1. Introduction

The purpose of this report is to document the results of the settlement monitoring program from the construction phase of the Saltstone Disposal Unit 6 (SDU 6).

1.1 Background

SDU 6 is a cylindrical tank approximately 375 feet in diameter and 43 feet tall with a volume of approximately 32-million gallons. The tank is constructed of cast-in-place concrete walls on a cast-in-place concrete slab. The concrete slab is underlain by a two-layer concrete mud mat (4-inch and 6-inch thick).

SDU 6 was constructed in a large excavation; overburden excavated for construction ranged from approximately 10 to 17 feet. SDU 6 was not backfilled following construction. The base of the excavation ranged from approximately 265 feet to 269 feet, msl. The floor of SDU 6 is sloped to facilitate future operations.

2. Data Collected

The settlement survey markers used during construction of SDU 6 are described in the following sections. Table 1 summarizes the types and locations of the markers used at SDU 6. Figure 1 illustrates the locations of the markers described in the following sections.

Settlement surveys were performed by the subcontractor throughout construction until June 2015. In July 2015, SRR took responsibility for surveying. SRNS took over responsibility for settlement surveying beginning November 10, 2015, during the initial leak testing.

2.1 Heave markers

Five borros anchor markers were installed across the footprint of the SDU6 to monitor rebound during the excavation process. The anchors were installed to a depth below the bottom of the excavation floor. The heave markers are designated with an “HM” prefix. Locations HM1 and HM5 were also instrumented with a metal pipe installed as an alternative to borros anchors. The pipe were installed the in the same manner as the borros anchors, except there were no prongs to extend. Construction activities for the tank did not begin until about one year following the completion of the excavation.

2.2 Settlement Markers

A series of settlement markers were used throughout the different phases of construction. During construction, settlement readings were generally obtained weekly.

2.2.1 Mud Mat Markers

Mud mat markers were installed following the placement of the lower mud mat. The mud mat markers are designated with an “MM” prefix. The markers were installed in the subgrade adjacent to the concrete mud mats to monitor movements prior to the installation of other permanent settlement markers on the SDU. The mud mat markers were monitored through the construction of the SDU, prior to the first leak test.

2.2.2 Footing Markers

Settlement markers were installed on the footings of the interior columns. The foot markers are designated with a “BM” prefix (C-CY-Z-00005 & C-CY-Z-00007). The footing markers were installed during the placement of the concrete for the footings and were monitored during construction until the final wall panel was installed.

2.2.3 Curb Markers

Settlement markers were installed on the exterior floor (“curb”) of the SDU 6 upon completion of the wire-wrapping and the application of the shotcrete to the exterior of the tank. The curb markers are designated with an “SM” prefix (C-CY-Z-00005 & C-CY-Z-00007). Initial baseline readings were taken on the curb markers approximately one week prior to the beginning of the initial leak test.

2.2.4 Roof Markers

Settlement markers were installed on the roof of the SDU 6, above the curb markers and directly above the foot markers. The roof markers are designated with an “RM” prefix. The roof markers were installed during the placement of the concrete for the roof panels. The roof markers were installed throughout construction.

2.3 Settlement Marker Pairings

Settlement markers (curb markers, roof markers, etc) were paired together to evaluate the movement of the subgrade and tank at various locations across the footprint of the tank. Potential differential movements of the tank top and the tank foundation could be observed using paired settlement markers.

Marker pairings were designated as either Interior Locations (IL#) or Perimeter Locations (PL#). Table 2 summarizes the marker pairings.

2.4 Loading

Spatial estimates of the loading were made for each of the settlement pairing during construction. Table 3 through Table 5 summarize the incremental loads during construction. Table 6 summarizes the net loads during construction of the tank by location.

During the excavation process, the net load at the final subgrade elevation was approximated using topographic surveys taken at various times during the excavation. Table 3 summarizes the loading estimate during excavation.

During construction changes in the net pressure at the final subgrade elevation were based on the spatial placements of the upper and lower mud mats and the floor slabs. Concrete placement diagrams were provided with the settlement monitoring reports. Table 4 summarizes the estimated incremental loads during construction of the mud mats and the floor slab.

Load increases due the placement of the tank walls, columns, and roof slabs were not spatially considered, but rather uniformly distributed over the footprint of the tank. Incremental loads were based the reported cumulative weight of concrete placed. Spatial consideration of the wall,

column, and roof loads was not deemed necessary due to lack of movement observed during their construction. Table 5 summarizes the estimated incremental loads during construction of the walls, columns, and the roof.

During leak testing of the SDU 6 tank, the increase in load was based on the measured volume of water pumped into the tank. At capacity, the 32 million gallons resulted in a net pressure increase of approximately 2,500 psf.

3. Results and Discussion

Observed movements of the subgrade and tank are discussed in the following sections. The figures include movements and estimates of net subgrade pressure.

Survey data received for the heave markers may be found in document control under the contract number SRRA008515. Survey data received from the tank subcontractor (mud mat through hydro leak test) are found in document control under the contract number SRRA023445. Survey data received from site surveying (SRR and SRNS) are provided as an attachment to this document. Appendix B lists the files contained in the electronic attachment.

3.1 Heave Data

During excavation, approximately 8 to 14 feet of overburden were removed from the SDU 6 footprint. Table 7 summarizes the readings and movements of the heave markers; Figure 2 illustrates the measured movements during the excavation process. The measured heave ranged from 0.1 to 0.4 inches immediately following excavation in 2012. The excavation remained open for approximately one year prior to any further significant construction activities.

A final survey was taken of the heave markers in 2013; however the results showed all makers settled approximately $\frac{1}{4}$ -inch, except for markers 5 and 5A which settled more than 2 inches. The results were unrealistic of an exposed excavation and are not illustrated in Figure 2.

3.2 Settlement Markers

Movements of the settlement markers are summarized in the following sections.

3.2.1 Mud Mat Markers

Table 8 summarizes the readings and movements of the mud mat markers; Figure 3 illustrates the measured movements of the mud mat markers. The mud mat markers experienced only small movements during construction. The measured movements ranged generally between 0.1 inches and -0.1 inches throughout construction. One marker (MM7) experienced higher settlements, but this was likely due to the monument getting disturbed, as there was no significant load in the vicinity of MM7 at the time of measured movement (Table 4 and Table 8); otherwise the monument maintained a relatively constant elevation throughout construction.

3.2.2 Footing Markers

Table 9 summarizes the readings and movements of the footing markers; Figure 4 illustrates the measured movements of the footing markers. The footing markers experienced only small movements during construction. The measured settlements for all markers were approximately

0.1 inches at the final reading, except for two markers which were less than $\frac{1}{4}$ - inch.

3.2.3 Curb Markers

Table 10 summarizes the readings and movements of the curb markers; Figure 5 illustrates the movements of the curb markers since their installation. The response of the monuments due to the leak testing can be observed as settlement during loading and rebound during unloading. Figure 6 illustrates in greater detail the response of the tank during the initial leak testing. Although the reported movements differ, the relative movements of the curb markers are consistent with one another. Seven of the ten curb markers showed approximately $\frac{1}{4}$ -inch of upward movement relative to their installation elevation, potentially due to differences in baselining between the two different survey groups during the leak test. During the initial leak testing, the tank settled approximately 0.2 to 0.35 inches.

3.2.4 Roof Markers

Table 11 and Table 12 summarize the readings and movements of the roof markers. Figure 7 and Figure 8 illustrate the movements of the interior and perimeter roof markers, respectively, since their installation. Figure 9 and Figure 10 illustrate in greater detail the response of the tank during the initial leak testing. During the initial leak testing, the interior and perimeter roof markers settled approximately 0.1 to 0.3 inches. The rebound of the interior roof markers was approximately $\frac{1}{2}$ -inch, while the rebound of the perimeter markers was approximately $\frac{1}{4}$ -inch. As with the curb markers, several of the roof markers indicated a net heave following the leak testing, which could likely be attributed to differences in baselining between the various survey groups.

Roof markers RM5 and RM7 are located beneath a pipe bridge and survey has been unable to access these points during the final few surveys.

3.3 Settlement Marker Pairings

Graphs illustrating the movements of the paired settlement markers are provided in Appendix A. The graphs illustrate the monument movements and the net loading at the tank subgrade level. Also provided are graphs of the paired movements during the leak testing. An estimate of predicted movements (0.2 to 0.8 inches) under an estimated 3,300 psf gross load at the foundation level is provided in the figures. The estimate is based on the Schmertmann approach outlined in the SDU 6 final geotechnical evaluation report (Ref. SRS 2012). All of the settlements in Appendix A are less than the Average predicted settlements, many are less than the minimum predicted settlements. Settlements less than predicted could be due conservative estimates of settlement or possibly due to incomplete consolidation of the soil column, due to the relatively short duration of the hydro tests.

4. Conclusions

The settlement surveys did not indicate any significant movements or differential settlements of the structure during construction or during the leak testing. It is recommended that settlement surveys be continued during the operation of the SDU.

No significant differences were observed in the relative moments of the roof and curb markers during construction or leak testing.

The use of a metal pipe as an alternative to borros anchors for heave monitoring did not provide any significant results. The continued use of borros anchors for future excavations is recommended.

During construction, the frequency of the settlement readings could be reduced, at the discretion of the geotechnical engineer, particularly when the net contact pressures at the subgrade are less than zero. During construction phases where significant loads are added (or removed) weekly monitoring appears to be sufficient.

Based on the limited movements observed and relatively low net pressures, a detailed loading schedule for the walls, columns and roof is not utilized.

The loads are based on a percentage of the total load. The initial 9/30/2014 63 psf load is estimated based on the total concrete poured to date, less the pressure of the mud mats and floor slab.
