TEXT

On July 2, 1997, at 0452 PDT, MFW flow control valve (FCV-520) to Steam Generator (SG) 2-2 transferred to manual mode in the full open position consistent with design due to a momentarily high MFW flow condition following the condensate pump and booster pump start. Plant operators responded to the CR alarm and confirmed FCV-520 manual control mode. A load reduction was initiated. MFWP suction pressure and condenser vacuum continued to degrade and an order was given to increase the electrical load reduction rate.

On July 2, 1997, at 0456 PDT, MFWPs 2-1 and 2-2 tripped on mechanical overspeed trip device actuation due to flashing of condensate in the MFW suction line caused by low suction pressure and high MFW flow demand.

On July 2, 1997, at 0456 PDT, a Unit 2 manual reactor trip was initiated at the shift foreman's order. Plant operators entered Emergency Operating Procedure (EOP) E-0, "Reactor Trip or Safety Injection," transitioned to EOP E-0.1, "Reactor Trip Response," and confirmed proper equipment actuation.

On July 2, 1997, at approximately 0515 PDT, plant operators stabilized the Unit in Mode 3 (Hot Standby) at normal operating pressure and temperature.

On July 2, 1997, at 0853 PDT, a 4-hour, non-emergency report was made to the NRC, in accordance with 10 CFR 50.72(b)(2)(ii). Event Response Plan (ERP 97-03) was initiated to investigate the cause of the event and implement immediate corrective actions to return Unit 2 to Mode 1. ERP actions included verification of proper operation of condensate system components and additional system monitoring during the Unit startup.

On July 5, 1997, Operations Department personnel reviewed the additional system monitoring data, identified intermittent erratic flow of the condensate system and requested technical maintenance perform additional investigation of TCV-23 control loop response.

On July 10, 1997, a suspect module in the TCV-23 positioner control was replaced. Technical maintenance personnel confirmed the failure of a voltage to pneumatic (E/P) converter (TM-3) utilized for TCV-23 position control under test conditions. The TM-3 failure would cause an intermittent large position change demand to TCV-23 in response to small input changes.
