MFRVs and associated bypass valves also close on receipt of a T₁₀-Low coincident with reactor trip (P-4). In addition to the MFIVs and associated bypass valves, and the MFRVs and associated bypass valves, a check valve inside containment located upstream of the MFIV is available. The check valve isolates the feedwater line, penetrating containment, and ensures that the consequences of events do not exceed the capacity of the containment heat removal systems. Intact steam generators do not continue to feed the feedwater line break in the non-safety related piping upstream of the feedwater isolation check valves and that the AFW flow will be to the steam generators.

A description of the MFIVs and MFRVs is found in the FSAR, Section 10.4.7 (Ref. 1).

APPLICABLE
SAFETY ANALYSES

The design basis of the MFIVs and MFRVs is established by the analyses for the large SLB. It is also influenced by the accident analysis for the large FWLB. Closure of the MFIVs and associated bypass valves, or MFRVs and associated bypass valves, may also be relied on to terminate an SLB for core and containment response analysis and excess feedwater event upon the receipt of a steam generator water level- high high signal or a feedwater isolation signal on high-high steam generator level.

Failure of an MFIV, MFRV, or the associated bypass valves to close following an SLB or FWLB can result in additional mass and energy being delivered to the steam generators, contributing to cooldown. This failure also results in additional mass and energy releases following an SLB or FWLB event.

The MFIVs and MFRVs satisfy Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

This LCO ensures that the MFIVs, MFRVs, and their associated bypass valves will isolate MFW flow to the steam generators, following an FWLB or main steam line break. These MFIVs valves will also isolate the non-safety related portions from the safety related portions of the system.

This LCO requires that four MFIVs and associated bypass valves and four MFRVs and associated bypass valves be OPERABLE. The MFIVs and MFRVs and their associated bypass valves are considered OPERABLE when isolation times are

(continued)

BASES

within limits and they close on an isolation actuation signal.

Failure to meet the LCO requirements can result in additional mass and energy being released to containment following an SLB or FWLB inside containment. If a feedwater isolation signal on high steam generator level is relied on to terminate an excess feedwater flow event, and failure to meet the LCO may result in the introduction of water into the main steam lines.

APPLICABILITY

The MFIVs and MFRVs and the associated bypass valves must be OPERABLE whenever there is significant mass and energy in the Reactor Coolant System and steam generators. This ensures that, in the event of an HELB, a single failure cannot result in the blowdown of more than one steam generator. In MODES 1, 2, and 3, the MFIVs and MFRVs and the associated bypass valves are required to be OPERABLE to limit the amount of available fluid that could be added to containment in the case of a secondary system pipe break inside containment. When the valves are closed and de-activated or isolated by a closed manual valve, they are already performing their safety function.

In MODES 4, 5, and 6, steam generator energy is low. Therefore, the MFIVs, MFRVs, and the associated bypass valves are normally closed since MFW is not required.

ACTIONS

The ACTIONS table is modified by a Note indicating that separate Condition entry is allowed for each valve.

A.1 and A.2

With one MFIV in one or more flow paths inoperable, action must be taken to restore the affected valves to OPERABLE status, or to close or isolate inoperable affected valves within 72 hours. When these valves are closed or isolated, they are performing their required safety function.

The 72 hour Completion Time takes into account the redundancy afforded by the remaining OPERABLE valves and the Class II main feedwater pump trip and the low probability of an event occurring during this time period that would require isolation of the MFW flow paths. The 72 hour Completion Time is reasonable, based on operating experience.

Inoperable MFIVs that are closed or isolated must be verified on a periodic basis that they are closed or isolated. This is necessary to ensure that the assumptions in the safety analysis

(continued)

BASES

remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of valve status indications available in the control room, and other administrative controls, to ensure that these valves are closed or isolated.

B.1 and B.2

With one MFRV in one or more flow paths inoperable, action must be taken to restore the affected valves to OPERABLE status, or to close or isolate inoperable affected valves within 72 hours. When these valves are closed or isolated, they are performing their required safety function.

The 72 hour Completion Time takes into account the redundancy afforded by the remaining OPERABLE valves and the Class II main feedwater pump trip and the low probability of an event occurring during this time period that would require isolation of the MFW flow paths. The 72 hour Completion Time is reasonable, based on operating experience.

Inoperable MFRVs, that are closed or isolated, must be verified on a periodic basis that they are closed or isolated. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of valve status indications available in the control room, and other administrative controls to ensure that the valves are closed or isolated.

C.1 and C.2

With one associated bypass valve in one or more flow paths inoperable, action must be taken to restore the affected valves to OPERABLE status, or to close or isolate inoperable affected valves within 72 hours. When these valves are closed or isolated, they are performing their required safety function.

The 72 hour Completion Time takes into account the redundancy afforded by the remaining OPERABLE valves and the Class II main feedwater pump trip and the low probability of an event occurring during this time period that would require isolation of the MFW flow paths. The 72 hour Completion Time is reasonable, based on operating experience.

Inoperable associated bypass valves that are closed or isolated must be verified on a periodic basis that they are closed or isolated. This is necessary to ensure that the assumptions in the safety analysis remain valid. The 7 day Completion Time is reasonable, based on engineering judgment, in view of valve status indications available in the control room, and other

(continued)

BASES

administrative controls, to ensure that these valves are closed or isolated.

D.1

With two inoperable valves in the same flow path, there may be no redundant system only the Class III main feedwater pump trip is available to operate automatically and perform the required safety function. Although the containment can be isolated with the failure of two valves in parallel in the same flow path, the double failure can be an indication of a common mode failure in the valves of this flow path, and as such, is treated the same as a loss of the isolation capability of this flow path. Under these conditions, affected valves in each flow path must be restored to OPERABLE status, or the affected flow path isolated within 8 hours. This action returns the system to the condition where at least one valve in each flow path is performing the required safety function. The 8 hour Completion Time is reasonable, based on operating experience, to complete the actions required to close the MFIV or MFRV, or otherwise isolate the affected flow path.

E.1 and E.2

If the MFIV(s) and MFRV(s) and the associated bypass valve(s) cannot be restored to OPERABLE status, or closed, or isolated within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 12 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.7.3.1 and SR 3.7.3.2

This These SRs verifies that the closure time of each MFIV is ≤ 60 seconds and that each MFRV, and associated bypass valves is ≤ 7 seconds on an actual or simulated actuation signal. The MFIV and MFRV closure times are assumed in the accident and containment analyses. This These Surveillances is are normally performed upon returning the unit to operation following a refueling outage. These valves should not be tested at power since even a part stroke exercise increases the risk of a valve closure with the unit generating power. This is consistent with the ASME Code Section XI (Ref. 2) quarterly stroke requirements during operation in MODES 1 and 2.

The Frequency for this these SRs is in accordance with the / Inservice Testing Program or [18] months. The [18] month

BASES

~~Frequency for valve closure is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency.~~

SR 3.7.3.3

This SR verifies that each MFIV can close on an actual or simulated actuation signal. This Surveillance is normally performed upon returning the plant to operation following a refueling outage. The Frequency of MFIV testing is every 18 months. The 18 month Frequency is based on the refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.

B 3.7 PLANT SYSTEMS

B 3.7.4 ~~10%~~ Atmospheric Dump Valves (ADV)

BASES

BACKGROUND

The ~~10%~~ ADVs (PCV-19, PCV-20, PCV-21, and PCV-22) provide a method for cooling the unit to residual heat removal (RHR) entry conditions should the preferred heat sink via the Steam Bypass System to the condenser not be available, as discussed in the FSAR, Section ~~[10.3]~~ 15 (Ref 1). This is done in conjunction with the Auxiliary Feedwater System providing cooling water from the condensate storage tank (CST) and ~~firewater storage tank (FWST)~~. The ADVs may also be required to meet the design cooldown rate during a normal cooldown when steam pressure drops too low for maintenance of a vacuum in the condenser to permit use of the Steam Dump System.

One ADV line for each of the ~~four~~ steam generators is provided. Each ADV line consists of one ADV and an associated ~~manual~~ block valve.

The ADVs are provided with upstream ~~manual~~ block valves to permit their being tested at power, and to provide an alternate means of isolation. The ADVs are equipped with pneumatic controllers to permit control of the cooldown rate.

The ADVs are ~~usually normally~~ provided with a ~~non-Class I~~ pressurized gas supply of ~~bottled nitrogen air~~ that, ~~on~~ with a loss of pressure in the normal instrument air supply the backup ~~non-Class I nitrogen supply~~, automatically supplies nitrogen to operate the ADVs. With the loss of both the normal air supply and the backup nitrogen supply, the normal supplies are blocked and the Class I backup air bottle system is activated. With the backup air bottle system activated, control of the valves is remote manual via the Class I control circuit from the Control Room. The nitrogen bottled air supply is sized to provide the sufficient pressurized gas to operate the ADVs for the time required for Reactor Coolant System cooldown to RHR entry conditions. In addition, ~~handwheels are provided for local manual operation~~.

~~A description of the ADVs is found in Reference 1. The ADVs are OPERABLE with only a DC power source available. In addition, handwheels are provided for local manual operation.~~

APPLICABLE
SAFETY ANALYSES

The design basis of the ADVs is established by the capability to cool the unit to RHR entry conditions ~~at the maximum allowable~~. The design rate of ~~[75]~~ 100°F per hour is applicable for two steam generators, each with one ADV. This rate is adequate to cool the unit to RHR entry conditions with

(continued)

BASES

only one steam generator and one ADV. The ADVs support the AFW cooldown function from normal zero-load temperature in the RCS to a hot leg temperature of 350°F (which is the maximum temperature allowed for placing the RHR system in service). Various cooldown rates are applicable depending upon the event and the assumed available equipment. These rates vary from a high of 100°F/hr for the SGTR event to 25°F/hr for a natural circulation cooldown event utilizing the cooling water supply available in the CST and FWST.

In the accident analysis presented in Reference 1, The ADVs are assumed to be used by the operator to cool down the unit to RHR entry conditions for accident events accompanied by a loss of offsite power. Prior to operator actions to cool down the unit, the ADVs and main steam safety valves (MSSVs) are assumed to operate automatically to relieve steam and maintain the steam generator pressure below the design value. For the recovery from a steam generator tube rupture (SGTR) event, the operator is also required to perform a limited cooldown to establish adequate subcooling as a necessary step to terminate the primary to secondary break flow into the ruptured steam generator. The time required to terminate the primary to secondary break flow for an SGTR and thus limit offsite dose is more critical than the time required to cool down to RHR conditions for this event and also for other accident events. Thus, the SGTR is the limiting event for the ADVs. The number of all four ADVs are required to be OPERABLE to satisfy the SGTR accident analysis requirements depends upon the number of unit loops and consideration of any single failure assumptions regarding the failure of one ADV to open on demand since the SGTR event assumes that the ADV on the faulted SG fails open to maximize the offsite dose and that the three intact SGs are utilized to cool the RCS at the Maximum allowable rate of 100°F/hr.

The once per 24 hour verification that backup air bottle pressure is greater than or equal to 260 psig assures that the ADVs will perform as required by the applicable safety analyses.

The ADVs are equipped with manual block valves in the event an ADV spuriously fails to open or fails to close during use.

The ADVs satisfy Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

[Three] Four ADV lines are required to be OPERABLE. One ADV line is required from each of [three] four steam generators to ensure that at least one two ADV lines is available to conduct a unit cooldown following an SGTR, in which one steam generator becomes unavailable, accompanied by a single, active failure of an second ADV line on an unaffected steam generator. The block

(continued)

BASES

valves must be OPERABLE to isolate a the failed open ADV line. A closed block valve does not renders it or its ADV line inoperable; if operator action time to open the block valve is supported in the accident analysis and the appropriate ACTION must be entered until such time that the block valve is opened.

Failure to meet the LCO can result in the inability to cool the unit to RHR entry conditions following an event in which the condenser is unavailable for use with the Steam Bypass System.

An ADV is considered OPERABLE when it is capable of providing controlled relief of the main steam flow and capable of fully opening and closing on demand.

APPLICABILITY

In MODES 1, 2, and 3, all four ADVs are required to be OPERABLE and in MODE 4, when only the ADVs associated with the a steam generator is being relied upon for heat removal, the ADVs are required to be OPERABLE.

In MODE 5 or 6, an SGTR is not a credible event.

ACTIONS

A.1

With one required ADV line inoperable, action must be taken to restore OPERABLE status within 7 days. The 7 day Completion Time allows for the redundant capability afforded by the remaining OPERABLE ADV lines, a non-safety grade backup in the Steam Bypass System, and MSSVs and is based on a PRA analysis and the low probability of a SGTR and LOOP event occurring during this period that would require the ADV lines. Required Action A.1 is modified by a Note indicating that LCO 3.0.4 does not apply.

B.1

With two or more ADV lines inoperable, action must be taken to restore all but one ADV line to OPERABLE status. Since the block valve can be closed to isolate an ADV, some repairs may be possible with the unit at power. The 24 72 hour Completion Time is reasonable to repair inoperable ADV lines, based on the availability of the Steam Bypass System and MSSVs, and the low probability of an event occurring during this period that would require the ADV lines.

(continued)

BASES

C.1

With three or more ADV lines inoperable, action must be taken to restore all but two ADV lines to OPERABLE status. Since the block valve can be closed to isolate an ADV, some repairs may be possible with the unit at power. The 24 hour Completion Time is reasonable to repair inoperable ADV lines, based on the availability of the Steam Bypass System and MSSVs, and the low probability of an event occurring during this period that would require the ADV lines.

C.1.1 and C.1.2

If the ADV lines cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4, without reliance upon steam generator for heat removal, within ~~18~~ hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

Plant procedures provide a 31 day verification that the 10% ADV manual block valves are open assures that the valves have not been inadvertently closed.

SR 3.7.4.1

To perform a controlled cooldown of the RCS, the ADVs must be able to be opened and closed either remotely or locally and throttled through their full range using the remote manual controls and the backup air bottles. This SR ensures that the ADVs are tested through a full control cycle at least once per fuel cycle. Performance of inservice testing or use of an ADV during a unit cooldown may satisfy this requirement. Operating experience has shown that these components usually are expected to pass the Surveillance when performed at the 18 month Frequency. The Frequency is acceptable from a reliability standpoint.

SR 3.7.4.2

While not a safety function, the function of the manual block valve is to isolate a failed open ADV or isolate an ADV for repair or testing during plant operation. Cycling the block valve both closed and open demonstrates its capability to perform this function. Performance of inservice testing or use of the block valve during unit cooldown may satisfy this requirement.

BASES

Operating experience has shown that these components usually are expected to pass the Surveillance when performed at the [18] month Frequency. The Frequency is acceptable from a reliability standpoint.

SR 3.7.4.3

The function of the back-up air bottles is to assure that the ADVs will be able to be opened as required to perform a controlled cooldown of the RCS in the event of a loss of the normal air supply system. The backup air bottle system was specifically installed to allow the RCS to be cooled for a SGTR coincident with a loss of offsite power. Verification of the bottle pressure once every 24 hours allows for timely bottle replacement and trending for leaks.

B 3.7 PLANT SYSTEMS

B 3.7.5 Auxiliary Feedwater (AFW) System

BASES

BACKGROUND

The AFW System automatically supplies feedwater to the steam generators to remove decay heat from the Reactor Coolant System upon the loss of normal feedwater supply. The AFW pumps take normal suction through separate and independent valve MU-671 on the single suction lines from the condensate storage tank (CST) (LCO 3.7.6) (this valve must remain open for the applicable accident analysis assumptions to be valid) and are capable of being aligned to the firewater storage tank (FWST) (LCO 3.7.6) and pump to the steam generator secondary side via separate and independent connections to the main feedwater (MFW) piping outside containment. The steam generators function as a heat sink for core decay heat. The heat load is dissipated by releasing steam to the atmosphere from the steam generators via the main steam safety valves (MSSVs) (LCO 3.7.1) or atmospheric dump valves (LCO 3.7.4). If the main condenser is available, steam may be released via the condenser steam bypass dump valves and recirculated to the CST.

The AFW System consists of two motor driven AFW pumps and one steam turbine driven pump configured into three trains. Each motor driven pump provides 100% of AFW flow capacity, and the turbine driven pump provides 200% of the required capacity to the steam generators, with 100% capacity defined as the flow required to two steam generators during the AFW design basis accident analysis (loss of normal feedwater flow (Ref. 1) as assumed in the accident analysis). The pumps are equipped with independent recirculation lines to prevent pump operation against a closed system. Each motor driven AFW pump is powered from an independent Class 1E power supply and feeds two steam generators, although each pump has the capability to be manually realigned from the control room to feed other steam generators. The steam turbine driven AFW pump receives steam from two main steam lines upstream of the main steam isolation valves. Each of the steam feed lines will supply 100% of the requirements of the turbine driven AFW pump.

The AFW System is capable of supplying feedwater to the steam generators during normal unit startup, shutdown, and hot standby conditions.

The turbine driven AFW pump supplies a common header capable of feeding all steam generators with DG Vital AC powered control valves actuated to the appropriate steam generator by the Engineered Safety Feature Actuation System (ESFAS). One pump at full flow is sufficient to remove decay heat and cool the unit to residual heat removal (RHR) entry conditions. Thus, the

(continued)

BASES

requirement for diversity in motive power sources for the AFW System is met.

The AFW System is designed to supply sufficient water to the steam generator(s) to remove decay heat with steam generator pressure at the setpoint of the MSSVs. Subsequently, the AFW System supplies sufficient water to cool the unit to RHR entry conditions, with steam released through the ADVs.

~~The AFW System actuates automatically on steam generator water level low low by the ESFAS (LCO 3.3.2). The system also actuates on loss of offsite power, safety injection and by trip of all MFW pumps. The AFW System (both the one turbine-driven and two motor-driven AFW pumps) actuates automatically upon actuation of the anticipated transient without scram mitigating system actuation circuitry (AMSAC). The motor-driven pumps are additionally actuated by: (1) safety injection; (2) an associated bus transfer to the diesel generator signal; (3) a trip of both MFW pumps; or (4) steam generator water level low low in one of four SGs. The turbine-driven pump is additionally actuated by 12 KV bus undervoltage or steam generator low low level in two of four SGs via ESFAS (LCO 3.3.2).~~

The AFW System is discussed in the FSAR, Section [10.4.9] 6.5 (Ref. 1).

APPLICABLE
SAFETY ANALYSES

The AFW System mitigates the consequences of any event with loss of normal feedwater.

The design basis of the AFW System is to supply water to the steam generator to remove decay heat and other residual heat by delivering at least the minimum required flow rate to the at least two steam generators at pressures corresponding to the lowest steam generator safety valve set pressure plus 3% tolerance plus 3% accumulation within 1 minute after event initiation.

In addition, the AFW System must supply enough makeup water to replace steam generator secondary inventory lost as the unit cools to MODE 4 conditions. Sufficient AFW flow must also be available to account for flow losses such as pump recirculation and AFW spillage through feedwater line breaks.

The limiting Design Basis Accidents (DBAs) and transients for the AFW System are as follows:

- a. Feedwater or Main Steam Line Break (FWLB); and

(continued)

BASES

- b. Loss of MFW (the coincident loss of offsite power is a less limiting transient since RGP heat input is lost).

In addition, the minimum available AFW flow and system characteristics are serious considerations must be considered in the analysis of normal cooldown and of a small break loss of coolant accident (LOCA) due to their potential impact.

The AFW System is also designed for decay heat removal following a Steam Generator Tube Rupture (SGTR). As such the steam turbine driven AFW pump has redundant steam supplies to assure continued availability following a SGTR or MSIB event.

The AFW System design is such that it can perform its function following an FWLB between the MFW isolation valves and containment on loss of MFW, combined with a loss of offsite power following turbine trip, and a single active failure of the steam turbine driven AFW pump. In such a case, the ESFAS logic may not detect the affected steam generator if the backflow check valve to the affected MFW header worked properly. One motor driven AFW pump would deliver to the broken MFW header at the pump runout maximum flow until the problem was detected, and flow terminated by the operator. Sufficient flow would be delivered to the intact steam generator by the redundant AFW pump.

The ESFAS automatically actuates the AFW turbine driven pump and associated power operated valves and controls when required to ensure an adequate feedwater supply to the steam generators during loss of power. DC Vital AC power operated valves are provided for each AFW line to control the AFW flow to each steam generator.

The AFW System satisfies the requirements of Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

This LCO provides assurance that the AFW System will perform its design safety function to mitigate the consequences of accidents that could result in overpressurization of the reactor coolant pressure boundary. [Three] independent AFW pumps in [three] diverse trains are required to be OPERABLE to ensure the availability of RHR decay and residual heat removal capability for all events accompanied by a loss of offsite power and a single failure. This is accomplished by powering two of the pumps from independent emergency buses. The and having the third AFW pump is powered by a different means, a steam driven turbine supplied with steam from a source that is not isolated by closure of the MSIVs. To assure steam turbine driven AFW pump operability via redundant steam supplies, steam traps 104, 105 and 106 on the supply lines must be operable or bypassed to

(continued)

BASES

ensure adequate condensate removal and check valves MS-6166 and MS-6167 must be operable

The AFW System supply is configured into three trains. The AFW System is considered OPERABLE when the components and flow paths required to provide redundant AFW flow to the steam generators are OPERABLE. This requires that the two motor driven AFW pumps, each powered by a separated vital bus, be OPERABLE in two diverse paths, each supplying AFW to separate steam generators. The turbine driven AFW pump is required to be OPERABLE with redundant steam supplies from each of two main steam lines upstream of the MSIVs, and shall be capable of supplying AFW to any of the steam generators. The piping, valves, instrumentation, and controls in the required flow paths also are required to be OPERABLE.

The operability of the AFW suction flow path is assured by verifying the condensate storage tank outlet valve open and by verifying the capability to align the fire water storage tank to the AFW pump suction.

The LCO is modified by a Note indicating that one AFW train, which includes a motor driven pump, is required to be OPERABLE in MODE 4. This is because of the reduced heat removal requirements and short period of time in MODE 4 during which the AFW is required and the insufficient steam available in MODE 4 to power the turbine driven AFW pump.

APPLICABILITY

In MODES 1, 2, and 3, the AFW System is required to be OPERABLE in the event that it is called upon to function when the MFW is lost. In addition, the AFW System is required to supply enough makeup water to replace the steam generator secondary inventory, lost as the unit cools to MODE 4 conditions.

In MODE 4 the AFW System may be used for heat removal via the steam generators.

In MODE 5 or 6, the steam generators are not normally used for heat removal, and the AFW System is not required.

ACTIONS

A.1

If one of the two steam supplies to the turbine driven AFW train is inoperable, action must be taken to restore OPERABLE status within 7 days. The 7 day Completion Time is reasonable, based on the following reasons:

(continued)

BASES

- a. The redundant OPERABLE steam supply to the turbine driven AFW pump;
- b. The availability of redundant OPERABLE motor driven AFW pumps; and
- c. The low probability of an event occurring that requires the inoperable steam supply to the turbine driven AFW pump.

The second Completion Time for Required Action A.1 establishes a limit on the maximum time allowed for any combination of Conditions to be inoperable during any continuous failure to meet this LCO.

If Condition A, an inoperable steam supply to the turbine driven AFW pump, is entered while, for instance, motor driven AFW pump 1-2 is inoperable and the motor driven AFW pump 1-2 is subsequently returned to an OPERABLE condition shortly after Condition A is entered, the LCO may already have not been met for up to 72 hours. This could lead to a total of up to 10 days for restoration of the motor driven AFW pump 1-2 and the turbine driven AFW pump steam supply. If before the steam supply is returned OPERABLE motor driven AFW pump 1-3 becomes inoperable, the AFW system could be inoperable for as long as 13 days.

The 10 day Completion Time provides a limitation time allowed in this specified Condition after discovery of failure to meet the LCO. This limit is considered reasonable for situations in which Conditions A and B are entered concurrently. The AND connector between 7 days and 10 days dictates that both Completion Times apply simultaneously, and the more restrictive must be met.

B.1

With one of the required AFW trains (pump or flow path) inoperable in MODE 1, 2, or 3 for reasons other than Condition A, action must be taken to restore OPERABLE status within 72 hours. This Condition includes the loss of two steam supply lines to the turbine driven AFW pump. The 72 hour Completion Time is reasonable, based on redundant capabilities afforded by the AFW System, time needed for repairs, and the low probability of a DBA occurring during this time period.

The second Completion Time for Required Action B.1 establishes a limit on the maximum time allowed for any combination of Conditions to be inoperable during any continuous failure to meet this LCO.

The 10 day Completion Time provides a limitation time allowed in this specified Condition after discovery of failure to meet the

(continued)

BASES

LCO. This limit is considered reasonable for situations in which Conditions A and B are entered concurrently. The AND connector between 72 hours and 10 days dictates that both Completion Times apply simultaneously, and the more restrictive must be met.

C.1 and C.2

When Required Action A.1 or B.1 cannot be completed within the required Completion Time, or if two AFW trains are inoperable in MODE 1, 2, or 3, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 within 18 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

In MODE 4 with two AFW trains inoperable, operation is allowed to continue because only one motor driven pump AFW train is required in accordance with the Note that modifies the LCO. Although not required, the unit may continue to cool down and initiate RHR.

D.1

If all three AFW trains are inoperable in MODE 1, 2, or 3, the unit is in a seriously degraded condition with no safety related means for conducting a cooldown, and only limited means for conducting a cooldown with non-safety related equipment. In such a condition, the unit should not be perturbed by any action, including a power change, that might result in a trip. The seriousness of this condition requires that action be started immediately to restore one AFW train to OPERABLE status.

Required Action D.1 is modified by a Note indicating that all required MODE changes or power reductions are suspended until one AFW train is restored to OPERABLE status. In this case, LCO 3.0.3 is not applicable because it could force the unit into a less safe condition.

E.1

In MODE 4, either the reactor coolant pumps or the RHR loops can be used to provide forced circulation. This is addressed in LCO 3.4.6, "RCS Loops - MODE 4." With one required AFW train inoperable, action must be taken to immediately restore the

(continued)

BASES

inoperable train to OPERABLE status. The immediate Completion Time is consistent with LCO 3.4.6.

F.1

With the CST supply to the AFW pump suction unavailable, the primary safety related source of water required for cooldown is unavailable. The four hours required to restore the CST supply to the AFW pumps is a reasonable time to limit the risk from an event requiring the plant to cooldown.

G.1

With the FWST supply incapable of alignment to the AFW suction the required additional source of water needed for a natural circulation cooldown is unavailable. The seven days required to restore the ability for FWST realignment is a reasonable time to limit the risk from an event requiring a natural circulation cooldown based upon the available non-Class I AFW sources.

H.1 and H.2

When the Required Action F.1 or G.1 cannot be completed within the Required Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4 without reliance upon the steam generator for heat removal within 18 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.7.5.1

Verifying the correct alignment for manual, power operated, and automatic valves in the AFW System water and steam supply flow paths provides assurance that the proper flow paths will exist for AFW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since they are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulation; rather, it involves verification that those valves capable of being mispositioned are in the correct position.

(continued)

BASES

The 31 day Frequency ~~is~~ based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.

SR 3.7.5.2

Verifying that each AFW pump's developed head at the flow test point is greater than or equal to the required developed head ensures that AFW pump performance has not degraded during the cycle. Flow and differential head are normal tests of centrifugal pump performance required by ~~Section XI~~ of the ASME Code (Ref 2). Because it is undesirable to introduce cold AFW into the steam generators while they are operating, this testing is performed on recirculation flow. This test confirms one point on the pump design curve and is indicative of overall performance. Such inservice tests confirm component OPERABILITY, trend performance, and detect incipient failures by indicating abnormal performance. Performance of inservice testing discussed in the ASME Code, ~~Section XI~~ (Ref. 2) (only required at 3 month intervals) satisfies this requirement. ~~The [31] day Frequency on a STAGGERED TEST BASIS results in testing each pump once every 3 months, as required by Reference 2.~~

This SR is modified by a Note indicating that the SR ~~for the turbine-driven AFW pump~~ should be deferred until suitable test conditions are established. This deferral is required because there is insufficient steam pressure to perform the test.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)SR 3.7.5.3

This SR verifies that AFW can be delivered to the appropriate steam generator in the event of any accident or transient that generates an ESFAS, by demonstrating that each automatic valve in the flow path actuates to its correct position on an actual or simulated actuation signal. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. The 18 month Frequency is acceptable based on operating experience and the design reliability of the equipment.

This SR is modified by a Note that states the SR is not required in MODE 4 when the steam generator is being relied upon for heat removal. In MODE 4, the required AFW train may already be aligned and operating.

SR 3.7.5.4

This SR verifies that the AFW pumps will start in the event of any accident or transient that generates an ESFAS by demonstrating that each AFW pump starts automatically on an actual or simulated actuation signal in MODES 1, 2, and 3. In MODE 4, the required pump is already operating and the autostart function is not required. The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power.

This SR is modified by two Notes. Note 1 indicates that the SR for the turbine-driven pump can be deferred until suitable test conditions are established. This deferral is required because there is insufficient steam pressure to perform the test. [The] Note 2 states that the SR is not required in MODE 4. In MODE 4, the required motor-driven pump is already operating and the autostart function is not required. In MODE 4, the heat removal requirements would be less providing more time for operator action to manually start the required AFW pump.

. (continued)

BASES

SURVEILLANCE
REQUIREMENTS

~~SR 3.7.5.4 (continued)~~

~~Reviewer's Note: Some plants may not routinely use the AFW for heat removal in MODE 4. The second justification is provided for plants that use a startup feedwater pump rather than AFW for startup and shutdown.~~

~~SR 3.7.5.5 NOT USED~~

~~This SR verifies that the AFW is properly aligned by verifying the flow paths from the CST to each steam generator prior to entering MODE 2 after more than 30 days in MODE 5 or 6. OPERABILITY of AFW flow paths must be verified before sufficient core heat is generated that would require the operation of the AFW System during a subsequent shutdown. The Frequency is reasonable, based on engineering judgement and other administrative controls that ensure that flow paths remain OPERABLE. To further ensure AFW System alignment, flow path OPERABILITY is verified following extended outages to determine no misalignment of valves has occurred. This SR ensures that the flow path from the CST to the steam generators is properly aligned. (This SR is not required by those units that use AFW for normal startup and shutdown.)~~

~~SR 3.7.5.6~~

~~This SR verifies that the FWST is capable of being aligned to the AFW pump suction. This assures that this additional supply of required AFW is available from the seismically qualified FWST should it be needed for a natural circulation cooldown.~~

~~The 92 day Frequency, based on engineering judgement, is consistent with procedural controls governing valve operation, and ensures correct valve positions.~~

~~A similar SR is not required for the CST alignment since the AFW system is used for startup and an AFW pump is tested each month. This operation and the pump tests assure proper valve alignment.~~

B 3.7 PLANT SYSTEMS

B 3.7.6 Condensate Storage Tank (CST) and Feed Water Storage Tank (FWST)

BASES

BACKGROUND

The CST supplemented by the FWST provides a safety grade source of water to the steam generators for removing decay and sensible heat from the Reactor Coolant System (RCS). The CST and FWST provides a passive flow of water, by gravity, to the Auxiliary Feedwater (AFW) System (LCO 3.7.5). The steam produced is released to the atmosphere by the main steam safety valves or the atmospheric dump valves if the main steam isolation valves are closed. The AFW pumps operate with a continuous recirculation to the CST.

When the main steam isolation valves are open, the preferred means of heat removal is to discharge steam to the condenser by the nonsafety grade path of the steam-bypass condenser dump valves. The condensed steam is returned to the CST by the condensate transfer pumps. This has the advantage of conserving condensate while minimizing releases to the environment.

Because the CST and FWST are the principal components in for removing residual heat from the RCS, it is they are designed to withstand earthquakes and other natural phenomena, including missiles that might be generated by natural phenomena. The CST and FWST are designed to Seismic Category I to ensure availability of the feedwater supply. Feedwater is also available from alternate sources as described in the FSAR.

A description of the CST is found in the FSAR, Section 9.2.6 (Ref. 1).

APPLICABLE
SAFETY ANALYSES

The CST and FWST provides cooling water to remove decay heat and to cool down the unit following all events in the accident analysis as discussed in the FSAR, Chapters 6 and 15 (Refs. 2 and 3, respectively). For anticipated operational occurrences and accidents that do not affect the OPERABILITY of the steam generators, the analysis assumption is generally 30 minutes at MODE 3, steaming through the MSSVs, followed by a cooldown to residual heat removal (RHR) entry conditions at the design cooldown rate. The limiting event for AFW supply, i.e., CST and FWST minimum volumes, is based on a loss of offsite power which assumes a reduced Reactor Coolant System (RCS) cooldown rate and requires seismically qualified water sources. The lower RCS cooldown rate on natural circulation increases the cooldown period until the residual heat removal (RHR) system can be used to remove further decay heat. The extended cooldown time thus

(continued)

BASES

~~requires more AFW supply than can be provided by the seismically qualified portion of the CST~~

~~The limiting event for the~~ Other events requiring condensate volume is ~~are~~

- 1) ~~the large feedwater line break coincident with a loss of offsite power. Single failures that also affect this event include the following:~~
 - a. Failure of the diesel generator powering the motor driven AFW pump to the unaffected steam generator (requiring additional steam to drive the remaining AFW pump turbine); and
 - b. Failure of the steam driven AFW pump (requiring a longer time for cooldown using only one motor driven AFW pump).

These are not usually the limiting failures in terms of consequences for these events.

~~A nonlimiting event considered in CST inventory determinations is and:~~

- 2) ~~a break in either the main feedwater or AFW line near where the two join. This break has the potential for dumping condensate until terminated by operator action, since the Emergency Feedwater Actuation System would not detect a difference in pressure between the steam generators for this break location. This loss of condensate inventory is partially compensated for by the retention of steam generator inventory.~~

The CST satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

To satisfy ~~accident Hosgr~~ analysis assumptions, the CST and FWST must contain sufficient cooling water to remove decay heat for ~~[30-60 minutes]~~ following a reactor trip from 102% RTP, and then to cool down the RCS to RHR entry conditions, assuming a coincident loss of offsite power and the most adverse single failure. In doing this, it must retain sufficient water to ensure adequate net positive suction head for the AFW pumps during cooldown, as well as account for any losses from the steam driven AFW pump turbine, ~~or before isolating AFW to a broken line.~~

The CST level required is equivalent to a usable volume of ~~> [110,000 gallons]~~ 41.3% indicated level (164,678 gallons), which is ~~The FWST level required is equivalent to a usable volume~~

(continued)

BASES

of $\geq 41.75\%$ indicated level (115,844 gallons) for two units operating and $\geq 22.2\%$ indicated level (57,922 gallons) for one unit operating. These levels are based on holding the unit in MODE 3 for 2 hours, followed by a natural circulation cooldown to RHR entry conditions at $[75] 25^\circ\text{F}/\text{hour}$. This basis is established in Reference 4 and exceeds the volume required by the accident analysis.

The OPERABILITY of the CST and FWST is determined by maintaining the tank levels at or above the minimum required levels.

APPLICABILITY

In MODES 1, 2, and 3, and in MODE 4, when steam generator is being relied upon for heat removal, the CST is and FWST are required to be OPERABLE.

In MODE 5 or 6, the CST is or FWST are not required because the AFW System is not required.

ACTIONS

A.1 and B.1

If the CST level is not within limits, the OPERABILITY of the backup supply should be verified by administrative means within 4 hours and once every 12 hours thereafter. OPERABILITY of the backup feedwater supply must include verification that the flow paths from the backup water supply to the AFW pumps are OPERABLE, and that the backup supply has the required volume of water available. The CST must be restored to OPERABLE status within 7 days, because the backup supply may be performing this function in addition to its normal functions. The 4 hour Completion Time is reasonable, based on operating experience, to verify the OPERABILITY of the backup water supply. The 7 day Completion Time is reasonable, based on an OPERABLE backup water supply being available, and the low probability of an event occurring during this time period requiring the CST. If the CST or FWST levels are not within limits, the CST level must be restored within 4 hours and the FWST level must be restored within 7 days to return the AFW sources to an OPERABLE status. The CST must be restored to OPERABLE status within 4 hours because it is the primary Class 1 AFW supply. The 4 hour Completion Time provides time to restore the required CST level from the condenser or other source, and is a reasonable time to limit the risk from accidents or events requiring the plant to cooldown. The 7 day Completion Time provides time to restore the required FWST level is a reasonable time to limit the risk of a natural circulation cooldown event that would require the use of the backup volume in addition to the volume contained in the CST. Alternate non-

(continued)

BASES (continued)

seismically qualified water sources are also available to supply water to supplement the CST volume.

C.1 and C.2

If the CST or FWST cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 4, without reliance on the steam generator for heat removal, within 18 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTSSR 3.7.6.1

This SR verifies that the CST contains the required volume of cooling water. ~~(The required CST volume may be single value or a function of RCS conditions.)~~ The 12 hour Frequency is based on operating experience and the need for operator awareness of unit evolutions that may affect the CST inventory between checks. Also, the 12 hour Frequency is considered adequate in view of other indications in the control room, including alarms, to alert the operator to abnormal deviations in the CST levels.

SR 3.7.6.2

This SR verifies that the FWST contains the required volume of cooling water. The 12 hour Frequency is based on operating experience and the need for operator awareness of unit evolutions that may affect the FWST inventory between checks. Also, the 12 hour Frequency is considered adequate in view of other indications in the control room, including alarms, to alert the operator to abnormal deviations in the FWST levels.

B 3.7 PLANT SYSTEMS

B 3.7.7 ~~Vital~~ Component Cooling Water (CCW) System

BASES

BACKGROUND

The CCW System provides a heat sink for the removal of process and operating heat from safety related components during a Design Basis Accident (DBA) or transient. During normal operation, the CCW System also provides this function for various nonessential components, as well as the spent fuel storage pool. The CCW System serves as a barrier to the release of radioactive byproducts between potentially radioactive systems and the Service Water Auxiliary Saltwater (ASW) System, and thus to the environment.

~~A typical CCW System is arranged as two independent, full capacity cooling loops, and has isolatable nonsafety related components. Each safety related train includes a full capacity pump, surge tank, heat exchanger, piping, valves, and instrumentation. Each safety related train is powered from a separate bus. The CCW system consists of three CCW pumps powered by separate vital buses, two CCW heat exchangers, and an internally baffled two chamber CCW surge tank. The piping system consists of three parallel loops headered out of the two parallel 100% capacity heat exchangers. Two loops are separable redundant full capacity vital service loops which serve only ESF equipment and the non-redundant post-LOCA sample cooler. The vital loops are separable to mitigate a single passive failure during post-LOCA long term cooling. A third miscellaneous service loop serves nonvital equipment. The divided surge tank is connected to the vital header return piping and is sized to meet system leakage requirements and maintain adequate NPSH on system pumps.~~

~~The CCW system is hydraulically balanced to ensure that sufficient cooling water is delivered to ESF loads on the vital loops during a DBA.~~

~~The CCW system is designed to perform its function with a single failure of any component. An open surge tank in the system provides pump trip protective functions to ensure that sufficient net positive suction head is available. The All three pumps are in each train is automatically started on receipt of a safety injection signal, and all nonessential components are isolated. the miscellaneous service loop is automatically isolated on hi-hi containment pressure.~~

Additional information on the design and operation of the system, along with a list of the components served, is presented in the FSAR, Section 9.2.2 (Ref. 1). The principal safety related function of the CCW System is the removal of accident generated containment heat via the containment fan cooling units (CFCUs).

(continued)

BASES

and removal of decay heat from the reactor via the Residual Heat Removal (RHR) System. This Decay heat removal may be during a normal or post accident cooldown and shutdown.

APPLICABLE
SAFETY ANALYSES

The design basis of the CCW System is for one CCW train loop to remove the post loss of coolant accident (LOCA) DBA heat load from the containment sump during the recirculation phase, without exceeding the design basis continuous a maximum CCW temperature of [120]°F (Ref. 2). The Emergency Core Cooling System (ECCS) LOCA and containment OPERABILITY LOCA each model the maximum and minimum performance of the CCW System, respectively. The normal temperature of the CCW is [80]°F, and, during unit cooldown to MODE 5 ($T_{\text{cold}} < [200]^\circ\text{F}$), a maximum temperature of 95°F is assumed. This prevents the containment sump fluid from increasing in temperature during the recirculation phase following a LOCA, and provides a gradual reduction in the temperature of this fluid as it is supplied to the Reactor Coolant System (RCS) by the ECCS pumps, 132°F and not to exceed 120°F with an allowable transient not to exceed 140°F for more than 6 hours (Ref. 1).

In accordance with GDC 44, the CCW system is designed to provide sufficient heat removal for normal and post accident ESF heat loads without overheating. The CCW system and ASW system are essentially considered a single heat removal system for the purpose of assessing the ability to sustain either a single active or passive failure and still perform design basis heat removal. Only one ASW pump and one CCW heat exchanger is required, as assumed in the safety analysis, to provide sufficient heat removal from containment to mitigate a DBA. However, to ensure maximum heat removal capability, operators are instructed to place the second CCW heat exchanger in service early in the emergency operating procedures.

The CCW System also functions to cool the unit from RHR entry conditions ($T_{\text{coldave}} < 350^\circ\text{F}$), to MODE 5 ($T_{\text{coldave}} < 200^\circ\text{F}$), during normal and post accident operations. The time required to cool from 350°F to 200°F is a function of the number of CCW heat exchangers and RHR trains heat exchangers operating. One CCW train exchanger is sufficient to remove decay heat during subsequent operations with $T_{\text{cold}} < [200]^\circ\text{F}$. This assumes a maximum service water temperature of [95]°F occurring simultaneously with the maximum heat loads on the system.

In the event that CCW system leakage occurs and system makeup is not available, the surge tank volume provides a minimum of 20 minutes, based on a non-mechanistic leakage rate of 200 gpm, for operators to locate and isolate the leak or realign the CCW

(continued)

BASES

system into two separate loops before the system becomes impaired due to water loss.

The CCW System satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

In the event of a DBA, one CCW loop is required to provide the minimum heat removal capability assumed in the safety analysis for the systems to which it supplies cooling water. To ensure this requirement is met, two vital loops of CCW must be OPERABLE. At least one CCW loop will operate assuming the worst case single active failure occurs coincident with a loss of offsite power. To meet the LCO on Component Cooling Water loops, vital headers A and B, both CCW heat exchangers, the surge tank, and all three CCW pumps must be operable.

A vital CCW loop is considered OPERABLE when:

- a. Two CCW pumps, one CCW heat exchanger, and the surge tank are OPERABLE; and
- b. The associated piping, valves, heat exchanger, and instrumentation and controls required to perform the safety related function are OPERABLE.

The isolation of CCW from other components or systems not required for safety may render those components or systems inoperable but does not affect the OPERABILITY of the CCW System except for isolation of CCW to the CFCUS. Isolation of CCW to the CFCUS could potentially affect the flow balance and requires evaluation to ensure continued operability.

Split loop alignment of the CCW system during normal operation requires Condition A to be entered because the CCW system cannot tolerate a single failure in this configuration.

In MODES 1, 2, 3, and 4, the CCW System is a normally operating system, which must be prepared to perform its principal safety related function of removal of accident generated containment heat via the CFCUS and removal of decay heat from the reactor via the Residual Heat Removal (RHR) System.

In MODE 5 or 6, the OPERABILITY requirements of the CCW System are determined by the systems it supports.

(continued)

BASES

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating that the applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops - MODE 4," be entered if an inoperable vital CCW train loop results in an inoperable RHR loop. This is an exception to LCO 3.0.6 and ensures the proper actions are taken for these components.

If one vital CCW train loop is inoperable, action must be taken to restore two vital CCW loops to OPERABLE status within 72 hours. In this Condition, the remaining OPERABLE vital CCW train loop is adequate to perform the heat removal function. The 72 hour Completion Time is reasonable, based on the redundant capabilities afforded by the OPERABLE train overall heat transfer capability of ultimate heat sink system, operator action, and the low probability of a DBA occurring during this period.

Split loop alignment of the CCW system during normal operation requires Condition A to be entered because the CCW system cannot tolerate a single failure in this configuration.

B.1 and B.2

If the vital CCW train loop cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.7.7.1

This SR is modified by a Note indicating that the isolation of the CCW flow to individual components may render those components inoperable but does not affect the OPERABILITY of the CCW System. A possible exception to this note is isolation of CCW to the CFCUs. Isolation of CCW to the CFCUs could potentially affect the flow balance and requires evaluation to ensure continued operability.

Verifying the correct alignment for manual, power operated, and automatic valves in the CCW flow path provides assurance that the

(continued)

proper flow paths exist for CCW operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since these valves are verified to be in the correct position prior to locking, sealing, or securing. This SR also does not apply to valves that cannot be inadvertently misaligned, such as check valves. This Surveillance does not require any testing or valve manipulation; rather, it involves verification that those valves capable of being mispositioned are in the correct position.

The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.

SR 3.7.7.2

This SR verifies proper automatic operation of the CCW valves on an actual or simulated actuation signal. The CCW System is a normally operating system that cannot be fully actuated as part of routine testing during normal operation. This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. Operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.

SR 3.7.7.3

This SR verifies proper automatic operation of the CCW pumps on an actual or simulated ~~safety related~~ actuation signal. ~~The CCW System is a normally operating system that cannot be fully actuated as part of routine testing during normal operation.~~ The 18 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. ~~This surveillance requirement applies to the SIS auto-start and the 4KV auto-transfer automatic starts only.~~ Operating experience has shown that these components usually pass the Surveillance when performed at the 18 month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.

BASES

B 3.7 PLANT SYSTEMS

B 3.7.8 Service Water Auxiliary Saltwater System (SWS) (ASW)

BASES

BACKGROUND

The SWS ASW provides a heat sink from the Pacific Ocean for the removal of process and operating heat from safety related components via the component cooling water (CCW) system during all modes of operation including a Design Basis Accident (DBA) or transient. During normal operation, and a normal shutdown, the SWS ASW also provides this function for various safety related and non-safety related components. The safety related function is covered by this LCO.

The SWS ASW consists of two separate, 100% capacity, safety related, cooling water trains. Each train consists of two one 100% capacity pump, one component cooling water (CCW) heat exchanger, piping, valving, and instrumentation, and two cyclone separators. The pumps and valves are remote and manually aligned, except in the unlikely event of a loss of coolant accident (LOCA). The pumps aligned to the critical loops are automatically started upon receipt of a safety injection signal or 4KV automatic transfer, and all essential valves are aligned to their post accident positions. The SWS also provides emergency makeup to the spent fuel pool and CCW System [and is the backup water supply to the Auxiliary Feedwater System]. Normal configuration is for one train operation with the second pump cross-tied in stand-by and the second heat exchanger valved out-of-service except when the UHS temperature is 64°F or higher therefore no valve realignment occurs with a safety injection signal. Manual and remote manual system realignment provides for utilization of the second CCW heat exchanger, for use of the standby pump on the same unit, for cross-tying the standby ASW pump from opposite unit, and for train separation for long term cooling. The ASW unit cross-tie valve (FCV-601) allows one ASW pump on one unit to supply the CCW heat exchanger(s) on the other unit. FCV-601 is controlled by ECG 17.1.

Additional information about the design and operation of the SWS ASW system, along with a list of the components served, is presented in the FSAR, Section [9-2-1] 9-2-7 (Ref. 1). The principal safety related function of the SWS ASW system is the removal of decay heat from the reactor via the vital CCW System.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES

The design basis of the SWS ASW system is for one SWS ASW train, in conjunction with the CCW System and a 100% capacity the containment cooling systems, to remove accident generated and core decay heat following a design basis LOCA as discussed in the FSAR, Section [6.2] (Ref. 2). This prevents the containment sump fluid from increasing in temperature during the recirculation phase following a LOCA and provides for a gradual reduction in the temperature of this fluid as it is supplied to the Reactor Coolant System by the ECCS pumps. The ASW system can be re-configured to maintain the CCW temperature to within its design bases limits. The SWS ASW system is designed to perform its function with a single failure of any active component, assuming with or without the loss of offsite power. This assumes a maximum SWS ASW temperature of [95] 64°F occurring simultaneously with maximum heat loads on the system.

The SWS ASW system, in conjunction with the CCW System, also cools the unit from residual heat removal (RHR), as discussed in the FSAR, Section [5.4.7], (Ref. 3) entry conditions to MODE 5 during normal and post accident operations. The time required for this evolution is a function of the number of ASW pumps, CCW heat exchangers, and RHR System trains/heat exchangers that are operating. One SWS train is sufficient to remove decay heat during subsequent operations in MODES 5 and 6.

The SWS ASW system satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

Two SWS ASW trains are required to be OPERABLE to provide the required redundancy to ensure that the system functions to remove post accident heat loads, assuming that the worst case single active failure occurs coincident with the loss of offsite power.

An SWS ASW train is considered OPERABLE during MODES 1, 2, 3, and 4 when:

- a. The pump is OPERABLE; and
- b. The associated piping, valves, heat exchanger, and instrumentation and controls required to perform the safety related function are OPERABLE capable of performing their intended safety functions. The standby cross-tied ASW pump discharge (via FCV 495 and 496) provides redundancy for the operating ASW pump. The standby heat exchanger, valved out for operating convenience, is available to provide additional heat removal capability by valving in the second heat exchanger. Valving is provided to permit train

(continued)

BASES

separation during the long term cooling phase of a LOCA should a single passive failure occur.

APPLICABILITY

In MODES 1, 2, 3, and 4, the SWS ASW system is a normally operating system that is required to support the OPERABILITY of the equipment serviced by the SWS ASW system and required to be OPERABLE in these MODES.

In MODES 5 and 6, the OPERABILITY requirements of the SWS ASW system are determined by the systems it supports.

ACTIONS

A.1

If one SWS ASW train is inoperable, action must be taken to restore OPERABLE status within 72 hours. In this Condition, the remaining OPERABLE SWS ASW train is adequate to perform the heat removal function. However, the overall reliability is reduced because a single failure in the OPERABLE SWS ASW train could result in loss of SWS ASW system function. Required Action A.1 is modified by two Notes. The first Note indicates that the applicable Conditions and Required Actions of LCO 3.8.1, "AC Sources Operating," should be entered if an inoperable SWS train results in an inoperable emergency diesel generator. The second Note indicates that the applicable Conditions and Required Actions of LCO 3.4.6, "RCS Loops—MODE 4," should be entered if an inoperable SWS ASW train results in an inoperable decay heat removal train. This is an exception to LCO 3.0.6 and ensures the proper actions are taken for these components. The 72 hour Completion Time is based on the redundant capabilities afforded by the OPERABLE train, and the low probability of a DBA occurring during this time period.

B.1 and B.2

If the SWS ASW train cannot be restored to OPERABLE status within the associated Completion Times, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours.

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

BASES

SURVEILLANCE
REQUIREMENTSSR 3.7.8.1

~~This SR is modified by a Note indicating that the isolation of the SWS components or systems may render those components inoperable, but does not affect the OPERABILITY of the SWS.~~

Verifying the correct alignment for manual, and power operated, and automatic valves in the SWS ASW system flow path provides assurance that the proper flow paths exist for SWS ASW system operation. This SR does not apply to valves that are locked, sealed, or otherwise secured in position, since they are verified to be in the correct position prior to being locked, sealed, or secured. This SR does not require any testing or valve manipulation; rather, it involves verification that those valves capable of being mispositioned are in the correct position and that those valves requiring remote positioning have available power and air supplies such that if required, the valve would be capable of being placed in its required position. This SR does not apply to valves that cannot be inadvertently misaligned, such as check valves.

The 31 day Frequency is based on engineering judgment, is consistent with the procedural controls governing valve operation, and ensures correct valve positions.

SR 3.7.8.2

This SR verifies proper automatic remote manual full stroke operation of the SWS ASW valves on an actual or simulated actuation signal. ~~The SWS is a normally operating system that cannot be fully actuated as part of normal testing.~~ This Surveillance is not required for valves that are locked, sealed, or otherwise secured in the required position under administrative controls. The [18] month 92 day Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. ~~engineering judgement is consistent with procedural controls governing valve operation~~ the IST program frequency and is consistent with the ASME O&M Code testing requirements, and ensures the ability to correctly align the valves. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month 92 day Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.

(continued)

BASES

SR 3.7.8.3

This SR verifies proper automatic operation of the SWS ASW pumps on an actual or simulated safety related actuation signal. The SWS ASW is a normally operating system that cannot be fully actuated as part of normal testing during normal operation. The [18] month Frequency is based on the need to perform this Surveillance under the conditions that apply during a unit outage and the potential for an unplanned transient if the Surveillance were performed with the reactor at power. This surveillance requirement applies to the SIS auto-start and the 4kV auto transfer automatic starts only. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.

B 3.7 PLANT SYSTEMS

B 3.7.9 Ultimate Heat Sink (UHS)

BASES

BACKGROUND

The UHS provides a heat sink for processing and operating transferring heat from safety related components during a transient or accident, as well as safety related and non-safety related heat loads during normal operation. This is done by utilizing the service Water Pacific Ocean, the Auxiliary Saltwater System (ASW) and the Component Cooling Water (CCW) System.

The UHS is common to both units and has been defined as that complex of water sources, including necessary retaining structures (e.g., a pond with its dam, or a river with its dam), the Pacific Ocean and the canals or conduits connecting the sources with, but not including, the cooling water system intake structures as discussed in the FSAR, Section [9.2.5] (Ref. 1). If cooling towers or portions thereof are required to accomplish the UHS safety functions, they should meet the same requirements as the sink. The two principal functions of the UHS are dissipation of heat during normal operation, the dissipation of residual heat after reactor shutdown, and dissipation of residual heat after an accident.

A variety of complexes is used to meet the requirements for a UHS. A lake or an ocean may qualify as a single source. If the complex includes a water source contained by a structure, it is likely that a second source will be required.

The basic performance requirements are that a 30 day supply of water be available, and that the design basis temperatures of safety related equipment not be exceeded. Basins of cooling towers generally include less than a 30 day supply of water, typically 7 days or less. A 30 day supply would be dependent on other source(s) and makeup system(s) for replenishing the source in the cooling tower basin. For smaller basin sources, which may be as small as a 1 day supply, the systems for replenishing the basin and the backup source(s) become of sufficient importance that the makeup system itself may be required to meet the same design criteria as an Engineered Safety Feature (e.g., single failure considerations), and multiple makeup water sources may be required. To ensure UHS availability, ASW components located within the projected sea wave zone are designed to operate during extreme ocean levels for a short duration (for example, tsunami run up and draw down conditions) per Reference 2. To maintain adequate cooling for safety related equipment, operational limits are established based on ocean supply temperature per Reference 4.

BASES

Additional information on the design and operation of the system along with a list of components served, can be found in Reference 1.

APPLICABLE
SAFETY ANALYSES

The UHS is the sink for heat removed from the reactor core and containment following all accidents and anticipated operational occurrences in which the unit is cooled down and placed on residual heat removal (RHR) operation. For units that use UHS as the normal heat sink for condenser cooling via the Circulating Water System, unit operation at full power is its maximum heat load. Its maximum post accident heat load occurs 20 minutes after a design basis loss of coolant accident (LOCA). Near this time, the unit switches from injection to recirculation and the containment cooling systems and RHR are required to remove the core decay heat. The Pacific Ocean as a single water source for the Ultimate Heat Sink will provide in excess of 30 days of cooling water during normal and emergency shutdown conditions as required by AEC Safety Guide 27 (Ref. 3).

The operating limits are based on conservative heat transfer analyses for the worst case LOCA. Reference 1 provides the details of the assumptions used in the analysis, which include worst expected meteorological conditions, conservative uncertainties when calculating decay heat, and worst case single active failure (e.g., single failure of a manmade structure). The UHS is designed in accordance with Regulatory Guide 1.27 (Ref. 2), which requires a 30 day supply of cooling water in the UHS.

The UHS satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

The UHS is required to be OPERABLE and is considered OPERABLE if it contains a sufficient volume of water is at or below the maximum temperature that would allow the SWS ASW to operate for at least 30 days following the design basis LOCA without the loss of net positive suction head (NPSH), and DBA without exceeding the maximum design temperature of the equipment served by the SWS CCW system. To meet this condition, the UHS temperature should not exceed [90 F] 64°F unless two CCW heat exchangers are in service and the level should not fall below [562 ft mean sea level] during normal unit operation.

APPLICABILITY

In MODES 1, 2, 3, and 4, the UHS is required to support the OPERABILITY of the equipment serviced by the UHS and required to be OPERABLE in these MODES.

BASES

In MODE 5 or 6, the OPERABILITY requirements of the UHS are determined by the systems it supports.

ACTIONS

A.1

~~If one or more cooling towers have one fan the UHS is inoperable (i.e., up to one fan per cooling tower inoperable inlet water temperature > 64°F), action must be taken to restore the inoperable cooling tower fan(s) UHS to OPERABLE status within 7 days 8 hours by placing a second CCW heat exchanger in service must be performed within 8 hours. This action provides assurance that the ASW system and the CCW system can operate within its temperature limit.~~

The 7-day 8 hour Completion Time is reasonable based on the low probability of an accident occurring during the 7 days 8 hours that one cooling tower fan is inoperable (in one or more cooling towers), the number of available systems, the temperature is > 64°F without two CCW heat exchangers in service and the time required to reasonably complete the Required Action.

B.1 and B.2

~~If the cooling tower fan the second heat exchanger cannot be restored to OPERABLE status placed in service within the associated Completion Time or] if the UHS is inoperable for reasons other than Condition A, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours and in MODE 5 within 36 hours.~~

The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.7.9.1 ~~Not used~~

~~This SR verifies that adequate long term (30 day) cooling can be maintained. The specified level also ensures that sufficient NPSH is available to operate the SWS pumps. The [24] hour Frequency is based on operating experience related to trending of the parameter variations during the applicable MODES. This SR verifies that the UHS water level is [562] ft [mean sea level].~~

BASESSR 3.7.9.2

~~This SR verifies that the SWS is available to cool the CCW System to at least its maximum design temperature with the maximum accident or normal design heat loads for 30 days following a Design Basis Accident. The 24 hour Frequency is based on operating experience related to trending of the parameter variations during the applicable MODES. This SR verifies that the average water temperature of the UHS is [90 F].~~

~~This SR verifies that adequate long term (30 day) cooling can be maintained. The 24, 12 and 2 hour surveillance Frequencies are based on operating experience related to trending of the temperature variations during the applicable MODES. This SR verifies the temperature of the UHS so that appropriate actions can be taken to assure that the ASW system can continue to assure that the CCW system will not exceed its design temperature profile.~~

SR 3.7.9.3 Not Used

~~Operating each cooling tower fan for > [15] minutes ensures that all fans are OPERABLE and that all associated controls are functioning properly. It also ensures that fan or motor failure, or excessive vibration, can be detected for corrective action. The 31 day Frequency is based on operating experience, the known reliability of the fan units, the redundancy available, and the low probability of significant degradation of the UHS cooling tower fans occurring between surveillances.~~

SR 3.7.9.4 Not Used

~~This SR verifies that each cooling tower fan starts and operates on an actual or simulated actuation signal. The [18] month Frequency is consistent with the typical refueling cycle. Operating experience has shown that these components usually pass the Surveillance when performed at the [18] month Frequency. Therefore, the Frequency is acceptable from a reliability standpoint.~~

B 3.7 PLANT SYSTEMS

B 3.7.10 Control Room Emergency Filtration Ventilation System (CREEVS)

BASES

BACKGROUND

The CREEVS provides a protected environment from which operators can control the units from the common control room following an uncontrolled release of radioactivity, chemicals, or toxic gas.

The CREEVS consists of two independent, redundant trains that recirculate and filter the control room air (one train from each unit). Each train consists of a heater, a prefilter or demister, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a one pressurization supply fan, one filter booster fan, and one main supply fan. Ductwork, valves or dampers, and instrumentation also form part of the system, as well as demisters to remove water droplets from the air stream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case of failure of the main HEPA filter bank.

The CREEVS is an emergency system, parts of which may also operate during normal unit operations, in the standby mode of operation. Upon receipt of the an actuating signal(s), the normal air supply to the control room is isolated, and the stream of outside ventilation air from the pressurization system and is recirculated control room air is passed through the system filter trains. The pressurization system draws outside air from either the north end or the south end of the turbine building based upon the wind direction or the absence of releases at the inlet. The prefilters or demisters remove any large particles in the air, and any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers. Continuous operation of each filter train for at least 10 hours per month, with the heaters on, reduces moisture buildup on the HEPA filters and adsorbers. Both the demister and heater is are important to the effectiveness of the charcoal adsorbers.

Manual or automatic actuation of the CREEVS places the system in one of three either of two separate states: 1) pressurization (MODE 4), 2) recirculation (MODE 3), or 3) smoke removal (MODE 2) (emergency radiation state or toxic gas isolation state) of the emergency mode of operation, depending on the initiation signal. Actuation of the system to the recirculation mode emergency radiation state of the emergency mode of operation, closes the unfiltered outside air intake and unfiltered exhaust dampers, and aligns the system for recirculation of the control room air through the redundant trains of HEPA and the charcoal filters. The pressurization mode emergency radiation state also

(continued)

BASES

initiates pressurization and filtered ventilation of the air supply to the control room.

Outside air is filtered, diluted via pressure equalization with building air from the mechanical electrical equipment and cable spreading rooms, and added to the air being recirculated from the control room. Pressurization of the control room prevents infiltration of unfiltered air from the surrounding areas of the building. The actions taken in the manual actuation of the recirculation mode toxic gas isolation state are the same, except that the signal switches control room ventilation to an isolation alignment to prevent outside air from entering the control room.

To monitor the status of the booster fan(s) small plastic streamers are installed on the exhaust duct grates. These exhaust ducts are located in the back of the control room in the ceiling and are used to take suction on the control room atmosphere. These streamers will hang down when the booster fan(s) are not operating. Therefore if a booster fan is in operation the streamers will be up. This will permit the operators to diagnose a problem with the booster fan or with the booster fan supply damper.

The pressurization mode is the only automatically actuated mode change since bulk chlorine gas is no longer kept onsite and the chlorine monitors which previously initiated the recirculation mode have been deactivated.

The air entering the control room is continuously monitored by radiation and toxic gas detectors. One detector output above the setpoint will cause actuation of the pressurization mode emergency radiation state or toxic gas isolation state, as required. The actions of the toxic gas isolation state are more restrictive, and will override the actions of the emergency radiation state.

A single train will pressurize the control room equal to about or greater than 0.125 inches water gauge. The CREEVS operation in maintaining the control room habitable is discussed in the FSAR, Section 9.4.1 [6.4] (Ref. 1).

Redundant supply and recirculation trains provide the required filtration should an excessive pressure drop develop across the other filter train. Normally open isolation dampers are arranged in series pairs so that the failure of one damper to shut will not result in a breach of isolation. The CREEVS is designed in accordance with Seismic Category I requirements.

The CREEVS is designed to maintain the control room environment for the duration of the most severe 30 days of continuous

(continued)

BASES

occupancy after a Design Basis Accident (DBA) without exceeding a 5 rem whole body dose or its equivalent to any part of the body.

APPLICABLE
SAFETY ANALYSES

The CREEVS components are arranged in redundant, safety related ventilation trains. The location of components and ducting within the control room envelope ensures an adequate supply of filtered air to all areas requiring access. The CREEVS provides airborne radiological protection for the control room operators, as demonstrated by the control room accident dose analyses for the most limiting design basis loss of coolant accident, fission product release presented in the FSAR, Chapter 15 (Ref. 2).

The analysis of toxic gas releases demonstrates that the toxicity limits are not exceeded in the control room following a toxic chemical release, as presented in Reference 1.

The worst case single active failure of a component of the CREEVS, assuming a loss of offsite power, does not impair the ability of the system to perform its design function.

The CREEVS satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

Two independent and redundant CREEVS trains are required to be OPERABLE to ensure that at least one is available assuming a single failure disables the other train. The redundant train means a second train from the other unit (Ref. 5). Total system failure could result in exceeding a dose of 5 rem to the control room operator in the event of a large radioactive release.

The CREEVS is considered OPERABLE when the individual components necessary to limit operator exposure are OPERABLE in both trains. A CREEVS train is OPERABLE when the associated:

- a. main supply fan (one), filter booster fan (one) and pressurization fan (one) Fan are ~~is~~ OPERABLE;
- b. HEPA filters and charcoal adsorbers are not excessively restricting flow, and are capable of performing their filtration functions; and
- c. Heaters, demister, ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained.

In addition, the control room boundary must be maintained, including the integrity of the walls, floors, ceilings, ductwork, and access doors.

(continued)

BASES

APPLICABILITY

In MODES 1, 2, 3, 4, [5, and 6,] and during movement of irradiated fuel assemblies [and during CORE ALTERATIONS], CREEVS must be OPERABLE to control operator exposure during and following a DBA or the the CREEVS is required to cope with the release from the rupture of an outside waste gas tank.

During movement of irradiated fuel assemblies [and CORE ALTERATIONS], the CREEVS must be OPERABLE to cope with the release from a fuel handling accident.

~~CRVS OPERABILITY requires that for MODE 5 and 6 and during movement of irradiated fuel assemblies in either unit, when there is only one OPERABLE train of CRVS, the OPERABLE CRVS train must be capable of being powered from an OPERABLE diesel generator that is directly associated with the bus which is energizing the OPERABLE CRVS train. This is an exception to LCO 3.0.6.~~

ACTIONS

A.1

When one CREEVS train is inoperable, action must be taken to restore OPERABLE status within 7 days. In this Condition, the remaining OPERABLE CREEVS train is adequate to perform the control room protection function. However, the overall reliability is reduced because a single failure in the OPERABLE CREEVS train could result in loss of CREEVS function. The 7 day Completion Time is based on the low probability of a DBA occurring during this time period, and ability of the remaining train to provide the required capability.

~~CRVS OPERABILITY requires that for MODE 5 and 6 and during movement of irradiated fuel assemblies, when there is only one OPERABLE train of CRVS, the OPERABLE CRVS train must be capable of being powered from an OPERABLE diesel generator that is directly associated with the bus which is energizing the OPERABLE CRVS train. This is an exception to LCO 3.0.6.~~

B.1 and B.2

In MODE 1, 2, 3, or 4, if the inoperable CREEVS train cannot be restored to OPERABLE status within the required Completion Time, the unit must be placed in a MODE that minimizes accident risk. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

(continued)

BASES

C.1, C.2.1, and C.2.2

In ~~MODE 5 or 6, or~~ during movement of irradiated fuel assemblies [~~or during CORE ALTERATIONS~~], if the inoperable CREEVS train cannot be restored to OPERABLE status within the required Completion Time, action must be taken to immediately place the OPERABLE CREEVS train in the recirculation emergency mode. This action ensures that the remaining train is OPERABLE, that no failures preventing automatic actuation will occur, and that any active failure would be readily detected. As noted above, if only one CRVS train is OPERABLE, the OPERABLE train must be capable of being powered from an OPERABLE diesel generator that is directly associated with the bus which is energizing the OPERABLE CRVS train. The power requirements for the one OPERABLE CRVS train assures that the ventilation function will not be lost during a fuel handling accident with a subsequent loss of off-site power.

An alternative to Required Action C.1 is to immediately suspend activities that could result in a release of radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes risk. This does not preclude the movement of fuel to a safe position.

~~Required Action C.1 is modified by a Note indicating to place the system in the toxic gas protection mode if automatic transfer to toxic gas protection mode is inoperable.~~

D.1 and D.2

In ~~MODE 5 or 6, or~~ during movement of irradiated fuel assemblies [~~or during CORE ALTERATIONS~~], with two CREEVS trains inoperable, action must be taken immediately to suspend activities, including positive reactivity changes, that could result in a release of radioactivity that might enter the control room. This places the unit in a condition that minimizes accident risk. This does not preclude the movement of fuel to a safe position.

E.1

If both CREEVS trains are inoperable in MODE 1, 2, 3, or 4, the CREEVS may not be capable of performing the intended function and the unit is in a condition outside the accident analyses. Therefore, LCO 3.0.3 must be entered immediately.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

Once actuated due to a fuel handling accident the CRVS must be protected against a single failure. This protection, although not required for immediate accident response, is assured by requiring that a backup power supply be provided as described above in Applicability. This back up is assured via the performance of non-TS surveillances that verify the ability to transfer power supplies.

The 31 day procedural verification of the separate vital power supplies for the redundant fans and the one hour operation of each supply, booster and pressurization supply fan (unless already operating) assures system reliability and two train redundancy.

SR 3.7.10.1

Standby systems should be checked periodically to ensure that they function properly. As the environment and normal operating conditions on this system are not too severe, testing each train once every month provides an adequate check of this system. Monthly heater operations dry out any moisture accumulated in the charcoal from humidity in the ambient air. [Systems with heaters must be operated for ≥ 10 continuous hours with the heaters energized and operating automatically (filter temperature control)]. ~~Systems without heaters need only be operated for ≥ 15 minutes to demonstrate the function of the system.~~ The 31 day Frequency is based on the reliability of the equipment and the two train redundancy availability.

SR 3.7.10.2

This SR verifies that the required CREEVS testing is performed in accordance with the [Ventilation Filter Testing Program (VFTP)]. The CREEVS filter tests are in accordance with Regulatory Guide 1.52 ANSI 510-1980 (Ref. 3). The [VFTP] includes testing the performance of the HEPA filter, charcoal adsorber efficiency, minimum flow rate, and the physical properties of the activated charcoal. Specific test Frequencies and additional information are discussed in detail in the [VFTP].

SR 3.7.10.3

This SR verifies that each CREEVS train automatically starts and operates in the pressurization mode on an actual or simulated actuation signal generated from a Phase A Isolation. The Frequency of [18] months is specified in Regulatory Guide 1.52 ANSI 510-1980 (Ref. 3).

(continued)

BASES

SR 3.7.10.4

This SR verifies the integrity of the control room enclosure, and the assumed inleakage rates of the potentially contaminated air. The control room positive pressure, with respect to potentially contaminated adjacent areas, is periodically tested to verify proper functioning of the CREEVS. During the ~~pressurization~~ emergency mode of operation, the CREEVS is designed to pressurize the control room \geq ~~{0.125}~~ inches water gauge positive pressure with respect to ~~the outside atmosphere and~~ adjacent areas in order to prevent unfiltered inleakage. The CREEVS is designed to maintain this positive pressure with one train ~~at a makeup flow rate of [3000] cfm.~~ The Frequency of ~~{18}~~ months on a STAGGERED TEST BASIS is consistent with the guidance provided in NUREG-0800 (Ref. 4).

B 3.7 PLANT SYSTEMS

B 3.7.11 ~~Not Used~~ Control Room Emergency Air Temperature Control System (CREATCS)

BASES

BACKGROUND

~~The CREATCS provides temperature control for the control room following isolation of the control room.~~

~~The CREATCS consists of two independent and redundant trains that provide cooling and heating of recirculated control room air. Each train consists of heating coils, cooling coils, instrumentation, and controls to provide for control room temperature control. The CREATCS is a subsystem providing air temperature control for the control room.~~

~~The CREATCS is an emergency system, parts of which may also operate during normal unit operations. A single train will provide the required temperature control to maintain the control room between [70]°F and [85]°F. The CREATCS operation in maintaining the control room temperature is discussed in the FSAR, Section [6.4](Ref. 1).~~

APPLICABLE
SAFETY ANALYSES

~~The design basis of the CREATCS is to maintain the control room temperature for 30 days of continuous occupancy.~~

~~The CREATCS components are arranged in redundant, safety related trains. During emergency operation, the CREATCS maintains the temperature between [70]°F and [85]°F. A single active failure of a component of the CREATCS, with a loss of offsite power, does not impair the ability of the system to perform its design function. Redundant detectors and controls are provided for control room temperature control. The CREATCS is designed in accordance with Seismic Category I requirements. The CREATCS is capable of removing sensible and latent heat loads from the control room, which include consideration of equipment heat loads and personnel occupancy requirements, to ensure equipment OPERABILITY.~~

~~The CREATCS satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).~~

(continued)

BASES (continued)

LCO

~~Two independent and redundant trains of the CREATCS are required to be OPERABLE to ensure that at least one is available, assuming a single failure disabling the other train. Total system failure could result in the equipment operating temperature exceeding limits in the event of an accident.~~

~~The CREATCS is considered to be OPERABLE when the individual components necessary to maintain the control room temperature are OPERABLE in both trains. These components include the heating and cooling coils and associated temperature control instrumentation. In addition, the CREATCS must be operable to the extent that air circulation can be maintained.~~

APPLICABILITY

~~In MODES 1, 2, 3, 4, and during movement of irradiated fuel assemblies [and during CORE ALTERATIONS], the CREATCS must be OPERABLE to ensure that the control room temperature will not exceed equipment operational requirements following isolation of the control room.~~

~~[In MODE 5 or 6,] CREATCS may not be required for those facilities that do not require automatic control room isolation.~~

ACTIONS

A-1

~~With one CREATCS train inoperable, action must be taken to restore OPERABLE status within 30 days. In this Condition, the remaining OPERABLE CREATCS train is adequate to maintain the control room temperature within limits. However, the overall reliability is reduced because a single failure in the OPERABLE CREATCS train could result in loss of CREATCS function. The 30 day Completion Time is based on the low probability of an event requiring control room isolation, the consideration that the remaining train can provide the required protection, and that alternate safety or nonsafety related cooling means are available.~~

(continued)

BASES

ACTIONS
(continued)

B.1 and B.2

~~In MODE 1, 2, 3, or 4, if the inoperable CREATCS train cannot be restored to OPERABLE status within the required Completion Time, the unit must be placed in a MODE that minimizes the risk. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.~~

C.1, C.2.1, and C.2.2

~~[In MODE 5 or 6, or] during movement of irradiated fuel [or during CORE ALTERATIONS], if the inoperable CREATCS train cannot be restored to OPERABLE status within the required Completion Time, the OPERABLE CREATCS train must be placed in operation immediately. This action ensures that the remaining train is OPERABLE, that no failures preventing automatic actuation will occur, and that active failures will be readily detected.~~

~~An alternative to Required Action C.1 is to immediately suspend activities that present a potential for releasing radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes accident risk. This does not preclude the movement of fuel to a safe position.~~

D.1 and D.2

~~[In MODE 5 or 6, or] during movement of irradiated fuel assemblies [or during CORE ALTERATIONS], with two CREATCS trains inoperable, action must be taken immediately to suspend activities that could result in a release of radioactivity that might require isolation of the control room. This places the unit in a condition that minimizes risk. This does not preclude the movement of fuel to a safe position.~~

ACTIONS
(continued)

E.1

~~If both CREATCS trains are inoperable in MODE 1, 2, 3, or 4, the control room CREATCS may not be capable of performing its intended function. Therefore, LCO 3.0.3 must be entered immediately.~~

SURVEILLANCE
REQUIREMENTS

SR 3.7.11.1

~~This SR verifies that the heat removal capability of the system is sufficient to remove the heat load assumed in the [safety analyses] in~~

(continued)

BASES

~~the control room. This SR consists of a combination of testing and calculations. The 18 month Frequency is appropriate since significant degradation of the CREATCS is slow and is not expected over this time period.~~

B 3.7 PLANT SYSTEMS

B 3.7.12 Emergency Core Cooling System (ECCS) Pump Room Exhaust Air Cleanup System (PREACS) Auxiliary Building Ventilation System (ABVS)

BASES

BACKGROUND

The ECCS PREACS ABVS filters air from the area of the active ECCS components during the recirculation phase of a loss of coolant accident (LOCA). The ECCS PREACS ABVS, in conjunction with other normally operating systems, also provides environmental control of temperature and humidity in the ECCS pump room area. If one of the pumps is operating and the lower reaches of the auxiliary building.

The ECCS PREACS ABVS consists of two independent and redundant trains. Each train is powered by a separate vital bus and consists of a supply fan and an exhaust fan. A single roughing and HEPA filter is common to both trains for normal operations and a single roughing filter HEPA filter and charcoal adsorber bank and a single manually initiated heater are common to both trains for emergency operations. Each train consists of a heater, a prefilter or demister, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, and instrumentation also form part of the system, as well as demisters functioning to reduce the relative humidity of the air stream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case the main HEPA filter bank fails. The downstream HEPA filter is not credited in the accident analysis, but serves to collect charcoal fines, and to back up the upstream HEPA filter should it develop a leak. The system initiates filtered ventilation of the pump room following receipt of a safety injection (SI) signal.

The ABVS has several modes of operation. These modes include: (1) Building Only; (2) Building and Safeguards; and (3) Safeguards only. In the Building Only mode of operation, the ABVS provides ventilation flow to all parts of the auxiliary building except for the ECCS pump rooms, but does take suction from the ECCS rooms. If any ECCS pump is started, the ABVS will automatically re-align to the Building and Safeguards mode of operation. In the Building and Safeguards mode of operation, ventilation is provided to the entire auxiliary building, including the ECCS pump rooms. In the Safeguards Only mode of operation, only the ECCS pump rooms and the lower reaches of the auxiliary building are provided with ventilation. If a SI signal is generated, the system will automatically realign such that all exhaust flow from the ECCS pump rooms passes through the common HEPA filter/charcoal adsorber bank prior to being exhausted to

(continued)

BASES

atmosphere. Whenever an SI signal is generated, the operator must manually energize the heater from the control room.

The ECCS PREACS is a standby system, aligned to bypass the system HEPA filters and charcoal adsorbers. During emergency operations, the ECCS PREACS dampers are realigned, and fans are started to begin filtration. Upon receipt of the actuating Engineered Safety Feature Actuation System signal(s), normal air discharges from the ECCS pump room isolate, and the stream of ventilation air discharges through the system filter trains. The prefilters remove any large particles in the air, and any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers.

The ECCS PREACS ABVS is discussed in the FSAR, Sections [6.5.1], [9.4.5] 2, and [15.6.5] 5 (Refs. 1, and 2, and 3, respectively) since it may be used for normal, as well as post accident, ventilation and atmospheric cleanup functions. The primary purpose of the single manually initiated heaters is to maintain the relative humidity at an acceptable level, consistent with iodine removal efficiencies per Regulatory Guide 1.62 ASTM D 3803-1989 (Ref. 4 3). There is no redundant heater since the failure of the charcoal absorber and heater train would constitute a second failure in addition to the RHR pump seal failure assumed in conjunction with a LOCA (Ref 7).

APPLICABLE
SAFETY ANALYSES

The design basis of the ECCS PREACS ABVS is established by the large break LOCA. The system evaluation assumes a passive failure of the ECCS outside containment, such as an SI RHR pump seal failure, during the recirculation mode. In such a case, the system limits radioactive release to within the 10 CFR 100 (Ref. 5) limits, or the NRC staff approved licensing basis (e.g., a specified fraction of Reference 5 limits). The analysis of the effects and consequences of a large break LOCA is presented in Reference 3 2. The ECCS PREACS ABVS also functions, following a small break LOCA, in those cases where the ECCS goes into the recirculation mode of long term cooling, to clean up releases of smaller leaks, such as from valve stem packing.

The ventilation flow is also required to maintain the temperatures of the operating ECCS motors within allowable limits. The ventilation function has been designed for single failure and the system will continue to function to provide its ECCS motor cooling function.

Two types of system failures are considered in the accident analysis for radiation release: complete loss of function, and excessive LEAKAGE. Either type of failure may result in a lower

(continued)

BASES

efficiency of removal for any gaseous and particulate activity released to the ECCS pump rooms following a LOCA.

The ~~ECCS PREACS~~ ABVS satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

Two independent and redundant trains of the ~~ECCS PREACS~~ ABVS are required to be OPERABLE to ensure that at least one is available, assuming that a single failure disables the other train coincident with loss of offsite power. Total system failure could result in the atmospheric release from the ECCS pump room exceeding 10 CFR 100 limits in the event of a Design Basis Accident (DBA).

~~ECCS PREACS~~ ABVS is considered OPERABLE when the individual components necessary to maintain the ECCS pump room filtration and temperature are OPERABLE in both trains.

An ~~ECCS PREACS~~ ABVS train is considered OPERABLE when its associated:

- a. ~~Supply and exhaust fans~~ are OPERABLE;
 - b. ~~The common roughing filter~~ HEPA filter and charcoal adsorbers are not excessively restricting flow, and are capable of performing their filtration functions; and
 - c. ~~A heater, demister, ductwork, valves, and dampers~~ are OPERABLE and air circulation can be maintained.
-

APPLICABILITY

In MODES 1, 2, 3, and 4, the ~~ECCS PREACS~~ ABVS is required to be OPERABLE consistent with the OPERABILITY requirements of the ECCS.

In MODE 5 or 6, the ~~ECCS PREACS~~ ABVS is not required to be OPERABLE since the ECCS is not required to be OPERABLE.

ACTIONS

ACT

~~With the common HEPA filter and charcoal adsorber bank inoperable, the cooling function of the ABVS for ECCS motors is maintained; however, the filtration system function is lost. Since the entire function of the system is not lost, a 24 hour completion time is provided to restore the filters.~~

(continued)

BASES

The 24 hour completion time is acceptable because it is a common filter system and the completion time is shorter than the EGCS completion time. The 24 hour completion time is based on the low probability of a DBA occurring during this time period.

A B.1

With one EGCS PREACS ABVS train inoperable, action must be taken to restore OPERABLE status within 7 days. During this time, the remaining OPERABLE train is adequate to perform the EGCS PREACS ABVS function.

The 7 day Completion Time is appropriate because the risk contribution is less than that for the EGCS (72 hour Completion Time), and this system is not a direct support system for the EGCS. The 7 day Completion Time is based on the low probability of a DBA occurring during this time period, and ability of the remaining train to provide the required capability.

Concurrent failure of two EGCS PREACS ABVS trains would result in the loss of functional both filtration and cooling capability; therefore, LCO 3.0.3 must be entered immediately.

BC.1 and BC.2

If the EGCS PREACS ABVS train cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.7.12.1

Standby systems should be checked periodically to ensure that they function properly. As the environment and normal operating conditions on this system are not severe, testing each train once a month provides an adequate check on this system. Monthly heater operations dry out any moisture that may have accumulated in the charcoal from humidity in the ambient air. Systems with heaters must be operated ≥ 10 continuous hours with the heaters energized and operating automatically (filter temperature control). Since the ABVS has only one common charcoal filter, one train needs to be operated for ≥ 10 hours to dry out the filter and the other train only needs to be operated long enough (≥ 15 minutes) to verify all components are operating correctly. Monthly verification of the separate OPERABLE vital power

(continued)

BASES

~~supplies for the exhaust fans, via a non-IS surveillance, assures system redundancy. Systems without heaters need only be operated for > 15 minutes to demonstrate the function of the system.] The 31 day Frequency is based on the known reliability of equipment and the two train redundancy available.~~

SR 3.7.12.2

This SR verifies that the required ECSS PREACS ABVS testing is performed in accordance with the Ventilation Filter Testing Program (VFTR). The ECSS PREACS ABVS filter tests are in accordance with References 3 and 4. The VFTR includes testing HEPA filter performance, charcoal adsorbers efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test Frequencies and additional information are discussed in detail in the VFTR.

SR 3.7.12.3

This SR verifies that each ECSS PREACS ABVS train starts and operates on an actual or simulated actuation signal and that the system aligns to exhaust through the common HEPA filter and charcoal adsorber. The 18 month Frequency is consistent with that specified in References 3 and 4.

SR 3.7.12.4 Not Used

~~This SR verifies the integrity of the ECSS pump room enclosure. The ability of the ECSS pump room to maintain a negative pressure, with respect to potentially uncontaminated adjacent areas, is periodically tested to verify proper functioning of the ECSS PREACS. During the [post accident] mode of operation, the ECSS PREACS is designed to maintain a slight negative pressure in the ECSS pump room, with respect to adjacent areas, to prevent unfiltered LEAKAGE. The ECSS PREACS is designed to maintain a \leq [0.125] inches water gauge relative to atmospheric pressure at a flow rate of [3000] cfm from the ECSS pump room. The Frequency of [18] months is consistent with the guidance provided in NUREG 0800, Section 6.5.1 (Ref. 6).~~

~~This test is conducted with the tests for filter penetration; thus, an [18] month Frequency on a STAGGERED TEST BASIS is consistent with that specified in Reference 4.~~

SR 3.7.12.5 Not Used

~~Operating the ECSS PREACS bypass damper is necessary to ensure that the system functions properly. The OPERABILITY of the ECSS PREACS bypass damper is verified if it can be specified in Reference 4.~~

BASES

SURVEILLANCE REQUIREMENT
(continued) SR 3.7.12.6

This SR verifies the leak tightness of dampers that isolate flow to the normally operating filter train. This SR assures that the flow from the auxiliary building passes through the HEPA filter and charcoal absorber unit when the ABVS Buildings and Safeguards or Safeguards Only modes have been actuated coincident with an SI. The 18 month frequency is consistent with the requirements of Reference 4.

B 3.7 PLANT SYSTEMS

B 3.7.13 Fuel Handling Building Air Cleanup Ventilation System (FBACS FHBVS)

BASES

BACKGROUND

The FBACS FHBVS filters airborne radioactive particulates and radioactive iodine from the area of the fuel pool following a fuel handling accident or loss of coolant accident (LOCA). The FBACS FHBVS, in conjunction with other normally operating systems, also provides environmental control of temperature and humidity in the fuel pool area.

The FBACS FHBVS consists of two independent and redundant trains. Each train consists of a heater, a prefilter or demister, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and an exhaust fan. A third non-vital exhaust fan is used for normal operation and has only a prefilter and a HEPA filter. Ductwork, valves or dampers, and instrumentation also form part of the system, as well as demisters, functioning to reduce the relative humidity of the airstream. A second bank of HEPA filters follows the adsorber section to collect carbon fines and provide backup in case the main HEPA filter fails. The downstream HEPA filter is not credited in the analysis, but serves to collect charcoal fines, and to back up the upstream HEPA filter should it develop a leak. The system initiates filtered ventilation of the fuel handling building following receipt of a high radiation signal or loss of the normal exhaust fan E-4.

The FBACS FHBVS is a standby system, parts of which may also be operated during normal plant operations. Upon receipt of the actuating signal, normal air discharges from the building, the fuel handling building is isolated and the normal exhaust fan shuts down and the vital exhaust fans start and the stream of ventilation air discharges through the system filter trains. The prefilters or demisters remove any large particles in the air, and any entrained water droplets present, to prevent excessive loading of the HEPA filters and charcoal adsorbers.

The FBACS FHBVS is discussed in the FSAR, Sections [6.5.1] 9.4.4, [9.4.5], and [15.7.4] 15.5 (Refs. 1, and 2, and 3, respectively) because it may be used for normal, as well as post (fuel handling) accident, atmospheric cleanup functions.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES

The FBACS FHBVS design basis is established by the consequences of the limiting Design Basis Accident (DBA), which is a fuel handling accident. The analysis of the fuel handling accident, given in Reference 3 2, assumes that all fuel rods in an assembly are damaged. The analysis of the LOCA assumes that radioactive materials leaked from the Emergency Core Cooling System (ECCS) are filtered and adsorbed by the FBACS. The DBA analysis of the fuel handling accident assumes that only one train of the FBACS FHBVS is functional due to a single failure that disables the other train. The accident analysis accounts for the reduction in airborne radioactive material provided by the one remaining train of this filtration system. The amount of fission products available for release from the fuel handling building is determined for a fuel handling accident and for a LOCA. In accordance with assumptions made in the fuel handling accident analysis, loss of offsite power is not considered concurrent with a fuel handling accident. However, loss of power is enveloped by the fuel handling accident analysis. To maximize FHBVS capability to mitigate the consequences of a fuel handling accident, at least one of the FHBVS trains must be capable of being supplied from an operable emergency diesel generator at all times whenever fuel movement is taking place in the spent fuel pool. These assumptions and the analysis follow the guidance provided in Regulatory Guide 1.25 (Ref. 4 3).

The FBACS FHBVS satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).

LCO

Two independent and redundant trains of the FBACS FHBVS are required to be OPERABLE to ensure that at least one train is available, assuming a single failure that disables the other train, coincident with a loss of offsite power. This requires that when two trains of the FHBVS are OPERABLE, at least one train of the FHBVS must be capable of being powered from an OPERABLE diesel generator that is directly associated with the bus which energizes the FHBVS train. When only one train is OPERABLE, an OPERABLE diesel generator must be directly associated with the bus which energizes that one OPERABLE FHBVS train. Total system failure could result in the atmospheric release from the fuel handling building exceeding the 10 CFR 100 (Ref. 5 4) limits in the event of a fuel handling accident.

The FBACS FHBVS is considered OPERABLE when the individual components necessary to control exposure in the releases from fuel handling building are OPERABLE in both trains. An FBACS FHBVS train is considered OPERABLE when its associated:

- a. Exhaust Fan Fan is OPERABLE;

(continued)

BASES

- b. HEPA filter and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration function; and
 - c. Heater, demister, Ductwork, valves, and dampers are OPERABLE, and air circulation can be maintained.
-

APPLICABILITY

In MODE 1, 2, 3, or 4, the FBACS is required to be OPERABLE to provide fission product removal associated with ECCS leaks due to a LOCA and leakage from containment and annulus.

In MODE 1, 2, 3, 4, 5 or 6, the FBACS FHBVS is not required to be OPERABLE since the ECCS is not required to be OPERABLE if provides no safety function associated with these MODES of operation.

During movement of irradiated fuel in the fuel handling areabuilding, the FBACS FHBVS is required to be OPERABLE to alleviate the consequences of a fuel handling accident.

ACTIONS

The Required Actions are modified by a Note indicating that LCO 3.0.3 does not apply.

If moving irradiated fuel assemblies in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, and 4, the fuel movement is independent of reactor operations. Therefore, inability to suspend movement of irradiated fuel assemblies is not sufficient reason to require a reactor shutdown.

A.1, A.2 and A.3

With one FBACS FHBVS train inoperable, action must be taken to restore OPERABLE status within 7 days. During this period, immediately or place the remaining OPERABLE train is adequate to perform the FBACS function. The 7 day Completion Time is based on the risk from an event occurring requiring the inoperable FBACS train, and the remaining FBACS train providing the required protection, in operation and verify that it has an OPERABLE emergency power source, or suspend movement of irradiated fuel assemblies in the fuel handling building. This The suspension of movement of fuel assemblies does not preclude movement of assemblies to a safe position.

(continued)

BASES

B.1 and B.2

~~In MODE 1, 2, 3, or 4, when Required Action A.1 cannot be completed within the associated Completion Time, or when both FBACS trains are inoperable, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in MODE 3 within 6 hours, and in MODE 5 within 36 hours. The Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.~~

C.1 and C.2

~~When Required Action A.1 cannot be completed within the required Completion Time, during movement of irradiated fuel assemblies in the fuel building, the OPERABLE FBACS train must be started immediately or fuel movement suspended. This action ensures that the remaining train is OPERABLE, that no undetected failures preventing system operation will occur, and that any active failure will be readily detected.~~

~~If the system is not placed in operation, this action requires suspension of fuel movement, which precludes a fuel handling accident. This does not preclude the movement of fuel assemblies to a safe position.~~

(continued)

BASES

ACTIONS
(continued)

B.1

When two trains of the FBACS FHBVS are inoperable during movement of irradiated fuel assemblies in the fuel handling building, ~~action must be taken to place the unit in a condition in which the LCO does not apply. Action must be taken immediately to suspend movement of irradiated fuel assemblies in the fuel handling building.~~ This does not preclude the movement of fuel assemblies to a safe position.

SURVEILLANCE
REQUIREMENTS

Once actuated due to a fuel handling accident the FHBVS must be protected against a single failure coincident with a loss of offsite power. Protection against a loss of power, although not required for immediate accident response, is assured by requiring that a backup power supply be provided as described above in the LCO section. This back up is assured via the performance of non-IS surveillances.

SR 3.7.13.1

Standby systems should be checked periodically to ensure that they function properly. As the environmental and normal operating conditions on this system are not severe, testing each train once every month provides an adequate check on this system.

~~Monthly heater operation dries out any moisture accumulated in the charcoal from humidity in the ambient air. [Systems with heaters must be operated for > 10 continuous hours with the heaters energized. Systems without heaters need only be operated for > 15 minutes to demonstrate the function of the system.]~~ The 31 day Frequency is based on the known reliability of the equipment and the two train redundancy available.

SR 3.7.13.2

This SR verifies that the required FBACS FHBVS testing is performed in accordance with the Ventilation Filter Testing Program (VFTP). The FBACS FHBVS filter tests are in accordance with Regulatory Guide 1.52 (Ref. 5 and 6). The VFTP includes testing HEPA filter performance, charcoal adsorber efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test-frequencies and additional information are discussed in detail in the VFTP.

(continued)

BASES

SR 3.7.13.3

This SR verifies that each FBACS FHBVS train starts and operates on an actual or simulated actuation signal and directs its exhaust flow through the HEPA Filters and charcoal absorber banks. The 18 month Frequency is consistent with Reference 6.

SR 3.7.13.4

This SR verifies the integrity of the fuel handling building enclosure. The ability of the fuel handling building to maintain negative pressure with respect to potentially uncontaminated adjacent areas is periodically tested to verify proper function of the FBACS FHBVS. During the [post accident]-mode of operation, the FBACS FHBVS is designed to maintain a slight negative pressure in the fuel handling building, to prevent unfiltered LEAKAGE. The FBACS FHBVS is designed to maintain a the building pressure \leq 0.125 inches water gauge with respect to atmospheric pressure at a flow rate of [20,000]cfm to the fuel building. The Frequency of 18 months is consistent with the guidance provided in NUREG-0800, Section 6.5.1 (Ref. 7).

An 18 month Frequency (on a STAGGERED TEST BASIS) is consistent with Reference 6.

SR 3.7.13.5 ~~Not Used~~

~~Operating the FBACS filter bypass damper is necessary to ensure that the system functions properly. The OPERABILITY of the FBACS filter bypass damper is verified if it can be closed. An [18] month Frequency is consistent with Reference 6.~~

BACKGROUND

~~The PREACS filters air from the penetration area between containment and the auxiliary building.~~

~~The PREACS consists of two independent and redundant trains. Each train consists of a heater, a prefilter or demister, a high efficiency particulate air (HEPA) filter, an activated charcoal adsorber section for removal of gaseous activity (principally iodines), and a fan. Ductwork, valves or dampers, and instrumentation, as well as demisters, functioning to reduce the relative humidity of the air stream, also form part of the system. A second bank of HEPA filters, which follows the adsorber section, collects carbon fines and provides backup in case of failure of the main HEPA filter bank. The downstream HEPA filter, although not credited in the accident analysis, collects charcoal fines and serves as a backup should the upstream HEPA filter develop a leak. The system initiates filtered ventilation following receipt of a safety injection signal.~~

~~The PREACS is a standby system, parts of which may also operate during normal unit operations. During emergency operations, the PREACS dampers are realigned and fans are started to initiate filtration. Upon receipt of the actuating signal(s), normal air discharges from the penetration room, the penetration room is isolated, and the stream of ventilation air discharges through the system filter trains. The prefilters remove any large particles in the air, as well as any entrained water droplets, to prevent excessive loading of the HEPA filters and charcoal adsorbers.~~

~~The PREACS is discussed in the FSAR, Sections [6.5.1], [9.4.5], and [15.6.5] (Refs. 1, 2, and 3, respectively) since it may be used for normal, as well as post accident, atmospheric cleanup functions. Heaters may be included for moisture removal on systems operating in high humidity conditions. The primary purpose of the heaters is to maintain the relative humidity at an acceptable level consistent with iodine removal efficiencies per Regulatory Guide 1.52 (Ref. 4).~~

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES

~~The PREACS design basis is established by the large break loss of coolant accident (LOCA). The system evaluation assumes a passive failure outside containment, such as valve packing leakage during a Design Basis Accident (DBA). In such a case, the system restricts the radioactive release to within the 10 CFR 100 (Ref. 4) limits, or the NRC staff approved licensing basis (e.g., a specified fraction of 10 CFR 100 limits). The analysis of the effects and consequences of a large break LOCA are presented in Reference 3.~~

~~Two types of system failures are considered in the accident analysis: a complete loss of function, and excessive LEAKAGE. Either type of failure may result in less efficient removal of any gaseous or particulate material released to the penetration room following a LOCA.~~

~~The PREACS satisfies Criterion 3 of 10 CFR 50.36 (c) (2) (ii).~~

LCO

~~Two independent and redundant trains of the PREACS are required to be OPERABLE to ensure that at least one train is available, assuming there is a single failure disabling the other train coincident with a loss of offsite power.~~

~~The PREACS is considered OPERABLE when the individual components necessary to control radioactive releases are OPERABLE in both trains. A PREACS train is considered OPERABLE when its associated:~~

- ~~a. Fan is OPERABLE;~~
- ~~b. HEPA filter and charcoal adsorber are not excessively restricting flow, and are capable of performing their filtration functions; and~~
- ~~c. Heater, demister, ductwork, valves, and dampers are OPERABLE and air circulation can be maintained.~~

APPLICABILITY

~~In MODES 1, 2, 3, and 4, the PREACS is required to be OPERABLE, consistent with the OPERABILITY requirements of the Emergency Core Cooling System (ECCS).~~

~~In MODE 5 or 6, the PREACS is not required to be OPERABLE since the ECCS is not required to be OPERABLE.~~

ACTIONS

A-1

(continued)

BASES

~~With one PREACS train inoperable, the action must be taken to restore OPERABLE status within 7 days. During this period, the remaining OPERABLE train is adequate to perform the PREACS function. The 7 day Completion Time is appropriate because the risk contribution of the PREACS is less than that of the ECCS (72 hour Completion Time), and this system is not a direct support system for the ECCS. The 7-day Completion Time is based on the low probability of a DBA occurring during this period, and the remaining train providing the required capability.~~

B.1 and B.2

~~If the inoperable train cannot be restored to OPERABLE status within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 5 within 36 hours. The Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.~~

SURVEILLANCE
REQUIREMENTS

SR 3.7.14.1

~~Standby systems should be checked periodically to ensure that they function properly. As the environmental and normal operating conditions on this system are not severe, testing each train once every month provides an adequate check on this system. Monthly heater operation dries out any moisture that may have accumulated in the charcoal as a result of humidity in the ambient air. [Systems with heaters must be operated for > 10 continuous hours with the heaters energized. Systems without heaters need only be operated for > 15 minutes to demonstrate the function of the system.] The 31 day Frequency is based on the known~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

~~SR 3.7.14.1 (continued)~~

~~reliability of equipment and the two train redundancy available.~~

~~SR 3.7.14.2~~

~~This SR verifies that the required PREACS testing is performed in accordance with the [Ventilation Filter Testing Program (VFTP)]. The PREACS filter tests are in accordance with Regulatory Guide 1.52 (Ref. 5). The [VFTP] includes testing HEPA filter performance, charcoal adsorber efficiency, minimum system flow rate, and the physical properties of the activated charcoal (general use and following specific operations). Specific test frequencies and additional information are discussed in detail in the [VFTP].~~

~~SR 3.7.14.3~~

~~This SR verifies that each PREACS starts and operates on an actual or simulated actuation signal. The [18] month Frequency is consistent with that specified in Reference 5.~~

~~SR 3.7.14.4~~

~~This SR verifies the integrity of the penetration room enclosure. The ability of the penetration room to maintain a negative pressure, with respect to potentially uncontaminated adjacent areas, is periodically tested to verify proper function of PREACS. During the [post accident] mode of operation, the PREACS is designed to maintain a \leq [0.125] inches water gauge relative to atmospheric pressure at a flow rate of [3000] cfm in the penetration room, with respect to adjacent areas, to prevent unfiltered LEAKAGE. The Frequency of [18] months is consistent with the guidance provided in NUREG 0800 (Ref. 6).~~

~~The minimum system flow rate maintains a slight negative pressure in the penetration room area, and provides sufficient air velocity to transport particulate~~

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

~~SR 3.7.14.4 (continued)~~

~~contaminants, assuming only one filter train is operating. The number of filter elements is selected to limit the flow rate through any individual element to about [3000] cfm. This may vary based on filter housing geometry. The maximum limit ensures that the flow through, and pressure drop across, each filter element are not excessive.~~

~~The number and depth of the adsorber elements ensure that, at the maximum flow rate, the residence time of the air stream in the charcoal bed achieves the desired adsorption rate. At least a [0.125] second residence time is necessary for an assumed [99]% efficiency.~~

~~The filters have a certain pressure drop at the design flow rate when clean. The magnitude of the pressure drop indicates acceptable performance, and is based on manufacturers' recommendations for the filter and adsorber elements at the design flow rate. An increase in pressure drop or a decrease in flow indicates that the filter is being loaded or that there are other problems with the system.~~

~~This test is conducted along with the tests for filter penetration; thus, the [18] month Frequency is consistent with that specified in Reference 5.~~

~~SR 3.7.14.5~~

~~It is necessary to operate the PREACS filter bypass damper to ensure that the system functions properly. The OPERABILITY of the PREACS filter bypass damper is verified if it can be closed. An [18] month Frequency is consistent with that specified in Reference 5.~~

B 3.7 PLANT SYSTEMS

B 3.7.15 Spent Fuel Storage Pool Water Level

BASES

BACKGROUND

The minimum water level in the spent fuel storage pool meets the assumptions of iodine decontamination factors following a fuel handling accident. The specified water level shields and minimizes the general area dose when the storage racks are filled to their maximum capacity. The water also provides shielding during the movement of spent fuel.

A general description of the spent fuel storage pool design is given in the FSAR, Section 9.1.2 (Ref. 1). A description of the Spent Fuel Pool Cooling and Cleanup System is given in the FSAR, Section 9.1.3 (Ref. 2). The assumptions of the fuel handling accident are given in the FSAR, Section [15.7.4], 15.4.5 and 15.5.22 (Ref. 3).

APPLICABLE
SAFETY ANALYSES

The minimum water level in the spent fuel storage pool meets the assumptions of the fuel handling accident described in Regulatory Guide 1.25 (Ref. 4). The resultant 2 hour thyroid dose per person at the exclusion area boundary is a small fraction of the 10 CFR 100 (Ref. 5) limits.

According to Reference 4, there is 23 ft of water between the top of the damaged fuel bundle rods and the fuel pool surface during a fuel handling accident. With 23 ft of water, the assumptions of Reference 4 can be used directly. Although there are other spent fuel pool elevations where fuel handling accidents can occur, the design basis fuel handling accident, which uses the conservative assumptions of RG 1.25, is expected to be bounding. To add conservatism, the analysis assumes that all fuel rods of the damaged fuel assembly fail. In practice, this LCO preserves this assumption for the bulk of the fuel in the storage racks. In the case of a single bundle dropped and lying horizontally on top of the spent fuel racks, however, there may be < 23 ft of water above the top of the fuel bundle and the surface, indicated by the width of the bundle. To offset this small nonconservatism, the analysis assumes that all fuel rods fail, although analysis shows that only the first few rows fail from a hypothetical maximum drop.

In practice, the water level maintained for fuel handling provides more than 23 feet of water over the top of irradiated fuel assemblies seated in the storage racks. FSAR Section 9.1.4.3.4 requires the water level to be at or above 137 feet 8 inches during fuel handling to assure 8 feet of water shielding.

(continued)

BASES

This water level corresponds to 24 feet 6 inches above the top of the fuel assemblies in the racks and to 23 feet above a fuel assembly lying horizontally on top of the racks.

The spent fuel storage pool water level satisfies Criterion 2 of 10 CFR 50.36 (c) (2) (ii).

LCO

The spent fuel storage pool water level is required to be \geq 23 ft over the top of irradiated fuel assemblies seated in the storage racks. The specified water level preserves the assumptions of the fuel handling accident analysis (Ref. 3). As such, it is the minimum required for fuel storage and movement within the fuel storage pool.

APPLICABILITY

This LCO applies during movement of irradiated fuel assemblies in the spent fuel storage pool, since the potential for a release of fission products exists.

ACTIONS

A.1

Required Action A.1 is modified by a Note indicating that LCO 3.0.3 does not apply.

When the initial conditions for prevention of an accident cannot be met, steps should be taken to preclude the accident from occurring. When the spent fuel storage pool water level is lower than the required level, the movement of irradiated fuel assemblies in the spent fuel storage pool is immediately suspended to a safe position. This action effectively precludes the occurrence of a fuel handling accident. This does not preclude movement of a fuel assembly to a safe position.

If moving irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not specify any action. If moving irradiated fuel assemblies while in MODES 1, 2, 3, and 4, the fuel movement is independent of reactor operations. Therefore, inability to suspend movement of irradiated fuel assemblies is not sufficient reason to require a reactor shutdown.

SURVEILLANCE
REQUIREMENTS

SR 3.7.15.1

This SR is done during the movement of irradiated fuel assemblies as stated in the Applicability. This SR verifies sufficient fuel

(continued)

BASES

storage pool water is available in the event of a fuel handling accident. The water level in the spent fuel storage pool must be checked periodically. The 7 day Frequency is appropriate because the volume in the pool is normally stable. Water level changes are controlled by plant procedures and are acceptable based on operating experience.

During refueling operations, the level in the spent fuel storage pool is in equilibrium with the refueling canal, and the level in the refueling canal is checked daily in accordance with ~~SR 3.9.6.1~~ SR 3.9.7.1.

B 3.7 PLANT SYSTEMS

B 3.7.16 Spent Fuel Storage Pool Boron Concentration

BASES

BACKGROUND

In the Maximum Density Rack (MDR) [(Refs. 1 and 2)] design, The spent fuel storage pool is divided into two separate and distinct regions which, for the purpose of criticality considerations, are considered as separate pools. [Region 1], with [336] 290 storage positions, is designed to accommodate has been analyzed for the storage of new fuel with a maximum enrichment of [4.65] wt% U-235, or spent fuel regardless of the discharge fuel burnup assemblies which meet the requirements of LCO 3.7.17.1. [Region 2], with [2670] 1034 storage positions, is designed to accommodate fuel of various initial enrichments which have accumulated minimum burnups within the acceptable domain according to Figure [3.7.17.12], in the accompanying has been analyzed for the storage of fuel assemblies which meet the requirements of LCO 3.7.17.2. Fuel assemblies not meeting the criteria of Figure [3.7.17] shall be stored in accordance with paragraph 4.3.1.1 in Section 4.3, Fuel Storage.

The water in the spent fuel storage pool normally contains soluble boron, which results in large subcriticality margins under actual operating conditions. However, the NRC guidelines, based upon the accident condition in which all soluble poison is assumed to have been lost, specify require that the limiting k_{eff} is at or below the limit of 0.95 be evaluated in the absence of soluble boron. Hence, the design analysis of both regions is based on the use of unborated water, which maintains each region in a subcritical condition during normal operation with the regions fully loaded. The double contingency principle discussed in ANSI N-16.1-1975 and the April 1978 NRC letter (Ref. 31) allows credit for soluble boron under other abnormal or accident conditions, since only a single accident need be considered at one time. For example, the most severe accident scenario is associated with the movement of fuel from [Region 1 to Region 2], and accidental misloading of a fuel assembly in [Region 2]. This could potentially increase the to criticality of [Region 2]. To mitigate these postulated criticality related accidents, boron is dissolved in the pool water. Safe operation of the MDR with no movement of assemblies may therefore be achieved by controlling the location of each assembly in accordance with LCO 3.7.17, "Spent Fuel Assembly Storage." Prior to movement of an assembly, it is necessary to perform SR 3.7.16.1.

BASES

APPLICABLE
SAFETY ANALYSES

Most accident conditions do not result in an increase in the negligible reactivity effect for either of the two regions (Ref. 2 and 3). Examples of these accident conditions are the loss of cooling (reactivity increase with decreasing water density) and the dropping of a fuel assembly on the top of the rack. However, accidents scenarios can be postulated that could have more than a negligible positive reactivity effect increase the reactivity. One such scenario is associated with placing a fuel assembly which is required to be stored in Region 1 in Region 2. This could potentially increase the k_{eff} of Region 2 above 0.95 reactivity is unacceptable with unborated water in the storage pool. Thus, to compensate for reductions in the subcriticality margin from postulated these accident occurrences conditions, the presence of spent fuel pool contains 2000 ppm soluble boron in the pool prevents criticality in both regions. The postulated accidents are basically of two types. A fuel assembly could be incorrectly transferred from [Region 1 to Region 2] (e.g., an unirradiated fuel assembly or an insufficiently depleted fuel assembly). The second type of postulated accidents is associated with a fuel assembly which is dropped adjacent to the fully loaded [Region 2] storage rack. This could have a small positive reactivity effect on [Region 2]. However, The negative reactivity effect of the soluble boron more than compensates for the increased reactivity caused by either one of the two postulated accident scenarios. The accident analyses is provided in the FSAR, Section [15.7.4] 15.5.22 (Ref. 4).

The concentration of dissolved boron in the spent fuel storage pool satisfies Criterion 2 of 10 CFR 50.36 (c) (2) (ii).

LCO

The spent fuel storage pool boron concentration is required to be \geq [2300] 2000 ppm. The specified concentration of dissolved boron in the fuel storage pool preserves the assumptions used in the analyses of the potential criticality accident scenarios as described in Reference 4 2, 3, and 4. This concentration of dissolved boron is the minimum required concentration for fuel assembly storage and movement within the spent fuel storage pool.

APPLICABILITY

This LCO applies whenever fuel assemblies are stored in the spent fuel storage pool, until a complete spent fuel storage pool verification has been performed following the last movement of

(continued)

BASES

~~fuel assemblies in the spent fuel storage pool. This LCO does not apply following the verification, since the verification would confirm that there are no misloaded fuel assemblies. With no further fuel assembly movements in progress, there is no potential for a misloaded fuel assembly or a dropped fuel assembly.~~

ACTIONS

A.1, A.2.1, and A.2.2

The Required Actions are modified by a Note indicating that LCO 3.0.3 does not apply.

When the concentration of boron in the ~~spent~~ fuel storage pool is less than required, immediate action must be taken to preclude the occurrence of an accident or to mitigate the consequences of an accident in progress. This is most efficiently achieved by ~~immediately suspending the movement of fuel assemblies and immediately taking actions to restore the spent fuel pool boron concentration to greater than or equal to 2000 ppm. The concentration of boron is restored simultaneously with suspending movement of fuel assemblies. An acceptable alternative is to verify by administrative means that the fuel storage pool verification has been performed since the last movement of fuel assemblies in the fuel storage pool. However, prior to resuming movement of fuel assemblies, the concentration of boron must be restored. This suspension of fuel movement does not preclude movement of a fuel assemblies to a safe position.~~

If the LCO is not met while moving irradiated fuel assemblies in ~~MODE 5 or 6~~, LCO 3.0.3 would not be applicable. ~~If moving irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the fuel movement is independent of reactor operation. Therefore, since the inability to suspend movement of fuel assemblies is not sufficient reason to require a reactor shutdown.~~

SURVEILLANCE
REQUIREMENTS

SR 3.7.16.1

This SR verifies ~~by chemical analysis~~ that the concentration of boron in the ~~spent~~ fuel storage pool is ~~within at or above~~ the required limit. AS long as this SR is met, the analyzed accidents are fully addressed. The ~~7 31~~ day Frequency is appropriate because no major replenishment of pool water is expected to take place ~~ever such a short period of time.~~

B 3.7 PLANT SYSTEMS

B 3.7.17 Spent Fuel Assembly Storage

BASES

BACKGROUND

~~In the Maximum Density Rack (MDR) [(Refs. 1 and 2)] design, The spent fuel storage pool is divided into two separate and distinct regions which, for the purpose of criticality considerations, are considered as separate pools. [Region 1], with [336] 290 storage positions, is designed to accommodate [has been analyzed for the storage of new fuel with a maximum enrichment of [4.65] wt% U-235, or spent fuel regardless of the discharge fuel burnup assemblies which meet the requirements of LCO 3.7.17.1. [Region 2], with [2670] 1034 storage positions, is designed to accommodate fuel of various initial enrichments which have accumulated minimum burnups within the acceptable domain according to Figure [3.7.17.12], in the accompanying [has been analyzed for the storage of fuel assemblies which meet the requirements of LCO 3.7.17.2. Fuel assemblies not meeting the criteria of Figure [3.7.17.1] shall be stored in accordance with paragraph 4.3.1.1 in Section 4.3, Fuel Storage.~~

The water in the spent fuel storage pool normally contains soluble boron, which results in large subcriticality margins under actual operating conditions. However, the NRC guidelines, based upon the accident condition in which all soluble poison is assumed to have been lost, ~~specify require~~ that the limiting k_{eff} of the fuel configuration is at or below the limit of 0.95 be evaluated in the absence of soluble boron. Hence, the design analysis of both regions is based on the use of unborated water, which maintains each region in a subcritical condition during normal operation with the regions fully loaded. The double contingency principle discussed in ANSI N-16.1-1975 and the April 1978 NRC letter (Ref. 3) allows credit for soluble boron under other abnormal or accident conditions, since only a single accident need be considered at one time. ~~For example, the most severe accident scenario is associated with the movement of fuel from [Region 1 to Region 2], and accidental misloading of a fuel assembly in [Region 2]. This could potentially increase the criticality of [Region 2]. To mitigate these postulated criticality related accidents, boron is dissolved in the pool water. Safe operation of the MDR with no movement of assemblies may therefore be achieved by controlling the location of each assembly in accordance with the accompanying LCO.~~

Prior to movement of an assembly, it is necessary to ~~verify that perform SR 3.7.16.1 is current.~~

(continued)

BASES

APPLICABLE
SAFETY ANALYSES

The hypothetical accidents can only take place during or as a result of the movement of an assembly. The analyzed accidents that could have significant reactivity effects are the misplacement of a fuel assembly, a significant increase in spent fuel pool temperature above the design basis temperature of 150°F, or a cask drop accident (Ref. 4 2, 3, and 4). For these accident occurrences, the presence of soluble boron in the spent fuel storage pool (controlled by LCO 3.7.16, "Spent Fuel Storage Pool Boron Concentration") ensures that k_{eff} will remain at or below 0.95 prevents criticality in both regions. By closely controlling the movement of each assembly and by checking the location of each assembly after movement, the time period for potential accidents may be limited to a small fraction of the total operating time. During the remaining time period with no potential for accidents, the operation may be under the auspices of the accompanying LCO.

The configuration of fuel assemblies in the fuel storage pool satisfies Criterion 2 of 10 CFR 50.36 (c) (2) (ii).

LCO

The restrictions on the placement of fuel assemblies within the spent fuel pool, in accordance with LCO 3.7.17.1 and 3.7.17.2 Figure 3.7.17.1 or 3.7.17.2, in the accompanying LCO, ensures the k_{eff} of the spent fuel storage pool will always remain ≤ 0.95 , assuming the pool to be flooded with unborated water at a temperature of $\leq 150^\circ\text{F}$. Fuel assemblies not meeting the criteria of Figure [3.7.17.1] shall be stored in accordance with Specification 4.3.1.1 in Section 4.3.

APPLICABILITY

This These LCOs applies apply whenever any fuel assembly is stored in [Region 2] of the spent fuel storage pool.

ACTIONS

A.1

The Required Action A.1 is modified by a Note indicating that LCO 3.0.3 does not apply since the inability to move fuel assemblies is not sufficient reason to require a reactor shutdown.

When the configuration of fuel assemblies stored in [Region 2] the spent fuel storage pool is not in accordance with Figure 3.7.17.1 LCO 3.7.17.1 and 3.7.17.2, or paragraph 4.3.1.1, the immediate action is to initiate action to make the necessary fuel assembly movement(s) to bring the configuration into compliance with Figure 3.7.17.1 LCO 3.7.17.1 and 3.7.17.2 or

(continued)

BASES

~~Specification 4.3.1.1 which will return the fuel pool to an analyzed condition.~~

~~If unable to move irradiated fuel assemblies while in MODE 5 or 6, LCO 3.0.3 would not be applicable. If unable to move irradiated fuel assemblies while in MODE 1, 2, 3, or 4, the action is independent of reactor operation. Therefore, inability to move fuel assemblies is not sufficient reason to require a reactor shutdown.~~

SURVEILLANCE
REQUIREMENTS

~~SR 3.7.17.1.1 and SR 3.7.17.1.2~~

~~These SRs verify by administrative means that the each fuel assembly and its expected storage location are in accordance with the applicable LCO (3.7.17.1 or 3.7.17.2), prior to each fuel assembly move when the assembly is to be stored in Region 1 or 2 of the spent fuel pool. Initial enrichment and burnup of the fuel assembly is in accordance with Figure [3.7.17.1] in the accompanying LCO. For fuel assemblies in the unacceptable range of Figure 3.7.17.1, performance of this SR will ensure compliance with Specification 4.3.1.1.~~

B 3.7 PLANT SYSTEMS

B 3.7.18 Secondary Specific Activity

BASES

BACKGROUND

Activity in the secondary coolant results from steam generator tube outleakage from the Reactor Coolant System (RCS). Under steady state conditions, the activity is primarily iodines with relatively short half lives and, thus, indicates current conditions. During transients, I-131 spikes have been observed as well as increased releases of some noble gases. Other fission product isotopes, as well as activated corrosion products in lesser amounts, may also be found in the secondary coolant.

A limit on secondary coolant specific activity during power operation minimizes releases to the environment because of normal operation, anticipated operational occurrences, and accidents.

This limit is lower than the activity value that might be expected from a 1 gpm tube leak (LCO 3.4.13, "RCS Operational LEAKAGE") of primary coolant at the limit of 1.0 $\mu\text{Ci/gm}$ (LCO 3.4.16, "RCS Specific Activity"). The steam line failure is assumed to result in the release of the noble gas and iodine activity contained in the steam generator inventory, the feedwater, and the reactor coolant LEAKAGE. Most of the iodine isotopes have short half lives, (i.e., < 20 hours). I-131, with a half life of 8.04 days, concentrates faster than it decays, but does not reach equilibrium because of blowdown and other losses. ~~Operating at or below 0.1 $\mu\text{Ci/gm}$ ensures that in the event of a DBA, offsite doses will be less than 10 CFR 100 requirements.~~

~~With the specified activity limit, the resultant 2-hour thyroid dose to a person at the exclusion area boundary (EAB) would be about 0.58 rem if the main steam safety valves (MSSVs) open for 2 hours following a trip from full power.~~

~~Operating a unit at the allowable limits could result in a 2-hour EAB exposure of a small fraction of the 10 CFR 100 (Ref. 1) limits, or the limits established as the NRC staff approved licensing basis.~~

APPLICABLE
SAFETY ANALYSES

The accident analysis of the main steam line break (MSLB), as discussed in the FSAR, Chapter 15 (Ref. 2) assumes the initial secondary coolant specific activity to have a radioactive isotope concentration of 0.10 $\mu\text{Ci/gm}$ DOSE EQUIVALENT I-131. This assumption is used in the analysis for determining the radiological consequences of the postulated accident. The accident analysis, based on this and other assumptions, shows that the radiological consequences of an MSLB do not exceed a

(continued)

BASES

~~small fraction of the unit EAB10 CFR 100~~ limits (Ref. 1) for whole body and thyroid dose rates.

With the loss of offsite power, the remaining steam generators are available for core decay heat dissipation by venting steam to the atmosphere through the MSSVs and steam generator atmospheric dump valves (ADV). The Auxiliary Feedwater System supplies the necessary makeup to the steam generators. Venting continues until the reactor coolant temperature and pressure have decreased sufficiently for the Residual Heat Removal System to complete the cooldown.

In the evaluation of the radiological consequences of this accident, the activity released from the steam generator connected to the failed steam line is assumed to be released directly to the environment. The unaffected steam generators ~~are~~ ~~is~~ assumed to discharge steam and any entrained activity through the MSSVs and ADVs during the event. ~~Since no credit is taken in the analysis for activity plateout or retention, the quantity of radioactivity released to the environment due to an SGTR depends upon primary and secondary coolant activity, iodine spiking effects, primary to secondary break flow flashing fractions, attenuation of iodine carried by the flashed portion of the break flow, partitioning of iodine between the liquid and steam phases, the mass of fluid released from the steam generator, and liquid-vapor partitioning in the condenser hotwell. All of these parameters were conservatively evaluated in a manner consistent with the recommendations of Standard Review Plan Section 15.6.3 and the resultant radiological consequences represent a conservative estimate of the potential integrated dose due to the postulated steam line failure.~~

Secondary specific activity limits satisfy Criterion 2 of 10 CFR 50.36 (c) (2) (ii).

LCO

As indicated in the Applicable Safety Analyses, the specific activity of the secondary coolant is required to be $\leq 0.10 \mu\text{Ci/gm DOSE EQUIVALENT I-131}$ to limit the radiological consequences of a Design Basis Accident (DBA) to a small fraction of the required limit (Ref. 1).

Monitoring the specific activity of the secondary coolant ensures that when secondary specific activity limits are exceeded, appropriate actions are taken in a timely manner

BASES

to place the unit in an operational MODE that would minimize the radiological consequences of a DBA.

APPLICABILITY

In MODES 1, 2, 3, and 4, the limits on secondary specific activity apply due to the potential for secondary steam releases to the atmosphere.

In MODES 5 and 6, the steam generators are not being used for heat removal. Both the RCS and steam generators are depressurized, and primary to secondary LEAKAGE is minimal. Therefore, monitoring of secondary specific activity is not required.

ACTIONS

A.1 and A.2

DOSE EQUIVALENT I-131 exceeding the allowable value in the secondary coolant, is an indication of a problem in the RCS and contributes to increased post accident doses. If the secondary specific activity cannot be restored to within limits within the associated Completion Time, the unit must be placed in a MODE in which the LCO does not apply. To achieve this status, the unit must be placed in at least MODE 3 within 6 hours, and in MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required unit conditions from full power conditions in an orderly manner and without challenging unit systems.

SURVEILLANCE
REQUIREMENTS

SR 3.7.18.1

This SR verifies that the secondary specific activity is within the limits of the accident analysis. A gamma isotopic analysis of the secondary coolant, which determines DOSE EQUIVALENT I-131, confirms the validity of the safety analysis assumptions as to the source terms in post accident releases. It also serves to identify and trend any unusual isotopic concentrations that might indicate changes in reactor coolant activity or LEAKAGE. The 31 day Frequency is based on the detection of increasing trends of the level of DOSE EQUIVALENT I-131, and allows for appropriate action to be taken to maintain levels below the LCO limit.

Methodology For Mark-up of NUREG-1431 Bases

Enclosure 5B contains an electronic (or hand written) mark-up of the Bases portion of NUREG 1431, Rev. 1. The Bases is descriptive in nature but provides significant clarification and, in some cases, technical information which supports the specifications. The version in the NUREG is generic while the improved TS version has been made plant specific.

To the extent possible, the words of NUREG 1431, Rev. 1 are retained to maximize standardization. Where the existing words in the NUREG are incorrect or misleading, they have been corrected. In addition, descriptions have been added to cover plant specific portions of the specifications.

The changes are processed as follows:

There are four types of changes:

1. Deletions - Material which is removed from NUREG-1431, Rev. 1 Bases.
2. Additions - This includes material which is added to NUREG-1431, Rev. 1 Bases.
3. Modifications - This includes material which exist in NUREG-1431, Rev. 1 Bases but is being revised for the improved TS.
4. Bracket Inserts - These changes involve the insertion of plant specific information which is presently located in the current TS or other design basis document into a bracketed portion of NUREG-1431, Rev. 1 Bases.

The methodology of identifying the changes is :

- Deletions - The portion of the specification which is being deleted in non-bracketed areas of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletions are not identified by a change number or a change code in the adjacent right margin.
- Additions - The information being added to the non-bracketed portions of NUREG-1431, Rev. 1 Bases is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is not identified by a change number or a change code in the adjacent right margin.
- Modifications - The information being revised in the non-bracketed portions of NUREG-1431, Rev. 1 Bases is annotated using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the Bases in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is not identified by an item number or a change code in the adjacent right margin.
- Bracket Inserts - The plant specific information is entered into the bracketed area. If "generic" information had been provided in the bracketed area and that information is not correct, the "generic" information is "struck-out" and the correct material is inserted using the "red-line" feature. If the "generic" is correct, the information is "red-lined." The brackets are also deleted. An identification number to cross-reference to an explanation or justification is not provided.

Note: All brackets are deleted from the mark-up of NUREG-1431, Rev. 1 Bases as part of the mark-up process. Reviewer notes may be "struck-out" or deleted as preferred

In summary, "red-line" (or hand written/insert pages) is used to annotate new material, "strike-out" (or crossed out by hand) is used to annotate deleted material. Neither identification numbers nor change codes are used to identify changes in the Bases.

DIFFERENCES FROM NUREG-1431

Descriptions of NUREG-1431 Differences

(5 Pages)

JUSTIFICATION FOR DIFFERENCES FROM NUREG 1431

NUREG-1431 Section 3.7

This Enclosure contains a brief discussion/justification for each marked-up technical change to NUREG-1431 to make them plant specific or to incorporate generic changes resulting from the Industry/NRC generic change process. The change numbers are referenced directly from the NUREG-1431 mark-ups (Enclosure 5A). For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

CHANGE NUMBER

JUSTIFICATION

3.7-01

ACTION A.1 is revised, new ACTION A.2 is added, and Table 3.7.1-1 is revised consistent with Traveler WOG-83, Rev. 0 to account for the fact that a reduction in power level is not directly proportional to the reduction in main steam safety valves (MSSV) relieving capability and plants which may operate for some part of a fuel cycle with a positive moderator temperature coefficient (MTC). Per Westinghouse Nuclear Safety Advisory Letter, NSAL 94-001, if the MTC is positive at the required reduced power level, the reactor coolant system (RCS) heat up following a turbine trip event could result in a core power increase and additional heat transfer to the secondary system which may not be attenuated without over pressurizing the main steam system. To preclude this condition the power range neutron flux high trip set point is required to be reset to a power level consistent with the number of inoperable safety valves within 72 hours. [A Note is added that states that Required Action A.2 is only applicable in MODE 1]. These changes are consistent with Westinghouse Owners Group (WOG) Traveler WOG-83 and NSAL 94-001.

A recent revision to WOG-83 (Rev.1) has been proposed requiring that the power range neutron flux trip high setpoints be reduced when at a reduced reactor power level to account for a control rod withdrawal event at reduced reactor power. The identification of this issue has identified a non-conservatism in NUREG-1431. Consequently, the requirement in the CTS to reduce the power range neutron flux trip high setpoints with inoperable MSSVs [regardless of the value of MTC] is retained. However, the 72 hour Completion Time proposed in the traveler is incorporated into the ITS. These changes are acceptable because the retention of the requirement to reduce the power range flux trip high setpoint is more conservative than NUREG-1431 or WOG-83 and the extended Completion Time recognizes the low probability of an event occurring during the 72 hours allowed to reset the trip setpoints.

3.7-02

Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B)

3.7-03

SR 3.7.3.1 is divided into two surveillances since both the stroke time and the surveillance Frequency requirements are different for the feedwater regulation and associated bypass valves and the feedwater isolation valves.

3.7-04

Not applicable to DCPD. See Conversion Comparison Table (Enclosure 6B)

**CHANGE
NUMBER**

JUSTIFICATION

- 3.7-05 Required Action B.1 is revised to state and new C.1 states respectively that restoration of "all but one" and "all but two" atmospheric [dump] valves [(ADV)] is required which will effectively exit the respective Required Actions. This is consistent with the Bases of NUREG-1431. The specific change proposed by Industry Traveler TSTF-100 is to add the "all but one" phrase to Required Action B for plants that only require three [ADV]s to be OPERABLE. The addition of the "all but two" phrase to new Required Action C.1 is to account for the requirement to have four [ADV]s OPERABLE.
- 3.7-06 The Condition and Required Action for two or more inoperable [ADV] lines is revised to limit the applicability to only two inoperable [ADV] lines and the Completion Time is revised from 24 to 72 hours per the current licensing basis. A new Condition C for three or more [ADV] lines inoperable for plants that require four [ADV] lines is proposed. The original Condition C is retained and relabeled as Condition D. These changes are consistent with the intent of NUREG 1431.
- 3.7-07 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-08 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-09 New Conditions, F, G, and H, and the SR associated with the fire water storage tank (FWST) AFW pump supply are relocated from the CTS on AFW supply and included in the AFW specification for completeness.
- 3.7-10 Consistent with the CTS, ITS 3.7.6 specification description, the LCO, the ACTION requirements and the Surveillances are revised to incorporate the specific requirement of an OPERABLE AFW supply source via the CST and the FWST. The volumes in gallons are converted to the equivalent level in tank percent full. The control room readouts are in percent level.
- 3.7-11 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B)
- 3.7-12 Not applicable to DCP. See Conversion Comparison Table (Enclosure 6B)
- 3.7-13 ITS 3.7.8, ACTION A.1, Note 1, under Required Action A.1 is deleted consistent with the CTS. The emergency diesel generators have no interface with the auxiliary saltwater (ASW) system or the closed cooling water (CCW) system; each diesel has its own self contained cooling system.
- 3.7-14 Consistent with the CTS, the ITS SR 3.7.8.1 Note which states that isolation of individual components does not render the [ASW] inoperable is deleted since the [ASW] system supplies only the CCW heat exchanger and no other individual components.

**CHANGE
NUMBER**

JUSTIFICATION

- 3.7-15 SR 3.7.8.1 is revised to include a requirement to verify that power and air is available such that the valves may be placed in their required positions as described in the Bases. The normal operating configuration may require reconfiguration for an ASW pump failure or for train separation for long term heat removal following a DBA. The OPERABILITY defined in the LCO states valves must be capable of performing their safety-related function. Motive force is required for the valves to be OPERABLE.
- 3.7-16 SR 3.7.8.2 is revised to include only power operated valves since there are no automatically operated valves in the ASW system. The surveillance is revised to require movement of power operated valves to demonstrate the ability to reconfigure the ASW system as described in the FSAR and the ITS Bases. These changes assure continued compliance with the existing licensing basis.
- 3.7-17 The UHS specification is revised, per the current licensing basis, to specify that for the system to perform its intended function, it is temperature limited. The Required Action A is revised to include the CTS license basis requirements which encompasses ACTION B, thus the ACTION B inoperable statement is deleted. The surveillance requirements are revised per the CTS and renumbered with respect to temperature limits and frequencies and the remaining NUREG-1431 surveillances that are not applicable are deleted.
- 3.7-18 The CTS surveillance for leakage testing of ABVS dampers M2A and M2B is retained.
- 3.7-19 Not applicable to DCCP, See Conversion Comparison Table (Enclosure 6B).
- 3.7-20 Not applicable to DCCP, See Conversion Comparison Table (Enclosure 6B).
- 3.7-21 The ACTIONS are revised to include the CTS action requirement for an inoperable HEPA filter and/or charcoal absorber. SR 3.7.12.1 is revised to reflect the plant design of one common charcoal absorber bank and the appropriate charcoal absorber drying time.
- 3.7-22 SR 3.7.12.3 is revised consistent with the CTS, to describe the expected actions upon an actuation of the ABVS. This revision reflects the plant design of one common HEPA filter and charcoal absorber bank, and the need to verify alignment for flow through the bank.
- 3.7-23 ACTION C and SR 3.7.12.4 are deleted consistent with the CTS, since the ABVS was not designed to maintain a specific negative pressure. The system is designed and balanced to maintain building inflow, but not at a specific negative pressure.
- 3.7-24 SR 3.7.12.5 is deleted consistent with the CTS, since there are no ABVS bypass dampers and the dampers that activate to align the system to the common HEPA filter charcoal absorber bank are tested by SR 3.7.12.3.
- 3.7-25 Not applicable to DCCP. See Conversion Comparison Table (Enclosure 6B).

**CHANGE
NUMBER**

JUSTIFICATION

- 3.7-26 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-27 A Note is added to Table 3.7.1-2 under LIFT SETTING that specifies that the lift point of the lowest set safety is +3% and -2%.
- 3.7-28 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-29 Revise AFW pump testing Frequency to be "In accordance with Inservice Test Program." These changes are consistent with TSTF-101, and will eliminate any ambiguity associated with pump testing as a result of ASME changes.
- 3.7-30 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-31 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-32 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-33 The requirement to verify a make-up flow rate during the tests demonstrating the capability to maintain control room differential pressure above atmospheric pressure would be deleted. The current licensing basis of the plant is to be able to maintain a positive pressure in the control room with respect to the outside atmosphere.
- 3.7-34 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-35 SR 3.7.10.3 is revised to reflect plant configuration and current licensing basis required testing.
- 3.7-36 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-37 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-38 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-39 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-40 Not used.
- 3.7-41 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-42 This change adds a Note that states that LCO 3.0.3 is not applicable to the fuel handling building ventilation system during fuel movement since fuel movement is independent of reactor operation. This exemption is part of the DCPP CTS and has been proposed as a generic change to NUREG-1431 by Industry Traveler TSTF-36, Rev. 2.
- 3.7-43 ACTION A is revised and ACTIONS C and E are not used per the current licensing basis. The FHBVS for the plant does not act as part of the ventilation system used to filter post LOCA leakage external to the containment.

**CHANGE
NUMBER**

JUSTIFICATION

- 3.7-44 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-45 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-46 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-47 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-48 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).
- 3.7-49 The requirement to verify a make-up flow rate during the tests demonstrating the capability to maintain [fuel handling] building differential pressure below atmospheric pressure would be deleted. The current licensing basis of the plant is to be able to maintain a negative pressure [in the fuel handling building] with respect to the outside atmosphere.
- 3.7-50 The CTS ADV surveillance that verifies the back-up air bottle pressure once per 24 hours is retained.
- 3.7-51 A new spent fuel pool storage specification is created for Region 1 fuel storage due to the unique storage requirements.
- 3.7-52 ITS 3.7.11 is not used due to the mild coastal environment in which DCPP is located, consistent with the CTS.
- 3.7-53 ITS 3.7.16 is revised to be consistent with the current licensing basis and CTS. The boron concentration is required to be within limits whenever fuel is stored in the spent fuel pool to prevent an increase in the k_{eff} of the racks above 0.95 should the spent fuel pool temperature increase above 150°F. The Frequency for verification of the boron concentration is changed from 7 days to 31 days consistent with the CTS.
- 3.7-54 The LCO, Required Actions, and Surveillances are revised per the CTS. The CTS evaluates Region 2 fuel storage on fuel pellet diameter and a checker board loading pattern in addition to the other NUREG-1431 requirements.
- 3.7-55 The NUREG-1431 3.7.1.4 specification is not used since an equivalent safety grade system does not exist. Therefore, the deletion is per the current licensing basis.
- 3.7-56 This change creates a new SR for the MSIVs and MFIVs to distinguish between the IST and the automatic actuation testing of these isolation valves. The surveillance allows credit for an actual actuation, if one occurs, to satisfy the surveillance requirements. These changes are consistent with WOG-98. Although SRs 3.7.2.2 and 3.7.3.2 are new SRs, they may be performed in conjunction with SRs 3.7.2.1 and 3.7.3.1. Therefore, the Note allowing testing to be performed on MODE 3 is also needed for these new SRs.
- 3.7-57 Not applicable to DCPP. See Conversion Comparison Table (Enclosure 6B).

ENCLOSURE 6B

CONVERSION COMPARISON TABLE - NUREG-1431

Conversion Comparison Table

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-01	ACTION A.1 is revised [new ACTION A.2 is added , and Table 3.7.1-1 is revised] to account for operation with inoperable MSSVs and resetting the power range neutron flux high trip setpoints with inopreable MSSVs. The Compeltion Time to reset the power range neutron flux high trip setpoints is extended to 72 hours. [The table is revised based on NSAL 94-001 and deletes the reference to five OPERABLE MSSVs.]	Yes	Yes	Yes	YES
3.7-02	The CTS Applicability of MODES 1, 2, and 3 is being retained in ITS 3.7.2, MSIVs, and ITS 3.7.3, MFIVs.	No, DCPD is adopting ITS.	No, CPSES is adopting ITS.	Yes	YES
3.7-03	SR 3.7.3.1 is divided into two surveillances since both the stroke time and the Frequency requirements are different at DCPD for the feedwater regulation/bypass valves and the feedwater isolation valve.	Yes, per LA 7776	No	No	No
3.7-04	Requirements involving reliance on the SG heat removal system for heat removal in MODE 4 would be deleted.	No, DCPD is adopting ITS.	Yes	Yes	Yes
3.7-05	Required Action B.1 and new C.1 are revised to state that restoration of "all but one" and "all but two" [ADV] lines is required which will effectively exit the respective Required Action.	Yes	Yes	No, refer to 3.7-19.	No, refer to 3.7-19.
3.7-06	The Condition and Required Action for two or more inoperable [ADV] lines is limited to two [ADV] lines and the Completion Time is revised from 24 to 72 hours per the current licensing basis. A new Condition C is added.	Yes	Yes	No, not part of CTS.	No, not part of CTS.
3.7-07	Revised Conditions A and C to be consistent with CTS. The ITS as written would have allowed the OPERABLE EES train to remain in standby during movement of irradiated fuel.	No, not part of CTS.	No, not part of CTS.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-08	SR 3.7.5.1 is revised to add a Note consistent with the CTS and the plant specific design. The verification of flow control valve position is deferred until conditions are appropriate.	No, AFW valves have a correct position.	Yes	Yes	Yes
3.7-09	New Conditions F, G, and H and the surveillance requirement associated with the FWST AFW pump supply are relocated from the CTS on AFW supply and included in the DCPD AFW specification for completeness.	Yes	No	No	No
3.7-10	The specification description, the LCO, the ACTION requirements and the Surveillance are revised to incorporate the DCPD plant specific requirement for OPERABLE AFW supply sources via the CST and the FWST per the current licensing basis.	Yes	No	No	No
3.7-11	The Required Actions for CPSES feedwater isolation and associated bypass valves inoperable are revised consistent with the current licensing basis for a Completion Time of 4 hours and to credit the MFRVs (feedwater control valves (FCVs)) and associated bypass valves for a Completion Time of 72 hours. A new SR is added for the FCVs and associated bypass valves.	No	Yes	No	No
3.7-12	WOG-83 revised Condition A and Table 3.7-1 to account for plants that credit the Power Range High Neutron Flux trip function when MTC is positive (See 3.7-01 above). The wording of the traveler has been modified for CPSES to account for plant specific differences.	No	Yes	No	No
3.7-13	Note 1. under Action Required A.1 is deleted. The DCPD emergency diesel generators have self contained cooling systems that do not rely upon an external source of cooling water.	Yes	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-14	The Note for SR 3.7.8.1 is deleted since the DCPD ASW system supplies only the CCW heat exchanger and no other individual components.	Yes	No	No	No
3.7-15	SR 3.7.8.1 is revised to include a DCPD specific requirement to verify the availability of power and air so that the valves can be placed in their correct positions as described in the Bases.	Yes	No	No	No
3.7-16	SR 3.7.8.2 is revised to include only power operated valves since there are no automatically operated valves in the DCPD ASW system. The surveillance is revised to require movement of power operated valves to demonstrate the ability to reconfigure the ASW system as described in the FSAR and the ITS Bases.	Yes	No	No	No
3.7-17	The DCPD UHS specification is revised to reflect the fact that for the system to perform its intended function, it is temperature limited. The LCO is revised to note that the specification limits the temperature to less than or equal to 64°F. SR numbers are revised accordingly and the remaining surveillances are deleted as being not applicable.	Yes	No	No	No
3.7-18	The DCPD specific CTS surveillance for leakage testing of ABVS dampers M2A and M2B is retained.	Yes	No	No	No
3.7-19	Required Action B.1 is revised to state that restoration of "all but" one [ASD] line is required, which will effectively exit Required Action B.1 and re-enter Required Action A.1.	No, refer to change 3.7-5 and 3.7-6.	No, refer to change 3.7-5 and 3.7-6.	Yes	Yes
3.7-20	A Callaway specific Condition is added to address the inoperability of one of the Essential Service Water (ESW) supplies to the turbine-driven AFW pump.	No	No	No	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-21	The ACTIONS and SR 3.7.12.1 are revised to include the DCPD specific CTS ACTION requirement for an inoperable HEPA filter and/or charcoal absorber and to provide the appropriate charcoal absorber monthly drying time for the single common charcoal absorber.	Yes	No	No	No
3.7-22	SR 3.7.12.3 is revised for DCPD to describe the expected actions upon an actuation of the ABVS.	Yes	No	No	No
3.7-23	ACTION C and SR 3.7.12.4 are deleted since the DCPD ABVS was not designed to maintain a specific negative pressure.	Yes	No	No	No
3.7-24	SR 3.7.12.5 is deleted since there are no DCPD ABVS bypass dampers and the system automatic dampers are tested by SR 3.7.12.3.	Yes	No	No	No
3.7-25	Based on the CTS, a Note is added to [SR 3.7.3.1, 3.7.3.2, 3.7.4.1 and 3.7.4.2] to indicate that demonstration of valve OPERABILITY is only required to be performed for entry into (and continued operation in) MODES 1 and 2. This Note states that the SR is only required to be performed in MODES 1 and 2. This would allow entry into MODE 3 for the purpose of testing the valves.	No, note is not part of CTS.	No, note is not part of CTS.	Yes	Yes
3.7-26	Condition D is deleted to reflect the CPSES plant specific design of primary FIVs and associated bypass valves and isolation backup via the in series FCVs and associated bypass valves.	No	Yes	No	No
3.7-27	A Note is added to DCPD Table 3.7.1-2 under Lift Setting that specifies that the lift point of the lowest set safety is +3% and -2%.	Yes (per LA 108/107)	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-28	Revise [ADV] Frequency from 18 months to "in accordance with Inservice Test Program."	No, CTS is 18 months.	Yes	Yes	Yes
3.7-29	Revise AFW pump testing to be "In accordance with Inservice Test Program."	Yes	Yes	Yes	Yes
3.7-30	LCO 3.7.8 and ACTIONs are revised for CPSES to incorporate requirements for two units with station service water system cross connections.	No, covered by ECG per GL 91-13 response.	Yes	No, single unit plant.	No, single unit plant.
3.7-31	SR 3.7.8.2 is replaced with the current CPSES specific surveillance of the cross connections between units. The CPSES design has no automatic valves as per this SR in the ITS.	No, refer to 3.7-15 and 3.7-16.	Yes	No	No
3.7-32	CONDITION A for CPSES is changed to "SSI level less than required" and SR 3.7.9.3 and 3.7.9.4 are deleted.	No	Yes	No	No
3.7-33	The requirement to verify a make-up flow rate during the tests demonstrating the capability to maintain control room differential pressure above atmospheric pressure would be deleted.	Yes, per CTS.	No, retained CTS requirement.	Yes	Yes
3.7-34	In accordance with Traveler WOG-64, the Completion Time for closing one inoperable MSIV is extended to 72 hours; and separate Required Actions are included for either one MSIV inoperable or two or more MSIVs inoperable in MODES 2 and 3.	No, adopting 8 hour AOT from STS.	Yes	Yes	Yes
3.7-35	SR 3.7.10.3 is revised to reflect DCCP specific plant configuration and CTS required testing.	Yes	No	No	No
3.7-36	Required Actions D and E are revised for CPSES for two trains inoperable where at least 100% of the required heat removal capacity is available.	No	Yes	No	No

DCCP Conversion Comparison Table - Improved TS

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-37	Modifies LCO 3.7.2 Condition A and adds new Condition B and C to be consistent with the CPSES CTS.	No	Yes	No	No
3.7-38	This proposed change deletes reference to a specific flowrate for conducting the negative pressure test per the CPSES CTS.	No, see CN 3.7-49.	Yes	No, see CN 3.7-49.	No, see CN 3.7-49.
3.7-39	SR 3.7.12.6 is added to verify the shutdown of the non-ESF fans to prevent bypass of the ESF Filtration units (CPSES specific).	No	Yes	No	No
3.7-40	Not used.	N/A	N/A	N/A	N/A
3.7-41	The Main Feedwater Regulating and associated Bypass Valves are deleted from the ITS per current licensing basis.	No, CTS includes MFRVs.	No, refer to 3.7-11.	Yes	Yes
3.7-42	Add DCPD specific note that states that 3.0.3 is not applicable to the fuel handling building ventilation system during fuel movement since fuel movement is independent of reactor operation.	Yes	No	No	No
3.7-43	ACTION A of ITS 3.7.13 is revised and ACTIONS C, E and F.1 of ITS 3.7.13 are not used per the DCPD CTS.	Yes	No	No	No
3.7-44	This change would revise ITS 3.7.13 to add a new Note to the Applicability and change the Conditions, Required Actions, and SRs to conform to the design of the Emergency Exhaust System.	No, fuel building ventilation not required for post LOCA leakage.	No, CTS does not require this specification.	Yes	Yes

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-45	ITS 3.7.15 is revised to be CPSES specific to address the two spent fuel pools and the in-containment storage racks.	No	Yes	No	No
3.7-46	Revised to delete "irradiated fuel assemblies seated in" since accident analysis assumes fuel assembly lying on top of the fuel storage racks.	No, ITS is consistent with CTS.	Yes	No, ITS is consistent with CTS.	Yes
3.7-47	This change adds TS 3.7.19, a safety chilled water system which is in the CPSES CTS.	No	Yes	No	No
3.7-48	This change adds TS 3.7.20, an UPS HVAC system which is in the CPSES CTS.	No	Yes	No	No
3.7-49	The requirement to verify a make-up flow rate during the tests demonstrating the capability to maintain [fuel handling] building differential pressure below atmospheric pressure would be deleted. The current licensing basis of the plant is to be able to maintain a negative pressure [in the fuel handling building] with respect to the outside atmosphere.	Yes	No, see CN 3.7-38.	Yes	Yes
3.7-50	The CTS DCPD specific ADV surveillance that verifies the back-up air bottle pressure once per 24 hours is retained.	Yes	No	No	No
3.7-51	A new spent fuel pool storage specification is created for Region 1 fuel storage due to unique storage requirements at DCPD.	Yes	No	No	No
3.7-52	ITS 3.7.14 is not used due to the mild coastal environment in which the plant is located.	Yes	No	No	No
3.7-53	ITS 3.7.16 for DCPD is revised to be consistent with the current licensing basis and CTS.	Yes	No	No	No

CONVERSION COMPARISON TABLE FOR DIFFERENCES FROM NUREG-1431, SECTION 3/4.7

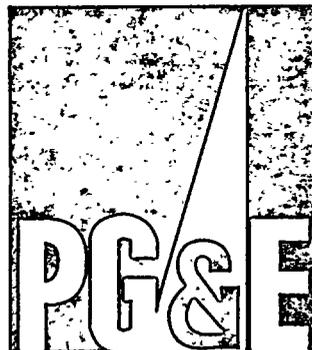

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
NUMBER	DESCRIPTION	DIABLO CANYON	COMANCHE PEAK	WOLF CREEK	CALLAWAY
3.7-54	The LCO, Required Actions, and Surveillances are revised per the DCPD specific CTS to incorporate Region 2 fuel storage requirements.	Yes, per LA 116/114.	No	No	No
3.7-55	NUREG-1431 Specification 3.7.14 is not used since an equivalent safety grade system does not exist. Therefore, the deletion is per the current licensing basis.	Yes	No	No	No
3.7-56	This change creates a new SR for the MSIVs [and MFIVs] to distinguish between the IST and the automatic actuation testing of these isolation valves. The SR allows credit for an actual actuation, if one occurs, to satisfy the surveillance requirements. Although SRs 3.7.2.2 and 3.7.3.2 are new SRs, they may be performed in conjunction with SRs 3.7.2.1 and 3.7.3.1. Therefore, the Note allowing testing to be performed on MODE 3 is also needed for these new SRs.	Yes	Yes	Yes	Yes
3.7-57	This change establishes appropriate Required Actions and Completion Times for ventilation system pressure envelope degradation.	{No, retained CTS.}	Yes	Yes	Yes

Methodology for Cross-Reference Tables

The cross-reference tables provide a guide to location of all current TS LCOs, ACTIONS, Surveillances, Tables, and Figures in the improved TS. It also includes the location of items that have been located out of the improved TS.

The cross-reference table contains the following columns:

Current TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated technical specification.

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	- The LCO operability requirement
APP	- The APPLICABILITY requirement
CONDITION / ACTION	- The ACTION requirements
SR	- The SURVEILLANCE REQUIREMENTS

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general, the numbering and lettering used in the current TS will be provided but in some cases it may be appropriate to provide a description. For example in specification 3/4.7.7.1, the actions are arranged by those that apply in MODES 1, 2, 3, & 4 and those that apply in MODES 5, 6 and during movement of irradiated fuel assemblies. Appropriate entries in this column for these respective actions might be "MODES 1-4" and "MODES 5, 6, etc." Multiple paragraphs are not listed in the same row (e.g., "a and b").

New This item has been added to reflect a requirement in NUREG-1431 that is not addressed in the current TS.

NA This item is not in the current TS because it does not apply.

Note: When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry is made for each cross-reference. A single entry is not used to identify the multiple paragraphs in the improved TS. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS, separate entries, each referencing the same location in the improved TS, are made for each such paragraph in the current TS.

**Methodology for Cross-Reference Tables
(Continued)**

Improved TS:

LCO/SR number (Item) -

This column lists the LCO or SR number which applies as listed in the associated specification or uses the following code:

Relocated	This item is relocated to another licensee control document outside the TS (see Code for specific reference location).
-----------	--

Requirement code (Code) -

This column identifies the portion of the specification affected using the following code:

LCO	-	The LCO operability requirement
APP	-	The APPLICABILITY requirement
CONDITION / ACTION	-	The ACTION requirements
SR	-	The SURVEILLANCE REQUIREMENTS

In addition, specific plant document acronyms are used to list the licensee controlled documents where the item will be relocated to (e.g., FSAR, TRM, etc.).

Note: The applicability of a current specification is assumed to transfer to the same improved specification as the LCO. The cross-reference for the applicability for the specification is only identified in the table by a separate entry if the cross-reference is not clear (e.g., several current specifications with different applicability are moved into the same specification in the improved TS, or a footnote in the applicability of the current TS is moved to a different portion of the specification in the improved TS).

Paragraph (Para) -

This column identifies the affected paragraph. In general the numbering and lettering used in the improved TS is provided but in some cases it may be appropriate to provide a description.

New	This item has been added to the improved TS and was not addressed in the NUREG-1431.
Not Used	This item will not be used in the improved TS, nor relocated to another document (e.g., requirements already adequately addressed by regulations).
NA	This item from NUREG-1431 is not included in the improved TS because it does not apply (e.g., specification unique to Ice Condenser Containments).

Note: The paragraph is only identified to the extent necessary to adequately describe the cross-reference. For example, if the cross-reference applies to the entire condition, it is appropriate to list the "Requirement Code" as "CONDITION" and the "Paragraph" as "A." If the correct cross-reference is only to the required action, an appropriate cross-reference would be to "Requirement Code" as "ACT" and "Paragraph" as "A.1."

Methodology for Cross-Reference Tables
(Continued)

Note:

When a single paragraph in the current TS crosses to multiple locations in the improved TS, a new entry for each cross-reference is made. Since multiple paragraphs in the current TS may cross-reference to the same paragraph in the improved TS; separate entries, each referencing the same location in the improved TS, is made for each such paragraph in the current TS. Multiple paragraphs are not listed (e.g. "A.1.1 and A.1.2") although a "higher tier" number is be used to cover all sub-paragraphs (e.g., "A.1" is be used to identify all subparagraphs such as A.1.1, A.1.2, etc.).

3/4.8 ELECTRICAL POWER SYSTEMS

3/4.8.1 A.C. SOURCES

OPERATING

LIMITING CONDITION FOR OPERATION

3.8.1.1 As a minimum, the following A.C. electrical power sources shall be OPERABLE:

- a. Two independent circuits (one with delayed access) between the offsite transmission network and the Onsite Class 1E Distribution System, and
- b. Three separate and independent diesel generators, each with:
 - 1. A separate engine-mounted fuel tank containing a minimum volume of 250 gallons of fuel, and
 - 2. Two supply trains of the Diesel Fuel Oil Storage and Transfer System containing a minimum combined storage of 33,000 gallons of fuel for one unit operation* and 65,000 gallons of fuel for two unit operation.**

01-01-A
01-31-A
01-48-M
01-48-M
01-64-M

(new) A lube oil inventory shall be within limits.

(new) A starting air receiver pressure shall be within limits, and

(new) A turbocharger air assist air receiver pressure shall be within limits.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

- a. With one offsite circuit of the above required A.C. electrical power sources inoperable, demonstrate the OPERABILITY of the remaining A.C. sources by performing Specification 4.8.1.1.a. within 1 hour and at least once per 8 hours thereafter. If each of the diesel generators have not been successfully tested within the past 24 hours demonstrate its OPERABILITY by performing Specification 4.8.1.1.2a.2) separately for each such diesel generator within 24 hours. Restore the offsite circuit to OPERABLE status within 72*** hours and within 10 days from discovery of failure to meet the LCO or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

.01-03-LS5
01-31-A
01-32-M

* The performance of diesel fuel oil tank cleaning Technical Specification Surveillance Requirement 4.8.1.1.3.e requires one fuel oil storage tank to be removed from service to be drained and cleaned. During this surveillance, the diesel generator fuel oil storage requirement for one unit operation in Modes 1 through 4 and one unit operation in Mode 6 with at least 23 feet of water above the reactor vessel flange or with the reactor vessel defueled is 35,000 gallons. The tank being cleaned may be inoperable for up to 10 days. For the duration of tank cleaning, temporary onsite fuel oil storage of 24,000 gallons will be maintained. Prior to removal of a tank from service, the offsite circuits required by Technical Specification 3.8.1.1.a will be verified to be OPERABLE.

01-38-R
01-01-A

** The performance of modifications to the diesel fuel oil storage and transfer system requires one fuel oil storage tank at a time to be drained and replaced with a new storage tank. During this period, the diesel generator fuel oil storage requirement for two unit operation in Modes 1, 4, or for one unit operation in Modes 1, 4 and one unit in Mode 5 or 6 is 35,000 gallons. A total of up to 120 days may be required to complete the replacement of both tanks. For the duration of the tank replacement, temporary onsite storage of 30,000 gallons will be maintained. Prior to removal of a tank from service, the offsite circuits required by Technical Specification 3.8.1.1.a. will be verified to be OPERABLE.

01-31-A

*** For Unit 1 Cycle 8, the allowed outage time may be extended to 120 hours on a one time basis for installation of auxiliary transformer 11.

01-31-A

ELECTRICAL POWER SYSTEMS

LIMITING CONDITION FOR OPERATION

ACTION (Continued)

b. With a diesel generator of the above required A.C. electrical power sources inoperable, demonstrate the OPERABILITY of the A.C. offsite sources by performing Specification 4.8.1.1.1a within 1 hour and at least once per 8 hours thereafter; and declare required feature supported by the inoperable diesel generator inoperable when its required redundant feature is inoperable within 4 hours from discovery of diesel generator inoperability concurrent with inoperability of redundant required feature; and determine the OPERABLE diesel generators are not inoperable due to a common cause failure or and if the diesel generator became inoperable due to any cause other than preventive maintenance or testing, demonstrate the OPERABILITY of the remaining OPERABLE diesel generators by performing Specification 4.8.1.1.2a.2) within 24 hours*; restore the diesel generator to OPERABLE status within 7 days and within 10 days from discovery of failure to meet the LCO or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

01-06-LS7

01-50-LS17

01-05-LS6

01-32-M

c. With one offsite circuit and one diesel generator of the above required A.C. electrical power sources inoperable, in addition to the requirements of ACTIONS a. and b. above demonstrate the OPERABILITY of the remaining A.C. sources by performing Specification 4.8.1.1.1a. within 1 hour and at least once per 8 hours thereafter; and if the diesel generator became inoperable due to any cause other than preventive maintenance or testing, demonstrate the OPERABILITY of the remaining OPERABLE diesel generators by performing Specification 4.8.1.1.2a.2) within 8 hours; restore at least one of the inoperable sources to OPERABLE status within 12 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. Restore the other A.C. power source (offsite circuit or diesel generator) to OPERABLE status in accordance with ACTION a. or b., as appropriate with the time requirement of that ACTION statement based on the time of initial loss of the remaining inoperable A.C. power source. A successful test of diesel OPERABILITY per Specification 4.8.1.1.2a.2) performed under this ACTION statement for OPERABLE diesels or a restored to OPERABLE diesel satisfies the diesel generator test requirement of ACTION a. or b.

01-08-LS8

d. With one diesel generator inoperable in addition to ACTION b. or c. above verify that:

1. All required systems, subsystems, trains, components and devices that depend on the remaining OPERABLE diesel generators as a source of emergency power are also OPERABLE, and
2. When in MODE 1, 2, or 3 that at least two auxiliary feedwater pumps are OPERABLE.

01-08-LS8

If these conditions are not satisfied within 2 hours be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.

01-06-LS7

*This test is required to be completed regardless of when the inoperable diesel generator is restored to operability.

ELECTRICAL POWER SYSTEMS

LIMITING CONDITION FOR OPERATION

ACTION (Continued)

- e. With two of the above required offsite A.C. circuits inoperable, ~~within 12 hours from the discovery of two offsite circuits inoperable concurrent with inoperability of redundant required feature(s) declare required feature(s) inoperable when its redundant required feature(s) is inoperable; and demonstrate the OPERABILITY of three diesel generators by performing the requirements of Specification 4.8.1.1.2a.2) within 8 hours, unless the diesel generators are already operating; restore at least one of the inoperable offsite sources to OPERABLE status within 24 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.~~ 01-22-M
~~Following restoration of one offsite source, follow ACTION a. with the time requirement of that ACTION statement based on the time of initial loss of the remaining inoperable offsite A.C. circuit. A successful test(s) of diesel generator OPERABILITY per Specification 4.8.1.1.2a.2) performed under this ACTION statement for the OPERABLE diesel generators satisfies the diesel generator test requirement of ACTION a.~~ 01-03-LS5
01-10-M
01-03-LS5
- f. With two or more of the above required diesel generators inoperable, demonstrate the OPERABILITY of two offsite A.C. circuits by performing the requirements of Specification 4.8.1.1.1a. within 1 hour and at least once per 8 hours thereafter; ensure at least two of the diesel generators are OPERABLE within 2 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. With two diesel generators OPERABLE follow ACTION b. with the time requirement of that ACTION statement based on the time of initial loss of the remaining inoperable diesel generator. A successful test of diesel generator OPERABILITY per Specification 4.8.1.1.2a.2) performed under this ACTION statement for a restored to OPERABLE diesel generator satisfies the diesel generator test requirement of ACTION b.
- g. With one supply train of the Diesel Fuel Oil Storage and Transfer System inoperable, restore the inoperable system to OPERABLE status within 72 hours or be in at least HOT STANDBY within the next 6 hours and be in ~~HOT~~ COLD SHUTDOWN within the following 6 ~~30~~ hours. 01-01-A
01-10-M
- h. With both supply trains of the Diesel Fuel Oil Storage and Transfer System inoperable, restore at least one supply train, ~~including the common storage system,~~ to OPERABLE status within 1 hour or be in at least HOT STANDBY within the next 6 hours and be in COLD SHUTDOWN within the following 30 hours. 01-01-A

ACTION (Continued)

- (new) With combined fuel oil in storage tanks not within limits, verify combined fuel oil level is at least 29,000 gallons for each unit operating in MODES 1, 2, 3, or 4, and at least 23,000 gallons for each unit operating in MODES 5 or 6 and restore fuel oil to within limits in 48 hours, or immediately declare associated diesel generators inoperable and if the associated unit is in MODES 1, 2, 3, or 4, be in HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours. 01-49-LS16
- (new) With both units in MODES 1, 2, 3, or 4 and a combined lube oil inventory less than 650 gallons but greater than 610 gallons, restore the lube oil inventory to greater than 650 gallons or with one unit in MODE 1, 2, 3, or 4 and the other unit in MODES 5 or 6 and a combined lube oil inventory of less than 590 gallons but greater than 520 gallons, restore the lube oil inventory to greater than 590 gallons in 48 hours, or immediately declare associated diesel generators inoperable and if the associated unit is in MODES 1, 2, 3, or 4, be in HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours. 01-48-M
- (new) With one or more diesel generators with starting air receiver pressures less than 180 psig but greater than 150 psig, restore at least one starting air receiver pressure per diesel generator to greater than 180 psig in 48 hours. 01-48-M
- (new) With one or more diesel generators with turbocharger air assist air receiver pressure less than 180 psig but greater than 150 psig, restore air receiver pressure to greater than 180 psig in 48 hours. 01-64-M
- (new) With one or more fuel oil storage tanks with stored fuel oil total particulates not within limits, restore fuel oil total particulates to within limits in 7 days, or immediately declare associated diesel generators inoperable and be in HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours. 01-49-LS16
- (new) With one or more fuel oil storage tanks with new fuel oil properties not within limits, restore stored fuel oil properties to within limits in 30 days, or immediately declare associated diesel generators inoperable and be in HOT STANDBY within the next 6 hours and COLD SHUTDOWN within the following 30 hours. 01-49-LS16
- (new) With starting air receiver pressure, or turbocharger air assist air receiver pressure not within limits for reasons other than above, immediately declare associated diesel generator inoperable. 01-48-M
01-64-M

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS

4.8.1.1.1 Each of the above required independent circuits between the offsite transmission network and the Onsite Class 1E Distribution System shall be:

- a. Determined OPERABLE at least once per 7 days by verifying correct breaker alignments, indicated power availability, and
- b. Demonstrated OPERABLE at least once per 18 months during shutdown by:
 - 1) Transferring 4 kV vital bus power supply from the normal circuit to the alternate circuit (manually and automatically) and to the delayed access circuit (manually), and
 - 2) Verifying that on a Safety Injection ~~actual~~ or test signal, without loss of offsite power, the preferred, immediate access offsite power source energizes the emergency busses with permanently connected loads and energizes the auto-connected emergency (accident) loads through sequencing timers. 01-11-TR1

4.8.1.1.2 Each diesel generator shall be demonstrated OPERABLE*:

- a. ~~In accordance with the frequency specified in Table 4.8-1 on a STAGGERED TEST BASIS At Least once per 31 days by:~~ 01-12-A
 - 1) ~~Verifying the fuel level in the engine-mounted fuel tank contains > 250 gallons of fuel oil.~~ 01-40-LS2
01-13-LS1
01-17-LS10
 - 2) Verifying the diesel starts from ~~standby~~ ambient condition and accelerates to at least 900 rpm in less than or equal to 10 seconds. The generator voltage and frequency shall be 4160 + 240/-375 volts and 60 ± 1.2 Hz within 13 seconds after the start signal. ~~The diesel generator shall be started for this test by using one of the following signals:~~
 - a) ~~Manual, or~~ 01-01-A
 - b) ~~Simulated loss of offsite power by itself (Startup bus undervoltage), or~~ 01-15-A
 - c) ~~A Safety Injection actuation test signal by itself.~~ 01-16-LG

* All diesel generator starts for the purpose of this surveillance test may be preceded by an engine prelube period. Further, all surveillance tests, with the exception of once per 184 days, may also be preceded by warmup procedures (e.g., gradual acceleration and/or gradual loading > 150 sec) as recommended by the manufacturer so that the mechanical stress and wear on the diesel engine is minimized. 01-12-A

** ~~Diesel generator loading may include gradual loading as recommended by the manufacturer, including a warmup period prior to loading.~~ 01-17-LS10

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

	01-53-M
3) Verifying the generator *** is synchronized, loaded to greater than or equal to 2484 kW in less than or equal to 60 seconds, and operates for greater than or equal to 60 minutes at a load ≥ 2370 kW and ≤ 2610 kW .	01-17-LS10 01-18-LS11 01-19-LS12
4) Verifying the diesel generator is aligned to provide standby power to the associated emergency busses, and	01-20-LG
5) Verifying the diesel engine protective relay trip cutout switch is returned to the cutout position following each diesel generator test.	01-20-LG
(new) Verifying lube oil inventory is at least 650 gallons	01-48-M
(new) Verifying each diesel generator has at least one starting air receiver with a pressure at least 180 psig, and	01-48-M
(new) Verifying each DG turbocharger air assist air receiver pressure is at least 180 psig	01-64-M
b. At least once per 18 months during shutdown, by:	
1) Subjecting the diesel to an inspection in accordance with procedures prepared in conjunction with its manufacturer's recommendations for this class of standby service;	01-20-LG 01-55-M
2) Verifying # that the load sequence timers are OPERABLE with each load sequence timer within the its limits specified in Table 4.8-2;	01-20-LG
3) Verifying the generator capability to reject a load of greater than or equal to 508 kW while maintaining voltage at 4160 ± 240/ 375 volts and frequency at 60 ± 3 Hz; Verifying each DG rejects a load** greater than or equal to its single largest post-accident load, and	01-26-M 01-23-LG
a. Following load rejection, the frequency is ≤ 63 Hz	
b. Within 2.4 seconds following load rejection, the voltage is ≥ 3785 V and ≤ 4400 V; and	01-24-LS13
c. Within 2.4 seconds following load rejection, the frequency is ≥ 58.8 Hz and ≤ 61.2 Hz	01-25-M
4) Verifying the generator capability to reject a load of greater than or equal to 2370 kW and ≤ 2610 kW while operating at a power factor of ≤ 0.87, 2484 kW without tripping. The generator voltage shall not exceed 6200 4580 volts during and following the load rejection;	01-18-LS11 01-26-M 01-27-LS9

- 5) Verify by Simulating or on an actual signal # a loss of offsite power by itself, and: 01-11-TR1
- a) Verifying de-energization of the emergency busses and load shedding from the emergency busses, and 01-55-M
- b) Verifying the diesel starts from standby conditions on the auto-start signal, energizes the emergency busses with permanently connected loads within 10 seconds, energizes the required auto-connected loads through sequencing timers and operates for greater than or equal to 5 minutes while its generator is loaded with the permanent and auto-connected loads. After energization of these loads, the steady state voltage and frequency of the emergency busses shall be maintained at 4160 + 240/-375 volts and 60 ± 1.2 Hz during this test. 01-15-A

Momentary transients outside the load range do not invalidate this test. 01-19-LS12

** If performed with the DG synchronized with offsite power, this Surveillance shall be performed at a power factor of ≥ 0.9 01-26-M

*** This surveillance shall be conducted on only one DG at a time 01-53-M

This surveillance shall not be performed in MODE 1, 2, 3, or 4. 01-55-M

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- 6) Verifying that on a Safety Injection actual or test signal without loss of offsite power, the diesel generator starts from standby conditions on the auto-start signal and operates on standby for greater than or equal to 5 minutes. The generator voltage and frequency shall be 4160 + 240/-375 volts and 60 + 1.2 Hz within 13 seconds after the auto-start signal; the steady state generator voltage and frequency shall be maintained within these limits during this test; 01-11-TR1
01-15-A

 - 7) Verify by Simulating# or by an actual a loss of offsite power in conjunction with a Safety Injection actual or test signal, and: 01-55-M
01-11-TR1
 - a) Verifying de-energization of the emergency busses and load shedding from the emergency busses;
 - b) Verifying the diesel starts from standby conditions on the auto-start signal, energizes the emergency busses with permanently connected loads within 10 seconds, energizes the auto-connected emergency (accident) loads through sequencing timers and operates for greater than or equal to 5 minutes while its generator is loaded with the emergency loads. After energization of these loads, the steady state voltage and frequency of the emergency busses shall be maintained at 4160 + 240/-375 volts and 60 ± 1.2 Hz during this test; and 01-15-A
 - e) Verifying that all automatic diesel generator trips, except engine overspeed, low lube oil pressure and generator differential, are bypassed when the diesel engine trip cutout switch is in the cutout position and the diesel is aligned for automatic operation. 01-29-A
01-26-M

 - 8) Verifying the diesel generator operates at a power factor $\leq 0.87^{**}$ for at least 24 hours. During the first 2 hours of this test, the diesel generator shall be loaded to greater than or equal to 2750 kW, 2625 kW and ≤ 2890 kW* and during the remaining 22 hours of this test, the diesel generator shall be loaded to greater than or equal to 2484, 2370 kW and ≤ 2610 kW*. The generator voltage and frequency shall be 4160 + 240/-375 volts and 60 + 1.2 Hz within 13 seconds after the start signal. For Units 1 and 2 Cycle 7: Within 5 minutes after completing this 24 hour test, perform Specification 4.8.1.1.2b.5)b);* 01-18-LS11
01-19-LS12
01-30-LG
01-31-A

 - 9) Verifying that the auto connected loads to each diesel generator do not exceed the maximum rating of 2750 kW; 01-20-LG

 - 10) Verifying# the diesel generator's capability to: 01-55-M
- * For Units 1 and 2 Cycle 7: If Specification 4.8.1.1.2b.5)b) is not satisfactorily completed, it is not necessary to repeat the preceding 24 hour test. Instead the diesel generator may be operated at 2484 kW for 1 hour or until operating temperature has stabilized. 01-31-A
- * Momentary transients outside the load range do not invalidate this test. 01-19-LS12
- ** Momentary transients outside the power factor range do not invalidate this test. 01-26-M
- # This surveillance shall not be performed in MODE 1, 2, 3, or 4. 01-55-M

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- a) Synchronize its isolated bus with the offsite power source while the generator is loaded with its emergency loads upon a simulated restoration of offsite power.
- b) Transfer its loads to the offsite power source, and
- c) Be restored to its ~~ready to load~~ standby status.

01-14-M

- 11) Verifying# that with the diesel generator operating in a test mode, connected to its bus, a simulated or actual Safety Injection signal opens the auxiliary transformer breaker and automatically sequences the emergency loads onto the diesel generator; and

01-55-M

01-11-TR1

- ~~12) Verifying that the shutdown relay lockout feature prevents diesel generator starting only when required:~~

- ~~a) Generator differential current high, or~~
- ~~b) Engine lube oil pressure low, or~~
- ~~c) Emergency stop button actuated, or~~
- ~~d) Overspeed trip actuated.~~

01-20-LG

01-66-TR3

- c. ~~At least once per 10 years or after any modifications which could affect diesel generator interdependence by starting all diesel generators simultaneously from standby conditions, during shutdown, and verifying that all diesel generators accelerate to at least 900 rpm in less than or equal to 10 seconds and achieve voltage ≥ 3785 V and ≤ 4400 V and frequency ≥ 58.8 Hz and ≤ 61.2 Hz within 13 seconds.~~

01-15-A

01-35-M

01-07-LS3

- d. ~~At least once per 31 days and after each operation of the diesel where the period of operation was greater than or equal to 1 hour by checking for and removing accumulated water from the day tank.~~

01-33-LS15

- e. ~~For Units 1 and 2, Cycle 8 and after:~~

01-31-A

~~At least once per 18 months by verifying the diesel generator starts and accelerates to at least 900 rpm in less than or equal to 10 seconds. The generator voltage and frequency shall be $4160 \pm 240/-375$ volts and 60 ± 1.2 Hz within 13 seconds after the start signal. This test shall be performed within 5 minutes of shutting down the diesel generator after the diesel generator has operated for at least 2 hours at a load of greater than or equal to 2484 2370 kW and ≤ 2610 kW.~~

01-19-LS12

01-18-LS11

4.8.1.1.3 The Diesel Fuel Oil Storage and Transfer System shall be demonstrated OPERABLE:

- a. At least once per 31 days by:

- 1) Verifying the fuel level in the fuel storage tank, and
- 2) Verifying that each fuel transfer pump starts and transfers fuel from the storage system to each engine-mounted tank via installed lines.

01-01-A

b. At least once per 31 days by checking for and removing accumulated water from the fuel oil storage tanks;

01-01-A

c. By sampling new fuel oil in accordance with the Diesel Fuel Oil Testing Program ASTM D4057 prior to addition to the storage tanks and:

01-37-LG

[REDACTED]

* Momentary transients outside the load range do not invalidate this test

01-19-LS12

This surveillance shall not be performed in MODE 1, 2, 3, or 4

01-55-M

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- 1) ~~By verifying in accordance with the tests specified in ASTM D975 81 prior to addition to the storage tanks that the sample has:~~
 - a) ~~An API Gravity of within 0.3 degrees at 60°F, or a specific gravity of within 0.0016 at 60/60°F, when compared to the supplier's certificate, or an absolute specific gravity at 60/60°F of greater than or equal to 0.83 but less than or equal to 0.89, or an API gravity of greater than or equal to 27 degrees but less than or equal to 39 degrees;~~
 - b) ~~A kinematic viscosity at 40°C of greater than or equal to 1.9 centistokes, but less than or equal to 4.1 centistokes, if gravity was not determined by comparison with the supplier's certification;~~
 - c) ~~A flash point equal to or greater than 125°F; and~~
 - d) ~~A clear and bright appearance with proper color when tested in accordance with ASTM D4176 82 or a water volume and sediment content of less than or equal to 0.05 volume percent when tested in accordance with ASTM D1796 83.~~
- 2) ~~By verifying within 30 and 31 days of obtaining the sample that the other properties specified in Table 1 of ASTM D975 81 are met when tested in accordance with ASTM D975 81 except that the analysis for sulfur may be performed in accordance with ASTM D1552 79 or ASTM D2622 82.~~
- d. ~~Verifying stored fuel oil is tested in accordance with the Diesel Fuel Oil Testing Program. At least once every 31 days by obtaining a sample of fuel oil in accordance with ASTM D2276 78, and verifying that total particulate contamination is less than 10 mg/liter when checked in accordance with ASTM D2276 78, Method A;~~
- e. ~~At least once per 10 years by:~~
 - 1) ~~Draining each fuel oil storage tank, removing the accumulated sediment and cleaning the tank using a sodium hypochlorite or equivalent solution, and~~
 - 2) ~~Performing a visual examination of accessible piping during an operating pressure leak test.~~

~~4.8.1.1.4 Reports All diesel generator failures, valid or non valid, shall be reported as a Special Report within 30 days to the Commission pursuant to Specification 6.9.2. Reports of diesel generator failures shall include the information recommended in Regulatory Position C.3.b of Regulatory Guide 1.108, Revision 1, August 1977. If the number of failures (on a per diesel generator basis) in the last 100 valid tests is greater than or equal to 7, the report shall be supplemented to include the additional information recommended in Regulatory Position C.3.b of Regulatory Guide 1.108, Revision 1, August 1977.~~

TABLE 4.8-1

DIESEL GENERATOR TEST SCHEDULE

<u>Number of Failures in Last 20 Valid Tests*</u>	<u>Number of Failures in Last 100 Valid Tests*</u>	<u>Test Frequency</u>
<u>≤ 1</u>	<u>≤ 5</u>	<u>At least once per 31 days</u>
<u>≥ 2**</u>	<u>≥ 6</u>	<u>At least once per 7 days</u>

01-13-LS1

~~* Criteria for determining number of failures and number of valid tests shall be in accordance with Regulatory Position C.2.e of Regulatory Guide 1.108, Revision 1, August 1977, where the last 20 and 100 tests and failures are determined on a per diesel generator basis. For the purpose of this schedule, only valid tests conducted after the completion of the preoperational test requirements of Regulatory Guide 1.108, Revision 1, August 1977, shall be included in the computation of the "Last 20 Valid Tests" and the "Last 100 Valid Tests." For the purpose of determining the required test frequency, the previous test failure count may be reduced to zero if the specific cause for the diesel unreliability has been identified and resolved; appropriate post maintenance operation and testing have been completed; and if acceptable reliability has been demonstrated. The reliability criterion shall be the successful completion of 14 consecutive tests in a single series. These tests shall be in accordance with Specification 4.8.1.1.2a.2).~~

~~** The associated test frequency shall be maintained until seven consecutive failure free demands have been performed and the number of failures in the last 20 valid demands has been reduced to one.~~

ELECTRICAL POWER SYSTEMS

A.C. SOURCES

SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.8.1.2 As a minimum, the following A.C. electrical power sources shall be OPERABLE:

a. One circuit between the offsite transmission network and the Onsite Class 1E Distribution System required by LCO 3.8.2.2, and

01-41-M

b. One diesel generator capable of supplying the onsite Class 1E AC electrical power distribution subsystem(s) required by LCO 3.8.2.2, with-

1. A separate engine-mounted fuel tank containing a minimum volume of 250 gallons of fuel,

01-01-A

2. One supply train of the Diesel Fuel Oil Storage and Transfer system containing a minimum storage of 26,000 gallons* of fuel in addition to the fuel required for the other unit**.

01-31-A

(new) A lube oil inventory shall be within limits

01-48-M

(new) A starting air receiver pressure shall be within limits, and

01-48-M

(new) A turbocharger air assist air receiver pressure shall be within limits

01-64-M

APPLICABILITY: MODES 5 and 6 and during movement of irradiated fuel assemblies

01-42-M

ACTION:

With less than the above minimum required A.C. electrical power sources OPERABLE, immediately suspend all operations involving CORE ALTERATIONS, positive reactivity changes, movement of irradiated fuel or crane operations with loads over the fuel storage pool. In addition, when in MODE 5 with the reactor coolant loops not filled, or in MODE 6 with the water level less than 23 feet above the reactor vessel flange, and immediately initiate corrective action to restore the required sources to OPERABLE status as soon as possible, or with one required offsite circuit inoperable, declare affected required features with no offsite power available inoperable. With one de-energized Class 1E AC electrical power subsystem as a result of the inoperable circuit, enter applicable Actions of LCO 3.8.2.2.

SURVEILLANCE REQUIREMENTS

NOTE:

The following SRs are not required to be performed: 4.8.1.1.2a.3), 4.8.1.1.2b.2) (auto-transfer timers), 4.8.1.1.2b.3), 4.8.1.1.2b.4), 4.8.1.1.2b.5), 4.8.1.1.2b.7)c), 4.8.1.1.2b.8), 4.8.1.1.2b.10), and 4.8.1.1.2e.

01-47-LS4

4.8.1.2 The above required A.C. electrical power sources shall be demonstrated OPERABLE by the performance of each of the following requirements of applicable Specifications 4.8.1.1.1, 4.8.1.1.2, 4.8.1.1.3, and 4.8.1.1.4, except for Specifications 4.8.1.1.1.b.2) and 4.8.1.1.2.a.2)c), b.2) for ESF timers, b.6), b.7), b.10), and b.11) 4.8.1.1.1a) 4.8.1.1.2a.2), 4.8.1.1.2a.3), 4.8.1.1.2a.1), 4.8.1.1.2d, 4.8.1.1.3a.2), 4.8.1.1.2b.4), 4.8.1.1.2b.5), 4.8.1.1.2e, and 4.8.1.1.2b.2).

01-47-LS4

~~* The performance of Technical Specification Surveillance Requirement 4.8.1.1.3.c requires one fuel oil storage tank to be removed from service to be drained and cleaned. During this surveillance, the diesel generator fuel oil storage requirement for one unit operation in Modes 5 or 6 and one unit operation in Mode 6 with at least 23 feet of water above the reactor vessel flange or with the reactor vessel defueled is 35,000 gallons. The tank being cleaned may be inoperable for up to 10 days. For the duration of tank cleaning, temporary onsite fuel oil storage of 24,000 gallons will be maintained. Prior to removal of a tank from service, the offsite circuits required by Technical Specification 3.8.1.2.a will be verified to be OPERABLE.~~

01-01-A

~~** The performance of modifications to the diesel fuel oil storage and transfer system requires one fuel oil storage tank at a time to be drained and replaced with a new storage tank. During this period, the diesel generator fuel oil storage requirement for one or two unit operation in Modes 5 and 6 is 35,000 gallons. A total of up to 120 days may be required to complete the replacement of both tanks. For the duration of the tank replacement, temporary onsite storage of 30,000 gallons will be maintained. Prior to removal of a tank from service, the offsite circuits required by Technical Specification 3.8.1.2a. will be verified to be OPERABLE.~~

01-31-A

ELECTRICAL POWER SYSTEMS

3/4.8.2 ONSITE POWER DISTRIBUTION

OPERATING

LIMITING CONDITION FOR OPERATION

3.8.2.1 The following electrical busses shall be energized in the specified manner:

- a. ~~4160 volt Vital Bus F,~~
- b. ~~480 volt Vital Bus F,~~
- c. ~~4160 volt Vital Bus G,~~
- d. ~~480 volt Vital Bus G,~~
- e. ~~4160 volt Vital Bus H,~~ 03-01-LG
- f. ~~480 volt Vital Bus H,~~
- g. ~~120 volt Vital Instrument A.C. Bus 1 energized from its associated inverter connected to D.C. Bus 1,~~
- h. ~~120 volt Vital Instrument A.C. Bus 2 energized from its associated inverter connected to D.C. Bus 2,~~
- i. ~~120 volt Vital Instrument A.C. Bus 3 energized from its associated inverter connected to D.C. Bus 3,~~ 03-02-A
- j. ~~120 volt Vital Instrument A.C. Bus 4 energized from its associated inverter connected to D.C. Bus 2,~~
- k. ~~125 volt D.C. Bus 1 energized from Battery Bank 1, and its associated full capacity charger,~~
- l. ~~125 volt D.C. Bus 2 energized from Battery Bank 2, and its associated full capacity charger, and~~
- m. ~~125 volt D.C. Bus 3 energized from Battery Bank 3, and its associated full capacity charger.~~

The required AC, DC, and AC vital bus electrical power distribution subsystems shall be OPERABLE.

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

- a. ~~With one of the required 4160 volt and/or associated 480 volt vital busses not energized, re energize them~~ 03-01-LG
~~AC electrical power distribution subsystem inoperable, restore within 8 hours and within at least 16 hours from discovery of failure to meet the LCO, or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.~~ 03-04-M

ELECTRICAL POWER SYSTEMS

LIMITING CONDITION FOR OPERATION (Continued)

- b. ~~With one vital instrument A.C. bus inoperable restore to OPERABLE status not energized from its associated inverter, or with one inverter not connected to its associated D.C. bus, re energize the vital instrument A.C. bus from an alternate source within 2 hours and within at least 16 hours from discovery of failure to meet the LCO~~ or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours; re-energize the vital instrument A.C. bus from its associated inverter connected to its associated D.C. bus within 24 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. 03-01-LG
03-04-M
- c. With more than one full capacity charger receiving power simultaneously from a single 480 volt vital bus or any D.C. bus not receiving power from its associated A.C. division, restore the system to a configuration wherein each charger is powered from its associated 480 volt vital bus within 14 days or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.
- d. ~~With one D.C. bus not energized from its associated battery bank and a full capacity charger, re energize it from its associated battery bank and a full capacity charger inoperable, restore to operable status within 2 hours and within at least 16 hours from discovery of failure to meet the LCO~~ or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours. 03-01-LG
03-04-M
- ~~(new) With two Glass 1E Vital busses with inoperable distribution subsystems that result in a loss of safety function enter LCO 3.0.3 immediately~~ 03-05-A

SURVEILLANCE REQUIREMENTS

4.8.2.1 The specified busses shall be determined energized in the required manner at least once per 7 days by verifying correct breaker alignment and indicated voltage on the busses.

ELECTRICAL POWER SYSTEMS

ONSITE POWER DISTRIBUTION

SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.8.2.2 ~~As a minimum, the following electrical busses shall be energized in the specified manner:-~~

- a. ~~One 4160 volt and its associated 480 volt A.C. vital bus,~~
- b. ~~Two 120 volt vital instrument A.C. busses energized from their associated inverters connected to their respective D.C. busses, and~~ 03-06-M
- c. ~~One 125 volt D.C. bus energized from its associated battery bank and full capacity charger supplied from its associated OPERABLE A.C. vital bus.~~

~~The necessary portion of the AC, DC, and AC vital bus electrical power distribution subsystems shall be OPERABLE to support equipment required to be OPERABLE~~

APPLICABILITY: ~~MODES 5 and 6 and during movement of irradiated fuel assemblies~~ 01-42-M

ACTION:

~~With any of the above required electrical busses inoperable, immediately declare associated supported required feature(s) inoperable, or not energized in the required manner, immediately suspend all operations involving CORE ALTERATIONS, positive reactivity changes, or movement of irradiated fuel, initiate corrective action to energize the required electrical busses in the specified manner as soon as possible and immediately declare associated required residual heat removal subsystem(s) inoperable and not in operation.~~ 03-03-LS20
03-07-M

SURVEILLANCE REQUIREMENTS

4.8.2.2 The specified busses shall be determined energized in the required manner at least once per 7 days by verifying correct breaker alignment and indicated voltage on the busses.

ELECTRICAL POWER SYSTEMS

3/4.8.3 D.C. SOURCES

OPERATING

LIMITING CONDITION FOR OPERATION

3.8.3.1 ~~The following Three Class 1E D.C. electrical sources shall be OPERABLE:~~

- ~~a. 125 volt D.C. Battery No. 1 and an associated full capacity charger,~~
- ~~b. 125 volt D.C. Battery No. 2 and an associated full capacity charger, and~~
- ~~c. 125 volt D.C. Battery No. 3 and an associated full capacity charger.~~

02-01-LG

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTION:

~~With one of the required battery banks and/or full capacity chargers DC electrical power subsystems inoperable, restore the inoperable battery bank and/or full-capacity charger to OPERABLE status within 2 hours or be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.~~

02-01-LG

SURVEILLANCE REQUIREMENTS

4.8.3.1 Each 125-volt battery bank and charger shall be demonstrated OPERABLE:

- a. At least once per 7 ~~DI~~ days by verifying that:
 - 1) The parameters in Table 4.8-3 meet the Category A limits, and
 - 2) The total battery terminal voltage is greater than or equal to 130-volts on float charge.

02-06-LS22

ELECTRICAL POWER SYSTEMS

SURVEILLANCE REQUIREMENTS (Continued)

- b. ~~At least once per 92 days and within 7 days after a battery discharge with D.C. bus voltage below 118 volts, or battery overcharge with D.C. bus voltage above 145 volts, by:~~ 02-17-LS2
- 1) ~~Verifying that the parameters in Table 4.8-3 meet the Category B limits, and within 7 days after a battery discharge with D.C. bus voltage below 118 volts, or battery overcharge with D.C. bus voltage above 145 volts.~~ 02-24-LG
02-23-A
 - 2) ~~Verifying there is no visible corrosion at either terminals or connectors, or the connection resistance of these items is less than or equal to 150×10^{-6} ohm,* and~~
 - 3) ~~Verifying that the average electrolyte temperature of 10 of the connected representative cells is above greater than or equal to 60°F.~~ 02-18-LG
02-22-A
- c. At least once per 18 months by verifying that:
- 1) ~~The cells, cell plates and battery racks show no visual indication of physical damage or abnormal deterioration that could degrade battery performance.~~ 02-02-A
 - 2) ~~The Remove visible terminal corrosion, verify battery cell-to-cell and terminal connections are clean, tight, and coated with anticorrosion material.~~ 02-03-M
 - 3) ~~The resistance of each cell-to-cell and terminal connection is less than or equal to 150×10^{-6} ohm,* and~~ 02-24-LG
 - 4) ~~The battery charger will supply at least 400 amperes at 130 volts for at least 4 hours~~
- d. ~~At least once per 18 months, during shutdown, by verifying that the battery capacity is adequate to supply and maintain in OPERABLE status all of the actual and/or simulated emergency loads for the design duty cycle when the battery is subjected to a battery service test. This surveillance shall not be performed in MODES 1, 2, 3, or 4 but credit may be taken for unplanned events that satisfy this SR.~~ 02-04-M
- e. ~~At least once per 60 months, during shutdown, by verifying that the battery capacity is at least 80% of the manufacturer's rating when subjected to a performance discharge test or a modified performance discharge test. This performance discharge test or modified performance discharge test may be performed in lieu of the battery service test required by Specification 4.8.3.1d. This surveillance shall not be performed in MODES 1, 2, 3, or 4 but credit may be taken for unplanned events that satisfy this SR, and~~ 02-05-M
02-04-M

- f. At least once per 18 months during shutdown, by giving performance discharge tests, or a modified performance discharge test, of battery capacity to any battery that shows signs of degradation or has reached 85% of the service life expected for the application. Degradation is indicated when the battery capacity drops more than 10% of rated capacity from its average on previous performance tests, or is below 90% of the manufacturer's rating, and at least once per 24 months when battery has reached 85% of service life for the application with capacity $\geq 100\%$ of manufacturer's rating, this surveillance shall not be performed in Mode 1, 2, 3, or 4, but credit may be taken for unplanned events that satisfy this SR.

02-21-LS1

02-05-M

02-18-LG

02-04-M

~~*The resistance of cell to cell connecting cables does not have to be included.~~

02-24-LG

TABLE 4.8-3

BATTERY SURVEILLANCE REQUIREMENTS

PARAMETER	CATEGORY A(1)	CATEGORY B(2) CATEGORY B CATEGORY C	<u>02-14-A</u>
	LIMITS FOR EACH DESIGNATED PILOT CELL	LIMITS FOR EACH CONNECTED CELL	ALLOWABLE(3) VALUE FOR EACH CONNECTED CELL
Electrolyte Level <u>02-07-A</u>	>Minimum level indication mark, and $\leq \frac{1}{4}$ " above maximum level indication mark	>Minimum level indication mark, and $\leq \frac{1}{4}$ " above maximum level indication mark	Above top of plates, and not overflowing
Float Voltage	≥ 2.13 volts	> 2.13 volt (6) <u>02-12-LG</u>	> 2.07 volts
Specific Gravity(4)	$\geq 1.195(5)$	≥ 1.190	Not more than 0.020 below the average of all connected cells
		Average of all connected cells > 1.200	Average of all connected cells $\geq 1.190(5)$

- (1) For any Category A or B parameter(s) outside the limit(s) shown, the battery may be considered OPERABLE provided that pilot cell level and float voltage meet Cat. B allowance value within 1 hour, within 24 hours and once every 7 days all the Category B measurements are taken and found to be within their allowable values, and provided all Category A and B parameter(s) are restored to within limits within the next 6 ~~30~~ days. 02-08-LS21
02-09-M
- ~~(2) For any Category B parameter(s) outside the limit(s) shown, the battery may be considered OPERABLE provided that the Category B parameters are within their allowable values and provided the Category B parameter(s) are restored to within limits within 7 days. 02-08-LS21~~
- (3) Any Category B parameter not within its allowable value indicates an inoperable battery.
- (4) Corrected for electrolyte temperature and level. Level correction is not required, however, when battery charging is < 2 amps when on float charge. 02-10-A
- (5) Or battery charging current is less than 2 amps when on charge. This is acceptable for meeting specific gravity limits following a battery recharge, for a maximum of 7 days. When charging current is used to satisfy specific gravity requirements, specific gravity of each connected cell shall be measured prior to expiration of the 7 day allowance. 02-11-A
- ~~(6) Corrected for average electrolyte temperature. 02-12-LG~~
- (new)(a) It is acceptable for the electrolyte level to temporarily increase above the specified maximum during equalizing charges provided it is not overflowing. 02-07-A

ELECTRICAL POWER SYSTEMS

D.C. SOURCES

SHUTDOWN

LIMITING CONDITION FOR OPERATION

3.8.3.2 ~~As a minimum, one 125-volt battery bank and an associated full capacity charger shall be OPERABLE. DC electrical power subsystem shall be OPERABLE to support the DC electrical power distribution subsystem required by LCO 3.8.2.2.~~

02-01-LG

02-13-A

APPLICABILITY: MODES 5 and 6 and during movement of irradiated fuel assemblies.

01-42-M

ACTION:

~~With the required battery bank and/or full capacity charger one or more required DC electrical power subsystems inoperable. Declare affected required feature(s) inoperable; or immediately suspend all operations involving CORE ALTERATIONS, positive reactivity changes or movement of irradiated fuel; initiate corrective action to restore the required battery bank and/or full capacity charger DC electrical power subsystems to OPERABLE status as soon as possible.~~

02-19-LS20

02-01-LG

SURVEILLANCE REQUIREMENTS

NOTE

~~The following SRs are not required to be performed: SR 4.8.3.1d, SR 4.8.3.1e and SR 4.8.3.1f.~~

02-15-LS4

4.8.3.2 ~~The above required 125-volt battery bank and charger DC Sources shall be demonstrated OPERABLE in accordance with Specification 4.8.3.1.~~

02-01-LG

ELECTRICAL POWER SYSTEMS

3/4.8.4 ELECTRICAL EQUIPMENT PROTECTIVE DEVICES

MOTOR OPERATED VALVES THERMAL OVERLOAD PROTECTION AND BYPASS DEVICES

04-01-R

LIMITING CONDITION FOR OPERATION

~~3.8.4.1 The thermal overload protection and bypass devices, integral with the motor starter, of each valve[#] used in safety systems shall be OPERABLE.~~

~~APPLICABILITY: Whenever the motor operated valve is required to be OPERABLE.~~

ACTION:

~~With one or more of the thermal overload protection and/or bypass devices inoperable, declare the affected valve(s) inoperable and apply the appropriate ACTION Statement(s) for the affected valves.~~

SURVEILLANCE REQUIREMENTS

~~4.8.4.1 The above required thermal overload protection and bypass devices shall be demonstrated OPERABLE:~~

~~a. At least once per 18 months, by the performance of a TRIP ACTUATION DEVICE OPERATIONAL TEST of the bypass circuitry for those thermal overload devices which are either:~~

- ~~1) Continuously bypassed and temporarily placed in force only when the valve motors are undergoing periodic or maintenance testing, or~~
- ~~2) Normally in force during plant operation and bypassed under accident conditions.~~

~~b. At least once per 18 months by the performance of a CHANNEL CALIBRATION of a representative sample of at least 25% of:~~

- ~~1) All thermal overload devices which are not bypassed, such that each non bypassed device is calibrated at least once per 6 years, and~~
- ~~2) All thermal overload devices which are continuously bypassed, such that each continuously bypassed device is calibrated and each valve is cycled through at least one complete cycle of full travel with the motor operator when the thermal overload device is OPERABLE and not bypassed at least once per 6 years.~~

~~# See AD13.DC1 for List of Motor Operated Valves Thermal Overload Protection and Bypass Devices~~

ELECTRICAL POWER SYSTEMS

CONTAINMENT PENETRATION CONDUCTOR OVERCURRENT PROTECTIVE DEVICES

04-01-R

LIMITING CONDITION FOR OPERATION

~~3.8.4.2 For each containment penetration provided with a containment penetration overcurrent protective device(s), each device shall be OPERABLE.~~

~~APPLICABILITY: MODES 1, 2, 3, and 4.~~

ACTION:

~~With one or more of the above required containment penetration conductor overcurrent protective device(s) inoperable:~~

- ~~a. Restore the protective device(s) to OPERABLE status or deenergize the circuit(s) by tripping the associated protective device or racking out or removing the inoperable protective device within 72 hours, declare the affected system or component inoperable, and verify the associated protective device to be tripped or removed, or the inoperable protective device racked out or removed at least once per 7 days thereafter; or~~
- ~~b. Be in at least HOT STANDBY within the next 6 hours and in COLD SHUTDOWN within the following 30 hours.~~

SURVEILLANCE REQUIREMENTS

~~4.8.4.2 Protective devices required to be operable as containment penetration overcurrent protective devices shall be demonstrated OPERABLE:~~

- ~~a. At least once per 18 months:~~
 - ~~1) By verifying that the medium voltage 12 kV circuit breakers are OPERABLE by selecting, on a rotating basis, at least 10% of the circuit breakers and performing the following:~~
 - ~~a) A CHANNEL CALIBRATION of the associated protective relays,~~
 - ~~b) An integrated system functional test which includes simulated automatic actuation of the system and verifying that each relay and associated circuit breaker and overcurrent control circuit function as designed, and~~

SURVEILLANCE REQUIREMENTS (Continued)

- ~~c) For each circuit breaker found inoperable during these functional tests, an additional representative sample of at least 10% of all the circuit breakers of the inoperable type shall also be functionally tested until no more failures are found or all circuit breakers of that type have been functionally tested.~~
- ~~2) By selecting and functionally testing a representative sample of at least 10% of each type of lower voltage circuit breakers. Circuit breakers selected for functional testing shall be selected on a rotating basis. Testing of "drawout" type circuit breakers shall consist of a CHANNEL CALIBRATION of the associated solid state trip device for both the long time delay trip element and the short time delay element along with a breaker functional test. Testing of molded case circuit breakers shall consist of injecting a current with a value equal to 200% (for D.C. breakers) and 300% (for A.C. breakers) of the pickup of the time delay element and verifying that the circuit breaker operates within the time delay band for that current specified by the manufacturer. The instantaneous element of molded case circuit breakers shall be tested by injecting a current equal to 25% +40% of the pickup value of the element and verifying that the circuit breaker trips with no intentional time delay. Circuit breakers found out of tolerance during functional testing shall be replaced prior to resuming operation. Circuit breakers that fail to trip magnetically before the withstand capability of the penetration conductor is reached shall be declared inoperable. Circuit breakers that fail to trip thermally before the manufacturer's maximum tolerance shall be declared inoperable. For each circuit breaker found inoperable during these functional tests, an additional representative sample of at least 10% of all the circuit breakers of the inoperable type shall also be functionally tested until no more failures are found or all circuit breakers of that type have been functionally tested; and~~
- ~~3) By verifying that the thermal overload devices integral with the motor starters, used for penetration overcurrent protection, are OPERABLE by selecting a representative sample of at least 10% of the motor overload devices and performing a CHANNEL CALIBRATION. Motor overloads found inoperable shall be restored to OPERABLE status prior to resuming operation. For each motor overload device found inoperable, a CHANNEL CALIBRATION shall be performed on an additional representative sample of at least 10% of all the motor overload devices of the inoperable type until no more failures are found or a CHANNEL CALIBRATION has been performed on all motor overload devices of that type.~~
- ~~b. At least once per 60 months by subjecting each circuit breaker to an inspection and preventive maintenance in accordance with procedures prepared in conjunction with its manufacturer's recommendations.~~

Methodology For Mark-Up of Current TS

This Enclosure contains the electronic (or hand written) mark-up of the current Technical Specifications (TS). The electronic (or hand written) mark-up is performed in accordance with the following guidelines:

- The current specifications are marked-up to reflect what they would look like when the substance of NUREG-1431 Revision 1 is incorporated.
- In general, only technical changes have been identified. However, some non-technical changes have also been included when the changes cannot easily be determined to be non-technical by a reviewer, or if an explanation is required to demonstrate that the change is non-technical.
- Changes are identified by a change number in the right margin. A description/justification for each change is contained in Enclosure 3A.

There are four types of changes:

1. **Deletions** - Material is no longer in the specifications. (This includes material which is moved to the Bases of the TS.)
2. **Additions** - This includes the addition of new requirements, restrictions, etc. to the specifications which are not in the current TS.
3. **Modifications** - This includes requirements which exist in the current TS but are being revised in the improved TS.
4. **Administrative** - These are non-technical changes to the TS. These include adopting the new format of the improved STS, moving the location of material within the specifications, etc.

The methodology of identifying the changes is:

- Deletions** - The portion of the specification which is being deleted is annotated using the strike-out feature of WordPerfect (or crossed out by hand). The deletion is identified by a change number or a change code in the adjacent right margin.
- Additions** - The information being added is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The addition is identified by a change number in the adjacent right margin.
- Modifications** - The information being revised is annotated in the current TS using the strike-out feature of WordPerfect (or crossed out by hand) and the revised information is inserted into the specification in the appropriate location and is annotated using the red-line feature of WordPerfect (or hand written/insert pages). The modification is identified by a change number in the adjacent right margin.
- Administrative** - The text of the current TS is not modified to reflect administrative changes. Where the administrative change might cause confusion to a reviewer, the change is identified by a change number in the right margin. For example, if a requirement is relocated to a specification in the improved TS which does not correspond with the specification in which that requirement is located in the current TS, a change number is provided in the mark-up of the current TS and an explanation is provided in Enclosure 3A which explains where that requirement has been located in the improved TS.

Methodology For Mark-Up of Current TS
(Continued)

CHANGE NUMBERS:

A change number, located in the right margin adjacent to a technical change mark-up, provides an identifier for its corresponding description/justification and indicates the type of NSHC used. The change number is of the form 4-13-LS. The first number (i.e., 4 in this example) is a number assigned to each LCO (or group of similar LCOs) such that it refers to the same specification for each member utility in the Joint Licensing Subcommittee (JLS) regardless of the actual TS number in their individual Technical Specifications. A table of the change number prefixes versus each plant's specification numbers is provided in Enclosure 3A. The next set of numbers (i.e., -13 in this example) is an assigned number to identify changes within a given specification (i.e., having the same prefix number). As a result of differences between the individual JLS member current specifications and because of changes that may occur after initial number assignments, the numbers may not appear sequentially in the TS mark-up. The letter suffix (i.e., LS in this example) indicates the type NSHC used (e.g., A, M, LG, TR, LS, R).

In summary, changes may be annotated electronically or by using a hand mark-up. For electronic mark-up, "red-line" is used to annotate new information, "strike-out" is used to annotate deleted material (which includes material that is moved out of the specifications), and change numbers are used in the right margin to identify technical changes. All technical changes (i.e., "red-line" or "strike-out" items) require a change number. In addition, certain administrative changes (e.g., requirements moved to another specification) are also assigned a change number to provide additional clarification.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

This Enclosure contains a brief description/justification for each marked-up change to existing current plant Technical Specifications (CTS). The changes are keyed to those identified in Enclosure 2 (mark-up of the CTS). The referenced No Significant Hazards Considerations (NSHC) are contained in Enclosure 4. All proposed technical changes to the CTS are discussed below; however, some administrative changes (i.e., format, presentation, and editorial changes made to conform to the Improved Technical Specifications (ITS)) may not be discussed. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is specific and is not common to all the Joint Licensing Subcommittee (JLS) Plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-01	A	<p>TS requirement for minimum diesel generator (DG) day tank fuel oil volume and fuel transfer pump would be moved to improved Technical Specification (ITS) Surveillance Requirement (SR) 3.8.1.4 and SR 3.8.1.6. This change does not result in a change to any technical requirement and is administrative in nature. This change is consistent with NUREG-1431.</p> <p>TS requirements for diesel fuel oil (DFO) storage would be moved to ITS LCO 3.8.3.</p>
01-02	A	Not applicable to Diablo Canyon Power Plant (DCPP). See Conversion Comparison Table (Enclosure 3B).
01-03	LS5	<p>CTS 3.8.1.1 ACTION requirements to demonstrate DG OPERABILITY is deleted. ACTIONS currently require all OPERABLE DGs that have not been tested within the previous 24 hours to be started within 24 hours to demonstrate their OPERABILITY in the event that one or both offsite A.C. circuits become inoperable. The normal TS surveillance testing already demonstrates that an OPERABLE DG is capable of performing its safety function. The inoperability of an offsite circuit does not in any way effect the DG(s). Therefore, this testing is unnecessary. This change is consistent with Generic Letter (GL) 93-05, "Line-Item Technical Specifications Improvements to Reduce Surveillance Requirement for Testing During Power Operation," and with NUREG-1431.</p>
01-04	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-05	LS6	<p>CTS 3.8.1.1 ACTIONS require that the remaining OPERABLE DG(s) be started to demonstrate OPERABILITY [within 24 hours] in the event a DG becomes inoperable due to any cause other than preventive maintenance or testing. The intent of this additional testing is to determine if a common cause failure exists and to provide added assurance that the remaining OPERABLE DG(s) is capable of supplying emergency power. The CTS also requires that this testing be completed even if the inoperable DG is restored to OPERABLE. However, this requirement results in unnecessary testing when there is no common cause failure. This proposed change incorporates the NUREG-1431 provision of "determining the OPERABLE DG(s) are not inoperable due to a common cause failure" and deletes the requirement to complete the test even if the ACTION is exited, which avoids unnecessary testing of OPERABLE DG(s), into ACTION requirements. The proposed change is acceptable because it would continue to assure that a common cause failure does not exist while reducing wear on the DG(s) as endorsed by GL 84-15, "Proposed staff actions to improve and maintain diesel generator reliability," and GL 93-05, "Line-Item Technical Specifications Improvements to Reduce Surveillance Requirement for Testing During Power Operation."</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
		This change is consistent with NUREG-1431.
01-06	LS7	<p>CTS 3.8.1.1 ACTION requirements allowed time for verification of required redundant feature OPERABILITY would be increased from 2 to 4 hours. The shutdown requirement would be replaced with a requirement to enter the required feature's ACTION statement.</p> <p>The ACTION currently requires that with one DG inoperable, all required safety equipment that depends on the remaining operable DG(s) be verified OPERABLE. If these requirements are not met within 2 hours, a unit shutdown is required. The proposed changes to the ACTION requirement would increase the allowed time from 2 hours to 4 hours. In addition, the Safety Function Determination Program would require an immediate evaluation of redundant features for inoperability. This would result in entering the required feature's TS ACTION statement.</p> <p>This change is acceptable because it would assure that appropriate ACTIONS are taken to assure the OPERABILITY of required systems before requiring a plant shutdown and is consistent with NUREG-1431.</p>
01-07	LS3	<p>CTS SR to start all DGs simultaneously at least once per 10 years or after any modification which could affect DG starting interdependence would be revised to delete the requirement to perform the SR during shutdown. This test does not require the DG to be paralleled and loaded onto the offsite source. In addition, the DG remains OPERABLE during this SR. This change is consistent with NUREG-1431.</p>
01-08	LS8	<p>CTS 3.8.1.1 ACTION requirement to demonstrate DG OPERABILITY within 8 hours would be increased to 24 hours. Extending the time required to demonstrate the OPERABILITY of the remaining OPERABLE DGs would allow 24 hours to determine the OPERABLE DGs are not inoperable due to a common cause failure or demonstrate OPERABILITY of the remaining OPERABLE DGs by testing. This proposed change avoids unnecessary DG testing. This change would allow the same time period (24 hours) for determining OPERABILITY of the remaining OPERABLE DG(s) as the ACTION for one inoperable DG currently allows and is consistent with the recommendations of GL 84-15, "Proposed staff actions to improve and maintain diesel generator reliability." This proposed change is consistent with NUREG-1431.</p>
01-09		Not used.
01-10	M	<p>CTS 3.8.1.1 ACTIONS would be revised to require transition to MODE 5 within 30 hours following transition to MODE 3 upon failure to meet the requirements of these ACTION statements. This change would require placing the plant in a MODE in which the limiting condition for operation (LCO) no longer applies. This change is consistent with NUREG-1431.</p>
01-11	TR1	<p>Several CTS SRs would be revised to clarify that an actual actuation signal, as well as a test or simulated signal, may be used. This change would allow satisfactory automatic systems actuations from actual signals to be used to fulfill the requirements of the SR. This proposed change is acceptable because data obtained during the performance of the surveillance must still be obtained and the acceptance criteria must be satisfied before credit can be taken for the actual actuation, e.g., an unplanned event.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-12	A	The footnote allowing an engine prelube period would be applicable to all DG SRs involving an engine start. The DGs are maintained in a prelubed condition, and therefore this change in format does not add or reduce any requirement. This change is administrative in nature and consistent with Regulatory Guide (RG) 1.9, "Selection and Diesel Generator Set Capacity for Standby Power Supplies," Rev. 3 and with NUREG-1431.
01-13	LS1	The CTS requiring DG reports and DG test schedule tables would be deleted, and other CTS would be revised to reflect deletion of the reporting requirement and DG test schedule. These proposed changes are consistent with the recommendations of GL 94-01, "Removal of Accelerated Testing and Special Reporting Requirements for Emergency Diesel Generators," dated May 31, 1994. With the proposed changes, accelerated testing of the DGs and DG special reporting requirements would be deleted.
01-14	A	CTS requirement of "standby status" would be replaced with "ready-to-load operation." This terminology is more precise. This change is consistent with NUREG-1431.
01-15	A	The requirement to start the DG from "ambient condition" would be replaced with "standby conditions," and description of these conditions added to the Bases. The phrase "standby conditions" more accurately reflects DG testing conditions. The DCPD DGs are provided with jacket water and lube oil warming systems. Also, the engine bearings are lubricated and ready for operation via the lube oil circulating pumps, which run continuously until the DG is started. If the lube oil warming system should become inoperable, the lube oil temperature is monitored to ensure it remains above the manufacturer's recommended temperature. This is consistent with [License Amendment Request (LAR) 97-02 (submitted 2/27/97) and] the definition provided in RG 1.9, "Selection and Diesel Generator Set Capacity for Standby Power Supplies," Rev. 3 of "standby conditions" and does not result in any technical relaxations or additions to the current operating understanding of "ambient conditions" in the CTS. This change is consistent with NUREG-1431.
01-16	LG	The normal monthly DG start SR would be revised to delete the method by which the DG is started. Currently, the TS specifies that the DG shall be started by using one of the start signals. Deleting the listing of the start signals that may be used to start the DG would eliminate unnecessary information contained in the TS. The specific method for starting a DG would be moved to the Bases. This change is consistent with NUREG-1431.
01-17	LS10	The SR to rapidly load the DG in less than or equal to 60 seconds would be deleted. Rapidly loading the DG introduces unnecessary mechanical stresses and engine wear. This change is consistent with GL 93-05, "Line-Item Technical Specifications Improvements to Reduce Surveillance Requirement for Testing During Power Operation," and NUREG-1431.
01-18	LS11	The current DG loading requirements are specified in SRs as "greater than or equal to" These SRs would be revised to specify the DG is loaded between a range of kW values. This change is consistent with NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-19	LS12	A footnote would be added to several SRs stating that momentary transients outside the load and/or power factor range do not invalidate the test, since DG loading could change during this test due to changing bus conditions. Some load fluctuation is expected and would occur during DG operation under post-accident conditions. Therefore, this change is acceptable and should not invalidate this test. This change is consistent with NUREG-1431.
01-20	LG	Several SRs would be moved to licensee-controlled documents. Moving these requirements would allow changes to these requirements without prior Commission approval and will further the Commission's goal of TS improvements, as delineated in NRC policy statements, without reducing the level of plant safety. The SRs that are being moved reflect normal design, maintenance or line-up activities/descriptions rather than features specifically needed to successfully mitigate a design basis accident (DBA) or design transient. These proposed changes are consistent with NUREG-1431.
01-21	M	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-22	M	An additional requirement would be added to TS 3.8.1.1 ACTION for two offsite circuits inoperable, requiring that concurrent with inoperability of required redundant feature(s), the required feature also be declared inoperable. This requirement is intended to provide assurance that an event with a coincident single failure would not result in a complete loss of redundant, required safety functions. The addition of this requirement is consistent with NUREG-1431.
01-23	LG	The DG partial load rejection SR would be revised to replace the requirement that the load be \geq [508] kW with "a load greater than or equal to its single largest post-accident load." The actual load and its corresponding horsepower and kW ratings would be included in the TS Bases. This change would eliminate unnecessary information contained in the TS and potentially reduce the need for a future LAR. This proposed change is consistent with NUREG-1431.
01-24	LS13	<p>The DG partial load rejection SR requirement that voltage be maintained would be replaced with a requirement that within 2.4 seconds following load rejection, the voltage is within steady state requirements. The voltage specified is consistent with the design range of the equipment powered by the DG.</p> <p>The 2.4 second allowance for voltage and frequency is based on the recommendations of RG 1.9, "Selection and Diesel Generator Set Capacity for Standby Power Supplies," Rev. 3, for recovery from transients caused by the disconnection of the largest single load. RG 1.9, Rev. 3, states that voltage and frequency should recover to within 10 percent and 2 percent of nominal, respectively, within 60 percent of the load sequence interval. The load sequence interval following addition of the largest load is 4 seconds. This change is consistent with NUREG-1431.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

CHANGE NUMBER	NSHC	DESCRIPTION
01-25	M	<p>The DG partial load rejection SR requirement to maintain frequency at 60 ± 3 Hz would be revised to require frequency be maintained at ≤ 63 Hz during load rejection, and an additional requirement would be added that the frequency recover to 60 ± 1.2 Hz within 2.4 seconds following load rejection. This more restrictive frequency recovery specification is consistent with RG 1.9, "Selection and Diesel Generator Set Capacity for Standby Power Supplies," Rev. 3, and the design range of the equipment powered by the DG. This change is consistent with NUREG-1431.</p>
01-26	M	<p>In order to ensure that the DG is tested under load conditions that are as close to design basis conditions as possible, power factor requirements would be added to several SRs.</p> <p>A power factor requirement of less than or equal to 0.9 lagging would be added to the DG partial load rejection SR as a note. This note would apply when the SR is performed with the DG synchronized with offsite power. A power factor requirement would be added to the DG full load rejection and 24-hour load run SRs. The addition of a power factor requirement is consistent with NUREG-1431.</p> <p>For DCCP, the single largest DG load is a centrifugal charging pump (CCP). This power factor is based on the actual design basis inductive loading demand of a CCP assumed in PG&E design calculations.</p> <p>A power factor requirement of less than or equal to 0.87 lagging would be added to the DG full load rejection and 24-hour load run SRs. This power factor is representative of the actual design basis inductive loading that the DGs would experience, and based on the load demands listed in PG&E design calculations (Final Safety Analysis Report (FSAR) Update Table 8.3-5 loads will be revised in the next FSAR Update to include these updated loads). The power factors corresponding to the inductive loading listed for the 4160 volt vital buses are as follows: 0.872, 0.870, and 0.886 for buses F, G, and H, respectively.</p> <p>Also, the DG 24-hour load run SR would be revised to add a note stating that momentary transients outside the power factor range do not invalidate the test, since power factor could change during this test due to changing bus conditions. Similar to real power loading, power factor fluctuation is expected and should not invalidate this test. PG&E believes the practice of monitoring and recording power factor every 15 minutes during the overload part of the 24 hour load test and once every hour for the remaining 22 hours is sufficient to ensure the DG power factor is within its range. DG power factor found out of the range and immediately returned to less than or equal to 0.87 would not invalidate the TS 24-hour load run SR.</p>
01-27	LS9	<p>The DG full load rejection SR maximum DG voltage following load rejection would be increased from 4580 V to 6200 V.</p> <p>The CTS voltage requirement of less than 4580 volts, which is based on the vital bus nominal voltage of 4160 volts plus 10 percent, is too restrictive, and not representative of potential SR testing overshoot voltage values. The proposed limit will allow flexibility in the adjustment of the DG droop settings to provide stable DG operation with the power factor requirements of ITS SR 3.8.1.10 while the DG is paralleled to offsite power for surveillance testing. This change is consistent RG 1.108, "Periodic Testing of Diesel-Generator Units Used as Onsite Electric Power Systems at Nuclear Power Plants," Rev. 1, and with NUREG-1431.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

CHANGE NUMBER

NSHC

DESCRIPTION

01-28	LG	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-29	A	<p>TS 4.8.1.1.2b.7) requires that at least every 18 months, during shutdown, each DG be demonstrated OPERABLE by simulating a loss of offsite power (LOOP) in conjunction with a safety injection (SI) test signal. Included in TS 4.8.1.1.2b.7) is part c), which requires verification that all automatic DG trips, except engine overspeed, low lube oil pressure, and generator differential, are bypassed when the DG trip cutout switch is in the cutout position and the DG is aligned for automatic operation.</p> <p>Including TS 4.8.1.1.2b.7)c) with the other tests which simulate proper DG response to a LOOP in conjunction with an SI test signal implies that the automatic DG trips, except as noted above, are bypassed only on a LOOP in conjunction with an SI signal. However, the design of the DCP DGs is such that all DG trip functions, with the exceptions noted above, are bypassed when the DG is started automatically (on loss of standby power, or SI signal, or both). Therefore, to clarify the DCP TS, TS 4.8.1.1.2b.7)c) would be separated from the requirements of TS 4.8.1.1.2b.7) and included as new TS 3.8.1.13. This change reorganizes these requirements but does not add or remove any technical requirements; therefore, this change is administrative in nature. This is consistent with NUREG-1431.</p>
01-30	LG	<p>The DG 24-hour full load SR voltage and frequency start requirements would be moved to the Bases. The current SR requires verification of DG voltage and frequency after start signal for the 24-hour load run. However, the purpose of the 24-hour load test is to verify the DG can operate, fully loaded, for an extended period of time. The verification of voltage and frequency following the start signal does not contribute to verifying the long term load carrying capability of the DG. This proposed change is consistent with NUREG-1431.</p>
01-31	A	<p>Cycle-specific information that is no longer applicable at the time the ITS is approved by the NRC would be deleted from the TS. This administrative change clarifies the TS by removing unnecessary information. This change is consistent with NUREG-1431.</p>
01-32	M	<p>This proposed change would revise TS 3.8.1.1 to require that with one or more A.C. electrical power sources inoperable, all A.C. electrical power sources be restored to OPERABLE status within 10 days from the time the first A.C. electrical power source became inoperable. The 10-day limit is based upon the addition of the time limit required for restoration of one offsite electrical source (72 hours) and one DG (7 days). This proposed change would add a more restrictive requirement to limit total time for not meeting the ITS LCO. This will provide additional assurance of the availability of the A.C. sources. The addition of a requirement limiting overall time for not meeting the LCO is consistent with NUREG-1431.</p>
01-33	LS15	<p>The SR to check for and remove accumulated water from the DG day tanks after each operation of the DG for greater than one hour would be deleted. Based upon operating experience, checking for accumulated water more often than once per 31 days is unwarranted and unnecessarily frequent. Deleting this requirement would eliminate unnecessary information contained in the TS. This change is consistent with NUREG-1431.</p>
01-34		Not used.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

CHANGE NUMBER

NSHC

DESCRIPTION

01-35	M	Adding the requirement to the 10-year simultaneous DG start SR to verify that the DGs achieve steady state voltage and frequency within the required time demonstrates that proper voltage and frequency performance is attained. This change is consistent with NUREG-1431.
01-36	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
01-37	LG	<p>The specific SRs for sampling new DFO prior to addition to the storage tanks and for sampling the stored DFO once every 31 days would be moved to the Diesel Fuel Oil Testing Program, which would be referenced by SR 3.8.3.3 and described in TS 5.5.13. The Diesel Fuel Oil Testing Program will function similar to other programs currently described in the Administrative Controls section of the TS.</p> <p>SR 3.8.3.3 would require that DFO properties of new and stored DFO are tested in accordance with, and maintained within the limits of, the Diesel Fuel Oil Testing Program. In addition, the SR 3.8.3 Bases will contain additional descriptive material regarding the DFO testing requirements of the current SRs.</p> <p>These changes are consistent with NUREG-1431.</p>
01-38	LG	The fuel oil storage tank cleaning SR would be moved to licensee-controlled documents. This change is consistent with NUREG-1431.
01-39	LG	The fuel oil transfer piping leak test SR would be moved to licensee controlled documents. This change is consistent with NUREG-1431.
01-40	LS25	The requirements for staggered DG testing would be deleted and replaced with a requirement to test each DG every 31 days. Deleting staggered DG testing is consistent with NUREG-1431 and results in no change in the Frequency of testing for each DG. This change is acceptable because studies have shown that staggered testing has negligible impact on equipment reliability. It is not as safety significant as originally thought, it is difficult to implement operationally, and may increase the chance of human error test performance.
01-41	M	The AC Sources - Shutdown LCO would be changed to specify that the required AC sources must be powering, or capable of powering, the required AC distribution busses. This change is an additional restriction consistent with the implicit assumptions for operation during shutdown conditions. This change is consistent with NUREG-1431. (See also CN 03-06-LS26)
01-42	M	CTS 3.8.1.2, CTS 3.8.2.2, and CTS 3.8.3.2 Applicability would be revised to add, "during movement of irradiated fuel assemblies." Addition of this restriction ensures that systems necessary to mitigate a fuel handing accident are available when the unit is not operating in MODEs 1-6. This change is consistent with NUREG-1431.
01-43	M	The AC Sources - Shutdown ACTION statement would be revised to specify that the offsite circuit must be capable of supplying power to the required onsite buses. This assures the single operable circuit is performing a vital function. Explicitly requiring entry into the applicable ACTIONS of LCO 3.8.10 clarifies the appropriate ACTION to take if the onsite distribution train becomes deenergized. This is consistent with NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-44	LG	The AC Sources - Shutdown ACTION statement reference to crane operations with loads over the spent fuel pool would be moved to licensee-controlled documents. This is consistent with NUREG-1431 and is an example of moving details not required for operational safety out of the TS.
01-45	M	The AC Sources - Shutdown ACTION statement requirement to initiate corrective action is expanded to match the Applicability of the TS (MODE 5 and 6). This will replace the current requirement to "immediately initiate corrective action" which is applicable only if reactor coolant system (RCS) loops not full in MODE 5 and less than 23 feet of water above the reactor vessel flange in MODE 6. This more restrictive requirement continues to ensure that qualified power is provided to systems required operable in these MODES. This change is consistent with NUREG-1431.
01-46	A	A Note would be added to the AC Sources - Shutdown ACTION statement to enter the Distribution Systems LCO if one required electrical distribution subsystem has no electrical power. The change is already implicitly a part of the CTS requiring one offsite circuit and the onsite distribution system required to support Onsite Power Distribution-Shutdown LCO. The added note clarifies that the need is to support necessary equipment. This change does not add or remove any technical requirements and is therefore administrative in nature. This change is consistent with NUREG-1431.
01-47	LS4	The SRs required for AC sources OPERABILITY in MODES 5 and 6 would be revised to include only those SRs which are applicable. SRs that are not applicable are those that depend on engineered safety feature (ESF) actuation signals (which are not required to be operational during MODE 5 and 6) and automatic load sequencing (most of these loads are not required in MODE 5 and 6). The 10-year simultaneous auto-start of all DGs is also not applicable to MODE 5 and 6. The note listing exceptions to SR required for MODES 5 and 6 in CTS 4.8.1.2 would be revised to include additional SRs. SRs that are applicable but not required to be performed are those that place a DG in parallel with offsite power which increases the probability of a station blackout. This change is consistent with NUREG-1431 and is acceptable because it would assure the performance of SRs that are necessary and safe to perform for the plant Conditions.
01-48	M	<p>New ITS LCO 3.8.3 would be added. This LCO adds new TS requirements for DG lube oil and starting air. The Applicability of this LCO is tied to DG OPERABILITY requirements.</p> <p>This provides conditions for these DG support systems which allow additional time before requiring that the DG be declared inoperable. However, this is considered a more restrictive generic change since the CTS did not previously include DG lube oil and starting air requirements.</p> <p>The Conditions provided for these support systems address the situation where the support system is degraded but still capable of supporting the associated DG. The time allowed by the new TS Conditions to correct the support system problem before declaring the DG inoperable is acceptable based on the remaining capacity or capability of the systems and the low probability of an event occurring during the allowed time that would require the support systems' full capacity/capability.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

CHANGE NUMBER

NSHC

DESCRIPTION

The new requirements for lube oil inventory (ITS Condition B. and ITS SR 3.8.3.2) verify sufficient lube oil is available to support DG operation. The lube oil storage volume requirement is based upon a percentage of the consumption rate of DFO and the storage assignment is therefore based upon the DBA calculation for diesel fuel oil usage.

The new requirements for air start receiver pressures (ITS Condition E. and ITS SR 3.8.3.4) verify sufficient capacity of the air start receivers.

These changes are consistent with NUREG-1431.

01-49

LS16

NUREG-1431 LCO 3.8.3, "Diesel Fuel Oil, Lube Oil, and Starting Air," includes Conditions and Required ACTIONS that allow reduced DFO inventory for up to 48 hours before requiring that the associated DG be declared inoperable. A new Condition would address stored DFO with total particulates out of limit and allow 7 days for restoration. A new Condition would address new fuel oil with properties not within limits and allow 30 days for restoration. The additional allowed outage time (AOT) for DFO is acceptable based on the remaining capacity of the DFO system and the low probability of an event occurring during the time that the DFO requirements were not met. This change is consistent with NUREG-1431.

01-50

LS17

CTS 3.8.1.1 ACTION shutdown requirement would be replaced with a requirement to enter the required feature's ACTION statement. The ACTION currently requires that with one DG inoperable, all required safety equipment that depends on the remaining OPERABLE DG(s) be verified OPERABLE. If these requirements are not met, a unit shutdown is required. Rather than requiring a unit shutdown, the proposed change would require declaring inoperable the required safety equipment powered from an inoperable DG. This would result in entering the required feature's TS ACTION statement. These ACTIONS would assure that specific measures, appropriate for a loss of safety function associated with inoperable redundant features, would be taken. From a safety standpoint it is preferable to avoid an unnecessary plant shutdowns. This change is consistent with NUREG-1431 and is acceptable because it would continue to assure the OPERABILITY of required features without requiring an unnecessary plant shutdown.

01-51

LS18

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

01-52

M

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

01-53

M

A Note would be added to the SR for monthly DG load test to allow testing on only one DG at a time. Consistent with current practice, this prevents having two DG synchronized and loaded on offsite power at one time. This reduces the risk of "common cause" failure. This change is consistent with NUREG-1431.

01-54

LS19

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

01-55

M

A Note would be added prohibiting several SRs from being performed in MODES 1 through 4. This change is consistent with NUREG-1431.

01-56

M

Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-57	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-58	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-59	LS20	AC Sources - Shutdown ACTION statement would be revised to provide the alternative to "declare affected required features with no offsite power available inoperable." Since the circuit OPERABILITY requirements are in terms of powering all distribution systems required to be OPERABLE by LCO 3.8.10, the Required ACTION for one circuit inoperable would be revised to add, "declare affected required features with no offsite power available inoperable," as an alternative to the other Required ACTIONS. In the event one or more required load centers, motor control centers, buses, etc., are not capable of being powered via an offsite circuit, it may not be necessary to suspend all CORE ALTERATIONS, positive reactivity changes, or movement of irradiated fuel. In this case, conservative ACTION can be assured if all required equipment without qualified offsite power availability is declared inoperable and the associated ACTIONS taken. This change is consistent with NUREG-1431.
01-60	LS24	Consistent with NUREG-1431; the surveillance interval for verifying that other properties are within limits for ASTM 2D fuel oil is changed from "within 30 days" to "within 31 days" after obtaining a sample. The fuel properties that can have an immediate detrimental impact on diesel combustion, (i.e., API gravity, kinematic viscosity, flash point and appearance) are verified prior to addition to the storage tank. The "other properties" may be analyzed after addition to the tank. The 31 day verification interval for these properties is acceptable because the fuel properties of interest, even if they are not within their stated limits, would not have an immediate affect on DG operation. The CTS 30 day verification interval was probably chosen because it was a convenient time interval for sending the sample and receiving the results from the laboratory selected for testing. NUREG-1431 has selected a 31 day testing interval. The 1 day increase in the interval would not have a significant affect on the acceptability of the DFO.
01-61	M	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-62	A	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-63	LG	Not applicable to DCPP. See Conversion Comparison Table (Enclosure 3B).
01-64	M	<p>The new requirements for turbocharger air assist air receiver pressures (ITS 3.8.3 LCO, Condition F. and ITS SR 3.8.3.6) verify sufficient capacity of the turbocharger air assist air receivers.</p> <p>This provides Conditions for these DG support systems which allow additional time before requiring that the DG be declared inoperable. However, this is considered a more restrictive generic change since CTS did not previously include turbocharger air assist air requirements.</p> <p>This change is consistent with the intent of NUREG-1431.</p>

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
01-65	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
01-66	TR3	<p>This SR currently requires that at least once per 10 years or after any modifications which could affect emergency diesel generator (EDG) interdependence, during shutdown, and verify that both EDGs accelerate to [at least 514 RPM] in less than or equal to [12 seconds]. It is being proposed that this SR be revised to eliminate the requirement to perform the test after any modifications which could affect EDG interdependence.</p> <p>This SR can be considered to be the "redundant unit test" in accordance with RG 1.9, "Selection and Diesel Generator Set Capacity for Standby Power Supplies," Rev. 3. This test demonstrates that by starting and running both redundant units simultaneously, potential "common cause failure" that may be undetected in single EDG unit tests do not occur. The proposed change to this SR will make it consistent with the ITS SR 3.8.1.20. The elimination of the requirement to perform this SR after any modification which could affect EDG interdependence is justified based upon the ability of the modification process to detect concerns related to the interdependence of the EDGs.</p>
02-01	LG	The list of batteries and chargers in the CTS DC Sources - Operating LCO and ACTION requirement would be moved to the Bases. This deletes descriptive information from the TS, consistent with NUREG-1431.
02-02	A	The phrase, "that could degrade battery performance," would be added to clarify the purpose of the battery inspection SR consistent with TSTF-38. This change does not add or remove any technical requirements and is administrative in nature.
02-03	M	The requirement to remove visible terminal corrosion would be added to the SR verifying on an 18-month frequency that cell-to-cell and terminal connections are clean, tight, and coated with anticorrosion material. These elements of a visual inspection are consistent with IEEE-450, 1995. This change is consistent with NUREG-1431.
02-04	M	A Note would be added to SRs that these SRs are not to be performed in MODEs 1, 2, 3, or 4. Since these surveillances discharge the battery such that it would not have capacity left to perform its required function, this SR must be performed when the battery is not required to support an operable vital bus. The addition of this Note is consistent with NUREG-1431.
02-05	M	The SR would be changed to allow performing a modified performance discharge test instead of the performance discharge test. The modified performance test is a more severe test and envelopes the battery service discharge test. The results of the modified performance test provides assurance of the battery capability as well as battery capacity. This change is consistent IEEE-450, 1995 and with NUREG-1431.
02-06	LS22	Consistent with industry Traveler TSTF-115, this change would allow the extension of the surveillance frequency verification for battery terminal voltage while on float charge, and for Category A battery cell parameters from 7 days to 31 days in accordance with the recommended frequency of at "least monthly" identified in IEEE 450-1995, Section 4.3.1.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
02-07	A	A Note would be added to the battery SRs table for Category A and B limits. This Note would allow the electrolyte level to temporarily increase above the maximum level during equalizing charges provided it does not overflow. This electrolyte level excursion is due to gas generation during the charge and is expected to return to normal after the charge. Therefore, the level excursion is acceptable. This change is consistent with NUREG-1431.
02-08	LS21	Notes contained in current battery SRs table for Category A and B limits would be combined in new LCO 3.8.6, "Battery Cell Parameters," as Condition A. A 31-day Completion Time would be added for restoring the Category A and B limits. This Completion Time is considered acceptable since sufficient battery capacity exists to perform the required function and new Required ACTIONS have been implemented to assure that the battery remains capable of performing its required function (Refer to 02-09-M). This change is consistent with NUREG-1431.
02-09	M	<p>To support the extended Completion Time of new Condition A, within one hour after any Category A or B battery not within limits, the pilot cell electrolyte level and float voltage must be verified within Category B allowable value. This provides a quick indication of the status of the remainder of the battery cells.</p> <p>For Category A and B parameters not restored to within limits, a new requirement would be added to verify the battery meets Category C allowable values once every 7 days.</p> <p>This is consistent with NUREG-1431.</p>
02-10	A	The battery SRs table notes would be revised to add an exception to the requirement to correct specific gravity readings for electrolyte level when the float charge is less than 2 amps. This exception is considered acceptable since charging current provides, in general, a good indication of overall battery condition. This change is consistent with NUREG-1431.
02-11	M	This change to the battery SRs table notes would place a 7-day limit on the use of charging current to satisfy the specific gravity requirements. This is more realistic because CTS does not place a time limit on use of charging current. This change is consistent with NUREG-1431.
02-12	LG	The battery SRs table Note regarding correction of float voltage for average electrolyte temperature would be moved to the Bases. This is consistent with NUREG-1431.
02-13	A	The DC Sources - Shutdown LCO would be revised to require that the DC power subsystem required to be OPERABLE must be the subsystem necessary to support the onsite power distribution-shutdown LCO. This requirement is currently required by CTS [3.8.2.2]. This change is consistent with NUREG-1431 (see also CN 03-06-LS26).
02-14	A	The battery cell parameters table would be revised to add Category C, which now contains the allowable value for each connected cell previously included in Category B. This change is consistent with NUREG-1431.

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
02-15	LS4	A Note would be added stating the SRs are not required to be performed for the DC source OPERABILITY in the MODEs governed by DC Sources - Shutdown Applicability. The Note does not delete the requirement that the battery be capable of performing these functions, just that the capacity need not be demonstrated while that battery is relied on to meet the LCO. This change is consistent with NUREG-1431.
02-16	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-17	LS2	The requirements to verify no visible terminal corrosion and minimum electrolyte temperature after a battery discharge or overcharge would be deleted. This is consistent with NUREG-1431.
02-18	LG	The definition of degradation provided in the battery service test SR would be moved to the SR Bases. The number of connected cells that constitutes the ITS SR 3.8.6.3, "representative cells," requirement would be moved to the Bases. This constitutes moving details that are not required to be in TS and therefore is acceptable. This change is consistent with NUREG-1431.
02-19	LS20	Since the DC sources OPERABILITY requirements are in terms of powering DC electrical subsystems required to be OPERABLE by ITS LCO 3.8.10, the Required ACTION would be revised to add, "declare affected required features inoperable," as an alternative to the other Required ACTIONS. In this Condition it may not be necessary to suspend all CORE ALTERATIONS, positive reactivity changes, or movement of irradiated fuel. In this case, conservative ACTION can be assured if all required equipment without DC power is declared inoperable and the associated ACTIONS taken. Therefore, this proposed change is acceptable from a safety standpoint. This change is consistent with NUREG-1431.
02-20	A	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).
02-21	LS14	The frequency for battery surveillance would be extended to 24 months if the battery has reached 85 percent of expected life and the rating is \geq 100 percent of manufacturer's capability.
02-22	A	The battery average electrolyte temperature SR would be changed from "above" the minimum temperature to " \geq " the minimum temperature. This change is consistent with NUREG-1431.
02-23	A	The quarterly battery connection resistance SR limit, if there is visible corrosion, would be changed from "less than 150×10^{-6} ohm" to " $\leq 150 \times 10^{-6}$ ohm." This would be consistent with the limit for the 18-month battery corrosion resistance SR. This change is consistent with NUREG-1431.
02-24	LG	The footnote allowing resistance of cell to cell connecting cables to not be included in the connection resistance SR would be moved to the SR Bases. This change is consistent with NUREG-1431.
02-25	LS23	Not applicable to DCP. See Conversion Comparison Table (Enclosure 3B).

DESCRIPTION OF CHANGES TO TS SECTION 3/4.8

<u>CHANGE NUMBER</u>	<u>NSHC</u>	<u>DESCRIPTION</u>
03-01	LG	The list of required electrical buses, batteries and chargers in the CTS Onsite Power Distribution - Operating [] LCO would be moved to the Bases. This deletes descriptive information from the TS, consistent with NUREG-1431.
03-02	A	Information and requirements for Class 1E inverters would be moved to ITS TS 3.8.7, "Inverters - Operating," ITS 3.8.8, "Inverters - Shutdown," and associated Bases. This change is consistent with NUREG-1431.
03-03	LS20	The Onsite Power Distribution - Shutdown ACTION statement would be revised to allow the option of declaring associated supported required feature(s) inoperable. Although the proposed change allows more operational flexibility, it would still ensure plant safety by taking the appropriate Required ACTION for equipment declared inoperable. Therefore, the change is acceptable. This change is consistent with NUREG-1431.
03-04	M	A second Completion Time for ACTIONS of CTS Onsite Power Distribution - Operating would be added. The Completion Time would place a limit of 16 hours on not meeting the LCO. This Completion Time is required by the NUREG-1431 format that potentially allows alternating between Conditions of ITS LCO 3.8.9 such that the LCO may not be met for an indefinite period of time. This change is consistent with NUREG-1431.
03-05	A	A new ACTION would be added to CTS Onsite Power Distribution - Operating that requires entry into ITS LCO 3.0.3 for two [Class 1E Vital Busses] with inoperable distribution subsystems that result in a loss of safety function. This change is consistent with NUREG-1431.
03-06	LS26	The existing requirement for "the following" distribution buses, lists [] Class 1E power required to be OPERABLE during shutdown . The proposed LCO specifies that the portion of these distribution subsystems necessary to supply AC and DC power to equipment required to be OPERABLE in this plant Condition must be OPERABLE.
03-07	M	An additional ACTION (ITS LCO 3.8.10, Condition A.2.5) would be added to immediately declare associated residual heat removal (RHR) subsystem(s) inoperable and not in operation. This ACTION is included because of the allowances of ITS LCO 3.0.6 (Support/Supported System OPERABILITY). ITS LCO 3.0.6 would allow only the ACTIONS for the inoperable distribution subsystem to be taken. ITS Condition A.2.5 would assure consideration is given to shutdown cooling systems that are without required power and that appropriate ACTIONS are taken to assure OPERABILITY of these required systems. This change is consistent with NUREG-1431.
03-08	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
03-09	A	Not applicable to DCCP. See Conversion Comparison Table (Enclosure 3B).
03-10		Not used.
03-11	A	Not applicable to DCCP. See Conversion Comparison Table Enclosure 3B).
04-01	R	The [Motor-operated Valve Thermal Overload Protection Bypass Devices CTS and] Containment Penetration Conductor Overcurrent Protective Devices CTS would be relocated to licensee-controlled documents . This change is consistent with NUREG-1431.

ENCLOSURE 3B

CONVERSION COMPARISON TABLE - CURRENT TS

Conversion Comparison Table

(16 pages)

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-01 A	<p>TS requirement for minimum DG day tank fuel oil volume and fuel transfer pump would be moved to ITS SR 3.8.1.4 and SR 3.8.1.6.</p> <p>TS requirements for DFO storage would be moved to ITS LCO 3.8.3.</p>	Yes	Yes	Yes	Yes
01-02 A	Footnote would be revised to specify "may" instead of "shall" in reference to the DG start being preceded by an engine prelube period to minimize wear on moving parts that do not get lubricated when the engine is not running.	No, CTS footnote specifies "may."	No, CTS footnote specifies "may."	Yes	Yes
01-03 LS5	TS 3.8.1.1 ACTION requirement to demonstrate DG OPERABILITY with an offsite circuit inoperable, two offsite circuits inoperable, or with an offsite circuit and a DG inoperable, is deleted.	Yes	Yes	No, already deleted per Amendment 101.	No, already deleted per Amendment 112.
01-04 M	This proposed change would revise TS 3.8.1.1 to require that with one or more A.C. electrical power sources inoperable, all A.C. electrical power sources be restored to OPERABLE status within 6 days from the time the first A.C. electrical power source became inoperable.	No, 10-day AOT proposed as Change 01-32-M.	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-05 LS6	This proposed change incorporates the NUREG-1431, provision of "determining the OPERABLE DGs are not inoperable due to a common cause failure," which avoids unnecessary testing of OPERABLE DGs, into ACTIONS for one DG inoperable and for one DG and an offsite circuit inoperable. In addition, the requirement to complete DG testing regardless of when the inoperable DG is restored to OPERABLE status would be deleted.	Yes	Yes	Yes	Yes
01-06 LS7	CTS 3.8.1.1 ACTION allowed time for verification of required redundant feature OPERABILITY would be increased from 2 to 4 hours. The requirements would be moved to LCO 3.8.1, ACTION B, and the shutdown requirement would be replaced with a requirement to enter the required feature's ACTION statement.	Yes	Yes	Yes	Yes
01-07 LS3	The CTS SR to start all DGs simultaneously would be revised to delete the requirement to perform this SR during shutdown.	Yes	Yes	No, not in CTS.	No, not in CTS.
01-08 LS8	The CTS 3.8.1.1 ACTION requirement to demonstrate DG operability in 8 hours would be changed to 24 hours.	Yes	Yes	Yes	Yes
01-09	Not Used.	N/A	N/A	N/A	N/A

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-10 M	CTS 3.8.1.1 ACTIONS would be revised to require transition to MODE 5 within 30 hours following transition to MODE 3 upon failure to meet the requirements of the ACTION statements.	Yes	No, already in CTS.	Yes	Yes
01-11 TR1	The phrase "or actual" in reference to an automatic actuation signal would be added to those SRs which verify actuation on a test (or simulated) automatic actuation signal.	Yes	Yes	Yes	Yes
01-12 A	The footnote allowing engine prelube period would be applicable to all DG SRs.	Yes	No, already in CTS.	Yes	No, already in CTS.
01-13 LS1	Accelerated testing of the DGs and DG special reporting requirements would be deleted consistent with the recommendations of GL 94-01.	Yes	No, not in CTS.	No, deleted per Amendment 101.	No, deleted per Amendment 112.
01-14 A	CTS requirement of "standby status" would be replaced with "ready-to-load operation."	Yes	Yes	Yes	Yes
01-15 A	The requirement to start the DG from "ambient condition" would be replaced with "standby conditions" and description of these Conditions added to the Bases.	Yes	No, already in CTS.	No, already in CTS.	No, already in CTS.
01-16 LG	The method by which the DG is started would be moved to the Bases.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-17 LS10	The requirement to rapidly load the DG in less than or equal to 60 seconds would be deleted.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
01-18 LS11	DG loading requirements would be revised.	Yes	Yes	No, load range already in CTS.	No, not applicable to CTS.
01-19 LS12	A footnote would be added to the several DG loading SRs stating that momentary transients outside the load and/or power factor range do not invalidate the test.	Yes	No, already in CTS.	Yes	Yes
01-20 LG	SRs that support normal design, maintenance, or line-up activities/descriptions would be moved to licensee-controlled documents.	Yes, moved to the Bases.	Yes, moved to TRM.	Yes, moved to USAR.	Yes, moved to the Bases.
01-21 M	An additional requirement would be added to TS 3.8.1.1 ACTION. This requirement would only apply if the inoperable offsite circuit results in no offsite power to a Class 1E electric power distribution system and affected ESF systems.	No, this requirement is not applicable due to plant electrical design.	Yes	Yes	Yes
01-22 M	An additional requirement would be added to TS ACTION for two offsite circuits inoperable. This requirement is intended to provide assurance that an event with a coincident single failure would not result in a complete loss of redundant, required safety functions.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-23 LG	The specific loading listed in the DG partial load rejection SR requirement would be replaced by "a load greater than or equal to its single largest post-accident load."	Yes	Yes, moved to Bases.	No, test deleted by Amendment 101.	No, not in CTS per Amendment 112.
01-24 LS13	The DG partial load rejection requirement that voltage be maintained would be replaced with a requirement that within 2.4 seconds following load rejection, the voltage recovers to steady-state requirements.	Yes	No, not in CTS.	No test deleted by Amendment 101.	No, not in CTS.
01-25 M	The DG partial load rejection requirement to maintain frequency at 60 ± 3 Hz would be revised to require that frequency recover to 60 ± 1.2 Hz within 2.4 seconds following load rejection.	Yes	No, not in CTS.	No, test deleted by Amendment 101.	No, not in CTS.
01-26 M	Power factor requirements would be added to the DG loading SRs.	Yes	No, maintain CTS.	No, requirement in CTS, see CN 01-36-A.	No, already in CTS.
01-27 LS9	The SR maximum allowed voltage following DG full load rejection would be increased from 4580 V to 6200 V.	Yes	No, maintains different voltage.	No, maintaining CTS.	No, not applicable to CTS.
01-28 LG	The requirement to verify the DG accelerates within required time would be moved to licensee-controlled documents.	No; CTS requirement retained.	Yes, moved to Bases.	No, not in CTS.	No, already moved per Amendment 112.

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-29 A	The SR to verify automatic DG trips are bypassed would be separated from the requirements under simulated SI signal DG testing and included as a separate SR.	Yes	No, different plant design.	No, already a separate CTS SR.	No, already in CTS.
01-30 LG	DG 24-hour load SR voltage and frequency start requirements would be moved to the Bases.	Yes	Yes	Yes	Yes
01-31 A	Cycle-specific requirements that are no longer applicable would be deleted.	Yes	Yes	No, not in CTS.	No, not in CTS.
01-32 M	This proposed change would revise CTS 3.8.1.1 to require that with one or more A.C. electrical power sources inoperable, all A.C. electrical power sources be restored to OPERABLE status within 10 days from the time the first A.C. electrical power source became inoperable.	Yes	No, adopting ITS requirement for 6 days see CN 01-04-M.	No, adopting ITS requirement for 6 days see CN 01-04-M.	No, adopting ITS requirement for 6 days see CN 01-04-M.
01-33 LS15	SR to check for and remove accumulated water from the DG day tanks after each operation of the DG for greater than one hour would be deleted.	Yes	Yes	No, deleted by Amendment 101.	No, deleted by Amendment 112.
01-34	Not used.	N/A	N/A	N/A	N/A
01-35 M	Voltage and frequency requirements would be added to the 10-year simultaneous DG start SR.	Yes	Yes	No, already in CTS.	No, already in CTS.
01-36 A	The DG power factor lower limit of 0.8 would be deleted from the power factor limits of between 0.8 and 0.9.	No, CTS does not contain power factor limits.	No, CTS does not contain power factor limits.	No, maintaining CTS.	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-37 LG	The specific requirements for sampling new DFO prior to addition to the storage tanks and for sampling the stored DFO once every 31 days would be moved to the Diesel Fuel Oil Testing Program, which would be referenced by ITS SR 3.8.3.3 and described in ITS 5.5.13.	Yes	Yes	Yes	Yes
01-38 LG	Fuel oil storage tank cleaning requirements would be moved to licensee-controlled documents.	Yes, moved to the FSAR.	Yes, moved to TRM.	No, maintaining CTS.	Yes, moved to the FSAR.
01-39 LG	Fuel oil transfer piping leak test would be moved to licensee controlled documents.	Yes, moved to the FSAR.	Yes, moved to TRM.	No, not in CTS.	No, not in CTS.
01-40 LS25	The requirement for staggered DG testing would be deleted and replaced with a requirement to test each DG every 31 days.	Yes	Yes	Yes	Yes
01-41 M	The AC Sources - Shutdown LCO would be changed to specify that the required AC sources must be powering, or capable of powering, the required AC distribution buses.	Yes	Yes	Yes	Yes
01-42 M	CTS 3.8.1.2, CTS 3.8.2.2, and CTS 3.8.3.2 Applicability would be revised to add "during movement of irradiated fuel assemblies."	Yes	No, maintain CTS.	No, maintain CTS.	No, maintain CTS.
01-43 M	An AC Sources - Shutdown ACTION statement would be revised to specify that the offsite circuit must be capable of supplying power to the required onsite buses, and therefore to all equipment required to be OPERABLE in the Applicable MODEs.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-44 LG	Reference to crane operations with loads over the spent fuel pool would be moved from the LCO ACTION to licensee-controlled documents.	Yes, move to the FSAR.	Yes, moved to Bases.	Yes, moved to the USAR.	Yes, moved to the FSAR.
01-45 M	The requirement to initiate corrective ACTION is expanded to match the Applicability of the TS.	Yes	Yes	Yes	Yes
01-46 A	A note would be added to the AC Sources - Shutdown ACTION statement to enter the Distribution Systems LCO if one required train has no electrical power.	Yes	Yes	Yes	Yes
01-47 LS4	The SRs required for AC sources OPERABILITY in MODEs 5 and 6 would be revised to include only those SRs which are applicable. The note listing exceptions to SR required for MODEs 5 and 6 in CTS 4.8.1.2 would be revised to include additional SRs.	Yes	Yes	Yes	Yes
01-48 M	A new LCO would be added with new TS requirements for DG lube oil and starting air.	Yes	Yes	Yes	Yes
01-49 LS16	A new LCO would be added. The Condition of degraded DFO capacity would be addressed by an ACTION statement allowing 48 hours to restore DFO level. A new Condition would address stored DFO with total particulates out of limit and allow 7 days for restoration. A new Condition would address new fuel oil with properties not within limits and allow 30 days for restoration.	Yes	Yes, for DFO capacity only, other changes already in CTS.	Yes	Yes
01-50 LS17	Required features supported by the inoperable DG would be declared inoperable when its required redundant feature is inoperable.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-51 LS18	The frequency for testing the DFO transfer pumps would be extended from 31 to 92 days.	No, CTS of 31 days is retained.	Yes	Yes	No, CTS frequency is retained.
01-52 M	SR would require the DFO transfer pumps to be started automatically.	No, DFO pumps started manually.	Yes	No, not a CTS requirement.	No, not a CTS requirement.
01-53 M	A Note would be added to the SR for monthly DG start and load test to allow testing on only one DG at a time.	Yes	Yes	Yes	Yes
01-54 LS19	DG partial load rejection SR frequency lower limit of 53.25 Hz would be deleted.	No, frequency limit not CTS.	Yes	No, test deleted by Amendment 101.	No, not in CTS.
01-55 M	A note would be added prohibiting several SRs from being performed in MODEs 1 - 4.	Yes	Yes	Yes	Yes
01-56 M	The required warmup period prior to hot restart DG SR would be changed from 1 hour to 2 hours.	No, CTS is 2 hour warmup period.	Yes	No, already in CTS.	No, already revised per Amendment 112.
01-57 A	The reference to depressurizing and venting the RCS is removed from this TS. The requirements for providing RCS capacity at low temperatures is covered in the RCS TS Low Temperature Overpressure Protection. Removal of this reference eliminates duplication and is consistent with NUREG-1431.	No, not in CTS.	Yes	No, not in CTS.	No, not in CTS.
01-58 LG	The requirement to verify that the DFO transfer pump transfers fuel from each storage tank to the day tank of each DG via the installed cross-connected lines would be moved to licensee-controlled documents.	No, not CTS requirement.	No, no cross-connected lines.	Yes, moved to the USAR.	Yes, moved to the FSAR.

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
01-59 LS20	AC Sources - Shutdown ACTION statement would be revised to provide the alternative to "declare affected required features with no offsite power available inoperable."	Yes	Yes	Yes	Yes
01-60 LS24	The surveillance interval for verifying that other properties are within limits for ASTM 2D fuel oil is changed from "within 30 days" to "within 31 days" after obtaining a sample.	Yes	Yes	No, not in CTS.	No, not in CTS.
01-61 M	The voltage tolerance would be revised to raise the minimum steady state output voltage requirement for the DGs.	No, CTS already requires adequate minimum voltage.	Yes	No, maintain CTS.	Yes
01-62 A	The verbiage from other applicable ACTIONS for one offsite circuit inoperable and for one DG inoperable would be deleted.	No, ITS format change.	No, alternate markup achieves same result.	Yes	Yes
01-63 LG	The requirement that the air roll test not be performed when the DGs are started per the ACTION requirements has been moved to the Bases.	No, air roll test not in CTS.	Yes	No, not in CTS.	No, not in CTS.
01-64 M	A new LCO requirement would be added with TS requirements for DG turbocharger air assist.	Yes	No, not in CTS.	No, not in CTS.	No, not in CTS.
1-65 A	This change deletes the note which states that "credit may be taken for unplanned events that satisfy this SR." This change eliminates the confusion that may arise with respect to the application of an unplanned event which satisfies the requirements of a given SR by including a discussion in the SR 3.0.1 and Bases. This change is based on Traveler TSTF-8, Rev. 2.	No, Note not in CTS.	No, note not in CTS.	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
1-66 TR3	It is being proposed that this SR be revised to eliminate the requirement to perform the test after any modifications which could affect EDG interdependence.	Yes	Yes	Yes	Yes
02-01 LG	The list of batteries and chargers would be moved to the Bases.	Yes	Yes	Yes	Yes
02-02 A	The phrase, "that could degrade battery performance," would be added to clarify the purpose of the battery inspection SR (TSTF-38).	Yes	Yes	Yes	Yes
02-03 M	The requirement to remove visible terminal corrosion would be added to the SR verifying on an 18-month frequency that cell-to-cell and terminal connections are clean, tight, and coated with anticorrosion material.	Yes	Yes	Yes	Yes
02-04 M	A Note would be added to several SRs that this surveillance is not to be performed in MODEs 1, 2, 3, or 4.	Yes	Yes	Yes	Yes
02-05 M	The SR would be changed to allow performing a modified performance discharge test instead of the performance discharge test. The results of the modified performance test could be used in lieu of performing the battery service test, SR 3.8.4.7.	Yes	Yes	Yes	Yes
02-06 LS22	Consistent with industry Traveler TSTF-115, this change would allow the extension of the surveillance frequency verification for battery terminal voltage while on float charge, and for Category A battery cell parameters from 7 days to 31 days in accordance with the recommended frequency of at "least monthly" identified in IEEE 450-1995, Section 4.3.1.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
02-07 A	A note would be added to the battery surveillance requirements table for Category A and B limits. This note would allow the electrolyte level to temporarily increase above the maximum level during equalizing charges provided it does not overflow.	Yes	Yes	Yes	Yes
02-08 LS21	A 31-day Completion Time would be added for restoring the Category A and B limits.	Yes	Yes	Yes	Yes
02-09 M	To support the extended Completion Time of new Condition A, within one hour after any Category A or B battery not within limits, the pilot cell electrolyte level and float voltage must be verified within Category B allowable value. For Category A and B parameters not restored to within limits, a new requirement would be added to verify the battery meets Category C allowable values once every 7 days.	Yes	Yes	Yes	Yes
02-10 A	The battery SRs table notes would be revised to add an exception to the requirement to correct specific gravity readings for electrolyte level when the float charge is less than 2 amps.	Yes	Yes	Yes	Yes
02-11 M	This change to the battery SRs table notes would place a 7-day limit on the use of charging current to satisfy the specific gravity requirements.	Yes	Yes	No, maintaining CTS.	Yes
02-12 LG	The battery SRs table note regarding correction of float voltage for average electrolyte temperature would be moved to the Bases.	Yes	Yes	Yes	Yes

CONVERSION COMPARISON TABLE - CURRENT TS

TECHNICAL SPECIFICATION CHANGE		APPLICABILITY			
	DESCRIPTION	Diablo Canyon	Comanche Peak	Wolf Creek	Callaway
02-13 A	The DC Sources - Shutdown LCO would be revised to require that the DC power subsystem required to be OPERABLE must be the subsystem necessary to support the Onsite Power Distribution - Shutdown LCO.	Yes	Yes	Yes	Yes
02-14 A	The battery cell parameters table would be revised to add Category C, which now contains the allowable value for each connected cell previously included in Category B.	Yes	Yes	Yes	Yes
02-15 LS4	A Note would be added stating SRs that are not required to be performed for the DC source OPERABILITY in the MODEs governed by DC Sources - Shutdown applicability.	Yes	Yes	Yes	Yes
02-16 A	The SR requiring bus breaker alignment and indicated voltage to be verified would be deleted from DC Sources - Shutdown. This requirement would be located in ITS 3.8.9.	No, not in CTS.	No, not in CTS.	No, not in CTS.	Yes
02-17 LS2	The requirements to verify no visible terminal corrosion and minimum electrolyte temperature after a battery discharge or overcharge would be deleted.	Yes	Yes	Yes	Yes
02-18 LG	The definition of degradation provided in the battery service test SR would be moved to the SR Bases. The number of connected cells that constitutes the ITS SR 3.8.6.3, "Representative Cells," requirement would be moved to the Bases.	Yes	Yes	Yes	Yes
02-19 LS20	DC Sources - Shutdown ACTION statement would be revised to allow the option of declaring affected required feature(s) inoperable.	Yes	Yes	Yes	Yes

I. NO SIGNIFICANT HAZARDS CONSIDERATIONS ORGANIZATION

In accordance with the provisions of 10CFR50.90, this License Amendment Request proposes to revise the CTS. The proposed revision includes converting the CTS to the Improved Standard Technical Specifications (ISTS) in NUREG-1431, Revision 1. The conversion to the ISTS (also referred to as the improved STS or ISTS) has generated a large number of changes. Evaluations pursuant to 10CFR50.92 showing that the proposed changes do not involve significant hazards considerations are provided for each TS chapter. However, due to the volume of changes, similar changes have been grouped in categories to facilitate the NSHCs required by 10CFR50.92.

Generic NSHCs have been developed that correspond to each category of changes. In addition, since each TS chapter has been evaluated individually, chapters may contain chapter-specific generic NSHCs. NSHCs for changes that cannot be grouped into a category have also been developed. Typically, less restrictive technical changes must be evaluated individually. Each TS chapter will, therefore, contain "change-specific" NSHCs for less restrictive technical changes as well as generic NSHCs.

Each change to the CTS is marked-up on the appropriate page and technical changes are assigned a change number. Obvious editorial or administrative changes are not marked-up. The change number in the right margin of the marked-up page is used in the Description of Changes (Enclosure 3A), which provides a detailed basis for each change and a reference to the applicable NSHC. For Enclosures 3A, 3B, 4, 6A, and 6B, text in brackets "[]" indicates the information is plant specific and is not common to all the JLS plants. Empty brackets indicate that other JLS plants may have plant specific information in that location.

II. DESCRIPTION OF NSHC EVALUATIONS

GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

The following are brief descriptions of the generic NSHCs contained within this TS chapter. The reference symbols are used in the Discussion of Changes to index the applicable NSHC for each change described and are incorporated into the change numbers. Additional generic subcategories may be developed and will be referenced by adding a numeric designator to the existing alpha reference symbol (i.e., LG1, LG2, A1, A2, etc).

Administrative

Reference symbol "A" (Administrative)

This category consists of changes which are editorial in nature, involve the movement of requirements within the TS without affecting their technical content, simply reformat a requirement, or clarify the TS (such as deleting a footnote no longer applicable due to a technical change to a requirement). It also includes nontechnical changes made to conform to the Writer's Guide or the ISTS in NUREG-1431. Most administrative changes have not been marked-up on the CTS, and thus are not specifically referenced to a discussion of change or NSHC. If no discussion of change or NSHC is referenced for a change it is considered administrative in nature and this generic NSHC applies. This NSHC may also be referenced in a discussion of change for an administrative change that is not obvious and requires an explanation.

Relocation of Technical Specification Requirements

Reference symbol "R" (Relocation)

This category applies to TS requirements that do not meet the criteria in 10CFR50.36(c)(2)(ii). TS requirements affected by the application of the criteria are annotated with an "R" in the description of the change (Enclosure 3A). The "R" designation and the description of the relocation direct the reviewer to this NSHC for a description and evaluation of the change.

Moving information out of Technical Specifications

Reference symbol "LG" (Less Restrictive, Generic)

In some cases, information will be moved out of the TS while the underlying requirement remains (e.g., the requirement for equipment operability is retained in the LCO but the definition of operability is moved to the Bases). The affected information maybe moved to the Bases, the Final Safety Analysis Report (FSAR), or other licensee controlled documents. This category of change is considered to be less restrictive (no longer controlled by TS) and usually involves moving information of a descriptive nature. These changes are generally made in order to conform with NUREG-1431 format and content.

Technical change, more restrictive

Reference symbol "M" (More Restrictive, Generic)

This category consists of changes that add new requirements to the TS or revise existing requirements to be more stringent. These changes are typically made to conform to applicable requirements of NUREG-1431.

II. DESCRIPTION OF NSHC EVALUATIONS

SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

Those TS changes that must be evaluated individually are typically the less restrictive technical changes. Each NSHC for less restrictive technical changes in this TS chapter will be numbered sequentially. The applicable NSHC for each less restrictive change will be referenced in the Description of Change (Enclosure 3A) for this chapter. The Description of Change contains the basis for the change.

Technical change, less restrictive

Reference symbol "LS" (Less Restrictive, Specific)

This category consists of changes which revise existing requirements such that more restoration time is provided, fewer compensatory measures are needed, or fewer or less restrictive surveillance requirements are required. This would also include requirements which are deleted from the TS (not relocated or moved to other documents).

Technical change, recurring - less restrictive

Reference symbol "TR-1, 2, 3...." (Technical Recurring)

This category consists of the same kind of changes as LS above except that they are generic to several specifications.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
10CFR50.92 EVALUATION
FOR
ADMINISTRATIVE REFORMATTING AND REWORDING

This proposed TS revision includes reformatting and rewording the remaining requirements in accordance with the NUMARC Technical Specification Writer's Guide and the Improved Standard Technical Specifications in NUREG-1431. This is intended to make the TS more readily understandable to plant operators and other users. Application of the Writer's Guide will also assure consistency between specifications. During this reformatting and rewording process, no technical changes (either actual or interpretational) were made to the TS unless they were identified and justified.

This proposed TS change has been evaluated and it has been determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change involves reformatting and rewording of the current Technical Specifications. The reformatting and rewording process involves no technical changes to the current Technical Specifications. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accidents or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. This change is administrative in nature. As such, no question of safety is involved.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"A"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "A" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
10CFR50.92 EVALUATION
FOR
RELOCATING TECHNICAL SPECIFICATION REQUIREMENTS
TO OTHER LICENSEE CONTROLLED DOCUMENTS

This proposed TS revision includes relocating requirements, which do not meet the TS criteria, to documents with established control programs. Relocation of these requirements allows the TS to be reserved only for those conditions or limitations upon reactor operation which are necessary to obviate the possibility of an abnormal situation or event giving rise to an immediate threat to the public health and safety thereby focusing the scope of the TS.

Therefore, requirements which do not meet the TS criteria in 10CFR50.36(c)(2)(ii) have been relocated to other licensee controlled documents. This regulation addresses the scope and purpose of TS. In doing so, it sets forth a specific set of objective criteria for determining which regulatory requirements and operating restrictions should be included in the TS. These criterias are as follows:

- Criterion 1: Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary;
- Criterion 2: A process variable, design feature, or operating restriction that is an initial condition of a Design Basis Accident or Transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier;
- Criterion 3: A structure, system or component that is part of the primary success path and which functions or actuates to mitigate a Design Basis Accident or Transient that either assumes the failure of or presents a challenge to the integrity of a fission barrier; and
- Criterion 4: A structure, system, or component which operating experience or probabilistic safety assessment has shown to be significant to public health and safety.

This proposed change has been evaluated and it is concluded that the change does not meet the criterias listed above. The Conversion Comparison Table (Enclosure 3B) specifies the proposed location of these relocated requirements.

TS requirements that do not meet the NRC's criteria are being relocated to other licensee controlled documents. Some of these requirements will be relocated to documents that are subject to the provisions of 10CFR50.59. This will ensure that changes to these relocated requirements will be limited to those that do not involve an unreviewed safety question. Other requirements will be relocated to other licensee documents which have similar regulatory controls (e.g., the Quality Assurance Plan, as described in the FSAR, which is controlled by 10CFR50.54a). The remainder of the requirements that do not meet the NRC criteria will be relocated to programs that are controlled via the Administrative Controls section of the improved TS. This will ensure an appropriate level of control over changes to these requirements. The TS change to relocate requirements has been reviewed by a multi-disciplinary group of responsible, technical supervisory personnel, including onsite operations personnel.

Compliance with the relocated requirements will not be affected by this proposed change to the current Technical Specifications. The required periodic surveillances will continue to be performed to ensure that limits on parameters are maintained. Therefore, relocation of these requirements will have no impact on system operability or the maintenance of controlled parameters within limits.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change relocates requirements and surveillances for structures, systems, components, or variables which did not meet the criteria for inclusion in the improved STS. The affected structures, systems, components, or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. These relocated operability requirements and surveillances will continue to be maintained pursuant to 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variables are the same as the current Technical Specifications. Since any future changes to these requirements and the associated surveillance procedures will be evaluated per the requirements of 10CFR50.59, other regulatory requirements (as applicable for the document to which the requirement is relocated), and/or the Administrative Controls section of the improved STS, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"R"
(Continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "R" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
10CFR50.92 EVALUATION
FOR
MOVING INFORMATION FROM TECHNICAL SPECIFICATIONS TO TECHNICAL SPECIFICATION BASES,
FSAR OR OTHER LICENSEE
CONTROLLED DOCUMENTS

Some information that is descriptive in nature regarding the equipment, system(s), actions or surveillances identified by the specification has been removed from the proposed specification and included in the proposed Bases, FSAR, or other licensee controlled document. Therefore, the descriptive information that has been moved continues to be maintained in an appropriately controlled manner due to the controls which presently exist on the documents where the information is being moved.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change moves requirements from the TS to the Bases, FSAR, or other licensee controlled documents. The Bases, FSAR, or other licensee controlled documents containing the moved requirements will be maintained using the provisions of 10CFR50.59 or other appropriate controls.

Since any changes to the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to adequately limit the probability or consequences of an accident previously evaluated. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change will not impose any different requirements and adequate control of the information will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"LG"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not reduce a margin of safety because it has no impact on any safety analysis assumptions. In addition, the requirements to be moved from the TS to the Bases, FSAR, or other licensee controlled documents are the same as the current TS. Since any future changes to these requirements in the Bases, FSAR, or other licensee controlled documents will be evaluated per the requirements of 10CFR50.59 or other appropriate regulatory controls, proper controls are in place to maintain an appropriate margin of safety. Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LG" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE MORE RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the current Technical Specifications to impose more stringent requirements and achieves consistency with the proposed improved Standard Technical Specifications (NUREG-1431).

The current Technical Specifications have been modified in some areas to impose more stringent guidelines than previously required. These more restrictive modifications are being imposed to be consistent with the proposed improved Standard Technical Specifications (NUREG-1431). Such changes have been made after ensuring the previously evaluated safety analysis was not affected. Also, other more restrictive technical changes have been made to achieve consistency, correct discrepancies, and remove ambiguities from the specification.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10CFR50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves NSHC, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change provides more stringent requirements for the improved TS. These more stringent requirements are not assumed initiators of analyzed events and will not alter assumptions relative to mitigation of accidents or transient events. The change has been confirmed to ensure no previously evaluated accident has been adversely affected. The more stringent requirements are imposed to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not necessitate a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation. The proposed change does impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

III. GENERIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

"M"
(Continued)

3. Does this change involve a significant reduction in a margin of safety?

The imposition of more stringent requirements either has no impact on or increases the margin of plant safety by:

- a) Increasing the analytical or safety limit,
- b) Increasing the scope of the specification to include additional plant equipment or to add additional requirements,
- c) Increasing the applicability of the specification,
- d) Providing additional actions,
- e) Decreasing restoration times,
- f) Imposing new surveillances, or
- g) Decreasing surveillance intervals.

The change is consistent with the safety analysis and licensing basis. Therefore, this change does not involve a reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "M" resulting from the conversion to the improved TS format satisfy the NSHC standards of 10CFR50.92(c), and accordingly a no significant hazards consideration finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed changes to delete TS 4.8.1.1.4 and Table 4.8-1, and the associated changes to TS 4.8.1.1.2a. and TS 4.8.1.2 are consistent with the recommendations of NRC GL 94-01, "Removal of Accelerated Testing and Special Reporting Requirements for Emergency Diesel Generators," dated May 31, 1994. With the proposed changes, accelerated testing of the DGs and DG special reporting requirements would be deleted.

Implementation of the maintenance rule for the DGs will continue to ensure DG performance. This program includes requirements to perform detailed root cause analyses of individual DG failures, take corrective actions in response to individual DG failures, and implement DG preventive maintenance actions consistent with the maintenance rule. These changes will enhance the DG reliability. Therefore, the proposed changes will not adversely affect the ability of the DGs to perform their intended safety function.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

Deleting the accelerated DG test frequency and special reporting requirements is consistent with GL 94-01. The provisions of the DCPM Maintenance Program that implements the maintenance rule will continue to ensure DG performance. The program will include requirements to perform detailed root cause analyses of individual DG failures, take corrective actions in response to individual DG failures, and implement DG preventive maintenance actions consistent with the maintenance rule. Deleting special DG reporting requirements is administrative in nature.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes are in accordance with NRC GL 94-01 recommendations. The proposed changes do not involve any physical alterations to the plant and will not affect any analyses assumptions regarding functioning of required equipment designed to mitigate the consequences of accidents.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS1
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

Deletion of the accelerated DG test frequency and special reporting requirements is consistent with GL 94-01. DCP's Maintenance Program will continue to provide assurance of reliable DG performance.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS1" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The requirements to verify no visible terminal corrosion and minimum electrolyte temperature after a battery discharge or overcharge would be deleted. After a battery discharge or overcharge, the requirement to verify that the Category B battery cell parameters are within limits would still be required and provides adequate assurance of battery OPERABILITY.

The requirements to verify temperature and no visible corrosion would continue to be verified every 92 days regardless of battery discharge or overcharge. The 92 day frequency is acceptable for detecting corrosion trends based on operating experience and is consistent with the recommendations of IEEE-450 for frequency of determining the temperature of electrolytes in representative cells. Therefore, the verification of Category B cell parameters following a discharge or overcharge provides adequate assurance of battery OPERABILITY. This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The batteries are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The elimination of these requirements does not affect the battery's capability to perform its required function. Performing verification of Category B battery cell parameters is sufficient to ensure battery OPERABILITY following a discharge or overcharge.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alterations to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed change does not affect the ability of the batteries to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS2 (continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently, the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS2" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS SR to start all DGs simultaneously at least once per 10 years or after any modification, which could affect DG starting interdependence, would be revised to delete the requirement to perform the SR during shutdown. This test does not require the DGs to be loaded and paralleled with the offsite power source. Therefore, a grid disturbance could not affect the DGs during performance of this SR. Further, the DGs remain operable during this SR. This change is consistent with NUREG-1431.

Evaluation of this proposed TS revision has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. Deleting the requirement to perform the 10-year DG independence test during shutdown has no effect on the capability of the DGs to perform their intended safety function. The DGs are not required to be paralleled to the offsite grid during this test, and would remain OPERABLE. Deleting this requirement would not effect the design or performance of the DGs.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alterations to the plant. No new failure mechanisms will be introduced by the proposed change. The DGs are designed to provide electrical power to equipment important to safety in the event of a loss of offsite power. The proposed change does not affect the ability of the DGs to start and fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS3

(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently, the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS3" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS4 10CFR50.92 EVALUATION FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The SRs required for AC sources and DC sources OPERABILITY in MODEs 5 and 6 would be revised to include only those which are applicable. In addition, notes would be added stating the SRs that are not required to be performed for OPERABILITY in the MODEs governed by the AC Sources - Shutdown LCO and DC Sources - Shutdown LCO, respectively. SRs were not listed as applicable when shutdown because 1) the SR is only required when DGs are required to be OPERABLE, 2) The SR is only required when the SI signal is OPERABLE, or 3) The SR is only required when the sequencers are required to be OPERABLE. This change is consistent with NUREG-1431.

AC Sources - Shutdown

Many of the currently required surveillances involve tests that would require the one required DG to be paralleled to offsite power; this condition presents a significant risk of a single fault resulting in a station blackout. Other tests, such as load rejection tests, put the availability of the OPERABLE DG at risk during the test. To address this concern and to avoid potential conflicting TS, a note is added to not require that these surveillances be performed in MODEs 5 and 6.

DC Sources - Shutdown

A note would be added stating which SRs are not required to be performed for the DC source OPERABILITY in MODEs 5 and 6. Certain of the currently required SRs involve tests that would cause the battery to be rendered inoperable. If the only required OPERABLE battery were inoperable due to testing, the risk of an event occurring that would require battery operation, would present an additional risk. The exception provided by the note does not exempt the battery from the requirement to be capable of performing the particular function, only that the capability need not be demonstrated while that source of power is being relied upon to support meeting the LCO. This change is consistent with NUREG-1431.

Evaluation of this proposed TS revision has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The electrical power sources support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed SR would continue to provide adequate assurance of the OPERABILITY of the required AC source and DC source functions. The proposed changes would delete the requirement to meet SRs that verify functions which are not required in the applicable MODEs of this TS

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS4
(continued)

Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not involve any physical modification to the plant. The proposed changes do not affect the ability of the AC sources or DC sources to fulfill their safety-related function, as required in the applicable MODES of this TS. Hence, no new failure mechanisms will be introduced.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

Elimination of the SRs for AC source functions not required in MODE 5 and 6 does not impact the capability of the AC sources to perform their safety function in these modes. The OPERABILITY of the required AC source and DC source functions would continue to be determined in the same manner.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS4" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The TS 3.8.1.1 ACTION requirements to demonstrate DG OPERABILITY are deleted. ACTIONS currently require all OPERABLE DGs that have not been tested within the previous 24 hours to be started within 24 hours to demonstrate their OPERABILITY in the event that one or both offsite A.C. circuits become inoperable. The intent of this additional testing is to provide added assurance that the remaining OPERABLE DG(s) are capable of supplying emergency power when the offsite sources are degraded.

The normal TS surveillance testing schedule (improved SR 3.8.1.2) demonstrates that OPERABLE DG(s) are capable of performing their intended safety function. The inoperability of one or both of the offsite A.C. circuits does not affect the reliability of the OPERABLE DG(s). Although the occurrence of an inoperable offsite A.C. circuit is infrequent, the present requirements result in an unnecessary test of the DGs, whose reliability is demonstrated by the performance of normal TS surveillance testing. Unnecessary DG testing should be avoided since excessive testing of DGs can cause reduced reliability. Therefore, the requirement to demonstrate OPERABILITY of the OPERABLE DGs whenever an A.C. circuit becomes inoperable would be deleted.

This proposed change is consistent with NRC GL 93-05, "Line-item Technical Specifications Improvements to Reduce Surveillance Requirements for Testing during Power Operation." This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The normal TS surveillance testing schedule (improved SR 3.8.1.2) demonstrates that OPERABLE DG(s) are capable of performing their intended safety function. The inoperability of one or both of the offsite A.C. circuits does not affect the reliability of the OPERABLE DG(s). Deleting this requirement would not effect the design or performance of the DGs.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS5 (Continued)

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The DGs are designed to provide electrical power to equipment important to safety in the event of a loss of offsite power. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. This proposed change should result in an overall improvement in DG reliability and availability due to reduced wear and tear on the DGs by eliminating unnecessary starts. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS5" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS 3.8.1.1 ACTIONS require that the remaining OPERABLE DG(s) be started to demonstrate OPERABILITY in the event a DG becomes inoperable due to any cause other than preventive maintenance or testing. The CTS also requires that the test be completed within 24 hours regardless of when the inoperable DG is returned to OPERABLE status.

The intent of this additional testing is to determine if a common cause failure exists and to provide added assurance that the remaining OPERABLE DG(s) is capable of supplying emergency power. However, this requirement results in unnecessary testing when there is no common cause failure.

This proposed change incorporates the NUREG-1431 provision of "determining the OPERABLE DG(s) are not inoperable due to a common cause failure," which avoids unnecessary testing of OPERABLE DG(s), into ACTION requirements.

Evaluation of this proposed TS revision has determined that it involves no significant hazards consideration. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The normal TS surveillance testing schedule (improved SR 3.8.1.2) demonstrates that OPERABLE DGs are capable of performing their intended safety function. The proposed change would provide an alternative to starting the OPERABLE DGs if it can be proven by reasoning and analysis that there is not a common cause failure, thus maintaining assurance the DGs would be OPERABLE to perform their intended safety function if needed. In providing this alternative, unnecessary DG starts may be reduced. Deleting this requirement would not effect the design or performance of the DGs.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS6 (Continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The DGs are designed to provide electrical power to equipment important to safety in the event of a loss of offsite power. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. This proposed change should result in an overall improvement in DG reliability and availability due to reduced wear and tear on the DGs by eliminating unnecessary starts. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS6" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

CTS 3.8.1.1 ACTION requirements allowed time for verification of required redundant feature OPERABILITY would be increased from 2 to 4 hours. The shutdown requirement would be replaced with a requirement to enter the required feature's ACTION statement.

Allowing 4 hours upon discovery of an otherwise OPERABLE required feature powered from an inoperable DG before declaring that required feature inoperable would allow a more reasonable time for repairs to be made prior to declaring the feature inoperable. The additional time proposed will reduce the probability of unnecessary plant transients and plant shutdowns, thus improving plant safety and increasing plant availability.

Increasing the required time to evaluate OPERABILITY of other equipment is consistent with the recommendations of NUREG-1024, "Technical Specifications - Enhancing the Safety Impact." NUREG-1024 states:

Allowable outage times that are too short will subject the plant to unnecessary trips, transients and fatigue cycling. Outage times that are too short also may result in less thorough repair and post-repair testing before equipment is returned to service.

This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. This proposed change would not effect the design or performance of the DGs.

The proposed 4-hour AOT, with entry into the inoperable safety equipment's ACTION statement, takes into account the capacity and capability of the remaining A.C. sources (i.e., the remaining operable offsite circuit(s)), a reasonable time for repairs, OPERABILITY of the redundant counterpart to the inoperable required safety feature, and the low probability of a design basis accident with a loss of offsite power.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS7 (Continued)

Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS7" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
10CFR50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The TS 3.8.1.1 ACTION requirement to demonstrate DG OPERABILITY within 8 hours would be increased to 24 hours. Extending the time required to demonstrate the OPERABILITY of the remaining OPERABLE DGs would allow 24 hours to determine the OPERABLE DGs are not inoperable due to a common cause failure or demonstrate OPERABILITY of the remaining OPERABLE DGs by testing. This proposed change avoids unnecessary DG testing. This change would allow the same time period (24 hours) for determining OPERABILITY of the remaining OPERABLE DG(s) as the ACTION for one inoperable DG currently allows. This proposed change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs.

The normal TS surveillance testing schedule (improved SR 3.8.1.2) demonstrates that OPERABLE DG(s) are capable of performing their intended safety function. The increased Completion Time of 24 hours would allow additional time for a more thorough examination and determination of no potential common cause failure, thus potentially reducing unnecessary DG testing. However, the AOT (12 hours) to return either the DG or offsite circuit would not be changed.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS8
(Continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS8" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A review of applicable documents (RG 1.108, Rev. 1, "Periodic Testing of Diesel Generator Units Used as Onsite Electric Power Systems at Nuclear Power Plants;" Institute of Electrical and Electronics Engineers (IEEE) Standard 387-1984, "IEEE Standard Criteria for Diesel-Generator Units Applied as Standby Power Supplies for Nuclear Power Generating Stations;" and NUREG-1431, Rev. 1) determined that the DG full load rejection test was designed to demonstrate that the DG would not trip on overspeed and that the resulting voltage will not exceed a level that will cause component damage during a full load rejection. A calculation determined that the proposed limit of 6200 volts will not result in component damage and will provide an acceptable voltage limit. Therefore, the proposed change will not adversely affect the ability of the DGs to perform their intended safety function.

Evaluation of this proposed TS revision has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. Thus, increasing the DG full load rejection SR allowed voltage continues to provide adequate assurance that the DGs are OPERABLE following surveillance testing.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alterations to the plant. No new failure mechanisms will be introduced by the proposed change. The DGs are designed to provide electrical power to equipment important to safety in the event of a loss of offsite power. The proposed change does not affect the ability of the DGs to start and fulfill their safety related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS9
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently, the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS9" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The requirement to rapidly load the DG in less than or equal to 60 seconds would be deleted. Rapid loading of the DG is currently required for the 6-month DG start. Rapidly loading the DG introduces unnecessary mechanical stresses and engine wear.

The purpose of this test is to demonstrate that the DG is capable of accepting loads by simulating the loading rate of the load sequence timers. However, other SRs, the Loss of Offsite Power (LOOP) and LOOP/SI tests, already adequately verify this requirement. Therefore, the SR for rapid loading is unnecessary.

This proposed change is consistent with NRC GL 93-05, "Line-item Technical Specifications Improvements to Reduce Surveillance Requirements for Testing during Power Operation." This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. The ability of the DGs to rapidly load is demonstrated by other SRs that are performed on a refueling frequency.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS10
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS10" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS11

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The DG loading specified in various SRs would be revised to be consistent with NUREG-1431 requirements. The DG loading requirements would specify a load range that still meets the objective of the loading tests. The load range is provided to avoid routine overloading of the DG. Routine overloading may result in more frequent tear down inspections in accordance with vendor recommendations. This proposed change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. Providing a load range prevents routine overloading of the DGs, which may result in more frequent tear down inspections.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed changes. The proposed changes do not affect the ability of the DGs to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS11
(continued)

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS11" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS12

10CFR50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

A footnote would be added to several SRs stating that momentary transients outside the load range do not invalidate the test, since DG loading could change during this test due to changing bus conditions. Some load fluctuation is expected and should not invalidate this test. The objective of testing controls in these tests is to assure that equilibrium conditions are obtained and maintained, that inadvertent overloads which may damage the machine are avoided and that the test demonstrates the prescribed elements of the machine's ability to carry accident loads and associated power factors. Monitoring/data collection periods during the tests are chosen to assure these criteria are maintained given the inherent margin and stability of the configuration. Therefore, DG load found out of the load range and returned to the band within the monitoring period would not invalidate an DG load test. This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. Allowing momentary transients outside the load range has no effect on demonstrating that the DG can provide its accident loads with associated power factor at the proper voltage and frequency. This proposed change provides an allowance which recognizes that the DG is paralleled to the offsite power source to supply the required load.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS12
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. The change does not affect the ability of the test to demonstrate OPERABILITY of the DGs. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS12" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS13

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The DG partial load rejection requirement that voltage be maintained would be replaced with a requirement that within 2.4 seconds following load rejection, the voltage is within steady state requirements. The voltage specified is consistent with the design range of the equipment powered by the DG.

The 2.4 second allowance for voltage and frequency is based on the recommendations of RG 1.9, "Selection and Diesel Generator Set Capacity for Standby Power Supplies," Rev. 3, for recovery from transients caused by the disconnection of the largest single load. This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. The ability of the DGs to properly recover from rejection of the single largest load will continue to be demonstrated.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS13
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS13" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS14

10CFR50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The CTS requires a battery discharge performance test every 18 months when the battery has reached 85 percent of its service life. Consistent with NUREG-1431, the proposed change extends the frequency for the battery performance discharge test surveillance to once per 24 months if the battery has reached 85 percent of expected service life and the capacity is ≥ 100 percent of manufacturer's rating.

The proposed TS has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The proposed change extends the frequency for the battery performance discharge test surveillance to once per 24 months if battery has reached 85 percent of expected service life and the capacity is ≥ 100 percent of manufacturer's rating. The surveillance limit of 80 percent capacity is based on meeting the requirements of the applicable safety analyses. This change is acceptable because the battery is still capable of providing its full 100 percent capacity and would not be expected to degrade below the surveillance limit of 80 percent between surveillances. In addition, if the battery were to experience a 10 percent degradation, the 18-month frequency would be required for all following surveillances. Because the capacity of the battery would not be expected to degrade below the acceptance limit between surveillances, this change does not involve a significant increase in probability or consequences of an accident previously evaluated.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed change extends the frequency for the battery surveillance and does not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed changes. The proposed changes do not affect the ability of the battery to fulfill its safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS14 (continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS14" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS15

10CFR50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The SR to check for and remove accumulated water from the DG day tanks after each operation of the DG for greater than 1 hour would be deleted. Checking for accumulated water more often than once per 31 days is unnecessarily frequent.

Once per 31 days corresponds to the frequency of the monthly DG test and is adequate to identify and remove any water from the fuel oil system. The main fuel oil storage tanks are checked for water every 31 days and this check would provide additional assurance that a minimal amount of water is present. Cleaning the main fuel oil storage tanks and visual inspection of the accessible DFO transfer piping during operating pressure leak test are required every 10 years and provide additional assurance that water is not introduced to the DFO storage and transfer system. This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. Deleting the requirement to check for and remove accumulated water from the DG day tank after the DG has operated for greater than or equal to 1 hour has no effect on DG OPERABILITY since presence of water in the DG day tank does not necessarily result in DG failure. This SR will continue to be performed once per 31 days, consistent with normal monthly DG start test and DG day tank fuel oil level test frequency.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS15 (continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS15" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS16

10CFR50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

NUREG-1431 LCO 3.8.3, "Diesel Fuel Oil, Lube Oil, and Starting Air," includes Conditions and Required ACTIONS that allow reduced DFO inventory for up to 48 hours before requiring that the associated DG be declared inoperable. A new Condition would address stored DFO with total particulates out of limit and allow 7 days for restoration. A new Condition would address new fuel oil with properties not within limits and allow 30 days for restoration.

The Conditions provided for these support systems address the situation where the support system is degraded but still capable of supporting the associated DG. The time allowed by these new TS Conditions to correct the support system problem before declaring the DG inoperable is acceptable based on the remaining capacity or capability of the systems and the low probability of an event occurring during the allowed time that would require the support system's full capacity/capability.

This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. The changes address the Condition of a support system being degraded but still capable of supporting the associated DG. Therefore, the DG would remain OPERABLE and able to perform its safety function with a degraded support system.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS16
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS16" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS17

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

TS 3.8.1.1 ACTION shutdown requirement would be replaced with a requirement to enter the required feature's ACTION statement. The ACTION currently requires that with one DG inoperable all required safety equipment that depends on the remaining OPERABLE DG(s) be verified OPERABLE. If these requirements are not met, a unit shutdown is required. Rather than requiring a unit shutdown, the proposed change would require declaring inoperable the required safety equipment powered from an inoperable DG. This would result in entering the required feature's TS ACTION statement.

This Required ACTION provides assurance that a loss of offsite power, during the period that a DG is inoperable, does not result in a complete loss of safety function of a critical system. The features covered by this action are designed with redundant safety-related trains. Single train systems, such as the turbine-driven auxiliary feedwater pump, are not included.

For systems where a loss of redundant features is not as significant (i.e., some time allowed prior to the requirement to shut down), recognition of the difference is appropriate and would be recognized.

This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The DGs are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the DGs. By declaring the required feature inoperable when its redundant required feature is inoperable and entering the ACTION requirement, the assumed OPERABILITY of safety-related equipment is maintained. This Required ACTION provides assurance that a postulated loss of offsite power, during the period that a DG is inoperable, does not result in a complete loss of safety function of a critical system.

V. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS17 (continued)

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the DGs to start and to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS17" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS20

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Since the AC sources and DC sources OPERABILITY requirements, ITS LCOs 3.8.2, 3.8.5, and 3.8.8 are in terms of powering AC and DC electrical subsystems required to be OPERABLE by LCO 3.8.10, the Required ACTION for these TS would be revised to declare affected required features inoperable, as an alternative to the other Required ACTIONS. In this Condition it may not be necessary to suspend all CORE ALTERATIONS, positive reactivity changes, or movement of irradiated fuel. In this case, conservative ACTION can be assured if all required equipment without the required power source (i.e., AC or DC power) is declared inoperable and the associated ACTIONS taken.

In the Condition of LCO 3.8.2, with one or more required load centers, motor control centers, buses, etc., not capable of being powered by an offsite circuit, it may not be necessary to perform ITS 3.8.2 Required ACTIONS A.2.1 through A.2.4. Plant safety would be assured by declaring inoperable all required equipment without qualified offsite power and taking the specified ACTIONS. The requirements for LCO 3.8.5 and LCO 3.8.8 would be similar.

This proposed change would provide additional flexibility in responding to an inoperable offsite circuit or inoperable DC source while in MODE 5 or 6. This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The electrical power sources are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change would not effect the design or performance of the electrical power sources. The allowance of declaring the required feature inoperable ensures a commensurate level of plant safety as the ACTIONS required with one offsite circuit inoperable or with one or more DC electrical power subsystem inoperable.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS20 (continued)

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the electrical power systems to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS20" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS21

10CFR50.92 EVALUATION

FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Notes contained in current battery SRs table for Category A and B limits would be combined in new LCO 3.8.6, "Battery Cell Parameters," as Condition A. A 31-day Completion Time would be added for restoring the Category A and B limits. This Completion Time is considered acceptable since sufficient battery capacity exists to perform the required function.

To support this extended Completion Time, two new requirements have been added. ITS Required ACTION A.1. requires that pilot cell electrolyte level and float voltage are within Category C limits within 1 hour whenever the Category A or B limits are not met. This proposed Required ACTION provides a quick indication of the status of the remainder of the battery cells. Required ACTION A.2., performed within 24 hours of entry into Condition A and once per 7 days thereafter, verifies battery cell parameters for all the cells are within the Category C limits. The Category C limits are the limits beyond which the battery is considered immediately inoperable. Performing Required ACTION A.2. provides assurance that the battery is still capable of performing its required function. If Category C limits are not met or the Category A and B limits are not restored within 31 days, ITS ACTION B. requires the affected battery to be declared inoperable.

This change is consistent with NUREG-1431.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The batteries are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any previously analyzed accident. The proposed change allows 31 days for restoration of battery cell parameters, provided Category C parameters are met. The proposed change will not allow continuous operation when sufficient battery capacity does not exist (i.e., Category C limits not met). The increased time allowed to continue operation with degraded batteries prior to requiring the batteries be declared inoperable is acceptable based on the low probability of a DBA requiring the DC power sources to perform their required function, considering the desire to minimize unnecessary plant transients.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS21 (continued)

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed changes do not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed changes do not affect the ability of the batteries to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed changes will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS21" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

10CFR50.92 EVALUATION
FOR

TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with industry Traveler TSTF-115, this change would allow the extension of the surveillance frequency for battery terminal voltage while on float charge, and for Category A battery cell parameters from 7 days to 31 days in accordance with the recommended frequency of at "least monthly" identified in IEEE-450-1995, Section 4.3.1. CTS [SRs 4.8.3.1a.1 and 4.8.2.1] require a once per 7 days frequency for surveillance verification and this proposed change would extend the surveillance frequency to 31 days consistent with [manufacturer's recommendations and] IEEE-450-1995.

Verifying battery terminal voltage while on float charge helps to ensure the effectiveness of the charging system and the ability of the batteries to perform their intended function. Float charge is the Condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery and maintain the battery in a fully charged state. Category A defines the normal parameter limit for each designated pilot cell in each battery. The cell selected as a pilot cell are those whose temperature, voltage, and electrolyte specific gravity approximate the Condition of the entire battery. The Category A limits specified are based on [manufacturer's recommendations and] IEEE-450-1995.

This proposed change would provide additional flexibility in allowing the extension of the surveillance frequency verifications for battery terminal voltage and Category A battery cell parameters from 7 to 31 days and the change is consistent with IEEE-450-1995.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The batteries are used to support mitigation of the consequences of an accident, and are not considered to be an initiator of any accident. The proposed change would not effect the design or performance of the batteries. The allowance to extend the surveillance frequency from 7 days to 31 days is consistent with the recommended frequency of at least monthly identified in IEEE-450-1995.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS22 (continued)

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed change does not involve any physical alterations to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed change does not affect the ability of the batteries to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed change will not alter any accident analysis assumptions, initial Conditions, or results. Consequently the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS22" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC LS24

10CFR50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

Consistent with NUREG-1431, the surveillance interval for verifying that other DFO properties are within limits for ASTM 2D fuel oil is changed from "within 30 days" to "within 31 days" after obtaining a sample. The fuel properties that can have an immediate detrimental impact on diesel combustion, (i.e., API gravity, kinematic viscosity, flash point and appearance) are verified prior to addition to the storage tank. The "other properties" may be analyzed after addition to the tank. The 31-day verification interval for these properties is acceptable because the fuel properties of interest, even if they are not within their stated limits, would not have an immediate effect on DG operation. The CTS 30-day verification interval was probably chosen because it was a convenient time interval for sending the sample and receiving the results from the laboratory selected for testing. NUREG-1431 has selected a 31-day testing interval. The 1 day increase in the interval would not have a significant effect on the acceptability of the DFO.

This proposed change would provide additional flexibility in allowing the performance of a modified performance discharge test in lieu of a service test at any time and the change is consistent with IEEE-450-1995.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The proposed change affects the interval for the verification of certain properties of diesel fuel. This testing interval does not impact an accident initiator and thus cannot increase the probability of an accident. The DGs are used to mitigate the consequences of accidents. However, even if the fuel properties of interest are not within their stated limits, the fuel would not have an immediate effect on DG operation. Thus, the diesel could continue to perform its safety function.

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed change does not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change. The proposed change does not affect the ability of the diesels to fulfill their safety-related function.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS24
(continued)

3. *Does this change involve a significant reduction in a margin of safety?*

The proposed change will not alter any accident analysis assumptions, initial Conditions, or results. Consequently, the proposed change does not have any effect on the margin of safety.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "LS24" resulting from the conversion to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS25 10 CFR 50.92 EVALUATION FOR TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

The proposed change would eliminate the requirement to test multi-train/multi-component systems on a STAGGERED TEST BASIS (STB) while maintaining the testing frequency for individual trains/components unchanged. As discussed in the NRC's safety evaluation report for Plant Vogtle's TS conversion, "the intent of a requirement for staggered testing is to increase the reliability of the component or system being tested. A number of studies have demonstrated that staggered testing has negligible impact on component reliability. These analytical and deterministic studies have shown that in most cases staggered testing (a) is operationally difficult, (b) has negligible impact on component reliability, (c) is not as safety significant as initially thought, (d) introduces additional stress on components such as DG potentially causing increased component failure rates and component wear out, (e) results in more frequent reductions in system redundancy for testing purposes, and (f) increases the likelihood of human error by increasing the number of separate test evolutions. Therefore, changes of this type are acceptable. Accordingly, many of the staggered testing requirements in the CTS have been omitted from the improved TS." Based on the NRC safety evaluation, removal of STB testing would have negligible negative impact, and potential positive impact, on plant safety.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

- 1. Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
- 2. Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
- 3. Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change would not have an appreciable effect any accident initiators or precursors. The change involves the testing frequency of accident mitigating systems, and therefore would not significantly effect the probability of occurrence of previously evaluated accidents. Also, the change would have a negligible impact on the availability of accident mitigating systems, so the consequences of any previously evaluated accidents would not be significantly increased.

Therefore, the proposed change would have no significant effect on the probability or consequences of any previously analyzed accidents.

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed changes would not involve any physical alteration to the plant or systems or change the manner in which any safety-related system performs its safety function.

Therefore, the proposed change would not create the possibility of a new or different kind of accident.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS25
(continued)

3. Does this change involve a significant reduction in a margin of safety?

The proposed change would not alter any accident analysis assumptions, initial Conditions, or results. Consequently it would not have any effect on margins of safety.

Therefore, the proposed change would have no significant adverse effect on margins of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "LS25" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS26
10 CFR 50.92 EVALUATION
FOR
TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE
REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change revises the requirement for OPERABLE onsite shutdown power. The CTS requires that 1 [bus] (subsystem) of the various power supplies and buses be OPERABLE. The change requires that only the necessary portion of these subsystems be OPERABLE. The necessary portion are those portions required to support the equipment on that [bus] which is required to be OPERABLE in the existing shutdown Condition. This change is consistent with NUREG-1431 and is acceptable because there is no reason to have portions of the power systems OPERABLE that are not supporting components which are being credited in the safety analysis for shutdown events.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?

The proposed change does not involve any physical changes to the plant. The change does change the way the plant is operated in that portions of the power system which are not supporting required equipment are no longer required to be OPERABLE. This change in the way the plant is operated has no impact on the probability of any of the accidents assumed during plant shutdown and will not impact the consequences of these accidents since the credited equipment will continue to be supported by power sources as they were prior to the change.

Therefore, this change does not involve a significant increase the probability or consequences of an accidents previously evaluated.

IV. SPECIFIC NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC LS26
(continued)

2. Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?

The proposed change does not involve any physical alteration to the plant. No new failure mechanisms will be introduced by the proposed change.

Therefore, the proposed change would not create the possibility of a new or different kind of accident.

3. Does this change involve a significant reduction in a margin of safety?

The proposed change will not alter any accident analysis assumptions, initial Conditions, or results. The equipment which is credited in the accident analyses will be powered in the same manner as before the change. Consequently, the proposed change does not have any effect on the margin of safety.

Therefore, the proposed change would have no significant adverse effect on margins of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, it is concluded that the activities associated with NSHC "LS26" resulting from the conversion to the improved TS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARD CONSIDERATIONS

NSHC TR1

10CFR50.59 EVALUATION

FOR

RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision involves modifying the CTS to allow the use of actual actuation signals for SRs that currently require testing using simulated test signals only. This change is consistent with NUREG-1431.

In several SRs in the CTS, OPERABILITY of certain equipment is demonstrated by ensuring that the equipment performs its safety function upon receipt of a simulated test signal. The intent of a 'simulated' signal was to be able to perform the required testing without the occurrence (or without causing) an actual signal generating event. However, the unintended effect was to require the performance of the SR (using a test signal) even if an actual signal had previously verified the operation of the equipment. This change allows credit to be taken for actual events when the required equipment actuates successfully.

While the occurrence of events that cause actuation of accident mitigation equipment is undesirable, the actuation of mitigation equipment on an actual signal is a better demonstration of its OPERABILITY than an actuation using a test signal. Thus, the change does not reduce the reliability of the equipment tested. The change also improves plant safety by reducing the amount of time the equipment is taken out of service for testing, and thereby increasing its availability during an actual event and by reducing the wear of the equipment caused by unnecessary testing.

Evaluation of this proposed TS has determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21(b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety.*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

The proposed change allows the use of an actual actuation signals (when/if it occurs) to satisfy SRs currently requiring simulated test signals to demonstrate equipment OPERABILITY. While the change takes advantage of events that may have occurred, it has no adverse effect on any accident initiators or accident consequences. In fact, by potentially reducing unnecessary testing, it may reduce the probability of an accident because the testing itself can increase the probability of an accident. It may also reduce accident consequences by increasing the equipment availability (i.e., less time in test).

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR1 (continued)

Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed) or changes in parameters governing normal plant operation.

Therefore, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

The use of an actual actuation signal to satisfy an SR has either no impact on, or increases the margin of plant safety by:

- a) Increasing mitigation equipment availability, and
- b) Improving mitigation equipment reliability by potentially reducing wear caused by unnecessary testing.

The change is consistent with the safety analysis and licensing basis.

Therefore, this change does not involve a significant reduction in a margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above safety evaluation, the activities associated with NSHC "TR1" resulting from the conversion of CTS 3/4.8 to the ITS format are concluded to satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR2

10 CFR 50.92 EVALUATION
FOR

RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This change in accordance with NUREG-1431, Rev. 1, removes the requirement for a special report to be generated and submitted to the NRC. Reporting to the NRC will be done commensurate with the reporting requirements of 10CFR 50.72 and 50.73.

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of an accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

This change is purely an administrative reporting change and cannot affect any accident probability or consequences.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

This change is purely an administrative reporting change and cannot create any new accident or affect any accident previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

This change is purely an administrative reporting change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "TR2" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

V. RECURRING NO SIGNIFICANT HAZARDS CONSIDERATIONS

NSHC TR3

10 CFR 50.92 EVALUATION FOR RECURRING TECHNICAL CHANGES THAT IMPOSE LESS RESTRICTIVE REQUIREMENTS WITHIN THE TECHNICAL SPECIFICATIONS

This proposed revision is to remove reference to specific post-maintenance tests from the ITS. Post-Maintenance Testing Programs are controlled via plant administrative procedures in accordance with licensee controlled document (ITS Section 5.4.1, Procedures commitments to NRC RG 1.33, "Quality Assurance Program Requirements (Operation)," and ANS 3.2-ANSI N18.7, "Administrative Controls and Quality Assurance for the Operational Phase of Nuclear Power Plants." Specific post-maintenance testing requirements are contingent on the type and scope of maintenance actually performed as well as the availability and viability of test equipment, techniques, etc. Removal of specific testing requirements from the ITS and reliance on normal post-maintenance testing programs addressed by licensee controlled documents allow flexibility to modify testing to address the circumstances of the maintenance performed while still assuring OPERABILITY of equipment returned to service,

This proposed TS change has been evaluated and it has been determined that it involves NSHC. This determination has been performed in accordance with the criteria set forth in 10 CFR 50.92(c) as quoted below:

"The Commission may make a final determination, pursuant to the procedures in 50.91, that a proposed amendment to an operating license for a facility licensed under 50.21 (b) or 50.22 or for a testing facility involves no significant hazards consideration, if operation of the facility in accordance with the proposed amendment would not:

1. *Involve a significant increase in the probability or consequences of a accident previously evaluated; or*
2. *Create the possibility of a new or different kind of accident from any accident previously evaluated; or*
3. *Involve a significant reduction in a margin of safety."*

The following evaluation is provided for the three categories of the significant hazards consideration standards:

1. *Does the change involve a significant increase in the probability or consequences of an accident previously evaluated?*

No, this is an administrative change which removes specific post-maintenance test requirements from TS. The testing, or equivalent testing, to assure equipment OPERABILITY prior to return to service would still be done as required by normal plant maintenance retest programs. Therefore, this change would not result in any increase in the probability or consequences of an accident previously evaluated.

2. *Does the change create the possibility of a new or different kind of accident from any accident previously evaluated?*

No, this is an administrative change and does not create a new or different kind of accident from any previously evaluated.

3. *Does this change involve a significant reduction in a margin of safety?*

No. This change is an administrative change and does not affect any margin of safety.

NO SIGNIFICANT HAZARDS CONSIDERATION DETERMINATION

Based on the above evaluation, it is concluded that the activities associated with NSHC "TR3" resulting from the conversion to the ITS format satisfy the NSHC standards of 10 CFR 50.92(c), and accordingly a NSHC finding is justified.

Table 3.8.1-1 (page 1 of 1)

~~Diesel Generator Test Schedule~~

NUMBER OF FAILURES IN LAST 25 VALID TESTS ^(a)	FREQUENCY
≤ 3	31 days
≥ 4	7 days ^(b) (but no less than 24 hours)

~~(a) Criteria for determining number of failures and valid tests shall be in accordance with Regulatory Position C.2.1 of Regulatory Guide 1.9, Revision 3, where the number of tests and failures is determined on a per DG basis.~~

3:8-05

~~(b) This test frequency shall be maintained until seven consecutive failure free starts from standby conditions and load and run tests have been performed. This is consistent with Regulatory Position [], of Regulatory Guide 1.9, Revision 3. If, subsequent to the 7 failure free tests, 1 or more additional failures occur, such that there are again 4 or more failures in the last 25 tests, the testing interval shall again be reduced as noted above and maintained until 7 consecutive failure free tests have been performed.~~

~~Note: If Revision 3 of Regulatory Guide 1.9 is not approved, the above table will be modified to be consistent with the existing version of Regulatory Guide 1.108, GL 84 15, or other approved version.~~

3.8 ELECTRICAL POWER SYSTEMS

3.8.2 AC Sources - Shutdown

LCO 3.8.2

The following AC electrical power sources shall be OPERABLE:

a. One qualified circuit between the offsite transmission network and the onsite Class 1E AC electrical power distribution subsystem(s) required by LCO 3.8.10, "Distribution Systems - Shutdown"; and

b. One diesel generator (DG) capable of supplying ~~one train of~~ the onsite Class 1E AC electrical power distribution subsystem(s) required by LCO 3.8.10-
and

3.8-15

~~c. One supply train of the diesel fuel oil (DFO) transfer system~~

3.8-04

APPLICABILITY:

MODES 5 and 6.

During movement of irradiated fuel assemblies.

ACTIONS

NOTE
 LCO 3.0.3 is not applicable

3.8-35

SURVEILLANCE	FREQUENCY
<p>SR 3.8.2.1 -----NOTE----- The following SRs are not required to be performed: SR 3.8.1.3, SR 3.8.1.9 through SR 3.8.1.11, SR 3.8.1.13, SR 3.8.1.14 through SR 3.8.1.16, and SR 3.8.1.18 (for auto transfer timers). ----- For AC sources required to be OPERABLE, the following SRs of Specification 3.8.1, "AC Sources - Operating," except SR 3.8.1.8, SR 3.8.1.12, SR 3.8.1.16, SR 3.8.1.17, SR 3.8.1.18 (for ESF timers), SR 3.8.1.19, and SR 3.8.1.20, are applicable: SR 3.8.1.1 through SR 3.8.1.7, SR 3.8.1.9 through SR 3.8.1.11, SR 3.8.1.14 through SR 3.8.1.16, and SR 3.8.1.18 (for auto transfer timers).</p>	<p style="text-align: center;"><u>3.8-17</u></p> <p>In accordance with applicable SRs</p> <p style="text-align: center;"><u>ED</u></p> <p style="text-align: center;"><u>B</u></p> <p style="text-align: center;"><u>3.8-17</u></p>

3.8 ELECTRICAL POWER SYSTEMS

3.8.3 Diesel Fuel Oil, Lube Oil, and Starting Air, and Turbocharger Air Assist

3.8-18

LCO 3.8.3 The stored diesel fuel oil, lube oil, and starting air, and turbocharger air assist subsystems shall be within limits for each required diesel generator (DG). The fuel level for the stored diesel fuel oil shall be within the following limits:

PS

a. Combined storage of $\geq 65,000$ gal for two units in MODES 1, 2, 3, and 4, or

b. Combined storage of

3.8-10

1. $\geq 33,000$ gal for one unit (if any) in MODES 1, 2, 3, and 4, and

2. $\geq 26,000$ gal for each unit in MODES 5 and 6.

NOTE

The performance of diesel fuel oil tank cleaning requires one fuel oil storage tank to be removed from service to be drained and cleaned. During this time, the fuel oil storage requirement for one unit operation in MODES 1, 2, 3, and 4 and one unit operation in MODE 6 with at least 23 feet of water above the reactor vessel flange or with the reactor vessel defueled is $\geq 35,000$ gallons. The tank being cleaned may be inoperable for up to 10 days. For the duration of the tank cleaning, temporary onsite fuel oil storage of $\geq 24,000$ gallons will be maintained. Prior to removal of a tank from service, the offsite circuits required by LCO 3.8.1 or 3.8.2 will be verified to be OPERABLE.

3.8-11

APPLICABILITY: When associated DG(S) is required to be OPERABLE.

PS

SURVEILLANCE REQUIREMENT (continued)

SURVEILLANCE	FREQUENCY
<p>SR 3.8.4.8</p> <p>-----NOTE----- This Surveillance shall not be performed in MODE 1, 2, 3, or 4. However, credit may be taken for unplanned events that satisfy this SR.</p> <p>-----</p> <p>Verify battery capacity is $\geq 80\%$ of the manufacturer's rating when subjected to a performance discharge test or a modified performance discharge test.</p>	<p><u>3.8-20</u></p> <p>60 months <u>B</u></p> <p>AND</p> <p>18 12 months when battery shows degradation or has reached 85% of expected life for the application with capacity < 100% of manufacturer's rating</p> <p>AND <u>3.8-16</u></p> <p>24 months when battery has reached 85% of the expected life with capacity $\geq 100\%$ of manufacturer's rating</p>

3.8 ELECTRICAL POWER SYSTEMS

3.8.5 DC Sources - Shutdown

LCO 3.8.5

~~The Class 1E~~ DC electrical power subsystem shall be OPERABLE to support the DC electrical power distribution subsystem(s) required by LCO 3.8.10, "Distribution Systems - Shutdown."

3.8-13

APPLICABILITY:

MODES 5 and 6,

During movement of irradiated fuel assemblies.

ACTIONS

NOTE
LCO 3.0.3 is not applicable.

3.8-35

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>A. One or more required DC electrical power subsystems inoperable.</p>	<p>A.1-1 Declare affected required feature(s) inoperable.</p>	<p>Immediately <u>ED</u></p>
	<p><u>OR</u></p>	
	<p>A.2.1 Suspend CORE ALTERATIONS.</p>	<p>Immediately</p>
	<p><u>AND</u></p>	
	<p>A.2.2 Suspend movement of irradiated fuel assemblies.</p>	<p>Immediately</p>
	<p><u>AND</u></p>	
	<p>A.2.3 Initiate action to suspend operations involving positive reactivity additions.</p>	<p>Immediately</p>
	<p><u>AND</u></p>	<p>(continued)</p>

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. (continued)	A.2.4 Initiate action to restore required DC electrical power subsystems to OPERABLE status.	Immediately

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY									
<p>SR 3.8.5.1 -----NOTE----- The following SRs are not required to be performed: SR 3.8.4.6, SR 3.8.4.7, and SR 3.8.4.8. -----</p> <p>For DC sources required to be OPERABLE, the following SRs are applicable:</p> <table data-bbox="413 1092 1073 1218"> <tr> <td>SR 3.8.4.1</td> <td>SR 3.8.4.4</td> <td>SR 3.8.4.7</td> </tr> <tr> <td>SR 3.8.4.2</td> <td>SR 3.8.4.5</td> <td>SR 3.8.4.8.</td> </tr> <tr> <td>SR 3.8.4.3</td> <td>SR 3.8.4.6</td> <td></td> </tr> </table>	SR 3.8.4.1	SR 3.8.4.4	SR 3.8.4.7	SR 3.8.4.2	SR 3.8.4.5	SR 3.8.4.8.	SR 3.8.4.3	SR 3.8.4.6		<p>In accordance with applicable SRs</p>

SR 3.8.4.2	SR 3.8.4.5	SR 3.8.4.8.								
SR 3.8.4.3	SR 3.8.4.6									

3.8 ELECTRICAL POWER SYSTEMS

3.8.6 Battery Cell Parameters

LC0 3.8.6 Battery cell parameters for ~~the three Class 1E Train A and Train B~~ batteries shall be within the limits of Table 3.8.6-1.

3.8-13

APPLICABILITY: When associated DC electrical power subsystems are required to be OPERABLE.

ACTIONS

-----NOTE-----
Separate Condition entry is allowed for each battery.

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>A. One or more batteries with one or more battery cell parameters not within Category A or B limits.</p>	<p>A.1 Verify pilot cell[s] electrolyte level and float voltage meet Table 3.8.6-1 Category C limits.</p> <p><u>AND</u></p>	<p>1 hour <u>B-PS</u></p>
	<p>A.2 Verify battery cell parameters meet Table 3.8.6-1 Category C limits.</p> <p><u>AND</u></p>	<p>24 hours</p> <p><u>AND</u></p> <p>Once per 7 days thereafter</p>
	<p><u>AND</u></p> <p>A.3 Restore battery cell parameters to Category A and B limits of Table 3.8.6-1.</p>	<p>31 days</p>

(continued)

ACTIONS (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
<p>B. Required Action and associated Completion Time of Condition A not met.</p> <p><u>OR</u></p> <p>One or more batteries with average electrolyte temperature of the representative cells 60°F.</p> <p><u>OR</u></p> <p>One or more batteries with one or more battery cell parameters not within Category C values.</p>	<p>B.1 Declare associated battery inoperable.</p>	<p>Immediately</p> <p style="text-align: center;"><u>B</u></p>

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
<p>SR 3.8.6.1 Verify battery cell parameters meet Table 3.8.6-1 Category A limits.</p>	<p>7 ^{3.8-34} days</p> <p>(continued)</p>

SURVEILLANCE REQUIREMENTS (continued)

SURVEILLANCE	FREQUENCY
<p>SR 3.8.6.2 Verify battery cell parameters meet Table 3.8.6-1 Category B limits.</p>	<p>92 days 3.8-14</p> <p>AND</p> <p>Once within 7 days 24 hours after a battery discharge < 118 110 V</p> <p>AND B-PS</p> <p>Once within 7 days 24 hours after a battery overcharge > 145 150 V</p> <p>3.8-14</p> <p>B-PS</p>
<p>SR 3.8.6.3 Verify average electrolyte temperature of representative cells is $\geq 60^{\circ}\text{F}$.</p>	<p>92 days B</p>

SURVEILLANCE REQUIREMENTS (continued)

Table 3.8.6-1 (page 1 of 1)
Battery Cell Parameters Requirements

PARAMETER	CATEGORY A: LIMITS FOR EACH DESIGNATED PILOT CELL	CATEGORY B: LIMITS FOR EACH CONNECTED CELL	CATEGORY C: ALLOWABLE LIMITS FOR EACH CONNECTED CELL
Electrolyte Level	> Minimum level indication mark, and $\leq \frac{1}{4}$ inch above maximum level indication mark(a)	> Minimum level indication mark, and $\leq \frac{1}{4}$ inch above maximum level indication mark(a)	Above top of plates, and not overflowing
Float Voltage	≥ 2.13 V	≥ 2.13 V	> 2.07 V
Specific Gravity(b)(c)	≥ 1.195 [1.200]	≥ 1.190 [1.195] AND Average of all connected cells > 1.200 [1.205]	Not more than 0.020 below average of all connected cells AND Average of all connected cells ≥ 1.190 [1.195]

- (a) It is acceptable for the electrolyte level to temporarily increase above the specified maximum during equalizing charges provided it is not overflowing.
- (b) Corrected for electrolyte temperature and level. Level correction is not required, however, when battery charging current is < 2 amps when on float charge. B
ED
- (c) A battery charging current of < 2 amps when on float charge is acceptable for meeting specific gravity limits following a battery recharge, for a maximum of 7 days. When charging current is used to satisfy specific gravity requirements, specific gravity of each connected cell shall be measured prior to expiration of the 7 day allowance. B

3.8 ELECTRICAL POWER SYSTEMS

3.8.7 Inverters - Operating

LCO 3.8.7 3.8-15
Four ~~Class 1E Vital 120 V UPS~~ Train A and Train B inverters shall be OPERABLE.

NOTE
[One/two] inverter[s] may be disconnected from [its/their] associated DC bus for < 24 hours to perform an equalizing charge on [its/their] associated [common] battery, provided:
a. The associated AC vital bus(es) [is/are] energized from [its/their] [Class 1E constant voltage source transformers] [inverter using internal AC source]; and
b. All other AC vital buses are energized from their associated OPERABLE inverters.

B-PS

APPLICABILITY: MODES 1, 2, 3, and 4.

ACTIONS

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One required inverter inoperable.	A.1 -----NOTE----- Enter applicable Conditions and Required Actions of LCO 3.8.9, "Distribution Systems - Operating" with any vital 120 V AC bus de-energized. ----- Restore inverter to OPERABLE status.	<u>B</u> <u>3.8-15</u> 24 hours (continued)

CONDITION	REQUIRED ACTION	COMPLETION TIME
B. Required Action and associated Completion Time not met.	B.1 Be in MODE 3.	6 hours
	AND B.2 Be in MODE 5.	36 hours

SURVEILLANCE REQUIREMENTS

SURVEILLANCE	FREQUENCY
SR 3.8.7.1 Verify correct inverter voltage, [frequency.] and alignment to required AC vital buses.	7 days <u>B-PS</u>

3.8 ELECTRICAL POWER SYSTEMS

3.8.8 Inverters - Shutdown

LCO 3.8.8 The ~~Class 1E UPS~~ Inverters shall be OPERABLE to support the onsite Class 1E 120 VAC vital bus electrical power distribution subsystem(s) required by LCO 3.8.10, "Distribution Systems - Shutdown."

3.8-15

APPLICABILITY: MODES 5 and 6,
During movement of irradiated fuel assemblies.

ACTIONS

NOTE
LCO 3.0.3 is not applicable.

3:8-35

CONDITION	REQUIRED ACTION	COMPLETION TIME
A. One or more required inverters inoperable.	A.1 Declare affected required feature(s) inoperable.	Immediately <u>B</u>
	OR	
	A.2.1 Suspend CORE ALTERATIONS.	Immediately
	AND	
	A.2.2 Suspend movement of irradiated fuel assemblies.	Immediately
AND
