LIST OF FIGURES

ABBREVIATIONS

A&NS	alert and notification system
A2LA	American Association for Laboratory Accreditation
ac	alternating current
ACES	Automated Coastal Engineering System
ACI	American Concrete Institute
ACP	access control point
ACRS	Advisory Committee on Reactor Safeguards
ADAMS	Agencywide Documents Access and Management System
ADB	ancillary diesel building
ADG	ancillary diesel generator
ADS	automatic depressurization system
AEA	Atomic Energy Act
AEOF	Alternate EOF
AF	amplitude function
AFT	as-found tolerance
AFU	air filtration unit AHEX
ALARA	as low as reasonably achievable
ANI	American Nuclear Insurers
ANS	American Nuclear Society
ANSI	American National Standards Institute
ANSS	Advanced National Seismic System
AOO	anticipated operational occurrence
AOV	air-operated valve
API	American Petroleum Institute
AREOR	Annual Radiological Environmental Operating Report
ASHRAE	American Society of Heating, Refrigerating, and Air-Conditioning Engineers
ASME	American Society of Mechanical Engineers
ASCE	American Society of Civil Engineers
ASCE/SEI	American Society of Civil Engineers/Structural Engineering Institute
ASR	alkali-silica reactivity
ASTM	American Society of Testing and Materials
ATWS	anticipated transient without scram
B&V	Black & Veatch
BDBE	beyond-design-basis event
BE	best estimate
BL	bulletin
BPV	Boiler and Pressure Vessel
BPVC	Boiler and Pressure Vessel Code
BRE	bullet resisting enclosure
BTP	branch technical position
Btu	British thermal unit
BWR	boiling-water reactor
C	Celsius
cc	Cubic-centimeters

CAM	continuous air monitor
CAV	cumulative absolute velocity
CB	control building
CD-144	card deck-144 (format used in NCDC meteorological data)
CDA	critical digital asset
CDF	core damage frequency
CDI	conceptual design information
CEM	Coastal Engineering Manual
CENA	central and eastern North America
CEUS	central and eastern United States
CEUSSSC	Central and Eastern United States Seismic Source Characterization
CF	chemistry factor
cfm	cubic feet per minute
CFR	Code of Federal Regulations
CHS	Charleston
CHV	Charlevoix
CIRC	circulating water system
CLSM	controlled low-strength material
cm	centimeter(s)
CMZ	Commerce fault zone
COCORP	Consortium for Continental Reflection Profiling
COL	combined license
COLA	combined license application
COOP	Cooperative Observation Program
CP	construction permit
CPS	condensate purification system
CPTs	cone penetrometer tests
CR	Coefficient Ratio-(SER Chapter 2)
CR	control room
CRD	control rod drive
CRHA	control room habitability area
CSTS	condensate storage and transfer system
CSAT	Cyber Security Assessment Team
CSDRS	certified seismic design response spectra
CSF	condensate storage facility
CSIRT	Cyber Security Incident Response Team
CSP	cyber security plan
CST	condensate storage tank
CVAP	Comprehensive Vibration Assessment Program
CVSZ	Central Virginia Seismic Zone

WHTF	waste heat treatment facitlity
ZIS	zinc injection system

ABSTRACT

This final safety evaluation report[1] (FSER) documents the U.S. Nuclear Regulatory Commission (NRC or the Commission) staff's technical review of the combined license (COL) application (COLA) submitted by Dominion Virginia Power (Dominion) [2] (Dominion, or the applicant), for North Anna 3.

In a letter dated November 26, 2007, the Dominion submitted its application to the NRC for a COL to construct and operate a General Electric-Hitachi Economic Simplified Boiling-Water Reactor (ESBWR) pursuant to the requirements of Section 103 and 185(b) of the *Atomic Energy Act of 1954 as Amended (AEA),* Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications and Approval for Nuclear Power Plants," and the associated material licenses under 10 CFR Part 30, "Rules of General Applicability to Domestic Licensing of Byproduct Material"; 10 CFR Part 40, "Domestic Licensing of Source Material"; and 10 CFR Part 70, "Domestic Licensing of Special Nuclear Material." This reactor will be identified as North Anna 3 and will be located on the existing North Anna Power Station site (North Anna site) in Louisa County, Virginia, approximately 40 miles north northwest of Richmond, Virginia.

As indicated in the applicant's November 26, 2007 submittal, the application incorporated by reference Revision 4 of the ESBWR Design Control Document (DCD) and Revision 9 of the North Anna 3 Early Site Permit (ESP) for the North Anna 3 site. The NRC issued the North Anna ESP (ESP-003) on November 27, 2007 based on Revision 9 of the ESP application (ADAMS Accession No. ML073180421).

By letter dated June 28, 2010, Dominion revised its application to incorporate by reference the Mitsubishi Heavy Industries', Ltd. United States – Advanced Pressurized Water Reactor (US-APWR). By letter dated April 25, 2013, Dominion notified the staff that it planned to revert back to ESBWR reactor technology for its North Anna 3 COLA. Dominion then submitted a revised application that incorporated by reference the ESBWR DCD, Revision 9 by letter dated December 18, 2013.

By letter dated June 24, 2014, Dominion submitted a revised application that incorporated by reference the ESBWR DCD, Revision 10. In a letter dated January 23, 2015, Dominion followed the design center approach and reviewed the Detroit Edison Company Fermi 3 COLA updates (ADAMS Accession Nos. ML14295A354 and ML14308A337) that reflected the changes to the Fermi 3 COLA incorporating by reference the codified version of the ESBWR design certification rule (DCR) which is contained in 10 CFR Part 52, Appendix E, "Design Certification Rule for the U.S. Economic Simplified Boiling Water Reactor." The ESBWR DCR was published on October 15, 2014 (79 FR 61944) and is effective as of November 14, 2014. The ESBWR DCR references Revision 10 of the ESBWR DCD.

This FSER presents the results of the staff's review of information submitted in conjunction with the North Anna 3 COLA, except those matters resolved as part of the referenced design certification rule. In Appendix A to this FSER, the staff has identified certain license conditions and inspections, tests, analyses and acceptance criteria (ITAAC) that the staff recommends the Commission impose, should the COL be issued to the applicant. In addition to the ITAAC in Appendix A, the ITAAC found in the

---

[1] This FSER documents the NRC staff's position on all safety issues associated with the combined license application. The Advisory Committee on Reactor Safeguards (ACRS) independently reviewed those aspects of the application that concern safety, as well as the advanced safety evaluation report without open items (an earlier version of this document), and provided the results of its review to the Commission in a report dated November 15, 2016. This report is included as Appendix F to this SER.

ESBWR DCD Revision 10 Tier 1 material will also be incorporated into the COL should the COL be issued to the applicant.

On the basis of the staff's review[2] of the application, as documented in this FSER, the staff recommends that the Commission find the following with respect to the safety aspects of the COL application: 1) the applicable standards and requirements of the Atomic Energy Act and Commission regulations have been met, 2) required notifications to other agencies or bodies have been duly made, 3) there is reasonable assurance that the facility will be constructed and will operate in conformity with the license, the provisions of the Atomic Energy Act, and the Commission's regulations, 4) the applicant is technically and financially qualified to engage in the activities authorized, and 5) issuance of the license will not be inimical to the common defense and security or to the health and safety of the public.

[2] An environmental review was also performed of the COL application and its evaluation and conclusions are documented in NUREG-2105, "Final Supplemental Environmental Impact Statement for Combined License (COL) for North Anna 3."

1.0 INTRODUCTION AND GENERAL DESCRIPTION OF PLANT

1.0 INTRODUCTION AND GENERAL DESCRIPTION OF PLANT

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the NRC staff overview of the North Anna 3 Combined License (COL) application (COLA), the COL applicants design, site plan, material licenses, application submittal information, financial qualifications and the staff review principals and regulations. This chapter of the SER is organized as follows:

- Section 1.1 provides an overview of the North Anna 3 COLA.
- Section 1.2 provides the regulatory basis for the COL licensing process.
- Section 1.3 provides an overview of the principal review matters in the COLA and where the staff's reviews of the ten parts of the COLA are documented.
- Section 1.4 documents the staff's review of Chapter 1 of the Final Safety Analysis Report (FSAR).
- Section 1.5 documents the staff's review of other regulatory considerations for Chapter 1.

1.1 Summary of Application

By letter dated November 26, 2007 (Agencywide Documents Access and Management System (ADAMS) Accession No. ML073320913), Dominion Virginia Power (Dominion) submitted its application to the NRC for a COL to construct and operate a General Electric-Hitachi Economic Simplified Boiling-Water Reactor (ESBWR) at North Anna Power Station site (North Anna site) pursuant to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certification, and Approvals for Nuclear Power Plants," and the associated material licenses under 10 CFR Part 30, "Rules of General Applicability to Domestic Licensing of Byproduct Material," 10 CFR Part 40, "Domestic Licensing of Source Material," and 10 CFR Part 70, "Domestic Licensing of Special Nuclear Material."

The ESBWR nuclear reactor design is a 4,500-megawatt thermal reactor that uses natural circulation for normal operations and has passive safety features. This reactor will be identified as North Anna 3 and will be located on Dominion's existing North Anna site in Louisa County, Virginia, approximately 40 miles north northwest of Richmond, Virginia. There are two existing nuclear reactors in operation at the North Anna site, as well as an Independent Spent Fuel Storage Installation (ISFSI). North Anna 3 will be located adjacent to and generally west of the existing units on the North Anna site.

As indicated in the applicant's November 26, 2007 submittal, the application incorporated by reference Revision 4 of the ESBWR Design Control Document (DCD) and Revision 9 of the North Anna 3 Early Site Permit (ESP) for the North Anna 3 site. The NRC issued the North Anna ESP (ESP-003) on November 27, 2007 based on Revision 9 of the ESP application (ADAMS Accession No. ML073180421).

By letter dated June 28, 2010, Dominion revised its application to incorporate by reference the Mitsubishi Heavy Industries', Ltd. United States – Advanced Pressurized Water Reactor

(US-APWR) technology to construct and operate at the North Anna 3 site. By letter dated April 25, 2013, Dominion notified the staff that it planned to revert back to ESBWR reactor technology for its North Anna 3 COLA. Dominion then submitted a revised application that incorporated by reference the ESBWR DCD, Revision 9 by letter dated December 18, 2013.

By letter dated June 24, 2014, Dominion submitted a revised application that incorporated by reference the ESBWR DCD, Revision 10. In a letter dated January 23, 2015, Dominion followed the design center approach and reviewed the recent Detroit Edison Company Fermi 3 COLA updates (ADAMS Accession Nos. ML14295A354 and ML14308A337) that reflected the changes to the Fermi 3 COLA incorporating by reference the codified version of the ESBWR design certification rule (DCR) which is contained in 10 CFR Part 52, Appendix E, “Design Certification Rule for the U.S. Economic Simplified Boiling Water Reactor.” The ESBWR DCR was published on October 15, 2014 (79 FR 61944) and is effective as of November 14, 2014. The ESBWR DCR references Revision 10 of the ESBWR DCD.

In developing the Final Safety Evaluation Report (FSER) for North Anna 3, the staff reviewed the ESBWR DCD, Revision 10 and the North Anna ESP to ensure that the combination of the information in the DCD and the information in the COLA represents the complete scope of information relating to a particular review topic.

There is a North Anna 3 FSER chapter that was issued without a corresponding ESBWR DCD chapter. Specifically, North Anna 3 FSER Chapter 20, “Requirements Resulting from Fukushima Near-Term Task Force Recommendations,” does not have a corresponding ESBWR DCD Chapter 20. The FSER Chapter 20 describes the staff’s evaluation and findings for the requirements resulting from the Fukushima Near-Term Task Force recommendations that are applicable to the North Anna 3 COL. The applicable recommendations address the following four topics:

- A re-evaluation of the seismic hazard (related to Recommendation 2.1).
- Mitigation strategies for beyond-design-basis external events (related to Recommendation 4.2).
- Spent fuel pool instrumentation (related to Recommendation 7.1).
- Emergency preparedness (EP) staffing and communications (related to Recommendation 9.3).

For more information on the staff’s review of the above four topics, please refer to Chapter 20 of this SER.

The North Anna 3 COLA is organized as follows:

- **Part 1 General and Administrative Information**

  Part 1 provides an introduction to the application and includes certain corporate information regarding Dominion pursuant to 10 CFR 50.33(a)–(d).

- **Part 2 Final Safety Analysis Report**

  Part 2 contains information pursuant to the requirements of 10 CFR 52.79 “Contents of applications; technical information in final safety analysis report,” and, in general, adheres to the content and format guidance in Regulatory Guide (RG) 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition).”

- **Part 3 Environmental Report**

  Part 3 contains environmental-related information pursuant to the requirements of 10 CFR 52.80, “Contents of applications; additional technical information,” and 10 CFR 51.50(c).

- **Part 4 Technical Specifications and Bases**

  Part 4 addresses how the ESBWR generic technical specifications (TS) and bases of the design are incorporated by reference into the North Anna 3 plant-specific TS and bases.

- **Part 5 Emergency Plan**

  Part 5 contains the North Anna 3 Emergency Plan with supporting information such as evacuation time estimates for the North Anna 3 plume exposure pathway and applicable offsite state and local emergency plans.

- **Part 6 [Not Used - reserved for Limited Work Authorization/site redress information]**

- **Part 7 Departures Report**

  Part 7 contains information from the applicant regarding departures, exemptions, and variances from the ESBWR DCD and the North Anna ESP accordingly. The departures, exemptions, and variances are all evaluated by the staff within their respective SER sections. However, the applicant has included one exemption request from 10 CFR 70.22(c); 70.32(c); 74.31, “Nuclear material control and accounting for special nuclear material of low strategic significance”; 74.41, “Nuclear material control and accounting for special nuclear material of moderate strategic significance”; and 74.51, “Nuclear material control and accounting for strategic special nuclear material.” The staff evaluated this exemption request in Section 1.5.5 of this SER chapter.

- **Part 8 Safeguards and Security Plans**

  Part 8 was submitted concurrent with the application to the NRC as separate licensing correspondence in order to fulfill the requirements of 10 CFR 52.79(a)(35) and 10 CFR 52.79(a)(36). Part 8 contains the North Anna 3 Security Plan and Safeguards Information (SGI) that is withheld from public disclosure pursuant to 10 CFR 73.21, “Protection of Safeguards Information: Performance Requirements.” The information in Part 8 consists of the Physical Security Plan, the Training and Qualification Plan, the Safeguards Contingency Plan, the Cyber Security Plan, the Mitigative Strategies Description and Plans, and the Special Nuclear Material Physical Protection Program. Portions of Part 8 contain Security-Related information and are withheld from public disclosure pursuant to 10 CFR 2.390, “Public inspections, exemptions, requests for withholding.”

- **Part 9 [Not used – Reserved for Withheld Information]**

- **Part 10 ITAAC**

  Part 10 contains the applicant’s Tier 1 information incorporated by reference from the ESBWR DCD. This part also contains the North Anna 3 Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC). The entire set of North Anna 3 COL ITAAC are addressed in four parts: (1) Design Certification (DC), (2) Emergency Planning, (3) Physical Security, and (4) Site-Specific. In addition, Part 10 includes a list of proposed license conditions from the applicant.

1.2 Regulatory Basis

1.2.1 Applicable Regulations

10 CFR Part 52, Subpart C, “Combined Licenses,” establishes the requirements and procedures applicable to the Commission-issued COL for nuclear power facilities. The following requirements are of particular significance:

- 10 CFR 52.79, identifies the technical information required in the FSAR.
- 10 CFR 52.79(d) provides additional requirements for a COL referencing a standard certified design.
- 10 CFR 52.80, provides additional technical information outside of the FSAR (ITAAC and the environmental report).
- 10 CFR 52.81, “Standards for review of applications,” provides standards for reviewing the application.
- 10 CFR 52.83, “Finality of referenced NRC approvals; partial initial decision on site suitability,” provides for the finality of the referenced NRC approvals (e.g., standard DC approvals).
- 10 CFR 52.85, “Administrative review of applications; hearings,” provides requirements for administrative reviews and hearing.
- 10 CFR 52.87, “Referral to the Advisory Committee on Reactor Safeguards (ACRS),” provides for referral to the ACRS.

The staff reviewed this application according to the following requirements:

- 10 CFR Part 20, “Standards for Protection Against Radiation”
- 10 CFR Part 30
- 10 CFR Part 40

- 10 CFR Part 50, “Domestic Licensing of Production and Utilization Facilities”

- 10 CFR Part 51, “Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions”

- 10 CFR Part 52

- 10 CFR Part 54, “Requirements for Renewal of Operating Licenses for Nuclear Power Plants”

- 10 CFR Part 55, “Operators’ Licenses”

- 10 CFR Part 70

- 10 CFR Part 73, “Physical Protection of Plants and Materials”

- 10 CFR Part 74, “Material Control and Accounting of Special Nuclear Material”

- 10 CFR Part 100, “Reactor Site Criteria”

- 10 CFR Part 140, “Financial Protection Requirements and Indemnity Agreements”

The staff evaluated the application against the guidance and acceptance criteria in the following:

- NUREG–0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition)”

- NUREG–1520, “Standard Review Plan for Fuel Cycle Facilities License Applications”

- NUREG–1555, Revision 1: “Standard Review Plans for Environmental Reviews for Nuclear Power Plants: Environmental Standard Review Plan (with Supplement 1 for Operating Reactor License Renewal)”

- NUREG–1556, “Consolidated Guidance About Materials Licenses”

- NUREG–1577, “Standard Review Plan on Power Reactor Licensee Financial Qualifications and Decommissioning Funding Assurance”

In addition, the staff considered the format and content guidance in RG 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” for the COLA.

1.2.2 Finality of Referenced NRC Approvals

The North Anna 3 COL references the codified version of the ESBWR DCD (ESBWR DCD, Revision 10). The regulatory basis of the information incorporated by reference is addressed in NUREG–1966, the FSER related to the certified ESBWR DCD (ADAMS Accession No. ML103470210) and NUREG–1966, Supplement 1 (ADAMS Accession No. ML14265A084). In addition, the North Anna 3 COLA references the North Anna ESP Site Safety Analysis Report (SSAR), Revision 9. The ESP was issued by the NRC on November 27, 2007. The staff documented its review of the North Anna 3 ESP SSAR in NUREG–1835 (ADAMS Accession

No. ML052710305), the staff FSER for the North Anna 3 ESP and NUREG–1835, Supplement 1 (ADAMS Accession No. ML063170371). In addition, the acceptance criteria associated with the relevant requirements of the Commission regulations for the North Anna 3 COLA and the associated acceptance criteria, are given in NUREG–0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition)," (SRP) (54 FR 31268).

Based on the finality afforded to referenced certified designs and ESPs, the scope of this COLA review, as it relates to the referenced certified design and ESP, is limited to items that fall outside the scope of the certified design (e.g., COL information items, design information replacing conceptual design information (CDI), and programmatic elements that are the responsibility of the COL) or the ESP. During its evaluation of the COLA, the staff confirmed that the complete set of information required to be addressed in the COLA was addressed in the DC or referenced ESP, the DC or ESP as supplemented by the COLA, or completely in the COLA. Following this confirmation, the staff's review of the COLA is limited to the COL-specific review items.

In accordance with 10 CFR 52.83, if the application for a COL references a DCD or ESP, the scope and nature of matters resolved for the application and any COL issued are governed by the applicable relevant provisions. For the ESBWR DCD, finality is specifically addressed in 10 CFR 52.63, "Finality of standard design certifications." In addition, if the application for a COL references an ESP, the scope and nature of matters resolved in the ESP for the application and any COL issued are governed by 10 CFR 52.39, "Finality of early site permit determinations."

The contents of the FSAR are specified in 10 CFR 52.79(a), which requires the information submitted in the FSAR to describe the facility; identify the design bases and the limits on its operation; and present a safety analysis of the structures, systems, and components (SSCs) of the facility as a whole. For a COLA that references a DC, Section 52.79(d) requires the DCD to be included in or incorporated by reference into the FSAR. Additionally, a COLA that references a DC must also contain the information and analysis required to be submitted within the scope of the COLA but is outside the scope of the DCD. This combined information addresses plant- and site-specific information and includes all COL action or information items; design information that replaces CDI; and programmatic information that was not reviewed and approved in connection with the DC rulemaking.

For a COLA that references an ESP, Section 52.79(b) requires; that the ESP SSAR to be included in or incorporated by reference into the FSAR, that information and analyses that demonstrate that the design of the facility fall within the North Anna site and design characteristics specified in the ESP, and that application must include any updates or changes related to any previously approved emergency plans.

The initial step in the staff's evaluation of the COLA is to confirm that the complete set of information required to be addressed in the COLA is also in the DC or ESP as supplemented by the COLA or completely included in the COLA. Following this confirmation, the staff's review of the COLA is limited to the COL review items. This FSER is based on the applicant's Revision 8 of the North Anna 3 FSAR, which incorporates by reference ESBWR DCD, Revision 10. In addition the changes to the North Anna 3 site-specific seismic hazard evaluation were confirmed by the staff in the North Anna 3 FSAR Revision 9, submitted in June 2016, which considered the latest seismic hazards information as described in this SER for North Anna 3, Chapter 3, Section 3.7, Section 3.8 and Chapter 2, Section 2.5.2. The results of the staff's technical evaluation of the ESBWR DCD application are in NUREG–1966, "Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-Water Reactor Standard Design" (ADAMS Accession No. ML14100A304), and its Supplement 1 (ADAMS Accession No. ML14265A084).

The outcome of the ESBWR DC rulemaking was previously tracked as Open Item 1-1. This rulemaking has been completed and the application and the staff's safety evaluations have been updated accordingly. This Open Item is now considered closed.

1.2.3 Overview of the Design-Centered Review Approach

The design-centered review approach (DCRA) is described in Regulatory Issue Summary 2006-06, "New Reactor Standardization Needed to Support the Design-Centered Licensing Review Approach." The DCRA is endorsed by the Commission's Staff Requirements Memorandum SECY-06-0187, "Semiannual Update of the Status of New Reactor Licensing Activities and Future Planning for New Reactors," dated November 16, 2006. The DCRA is the Commission's policy intended to promote a standardization of COLAs; it is beyond the scope of information included in the DC. This policy directs the staff to perform one technical review for each standard issue outside the scope of the DC and to use this decision to support decisions on multiple COLAs. In this context, "standard" refers to essentially identical information and may include information provided by the applicant(s) to resolve plant-specific issues.
The first COLA submitted for the staff to review is designated in a design center as the referenced COL (R-COL) application, and the subsequent applications in the design center are designated as subsequent COL (S-COL) applications. The North Anna 3 COLA was originally designated as the R-COLA for the ESBWR design center, and the staff issued an SER with open items that documented a review of both standard and site-specific information. In a letter dated May 18, 2010, Dominion Energy, Inc. informed the NRC that it had changed reactor technology and had selected the US-APWR for its North Anna 3 COLA. As a result of Dominion's decision, for the Fermi 3 COLA, Detroit Edison responded to all of the open items in the staff's North Anna 3 SER that related to standard content on behalf of the ESBWR design center and consistent with its new position as the R-COL for the ESBWR design center.[1] Thus, the Final SER for the Fermi 3 COL documents the staff's review of both standard and site-specific information and is the first complete SER for a COLA in the ESBWR design center.

In a letter dated January 23, 2015, Dominion followed the design center approach and reviewed the recent Detroit Edison Company Fermi 3 COLA Revision 8 updates (ADAMS Accession Nos. ML14295A354 and ML14308A337) that reflected the changes to the Fermi 3 COLA incorporating by reference the codified version of the ESBWR DCD.

To ensure that the staff's findings on standard content that were documented in the Final SER for the Fermi 3 COLA are equally applicable to the North Anna 3 COLA, the staff undertook the following reviews:

[1] By letter dated April 25, 2013 (ADAMS Accession No. ML13120A016), the applicant for the North Anna 3 COL application informed the NRC that it had revised its technology selection and selected the General Electric (GEH) ESBWR nuclear technology for the North Anna 3 project. The applicant submitted a revised North Anna 3 COL application to the NRC on July 31, 2013 (ADAMS Accession No. ML13221A504). However, the Fermi COL application remains as the ESBWR design center R-COL.

- The staff compared the North Anna 3 COL FSAR, Revision 8, to the Fermi 3 COL FSAR Revision 8. In performing this comparison, the staff considered changes to the Fermi 3 COL FSAR (and other parts of the COLA, as applicable) resulting from requests for additional information (RAIs) and open and confirmatory items identified in the Fermi 3 SER with open items.

- The staff confirmed that all responses to RAIs identified in the corresponding standard content evaluation (the Fermi 3 FSER) were endorsed.

- The staff verified that the site-specific differences are not relevant.

Where there were differences between the information provided by the Fermi 3 applicant and that provided by the North Anna 3 applicant regarding details in the application for the standard content material, the staff evaluated the differences and determined whether the standard content material of the Fermi 3 FSER was still applicable to the North Anna 3 application. These evaluations are in the SERs that reference the standard content. In various portions of this SER, the technical review of the related standard content material is identified by using italicized, double-indented formatting.

1.3 Principal Review Matters

The staff's evaluations related to the COLA review are addressed as follows:

- **Part 1 General and Administrative Information**

The staff's evaluation of the corporate information regarding Dominion that is pursuant to 10 CFR 50.33, "Contents of applications; general information," is in Section 1.5.1 of this SER.

- **Part 2 Final Safety Analysis Report**

The staff's evaluation of information in the North Anna 3 FSAR is in the corresponding sections of this SER.

- **Part 3 Environmental Report**

The staff's evaluation of environmental information pursuant to the requirements of 10 CFR 51.50(c) addressed in the environmental report is in the staff's Supplemental Environmental Impact Statement in NUREG–1917, "Supplemental Environmental Impact Statement for Combined License (COL) for North Anna Power Station Unit 3."

- **Part 4 Technical Specifications**

Chapter 16 of this SER contains the staff's evaluation of the North Anna 3 plant-specific TS (PTS), and the associated PTS bases.

- **Part 5 Emergency Plan**

Chapter 13 of this SER includes the staff's evaluation of the North Anna 3 Emergency Plan, including related ITAAC, and the Federal Emergency Management Agency's review of State and local emergency plans.

- **Part 6** **[Not Used - reserved for Limited Work Authorization/site redress information]**

- **Part 7** **Departures Report**

The staff's evaluation of departures and exemptions is provided in the applicable chapters of this SER (i.e., Chapters 1 through 19). In addition, the staff's review of one requested exemption is included in Section 1.5.4 of this SER. Any associated exemptions are granted separately from this SER.

- **Part 8** **Safeguards and Security Plans**

The information in Part 8 consists of the Physical Security Plan, the Training and Qualification Plan, the Safeguards Contingency Plan, the Cyber Security Plan, the Mitigative Strategies Description and Plans, and the Special Nuclear Material Physical Protection Program. Portions of Part 8 contain Security-Related information and are withheld from public disclosure pursuant to 10 CFR 2.390. The staff's evaluation of the sensitive information, withheld information in Part 8 occurs in the context of the specific subject being reviewed and is documented by the staff accordingly throughout the staff's SER.

The staff's evaluation of the North Anna 3 Security Plan and SGI is documented separately from this SER and is withheld from the public in accordance with 10 CFR 73.21. A non-sensitive summary of the staff's evaluation is in Section 13.6 of this SER.

The applicant has included withheld portions of the applicant's Cyber Security Plan as required by 10 CFR 73.54, "Protection of digital computer and communication systems and networks." The staff's evaluation of the cyber security-related plans is included in SER Section 13.8.

The applicant has provided withheld portions of the Mitigative Strategies Description and Plans for the loss of large areas of the plant due to explosions or fire, as required by 10 CFR 52.80(d). A summary of the staff's evaluation of this information is in Appendix 19A of this SER. The staff's complete evaluation is documented separately from this SER and is withheld from the public in accordance with 10 CFR 2.390. The applicant has provided withheld portions of the Special Nuclear Material Physical Protection Program as required by 10 CFR 73.67, "Licensee fixed site and in-transit requirements for the physical protection of special nuclear material of moderate and low strategic significance." A summary of the staff's evaluation of this information is in SER Section 1.6.

- **Part 9** **[Not used – Reserved for Withheld Information]**

- **Part 10** **ITAAC and Proposed License Conditions**

Chapter 14 of this SER contains the staff's evaluation of the ITAAC, except for the Physical Security ITAAC in SER Section 13.6. In addition, Part 10 of the application includes a list of proposed license conditions that are evaluated by the staff throughout this SER. At the completion of the staff's North Anna 3 COLA review, the staff will identify all proposed license conditions and ITAAC for recommendation that the Commission should impose if a COL is issued to the applicant.

Organization of SER

The staff's SER is structured as follows:

- The SER adheres to the "finality" afforded to COLAs that incorporate by reference a standard certified design or ESP. As such, rather than repeat any technical evaluation of material incorporated by reference, this SER points to the corresponding review findings of NUREG–1966, NUREG–1811, "Final Environmental Impact Statement for an Early Site Permit (ESP) at the North Anna ESP Site," and NUREG–1917 "Supplemental Environmental Impact Statement for the Combined License (COL) for North Anna Power Station Unit 3). However, the referenced ESBWR DCD, ESP and the North Anna 3 COL FSAR are considered in the staff's safety evaluation—to the extent necessary—to ensure that the expected scope of information to be included in a COLA is adequately addressed in the DCD, ESP and/or in the COL FSAR.

- For sections that were completely incorporated by reference without any supplements or departures, the SER simply points to the ESBWR DCD and the related NUREG–1966 to confirm that all relevant review items are addressed in the ESBWR DCD and the staff's evaluation is documented in NUREG–1966.

- Staff made its safety determinations on specific COLA items based on the applicants FSAR revision and the DCD revision in which final staff conclusions were made. For example the staff SER with Open Items was based on FSAR Revision 2 and DCD Revision 5. Open items were closed and information confirmed based on FSAR Revision 8 and DCD Revision 10. The final FSAR Revision 9, submitted in June, 2016 included all changes based on staff review of final confirmatory items principally from the seismic re-evaluations changes and confirmed by the staff as discussed in the staff FSER for North Anna 3.

- For subject matter within the scope of the COLA that supplements or departs from the DCD, this SER generally follows a six-section organization as follows:

  - "Introduction," which provides a brief overview of the specific subject matter.

  - "Summary of Application," which identifies whether portions of the review have received finality and clearly identify the scope of the COL review.

  - "Regulatory Basis," which identifies the regulatory criteria for the information addressed by the COLA.

  - "Technical Evaluation," which focuses on the information addressed by the COLA.

  - "Post Combined License Activities," which identifies the proposed license conditions, the ITAAC, or the FSAR information commitments that are post COL activities.

  - "Conclusion," which summarizes how the technical evaluation resulted in a reasonable assurance determination by the staff on the basis that the relevant acceptance criteria have been met.

1.4 Staff Review of North Anna 3 COL FSAR Chapter 1:

1.4.1 Introduction

There are two types of information in Chapter 1 of the North Anna 3 COL FSAR:

- General information that enables the reviewer or reader to obtain a basic understanding of the overall facility without having to refer to the subsequent chapters. A review of the remainder of the application can then be completed with a better perspective and recognition of the relative safety significance of each individual item in the overall plant description.

- Specific information relating to qualifications of the applicant, construction impacts, and regulatory considerations that applies throughout the balance of the application (e.g., conformance with the acceptance criteria in the SRP).

This section of the Chapter 1 SER (1) identifies the information in Chapter 1 incorporated by reference, (2) summarizes all of the new information, and (3) documents the staff's evaluation of the sections addressing regulatory considerations.

1.4.2 Summary of Application

The information related to COL and supplemental (SUP) items included in Chapter 1 of the North Anna 3 COL FSAR includes either statements of fact or information recommended in RG 1.206. No staff technical evaluation was necessary where the statements were strictly background information. However, where technical evaluation of these COL/SUPs was necessary, the evaluation is not in this SER section, but in subsequent sections as referenced below.

<u>Section 1.1 – Introduction</u>

Section 1.1 of the North Anna 3 FSAR, Revision 8, incorporates by reference Section 1.1 of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.1, the applicant provides the following:

<u>COL Item:</u>

- NAPS COL 1.1-1-A

The applicant provides information regarding the site-specific values for the North Anna 3 power output.

<u>Supplemental Information:</u>

- NAPS SUP 1.1-1 and NAPS SUP 1.1-2

The applicant provides supplemental information that includes general information regarding format and content of the application. The applicant provides a description of incorporating by reference the North Anna ESPA (Early Site Permit Application) SSAR. The applicant also identifies systems and structures outside the scope of the ESBWR standard plant that are discussed in the applicable chapter (i.e., Chapters 2 through 20) of this SER.

- NAPS SUP 1.1-3

The applicant indicates that the Virginia Electric and Power Company was submitting the application to the NRC under Section 103 of the Atomic Energy Act of 1954, as amended, (the Act) to construct and operate a nuclear plant to be located on the existing North Anna site in Louisa County, Virginia.

- NAPS SUP 1.1-4

The applicant incorporates by reference the North Anna ESPA SSAR Section 2.1.1.1 to provide a description of the plant location.

- NAPS SUP 1.1-5

The applicant provides the anticipated schedule for the construction and operation of the North Anna 3 plant.

Conceptual Design Information:

- NAPS CDI

The applicant indicates that FSAR Figure 2.1-201 provides the orientation of the principal North Anna 3 plant structures.

Section 1.2 – General Plant Description

Section 1.2 of the North Anna 3 FSAR, Revision 8, incorporates by reference Section 1.2 of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.2, the applicant provides the following:

Departure Not Requiring NRC Approval:

- NAPS DEP 11.4-1

The applicant states that the radwaste building is configured to accommodate at least 10 years of packaged Class B and Class C waste and approximately 3 months of packaged Class A waste based on routine operations and anticipated operational occurrences. The applicant also provides the revised radwaste building elevation plans in Figures 1.2-21R to 1.2-25R, which contain security-related information and are therefore withheld under 10 CFR 2.390. This departure is discussed and reviewed in Chapter 11 of this SER.

Supplemental Information:

- STD SUP 1.2-1

The applicant provides a general statement regarding modular construction techniques to be used during ESBWR construction.

Conceptual Design Information:

- STD and NAPS CDI

The applicant provides CDI regarding the general plant descriptions of the main turbine, main condenser, plant service water system, hydrogen water chemistry system, zinc injection system, and freeze protection as well as other building structures. This information is discussed in the applicable chapter (i.e., Chapters 2 through 20) of this SER.

Section 1.3 – Comparison Tables

Section 1.3 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.3, "Comparison Tables", of the ESBWR DCD, Revision 10. In addition, in COL FSAR Section 1.3 the applicant provides the following:

Departure Requiring NRC Approval:

- NAPS DEP 3.7-1

The applicant has provided information for a departure regarding ground response spectra for seismic structural loads and floor response spectra in Table 1.3-4R "Comparison of Structural Design Characteristics." This departure is discussed and reviewed in Chapter 3 and Section 3.7 of this SER.

COL Item:

- NAPS COL 1.3-1-A

The applicant states that there are no updates to DCD Tier 2, Table 1.3-1 based on unit-specific information.

Section 1.4 – Identification of Agents and Contractors

Section 1.4 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.4, "Identification of Agents and Contractors", of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.4, the applicant provides the following:

Supplemental Information:

- NAPS SUP 1.4-1

The applicant provides additional information to identify Dominion (the applicant) as the licensee and operator of North Anna 3. Dominion also identifies GE-Hitachi Nuclear Energy Americas, LLC (GEH) as the primary contractor for the design of the unit, preparation of the COLA, and will support deployment of the ESBWR design on the North Anna 3 site. Dominion has identified Fluor Corporation (Flour) as the primary contractor for site engineering, along with construction of the turbine island and the nuclear island. Other contractors are listed for the environmental, geotechnical, and seismic hazard analysis support.

Section 1.5 Requirements for Further Technical Information

Section 1.5 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.5 of the ESBWR DCD, Revision 10.

Supplemental Information:

- CWR SUP 1.5-1

The applicant provides information regarding Post-Fukushima Near-Term Task Force Recommendations.

Section 1.6 – Material Incorporated by Reference

Section 1.6 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.6, "Material Incorporated By Reference," of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.6, the applicant provides the following:

Supplemental Information:

- NAPS SUP 1.6-1

Table 1.6-201 lists technical reports (TRs) not included in DCD Section 1.6 that are incorporated by reference in whole or in part into the North Anna 3 FSAR.

Section 1.7 – Drawings and Other Detailed Information

Section 1.7 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.7 of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.7, the applicant provides the following:

Departures Requiring NRC Approval:

- NAPS DEP 8.1-1

The applicant has provided information for a departure regarding the electrical power distribution system in FSAR Table 1.7-201. This departure is discussed and reviewed in Chapter 8 of this SER.

- NAPS DEP 12.3-1

The applicant has provided information for a departure regarding the liquid radwaste effluent discharge piping flow path in FSAR Table 1.7-202. This departure is discussed and reviewed in Chapters 11 and 12 of this SER.

Departure Not Requiring NRC Approval:

- NAPS DEP 11.4-1

The applicant has provided information for a departure regarding the long-term, temporary storage of Class B and C low-level radioactive waste in FSAR Table 1.7-202. This departure is discussed and reviewed in Chapter 11 of this SER.

Supplemental Information:

- NAPS SUP 1.7-1

FSAR Table 1.7-201 supplements DCD Table 1.7-2 for those portions of the electrical system configuration drawings outside the scope of the DCD. FSAR Table 1.7-202 supplements DCD Table 1.7-3 for those portions of the mechanical system configuration drawings outside the scope of the DCD. In addition, COL Item 1.7-1-H was deleted from the referenced DCD.

Section 1.8 – Interfaces with Standard Design and Early Site Permits

Section 1.8 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.8, “Interfaces with Standard Design,” of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.8, the applicant provides the following:

Supplemental Information:

- NAPS SUP 1.8-1

The applicant states that information in FSAR Chapter 2 demonstrates that the site characteristics fall within the ESBWR site parameters specified in the referenced certified design. The applicant also states that FSAR Chapter 2 provides information that the facility falls within the North Anna site characteristics and bounding design parameters for the referenced ESP.

- NAPS SUP 1.8-2

The applicant states that Section 1.10 identifies specific FSAR sections that address the COL information items from the referenced certified design, and the COL action items and Permit Conditions from the ESP.

- NAPS SUP 1.8-3

The applicant has provided FSAR Table 1.8-201 that identifies the site-specific departures taken from the referenced certified design. These departures are fully described in Part 7 of the COLA and listed in FSAR Table 1.8-201. These departures are evaluated in the respective Chapters of this SER.

- NAPS SUP 1.8-4

The applicant has provided FSAR Table 1.8-202 which identifies the requested variances from the referenced ESP. These variances are fully described in Part 7 of the COLA and evaluated in the respective Chapters of this SER.

- NAPS SUP 1.8-5

The applicant includes FSAR Table 1.8-203, which identifies systems that either adopt the CDI in the DCD as the actual system design information or replace the CDI in the DCD with site-specific design information. Information adopted from the DCD is evaluated by the NRC in NUREG–1966. Information replaced by site-specific design information is evaluated in the applicable chapters of this SER (i.e., Chapters 2 through 20).

- NAPS SUP 1.8-6

The FSAR states that the applicant reviewed site- and plant-specific information that included North Anna site meteorological data, site-specific population distribution, and plant-specific design information that replaced CDI described in the DCD with respect to the DC probabilistic risk assessment (PRA). FSAR Section 19.5 documents the conclusion that there is no significant change from the certified design PRA. The staff's evaluation is in Section 19.5 of this SER.

- NAPS SUP 1.8-7

The applicant states that there are no current plans for an independent North Anna 3 spent ISFSI.
Conceptual Design Information:

- STD CDI

The applicant states that DCD Tier 1 identifies significant interface requirements for those systems that are beyond the scope of the DCD.

Section 1.9 – Conformance with Standard Review Plan and Applicability of Codes and Standards

Section 1.9 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.9, "Conformance with Standard Review Plan and Applicability of Codes and Standards," of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.9, the applicant provides the following:

COL Item:

- NAPS COL 1.9-3-A

The applicant adds three FSAR tables. Table 1.9-201 evaluates conformance with the SRP sections and the Branch Technical Positions that were in effect 6 months before submitting the COLA. Table 1.9-202 evaluates conformance with Division 1, 4, 5, and 8 RGs in effect 6 months before submittal of the COLA. Table 1.9-203 evaluates conformance with FSAR content information and format guidance in RG 1.206.

Supplemental Information:

- NAPS SUP 1.9-1

The applicant provides FSAR Table 1.9-204, which identifies the industrial codes and standards applicable to those portions of the North Anna 3 design that are beyond the scope of the DCD and to the operational aspects of the facility.

- NAPS SUP 1.9-2

The applicant provides FSAR Table 1.9-205, which addresses operational experience information as described in the applicable NUREG and NUREG/CR reports, for those portions of the North Anna 3 design and operation that are beyond the scope of the ESBWR DCD. The comment column of Table 1.9-205 includes a reference to the applicable FSAR section that provides further discussion of the operational experience.

Departure Not Requiring NRC Approval:

- NAPS DEP 8.1-2

The applicant has provided information for a departure regarding their switchyard and lightning protection system as it relates to RG 1.204, "Guidelines for Lightning Protection of Nuclear Power Plants." This departure is discussed in Chapter 8 of this SER.

- NAPS DEP 11.4-1

The applicant has provided information for a departure regarding the long-term, temporary storage of Class B and C low-level radioactive waste in FSAR Table 1.9-11R. This departure is discussed in Chapter 11 of this SER.

Section 1.10 – Summary of COL Items

Section 1.10 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.10, "Summary of COL Items," of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.10, the applicant provides the following:

Supplemental Information:

- NAPS SUP 1.10-1

The applicant includes FSAR Table 1.10-201, which lists the FSAR locations that address the individual COL items from the DCD and FSAR Table 1.10-202 which lists the FSAR locations that address the individual COL items and permit conditions from the ESP.

Section 1.11 – Technical Resolutions of Task Action Plan Items, New Generic Issues, New Generic Safety Issues, and Chernobyl Issues

Section 1.11 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 1.11, “Technical Resolutions of Task Action Plan Items, New Generic Issues, New Generic Safety Issues and Chernobyl Issues,” of the ESBWR DCD, Revision 10.

In addition, in COL FSAR Section 1.11, the applicant provides the following:

COL Items:

- NAPS COL 1.11-1-A

The applicant provides FSAR Table 1.11-201, which supplements DCD Table 1.11-1 to address the site-specific aspects of activities required by the action plan that the COL applicant must complete (i.e., Note 2) and environmental issues that are outside the scope of the DCD (i.e., Note 7). The staff’s technical evaluations of these topics are addressed in the environmental report in the staff’s Supplemental Environmental Impact Statement in NUREG–1917 and the relevant sections of this SER.

Supplemental Information:

- NAPS SUP 1.11-1 and NAPS SUP 1.11-2

The applicant adds FSAR Table 1.11-202, which supplements DCD Table 1.11-1 with references to FSAR locations that provide additional information on specific issues. In addition, the applicant adds references to new generic issues from NUREG–0933, “A Prioritization of Generic Safety Issues,” through Supplement 34.

Section 1.12 – Impact of Construction Activities on Units 1 and 2

The applicant includes a supplemental information section not provided in the referenced DCD, which addresses an evaluation of the impacts from North Anna 3 construction activities on North Anna 1 and 2.

In addition, in COL FSAR Section 1.12, the applicant provides the following:

COL Item:

- NAPS ESP COL 2.4-1

The applicant has provided information to address ESP COL Item 2.4-1. This item requires the COL applicant to provide for NRC review the layout of intake and discharge tunnels and the construction techniques to be used before construction activities begin. The staff reviewed this information in Chapter 2 of this SER.

Supplemental Information:

- NAPS SUP 1.12-1

The applicant provides FSAR Section 1.12, which summarizes the applicant's evaluation of the potential impact from the construction of North Anna 3 on North Anna 1 and 2 SSCs important to safety. Section 1.12 also describes the managerial and administrative controls used to provide assurance that North Anna 1 and 2 limiting conditions for operation (LCOs) will not be exceeded as a result of North Anna 3 construction activities. This evaluation involved the following sequential steps:

- Identification of potential construction activity hazards
- Identification of SSCs important to safety
- Identification of LCOs
- Identification of impacted SSCs and LCOs
- Identification of applicable managerial and administrative controls

Appendices 1A – 1D

The applicant has provided four appendices which contain information that the staff has identified and evaluated in Section 1.4.4 below.

1.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, NUREG-1811, and NUREG–1917. In addition, the relevant requirements of the Commission regulations for the information in FSAR Chapter 1, and the associated acceptance criteria, are in SRP Section 1.0.

The applicable regulatory requirements are as follows:

- 10 CFR 50.43(e), as it relates to requirements for approving applications for a DC, COL, manufacturing license, or operating license that proposes nuclear reactor designs that differ significantly from light-water reactor designs licensed before 1997 or that use simplified, inherent, passive, or other innovative means to accomplish their safety functions.

- 10 CFR 52.77 and 10 CFR 52.79, as they relate to general introductory matters.

- 10 CFR 52.79(a)(17), as it relates to compliance with technically relevant positions of the Three Mile Island (TMI) requirements.

- 10 CFR 52.79(a)(20), as it relates to proposed technical resolutions of those unresolved safety issues and medium- and high-priority generic safety issues that are identified in the current version of NUREG–0933 on the date up to 6 months before the docket date of the application and that are technically relevant to the design.

- 10 CFR 52.79(a)(31), as it relates to nuclear power plants that will be operated on multiunit sites and to an evaluation of potential hazards to the SSCs important to safety of operating units resulting from construction activities; in addition to providing a description of the managerial and administrative controls to be used to provide assurance that the LCO will not be exceeded as a result of construction activities at the multiunit sites.

- 10 CFR 52.79(a)(37), as it relates to the information necessary to demonstrate how operating experience insights are incorporated into the plant design.

- 10 CFR 52.79(a)(41), as it relates to an evaluation of the application against the applicable NRC review guidance in effect 6 months before the docket date of the application.

- 10 CFR 52.79(d)(2), which requires that for a COL referencing a standard DC, the FSAR must demonstrate that the interface requirements established for the design under 10 CFR 52.47, "Contents of applications; technical information," have been met.

- 10 CFR 52.97(a)(1)(iv), which states that an applicant is technically and financially qualified to engage in the activities authorized.

The related acceptance criteria are as follows:

- There are no specific SRP acceptance criteria associated with the general requirements.

- For regulatory considerations, acceptance is based on addressing the regulatory requirements discussed in FSAR Chapter 1 or in the FSAR section referenced in Chapter 1. The SRP acceptance criteria associated with the referenced section will be reviewed within the context of that review.

- For the performance of new safety features, the FSAR information should be sufficient to provide reasonable assurance that (1) the new safety features will perform as predicted in the applicant's FSAR; (2) the effects of system interactions are acceptable; and (3) the applicant's data are sufficient to validate analytical codes. The design qualification testing requirements may be met with either separate effects or integral system tests; prototype tests; or a combination of tests, analyses, and operating experience.

- For conformance with regulatory criteria, RG 1.206 states that an applicant should perform an evaluation for conformance with the RGs that were in effect 6 months before the submittal of the COLA.

1.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Chapter 1 of the certified ESBWR DCD. The staff also reviewed Chapter 1 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic[2]. The staff's review confirms that information in the application and information incorporated by reference address the required information related to this chapter.

The staff notes that the information in the following sections of North Anna 3 FSAR Chapter 1 is for general informational purposes, and no specific technical or regulatory findings are made within the review scope of SER Chapter 1. The applicant's information in these sections are used as reference material to support the staff's technical reviews in Chapters 2 through 20 of this SER.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

<u>Section 1.1 – Introduction</u>

In this section, the applicant briefly discusses the principal aspects of the overall application. There are no specific SRP acceptance criteria related to the general information in Section 1.1 and no specific regulatory findings. The applicant's information gives the reader a basic overview of the nuclear power plant and the construct of the North Anna 3 FSAR itself. The applicant also identifies systems and structures outside the scope of the ESBWR standard plant that are discussed in the applicable chapter (i.e., Chapters 2 through 20) of this SER. The staff finds that the applicant's information provided in FSAR Section 1.1 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.1.

<u>Section 1.2 – General Plant Description</u>

In this section, the applicant summarizes the principal characteristics of the site and describes the facility. There are no specific SRP acceptance criteria related to the general information in FSAR Section 1.2 and no specific regulatory findings. The applicant's information gives the reader a general plant description. The staff finds that the applicant's information provided in FSAR Section 1.2 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.2.

<u>*Departure Not Requiring NRC Approval:*</u>

- NAPS DEP 11.4-1

The staff notes the following for Departure NAPS DEP 11.4-1 identified in this section:

The applicant states that the radwaste building is configured to accommodate at least 10 years of packaged Class B and Class C waste and approximately 3 months of packaged Class A

[2] See *"Finality of Referenced NRC Approvals"* in this SER Section 1.2.2 for a discussion on the staff's review related to verification of the scope of information to be included in a COL application that references a design certification.

waste based on routine operations and anticipated operational occurrences. The applicant also provides the revised radwaste building elevation plans in Figures 1.2-21R to 1.2-25R. This departure is discussed in Chapter 11 of this SER.

Conceptual Design Information:

- STD and NAPS CDI

The applicant provides CDI regarding the general plant descriptions of the main turbine, main condenser, plant service water system, hydrogen water chemistry system, zinc injection system, and freeze protection as well as other building structures. The CDI information presented in this section is discussed in the applicable chapter (i.e., Chapters 2 through 20) of this SER.

Section 1.3 – Comparison Table

In this section, the applicant provides information regarding a comparison with other facilities of a similar design and comparable power level. There are no specific SRP acceptance criteria related to the general information in Section 1.3 and no specific regulatory findings. The staff finds that the applicant's information provided in FSAR Section 1.3 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.3.

Departure Requiring NRC Approval:

- NAPS DEP 3.7-1

The applicant has provided information for a departure regarding ground response spectra for seismic structural loads and floor response spectra in Table 1.3-4R "Comparison of Structural Design Characteristics." This departure is discussed and reviewed in Section 3.7 of this SER.

COL Item:

- NAPS COL 1.3-1-A

The applicant provided North Anna 3 COL 1.3-1-A, which states that there are no updates to DCD Table 1.3-1 based on unit-specific information. The staff finds that the applicant's information satisfies COL Item 1.3-1-A, and the information in FSAR Section 1.3 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.3.

Section 1.4 – Identification of Agents and Contractors

This section identifies primary agents or contractors for the design, construction, and operation of the nuclear power plant. SRP Section 1.4 does not identify specific acceptance criteria related to the general information in Section 1.4 or specific regulatory findings. The quality assurance measure applied to these agents or contractors are specified in Chapter 17 of the FSAR. The staff finds that the applicant's information provided in FSAR Section 1.4 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.4.

Supplemental Information:

- NAPS SUP 1.4-1

The staff notes the following for NAPS SUP 1.4-1 identified in this section:

In accordance with RG 1.206, Regulatory Position C.I.1.4, "Identification of Agents and Contractors," the applicant's supplemental information identifies the primary agents for the design, construction, and operation of the proposed facility with the exception of contractors for the site engineering and for the construction of the Turbine Island and nuclear island. In addition, the applicant delineates the division of responsibility among the contractors cited in the FSAR.

North Anna 3 FSAR Chapter 17, "Quality Assurance [QA]," and the North Anna 3 Quality Assurance Program Description (QAPD) describe the Dominion QA Program and QA controls for contractors performing safety-related work activities associated with the North Anna 3 COLA. The staff's evaluation of Chapter 17 of the North Anna 3 FSAR is in Chapter 17 of this SER.

Section 1.5 – Requirements for Further Technical Information

In this section, an applicant who does not reference a certified design should provide information to demonstrate the performance of new safety features. The North Anna 3 application references the ESBWR DCD application. There are no specific SRP acceptance criteria related to the general information in Section 1.5 and no specific regulatory findings. The applicant incorporates by reference Section 1.5 of the ESBWR DCD. Per RG 1.206, Regulatory Position C.I.1.5, only an applicant who does not reference a certified design would need to provide additional information for this section. The staff finds that the applicant's information provided in FSAR Section 1.5 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.5.

Supplemental Information:

- CWR SUP 1.5-1

The applicant provides summary information regarding Post-Fukishima Near-Term Task Force Recommendations with respect to the ESBWR design and North Anna 3. The staff's evaluation of Fukishima Recommendations 2.1, 4.2, 7.1, and 9.3 for the North Anna 3 COLA are provided in Chapter 20 of the SER as stated in Section 1.1, Summary of Application, above.

Section 1.6 – Material Incorporated by Reference

In this section, an applicant provides a tabulation of all TRs that are incorporated by reference as part of the application. There are no specific SRP acceptance criteria related to the general information in Section 1.6 and no specific regulatory findings. The staff finds that the applicant's information provided in FSAR Section 1.6 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.6.

COL Item:

- NAPS SUP 1.6-1

In site-specific COL Item NAPS SUP 1.6-1, the applicant includes FSAR Table 1.6-201 which lists the TRs that are incorporated by reference in whole or in part into the FSAR that were not included in ESBWR DCD, Section 1.6. The incorporation of these TRs are discussed accordingly within the relevant Sections of this SER.

Section 1.7 – Drawings and Other Detailed Information

In this section, the applicant provides a tabulation of all instrument and control functional diagrams cross-referenced to the related application sections. There are no specific SRP acceptance criteria related to the general information in Section 1.7 and no specific regulatory findings. The staff finds that the applicant's information provided in FSAR Section 1.7 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.7.

Departures Requiring NRC Approval:

- NAPS DEP 8.1-1

The applicant has provided information for a departure regarding the electrical power distribution system in FSAR Table 1.7-201. This departure is discussed and reviewed in Chapter 8 of this SER.

- NAPS DEP 12.3-1

The applicant has provided information for a departure regarding the liquid radwaste effluent discharge piping flow path in FSAR Table 1.7-202. This departure is discussed and reviewed in Chapters 11 and 12 of this SER.

Departure Not Requiring NRC Approval:

- NAPS DEP 11.4-1

The applicant has provided information for a departure regarding the long-term, temporary storage of Class B and C low-level radioactive waste in FSAR Table 1.7-202. This departure is discussed in Chapter 11 of this SER.

Supplemental Information:

- NAPS SUP 1.7-1

NAPS SUP 1.7-1, includes FSAR Tables 1.7-201 and 1.7-202, which list the supplemental drawings of electrical system and mechanical system configurations, in addition to the information in ESBWR DCD, Tables 1.7-2 and 1.7-3.

Section 1.8 – Interfaces with Standard Design and Early Site Permits

In this section, an applicant who references a certified design has to satisfy interface requirements established for the certified design. There are no specific SRP acceptance criteria related to the general information in Section 1.8 and no specific regulatory findings. The staff finds that the applicant's information provided presented in FSAR Section 1.8 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.8.

The applicant provides the following supplemental information and CDI:

Supplemental Information:

- NAPS SUP 1.8-1

The applicant states that FSAR Chapter 2 provides information demonstrating that site characteristics fall within the ESBWR site parameters specified in the referenced certified design. The review of the site characteristics is in Chapter 2 of this SER.

- NAPS SUP 1.8-2

The applicant states that FSAR Section 1.10 identifies specific sections that address the COL information items from the referenced certified design and the COL action items. The review of the COL items listed in Table 1.10-201 is in the applicable chapter (i.e., Chapters 1 through 19) of this SER.

- NAPS SUP 1.8-3

The applicant identifies site-specific departures from the referenced certified design, which are fully described in Part 7 of the COLA. The applicant provides Table 1.8-201 to identify FSAR sections affected by the requested departures listed in Part 7 of the COLA. These departures are evaluated in their respective Chapters throughout this SER.

- NAPS SUP 1.8-4

The applicant has provided FSAR Table 1.8-202 which identifies the requested variances from the referenced ESP. These variances are fully described in Part 7 of the COLA and evaluated in their respective Chapters throughout this SER.

- NAPS SUP 1.8-5

The applicant provides FSAR Table 1.8-203, which identifies systems that either adopt the CDI in the DCD as the actual system design information or replace the CDI in the DCD with site-specific design information. The table also includes cross references to FSAR sections that address the CDI. The DCD CDI that the applicant replaced with site-specific design information is reviewed in the applicable chapters of this SER (i.e., Chapters 1 through 19).

- NAPS SUP 1.8-6

As stated above, the applicant's review of site- and plant-specific information is in FSAR Section 19.5. The staff's review of the applicant's PRA conclusion is evaluated in Section 19.5 of this SER.

- NAPS SUP 1.8-7

As stated above, the applicant does not provide information pertaining to the ISFSI because no North Anna 3 ISFSI is currently planned. Therefore, the staff is not reviewing information associated with this supplemental information item.

Conceptual Design Information:

- STD CDI

The applicant states that DCD Tier 1 identifies significant interface requirements for those systems that are beyond the scope of the DCD. As indicated above in the evaluation of Supplemental Information NAPS SUP 1.8-5, the system design information is in FSAR Table 1.8-203 and evaluated in the applicable chapters of this SER.

Section 1.9 – Conformance with Standard Review Plan and Applicability of Codes and Standards

This FSAR section provides the information required by 10 CFR 52.47(a)(9) showing conformance with the SRP and applicable codes and standards. The section summarizes deviations from each SRP section and regulatory criteria (i.e., Division 1, 4, 5, and 8 RGs; RG 1.206; and industrial codes and standards). In addition, this section provides information on the applicability of operational experience. The staff finds that the applicant's information provided in FSAR Section 1.9 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.9.

COL Item:

- NAPS COL 1.9-3-A

The applicant provides additional information in FSAR Tables 1.9-201 through 1.9-203 that evaluate the conformance of technical information in the North Anna 3 FSAR with the SRP and applicable regulatory criteria. The staff evaluated the information in Section 1.9 as part of the technical evaluations in Chapters 2 through 20 of this SER, as needed.

Supplemental Information:

- NAPS SUP 1.9-1

As stated earlier, the applicant provides additional information in FSAR Table 1.9-204 that lists the industrial codes and standards applicable to those portions of the North Anna 3 design that are beyond the scope of the ESBWR DCD and are applicable to the operational aspects of the facility. This table also identifies additional codes and standards referenced in various chapters of the COLA. The staff's technical evaluations of the additional industrial codes and standards are in the relevant chapters of this SER.

- NAPS SUP 1.9-2

In FSAR Table 1.9-205, the applicant provides additional information on the operational experience applicable to North Anna 3. The staff finds that the applicant has provided sufficient information to address conformance with the operational experience information, as described in applicable NUREG reports, for those portions of the North Anna 3 design and operation that are beyond the scope of the ESBWR DCD. The staff's technical evaluations of the applicable operational experience are in the relevant chapters of this SER.

Departures Not Requiring NRC Approval:

- NAPS DEP 8.1-2

The applicant has provided information for a departure regarding their switchyard and lightning protection system as it relates to RG 1.204. This departure is discussed in Chapter 8 of this SER.

- NAPS DEP 11.4-1

The applicant has provided information for a departure regarding the long-term, temporary storage of Class B and C low-level radioactive waste in FSAR Table 1.9-11R. This departure is discussed in Chapter 11 of this SER.

Section 1.10 – Summary of COL Items

The applicant's supplemental information in this section specifies NAPS SUP 1.10-1 which provides FSAR Table 1.10-201 and Table 1.10-202. These tables list the COL items from both the DCD and ESP along with the permit conditions from the ESP. The ESBWR DCD and the North Anna ESP describe the information for each COL item that the COL applicant needs to provide in the application that include site-specific information; information related to operational program descriptions; and other required information to support the construction and operation of an ESBWR standard design at the North Anna 3 site. FSAR Table 1.10-201 lists the COL items and the proper references to the FSAR sections that describe each item. The applicant's supplemental information also includes FSAR Table 1.10-202 which identifies where the COL items and permit conditions identified in the ESP are addressed in the FSAR. The COL items and permit conditions listed in both of these tables are reviewed in the applicable chapter (i.e., Chapter 2 through Chapter 19) of this SER. There are no specific SRP acceptance criteria related to the general information in Section 1.10 and no specific regulatory findings. The staff finds that the applicant's information provided in FSAR Section 1.10 is acceptable within the review scope of Chapter 1.

Section 1.11 – Technical Resolutions of Task Action Plan Items, New Generic Issues, New Generic Safety Issues, and Chernobyl Issues

In accordance with 10 CFR 52.79(a)(20), this FSAR section provides technical resolutions of unresolved safety issues (USIs); new generic issues (GI); medium- and high-priority generic safety issues (GSIs); human factor issues (HFIs); and Chernobyl issues identified in NUREG–0933 and its supplements.

COL Item:

- NAPS COL 1.11-1-A

In FSAR Section 1.11.1, the applicant provides Table 1.11-201 to supplement DCD Table 1.11-1 (Notes 2 and 7) and to address the site-specific aspects of activities required by the action plan that the COL applicant must complete (i.e., Note 2) and environmental issues that are outside the scope of the DCD (i.e., Note 7).

ESBWR DCD, Table 1.11-1 identifies Task Action Items (i.e., GI and USI) A-33, B-1, B-28, B-37 through B-43, and C-16 and the two new GIs: 184 requiring site-specific information and 199 which the applicant has included information in FSAR Section 3.7.1. These issues are mainly associated with the site-specific environmental concerns addressed in the site environmental report. The applicant provides the required information in Table 1.11-201 with appropriate references to various sections in Parts 2, 3, and 4 of the COLA. The staff's technical evaluations of these topics are addressed in the environmental reports of NUREG–1811 and NUREG–1917.

Supplemental Information:

- NAPS SUP 1.11-1 and NAPS SUP 1.11-2

In Table 1.11-202, the applicant provides supplemental information to DCD Table 1-11 on the issues in the TMI Action Plan that relate to staffing, qualifications, quality assurance, post-accident sampling, in-plant radiation monitoring, and shift staff HFI. The table identifies the FSAR sections where each issue is discussed. The staff's evaluations of these issues are in Chapters 12, 13, and 17 of this SER. In addition, the applicant provided references to new GIs 201, 202, and 203 to Table 1.11-201 as identified in NUREG–0933 through Supplement 24, December 2011.

The staff finds that the applicant's COL Item NAPS COL 1.11-1-A, and supplemental information NAPS SUP 1.11-1 and NAPS SUP 1.11-2 in FSAR Section 1.11 are acceptable and consistent with the guidance in the SRP and NUREG–0933 and the requirements of 10 CFR 52.79(a)(20). The staff finds that the applicant's information provided in FSAR Section 1.11 is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.9.3.

Section 1.12 – Impact of Construction Activities on Units 1 and 2

In this section of the SER, the applicant evaluates the potential hazards to the SSCs important to safety of the operating North Anna 1 and 2 that would result from future construction activities of North Anna 3. The applicant also describes the managerial and administrative controls to be used to provide assurance that the LCO will not be exceeded as a result of construction activities, in accordance with 10 CFR 52.79(a)(31). This section was pending the staff's review and previously identified as Open Item 1-2. The review has been completed and is presented below. This Open item is now considered closed.

COL Item:

- NAPS ESP COL 2.4-1

The applicant has provided information to address ESP COL Item 2.4-1. This item requires the COL applicant to provide for NRC review the layout of intake and discharge tunnels and the construction techniques to be used before construction activities begin. The applicant has provided a statement that they will provide this information for NRC review at least 60 days before the commencement of construction. The staff reviewed this information in Chapter 2, Section 2.4 of this SER and found that since the ESBWR is based on a passive-cooling design, that neither Lake Anna nor the piping to and from Lake Anna provide safety functions and, therefore, ESP COL Action Item 2.4-1 is no longer required. With respect to North Anna 3 construction activities affecting Units 1 and 2, the staff notes below that other mechanisms will be used by the licensee of the operating Units 1 and 2 to address these considerations and to ensure that potential impacts from the construction of a new North Anna 3 are precluded and/or mitigated.

Supplemental Information:

- NAPS SUP 1.12-1

The applicant provides FSAR Section 1.12 as supplemental information. Based on the Interim Staff Guidance (ISG) COL ISG-022, "Interim Staff Guidance on Impact of Construction (under a Combined License) of New Nuclear Power Plants Units on Operating Units at Multi-Unit Sites," the applicant should address the requirements of 10 CFR 52.79(a)(31) with respect to ISG-022.

The requirements in 10 CFR 52.79(a)(31) can be viewed as having two subparts:

1. The COL applicant must evaluate the potential hazards from constructing new plants on SSCs important to safety for existing operating plants located at the North Anna site (i.e., North Anna 1 and 2).

2. The COL applicant must evaluate the potential hazards from constructing new plants on SSCs important to safety for newly constructed plants that begin operation at the North Anna site. This subpart will not be applicable to North Anna 3.

The applicant has provided a construction impact evaluation plan that contains the following six elements discussed in the ISG:

- A discussion of the construction activity identification process and the impact evaluation criteria used to evaluate the construction activities that may pose potential hazards to the SSCs important to safety for operating unit(s).

- A table of those construction activities and the potential hazards that are identified using that construction impact evaluation plan, the SSCs important to safety for the operating unit potentially impacted by the construction activity, and proposed mitigation methods.

- Identification of the managerial and administrative controls, such as proposed license conditions that may involve construction schedule constraints or other restrictions on construction activities, that are credited to manage the safety/security interface and to preclude and/or mitigate the impacts of potential construction hazards to the SSCs important to safety for the operating unit(s).

- A discussion of the process for communications and interactions planned and credited between the construction organization and the operations organization to ensure appropriate coordination and authorization of construction activities and implementation of the prevention or mitigation activities as necessary.

- A memorandum of understanding or agreement (MOU or MOA) between the COL applicant and the operating unit(s) licensee as a mechanism for communications, interactions, and coordination to manage the impact of the construction activities.

- An implementation schedule corresponding to construction tasks or milestones to ensure the plan is reviewed on a recurring basis and maintained current as construction progresses.

In NAPS SUP 1.12-1, the applicant has provided the following FSAR information with respect to each of the above six elements:

- A discussion of the construction activity identification process and the impact evaluation criteria used to evaluate the construction activities that may pose potential hazards to the SSCs important to safety for operating unit(s).

The process and criteria used to evaluate potential North Anna 3 construction hazards associated with North Anna 1 and 2 SSCs important to safety are discussed in FSAR Section 1.12. Section 1.12.1 specifically outlines a series of sequential steps that are discussed in further detail in FSAR Sections 1.12.2 through 1.12.6. These steps include the identification of potential construction activity hazards, SSCs important to safety, LCOs, impacted SSCs and LCOs, and applicable managerial and administrative controls.

- A table of those construction activities and the potential hazards that are identified using that construction impact evaluation plan, the SSCs important to safety for the operating unit potentially impacted by the construction activity, and proposed mitigation methods.

Using the identification and evaluation process described above, the applicant developed FSAR Table 1.12-201, “Potential Hazards to Units 1 and 2 from Unit 3 Construction Activities,” which delineates the North Anna 3 construction activities; identifies the potential hazards using this evaluation; and describes the potentially impacted Unit 1 and 2. The applicant also developed FSAR Table 1.12-202, “Potential Consequences to Units 1 and 2 Due to Potential Hazards Resulting from Unit 3 Construction Activities,” which describes the potential hazards and consequences specifically related to Units 1 and 2 SSCs. In addition, the applicant developed FSAR Table 1.12-203, “Managerial and Administrative Controls for Unit 3 Construction Activity Hazards,” which delineates the proposed mitigation methods.

- Identification of the managerial and administrative controls such as the proposed license conditions that may involve construction schedule constraints or other restrictions on construction activities that are credited to manage the safety/security interface and to preclude and/or mitigate the impacts of potential construction hazards to the SSCs important to safety for the operating unit(s).

The managerial and administrative controls to manage the safety/security interface and to mitigate the impacts of potential North Anna 3 construction hazards to the Units 1 and 2 SSCs important to safety and security are discussed in Section 1.12.6, “Managerial and Administrative Controls,” and in FSAR Table 1.12-203, “Managerial and Administrative Controls for North Anna 3 Construction Activity Hazards.” FSAR Section 1.12.6 also states that there are additional controls established during construction as described and addressed in FSAR Section 13AA.1.9, “Management and Review of Construction Activities.”

- A discussion of the process for communications and interactions planned and credited between the construction organization and the operations organization to ensure appropriate coordination and authorization of construction activities and implementation of the prevention or mitigation activities as necessary.

FSAR Table 1.12-203 provides the managerial and administrative controls for preventative and mitigation activities that outline the planned interactions between Units 1 and 2 and North Anna 3. In addition, FSAR Subsection 13.AA.1.9 includes a description of the process for Units 1 and 2 and North Anna 3 communications and interactions to ensure organizational coordination and authorization requirements for construction activities with potential Units 1 and 2 impacts, as well as implementation plans for the mitigation controls identified.

- A memorandum of understanding or agreement (MOU or MOA) between the COL applicant and the operating unit(s) licensee as a mechanism for communications, interactions, and coordination to manage the impact of the construction activities.

The North Anna 3 COL applicant and the Units 1 and 2 operating licensee are the same entity. Therefore, an MOU or MOA is not considered necessary.

- An implementation schedule corresponding to construction tasks or milestones to ensure the plan is reviewed on a recurring basis and maintained current as construction progresses.

FSAR Section 1.12.6 describes the identification of specific hazards, impacted SSCs, and managerial and administrative controls including safety/security interfaces to be developed and implemented as work progresses on the site. FSAR Table 1.12-201 describes the work progression via identification of construction activities. FSAR Subsection 13.AA.1.9 states that assessments will be performed to facilitate an implementation schedule for the administrative and managerial controls that correspond with the scheduled construction activities. The applicant also describes periodic assessments involving both Units 1 and 2 and North Anna 3 organizations to identify Units 1 and 2 SSCs that could be reasonably expected to be impacted by scheduled construction activities.

In conclusion, based on a review of the information discussed above, the staff finds that the applicant’s Supplemental Information NAPS SUP 1.12-1 in FSAR Section 1.12 is acceptable and consistent with the six program elements of 10 CFR 52.79(a)(31) as expressed in COL ISG-022.

In addition, the staff notes that other mechanisms will be used by the licensee of the operating Units 1 and 2 to address these considerations and to ensure that potential impacts from the construction of a new North Anna 3 are precluded and/or mitigated. Examples include the 10 CFR 50.59 change process, the 10 CFR 50.65 risk assessment process, the 10 CFR 73.58

safety/security interface process, the technical specification change process, the EP change process, and the FSAR update process.

Appendix 1A – Response to TMI Matters

This FSAR Appendix supplements ESBWR DCD, Table 1A-1 with STD SUP 1A.1-1, which provides assessments of the TMI Action Plan items listed in 10 CFR 50.34(f). There are no specific SRP acceptance criteria related to the general information in FSAR Appendix 1A. The applicant provides supplemental information to DCD Table 1A-1 that addresses site-specific items related to construction, operations, and quality assurance. The detailed technical evaluations of these items are in Chapters 13 and 17 of this SER. The staff finds that the applicant's supplemental information provided in FSAR Appendix 1A is acceptable within the review scope of Chapter 1.

Appendix 1B – Plant Shielding To Provide Access to Areas and To Protect Safety Equipment for Post-Accident Operation [II.B.2]

The applicant has incorporated by reference this section of the DCD with no departures or supplements.

Appendix 1C – Industry Operating Experience

This FSAR Appendix supplements ESBWR Tables 1C-1 and 1C-2 with FSAR Tables 1C-201 and 1C-202. The DCD tables review industry operating experience issued in the Generic Letters (GL) and Bulletins (BL) that are potentially applicable to the ESBWR design or operation. These tables address GLs and BLs that were in effect/issued up to 6 months before a COLA submittal, and after the SRP revisions that are applicable to the FSAR. They also address GL 82-39 and Industry Experience (IE) BL 2005-02, which were identified in the DCD as the responsibility of the COL applicant. There are no specific SRP acceptance criteria related to the general information in Appendix 1C and no specific regulatory findings; however, the applicant provides its evaluation results in Table 1C-201. The applicant states that GL 82-39 is not applicable and is an administrative communication. The site has an approved procedure for handling SGI including how to mail such information to authorized recipients. IE Bulletin 2005-02 is discussed in the North Anna 3 COLA Part 5, Emergency Plan. The staff's evaluation of the Emergency Plan is in Section 13.3 of this SER.

Departure Not Requiring NRC Approval:

- NAPS DEP 11.4-1

In FSAR Table 1C-201, the applicant states under GL 81-38 that the radwaste building includes space for processing and storing low-level radioactive wastes. The radwaste building provides storage space for at least 10 years of packaged Class B and Class C wastes and approximately 3 months of packaged Class A waste. FSAR Section 11.4 provides additional information regarding the onsite storage of low-level radioactive wastes. This departure is discussed in Chapter 11 of this SER.

COL Items:

- STD COL 1C.1-1-A

In FSAR Table 1C-201, the applicant states that the site has an administrative procedure for handling SGI that meets the requirements of 10 CFR 73.21. This procedure also includes how to mail SGI to authorized recipients.

The staff finds that this response adequately addresses COL Item STD COL 1.C.1-1A, because the North Anna site has a procedure for handling SGI. However, the staff's review noted that ESBWR DCD Table 1C-1 conforms to the applicable GLs up to June 2006. The staff's review of the GLs in effect 6 months before the submittal date of the North Anna 3 COLA identified GL 2007-01, "Inaccessible or Underground Power Cable Failures that Disable Accident Mitigation Systems or Cause Plant Transients," as not listed in FSAR Table 1C-201. The staff's review finds that SER Section 8.2 evaluates the applicability of this GL to North Anna 3. According to SER Section 8.2, the applicant revised FSAR Section 17.6.4 to include the underground cable monitoring program regardless of the voltage. This FSAR section states that the condition monitoring underground or inaccessible cables is in the Maintenance Rule (MR) Program. The cable condition monitoring program incorporates lessons learned from industry operating experience (e.g., GL 2007-01); addresses regulatory guidance; and utilizes information from detailed design and procurement documents to determine the appropriate inspections, tests, and monitoring criteria for underground and inaccessible cables within the scope of the MR (10 CFR 50.65).

- STD COL 1C.1-2-A

In FSAR Table 1C-202, the applicant states that COLA Part 5 provides the North Anna 3 Emergency Plan. The staff finds that this response adequately addresses COL Item STD COL 1C.1-2-A. The staff's evaluation of the North Anna 3 Emergency Plan is in Section 13.3 of this SER.

STD SUP 1C-1 and NAPS SUP 1C-2, address GL 2007-01 and the staff has reviewed this information as discussed above.

In conclusion, the staff finds that the applicant's COL and supplemental information in FSAR Appendix 1.C is acceptable within the review scope of Chapter 1 and satisfies RG 1.206, Regulatory Position C.I.1.9.4.

Appendix 1D – Summary of Tier 2* Information

This FSAR Appendix supplements ESBWR DCD Table 1D-1 with NAPS SUP 1AA.1-1, which provides the incorporation of the North Anna ESP SSAR Chapter 1 for historical purposes. There are no specific SRP acceptance criteria related to the general information in FSAR Appendix 1D. The staff finds that the supplemental information submitted by the applicant is acceptable with the review scope of Chapter 1.

1.4.5 Post Combined License Activities

There are no post COL activities applicable to this Section.

1.4.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information; and no outstanding information is expected to be addressed in the COL FSAR related to these sections. Pursuant to 10 CFR 52.63(a)(5), all nuclear safety issues relating to these sections that were incorporated by reference have been resolved.

1.5 Additional Regulatory Requirements

1.5.1 Financial Qualifications

1.5.1.1 Introduction

By letter dated November 27, 2007, as supplemented on December 12, 2008, Virginia Electric and Power Company, doing business as Dominion, and Old Dominion Electric Cooperative (ODEC), submitted a COL application (Revision 1) for a proposed reactor at the North Anna site pursuant to 10 CFR Part 52, Subpart C, "Combined Licenses." In their submittal, Dominion and ODEC requested that the NRC issue a COL under Section 103 of the Act, for construction and operation of North Anna 3, which will be located in Louisa County, Virginia, approximately 40 miles north, northwest of Richmond.

Dominion and ODEC currently own NAPS, which includes the two existing nuclear units (Units 1 and 2) and an ISFSI at that site, as tenants in common, with respective undivided ownership interests of 88.4 and 11.6 percent. Dominion is the licensed operator of the existing facilities, with control of the North Anna site and authority to act as ODEC's agent. According to Revision 4 of the COLA, Dominion (hereafter, the applicant) has acquired sole title to the portion of the North Anna site on which North Anna 3 will be located, will own North Anna 3, and will construct and operate the proposed reactor.

The COLA incorporates by reference the GE-Hitachi Nuclear Energy Americas' ESBWR DCD, Revision 10. The codified version of the ESBWR DCR is contained in 10 CFR Part 52, Appendix E. The ESBWR DCR was published on October 15, 2014 (79 FR 61944) and is effective as of November 14, 2014. The ESBWR DCR references Revision 10 of the ESBWR DCD.

1.5.1.2 Regulatory Evaluation

The applicant's request for the NRC to issue a COL under Section 103 of the Act, as amended, for construction and operation of North Anna 3 is subject to, among other things, the requirements of the Act, as amended; Subpart C to 10 CFR Part 52; 10 CFR Part 50; and 10 CFR Part 140.

In its review, the staff used guidance in NUREG–1577, Revision 1, issued February 1999, to evaluate the financial qualifications of the applicant to construct, operate, and decommission the proposed facility.

In addressing foreign ownership, control, or domination (FOCD), the staff used guidance in the SRP, "Foreign Ownership, Control, or Domination of applicants for Reactor Licenses," dated

June 1999 (SRP on FOCD), to determine whether the applicant is owned, controlled, or dominated by an alien, a foreign corporation, or a foreign government. The NRC published the SRP on FOCD in the *Federal Register* on September 28, 1999 (64 FR 52357–52359).

The staff also used guidance in NUREG–1307, Revision 15, “Report on Waste Burial Charges: Changes in Decommissioning Waste Disposal Costs at Low-Level Waste Burial Facilities,” to independently validate the licensee’s calculation of the minimum funding needed for decommissioning.

This safety evaluation documents the staff’s review and analysis of financial qualifications, decommissioning funding assurance, FOCD, and nuclear insurance and indemnity. In addition, this safety evaluation contains proprietary information that is withheld from public disclosure per 10 CFR 2.390 as commercially sensitive. Therefore, there will be both public and non-public versions of this safety evaluation with proprietary information marked with doubled brackets [[ ]].

1.5.1.3 Financial Qualifications

Pursuant to 10 CFR 52.77, “Contents of applications; technical information,” the application must contain all of the information required in 10 CFR 50.33, “Contents of applications; general information.”

<u>Construction Costs</u>

Pursuant to 10 CFR 50.33(f)(1):

> [T]he applicant shall submit information that demonstrates that the applicant possesses or has reasonable assurance of obtaining the funds necessary to cover estimated construction costs and related fuel cycle costs. The applicant shall submit estimates of the total construction costs of the facility and related fuel cycle costs, and shall indicate the source(s) of funds to cover these costs.

Under 10 CFR Part 50, Appendix C, “A Guide for the Financial Data and Related Information Required to Establish Financial Qualifications for Construction Permits and Combined Licenses,” Section I.A.1:

> [E]ach applicant's estimate of the total cost of the proposed facility should be broken down as follows and be accompanied by a statement describing the bases from which the estimate is derived:
>
> > (a) Total nuclear production plant costs; [and]
> >
> > (b) Transmission, distribution, and general plant costs; [and]
> >
> > (c) Nuclear fuel inventory cost for first core
> >
> > If the fuel is to be acquired by lease or other arrangement than purchase, the application should so state. The items to be included in these categories should be the same as those defined in the applicable electric plant and nuclear fuel inventory accounts prescribed by the Federal

Energy Regulatory Commission [FERC] or an explanation given as to any departure therefrom.

In Part 1 of the COLA (Revision 4), the applicant provided projected overnight costs for the construction of one ESBWR nuclear unit at the North Anna site. Under 10 CFR 2.390, this information was withheld as information that is commercially confidential.

PROJECTED PROJECT COST
NORTH ANNA POWER STATION UNIT 3
DOMINION VIRGINIA POWER
(In millions of 2013 $)[3]

	TOTAL
Total Nuclear Production Plant Costs	[[ ]]
Transmission, Distribution & General Plant Costs	[[ ]]
Nuclear Fuel Inventory & Cost for First Core	[[ ]]
TOTAL (OVERNIGHT COST)	**[[ ]]**
Interest & Escalation	[[ ]]
Total w/ Interest & Escalation	**[[ ]]**

According to the applicants, North Anna 3 is expected to operate at an estimated gross electrical power output of approximately 1,594 MWe installed (as shown in DCD Section 10.1). Therefore, the total overnight cost of [[ ]] million is equivalent to [[ ]]/kWe installed. The applicants describe, in part, the foregoing cost estimate to be based on assumptions set forth in the application and attributable to the GE Hitachi ESBWR design.

The staff finds the applicant's ESBWR overnight construction cost estimate to be a reasonable projection based on a number of studies[4] that have been conducted by governmental agencies, universities and other entities. In particular, the U.S. Energy Information Administration's (EIA) June 2012 report, "Annual Energy Outlook (AEO) 2012 with Projections to 2035," (DOE/EIA-0383(2012)), states that "…the overnight capital costs associated with building a nuclear power plant planned in 2012 are assumed to be $5,335 per kilowatt of capacity…" The staff applied an annual adjustment factor ranging from 3% to 10% to the EIA overnight capital cost estimate to account for inflation beyond 2012, and determined that the EIA projected 2015 overnight cost would range from $5,830 to $7,101/kWe installed. The construction cost estimate is expressed in terms of "overnight cost," which is a term commonly used in describing the cost of large capital projects[5] . As stated in the application, this overnight cost includes the engineering,

[3] Commercially sensitive data. The data in brackets is exempt from public disclosure under 10 CFR 2.390(a)(4).

[4] See, e.g., the 2003 the Massachusetts Institute of Technology (MIT) interdisciplinary study entitled The Future of Nuclear Power; the U.S. Department of Energy's (EIA 2012 AEO; the Nuclear Energy Agency (NEA) of the Organization for Economic Cooperation and Development 2005 update on Projected Costs of Generating Electricity; and the Keystone Center 2007 report entitled Nuclear Power Joint Fact-Finding.

[5] overnight cost is the cost of a construction project if no interest was incurred during construction, as if the project was completed "overnight." An alternate definition is: the present value cost that would have to be paid as a lump sum up front to completely pay for a construction project. The overnight cost is frequently used when descr bing power plants.

procurement, and construction costs for the ESBWR plant, owner's costs, and contingencies, but excludes interest and escalation during the construction period. Owner's costs include site work and preparation, cooling water intake structures and cooling towers, import duties on components, insurance, spare parts, transmission interconnection, development costs, project management costs, owner's engineering, state and local permitting, legal fees, and staffing-related training. The applicant's overnight cost estimate of [[ ]]/kWe installed exceeds the most recent EIA 2012 range of overnight costs as adjusted for inflation. Accordingly, the staff finds Dominion's overnight cost estimate to be reasonable as presented in its COLA.

Sources of Construction Funds

Pursuant to 10 CFR Part 50, Appendix C, I.A.2:

> The application should include a brief statement of the applicant's general financial plan for financing the cost of the facility, identifying the source or sources upon which the applicant relies for the necessary construction funds, e.g., internal sources such as undistributed earnings and depreciation accruals, or external sources such as borrowings.

Dominion's Source of Construction Funds

According to the application, Dominion plans to finance the cost to construct North Anna 3 through a combination of debt and equity. The relative amount of debt and equity may depend on the availability of Federal loan guarantees under the provisions of the Energy Policy Act of 2005 (EPAct). If Federal loan guarantees are available on satisfactory terms, Dominion may be able to issue Federally guaranteed debt for a greater portion of the total financing need. If Federal loan guarantees are not available on satisfactory terms, Dominion may issue debt for a lesser portion of the total financing need. In either case, Dominion has sufficient capacity from a combination of internal and external funds for the equity and debt financing of the project through various means such as rate regulation under Virginia Code § 56-585.1.A.6, as described below, and also internal cash flows. The traditional capital markets will serve as the sources for the financing of North Anna 3.

Under Virginia Code § 56-585.1.A.6, a utility that constructs a nuclear generation facility has the right to recover the costs of the facility through a rate adjustment clause. This rate recovery includes projected construction work in progress (CWIP), and associated allowance for funds used during construction (AFUDC). Allowable costs include planning, development and construction costs, life-cycle costs, and costs of infrastructure associated therewith. Projected CWIP and AFUDC can be recovered prior to the date the facility begins commercial operation. As an incentive to undertake a nuclear generation facility, the statute allows an enhanced rate of return on common equity of 100 basis points above the utility's general rate of return on common equity.

This enhanced rate of return on common equity is applied to CWIP and the calculation of AFUDC during the facility construction phase. It is also applied to the nuclear facility from the date of the commencement of commercial operation and continuing for a period of 12 to 25 years, as the Virginia State Corporation Commission (VSCC) shall determine. After this period, the general rate of return is applied to the facility for the remainder of its service life.

In consideration of the foregoing, the staff finds that Dominion has demonstrated it possesses or has reasonable assurance of obtaining the funds necessary to cover estimated construction costs and related fuel cycle costs.

Financial Statements

Pursuant to 10 CFR Part 50, Appendix C, I.A.3:

> The application should also include the applicant's latest published annual financial report, together with any current interim financial statements that are pertinent. If an annual financial report is not published, the balance sheet and operating statement covering the latest complete accounting year together with all pertinent notes thereto and certification by a public accountant should be furnished.

Dominion's Financial Statements

Dominion files its financial statements with the Securities and Exchange Commission (SEC).

Dominion submitted, pursuant to Appendix C.I.A.3 to 10 CFR Part 50, annual financial statements. The staff did not identify anything in Dominion's financial statements that warranted further inquiry.

1.5.1.4 Operating License

Pursuant to 10 CFR 50.33(f)(3),

> If the application is for a combined license under subpart C of part 52 of this chapter, the applicant shall submit the information described in paragraphs (f)(1) and (f)(2) of this section.

Section 50.33(f) of 10 CFR provides that each application shall state:

> [e]xcept for an electric utility applicant for a license to operate a utilization facility of the type described in [10 CFR] § 50.21(b) or § 50.22, information sufficient to demonstrate to the Commission the financial qualification[s] of the applicant to carry out, in accordance with the regulations in this chapter, the activities for which the permit or license is sought.

Section 50.2, "Definitions," of 10 CFR states, in part, that an electric utility is:

> any entity that generates or distributes electricity and which recovers the cost of this electricity, either directly or indirectly, through rates established by the entity itself or by a separate regulatory authority.

According to the application, Dominion is an electric utility as defined in 10 CFR 50.2. Dominion generates and distributes electricity and recovers the cost of this electricity through cost-of-service based rates established by the VSCC, the North Carolina Utilities Commission (NCUC), and FERC.

Based on the foregoing, the staff finds that Dominion is not subject to a financial qualifications review pursuant to 10 CFR 50.33(f)(2).

1.5.1.5 Decommissioning Funding Assurance

Pursuant to the requirements of 10 CFR 50.33(k)(1), an applicant for a COL for a production or utilization facility will state information in the form of a report, as described in 10 CFR 50.75, "Reporting and recordkeeping for decommissioning planning," indicating how reasonable assurance will be provided that sufficient funds will be available to decommission the facility.

Under 10 CFR 50.75, the report must contain a certification that the applicant will provide financial assurance for decommissioning no later than 30 days after the Commission publishes notice in the *Federal Register* under 10 CFR 52.103(a), using one or more of the methods allowed under the regulation at 10 CFR 50.75(e). In addition, the amount of the financial assurance may be more, but not less, than the amount stated in the table in 10 CFR 50.75(c)(1), as adjusted under § 50.75(c)(2). Under 10 CFR 50.75(b)(4), a COL applicant need not obtain a financial instrument appropriate to the method to be used or submit a copy of the instrument to the Commission. (Once the COL is granted, the holder of a COL must submit an instrument as provided in § 50.75(e)(3)).

Decommissioning Funding Estimate

According to the COLA, Dominion certified that it will provide decommissioning funding assurance in the amount of $672,826,269 (2012 dollars). This value was derived using the methodology delineated in 10 CFR 50.75(b) and (c), and guidance in NUREG–1307, Revision 15. The staff independently calculated the minimum funding needed for North Anna 3 using the regulations and guidance described above, and obtained results similar to Dominion's. Accordingly, the staff finds that the amount provided by Dominion is acceptable.

Decommissioning Funding Mechanism

Pursuant to 10 CFR 50.75(b), a reactor licensee is required to provide decommissioning funding assurance by one or more of the methods described in 10 CFR 50.75(e), as determined to be acceptable to the NRC. According to the COLA, Dominion has chosen to provide decommissioning funding assurance for North Anna 3 using an external sinking fund. Dominion's external sinking fund will be in the form of a trust; will be established in writing and maintained at all times in the United States with an entity that is an appropriate State or Federal government agency, or an entity whose operations are regulated and examined by a State or Federal agency; and will include the provisions required by 10 CFR 50.75(h)(2). The staff finds that Dominion's use of an external sinking fund is acceptable since it will recover, either directly or indirectly, the estimated total cost of decommissioning through rates established by "cost of service" or similar ratemaking regulation. Therefore, the staff finds this method to be acceptable since it meets the requirements in 10 CFR 50.75(e)(1)(ii).

Certification Updates, Financial Instruments, and Annual Adjustment

According to the application, 2 years and 1 year before the scheduled date for initial loading of fuel, Dominion will submit a report updating this certification in accordance with 10 CFR 50.75(e)(3) and providing copies of the financial instruments to be used. In addition, no later than 30 days after the NRC publishes the notice in the *Federal Register* under 10 CFR

52.103(a), Dominion will submit a report containing a certification that the financial assurance for decommissioning is being provided in an amount specified in the most recent updated certification and will include a copy of the executed financial agreements obtained to satisfy the requirements of 10 CFR 50.75(e). Thereafter, the decommissioning funding amount will be adjusted annually using a rate at least equal to that stated in 10 CFR 50.75(c)(2). The staff finds Dominion's proposed plan as described above and in the application to be reasonable.

1.5.1.6 Antitrust

The EPAct removed the antitrust review authority contained in Section 105.c of the Act, regarding license applications for production or utilization facilities submitted under Sections 103 or 104b. of the Act after the date of enactment of the EPAct. Accordingly, the NRC is not authorized to conduct an antitrust review in connection with this COLA.

1.5.1.7 Foreign Ownership, Control, or Domination

Section 103 of the Act prohibits the Commission from issuing a license for a nuclear power plant to:

> an alien or any corporation or other entity if the Commission knows or has reason to believe it is owned, controlled, or dominated by an alien, a foreign corporation or a foreign government.

10 CFR 50.38, "Ineligibility of certain applicants," is the regulatory provision that implements this statutory prohibition.

The staff reviewed the application pursuant to the guidance provided in the SRP on FOCD to determine whether the applicant is owned, controlled, or dominated by an alien, a foreign corporation, or a foreign government.

Dominion Foreign Ownership, Control, or Domination

According to the application, Dominion is not owned, controlled, or dominated by an alien, a foreign corporation, or a foreign government. Dominion was incorporated in 1909 as a Virginia public service corporation, with its principal business location in Richmond, Virginia. Dominion is a wholly owned subsidiary of Dominion Resources, Inc. (DRI), an investor-owned electric utility. The shares of common stock of DRI are publicly traded and widely held. The application also contained the names and addresses of the Dominion directors and principal officers, and stated that all are United States citizens.

The staff performed an independent analysis of the information provided in the application for Dominion and DRI, including open-source research, and found no evidence of FOCD. Based on this review, the staff does not know or have reason to believe that Dominion is owned, controlled, or dominated by a foreign interest. Therefore, Dominion conforms to the guidance provided in the SRP for FOCD and meets the requirements of 10 CFR 50.38.

1.5.1.8 Nuclear Insurance & Indemnity

This section of the SER addresses the applicant's offsite and onsite insurance requirements found in 10 CFR Part 140 and 10 CFR 50.54(w), respectively.

The provisions of the Price-Anderson Act (Section 170 of the Act) and the Commission's regulations in 10 CFR Part 140, require, in part, that each holder of a license issued pursuant to 10 CFR Part 52 have and maintain financial protection. Further, 10 CFR 50.54(w) establishes requirements for each power reactor licensee to obtain insurance or provide an equivalent amount of protection for the onsite costs of an accident. Under these regulations, Dominion is required to provide satisfactory documentation that it has obtained the amount of financial protection required by (1) 10 CFR 140.13, "Amount of financial protection required of certain holders of construction permits and combined licenses under 10 CFR part 52," (2) 10 CFR 140.11(a)(4), and (3) 10 CFR 50.54(w). In addition, each licensee required to have and maintain financial protection under 10 CFR 140.11(a)(4) shall provide evidence that it maintains a guarantee of payment of deferred premiums pursuant to 10 CFR 140.21, "Licensee guarantees of payment of deferred premiums." Finally, as required by 10 CFR 140.20, "Indemnity agreements and liens," the staff will amend Dominion's current indemnity agreement for existing NAPS 1 and 2 to include the addition of North Anna 3.

The regulation in 10 CFR 140.13 provides the amount of financial protection required by a 10 CFR Part 52 license holder who also holds a license under 10 CFR Part 70 during the period before the Commission makes the finding under 10 CFR 52.103(g) (i.e., a finding that the acceptance criteria in the license are met, which allows the licensee to initially load fuel and operate). Because the 10 CFR Part 70 license will be issued with the COL, Dominion must have and maintain $1,000,000 in financial protection from issuance of the COL until the 10 CFR 52.103(g) finding is made. In addition, as required by 10 CFR 140.11(a)(4), after the 10 CFR 52.103(g) finding is made, each licensee must have and maintain financial protection in an amount equal to the sum of primary financial protection ($375,000,000) and the amount available as secondary financial protection. Since the existing reactors (Units 1 and 2) at the North Anna site already have primary financial protection in the amount of $375,000,000, the current policy covering the North Anna site will be amended to include North Anna 3.

Because Dominion did not address the above requirements in its initial COLA submittal and supplements thereafter, the staff issued RAI 01-6 on May 18, 2016 to determine how Dominion will comply with these regulations ADAMS Accession No. ML16139A590). By letter dated June 9, 2016, Dominion responded to the RAI (ADAMS Accession No. ML16168A027). The RAI response included a letter of intent from American Nuclear Insurers (ANI) that documents its commitment to amend the nuclear liability insurance policy for North Anna 1 and 2 to include the primary financial protection coverage of $375,000,000 for North Anna 3. This coverage will be effective concurrent with the NRC's issuance of a COL to Dominion. Therefore, the staff concludes that the $375,000,000 coverage satisfies the $1,000,000 requirement of 10 CFR 140.13, and the primary financial protection requirement in 10 CFR 140.11(a)(4).

The staff notes that although licensees of large operating reactors under Parts 50 and 52 must have and maintain protection under 10 CFR 140.11(a)(4) upon NRC action authorizing operation, the timing provisions for reporting under 10 CFR 140.21 do not explicitly address the Part 52 process. Under the requirements in 10 CFR 140.11(a)(4) and 10 CFR 140.21, the coverage for secondary financial protection and the guarantee of payment of deferred premiums are only required for reactors authorized to load fuel and operate. Under the 10 CFR Part 52 COL process, the license authorizes operation only upon a Commission finding pursuant to 10 CFR 52.103(g). Therefore, these requirements apply as of the date the Commission makes such a finding. As such, Dominion's RAI response also included proposed license conditions to meet the requirements in 10 CFR 140.11(a)(4) and 10 CFR 140.21. While 10 CFR 50.54(w) by its terms applies upon a Commission finding under 10 CFR 52.103(g), Dominion also included a reporting requirement for 10 CFR 50.54(w) in its proposed condition.

Dominion proposed the following license condition to address the reporting of 10 CFR 140.11(a)(4) requirements for secondary financial protection, and the reporting of 50.54(w) requirements for onsite financial protection. The staff agreed with the proposed license condition but made some modifications. The staff's recommended license condition is stated below:

> Before the scheduled date for initial fuel load, and within ninety (90) days after the NRC publishes the notice of intended operation in the Federal Register, Dominion Virginia Power shall provide satisfactory documentary evidence to the Director of the Office of Nuclear Reactor Regulation, or designee, that it has obtained the appropriate amount of secondary financial protection pursuant to 10 CFR Part 140.11(a)(4) and the appropriate amount of financial protection pursuant to 10 CFR 50.54(w).

With the license condition as described above, the staff concludes that Dominion will satisfy the requirements of 10 CFR 140.11(a)(4) with respect to obtaining an appropriate amount of secondary financial protection and 10 CFR 50.54(w) with respect to obtaining the appropriate amount of financial protection. The staff notes that it will conform any license condition to the correct format if the Commission determines to issue the license. For example, the staff may change "the Director of the Office of Nuclear Reactor Regulation" to "the Director of the Office of New Reactors" and the like.

Dominion also proposed the following license condition to address the reporting of 10 CFR 140.21 for guarantee of payment of deferred premiums. The staff agreed with the proposed license condition but made some modifications. The staff's recommended license condition is stated below:

> Before the scheduled date of initial fuel load, and within ninety (90) days after the NRC publishes the notice of intended operation in the Federal Register, Dominion Virginia Power shall provide evidence to the NRC that it would have the ability to pay into the nuclear industry retrospective rating plan in the event of a nuclear incident and in the amount specified in 10 CFR Part 140.11(a)(4) for one calendar year using one of the following methods:
>
> (a) Surety bond,
> (b) Letter of credit,
> (c) Revolving credit/term loan arrangement,
> (d) Maintenance of escrow deposits of government securities, or
> (e) Annual certified financial statement showing either that a cash flow (i.e., cash available to a company after all operating expenses, taxes, interest charges, and dividends have been paid) can be generated and would be available for payment of retrospective premiums within three (3) months after submission of the statement, or a cash reserve or a combination of cash flow and cash reserve.
>
> Thereafter, Dominion Virginia Power shall provide evidence of the guarantees of payment of deferred premiums in accordance with the provisions specified in 10 CFR 140.21.

With the license condition as described above, the staff concludes that Dominion will satisfy the requirement in 10 CFR 140.21.

In consideration of the staff's evaluation and license conditions as described above, the staff concludes that Dominion will satisfy the provisions of the Price-Anderson Act (Section 170 of the Act) and the Commission's applicable regulations in 10 CFR Part 140, 10 CFR Part 52, and 10 CFR Part 50 for insurance and indemnity.

1.5.1.9 Conclusion

Based on the evaluation above, in consideration of the proposed license conditions, the staff finds reasonable assurance that Dominion is financially qualified to engage in the proposed activities regarding North Anna 3, and that Dominion satisfies the NRC requirements relating to financial qualification, decommissioning funding assurance, FOCD, and nuclear insurance and indemnity. The staff finds this acceptable since it conforms to the guidance in NUREG–1577, the SRP on FOCD, NUREG–1307, and meets the applicable regulations in 10 CFR Part 52, 10 CFR Part 50, and 10 CFR Part 140 as described above.

1.5.2 Nuclear Waste Policy Act

Section 302(b) of the Nuclear Waste Policy Act of 1982, as amended, states:

> The Commission, as it deems necessary or appropriate, may require as a precondition to the issuance or renewal of a license under Section 103 or 104 of the Atomic Energy Act of 1954 [42 U.S.C. 2133, 2134] that the applicant for such license shall have entered into an agreement with the Secretary for the disposal of high-level radioactive waste and spent nuclear fuel that may result from the use of such license.

In a letter dated March 26, 2009 (ADAMS Accession No. ML090840271) the staff issued RAI 01-3 requesting the applicant to identify the Department of Energy (DOE) contract number applicable to North Anna 3 for disposal of high-level radioactive waste and spent nuclear fuel. In a letter dated June 17, 2009 (ADAMS Accession No. ML091700117), the applicant stated that:

> The DOE contract number applicable to North Anna 3 for disposal of high-level radioactive waste and spent nuclear fuel is Contract No. DE-CR01-09RW09011.

Because Dominion has entered into a contract with the DOE for the disposal of high-level radioactive waste and spent nuclear fuel for North Anna 3, the staff accepts that Dominion has met the applicable requirements of Section 302(b) of the Nuclear Waste Policy Act of 1982. This RAI was previously tracked as an Open Item and is now closed.

1.5.3 Consultation with Department of Homeland Security and Notifications

In accordance with Section 657 of the EPAct, the NRC consulted with the Department of Homeland Security.

In April 2008, the NRC published notices of the application in the local newspapers: *The Richmond Times-Dispatch, The Daily Progress, The Free-Lance Star,* and *The Central Virginian.* As required by Section 182c. of the Act and 10 CFR 50.43(a), the NRC took the following actions. On April 20, 2016, the NRC notified the VSCC (ADAMS Accession No. ML16064A508), the NCUC (ADAMS Accession No. ML16064A507) and the Federal Energy Regulatory Commission (FERC) (ADAMS Accession No. ML16064A506) regarding the North Anna 3 COL application.

In addition, the staff also published a notice of the application in the *Federal Register* (FR) on April 27, May 4, May 11, and May 18, 2016 (81 FR 24900, 81 FR 26837, 81 FR 29308, and FR 31263).

Based on the staff's completion of notifications to regulatory agencies and the public notices described above, the staff concludes that, for the purposes of issuing a COL for North Anna 3, all required notifications to other agencies or bodies have been duly carried out.

1.5.4 Evaluation of Exemptions Associated with the Special Nuclear Material (SNM) Material Control and Accounting (MC&A) Program

In Revision 6 of their application, the applicant updated Part 7 to include exemption requests from 10 CFR 70.22(b), 70.32(c), 74.31, 74.41, and 74.51. The provisions of 10 CFR 70.22(b) require an application for a SNM license to include a full description of the applicant's program for MC&A of SNM under 10 CFR 74.31, 10 CFR 74.33, "Nuclear material control and accounting for uranium enrichment facilities authorized to produce special nuclear material of low strategic significance," 10 CFR 74.41; and 10 CFR 74.51.[6] The provisions of 10 CFR 70.32(c) require a license authorizing the use of SNM to include and be subject to a condition requiring the licensee to maintain and follow an SNM MC&A Program, a measurement control program, and other material control procedures that include corresponding record management requirements. However, 10 CFR 70.22(b), 70.32(c), 74.31, 74.41, and 74.51 contain exceptions for nuclear reactors licensed under 10 CFR Part 50. The regulations applicable to the MC&A of SNM for nuclear reactors licensed under 10 CFR Part 50 are in 10 CFR Part 74, Subpart B and 74.11 through 74.19, except for 74.17. The applicant states that the purpose of this exemption request is to seek similar exceptions for this COL under 10 CFR Part 52, so that the same regulations applicable to nuclear reactors licensed under 10 CFR Part 50 will apply to the SNM MC&A Program.

The applicant also states that that there is no technical or regulatory reason to treat nuclear reactors licensed under 10 CFR Part 52 differently from reactors licensed under 10 CFR Part 50, with respect to MC&A for SNM provisions in 10 CFR Part 74. The staff finds the applicant's justifications in Part 7 of the application acceptable in that nuclear reactors licensed under 10 CFR Part 52 should be treated the same as reactors licensed under 10 CFR Part 50 regarding MC&A for SNM.

For 10 CFR Part 52, an exemption request is evaluated under 10 CFR 52.7, "Specific exemptions," which incorporates the requirements of 10 CFR 50.12, "Specific exemptions," and states that the Commission may grant exemptions from the requirements of the regulations in 10 CFR 50.12 if (1) the exemption is authorized by law and will not present an undue risk to public health and safety and is consistent with common defense and security; and 2) special

---

[6] Although it does not include an explicit exception for 10 CFR Part 50 reactors, 10 CFR 74.33 applies only to uranium enrichment facilities and thus is not directly impacted by this exemption request.

circumstances are present as specified in 10 CFR 50.12(a)(2). According to 10 CFR 50.12(a)(2)(ii), special circumstances are present whenever the application of the regulation in particular circumstances would not serve the underlying purpose of the rule or is not necessary to achieve the underlying purpose of the rule. In addition, the criteria in 10 CFR 50.12 encompass the criteria for an exemption in 10 CFR 70.17(a) and 10 CFR 74.7, the specific exemption requirements for 10 CFR Part 70 and 10 CFR Part 74, respectively. Therefore, by demonstrating that the exemption criteria in 10 CFR 50.12 are satisfied, these exemption requests also demonstrate that the exemption criteria in 10 CFR 52.7, 10 CFR 70.17(a), and 10 CFR 74.7 will be satisfied.

The staff reviewed the subject exemption requests that will allow the applicant to have similar exceptions for the COL under 10 CFR Part 52. The same regulations applied to nuclear reactors licensed under 10 CFR Part 50 (i.e., the regulations under Part 74 Subpart B) will apply to the SNM MC&A Program. The staff determined that (1) these requested exemptions are consistent with the Act and are authorized by law; (2) the exemptions will not present an undue risk to public health and safety; (3) these exemptions are consistent with common defense and security; and (4) special circumstances may exist so that the application of the regulations is not necessary to achieve the underlying purpose of the rule.

Because the staff finds that the applicant has satisfied the exemption criteria in 10 CFR 50.12, the staff considers these exemption requests to also satisfy the exemption criteria in 10 CFR 52.7, 70.17(a) and 74.7. Therefore, the staff finds that the exemptions from 10 CFR 70.22(b), 70.32(c), 74.31, 74.41 and 74.51 are justified.

1.5.5 Receipt, Possession, and Use of Source, Byproduct, and SNM Authorized by 10 CFR Part 52, Subpart C

1.5.5.1 Introduction

The reviews conducted for compliance with the requirements of 10 CFR Part 52 to support the issuance of the COLs encompass those requirements necessary to support granting 10 CFR Parts 30, 40, and 70 licenses. As a result, the 10 CFR Part 52 COL for North Anna 3 will be consistent with the licensing requirements in 10 CFR Parts 30, 40, and 70 for nuclear power plant licenses in accordance with 10 CFR Part 50.

In SECY-00-0092, “Combined License Review Process,” dated April 20, 2000, the Commission approved generic license conditions for 10 CFR Parts 30, 40, and 70. In addition, per the memorandum dated December 9, 2008, from the Director of the Division of New Reactor Licensing in the Office of New Reactors (ADAMS Accession No. ML083030065); holders of a COL under 10 CFR Part 52 will also be authorized to receive, possess, and use source, byproduct, and SNM in accordance with Commission regulations in 10 CFR Parts 30, 40, and 70 including 10 CFR Sections 30.33, “General requirements for issuance of specific licenses;” 40.32, “General requirements for issuance of specific licenses;” 70.23, “Requirements for the approval of applications;” and 70.31, “Issuance of licenses,” under their 10 CFR Part 52 COL. Licensees will be required to comply with all applicable regulations in 10 CFR Parts 30, 40, and 70, as well as the regulations in 10 CFR Parts 20, 50, and 52.

In order to meet these requirements, the applicant needed to supplement the COLA with a request to receive, possess, and use source, byproduct, and SNM accordingly and provide sufficient information to support compliance with the applicable portions of 10 CFR Parts 30, 40, and 70. In RAI 01-4 (ADAMS Accession No. ML091550016), the staff requested for Dominion to address these items and on September 25, 2009 (ADAMS Accession No. ML092730455) the applicant responded. The staff reviewed this information and detailed the privileges to be granted under 10 CFR Parts 30, 40 and 70 licenses in the proposed "License Conditions" section specified below. This RAI was previously tracked as an Open Item and is now closed.

1.5.5.2 Parts 30, 40, and 70 License Requests

Pursuant to 10 CFR 52.8, "Combining licenses; elimination of repetition," Part 1, "General and Administrative Information"; Section 2 (e), "Information Required by 10 CFR 50.33," of the North Anna 3 application, Dominion requested additional Parts 30, 40 and 70 licenses to be incorporated into the COL to receive, possess and use source, SNM, and byproduct material in connection with the operation of North Anna 3.

Pursuant to 10 CFR 52.8, this application also seeks licenses that would be incorporated into the COL to receive, possess, and use source, SNM, and byproduct material in connection with the operation of North Anna 3. Specifically, as the proposed operator of North Anna 3, Dominion seeks authority for the following:

- To receive, possess, and use at any time SNM as reactor fuel.

- To receive, possess, and use at any time any byproduct, source, and SNM, as sealed neutron sources for reactor startup, sealed sources for instrumentation, and radiation monitoring equipment calibration, and as fission detectors in amounts as required.

- To receive, possess, and use in the amounts as required any byproduct, source, or SNM without restriction to chemical or physical form, for a sample analysis or instrument and equipment calibration, or associated with radioactive apparatus or components.

- To possess, but not separate, such by-product and SNM as may be produced by the operation facility.

1.5.5.3 Parts 30, 40, 70 License Request Clarifications

In Part 10, Revision 7, the applicant has updated these proposed license requests. The staff notes that the initial license requests and conditions, stated above, have evolved based on the staff's review of information in the application. The full set of applicable license conditions for Parts 30, 40, and 70 to be proposed by the staff for North Anna 3 are listed below in Subsection 1.5.5.6, Parts 30, 40, and 70 License Conditions. In addition, the program elements to be in place to allow for receipt of byproduct and special materials before the 10 CFR 52.103(g) finding are discussed more specifically in the staff's review below and are also provided in the applicant's FSAR Table 13.4-201 "Operational Programs Required by NRC Regulations."

1.5.5.4 Exemptions from Part 70 License Request

In Part 7, Revision 6, of the application, the applicant has requested exemptions from 10 CFR 70.22(b), 70.32(c), 74.31, 74.41, and 74.51 as they relate the SNM Accountability. The staff's review for the SNM MC&A is provided below and discusses these exemptions. In addition, the evaluation of these exemption requests are summarized in SER Section 1.5.4.

1.5.5.5 Parts 30, 40, and 70 Materials and Use Clarifications

In order to clarify the specific types of byproducts, sources, and SNMs; the chemical or physical forms; and the maximum amount at any one time of the requested material licenses under 10 CFR Parts 30, 40, and 70, the applicant has provided supplemental information in FSAR Section 12.2 to identify additional byproduct, source, and SNM materials beyond what has been described in the ESBWR DCD. The information in the section has been reviewed by the staff below, and was found to be acceptable.

10 CFR Part 30 Materials

With respect to the amount of 10 CFR Part 30 materials specified by the applicant between the issuance of the COL and before the 10 CFR 52.103(g) finding, the applicant has provided FSAR Table 12.2-206 which indicates that the quantity of any sealed calibration and referenced sources of byproduct material with the atomic numbers 1 through 93 would not exceed 100 millicuries for a single source and 5 curies total. In addition, the maximum for americium-241 would not exceed 300 millicuries for a single source and a total of 500 millicuries. The applicant has also provided STD SUP 12.2-1 in Subsection 12.2.1.1.2 to state that the Californium-252 (Cf) Cf-252 reactor startup source is a sealed source and each source capsule contains 0.5 to 0.822 mg of Cf-252. Six sources are required, resulting in a total of 3 to 5 mg Cf-252.

The applicant stated that this information remains in effect between the issuance of the COL and the 10 CFR 52.103(g) finding. The applicant included this information as Table 12.2-206 in FSAR Chapter 12. Further clarifications of the licensing for the receipt, possession, and use of 10 CFR Part 30 materials are outlined below in Subsection 1.5.5.6, Parts 30, 40, and 70 License Conditions.

10 CFR Part 40 Materials

In FSAR Section 12.2, the applicant states that no 10 CFR Part 40 specifically licensed material, including natural uranium, depleted uranium, and uranium hexafluoride will be received, possessed, or used during the period prior to implementation of the Emergency Plan (in preparation for initial fuel load following the 52.103(g) finding.) Accordingly, the license conditions described below only grant licenses for Parts 30 and 70 materials between the issuance of the COL and the 10 CFR 52.103(g) finding. Further clarifications of the licensing for the receipt, possession, and use of 10 CFR Part 40 materials after a 10 CFR 52.103(g) finding are outlined below in Subsection 1.5.5.6, Parts 30, 40, and 70 License Conditions.

10 CFR Part 70 Materials (non-fuel)

In FSAR Section 12.2, the applicant states that the radioactive materials identified in the table below represent nominal values of known non-fuel SNM specifically required for use at North Anna 3. Table 1-1 includes the following data from Table 12.2-207 of the North Anna 3 COL FSAR:

Table 1-1 Non-Fuel Special Nuclear Material for Use

(a) Element and Mass Number	(b) Chemical or Physical Form	(c) Maximum Amount
U-234 (approx. 78%) U-235 (approx. 22%)	Local Power Range Monitor Assemblies – Each assembly includes four fission chambers (64 assemblies and 4 spares)	0.0104 grams of uranium per assembly. Total of approx. 0.71 grams.
U-234 (approx. 78%) U-235 (approx. 22%)	Startup Range Nuclear Monitor Assemblies – Fission chambers (12 installed assemblies and 1 spare)	0.0129 grams of uranium per assembly. Total approx. 0.17 grams.

Further clarifications of the licensing for the receipt, possession, and use of 10 CFR Part 70 materials as a non-fuel are outlined below in Subsection 1.5.5.6, Parts 30, 40, and 70 License Conditions.

10 CFR Part 70 Materials (fuel)

The receipt, possession, and use of 10 CFR Part 70 SNMs as fuel are fully described in accordance with the limitations for storage and in the amounts necessary for reactor operation in the applicant's FSAR, as supplemented and amended. Further clarifications of the licensing for the receipt, possession, and use of 10 CFR Part 70 materials as fuel are outlined below in the license conditions.

1.5.5.6 Parts 30, 40, and 70 License Conditions

Based on the discussions above and the reviews outlined below, the staff proposes to include the following license conditions for the North Anna 3 COL as they relate to authorization pursuant to the regulations in 10 CFR Parts 30, 40, and 70:

- License Condition (1-1) – Subject to the conditions and requirements incorporated herein, the Commission hereby licenses Dominion:

  (a) (i) Pursuant to the Act and 10 CFR Part 70, to receive and possess at any time SNM as reactor fuel in accordance with the limitations for storage and in the amounts necessary for reactor operation, as described in the FSAR as supplemented and amended;

  (ii) Pursuant to the Act and 10 CFR Part 70, to use SNM as reactor fuel, after a Commission finding under 10 CFR 52.103(g) has been made, in accordance with the limitations for storage and in amounts necessary for reactor operation, described in the FSAR, as supplemented and amended;

(b) (i) Pursuant to the Act and 10 CFR Parts 30 and 70, to receive, possess, and use, at any time before a Commission finding under 10 CFR 52.103(g), such byproduct and SNM as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts, as necessary;

(ii) Pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use, after a Commission finding under 10 CFR 52.103(g) any byproduct, source, and SNM as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts as necessary;

(c) (i) Pursuant to the Act and 10 CFR Parts 30 and 70, to receive, possess, and use, before Commission finding under 10 CFR 52.103(g), in amounts not exceeding those specified in 10 CFR 30.35(d) and 10 CFR 70.25(d) required for establishing decommissioning financial assurance, any byproduct or SNM that is (1) in unsealed form; (2) on foils or plated surfaces, or (3) sealed in glass, for sample analysis or instrument calibration or other activity associated with radioactive apparatus or components;

(ii) Pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use, after a Commission finding under 10 CFR 52.103(g), in amounts as necessary, any byproduct, source, or SNM without restriction as to chemical or physical form, for sample analysis or instrument calibration or other activity associated with radioactive apparatus or components but not uranium hexafluoride; and

(d) Pursuant to the Act and 10 CFR Parts 30 and 70, to possess, but not separate, such byproduct and SNMs as may be produced by the operation of the facility.

- License Condition (1-2) – Prior to initial receipt of SNM onsite, the licensee shall implement the SNM Material Control and Accounting Program. No later than 12 months after issuance of the COL, the licensee shall submit to the Director of Office of New Reactors (NRO) a schedule that supports planning for and conduct of NRC inspections of the SNM MC&A Program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the SNM MC&A Program has been fully implemented.

- License Condition (1-3) – The fire protection measures in accordance with RG 1.189, “Fire Protection for Nuclear Power Plants,” for designated storage building areas (including adjacent fire areas that could affect the storage area) shall be implemented before initial receipt of byproduct or SNMs that are not fuel (excluding exempt quantities as described in 10 CFR 30.18, “Exempt quantities”).

- License Condition (1-4) – The fire protection measures in accordance with RG 1.189 for areas associated with new fuel (including all fuel handling, fuel storage, and adjacent fire areas that could affect the new fuel) shall be implemented before receipt of fuel onsite.

- License Condition (1-5) – Prior to the receipt of fuel onsite, a formal letter of agreement shall be in place with the local fire department specifying the nature of arrangements in support of the Fire Protection Program (FPP).

- License Condition (1-6) – All FPP features shall be implemented before initial fuel load.

1.5.5.7 Operational Programs to Support 10 CFR Parts 30, 40, and 70

The staff notes that North Anna 3 COL FSAR Table 13.4-201, "Operational Programs Required by NRC Regulations," provides milestones and commitments for the implementation of various operational programs. Important milestones for the portions of operational programs applicable to radioactive materials that support the issuance of licenses and requirements relative to 10 CFR Parts 30, 40, and 70 are included in the following programs:

- Item 8: Fire Protection Program
- Item 10: Radiation Protection (RP) Program
- Item 11: Non-Licensed Plant Staff Training Program
- Item 15: Security Program
- Item 23: SNM Control and Accounting Program

1.5.5.8 Part 70 License Staff Review

The applicant's compliance with several applicable 10 CFR Part 70 requirements regarding RP, nuclear criticality safety (NCS), and environmental protection are already encompassed by the design information incorporated by reference from the ESBWR DCD. In addition, the staff evaluated the applicant's compliance with these requirements as part of the DC review. Other applicable 10 CFR Part 70 requirements to be addressed by the COL applicant are outlined below. In order to satisfy NRC regulations and requirements for licensing under 10 CFR Part 70 so as to receive, possess, and use SNM as fuel and non-fuel, the applicant addressed the following areas for review per the guidance in NUREG–1520 and the SRP:

- General Information – Applicant identifications, location, licenses sought, financial qualifications, exemption requests, site layout, population, geography, nearby facilities, meteorology, hydrology, geology, and seismicity

- Organization and Administration – Structure, management, functions, qualifications, experience, communications, and turnover of the construction to operation

- Radiation Protection

- Criticality Safety

- Fire Safety

- EP

- Effluent Controls and Monitoring Programs

- SNM MC&A–Exemptions, MC&A, and Fixed Site Security Review

- Physical Security

General Information

The legal identities of the applicant and the site location are described by the applicant in Part 1, Sections 1, 2(a-d), and Part 2, Subsection 1.1.2.2. The license action types requested by the applicant are described in Part 1, Section 2(e). However, the staff has further clarified the 10 CFR Parts 30, 40, and 70 licenses to be granted in the license conditions listed above in Section 1.5.5.6. Financial qualifications are in Part 1, Section 2(f), which the staff reviewed in SER Section 1.5.1. The exemption requests for 10 CFR Part 70 licensing are in Part 7 of the application, which the staff reviewed in Section 1.5.4. The facility layout, property boundaries, geography, and population are described in FSAR Section 2.1. Locations of nearby facilities are described in FSAR Section 2.2. Meteorology is described in FSAR Section 2.3, and site hydrology is described in FSAR Section 2.4. Site geology and seismicity are described in FSAR Section 2.5. These sections also incorporate information from the North Anna ESP Standard SSAR. Based on the above information, the staff finds that the applicant has satisfactorily addressed general information.

Organization Information

The applicant's organizational structure and charts are in FSAR Section 13.1 and Appendix 17AA. This information includes functional descriptions of the organizational groups—including those responsible for managing the design, construction, operations, and modifications of the facility; in addition to responsibilities, reporting hierarchy, and communications. FSAR Subsection 13.1.1.4 discusses the education and experience qualifications for managers, supervisors, and technicians. FSAR Appendix 13AA describes the activities required to transition the unit from the construction phase to the operation phase. Based on the above information, the staff finds that the applicant has satisfactorily addressed organizational information.

Radiation Protection

The staff's safety review under 10 CFR Part 52 for RP programs and systems for the construction and operation of North Anna 3 is in SER Chapter 12. The staff finds the applicant's RP programs and systems acceptable for construction and operation.

In FSAR Table 13.4-201, the applicant states that the following four commitments will be implemented for the RP Program at North Anna 3:

- Prior to initial receipt of byproduct, source, or SNMs (excluding Exempt Quantities as described in 10 CFR 30.18) for those elements of the RP Program necessary to support such receipt.

- Prior to fuel receipt for those elements of the RP Program necessary to support receipt and storage of fuel onsite.

- Prior to fuel load for those elements of the RP Program that are necessary to support fuel load and plant operation.

- Prior to first shipment of radioactive waste for those elements of the RP Program that are necessary to support shipment of radioactive waste.

The above commitments correspond to the four milestones for the RP Program that is specified in Nuclear Energy Institute (NEI) Template 07-03A, "Generic FSAR Template Guidance for Radiation Protection Program Description." NEI 07-03A is incorporated by reference by the applicant in Chapter 12, Appendix 12BB, of the North Anna 3 FSAR. By letter dated March 18, 2009 (ADAMS Accession No. ML090510379), the staff determined that NEI 07-03A provides an acceptable template for assuring that the RP program meets applicable NRC regulations and guidance. Therefore, the staff finds these commitments acceptable. With respect to the RP review of 10 CFR Part 70 licenses, the staff performed the following review:

The regulatory basis for this review of the North Anna 3 RP Program applicable to the fresh fuel assemblies for the first reactor core prior to commencement of operation is contained in 10 CFR Parts 19, "Notices, Instructions, and Reports to Workers: Inspections and Investigations," 20, and 70. The purpose of this review is to determine whether Dominion's proposed RP program is adequate to protect the radiological health and safety of workers, the public, and the environment during fresh fuel handling and storage operations under 10 CFR Part 70. This review is necessary in anticipation of the operation of the North Anna 3 ESBWR.

The applicable acceptance criteria for the NRC's 10 CFR Part 70 review of the North Anna 3 RP Program are outlined in Section 4.4 of NUREG–1520, Revision 1, *Standard Review Plan for the Review of a License Application for a Fuel Cycle Facility* (SRP). While some portions of the acceptance criteria in NUREG–1520, Section 4.4 are relevant to this incremental review, other portions are not. For example, certain RGs and other documents referenced in NUREG–1520, Section 4.4 are specific to fuel cycle facilities and are not applicable to reactor reviews. Also, reactors are not one of the engagements for which an Integrated Safety Analysis is required as per 10 CFR 70.60, "Applicability."

Operations pertaining to 10 CFR Part 70 include uncrating, handling, and inspection of fuel assemblies and storing them in the new fuel and spent fuel storage pool prior to loading into the reactor. As the fuel assemblies are effectively contained/sealed material with little associated external radiation, the radiological risks associated with this operation are considered minimal. Other forms (not fuel) of SNM on site include small amounts in fission chambers used for monitoring and wire sources used for startup operations. Similarly, because that is also contained/sealed material, the radiological risks associated with the materials are considered minimal.

The review documented here is not applicable in determining the acceptability of the described program with respect to operations under 10 CFR Part 52. The radiation protection methods and estimated occupational radiation exposures to operation and construction personnel during normal and anticipated operational occurrences will be reviewed with respect to issuance of the combined construction permit and operating license (COL) in Chapter 12 of the Advanced SER for the North Anna 3 COL Application. The staff will have to verify the resolution of all relevant issues when the North Anna 3 final SER is available in order to complete its 10 CFR Part 70 review.

In general, the NUREG–1520 acceptance criteria require descriptions to ensure the following topics will be adequately addressed at the facility: RP program implementation; radiation exposures as low as reasonably achievable (ALARA); RP organization and qualifications;

written procedures; training; ventilation and respiratory protection programs; radiation survey and monitoring programs; radiological risk associated with accidents; and additional programs normally impacting the RP function. The applicant's FSAR Section 12.5 provides a description of the operational RP program. The program incorporates by reference NEI Template 07-03A, Revision 0 (NEI, 2009a), with site-specific supplements or substitutions included elsewhere in the FSAR or ESBWR DCD (GE-Hitachi, 2014), as the operational RP Program description. NEI 07-03A is the final accepted version of the NRC reviewed NEI-07-03, Revision 7. The staff completed the review and safety evaluation of NEI 07-03, Revision 7, as documented in "Safety Evaluation Regarding the Nuclear Energy Institute Technical Report 07-03 "Generic FSAR Template Guidance for Radiation Protection Program Description, Revision 7". Table 13.4-201 (item 10) in the applicant's FSAR indicates that all necessary aspects of its RP program will be implemented prior to its receipt of any by-product, source, SNM (except as described in 10 CFR 30.18), or fuel.

The generic RP program template commits an applicant to NRC regulatory requirements and guidance and to acceptance criteria listed in RG 1.206 and SRP Section 12.5. While the SRP is not as prescriptive regarding the required information for a radiological protection program as NUREG–1520, the staff believes that a program established to address 10 CFR Part 52 operations would adequately address 10 CFR Part 70 operations as well. The staff reviewed NEI 07-03A, as well as the modifications and supplements to that information described in the FSAR and found that it adequately addressed the topics of evaluation in Section 4 of the NUREG–1520 (Radiation Protection) with the exceptions of ALARA, ventilation, and radiological risk associated with accidents.

With respect to ALARA, the applicant states in Appendix 12AA and Appendix 12BB of its FSAR that it incorporates NEI 07-08A (NEI, 2009b), "Generic FSAR Template Guidance for Ensuring That Occupational Radiation Exposures are As Low As Is Reasonably Achievable (ALARA), Revision 0," with modifications or supplements as noted in the section. Similar to NEI 07-03A, the staff previously reviewed NEI 07-08, Revision 3, and found it acceptable as documented via letter. The template, in conjunction with template NEI 07-03A, generally describes operational policies, regulatory compliance, and operational considerations applicable to the ALARA program. Compliance with the template, when considering the minimal risks associated with storage and handling fresh fuel under 10 CFR Part 70, is adequate to assure operations will be ALARA. The applicant's RP program to achieve occupational doses ALARA also addresses regulatory requirements for RP found in 10 CFR Part 20.

Regarding ventilation, the materials of interest for this license are expected to be contained and pose little airborne potential or risk of internal exposure. For this reason, staff found it unnecessary to evaluate the facility's ventilation systems.

The Integrated Safety Analysis requirements for control of radiological risk discussed in Section 4.4.8 of NUREG–1520 are not applicable to North Anna 3 because the operations proposed are excluded from the list of engagements in 10 CFR 70.60 for which 10 CFR Part 70, Subpart H, applies. The applicant did submit an emergency plan that addresses response to accident situations involving potential radiological exposures. As stated previously, it is expected that the unirradiated uranium contained in the fuel poses little radiological risk for the operations pertaining to 10 CFR Part 70.

The staff finds that Dominion will establish and maintain an acceptable RP program for North Anna 3 that addresses operations under 10 CFR Part 70, which includes:

- An effective documented program to ensure that occupational radiological exposures are ALARA;
- An organization with adequate qualification requirements for RP personnel;
- Approved, written RP procedures and RWPs for RP activities;
- RP training for all personnel who have access to radiologically restricted areas;
- A program to control airborne concentrations of radioactive material with engineering controls and respiratory protection.
- A radiation survey and monitoring program that includes requirements for controlling radiological contamination within the facility and monitoring of external and internal radiation exposures; and,
- Other programs to correct upsets at the facility, maintain records, and generate reports in accordance with 10 CFR Parts 20 and 70.

The staff concludes that the applicant's RP program for North Anna 3, with respect to the initial fresh fuel elements for the first reactor core and other forms of SNM as described in its COL application, complies with regulatory requirements in 10 CFR Parts 19, 20, and 70, adequately addresses the applicable acceptance criteria in Section 4.4 of NUREG–1520, Revision 1, and is, therefore, acceptable to the staff.

Criticality Safety

The assessment of criticality safety of fresh and spent fuel storage and handling is based, in part, on the information in the ESBWR DCD. The applicant has incorporated by reference Sections 9.1.1 and 9.1.2 of the ESBWR DCD. The ESBWR DCD, Tier 2, Subsection 9.1.1.7, "Safety Evaluation," for criticality control designates DCD COL Item 9.1-4-A for the applicant to describe the programs that address criticality safety of fuel handling operations. The staff's safety review of fuel handling is in SER Section 9.1.4. The staff has found that the applicant has satisfactorily addressed fuel handling operations, including criticality safety.

In addition, in SER Section 1.5.5.9 below, the staff finds that the applicant's request for a 10 CFR Part 70 SNM license did not involve an authorization to possess enriched uranium or plutonium for uranium hexafluoride in excess of 50 kilograms in a single container or 1,000 kilograms total; or in excess of 2 curies of plutonium in an unsealed form or on foils or plated sources. Therefore, a criticality alarm system is not required and implementation of the emergency plan before receipt of the SNM is also not required.

With respect to additional review of 10 CFR Part 70 licenses, the staff performed the following review. The regulatory basis for the review of North Anna 3 NCS is contained in 10 CFR 70.22, "Contents of applications;" 10 CFR 70.23; and 10 CFR 70.52, "Reports of accidental criticality." The purpose of this review is to determine whether the Dominion's North Anna 3 proposed NCS program is adequate to protect the radiological health and safety of workers, the public, and the environment during fresh fuel handling and storage operations under 10 CFR Part 70. This review is necessary in anticipation of the operation of the North Anna 3 ESBWR.

The acceptance criteria for NRC's 10 CFR Part 70 review of North Anna 3's NCS program are outlined in Section 5.4 of NUREG–1520. However, staff determined that few of the acceptance criteria in NUREG–1520 were applicable to the 10 CFR Part 70 operations proposed at North Anna 3 and, therefore, limited the review to that necessary to assure compliance with the applicable 10 CFR Part 70 requirements noted previously.

Dominion has submitted a COLA for an ESBWR design to be designated North Anna 3. This review is to focus on criticality safety for the receipt, possession, inspection, and storage of SNM in the form of fresh fuel assemblies as applicable under 10 CFR Part 70. Other forms of SNM are specified in Table 12.2-207 of the COLA (primarily fission chambers) and constitute less than 1 gram total of SNM which was considered negligible relative to NCS concerns. The operations relevant to the 10 CFR Part 70 portion of the license include the uncrating and inspection of the fuel assemblies and storing them in the new fuel racks and spent fuel storage pool prior to loading into the reactor. The applicant has prepared the FSAR to be consistent with guidance in the SRP. Consistent with the format of that guidance, Section 9.1 of the FSAR discusses criticality safety of fresh and spent fuel storage and handling, including movement of light and heavy loads (fuel assemblies).

Acceptance criteria for a 10 CFR Part 70 review are in Section 5.4 of NUREG–1520. However, the staff determined that few of those acceptance criteria are applicable to the proposed reactor operations. The staff therefore limited the review to what was necessary to assure compliance with the applicable 10 CFR Part 70 requirements noted previously.

The staff evaluation of criticality concerns relating to fresh and spent fuel storage for the standard ESBWR design is set forth in ESBWR FSER Sections 9.1.1, and 9.1.2.

Finally, staff determined that reporting compliant with 10 CFR 70.52 would be self-evident and no elaboration in the application should be required to assure compliance with those regulations. The information submitted by the applicant and reviewed by the staff assures the applicant's equipment, facilities and procedures will be adequate to assure subcriticality of the fresh fuel consistent with 10 CFR 70.23(a)(3) and (4), thus adequately protecting health and minimizing danger to life or property.

Fire Safety

The staff's safety review under 10 CFR Part 52 for the FPPs) and systems for the licensing and operation of North Anna 3 was completed and is contained in Chapter 9 SER, Subsection 9.5.1. In FSAR Table 13.4-201 the applicant has made three commitments to adhere to the FPP: 1) prior to initial receipt of byproduct, source, or SNM (excluding exempt quantities as described in 10 CFR 30.18) for portions of the FPP applicable to radioactive material; 2) prior to fuel receipt for the elements of the FPP necessary to support receipt and storage of fuel onsite, and; 3) prior to fuel load for the elements of the FPP necessary to support fuel load and plant operation. The staff found these commitments contribute to the reasonable assurance that adequate fire protection will be provided and maintained to meet the criteria of 10 CFR 70.23.

With respect to the fire safety review of 10 CFR Part 70 licenses, the staff performed the following review:

The purpose of this review is to determine, with reasonable assurance, that North Anna 3 has (1) designed a facility that provides adequate protection against fires and explosions that could affect the safety of licensed materials and thus present an increased radiological risk; (2) considered the radiological consequences of fires; and (3) instituted suitable safety controls to protect workers, the public, and the environment.

The regulatory basis for the fire safety review includes the general and additional contents of the application, as required by 10 CFR 70.22. In addition, the fire safety review must provide reasonable assurance of compliance with 10 CFR 70.23(a)(3) and 10 CFR 70.23(a)(4). The acceptance criteria that the NRC uses for reviews of fire safety of licensed material are outlined in Sections 7.4.3.1 through 7.4.3.5 of NUREG–1520.

The facility and its original fire protection systems are designed and will be constructed to industrial standards currently in effect. The licensee commits to meeting the prevailing codes whenever facilities are expanded or modified. Facilities are generally concrete, noncombustible masonry, or metal construction. Lightning protection is incorporated into the facility design. Facility exit routes are posted throughout and are unimpeded by physical security requirements. In addition, workers are trained in evacuation and periodic drills are conducted to verify the adequacy of egress.

Within the fuel building (FB), which is a seismic Category I structure, new fuel bundles are brought in through the rail car bay, uncrated, raised to the refueling floor, and transferred for storage on racks in the buffer pool within the reactor building, also a seismic Category I structure. The process itself utilizes methods and materials that have no fire safety concerns. The fire protection equipment in the fuel handling area of the FB includes fire detection, portable fire extinguishers, and hose stations for manual firefighting.

Site procedures for the maintenance and surveillance testing of the above-listed equipment, including fire pump, fire mains, standpipes, and hoses, have been developed and will be performed as described in the FPP and in accordance with applicable codes and standards. In addition, the compensatory actions described in the FPP will be used should any of the listed fire equipment become unavailable.

The staff has proposed the following license conditions regarding the FPP which requires:

- The fire protection measures in accordance with RG 1.189 for designated storage building areas (including adjacent fire areas that could affect the storage area) be implemented before initial receipt of byproduct or SNMs that are not fuel (excluding exempt quantities as described in 10 CFR 30.18).

- The fire protection measures in accordance with RG 1.189 for areas associated with new fuel (including all fuel handling, fuel storage, and adjacent fire areas that could affect the new fuel) be implemented before receipt of fuel onsite.

- Prior to the receipt of fuel onsite, a formal letter of agreement shall be in place with the local fire department specifying the nature of arrangements in support of the FPP.

- All FPP features be implemented before initial fuel load.

These license conditions are included in Subsection 1.5.4.6, Parts 30, 40, and 70 License Conditions, above.

Effective handling of fire emergencies is accomplished by trained and qualified emergency responders. The fire response organization is staffed and equipped for firefighting activities. The fire brigade is composed of a fire brigade leader and at least four fire brigade members. The fire brigade does not include the Shift Manager or other members of the minimum shift crew necessary for safe shutdown of the unit, nor any personnel required for other essential functions during a fire emergency or members of the fire brigade for Units 1 and 2. Additional support is available when needed through an agreement with the local fire department.

Training ensures that the fire brigade's capability to combat fires is established and maintained. The training program consists of initial (classroom and field) training and recurrent training which includes periodic instruction, fire drills, and annual fire brigade training.

Firefighting equipment is provided throughout the plant. Fire emergency procedures and pre-fire plans specify actions to be taken by the individual discovering the fire and by the emergency responders. Discussion of this pre-fire plan is included in the periodic classroom instruction's training program provided for the emergency responders.

Combustibles are controlled to reduce the severity of a fire which might occur in a given area and to minimize the amount and type of material available for combustion. The use and application of combustible materials at North Anna 3 are controlled utilizing the following methods:

- Instructions/guidelines provided during general employee training/orientation programs;
- A chemical control program;
- Periodic plant housekeeping inspections/tours by management and/or the plant fire protection organization;
- Design/modification review and installation process; and
- Administrative procedures (e.g., Transient Combustible Control Program).

The use of ignition sources such as welding, flame cutting, brazing, grinding, and soldering within safety-related areas are controlled through the approval and issuance of an ignition source permit. Permits are reviewed and approved by appropriate plant personnel. The ignition source permit is valid for 24 hours during plant operation and for the duration of one job during plant shutdown. Job area inspection will be performed and documented at the start of each shift that ignition source activities are being performed.

The Fire Hazards Analysis (FHA) is part of the FPP. The FHA results are documented on a fire area basis, broken down into separate discussions of classical fire protection features and safe shutdown analysis for each fire area. The FHA is required to be updated, prior to receipt of the new fuel, as part of the License Condition previously mentioned. The FHA includes the following:

- A summary of the evaluation performed to determine the adequacy of the fire protection features for each fire area; and

- A discussion of the ability to achieve safe shutdown in case of a fire in each fire area.

The fire hazards and safe shutdown evaluation were performed by qualified nuclear, mechanical, electrical, and fire protection engineers. FHA and Pre-Fire Plans conform to the applicable guidance provided in National Fire Protection Association (NFPA) 801, “Standard for Fire Protection for Facilities Handling Radioactive Materials” (NFPA, 2003) and NFPA 804, “Standard for Fire Protection for Advanced Light Water Reactor Electric Generating Plants” (NFPA, 2006).

The staff concluded that the licensee’s capabilities meet the criteria in Chapter 7 of NUREG–1520. The staff determined that the licensee’s equipment, facilities, and procedures provide reasonable assurance that adequate fire protection will be provided and maintained to meet the criteria of 10 CFR 70.23.

Emergency Preparedness

The staff’s evaluation of the applicant’s request for a 10 CFR Part 70 license, with regard to EP, is provided below in SER Section 1.5.5.9, “Parts 30 and 40 License Staff Review.” In this review, the staff also evaluated the applicant’s request for 10 CFR Parts 30 and 40 licenses in regards to EP. In regards to the 10 CFR Part 70 license request, the staff found that the applicant has met the emergency planning-related requirements of 10 CFR 70.22(i)(1) for SNM (fuel and non-fuel), such that prior to implementation of the North Anna 3 Emergency Plan (i.e., during the period of time between issuance of the COL and implementation of the North Anna 3 Emergency Plan, which will occur prior to the Commission’s 10 CFR 52.103(g) finding), an emergency plan that meets 10 CFR 70.22(i)(3) is not required.

Effluent Controls and Monitoring Programs

The staff’s complete reviews of environmental protection for the licensing and operation of North Anna 3 under 10 CFR Part 51 are in NUREG–1811 and NUREG–1917.

With respect to the applicant’s request for a 10 CFR Part 70 license, the staff performed the following review: The regulatory basis for the review of the North Anna 3 program applicable to the fresh fuel assemblies for the first reactor core before beginning operation is in 10 CFR Part 20, Subpart D and 10 CFR 70.22 and 70.23. The North Anna 3 facility will also use fission chamber detectors containing SNM for the reactor startup and neutron flux monitoring during reactor operations. The staff evaluated the use and handling of these fission chamber detectors for compliance with the applicable requirements in 10 CFR Parts 20 and 70.

The acceptance criteria for the NRC review of the portion of the North Anna 3 application for a 10 CFR Part 70 license described above are outlined in Section 9.4 of NUREG–1520, Revision 1. Although most portions of the acceptance criteria in Section 9.4 of NUREG–1520 are directly applicable to this review, other portions are not because of the scope of the proposed activities. For example, a review of an applicant’s Integrated Safety Analysis of accidents is conducted for fuel cycle facilities but not for reactors. In addition, certain regulatory guides and other documents referenced in Section 9.4 of NUREG–1520 are specific to fuel cycle facilities.

The radiological impacts assessment is based, in part, on information in the ESBWR DCD, Revision 10. The DCD is incorporated by reference into Revision 6 of the North Anna 3 FSAR, which was prepared to be consistent with the guidance in the SRP. This staff review focused on the incremental impact, if any, of the North Anna 3 application for the receipt, possession, inspection, and storage of SNM in the form of fresh fuel assemblies for the first reactor core loading, as applicable under 10 CFR Part 70. This review also evaluated the receipt, storage, use, and disposal of fission chamber detectors containing SNM. These detectors will be used for the reactor start up and neutron flux monitoring during reactor operations.

The staff reviewed FSAR Sections 11.4, 11.5, 12.1, 12.2, and 13.1, in addition to FSAR Table 13.4-201. These sections describe the RP and waste management program to be used for the entire facility, which includes the proposed activities that are within the scope of this review. The staff noted that several elements of Dominion's effluent controls and monitoring programs will be in place before the onsite receipt of fuel or initial fuel loading. These elements include but are not limited to the radiological environmental monitoring program, waste management program, offsite dose calculation manual, and the process and effluent monitoring and sampling program. The staff also noted that the incremental effects related to the fresh fuel assemblies for the first core loading, and the use of fission chamber detectors, do not change Dominion's ALARA goals or controls for liquid or air effluents. These goals include an analysis of the total effective dose equivalent to the maximally exposed individual member of the public who would receive the greatest radiation dose. Population dose estimates are also unaffected. Dominion's monitoring of liquid and air discharges, including monitoring locations and samples, will not be affected by receipt of fresh fuel.

As stated in FSAR Section 1.4.2.2 and Table 13.1-201, Dominion's plant personnel includes those involved in the proposed activities who will be qualified to meet the requirements in American National Standard Institute (ANSI)/American Nuclear Society 3.1-1993, "American National Standard for Selection, Qualification, and Training of Personnel for Nuclear Power Plants," as endorsed by RG 1.8, Revision 3, "Qualification and Training of Personnel for Nuclear Power Plants." FSAR Appendix 13BB, Training Program, references the NRC-approved NEI guidance NEI 06-13A, "Technical Report on a Template for an Industry Training Program Description." The staff recognizes that compliance with these documents is an acceptable method for ensuring that the facility's staff will have adequate education and training to engage in the proposed activities. The staff finds that the quality control procedures related to the collection and analyses of environmental monitoring samples will not be affected by the receipt of fresh fuel. ALARA reviews and reports to management will not be affected by activities involving the fresh fuel assemblies or the fission chamber detectors. Because the fresh fuel assemblies and fission chamber detectors contain SNM in the form of encapsulated material (i.e., not dispersible), they result in a low risk of environmental releases. Dominion's implementation of the effluent controls and monitoring programs as described in the North Anna 3 FSAR are commensurate with the activities and impacts associated with fresh fuel handling and storage and provide reasonable assurance that any releases or waste generated during the proposed activities will be adequately handled to protect the public health and safety.

Dominion has provided adequate measures including (1) environmental and effluent monitoring, (2) effluent controls to maintain public doses ALARA as part of the RP Program, and (3) waste management programs. The staff concludes, with reasonable assurance, that Dominion's conformance to the application and license conditions is adequate to protect public health and safety and complies with the regulatory requirements imposed by the Commission in 10 CFR

Parts 20 and 70. The staff finds that Dominion's effluent controls and monitoring programs, including sampling locations and frequency, staff training and qualifications, waste minimization practices, and proposed action levels for the proposed activities as described in the COLA adequately address the applicable acceptance criteria in Subsection 9.4.3.2 of NUREG–1520, Revision 1, and is therefore acceptable.

Special Nuclear Materials Material Control and Accounting Review

The staff conducted a review of the applicant's MC&A Program description. The purpose of this review was to determine whether the applicant had provided a description of an MC&A Program that would be capable of satisfying the regulatory requirements in 10 CFR Part 74, Subpart B. The staff's full evaluation has been provided in a non-publicly available Safety Related Information (SRI) Safeguards Evaluation Report (ADAMS Accession No. ML14262A315). The information below summarizes the conclusions made by the staff:

In accordance with 10 CFR 70.22(b), current applicants requesting a license to possess SNM must submit a full description of their program for the control and accounting of SNM in the applicant's possession and to show compliance with 10 CFR 74.31, 74.33, 74.41, or 74.51, as applicable. Also in accordance with 10 CFR 70.32(c), applicants requesting a license to possess SNM are subject to a license condition to maintain and follow a program for controlling and accounting for source material and SNM. Decreases in the program's effectiveness will be submitted as an amendment pursuant to 10 CFR 70.34. However, the requirements in 10 CFR 70.22(b) and 70.32(c) contain an exclusion for licensees governed by 10 CFR Part 50, including existing nuclear power plants. Moreover, the Dominion North Anna 3 COLA was submitted and accepted as a licensing action for a nuclear power plant under 10 CFR Part 52 instead of 10 CFR Part 50.

The 10 CFR Part 70 and 74 exclusions described above do not include 10 CFR Part 52 applicants, even though for purposes of the requirement, the applicants are the same facility type. For both 10 CFR Parts 50 and 52 applicants, 10 CFR Part 74, Subpart B (excluding 74.17) contains the appropriate MC&A performance requirements. An adequate applicant submittal would describe the licensee program elements that would meet the 10 CFR Part 74 requirements. Additionally, because the primary roles of the MC&A Program are to control and account for SNM, the licensee program elements would have to be developed and implemented before receiving SNM and be maintained as long as any SNM was onsite.

Since there was not any specific regulatory guidance related to MC&A licensing submittals by 10 CFR Parts 50 or 52 applicants, a process was developed that would be acceptable for this applicant and for other 10 CFR Part 52 applicants referencing the same design ESBWR. An ANSI publication, N15.8-2009, which specifically discusses MC&A methods for nuclear power plants, was identified as a resource for the applicant to use. The goal was for the applicant's MC&A description to provide assurance that the implemented program would meet the performance requirements of 10 CFR Part 74, Subpart B, excluding 74.17.

As a result it was determined that:

> (a) The applicant would provide a description of the MC&A Program and its related elements. The form and format submitted by the applicant would be informed by ANSI N15.8-2009;

(b) The applicant would request an exemption from 10 CFR 70.22(b), 70.32(c), and 10 CFR 74.31, 74.41, and 74.51, the purpose being to seek an exception for this application so that the same requirements would be applied to this program as to other reactors licensed under 10 CFR Part 50;

(c) The applicant would provide information relevant to the nuclear material they propose to possess (i.e. Category I-formula quantity, Category II-moderate strategic significance, Category III-low strategic significance);

(d) The MC&A Program will be an operational program, meaning that a formal process of ITAAC should not be necessary if the program and its implementation are fully described in the application;

(e) A licensing condition would be proposed that would require the implementation of the MC&A Program prior to the receipt of SNM on site.

MC&A Program Description

In the submittal dated July 31, 2013, the applicant's proposed Appendix 13CC titled, "Special Nuclear Material (SNM) Material Control and Accounting Program Description", provided a narrative of the MC&A Program that would be developed for the North Anna facility. The review of the applicant's proposed SNM MC&A Program in Appendix 13CC encompassed requirements in 70.22(a)(4); 74.11, "Reports of loss or theft or attempted theft or unauthorized production of special nuclear material"; 74.13, "Material status reports"; 74.15, "Nuclear material transaction reports"; and 74.19, "Recordkeeping."

The staff concluded that the scope and detail of the submittal provided reasonable assurance of program acceptability. The approaches, procedures, and commitments as outlined in the MC&A program description are likely to meet the 10 CFR Part 74, Subpart B, excluding 74.17, regulatory requirements.

Exemption Requests from 70.22(b), 70.32(c), 74.31, 74.41, and 74.51

In order for the applicant to have the same requirements applied to their SNM MC&A Program as are applied to other reactors licensed under 10 CFR Part 50, the applicant submitted requests for exemption from 10 CFR 70.22(b), 70.32(c), 74.31, 74.41, and 74.51 that are detailed in Part 7 of the application. The staff finds that these exemptions are justified and should be granted. The staff's reviews of these exemption requests are in SER Section 1.5.4.

Nuclear Material Category

The applicant's declaration that (1) the facility would be Category III as defined by the regulations and (2) the purpose of the facility was to engage in commercial power operations using small quantities of non-fuel SNM in support of that activity, provided assurance that the correct regulatory requirements for MC&A were being addressed in the submittal. For the purposes of this MC&A review, this portion of the submittal is acceptable.

MC&A Program Description and Operation Programs

Section 13 of the FSAR should address the addition of the MC&A Program to the COL application. During the review of the applicant's submittal of July 2013, it was noted that the applicant agrees with this approach. In Part 2 of the FSAR, the applicant has included a proposed Appendix 13CC, which discusses material control and SNM MC&A procedures. In addition, in FSAR Table 13.4-201, "Operational Programs Required by NRC Regulations", was revised to include item 23, SNM Material Control and Accounting Program." The table listed the implementation milestone as "prior to receipt of SNM" and the implementation requirement as "license condition." The staff agrees with the applicant's proposals, in particular that MC&A will be an operational program and that the development of MC&A procedures are formally annotated.

SNM MC&A License Condition

The staff included the following license condition previously for other applicants, as it relates to the MC&A requirements in 10 CFR Part 74. The following condition should be added to the applicant's license:

- **License Condition** - Prior to initial receipt of special nuclear materials (SNM) onsite, the licensee shall implement the SNM Material Control and Accounting program. No later than 12 months after issuance of the Combined Operating License, the licensee shall submit to the Director of Office of New Reactors (NRO) a schedule that supports planning for and conduct of NRC inspections of the SNM Material Control and Accounting program. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the SNM Material Control and Accounting program has been fully implemented.

This license condition is included in the Subsection 1.5.5.6, Parts 30, 40, and 70 License Conditions, above.

Conclusion

The staff reviewed Dominion's submitted description of the proposed MC&A Program for SNM for the North Anna 3 facility, the category of material to be possessed, and a licensing exemption request. The staff concluded that the scope and detail of the submittal provided reasonable assurance of program acceptability. The approaches, procedures, and commitments as outlined in the MC&A Program description are likely to meet the 10 CFR Part 74, Subpart B, excluding 74.17, regulatory requirements. The staff also concluded that the exemption request from certain Parts of 10 CFR Parts 70 and 74 met the criteria for exemptions as stated 10 CFR 70.17(a), 74.7, and 52.7, thus making the applicant subject to the same MC&A requirements as the existing commercial reactor fleet. Furthermore, the staff agreed that making the MC&A Program an operational program and proposing a license condition covering the implementation of the MC&A Program is consistent with the policy established in SECY-05-0197, "Review of Operational Programs in a Combined License Application and Generic Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria." The staff concludes that this MC&A description and approach is sufficient and is acceptable as described.

Fixed Site and Transportation Security for SNM in Regards to the 10 CFR 73.67 Review

This portion of the 10 CFR Part 70 materials review pertains to 10 CFR 73.67. The full technical evaluation on these topics can be found in ADAMS Access No. ML16061A038. The staff reviewed the application to determine if all fixed-site and in-transit physical protection guidance and requirements for SNM of low strategic significance were met as appropriate. The following sections represent a summary of the specific areas of the review and the staff's conclusions.

Introduction and Background

In developing the FSER for North Anna 3, the staff reviewed the ESBWR DCD to ensure that the combination of the information in the DCD and the information in the COLA represents the complete scope of information relating to a particular review topic. The staff finds that the applicant plans to bring SNM of low strategic significance in the form of new fuel assemblies on-site before the protected area is declared operational in accordance with 10 CFR 73.55(a) will be acceptable because the fresh fuel will be subject to the applicable portions of 10 CFR 73.67 and the applicable post September 11, 2001, security order measures for SNM of low strategic significance, and the applicant's plans are adequate for these purposes, as discussed below.

Regulatory Guidance and Evaluation

Fixed site and in-transit physical protection requirements:

- 10 CFR 73.67
- RG 5.59, "Standard Format and Content for a Licensee Physical Security Plan for the Protection of Special Nuclear Material of Moderate or Low Strategic Significance (1983)."
- NRC RIS 2005-22, "Requirements for the Physical Protection During Transportation of Special Nuclear Material of Moderate and Low Strategic Significance: 10 CFR Part 73 vs. Regulatory Guide 5.59 (1983)."

Technical Evaluation

A technical evaluation of the North Anna 3 COL FSAR against applicable 10 CFR 73.67 fixed site and in- transit: 1) general performance objectives, 2) general requirements, and 3) physical protection requirements for SNM of low strategic significance, was performed. In addition, the post September 11, 2001, security order measures for SNM of low strategic significance were sent to the applicant to be addressed. The letter conveying those order measures was sent on August 27, 2015 (ADAMS Accession No. ML15224B618) and the SGI containing order measures were sent under separate cover (Safeguards Local Area Network Electronic Safe (SLES) ADAMS Accession No. NS113220). Subsequently, the applicant submitted a letter dated October 9, 2015, which provided a reviewer's aid matrix that covered the applicable 10 CFR 73.67 requirements. The reviewer's aid matrix pointed out the text of the application that described the intent of meeting each element of the applicable portions of 10 CFR 73.67 (ADAMS Accession No. ML15288A072). In addition, the applicant submitted, in the same letter dated October 9, 2015, a revised Special Nuclear Material Physical Protection Program (SNMPPP) description and a response to the post September 11, 2001, security order measures for SNM of low strategic significance. The revised SNMPPP was labeled as: Revision 2, draft dated October 8, 2015, and is noted by the applicant, in the letter dated October 9, 2015, that it will be included in the next revision of the FSAR submitted to the NRC.

Fixed Site General Performance Objectives

The applicable physical protection requirements specified in 10 CFR 73.67, had general performance objectives described. The staff found that the applicant met the specified requirements.

Fixed Site General Requirements

The applicable requirements specified in 10 CFR 73.67, had general requirements. The staff found that the applicant met the specified requirements.

Fixed Cite Physical Protection Requirements

The applicable requirements specified in 10 CFR 73.67, had fixed site physical protection requirements for SNM of low strategic significance. The staff found that the applicant met the specified requirements.

In-transit General Performance Objectives

The applicable requirements specified in 10 CFR 73.67, had general performance objectives described. The staff found that the applicant met the specified requirements.

In-transit General Requirements

The applicable requirements specified in 10 CFR 73.67, had general requirements. The staff found that the applicant met the specified requirements.

In-transit Physical Protection Requirements

The applicable requirements specified in 10 CFR 73.67, had in-transit physical protection requirements described. The staff found that the applicant met the specified requirements.

Post September 22, 2011 Security Order Measures for SNM of Low Strategic Significance

Applicable Requirement: "General Performance Objectives and Requirements," described in the post September, 11, 2001, security order for SNM of low strategic significance, dated 2003 and titled, "Interim Compensatory Measures for Category-3 Fuel Cycle Facilities," has an analysis required. The applicant considered the order and assessed that only parts C and D of those order must be addressed. The discussion of the analysis that justified only Part C and D of the order needed to be addressed was within a letter sent to the NRC dated October 9, 2015, specifically in "Enclosure 2, Response to NRC RAI, Question 01.05-04, Part 2" (ADAMS Accession No. ML15288A072). In addition, in Section 1 "Scope" of the SNMPPP there is a statement reflecting that Sections A and B of the order were not applicable for particular reasons. Therefore, the analysis requirement presented in the beginning of the order, is met.

Conclusion

The staff reviewed North Anna 3 COLA and finds that the applicable requirements specified in 10 CFR 73.67 and the post September 11, 2001, security order measures for SNM of low strategic significance, are met.

Physical Protection Program in FSAR Section 13.6 in Regards to the 10 CFR 73.55 Review

Part 8 of the application contains the North Anna 3 security plan that is referenced in Part 2, FSAR Chapter 13, Section 13.6. This information includes the Physical Security Plan that contains SGI as defined by 10 CFR 73.21; its disclosure to unauthorized individuals is prohibited in Section 147 of the AEA. The staff's safety review of this information under 10 CFR Part 52 for the licensing and operation of North Anna 3 is in SER Chapter 13, Subsection 13.6. Because of information security requirements, the staff's evaluation of the physical security protection program is presented in the publicly available SER Section 13.6, but does not contain the same level of details as the SGI version. Those persons with the correct access authorization and a need to know basis may view the SGI version of the North Anna 3 COLA.

Per 10 CFR 73.55, "Requirements for physical security protection of licensed activities in nuclear power reactors against radiological sabotage," the staff reviewed the applicant's proposed security plan in Part 2 of FSAR Chapter 13, Subsection 13.6 and Part 8 of the application. The staff finds that the applicant has satisfied the regulatory requirements and provided the required information relating to physical security. The staff concludes that the applicant has provided the necessary programmatic elements in the physical security plan, the training and qualification plan, and the safeguards contingency plan, which provide a high assurance that activities involving SNM are not inimical to common defense and security and do not constitute an unreasonable risk to public health and safety.

1.5.5.9 Parts 30 and 40 License Staff Review

In order to satisfy NRC regulations and requirements for the receipt, possession, and use of byproduct and/or source materials, the applicant needed to address the following main areas for review per the guidance in NUREG–1556, Volume 7, Section 8:

- General Information – License action type, legal identities, address, points of contact.
- Materials to be possessed and used.
- Financial assurance and recordkeeping.
- Individuals responsible for the radiation safety program and training and experience, etc.
- Training for workers in restricted areas.
- Facilities and equipment.
- Radiation Safety Program.
- Waste management.
- Physical security.
- EP.

General Information

The 10 CFR Parts 30 and 40 licenses requested by the applicant are described above in Subsection 1.5.5.3, Parts 30, 40 and 70 License Request Clarifications, and in Subsection 1.5.5.6, Parts 30, 40, and 70 License Conditions. The legal identities, addresses, and points of contact are described in Part 1 of Section 2(a-d). The staff finds that the applicant has adequately addressed this information.

Materials To Be Possessed and Used

The possession and proposed uses of 10 CFR Parts 30 and 40 materials are described above in the Subsection 1.5.5.5, Parts 30, 40, and 70 Materials and Use Clarifications, in addition to the Subsection on 1.5.5.3, Parts 30, 40, and 70 License Request Clarifications. The staff finds that the applicant has adequately identified the possession and proposed uses of materials.

Financial Assurance and Recordkeeping for Decommissioning

In the application, the applicant describes this information in Part 1, Section 2(k), including Attachment E, "Decommissioning Funding Assurance Report," This information is discussed and reviewed in Section 1.5.1 of this SER. In addition, the QAPD in FSAR Appendix 17AA describes the decommissioning record keeping processes. The QAPD is reviewed in SER Chapter 17. The staff finds that the applicant has adequately addressed these items.

Individuals Responsible for the Radiation Safety Program: Qualifications, Training, and Experience

The RP Program for North Anna 3 is described in FSAR Section 12.5, Appendices 12AA and 12BB. In SER Chapter 12, the staff finds the applicant's programs acceptable. In regards to RP managers, supervisors, and technicians, FSAR Section 13.1 describes the job and function for these positions. In addition, qualifications and training for these positions are described in FSAR Sections 13.1 and 13.2. The staff reviewed this information in SER Chapter 13 and finds it acceptable.

Training for Workers in Restricted Areas

The RP Program for North Anna 3 is described in FSAR Section 12.5, Appendices 12AA and 12BB. In SER Chapter 12, the staff finds the applicant's programs acceptable. The training criteria for workers in restricted areas are described in FSAR Section 13.2. The staff reviewed this information in SER Chapter 13 and finds it acceptable.

Facilities and Equipment

The physical arrangement and design features for RP is described in FSAR Section 12.3. In addition, in FSAR Sections 12.5, Appendices 12AA and 12BB describe the programs, facilities, instrumentation, and equipment provided to support the implementation of the RP Program. The staff reviewed this information in SER Chapter 12 and finds it acceptable.

Radiation Safety Program

The applicant describes the Operational RP Program in FSAR Section 12.5. The staff finds the applicant's RP Program acceptable in SER Chapter 12. Qualifications, training, and experience for managers, supervisors, and technicians are described in FSAR Sections 13.1 and 13.2. The staff reviewed this information in SER Chapter 13. Radiation control procedures and the maintenance of radiation records will be established by the applicant's QAPD, as presented in FSAR Appendix 17AA. The QAPD is reviewed in SER Chapter 17. In addition, FSAR Table 13.4-201 provides the applicant's commitments to implement the RP programs. The staff reviewed this information in SER Chapters 12 and 13 and finds it acceptable. The staff finds that the applicant has adequately addressed these items.

Waste Management

The radioactive waste management system includes the liquid waste management system (LWMS, Section 11.2); gaseous waste management system (GWMS, Section 11.3); solid waste management system (SWMS, Section 11.4); and process effluent radiation monitoring and sampling systems (PERMS, Section 11.5) as described in the FSAR. The staff evaluated these systems and associated programs and information supplied by the applicant. The staff concludes that the information pertaining to the applicant's waste management systems and programs in Chapter 11 is acceptable.

Physical Security

The applicant's physical security program is described in FSAR Section 13.6. The staff reviewed the Physical Security Program in SER Section 13.6 and finds it acceptable.

Emergency Preparedness (10 CFR Parts 30, 40, and 70 (SNM, Fuel and Non-Fuel) Materials)

The following regulations address emergency planning requirements associated with issuance of licenses to receive, possess, and use source, byproduct, or SNM:

- 10 CFR 30.32(i)(1) requires that each application to possess radioactive materials in unsealed form, on foils or plated sources, or sealed in glass in excess of the quantities in 10 CFR 30.72, "Schedule C—Quantities of radioactive materials requiring consideration of the need for an emergency plan for responding to a release," must contain either: (1) an evaluation showing that the maximum dose to a person offsite due to a release of radioactive materials would not exceed 1 rem effective dose equivalent or 5 rems to the thyroid; or (2) an emergency plan for responding to a release of radioactive material, that provides the information identified in 10 CFR 30.32(i)(3).

- 10 CFR 40.31(j)(1) requires that each application to possess uranium hexafluoride in excess of 50 kilograms in a single container or 1000 kilograms total must contain either: (1) an evaluation showing that the maximum intake of uranium by a member of the public due to a release would not exceed 2 milligrams; or (2) an emergency plan for responding to the radiological hazards of an accidental release of source material and to any associated chemical hazards directly incident thereto, that provides the information identified in 10 CFR 40.31(j)(3).

- 10 CFR 70.22(i)(1) requires that each application to possess enriched uranium or plutonium for which a criticality accident alarm system is required, uranium hexafluoride in excess of 50 kilograms in a single container or 1000 kilograms total, or in excess of 2 curies of plutonium in unsealed form or on foils or plated sources, must contain either: (1) an evaluation showing that the maximum dose to a member of the public offsite due to a release of radioactive materials would not exceed 1 rem effective dose equivalent or an intake of 2 milligrams of soluble uranium; or (2) an emergency plan for responding to the radiological hazards of an accidental release of SNM and to any associated chemical hazards directly incident thereto, that provides the information identified in 10 CFR 70.22(i)(3).

In COLA Part 1, Section 1, “Introduction,” the applicant stated that Dominion applies for a COL of North Anna 3, as well as such other licenses as would be required to possess and use byproduct, source, and SNM in connection with the operation of North Anna 3. Pursuant to Section (a) of 10 CFR 52.8, the applicant further stated in COLA Part 1, Section 2(e), “Class of License, Use of Facility, Period of Time for which the License is Sought, and Other Licenses Issued or Applied for in Connection with the Proposed Facility,” that the application also seeks licenses to receive, possess and use source, byproduct, and SNM in connection with operation of North Anna 3.[7] Finally, in COLA Part 10, Section 3.3, “License Conditions for Byproduct, Source and Special Nuclear Material,” the applicant proposed four license conditions for byproduct, source, and SNM, which reflect the respective requirements in 10 CFR Parts 30, 40, and 70.[8] The staff’s proposed license conditions for the North Anna 3 COL, as they relate to authorization pursuant to the regulations in 10 CFR Parts 30, 40, and 70, are provided above in SER Section 1.5.5.6, “Parts 30, 40, and 70 License Conditions.”

The staff previously examined byproduct, source, and SNM associated with the ESBWR standard design, and discussed these materials in Section 12.3.3.1, “Contained Sources,” of NUREG–1966, Volume 3 (Chapters 9-15) (ADAMS Accession No. ML14099A532). The discussion identified COL Information Item 12.2-4-A, and stated that the addition of this COL information item ensures that any radiation sources containing byproduct, source, or SNM will either be described in the DCD or by the COL applicant, as specified in SRP Section 12.2, “Radiation Sources.”

DCD Tier 2, Section 12.2, “Plant Sources,” describes radiation sources associated with the ESBWR design, and DCD Tier 2, Section 12.2.4, “COL Information,” includes COL Information Item 12.2-4-A, which states that “[t]he COL applicant will address any additional contained radiation sources (including sources for instrumentation and radiography) not identified in [DCD Tier 2] Subsection 12.2.1.5.” In COLA Part 2, FSAR Section 12.2, “Plant Sources,” the COL applicant described the various types and quantities of radiation sources that may be used on the site, and incorporated by reference DCD Tier 2 Section 12.2 (with various departures and/or supplements). In addition, FSAR Section 12.2.1.1.2, “Other Radioactive Sources,” describes the Cf-252 reactor startup source (identified as STD SUP 12.2-1), which supplements the radioactive sources identified in DCD Tier 2, Section 12.2.1.1.2, “Other Radioactive Sources.”

---

[7] See also, 10 CFR 52.77 and its referenced Section (e) of 10 CFR 50.33, which requires the applicant to list other licenses, except operator’s licenses, issued or applied for in connection with the proposed facility.
[8] SECY-00-0092 dated April 20, 2000, and the associated September 5, 2000, Staff Requirements Memorandum address the form and content of the generic COL, issued pursuant to 10 CFR Part 52, which includes generic (standard) license conditions for 10 CFR Parts 30, 40, and 70 materials.

The applicant replaced DCD Tier 2 [Sub]section 12.2.1.5 with FSAR Section 12.2.1.5, "Other Contained Sources," which addresses COL Information Item 12.2-4-A (identified as COL Item CWR COL 12.2-4-A[9]) by describing additional contained (byproduct, source, or SNM) sources that may be maintained on the North Anna 3 site, and includes specific limitations (listed below) for these byproduct, source, and SNM that would apply during the period of time prior to the implementation of the Emergency Plan (i.e., between issuance of the COL and implementation of the North Anna 3 Emergency Plan, which will occur prior to the Commission's 10 CFR 52.103(g) finding). Specifically, the applicant stated that prior to the implementation of the North Anna 3 Emergency Plan, no emergency plan will be necessary because:

1. No byproduct material will be received, possessed, or used in a physical form that is "in unsealed form, on foils or plated sources, or sealed in glass," that exceeds the quantities in Schedule C in 10 CFR 30.72;

2. No 10 CFR [Part] 40 specifically licensed material, including natural uranium, depleted uranium, and uranium hexafluoride, will be received, possessed, or used during this period; and

3. The SNM to be received, possessed, or used does not involve enriched uranium for which a criticality accident alarm system is required, uranium hexafluoride in excess of 50 kilograms in a single container or 1000 kilograms total, or in excess of 2 curies of plutonium in unsealed form or on foils or plated sources.

The North Anna 3 Emergency Plan is included in COLA Part 5, "Emergency Plan," and the staff's evaluation of the Emergency Plan is addressed in SER Section 13.3, "Emergency Planning." The resolution of DCD COL Information Item 12.2-4-A is addressed in SER Section 12.2, "Radiation Sources."

In its December 18, 2013, letter (ADAMS Accession No. ML14013A113), the applicant provided the results of its review and disposition of RAIs and responses that are associated with the updated COLA content in the December 2013 COLA submission. These review results addressed whether an emergency plan that meets the requirements in 10 CFR 30.32(i)(3), 10 CFR 40.31(j)(3), or 10 CFR 70.22(i)(3) is required, in relation to the requested 10 CFR Parts 30, 40, and 70 (SNM, fuel and non-fuel) materials license applications, respectively. Specifically, in Enclosure 25, Attachment 1, of the December 18, 2013, letter, the applicant stated that the materials to be possessed and proposed uses are described in COLA Part 1, Section 2(e), and FSAR Chapter 12, including the portions of ESBWR DCD Chapter 12 incorporated by reference.

In Enclosure 25, Attachment 2, of the December 18, 2013, letter, the applicant further stated that an emergency plan that meets 10 CFR 70.22(i)(3) is not required because the request for a 10 CFR Part 70 license does not involve authorization to possess enriched uranium for which a criticality accident alarm system is required, uranium hexafluoride in excess of 50 kilograms in a single container or 1000 kilograms total, or in excess of 2 curies of plutonium in unsealed form or on foils or plated surfaces.

[9] As defined in FSAR Table 1.1-201, "Left Margin Annotations," CWR COL.X.Y-#-A identifies FSAR information that addresses a DCD COL Item and is similar to information presented in the R-COL application (i.e., Fermi 3 Reference COL application) for the same ESBWR DCD.

The staff reviewed the DCD and COLA information (described above) against the applicable requirements in 10 CFR 30.32(i)(1), 10 CFR 40.31(j)(1), and 10 CFR 70.22(i)(1), and concludes that the applicant's identified quantities of byproduct, source, and SNM do not exceed the respective threshold quantities that would require an emergency plan – that meets the respective requirements in 10 CFR 30.32(i)(3), 10 CFR 40.31(j)(3), and 10 CFR 70.22(i)(3) – prior to the implementation of the North Anna 3 Emergency Plan.

When the 10 CFR 52.103(g) finding is made, the North Anna 3 Emergency Plan will have been fully implemented, as reflected in the implementation milestones in FSAR Table 13.4-201, "Operational Programs Required by NRC Regulations" (i.e., Item 14, "Emergency Planning") and SER Section 13.3.4.19, "Implementation Milestones." In addition, completion of the emergency planning ITAAC in SER Table 13.3-1, "NAPS Unit 3 ITAAC," which address full implementation of the North Anna 3 Emergency Plan, is required prior to the Commission's 10 CFR 52.103(g) finding.

Therefore, the staff finds that the applicant has met the requirements of 10 CFR 30.32(i)(1), 10 CFR 40.31(j)(1), and 10 CFR 70.22(i)(1), such that prior to implementation of the North Anna 3 Emergency Plan, an emergency plan that meets 10 CFR 30.32(i)(3), 10 CFR 40.31(j)(3), or 10 CFR 70.22(i)(3) is not required.

1.5.5.10 Part 37 Staff Review

On March 19, 2013, a new 10 CFR Part 37, "Physical Protection of Category 1 and Category 2 Quantities of Radioactive Material," rule was published in the FR. The NRC amended its regulations to establish security requirements for the use and transport of Category 1 and Category 2 quantities of radioactive material. The NRC considers these quantities to be risk significant and, therefore, to warrant additional protection. Category 1 and Category 2 thresholds are based on the quantities established by the International Atomic Energy Agency (IAEA) in its Code of Conduct on the Safety and Security of Radioactive Sources, which the NRC endorses. The objective of the 10 CFR Part 37 rule is to provide reasonable assurance of preventing the theft or diversion of Category 1 and Category 2 quantities of radioactive material. The regulations also include security requirements for the transportation of irradiated reactor fuel that weighs 100 grams or less in net weight of irradiated fuel. The 10 CFR Part 37 rule affects any licensee that possesses an aggregated Category 1 or Category 2 quantity of radioactive material, any licensee that transports these materials using ground transportation, and any licensee that transports small quantities of irradiated reactor fuel. The 10 CFR Part 37 rule compliance date was March 19, 2014.

Upon further review by the staff, it was determined that the regulations of 10 CFR Part 37 do not require COL applicants to address 10 CFR Part 37. After COL issuance, a COL licensee becomes subject to the requirements of this regulation upon taking possession of an aggregated Category 1 or Category 2 quantity of radioactive material.

1.5.5.11 Conclusion

Based on the reviews discussed above, the staff finds that the applicant has used a combination of the information in the referenced ESBWR DCD and the information in the COLA, including supplemental COL information, in order to demonstrate compliance with the requirements of 10 CFR Part 52. The applicant's compliance with 10 CFR Part 52 licensing encompasses the necessary requirements to support granting 10 CFR Parts 30, 40, and 70 licenses consistent with operating licenses for nuclear power plants licensed in accordance with 10 CFR Part 50. The staff used the guidance in the SRP, NUREG–1520, and NUREG–1566.

The privileges to be granted under the 10 CFR Parts 30, 40, and 70 licenses are detailed by the staff in the proposed License Conditions specified above in Section 1.5.5.6. Therefore, the applicant for the North Anna 3 COL will also be authorized to receive, possess, and use source, byproduct, and SNM in accordance with the Commission's regulations in 10 CFR Parts 30, 40, and 70; including 10 CFR Sections 30.33, 40.32, 70.23, and 70.31. The applicant complies with all applicable regulations of 10 CFR Parts 30, 40, and 70; as well as the regulations in 10 CFR Parts 20, 50, 51 and 52.

2 SITE CHARACTERISTICS

2 SITE CHARACTERISTICS

2.0 North Anna 3 Site

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the NRC staff evaluation of the North Anna 3 Combined License (COL) Final Safety Analysis Report (FSAR) which addresses the geological, seismological, hydrological, and meteorological characteristics of the site and vicinity, in conjunction with present and projected population distributions and land use and site activities and controls.

2.0.1 Introduction

The site characteristics are reviewed by the staff to determine whether the applicant has accurately described the site characteristics and site parameters together with site-related design parameters and design characteristics in accordance with Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." The review is focused on the site characteristics and site-related design characteristics needed to enable the staff to reach a safety conclusion on the siting of North Anna 3. The North Anna 3 combined license application (COLA) references the Economic Simplified Boiling-Water Reactor (ESBWR) Design Control Document (DCD), referenced in Appendix E to 10 CFR Part 52 as well as the North Anna 3 early site permit (ESP), specifically ESP-003, the ESP for the North Anna 3 site, issued pursuant to 10 CFR 52.24, "Issuance of early site permit." For a COLA referencing a design certification (DC) and an ESP, the staff's review focuses on the applicant's demonstration that the site characteristics and site-related design parameters specified in the ESP fall within the site parameters and design characteristics specified in the DC.

2.0.2 Summary of Application

Section 2.0, "Site Characteristics," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 2.0 of the ESBWR DCD, Revision 10. In addition, North Anna 3 FSAR Section 2.0 incorporates by reference ESP-003. The staff review of the North Anna 3 site ESP Application includes the site safety analysis report (SSAR), Revision 9 (Agencywide Documents Access and Management System (ADAMS) Accession No. ML062580096)), which describes the applicant's safety assessment of the site, as required by 10 CFR 52.17, "Contents of application; technical information." The staff documented its review of the North Anna 3 ESP SSAR in NUREG-1835, "Safety Evaluation Report for an Early Site Permit (ESP) at the North Anna ESP Site" (ADAMS Accession No. ML052710305), the staff Final Safety Evaluation Report (FSER) for the North Anna 3 ESP and NUREG-1835 Supplement 1 (ADAMS Accession No. ML063170371).

In addition, in FSAR Section 2.0, the applicant provided the following information:

COL Items:

- NAPS COL 2.0-1-A Site Characteristics Demonstration

The applicant provided Table 2.0-201 in response to this COL item. Part 1 of Table 2.0-201 identifies each DCD site parameter value and the corresponding ESP and North Anna 3 site characteristic values. In addition, Part 1 provides an evaluation, as applicable, of whether (1) ESP site characteristic values fall within DCD site parameter values; (2) North Anna 3 site characteristic values fall within DCD site parameter values; and (3) North Anna 3 site characteristic values fall within ESP site characteristic values.

- NAPS COL 2.0-2-A - 2.0-30-A Standard Review Plan Conformance

The applicant provided detailed information related to North Anna 3 site characteristics in FSAR Sections 2.1 through 2.5, which incorporate by reference the corresponding ESP SSAR sections. In addition, the applicant provided Table 2.0-2R, which brings forward the ESBWR DCD Table 2.0-2, "Limits Imposed on Acceptance Criteria in Section II of Standard Review Plan (SRP) by ESBWR Design," and identifies specific COL items to be addressed in subsequent FSAR sections. In Table 2.0-2R, the COL Item from the DCD is replaced with information responding to the specific North Anna 3 COL item and identifying the FSAR section that addresses the SRP section invoked by the respective COL item.

Supplemental Information:

- NAPS SUP 2.0-1 Site Specific Parameter Values not in DCD

The applicant provided Part 2 of Table 2.0-201 as supplemental information. Part 2 of Table 2.0-201 identifies those ESP site characteristics and design parameters for which there is no corresponding DCD site parameter value. Part 2 also evaluates whether the North Anna 3 site characteristic or facility design value falls within the ESP site characteristic or ESP design parameter value.

- NAPS SUP 2.0-2 Site Specific Parameter Values not in DCD or ESP

The applicant provided Part 3 of Table 2.0-201 as supplemental information. Part 3 of Table 2.0-201 identifies those site characteristics and design parameters listed in SSAR Table 1.9-1, for which there is not already a comparison to a corresponding DCD or ESP value in the first two parts of Table 2.0-201. Part 3 also evaluates whether the North Anna 3 site characteristic or facility design value falls within the SSAR Table 1.9-1 site characteristic or design parameter value which has been incorporated by reference into the North Anna 3 FSAR.

Early Site Permit Variance:

The following variance from the ESP SSAR is discussed in Section 2, "Variances," of Part 7 to the COLA:

- NAPS ESP VAR 2.0-7 Coordinates/Removal of abandoned mat foundations

This variance is discussed in the Variances Section of the Departures Report (Part 7) of the COLA and contains two parts as discussed below:

The COL applicant requested a variance from one of the coordinate systems that define the "ESP Plant Parameter Envelope" shown in the ESP, Appendix A, Figure 1, which lists the coordinates of the site in State NAD 83 South Zone, as well as in the North Anna 3 site Grid coordinates. In the variance, the COL applicant requested to use the values given in North Anna 3 COL FSAR Figure 2.0-205 as "COORDINATES (STATE PLANE NAD 83 VA SOUTH ZONE)," to replace those in the ESP given as "Coordinates (State NAD 83 South Zone)." The review of this part of the variance request is discussed below in Section 2.4.1.

The COL applicant requested a variance from ESP, Appendix A, Figure 1, Note 2, which states, “Abandoned Unit 3 and 4 Reactor Building Mat Foundations are to be removed.” The applicant requests to not remove the abandoned mat foundations for the originally planned North Anna Units 3 and 4 unless a Unit 3 Seismic Category I or II structure would be located above an abandoned foundation. The review of this part of the variance request is discussed below.

2.0.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, “Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling Water Reactor” and in NUREG-1835. In addition, the acceptance criteria associated with the relevant requirements of the Commission regulations for the site characteristics, and the associated acceptance criteria, are given in Section 2.0 of NUREG-0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition),” the SRP.

The acceptance criteria for the additional information presented in the FSAR beyond that presented in the staff FSER related to the ESBWR DCD and the North Anna 3 site ESP are based on meeting the following relevant requirements of 10 CFR Parts 52 and 100, Reactor Site Criteria”:

The applicable regulatory requirements are the following:

- 10 CFR 52.79(a)(1)(i)-(vi) provides the site-related contents of a COLA.

- 10 CFR 52.79(b) applies to a COL referencing an ESP as the COL relates to information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP.

- 10 CFR 52.79(d)(1) applies to a COL referencing a DC as the COL relates to information sufficient to demonstrate that the characteristics of the site fall within the site parameters specified in the DC.

The related acceptance criteria are the following:

- The acceptance criteria associated with specific site characteristics/parameters and site-related design characteristics/parameters are contained in the related sections of SRP Chapter 2 or other referenced SRP sections.

For a COLA referencing an ESP and a DC, acceptance is based on the applicant’s demonstration that the site characteristics and site-related design parameters specified in the ESP fall within the site parameters and design characteristics specified in the DC. If the actual site characteristics do not fall within the certified standard design site parameters, the COL applicant should provide sufficient justification (e.g., by request for a variance from the ESP) that the proposed facility is acceptable at the proposed site.

2.0.4 Technical Evaluation

The staff reviewed Section 2.0 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD, Revision 10 and the North Anna 3 site ESP SSAR, Revision 9, to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and North Anna 3 site ESP appropriately represents the complete scope of information relating to this review topic.[1]

The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to this introductory section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

COL Items:

- NAPS COL 2.0-1-A — Site Characteristics Demonstration

The ESBWR DCD site parameter values for the standard plant are identified in DCD Tier 2, Table 2.0-1 and DCD Tier 1, Table 5.1-1.

- NAPS COL 2.0-2-A - 2.0-30-A — Standard Review Plan Conformance

Information on North Anna 3 site characteristics is provided in Section 2.1 through Section 2.5 of this SER. This information addresses NRC guidance in NUREG 0800 as identified in Table 2.0-2R. In the "COL Information" column, the COL item from the DCD is replaced with information responding to the COL item and identifying the FSAR section which addresses the SRP section invoked by the COL item.

The staff reviewed the COL information in North Anna 3 COL FSAR Section 2.0, "Site Characteristics," describing the characteristics and site-related design parameters for the North Anna 3 site. The appropriateness of the site characteristic values presented by the applicant for the North Anna 3 site is reviewed by the staff in Section 2.1 through 2.5 of this SER. The applicant compared its site-specific characteristics to the DCD site parameters from DCD Tier 2, Table 2.0-1 and DCD Tier 1, Table 5.1-1 in North Anna 3 COL FSAR Table 2.0-2R and Table 2.0-201.

The staff reviewed the applicant's comparison of site-specific characteristics against the ESBWR DCD and North Anna 3 site ESP for site-specific design parameters and finds the applicant provided in its FSAR Tables 2.0-2R, and 2.0-201 the applicable North Anna 3 site and design specific information that show that the COL design parameters are bounded or are addressed further in specific FSAR sections as noted and therefore is acceptable.

Supplemental Information:

- NAPS SUP 2.0-1 — Site Specific Parameter Values not in DCD

In North Anna 3 FSAR Table 2.0-201 Part 2 the applicant provided an evaluation of ESP site characteristics and design parameters for which there is no corresponding DCD site parameter and provided a reference as to where these parameters were evaluated in the North Anna 3 ESP or addressed in the North Anna 3 FSAR as applicable.

[1] See *"Finality of Referenced NRC Approvals"* in SER Section 1.2.2 for a discussion on the staff's review related to verification of the scope of information to be included in a COL application that references a design certification.
.

- NAPS SUP 2.0-2 Site Specific Parameter Values not in DCD or ESP

In North Anna 3 FSAR Table 2.0-201 Part 3 the applicant provided an evaluation of site-specific design parameters that were not included as part of the North Anna DCD or ESP. These parameters are described in the North Anna 3 ESP SSAR Table 1.9-1 which was incorporated by reference into the North Anna 3 FSAR and are not specifically evaluated by the staff.

The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this introductory section.

- NAPS ESP VAR 2.0-7 Coordinates/Removal of abandoned mat foundations

The COL applicant requested a variance from one of the coordinate systems that define the "ESP Plant Parameter Envelope" shown in the ESP, Appendix A, Figure 1, which lists the coordinates of the site in State NAD 83 South Zone, as well as in the North Anna 3 site Grid coordinates. In the variance, the COL applicant requested to use the values given in North Anna 3 COL FSAR Figure 2.0-205 as "COORDINATES (STATE PLANE NAD 83 VA SOUTH ZONE)," to replace those in the ESP given as "Coordinates (State NAD 83 South Zone)." The review of this part of the variance request is discussed below in Section 2.4.1.

The COL applicant requested a variance from ESP, Appendix A, Figure 1, Note 2, which states, "Abandoned Unit 3 and 4 Reactor Building Mat Foundations are to be removed." In the variance request, the COL applicant states that North Anna Unit 3 Site characteristics are such that removal of abandoned mat foundations is not necessary because the arrangement of a single ESBWR unit selected for this site allows the power block Seismic Category I and II structures to be located away from the abandoned mat foundations.

According to the layout of the ESBWR plant design at the North Anna Unit 3 site, COL site investigation results and the excavation and backfill plan of the applicant, all Seismic Category I structures will be founded on new concrete fill with underlying sound rock, and all safety-related or Seismic Category I or II structures will be away from the abandoned foundations. In view of the plant design layout, and insofar as the requested variance would allow the applicant to leave the abandoned Unit 3 and 4 Reactor Building Mat Foundations in place, the staff finds the variance acceptable because the abandoned foundations will have no adverse effect on Seismic Category I or II structures at the North Anna Unit 3 site.

The requested variance, however, also indicates that the applicant would "not remove the abandoned mat foundations . . . unless a Unit 3 Seismic Category I or II structure would be located above an abandoned foundation." In this regard, FSAR Figure 2.4-201 shows the site layout, and shows Unit 3 Seismic Category I and II structures in locations where they will not be adversely affected by the abandoned mat foundations. Changes to the site layout in FSAR Figure 2.4-201 are subject to control under the provisions of 10 CFR 50.59, and this control is sufficient to ensure that Dominion will account for any effect the abandoned mat foundations might have with respect to Unit 3 Seismic Category I and II structures as a result of an change to the site layout. Accordingly, the staff finds the requested variance acceptable in regard to removal of the abandoned mat foundations.

2.0.5 Post Combined License Activities

There are no post COL activities associated with this section.

2.0.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966 and NUREG-1835. The staff reviewed the application and checked the referenced DCD and the North Anna 3 site ESP. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, "Design Certification Rule for the ESBWR Design," Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference are resolved.

In addition, the staff compared the additional COL information in the application, and the applicant's supplemental COL information to the relevant NRC regulations, the guidance in Section 2.0 of NUREG–0800, and other NRC regulatory guides (RGs). The staff concludes that North Anna 3 COL FSAR, Section 2.0 is acceptable and meets NRC regulatory requirements in 10 CFR 52.79(a)(1)(i) - (vi), 10 CFR 52.79(d)(1), 10 CFR Part 100, and Section 2.0 of NUREG-0800.

Conclusions related to the staff's evaluation of information contained in North Anna Power Station (NAPS) COL 2.0-2-A - 2.0-30-A are provided in Sections 2.1 through 2.5 of this SER.

2.1 Geography and Demography

Section 2.1 of the North Anna 3 FSAR, Revision 8, discusses the site characteristics that could affect the safe design and siting of the plant and includes information about the site boundaries and location of the site with respect to prominent natural and man-made features.

The descriptions of the site area and reactor location are used to assess the acceptability of the reactor site. This review covers the following specific areas: (1) specification of reactor location with respect to latitude and longitude, political subdivisions; and prominent natural and man-made features of the area; (2) site area map to determine the distance from the reactor to the boundary lines of the exclusion area, including consideration of the location, distance, and orientation of plant structures with respect to highways, railroads, and waterways that traverse or lie adjacent to the exclusion area; and (3) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52. The purpose of the review is to ascertain the accuracy of the applicant's description for use in independent evaluations of the exclusion area authority and control, the surrounding population, and nearby manmade hazards.

2.1.1 Introduction

Section 2.1, "Geography and Demography," of the North Anna 3 COL FSAR addresses site-specific information related to the site location and description, exclusion area authority and control, and population distribution.

2.1.2 Summary of Application

Section 2.1 of the North Anna 3 COL FSAR incorporates by reference the ESP SSAR Section 2.1.1 and includes supplemental information.

COL Items:

- NAPS COL 2.0-2-A Site Location and Description

The proposed location for North Anna 3 is located within the existing North Anna Power Station site (North Anna site) located in Louisa County, Virginia, adjacent to North Anna 1 and 2. The North Anna 3 FSAR specifies the latitude, longitude, and coordinates for the North Anna 3 site.

- NAPS ESP COL 2.1-1 Coordinates of the Unit 3 Reactor Building

The applicant provided supplemental information on the site location and the site area pertaining to ownership and control; and the coordinates of the North Anna 3 Reactor Building (RB) to address ESP COL Action Item 2.1-1.

- NAPS COL 2.0-3-A Exclusion Area Authority and Control

The North Anna 3 Exclusion Area Boundary (EAB) is the perimeter of a 5,000ftradius circle from the center of the abandoned North Anna 3 containment. This is the same as the exclusion area for the existing units.

- NAPS ESP COL 2.1-2

The applicant provided supplemental information to satisfy the requirements of NAPS ESP COL Action Item 2.1-2.

- NAPS ESP Permit Condition 3.E(1)

The applicant provided supplemental information to address NAPS ESP Permit Condition 3.E(1). The information emphasizes that the applicant maintains current control of the North Anna site and exclusion area under an existing agreement with Old Dominion Electric Co-operative (ODEC), so no approvals are required by State law for shared control of the exclusion area. As the owners of the North Anna site, Dominion and ODEC possess the right to implement the site redress plan.

- NAPS COL 2.0-4-A Population Distribution

The permanent population data presented in this section are primarily derived using the 1990 Census and 2000 Census data as the basis.

2.1.3 Regulatory Basis

The acceptance criteria associated with the relevant requirements of the Commission regulations for the site characteristics are given in Section 2.0 of NUREG-0800.

The regulatory basis for incorporating information by reference into the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP, provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, sufficient information to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP. The regulatory basis for the information presented in the ESP SSAR is addressed in the staff FSER related to the ESP SSAR (i.e., NUREG-1835).

The applicable regulatory requirements for identifying the site location and description are as follows:

- 10 CFR Part 50, "Domestic Licensing of Production and Utilization Facilities," and 10 CFR Part 52, as they relate to inclusion in the Safety Analysis Report (SAR) of a detailed description and safety assessment of the site on which the facility is to be located, with appropriate attention to features affecting facility design (10 CFR 50.34(a)(1)) and 10 CFR 52.79(a)(1)).

- 10 CFR Part 100, as it relates to the following: (1) defining an exclusion area and setting forth requirements regarding activities in that area (10 CFR 100.3, "Definitions"); (2) addressing and evaluating factors that are used to determine the acceptability of the site as identified in 10 CFR 100.20(b); (3) determining an exclusion area where certain dose limits would not be exceeded in the event of a postulated fission product release, as identified in 10 CFR 50.34(a)(1) as it relates to site evaluation factors identified in 10 CFR Part 100; and (4) requiring that the site location and the engineered features included as safeguards against the hazardous consequences of an accident, should one occur, should ensure a low risk of public exposure.

- 10 CFR 100.20(a) and 10 CFR 100.20(b) as they relate to population densities.

- The acceptance criteria presented in the ESP SSAR are based on meeting the following relevant requirements of 10 CFR Parts 52 and 100.

The related acceptance criteria are:

- Specification of Location:

  The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.34(a)(1) and 10 CFR 52.79(a)(1) if it describes highways, railroads, and waterways that traverse the exclusion area in sufficient detail to allow the reviewer to determine that the applicant has met the requirements in 10 CFR 100.3.

- Site Area Map:

  The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.34(a)(1) and 10 CFR 52.79(a)(1) if it describes the site location, including the exclusion area and the location of the plant within the area, in sufficient detail to enable the reviewer to evaluate the applicant's analysis of a postulated fission product release, thereby allowing the reviewer to determine (in Sections 2.1.2 and 2.1.3 of NUREG-0800, and Chapter 15) that the applicant has met the requirements of 10 CFR 50.34(a)(1) and 10 CFR Part 100.

- Establishment of Authority:

  The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.33, "Contents of applications; general information," 10 CFR 50.34(a)(1), 10 CFR 52.79, "Contents of application; technical information in final safety analysis report," and

10 CFR Part 100 if it provides sufficient detail to enable the staff to evaluate the applicant's legal authority within the designated exclusion area.

- Exclusion or Removal of Personnel and Property:

  The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.33, 10 CFR 50.34(a) (1), 10 CFR 52.79, and 10 CFR Part 100 if it provides sufficient detail to enable the staff to evaluate the applicant's legal authority for the exclusion or removal of personnel or property from the exclusion area.

- Proposed and Permitted Activities:

  The information submitted by the applicant is adequate and meets the requirements of 10 CFR 50.33, 10 CFR 50.34(a)(1), 10 CFR 52.79, and 10 CFR Part 100 if it provides sufficient detail to enable the staff to evaluate the applicant's legal authority over all activities within the designated exclusion area.

- Population Data:

  The population data supplied by the applicant in the SAR is acceptable under the following conditions: (1) the SAR contains population data from the latest census and projected population at the year of plant approval and 5 years thereafter, in the geographical format given in Section 2.1.3 of RG 1.70, "Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants, LWR Edition," and in accordance with RG 1.206, "Combined License Applications for Nuclear Power Plants," (2) the SAR describes the methodology and sources used to obtain the population data, including the projections; (3) the SAR includes information on transient populations in the site vicinity.

- Exclusion Area:

  The exclusion area should either not contain any residents, or such residents should be subject to ready removal if necessary.

- Low-Population Zone (LPZ):

  The specified LPZ is acceptable if it is determined that appropriate protective measures could be taken on behalf of the enclosed populace in the event of a serious accident.

- Nearest Population Center Boundary:

  The nearest boundary of the closest population center containing 25,000 or more residents is at least one and one-third times the distance from the reactor to the outer boundary of the LPZ. Population Density: If the population density exceeds the guidelines in Regulatory Position C.4 of RG 4.7, "General Site Suitability Criteria for Nuclear Power Stations," the applicant must give special attention to the consideration of alternative sites with lower population densities.

- Population Density:

If the population density exceeds the guidelines in Regulatory Position C.4 of RG 4.7, the applicant must give special attention to the consideration of alternative sites with lower population densities.

2.1.4 Technical Evaluation

As documented in NUREG-1966, the staff reviewed and approved Section 2.1 of the certified ESBWR DCD, Revision 9. The staff reviewed Section 2.1 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESP SSAR, Revision 9 and the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 COL FSAR, the ESP SSAR, and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1]

The staff's review confirmed that the information contained in the application address the relevant information related to this section. The staff reviewed the information in the North Anna 3 COL FSAR as follows:

COL Items:

- NAPS COL 2.0-2-A Site Location and Description

The applicant incorporated by reference ESP SSAR Section 2.1.1 to resolve DCD COL Item 2.0-2-A, related to the site location and description, including political subdivisions, natural and man-made features, population, highways, railways, waterways, and other significant features of the area included under Section 2.1 of the COL FSAR.

The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to site location and description.

- NAPS ESP COL 2.1-1 Location Coordinates for the Unit 3

The applicant provided the following supplemental information regarding the site location:

> The site layout and boundary for the proposed North Anna 3, shown in Figure 2.1-201 of the COL FSAR, remains within the ESP proposed facility boundary as shown in Figure 2.0-205 of the COL FSAR. The center of the North Anna 3 RB is approximately 450 meters (m) (1,476 feet (ft)) southwest of the center of the Unit 2 Containment Building.
>
> The staff has independently estimated and verified the following latitude and longitude and universal transverse Mercator (UTM) coordinates of the proposed North Anna 3 site in the FSAR as summarized in the table below.

UTM coordinates (meters)	Latitude/longitude (degree/minute/second)
Zone 18, North American Datum (NAD) 83; 4,216,007 meters north; 254,783 meters east	38 03 31.01 north; 77 47 41.8 west

On the basis of the staff's review of the information addressed in the North Anna 3 COL FSAR, the staff's confirmatory review of pertinent information generally available in the literature and in the information provided by the applicant with regard to the site location is considered adequate and acceptable.

- NAPS COL 2.0-3-A Site Specific Exclusion Area Authority and Control

The applicant incorporated by reference ESP SSAR Section 2.1.2 to address DCD COL Item2.0-3-A. The staff finds the information incorporated by reference in the ESP acceptable because the information provided and reviewed in the ESP are still relevant and applicable to this COLA.

- NAPS ESP Permit Condition 3.E(1)

The applicant supplemented Section 2.1.2.1 of the ESP SSAR with the information to address the authority of the COL applicant, as described below.

Since Dominion submitted the ESP application, the Commonwealth of Virginia has passed legislation re-regulating the electric power industry in Virginia. ODEC has sold to Dominion its interest in the portion of NAPS on which Unit 3 will be located. Further ODEC will not jointly own entire site.

In order to resolve NAPS ESP Permit Condition 3.E(1), the applicant stated that Dominion currently controls the NAPS site and exclusion area under Dominion's existing agreement with ODEC, and no approvals are required by state law to share control of the exclusion area.

As a part of resolving NAPS ESP Permit Condition 3.E(1), the applicant supplemented the information by stating that as the owners of NAPS, Dominion possesses the right to implement the site redress plan under its agreement with ODEC.

Lastly, the applicant states that recreational use of the lake is consistent with lake access and control practices in effect for Units 1 and 2 and will be maintained for North Anna 3.

The staff reviewed the applicant's supplemental information regarding exclusion area authority. On the basis of this supplemental information, the staff concluded that the applicant has resolved NAPS ESP Permit Condition 3.E(1), pertaining to exclusion area authority and control and the site redress plan.

- NAPS ESP COL 2.1-2

The applicant supplemented the third paragraph in the ESP SSAR by addressing arrangements with appropriate agencies for emergencies.

To resolve NAPS ESP COL Action Item 2.1-2, the applicant supplemented the ESP SSAR with a description of the arrangements made with the appropriate agencies for emergencies. The information states that under the Commonwealth of Virginia's Radiological Emergency Response Plan (COVRERP), the Virginia Department of Game and Inland Fisheries (VDGIF) is responsible for warning people in boats and assisting with the traffic control of boats on Lake Anna in the vicinity of NAPS. This arrangement is documented in the COVRERP Appendix 1.

ESP COL Action Item 2.1-2 requires the applicant to address arrangements for controlling the portions of Lake Anna and the waste heat treatment facility (WHTF) that are within the exclusion area.

Since the supplemental information from the applicant addressed arrangements for controlling only Lake Anna on July 15, 2008, the staff issued a Request for Additional Information (RAI) 02.01.02-1 (ADAMS Accession No. ML081970390), which requested additional information on controls for portions of the WHTF within the exclusion area. The applicant responded to RAI 02.01.02-1 on August 28, 2008 (ADAMS Accession No. ML082460847), by stating that Lake Anna consists of both the WHTF and North Anna Reservoir, which are both partially within the NAPS exclusion area, and the VDGIF is responsible for controlling the portions of the North Anna Reservoir and the WHTF that are within the exclusion area. Therefore, RAI 02.01.02-1 is resolved and closed. Based on the staff's review of the supplemental information provided, the staff concludes that the applicant has appropriately resolved ESP COL Action Item 2.1.2.

- NAPS COL 2.0-4-A Site Specific Population

NAPS COL 2.0-4-A resolves DCD COL Item 2.0-4-A by addressing the provision of site-specific information related to population distribution of the site environs. The applicant incorporated by reference ESP SSAR Section 2.1.3 to resolve DCD COL Item 2.0-4-A, related to the population distribution included under Section 2.1 of the North Anna 3 COL FSAR.

The staff reviewed Section 2.1.3 of the North Anna 3 COL FSAR and checked the referenced ESP SSAR. The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to population distribution.

Under the provisions of 10 CFR 52.79(b), the staff accepted the information incorporated by reference to ESP SSAR Section 2.1.3. Therefore, the staff did not perform any technical evaluation of this FSAR section.

2.1.5 Post Combined License Activities

There are no post COL activities related to this section.

2.1.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff's review confirmed that the applicant has addressed the relevant information and there is no outstanding information expected to be addressed in the COL FSAR related to this subsection.

As discussed above, the applicant has provided an acceptable description of current and projected population densities in and around the site. The staff reviewed the information provided and, for the reasons given above, concluded that the population data provided is acceptable and meets the requirements of 10 CFR 50.34(a)(1), 10 CFR 52.79(a)(1), 10 CFR 100.20(a), 10 CFR 100.20(b), 10 CFR Part 100, and 10 CFR 100.3. In addition to the COL actions addressed above, the staff further concluded that the applicant had provided sufficient details in the ESP SSAR Section 2.1.3 about the population distribution to allow the staff to evaluate, as documented in Section 2.1.3 of NUREG-1835, whether the applicant meets the relevant requirements of 10 CFR 52.79(a)(1) and 10 CFR Part 100. This conclusion is based on the applicant's acceptable description and safety assessment of the site that contains present and projected population densities, which are within the guidelines of Regulatory Position C.4 of RG 4.7 and properly specified the distance from the LPZ population center. The applicant also calculated the radiological consequences of design-basis accidents at the outer boundary of the LPZ (SRP Chapter 15). The applicant provided reasonable assurance that appropriate protective measures can be taken within the LPZ to protect the population in the event of a radiological emergency. This information incorporated by reference, addressed NAPS COL

Item 2.0-4-A. In conclusion, the applicant has provided sufficient information to satisfy 10 CFR Parts 50, 52, and 100.

2.2 Nearby Industrial, Transportation, and Military Facilities

This section provides information on the site characteristics that could affect the safe design and siting of the plant. The information is addressed in three subsections: Section 2.2.1 provides information on locations and routes; Section 2.2.2 describes nearby industrial transportation facilities (airports, airways, roadways, railways, etc.) and military facilities; and Section 2.2.3 evaluates potential hazards.

2.2.1 Locations and Routes

The locations of and separation distances from transportation facilities and routes, including airports and airways, roadways, railways, and navigable bodies of water are addressed in ESP SSAR Sections 2.2.1 and 2.2.2, which are incorporated by reference. The staff's review of this information is in the following SER Section 2.2.2.

2.2.2 Descriptions

2.2.2.1 Introduction

The description of locations and routes refers to potential external hazards or hazardous materials that are present or may reasonably be expected to be present during the projected lifetime of the proposed plant. The purpose is to evaluate the sufficiency of information concerning the presence and magnitude of potential external hazards so that the reviews and evaluations described in SRP Sections 2.2.3, 3.5.1.5, and 3.5.1.6 can be performed. The review covers the following specific areas: (1) the locations of and separation distances to transportation facilities and routes, including airports and airways, roadways, railways, pipelines, and navigable bodies of water; (2) the presence of military and industrial facilities such as fixed manufacturing, processing, and storage facilities; and (3) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.2.2.2 Summary of Application

Section 2.2.2 of the FSAR addresses the need for locations and route descriptions and descriptions of nearby industrial and military facilities. The applicant addressed the information as follows:

COL Items:

- NAPS COL 2.0-5-A

NAPS COL 2.0-5-A resolves DCD COL Item 2.0-5-A by providing information about industrial, military, and transportation facilities and routes to establish the presence and magnitude of potential external hazards. The site-specific information needed to address DCD COL Item 2.0-5-A in the North Anna 3 FSAR is incorporated by reference to ESP SSAR Section 2.2.1-2.2.2.

- NAPS ESP COL 2.2-1

In accordance with RG 1.206 and relevant sections of 10 CFR Parts 50 and 100, the applicant provided supplemental information to address ESP COL Action Item 2.2.-1. The supplemental information identified and addressed the potential hazard facilities and routes within 5 miles of NAPS, three (3) airports within 10 miles of NAPS, and other significant facilities beyond 5 miles of NAPS. In addition, it is stated that no hazardous industrial facilities have been added at the industrial development near the North Anna 3 EAB.

2.2.2.3 Regulatory Basis

The regulatory basis for incorporating information by reference to the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP, provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP.

The applicable regulatory requirements for identifying locations and routes are:

- 10 CFR 100.20(b), which requires that the nature and proximity of human-related hazards (e.g., airports, dams, transportation routes, and military and chemical facilities) be evaluated to establish site parameters used to determine whether the plant's design can accommodate commonly occurring hazards, and whether the risk of other hazards is very low.

- 10 CFR 52.79(a)(1)(iv), as it relates to the factors to be considered in the evaluation of sites that require the location and description of industrial, military, or transportation facilities and routes.

- 10 CFR 52.79(a)(1)(vi), as it relates to compliance with 10 CFR Part 100.

The acceptance criteria in the ESP SSAR are based on meeting the following relevant requirements of 10 CFR Parts 52 and 100.

The related acceptance criteria are:

- Data in the SAR that adequately describe the locations of and distances from the plant of nearby industrial, military, and transportation facilities; and that the data are in agreement with data obtained from other sources, when available.

- Descriptions of the nature and extent of activities conducted at the site and in its vicinity, including the products and materials likely to be processed, stored, used, or transported; and that they are adequate to permit identification of the possible hazards cited in Section III of Section 2.2.1-2.2.2 of NUREG-0800.

- Sufficient statistical data with respect to hazardous materials that establish a basis for evaluating the potential hazards to the plant or plants considered at the site.

2.2.2.4 Technical Evaluation

The staff reviewed Section 2.2.2 of the North Anna 3 COL FSAR and checked the referenced ESP SSAR, Revision 9. The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to identification of potential hazards in the vicinity of the site.

The staff's technical evaluation of this application is limited to reviewing the supplemental information pertaining to NAPS COL Item 2.0.5-A and NAPS ESP COL Action Item 2.2-1.

The staff reviewed the resolution to DCD COL Item 2.0-5-A related to identification of potential hazards in the vicinity of the site, including nearby industrial, transportation, and military facilities and NAPS ESP COL Action Item 2.2-1 as follows:

<u>Industrial Facilities</u>

In order to resolve ESP COL Action Item 2.2-1, the applicant stated that since submitting the ESP SSAR, no hazardous industrial facilities have been added to the 620-acre industrial development near the North Anna 3 exclusion area boundary (EAB). The industrial site poses no hazard to North Anna 3.

<u>Airports</u>

This section of the ESP SSAR is supplemented with information that identifies an additional airport in the vicinity of North Anna 3.

A third airport (Seven Gables) within 10 miles of the North Anna 3 site opened in 2007. Seven Gables is a private landing strip with an unlighted 457 m (1,500 ft) turf runway approximately 12.4 km (7.7 miles) north-northwest of the site. This airport is not licensed for commercial use and is based with three small aircraft. The airport's location is shown along with other nearby airports in FSAR Figure 2.2-201. Flight operation information is in FSAR Table 2.2-201.

<u>Airways</u>

The supplemental information in this section of the ESP SSAR identifies an additional military training flight airway in the vicinity of NAPS.

One additional airway, VR1755, is identified and shown along with others in FSAR Figure 2.2-201. The center line of this airway is more than 8 miles from North Anna 3. Given that the U.S. Department of Navy projected a total of 306 flight operations for the 2007/2008 year for three of four military training routes, the applicant states that the assumed 6,000 flights per year in the ESP SSAR remain bounding.

2.2.2.5 Post Combined License Activities

There are no post-COL activities related to this subsection.

2.2.2.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff's review confirmed that the applicant has addressed the relevant information, and there is no outstanding information expected to be addressed in the COL FSAR related to this subsection. As set forth above, the applicant presented and substantiated information that identified potential hazards in the site vicinity. The staff reviewed the information in the ESP SSAR and supplemented in the FSAR and, for the reasons given above, concluded that the applicant had provided information that identified potential hazards in accordance with the requirements of 10 CFR 52.79(a)(1)(iv) and 10 CFR 52.79(a)(1)(vi) for compliance evaluation. The nature and extent of activities involving potentially hazardous materials that are conducted at nearby industrial, military, and transportation facilities have been evaluated to identify those activities that have the potential for adversely affecting plant safety-related structures. Based on an evaluation of information in the ESP SSAR and FSAR, as well as information that the staff had independently obtained, the staff concluded that all potentially hazardous activities on the site and in the vicinity of the plant have been identified. The hazards associated with these activities have been reviewed and are discussed in Sections 2.2.3, 3.5.1.5, and 3.5.1.6 of this SER. This information addresses NAPS ESP COL Action Item 2.2-1. In conclusion, the applicant has provided sufficient information to satisfy 10 CFR Parts 50, 52, and 100.

2.2.3 Evaluation of Potential Accidents

2.2.3.1 Introduction

The evaluation of potential accidents considers the applicant's probability analyses of potential accidents involving hazardous materials or activities on the site and in the vicinity of the proposed site to confirm that appropriate data and analytical models have been used. This review covers the following specific areas: (1) hazards associated with nearby industrial activities such as manufacturing, processing, or storage facilities; (2) hazards associated with nearby military activities such as military bases, training areas, or aircraft flights; and (3) hazards associated with nearby transportation routes (aircraft routes, highways, railways, navigable waters, and pipelines). Each hazard review area includes consideration of the following principal types of hazards: (1) toxic vapors or gases and their potential for incapacitating nuclear plant control room operators; (2) overpressure resulting from explosions or detonations involving materials such as munitions, industrial explosives, or explosive vapor clouds resulting from the atmospheric release of gases (such as propane and natural gas or any other gas) with a potential for ignition and explosion; (3) missile effects attributable to mechanical impacts such as aircraft impacts, explosion debris, and impacts from waterborne items such as barges; and (4) thermal effects attributable to fires.

2.2.3.2 Summary of Application

This section of the COL FSAR addresses the need to evaluate potential accidents. The applicant addressed the information as follows:

COL Items:

- NAPS COL 2.0-6-A Evaluation of Potential Accidents

NAPS COL 2.0-6-A resolves DCD COL Item 2.0-6-A by addressing the provision for evaluating potential accidents. The site-specific information needed to address DCD COL Item 2.0-6-A in North Anna 3 FSAR is incorporated by reference to ESP SSAR Section 2.2.3. In addition, as a part of NAPS COL 2.0-6-A, an evaluation of potential hazard due to gasoline delivery truck is supplemented. On-site and off-site toxic chemicals, aircraft hazards, explosive hazards (hydrogen) and fire hazards are also addressed.

- NAPS ESP COL 2.2-2 Interactions Between the Existing and New Unit

The applicant provided updated site-specific supplemental information to address ESP COL Action Item 2.2-2.

2.2.3.3 Regulatory Basis

The regulatory basis for incorporating information by reference to the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP, provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP.

The regulatory basis for the information presented in the ESP SSAR is addressed in the FSER related to the ESP SSAR (i.e., NUREG-1835).

The applicable regulatory requirements for identifying and evaluating potential accidents are:

- 10 CFR 52.79(a)(1)(iv) as it relates to the factors to be considered in the evaluation of sites, which require the location and description of industrial, military, or transportation facilities and routes.

- 10 CFR 52.79(a)(1)(vi), as it relates to compliance with 10 CFR Part 100.

The acceptance criteria presented in the ESP SSAR are based on meeting the relevant requirements of 10 CFR Parts 52 and 100.

The related acceptance criteria are:

- Event Probability: The identification of design-basis events resulting from the presence of hazardous materials or activities in the vicinity of the plant or plants of specified type is acceptable if all postulated types of accidents are included for which the expected rate of occurrence of potential exposures resulting in radiological dose in excess of the 10 CFR 50.34(a)(1) limits, as it relates to the requirements of 10 CFR Part 100, is estimated to exceed the NRC staff's objective of an order of magnitude of 10^{-7} per year.

- Design-Basis Events: The effects of design-basis events have been adequately considered, in accordance with 10 CFR 100.20(b), if analyses of the effects of those accidents on the safety-related features of the plant or plants of specified type have been performed and measures have been taken (e.g., hardening, fire protection) to mitigate the consequences of such events.

2.2.3.4 Technical Evaluation

The staff reviewed Section 2.2.3 of the North Anna 3 COL FSAR and checked the referenced ESP SSAR. The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to the evaluation of potential accidents. The staff's technical evaluation of this application is limited to reviewing the supplemental information pertaining to NAPS COL Item 2.0-6-A, and NAPS ESP COL Action items. The staff reviewed the resolution to DCD COL Item 2.0-6-A, related to the evaluation of potential accidents to be covered under ESP COL Action Item 2.2-2 addressed as follows:

COL Items:

- NAPS COL 2.0-6-A Evaluation of Potential Accidents

The applicant incorporated by reference ESP SSAR Section 2.2.3 to address DCD COL Item 2.0-6-A. In addition, as a part of NAPS COL 2.0-6-A, potential impacts due to gasoline delivery trucks are evaluated and presented as supplement information in new Section 2.2.3.1.1.

- NAPS ESP COL 2.2-2 Interactions between Existing Units and the New Unit

The applicant supplemented its application with a new section to ESP SSAR Section 2.2.3.1 on the evaluation of potential hazards of onsite chemicals to resolve ESP COL Action Item 2.2-2.

The chemicals stored onsite at Units 1 and 2 and to be stored at North Anna 3 are identified in FSAR Table 2.2-202. This table identifies the storage locations and quantities of each chemical. Properties relative to the hazards from each chemical and the results of the screening analyses are in FSAR Table 2.2-203. FSAR Table 2.2-204 provides the safe-separation distances for flammable and explosive chemicals and compares those distances to the actual distance to the nearest safety-related North Anna 3 structure, system, or component (SSC).

Explosions

The applicant evaluated hydrogen (gas and liquid) and Nalco H-130 (for Unit 3), and acetone, ammonium hydroxide, hydrazine and Nalco H-130, hydrogen, Carboline 2, and gasoline from delivery truck (for Units 1 and 2) for potential explosions resulting in blast overpressure using 1 psi overpressure as a criterion for adversely affecting plant operations or preventing the safe shutdown of the plant. In accordance with RG 1.91, "Evaluations of Explosions Postulated to Occur at Nearby Facilities and on Transportation Routes Near Nuclear Power Plants," peak-positive incident overpressures below 1 psi are not considered to cause significant damage.

The applicant determined a minimum safe-standoff distance from an in-vessel, confined vapor explosion by conservatively considering a volume of chemical vapor equal to the empty volume of the largest storage vessel that was available for combustion, with an explosion yield factor of 100 percent.

The applicant addressed the potential detonation and deflagration in a plume due to a flammable vapor cloud from the release of chemicals. This evaluation assumed a dispersion downwind toward the NAPS, with a delayed ignition. The typical vapor dispersion assumed a wind speed of 1 meter per second with an atmospheric stability class F, and a 77 degree Fahrenheit (°F) ambient air temperature, a relative humidity of 50 percent, a cloud cover of 50 percent, and an atmospheric pressure condition. However, meteorological sensitivity analysis with variation of wind speed, atmospheric stability and ambient air temperature is also performed to determine potential limiting impact. This dispersion analysis was conducted using the ALOHA model with a spectrum of meteorological conditions (stability class, wind speed, time of day, and cloud cover) to ensure the worst-case is captured. The meteorological sensitivity analysis includes the stable meteorological class, F, at a wind speed of 1 meter per second. The ALOHA computer model (ALOHA, 2007) was used to evaluate the dispersion and detonation of the vapor clouds. Each chemical was analyzed by assuming the maximum volume of the storage vessel leaked to form a 1-centimeter thick puddle, giving significant surface area to maximize evaporation and the formation of a vapor cloud.

The staff noted that there are two 10,000 gallon underground gasoline storage tanks onsite at the North Anna site as listed in FSAR Revision 1 Table 2.2-202 at existing North Anna 1 and 2. The applicant did not address the hazards posed by these tanks from either a confined vapor explosion or a flammable vapor cloud explosion. On June 3, 2004, the staff requested additional information in RAI 2.2.3-1 (ADAMS Accession No. ML050660242), the applicant to address the potential hazards of these tanks due to fuel storage and onsite delivery of fuel to the tanks. The response to RAI 2.2.3-1 provided in Dominion letter NA3-08-118 (ML082980061) documented that a vapor cloud explosion from underground gasoline tank was not a credible event. The applicant provided the information in an FSAR update and calculated the probability of 7.8×10^{-7} for an explosion from a gasoline tanker truck delivery resulting in an overpressure of 1 psi at the nearest North Anna 3 safety-related structure. However, in the FSAR Revision 8, the applicant performed the impact evaluation and determined the impacts by calculating the minimum safe distance of 227.7 m (747 ft) to 1 psi overpressure due to potential unconfined vapor cloud explosion, and 82.9 m (272 ft) due to confined vapor explosion from the gasoline delivery truck. Both the calculated minimum distances are lower than the actual distance to the nearest North Anna 3 safety-related structure. The staff performed independent confirmatory calculations and found the minimum safe distance determined by the applicant comparable to the staff's calculated distance. Therefore, staff considers the applicant analysis, assumptions, and conclusions are reasonable and acceptable in meeting the requirements and regulatory guidance. The applicant performed deterministic analysis by calculating the minimum safe distances to 1 psi overpressure, instead of screening out the potential accident based on originally calculated low probability basis. Therefore, the applicant requested that the original probability calculations addressed are no longer considered to be applicable or required. The staff considers this acceptable. The staff considers RAI 2.2.3-1 resolved and closed.

The minimum safe separation distances for flammable and explosive materials in relation to the actual distance to the nearest North Anna 3 safety related-structure are presented in the FSAR Table 2.2-204. The results indicate that a fire or explosion from identified hazardous chemicals and materials stored or transported at Units 1, 2, and 3 would not adversely affect the safe operation or shutdown of North Anna 3, with an exception of liquid hydrogen stored at North Anna 3 and a 13,000 gallon liquid hydrogen delivery truck.

North Anna 3 COLA FSAR Table 2.2-204 indicates that for the 6,000 gallon liquid hydrogen tank, the minimum safe distance to reach an over pressure of 1 psi due to source explosion is estimated to be 612 m (2,009 ft), which is greater than the actual distance to the safety-related structure of 228.6 m (750 ft). Therefore, the applicant performed further analysis using Appendix B of the Electric Power Research Institute (EPRI) Guideline NP-5283-SR-A, "Guidelines for Permanent BWR Hydrogen Water Chemistry Installations, " to determine the minimum safe distance of 150.9 m (495 ft) from source explosion and of 206.3 m (677 ft) from vapor cloud explosion. Since these two distances are less than the distance to the nearest safety-related structure distance of 228.6 m (750 ft), the applicant concluded that the storage of liquid hydrogen would not adversely affect the safe operation of North Anna 3. The staff reviewed the EPRI methodology and the applicant's approach and assumptions, and requested additional information on July 18, 2014, in RAI 2.2.3-10 (ADAMS Accession No. ML14283A550). In a letter dated September 3, 2014 (ADAMS Accession No. ML14251A060), the applicant responded and staff reviewed the information. The staff requested further supplemental information to complete the review as some information provided was unclear and inconsistent. In a letter dated February 16, 2015 (ADAMS Accession No. ML15051A288), the applicant provided information and associated inspections, tests, analyses, and acceptance criteria (ITAAC) and revision to the North Anna 3 FSAR. The revision to the response by the applicant included an ITAAC for verifying the minimum static lateral load capacity of 3 psi for the radwaste building (RW). Based on the review of the information provided and future ITAAC consideration, the staff considers the applicant approach reasonable and acceptable in meeting the requirements and guidance. Therefore this RAI 2.2.3-10 is resolved and closed.

For the 13,000 gallon liquid hydrogen delivery truck, the applicant determined minimum safe distance is greater than the actual distance of 228.6 m (750 ft) to the nearest SSC. For this reason, the applicant stated in the FSAR that a probability analysis was performed and the probability of accident involving a 13,000 gallon delivery truck is estimated to be less than 10^{-6} per year. The applicant stated that this is sufficiently low, and this scenario need not be considered as a design-basis event. Because no detailed information or calculations were provided, in RAI 2.2.3-10 the staff requested additional information regarding the calculation method, input data, assumptions and results along with the justification of this approach taken, and revisions to the FSAR Section as appropriate. In letters dated September 3, 2014 (ADAMS Accession No. ML14251A060) and February 16, 2015 (ADAMS Accession No. ML15051A288), a detailed and sufficient response of the screening analysis and approach along with committed proposed future revision to the FSAR section is provided by the applicant. The staff reviewed the response provided by the applicant, and confirmed that the calculation methods followed those found in RG 1.91, Revision 2, and that conservative input data and assumptions were used. The staff used data provided in the applicant's references as well as independent data on truck accident rates from the U.S. Department of Transportation to confirm that the applicant's results were reasonable. The applicant performed a screening analysis in accordance with the guidance in RG 1.91, Revision 2, that provides reasonable assurance that the risk of damage to safety-related structures, systems or components caused by an explosion from the 13,000 gallon liquid hydrogen delivery truck is sufficiently low, as defined in RG 1.91, Revision 2, such that further evaluation of the risk is not necessary. Therefore, staff considers the applicant's approach reasonable and acceptable. For the reasons described above, RAI 2.2.3-10 pertaining to the 13,000 gallon delivery truck is resolved and closed. In response to RAI 2.2.3-10, the applicant has proposed revisions to future FSAR Sections 2.2.3 and 3.7.2.8.2 and FSAR Tables 2.2-203, 2.2-204, 2.2.-205, and added a new Table 2.2-206 and revised COLA Part 10, Section 2.4.16 and associated ITAAC. The staff verified that the appropriate COLA revisions are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.2-01 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff performed independent calculations for the chemicals addressed by the applicant, and the staff's calculations confirmed the applicant's results. Therefore, the staff concluded that the applicant's assumptions and methodology are reasonable and acceptable.

Toxic Chemicals

The applicant identified the onsite storage of chemicals for North Anna 3 in FSAR, Revision 0, Table 2.2-203 and considered the potential for impacting control room habitability. In FSAR Section 2.2.3.1.3, the applicant stated that the effects of toxic vapors or gases and their potential for incapacitating North Anna 3 control room operators were evaluated. In FSAR, Revision 0, Section 6.4 under NAPS COL 6.4-2-A, the applicant conclusively stated, "The results of the analysis, when compared to the toxicity limits given in RG 1.78, "Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release," show hazardous concentrations of toxic gas in the control room are not reached." In that version of the application, the applicant did not provide the bases and methodology for calculating the toxic chemical concentrations at the intake of the control room; the potential toxic chemical concentrations inside the control room with potential air flow rates; the modeling assumptions and inputs for accidental chemical release scenarios; and evaporation characteristics, dispersion and transport mechanisms, and resulting concentrations. The staff requested this information in RAIs 2.2.3-2 and 2.2.3-3 (ADAMS Accession No. ML082250417). The applicant's response in a letter dated December 29, 2008 (ADAMS Accession No. ML083660043), identified two chemicals requiring control room habitability analyses, which were reviewed by the staff and further evaluated in Section 6.4 of this SER. The applicant identified in FSAR, Revision 0, eight additional chemicals that are stored onsite, but the applicant provided no rationale as to why those chemicals are not a hazard to the control room. Therefore, the staff issued a subsequent RAI 2.2.3-5 (ADAMS Accession No. ML090680312) requesting the applicant to provide a rationale for screening out those chemicals. In a letter dated May 27, 2009 (ADAMS Accession No. ML091490217), the applicant provided rationale by discussing the nature of the chemicals and addressed screening out of chemicals from further analysis. The staff reviewed and found the applicant's response reasonable and acceptable as it satisfies the NRC guidance provided in RG 1.78. Therefore RAI 2.2.3-5 is resolved and closed. As a follow-up to the applicant's response to RAI 2.2.3-2 and 2.2.3-3, the staff on March 26, 2009, issued RAI 2.2.3-7 (ADAMS Accession No. ML090840271) requesting a revised response regarding the modeling data and assumptions details for its analysis and conclusions. This RAI was superseded by RAI 2.2.3-8, and the applicant in a letter dated January 10, 2011 (ADAMS Accession No. ML110110613), provided response addressing ALOHA model methodology, assumptions and input data used. The staff considers that this information is adequate and acceptable for staff's confirmatory analysis. The staff performed confirmatory calculations and concluded that the applicant's results are comparable. The staff therefore considers the applicant's response acceptable, and RAI 2.2.3-7 and 2.2.3-8 are resolved and closed.

The staff noted that the quantity of sodium hydroxide in FSAR Table 2.2-202 (180 gallons for North Anna 3 and 700 gallons for Units 1 and 2) was not analyzed for toxicity, whereas Units 1 and 2 UFSAR Version 42 (Table 6.4-1) identifies a sodium hydroxide quantity of 55 gallons, which was analyzed for toxicity. The staff requested on August 12, 2008, clarification in RAI 2.2.3-4 *(*ADAMS Accession No. ML082250417). The applicant's response, dated October 20, 2008 (ADAMS Accession No. ML082980061) stated that the existing Unit 1 and 2 analyses were overly conservative, and assumed that all sodium hydroxide is volatile. However, based on the low volatility of sodium hydroxide, no significant concentrations would accumulate even with the higher quantities. The staff performed confirmatory calculations and concluded that the applicant's results are comparable; the staff therefore considers the applicant's response acceptable. Therefore, RAI 2.2.3-4 is resolved and closed. The staff also requested on March 9, 2009, additional information in RAI 2.2.3-6 (ADAMS Accession No. ML090680312), to provided rationale for screening sodium hydroxide on the basis of vapor pressure of 10 torr. The applicant in a letter dated May 27, 2009 (ADAMS Accession No. ML091490217), provided response and rationale by comparing United States Environmental Protection Agency (EPA) suggested threshold value of 10 torr to the NRC guidance value provided in RG 1.78, which the staff considers reasonable and acceptable as it satisfies the NRC guidance. This RAI 2.2.3-6 is resolved and closed.

In Enclosure 6 to a letter dated December 18, 2013 (ADAMS Accession No. ML14013A113), the applicant provided a response to RAI 2.2.3-8 and enclosed the list of onsite chemicals and the Control Room Toxic Gas concentrations, which are included in FSAR Table 2.2-205. In addition to these chemicals, potential releases from gasoline delivery trucks have been analyzed and included in the table. The applicant used immediate danger to life and health (IDLH) of 500 PPM for gasoline instead of 300 PPM that is based Time Weighted Average. Therefore, the staff requested the applicant in RAI 2.2.3-10 (ADAMS Accession No. ML14283A550), to revise the analysis using the IDLH of 300 ppm. The applicant performed the analysis and provided the results in a response letter (ADAMS Accession No. ML15051A288) dated February 16, 2015.

The staff considers that the applicant's response adequately addresses the control room concentration of gasoline, which is determined by the applicant to be lower than IDLH concentration of 300 ppm. The staff therefore finds the response acceptable. The applicant also provided proposed revisions to FSAR Section 2.2.3.3 and FSAR Table 2.2-205. The staff verified that the appropriate COLA revisions are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.2-02 from the staff's advanced SER for North Anna 3 is resolved and closed.

Each of the hazardous chemicals analyzed, with exception of nitrogen, oxygen, carbon dioxide, an 8,500 gallon gasoline delivery truck, and a 13,000 gallon liquid hydrogen delivery truck, had distances to their respective toxic or asphyxiating limit less than the distance to the control room. However, the control room concentrations for nitrogen, oxygen, carbon dioxide, gasoline, and liquid hydrogen were determined and reported to be below the asphyxiating or toxic limits for each hazardous chemical in FSAR Table 2.2-205. Since, the concentration of these chemicals exceeded their respective IDLH concentrations at the intake to the control room, these chemicals are further considered and evaluated in Section 6.4 of the SER in addressing for the control room habitability.

Airways

The staff evaluation for North Anna 3 airways is contained in the SER related to the ESP SSAR (NUREG-1835). Supplemental information contained in North Anna 3 FSAR Section 2.2.3.2.2 pertaining to effective plant areas for North Anna 3 was reviewed by the staff. However, the staff finds that this modification did not change any conclusions made by the staff in the ESP SER. Consequently, the staff finds that the modification in the COL FSAR, Revision 8, is acceptable and would not change the original conclusion that the two accident probabilities are within the NUREG-0800 guideline of less than 10^{-7} per year.

External Fires

The staff evaluation for North Anna 3 external fires is contained in the FSER related to the ESP SSAR (NUREG-1835). Supplemental information contained in North Anna 3 FSAR Section 2.2.3.4 included information regarding North Anna 3 external fires. The applicant performed an analysis of a wildfire near North Anna 3 using methodology discussed in the SER for the ESP, to determine the incident heat flux on North Anna 3. On the basis of a calculated heat flux with conservative assumptions to include wildfire at plant elevation, closest to the Unit 3 control building (CB) and fuel building (FB), the staff considers the applicant's analysis reasonable and the conclusion acceptable.

Collision with North Anna 3 Intake Structure

FSAR Section 2.2.3.5 states that the North Anna 3 intake structure is located on Lake Anna in a cove behind a cofferdam that is northeast of the North Anna 3 power block area, shown in FSAR Section 2.1-201. Lake Anna has small pleasure boats used solely for recreation; there are no large boats or barges on the lake. The area around the North Anna 3 intake structure is managed by Dominion as a part of the exclusion area. The cofferdam prevents a potential collision between a boat on Lake Anna and the North Anna 3 intake structure. Even if there is such a collision, the North Anna 3 intake structure is not a safety-related structure, and therefore the staff concluded that such a collision would not affect the safety of the plant.

Liquid Spills near the Intake Structure

FSAR Section 2.2.3.6 states that although small quantities of motor oil and gasoline may be spilled from the pleasure boats in Lake Anna, such spills would not affect the safe operation or shutdown of North Anna 3. The staff finds the applicant's assessment that minor spills into the lake will not affect safe operation or shutdown of the proposed unit is reasonable and therefore acceptable.

2.2.3.5 Post Combined License Activities

There are no post COL activities related to this subsection.

2.2.3.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff's review confirmed that the applicant has addressed the relevant information and no outstanding information is expected to be addressed in the COL FSAR related to this subsection.

As set forth above, the applicant identified potential accidents related to the presence of hazardous materials or activities in the site vicinity that could affect a nuclear power plant or plants of the specified type that might be constructed on the proposed site. The applicant also appropriately determined those events that should be considered as design-basis events and demonstrated that the plant is adequately protected and can be operated with an acceptable degree of safety, with regard to design-basis accidents. The staff reviewed the information in the ESP SSAR and supplemented in the FSAR and for the reasons given above, concluded that the applicant has provided information that identified potential hazards, and also has established that the construction and operation of North Anna 3 on the proposed site location is acceptable and meets the requirements of 10 CFR 52.79(a)(1)(iv) and 10 CFR 52.79(a)(1)(vi) for compliance with respect to determining the acceptability of the site. The information addresses COL Item 2.0.6-A and NAPS ESP COL Action Item 2.2-2. In conclusion, the applicant has provided sufficient information to satisfy 10 CFR Parts 50, 52, and 100.

2.3 <u>Meteorology</u>

To ensure that a nuclear power plant or plants can be designed, constructed, and operated on a COL applicant's proposed site in compliance with the NRC regulations, the staff evaluates regional and local climatological information, including climate extremes and severe weather occurrences that may affect the design and siting of a nuclear plant. The staff evaluates regional and local climatological information, including climate extremes and severe weather occurrences that may affect the design and siting of a nuclear plant. The staff also reviews the applicant's onsite meteorological monitoring program and information on the atmospheric dispersion characteristics of a nuclear power plant site to determine whether the radioactive effluents from postulated accidental releases, as well as routine operational releases, are within Commission guidelines.

The staff has prepared Sections 2.3.1 through 2.3.5 of this SER in accordance with the review procedures described in NUREG-0800, using information presented in Sections 2.0 and 2.3 of the North Anna 3 COL FSAR, Revision 8, which references ESBWR DCD, Revision 10, responses to staff RAIs, and applicable sections of NUREG-0800.

2.3.1 Regional Climatology

2.3.1.1 Introduction

North Anna 3 COL FSAR, Revision 9, Section 2.3.1, "Regional Climatology," of the North Anna 3 COL FSAR addresses averages and extremes of climatic conditions and regional meteorological phenomena that could affect the safe design and siting of the plant, including information describing the general climate of the region, seasonal and annual frequencies of severe weather phenomena, and other meteorological conditions to be used for design- and operating-basis considerations.

2.3.1.2 Summary of Application

North Anna 3 COL FSAR, Revision 9, Section 2.3.1, "Regional Climatology," incorporates by reference Section 2.3.1 of the ESBWR DCD, Revision 10, "Regional Climatology," and Section 2.3.1 of the North Anna 3 ESP SSAR, Revision 9, "Regional Climatology".

In addition, the North Anna 3 COL FSAR Section 2.3.1, the COL applicant provided the following:

COL Item:

- NAPS COL 2.0-7-A

The COL applicant provided information in NAPS COL 2.0-7-A to address site-specific information relating to regional climatology, site-specific meteorology, and the onsite meteorological measurements program.

Early Site Permit Variance:

- NAPS ESP VAR 2.3-1

The COL applicant proposed variance NAPS ESP VAR 2.3-1 from the ESP SSAR. This variance recalculated North Anna 3 tornado site characteristic values to replace corresponding values presented in the ESP SSAR.

2.3.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in the FSERs related to the ESBWR DCD and the North Anna 3 ESP.

In addition, the acceptance criteria associated with the relevant requirements of the NRC regulations for regional climatology are given in Section 2.3.1 of NUREG-0800.

The acceptance criteria for the additional regional climatic information presented in the FSAR beyond that presented in the ESP SSAR (i.e., NAPS COL 2.0-7-A and NAPS ESP VAR 2.3-1) are based on meeting the following relevant requirements of 10 CFR Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c)(2) and 10 CFR 100.21(d), as it relates to the consideration given to the regional meteorological characteristics of the site.

The climatological and meteorological information assembled in compliance with the above regulatory requirements are necessary to determine a proposed facility's compliance with the following requirements in Appendix A, "General Design Criteria for Nuclear Power Plants," of 10 CFR Part 50:

- General Design Criterion (GDC) 2, "Design Bases for Protection Against Natural Phenomena," which requires that SSCs important to safety be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions.

- GDC 4, "Environmental and Dynamic Effects Design Bases," which requires that SSCs important to safety be designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, included loss-of-coolant accidents.

The related acceptance criteria from Section 2.3.1 of NUREG-0800 are as follows:

- The description of the general climate of the region should be based on standard climatic summaries compiled by the National Oceanic and Atmospheric Administration (NOAA).

- Data on severe weather phenomena should be based on standard meteorological records from nearby representative National Weather Service (NWS), military, or other stations recognized as standard installations that have long periods of data on record. The applicability of these data to represent site conditions during the expected period of reactor operation should be substantiated.

- The tornado parameters should be based on RG 1.76, "Design-Basis Tornado and Tornado Missiles for Nuclear Power Plants," Revision 1. Alternatively, a COL applicant may specify any tornado parameters that are appropriately justified, provided that a technical evaluation of site-specific data is conducted.

- The extreme (straight-line) 100-year return period 3-second gust wind speed site characteristics should be based on appropriate standards, with suitable corrections for local conditions.

- In accordance with RG 1.27, "Ultimate Heat Sink for Nuclear Power Plants," Revision 2, the ultimate heat sink (UHS) meteorological conditions resulting in maximum evaporation and drift losses should be the worst 30-day average combination of controlling parameters (e.g., dewpoint, depression, wind speed, and solar radiation). The meteorological conditions resulting in minimum water cooling should be the worst combination of controlling parameters, including diurnal variations, where appropriate, for the critical time period(s) unique to the specific design of the sink. (Not applicable to a passive containment system design [such as the Passive Containment Cooling System used by the ESBWR design] that does not utilize a cooling tower or cooling pond).

- The 100-year ground-level snowpack or snowfall, whichever is greater, should be based on data recorded at nearby representative climatic stations or obtained from appropriate standards with suitable corrections for local conditions. The weight of the 48-hour probably maximum winter precipitation (PMWP) should be determined in accordance with reports published by NOAA's Hydrometeorological Design Studies Center.

- Ambient temperature and humidity statistics should be derived from data recorded at nearby representative climatic stations or obtained from appropriate standards with suitable corrections for local conditions.

- High air pollution potential information should be based on EPA studies.

- All other meteorological and air quality conditions identified by the COL applicant as design and operating bases should be documented and substantiated.

The information should be consistent with acceptable practices, data from NOAA, industry standards, and NRC RGs.

Interim Staff Guidance (ISG) document DC/COL-ISG-7, "Interim Staff Guidance on Assessment of Normal and Extreme Winter Precipitation Loads on the Roofs of Seismic Category I Structures" (74 FR 31470) (ADAMS Accession No. ML091490565), was issued subsequent to the publication of Section 2.3.1 in NUREG-0800. The ISG clarifies the Staff's position that the COL applicant should identify winter precipitation events as site characteristics and site parameters for determining normal and extreme winter precipitation loads on the roofs of seismic Category I structures.

To the extent that the data are applicable to the acceptance criteria outlined above, the applicant has applied the following NRC-endorsed meteorological information selection methodologies and techniques:

- RG 1.23, "Meteorological Monitoring Programs for Nuclear Power Plants," Revision 1, which provides criteria for an acceptable onsite meteorological measurements program, which can be used to monitor regional meteorology site characteristics.

- RG 1.76, Revision 1, which provides criteria for selecting the design-basis tornado parameters.

- RG 1.206, which describes the type of regional meteorological data that should be presented in FSAR Section 2.3.1.

- RG 1.221, "Design-Basis Hurricane and Hurricane Missiles for Nuclear Power Plants," which provides criteria for selecting the design basis hurricane parameters.

2.3.1.4 Technical Evaluation

The staff reviewed Section 2.3.1 of the North Anna 3 COL FSAR and checked the referenced North Anna 3 ESP SSAR, Revision 9. The staff's review confirmed that the information in the North Anna 3 COLA and incorporated by reference to Section 2.3.1 of the North Anna 3 ESP

SSAR, addresses the relevant information related to the regional meteorology. The staff's technical evaluation of the information incorporated by reference to the North Anna 3 ESP SSAR related to regional climatology is documented in the corresponding SER (i.e., NUREG-1835).

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

COL Item:

- NAPS COL 2.0-7-A

The staff reviewed NAPS COL 2.0-7-A related to the provision of regional climatology. The staff found that the COL applicant had appropriately supplied site-specific regional climatological information by incorporating by reference Revision 9 to the North Anna 3 ESP SSAR Section 2.3.1, except as discussed below.

Early Site Permit Variance:

- NAPS ESP VAR 2.3-1

The staff reviewed NAPS ESP VAR 2.3-1 related to from the ESP SSAR. This variance recalculated North Anna 3 tornado site characteristic values as evaluated below by the staff under Section "Tornado Characteristics."

Evaluation of Site Parameters and Site Characteristics

Section 2.0 of the North Anna 3 COL FSAR evaluates whether the North Anna 3 site characteristics fall within the ESBWR DCD site parameter values. A comparison of ESBWR DCD climatic site parameters with the North Anna 3 climatic site characteristics is in North Anna 3 COL FSAR Table 2.0-201, "Evaluation of Site/Design Parameters and Characteristics." Unless otherwise noted in North Anna 3 COL FSAR Table 2.0-201, the North Anna 3 site characteristic values are acceptable to the staff because NUREG-0800, Section 2.3.1, states that a COLA referencing an ESP need not include a reinvestigation of the site characteristics that were previously accepted in the referenced ESP. The staff found that the COL applicant had appropriately compared the ESBWR DCD site parameter values with the North Anna 3 site characteristics, except as discussed below.

Design Basis Dry and Wet Bulb Temperatures

The ESBWR DCD site parameters for ambient air temperature are as follows:

- Ambient Design Air Temperature (0 percent exceedance maximum dry bulb and mean coincident wet bulb): These site parameter values represent a maximum dry bulb temperature that exists for 2 hours or more, combined with the maximum wet bulb temperature that exists in that population of dry bulb temperatures.

- Ambient Design Air Temperature (0 percent exceedance minimum dry bulb): This site parameter value represents a minimum dry bulb temperature that exists within a set of hourly data for duration of 2 hours or more.

- Ambient Design Air Temperature (0 percent exceedance maximum non-coincident wet bulb): This site parameter value represents a maximum wet bulb temperature that exists within a set of hourly data for duration of 2 hours or more.

- Ambient Design Air Temperature (1 percent annual exceedance maximum dry bulb and mean coincident wet bulb): These site parameter values represent a 1-percent annual exceedance dry bulb temperature combined with the corresponding wet bulb temperature that exists in that population of dry bulb temperatures.

- Ambient Design Air Temperature (1 percent annual exceedance minimum dry bulb): The minimum normal value is the 99-percent annual exceedance temperature.

- Ambient Design Air Temperature (1 percent annual exceedance maximum non-coincident wet bulb): The maximum normal value is the 1-percent annual exceedance non-coincident wet bulb temperature.

- Ambient Design Air Temperature (2 percent annual exceedance maximum dry bulb and mean coincident wet bulb): These site parameter values represent a 2-percent annual exceedance dry bulb temperature combined with the corresponding wet bulb temperature that exists in that population of dry bulb temperatures.

- Ambient Design Air Temperature (2 percent annual exceedance minimum dry bulb): The minimum normal value is the 98-percent annual exceedance temperature.

- Ambient Design Air Temperature (2 percent annual exceedance maximum non-coincident wet bulb): The maximum normal value is the 2-percent annual exceedance non-coincident wet bulb temperature.

North Anna 3 COL FSAR Table 2.0-201 compares the ESBWR ambient design temperature site parameters against the corresponding 100-year return period temperatures estimated near the North Anna 3 site. 10 CFR 52.79(a)(1)(iii) states that COLAs must identify the meteorological characteristics of the proposed site with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated. Temperatures based on a 100-year return period are considered to provide sufficient margin for the limited accuracy, quantity, and period of time in which historical data have been accumulated.

As shown in North Anna 3 COL FSAR Table 2.0-201, all of the COL applicant's site characteristics for ambient design air temperature are bounded by the ESBWR DCD site parameters. These temperatures include the 100-year return period dry bulb temperatures with the mean coincident wet bulb temperatures and the 100-year return period noncoincident wet bulb temperatures. The COL applicant derived a 100-year return period, maximum coincident wet bulb temperature value of 76 °F by extrapolating a curve of Richmond's dry bulb temperatures, plotted with their maximum observed coincident wet bulb temperatures, to the 100-year return period maximum dry bulb temperature value of 109 °F. The staff performed an independent evaluation of the site characteristic temperatures that resulted in generally similar temperatures. Although the staff's calculation determined the 100-year return period coincident wet bulb temperature to be higher than the COL applicant's, both the staff's and COL applicant's dry bulb and coincident wet bulb temperatures are well within bounds of the ESBWR DCD site parameter value of 80.0 °F for the coincident wet bulb temperature. RAI 02.03.01-6 requested that the COL applicant provide a 100-year return period minimum dry bulb temperature for comparison against the US-APWR [Advanced Pressurized Water Reactor] site parameter temperature (in previous revisions of the North Anna 3 COL FSAR when the reference DCD was the US-APWR). The COL applicant responded by committing to include a justification for the use of a 0 percent exceedance minimum dry bulb temperature instead of the 100-year return period temperature. North Anna 3 COL FSAR Table 2.0-201 included a 0 percent annual exceedance minimum temperature of -21 °F for comparison against the US-APWR (now ESBWR) site characteristic 0 percent annual exceedance minimum temperature. The 0 percent annual exceedance temperature is used as the North Anna 3 site characteristic minimum dry bulb temperature because it bounds the calculated 100-year return period minimum dry bulb temperature of -19 °F. The -21 °F temperature was recorded at the Louisa Cooperative observation site, which is located about 10 miles WSW of the North Anna 3 site, whereas the 100-year return period temperature is an extrapolation of data from Richmond, VA. Both the 100-year return period temperature and 0 percent exceedance temperature presented by the COL applicant bound the Staff's independently calculated 100-year return period minimum dry bulb temperature, and are, therefore, acceptable to the staff. The staff reviewed the changes proposed in the response to RAI 02.03.01-6 and finds them to be acceptable. Therefore, the staff has determined that RAI 02.03.01-6 is resolved and closed.

Using a combination of National Climatic Data Center (Hourly data from Richmond, VA (1978-2009)), and climate data from the American Society of Heating, Refrigerating and Air-Conditioning Engineers, the staff was able to verify the COL applicant's site characteristic temperatures presented in North Anna 3 COL FSAR, Table 2.0-201. The staff, therefore, accepts them as correct.

Extreme Winds

Section 2.3.1.3.1 of the North Anna 3 FSAR includes a description of extreme wind, including estimates of 10^{-7} per year hurricane wind speeds. Using the guidance in RG 1.221, the applicant chose a 3-second gust hurricane wind speed value of 62 m/s (140 mph). This wind speed represents the maximum nominal 3-second gust wind speed at 10 m (33 ft) above ground over open terrain having a probability of exceedance of 10^{-7} per year. The staff, using the guidance provided in RG1.221, confirmed the hurricane wind speed value chosen by the applicant.

Section 2.3.1.3.1 of the North Anna 3 FSAR also presents a basic wind speed value of 40 m/s (90 mph) for Unit 3 nonsafety-related structures not included in the certified design. The applicant used the American Society of Civil Engineers/Structural Engineering Institute (ASCE/SEI) Standard 7-05, "Minimum Design Loads for Buildings and Other Structures," to determine the value. The value was confirmed by the staff through the use of ASCE/SEI Standard 7-05.

The applicant presents a 50-year wind speed site characteristic of 42.9 m/s (96 mph) in Table 2.0-201 for "Other Seismic NS Standard Plant Structures." This site characteristic value is the same as the ESP and Unit 3 site characteristic value for a 100-year wind speed. The 100-year wind speed site characteristic value is higher than a 50-year wind speed. This is a conservative assumption and is therefore acceptable to the staff.

The applicant specified exposure Category D in Table 2.0-201 for Unit 3 as part of the extreme wind site characteristics for Seismic Category I, II, and radwaste building structures. ASCE/SEI Standard 7-05 describes Exposure Category D as having flat, unobstructed area and water surfaces that prevail in the upwind direction for a distance greater than 5,000 ft (1,525 m) or 20 times the building height, whichever is greater. The use of Exposure Category D results in the most severe design wind pressures and is therefore a conservative assumption and is acceptable to the staff. Hurricane wind speed effect on safety systems and structures is evaluated in Chapter 3 Section 3.3 and Chapter 19 Appendix 19A of this SER.

Tornado Characteristics

Revision 3 of the North Anna 3 COL FSAR presented tornado site characteristics that differed from those presented in the North Anna 3 ESP. The tornado site characteristics approved in the North Anna 3 ESP were based on RG 1.76, Revision 0. The most recent guidance provided for determining tornado site characteristics is RG 1.76, Revision 1. This updated guidance effectively lowered the wind speeds based on the Enhanced Fujita scale. In RAI 02.03.01-5, the staff asked the COL applicant to include in the North Anna 3 COL FSAR either a request for a variance (NAPS ESP VAR 2.3-1) related to the ESP tornado site characteristic values, or request an amendment to the North Anna 3 ESP.

In response to RAI 02.03.01-5, the COL applicant proposed an update to Part 7, "Departures Report," of the North Anna 3 COL that includes a variance in accordance with 10 CFR 52.79(b)(2), CFR 52.93(b) and 10 CFR 52.39(d). The staff has determined that the COL applicant's updated tornado site characteristics are appropriate for the North Anna 3 site. Additional staff evaluation of this variance is below. The staff has confirmed that the COL applicant included this variance request in Part 7 of the COLA and therefore determines that RAI 02.03.01-5 is resolved.

The COL applicant chose tornado site characteristics based on RG 1.76, Revision 1. RG 1.76, Revision 1 provides design-basis tornado characteristics for three tornado intensity regions throughout the United States, each with a 10^{-7} per year probability of occurrence. The proposed COL site is located in Tornado Intensity Region II where severe tornadoes have been observed. The COL applicant proposed the following tornado site characteristics, which are listed in North Anna 3 COL FSAR Table 2.0-201 and North Anna 3 COL FSAR Table 2.3-225:

- Maximum wind speed 200 mph
- Maximum translational speed 40 mph
- Maximum rotational speed 160 mph
- Radius of maximum rotational speed 150 ft.
- Pressure drop 0.9 psi
- Rate of pressure drop 0.4 psi/sec

Because the COL applicant has identified design-basis tornado site characteristics based on RG 1.76, Revision 1, the staff concludes that the COL applicant's tornado site characteristics are acceptable. As shown in North Anna 3 COL FSAR Table 2.0-201, the North Anna 3 COL tornado site characteristics are bounded by the ESBWR DCD site parameter values.

Precipitation Extremes

The staff also reviewed the COL applicant's additional information related to winter precipitation roof loading provided in North Anna 3 COL FSAR Section 2.3.1.3.4. The staff issued DC/COL-ISG-7, which clarifies the Staff's position on identifying winter precipitation events as site characteristics and site parameters for determining normal and extreme winter precipitation loads on the roofs of seismic Category I structures. The ISG revises the previously issued staff guidance as discussed in Section 2.3.1 in NUREG-0800.

The ISG states that normal and extreme winter precipitation events should be identified in Section 2.3.1 of NUREG-0800, as COL site characteristics to compare against site parameters related to normal and extreme winter precipitation loads on the roofs of seismic Category I structures. The normal winter precipitation roof load is a function of the normal winter precipitation event; whereas, the extreme winter precipitation roof loads are based on the weight of the antecedent snowpack resulting from the normal winter precipitation event plus the larger resultant weight from either: (1) the extreme frozen winter precipitation event; or (2) the extreme liquid winter precipitation event. The extreme frozen winter precipitation event is assumed to accumulate on the roof on top of the antecedent normal winter precipitation event; whereas, the extreme liquid winter precipitation event may or may not accumulate on the roof, depending on the geometry of the roof and the type of drainage provided. The ISG further states:

- The normal winter precipitation event should be the highest ground-level weight (in pounds per square foot (lb/ft^2)) among: (1) the 100-year return period snowpack; (2) the historical maximum snowpack; (3) the 100-year return period two-day snowfall event; or (4) the historical maximum two-day snowfall event in the site region.

- The extreme frozen winter precipitation event should be the higher ground-level weight (in lb/ft^2) between: (1) the 100-year return period two-day snowfall event; and (2) the historical maximum two-day snowfall event in the site region.

- The extreme liquid winter precipitation event is defined as the theoretically greatest depth of precipitation (in inches of water) for a 48-hour period that is physically possible over a 25.9-square-kilometer (km) (10-square-mile (mi)) area at a particular geographical location during those months with the historically highest snowpack.

The COL applicant identified the maximum snowfall events for the area surrounding the North Anna 3 site to be 25.5 inches. This was measured at two different stations; Piedmont Research Station on January 8, 1996, and Fredericksburg on January 28, 1922. The COL applicant presented the normal winter precipitation roof load of 30.5 lb/ft^2. The staff notes that the normal winter precipitation roof load resulting from the 100-year return period snowpack (30.5 lb/ft^2) is less than the ESBWR design basis normal winter precipitation roof load site parameter value of 50 lb/ft^2. The COL applicant also presented its extreme winter precipitation ground load of 141.3 lb/ft^2. This value is based on the sum of the site characteristic normal winter precipitation event plus the liquid 48-hr PMWP. The staff notes that this extreme winter precipitation ground snow load is less than the ESBWR site parameter value of 162 lb/ft^2. The staff performed an independent evaluation following the methodology provided in DC/COL-ISG-7 and determined that the COL applicant's snow load calculations are conservative and acceptable.

A comparison between the ESBWR site parameter and the North Anna 3 site characteristic for snow load is presented in North Anna 3 COL FSAR Table 2.0-201. The COL applicant's site characteristic for snow load is conservatively bounded by the ESBWR DCD site parameter.

2.3.1.5 Post Combined License Activities

There are no post-COL activities to this section.

2.3.1.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff finds that the COLA includes all the information relevant to this subsection and the staff confirmed that there is no outstanding information that remains to be addressed in the COL FSAR related to this section.

The staff concluded that the information pertaining to North Anna 3 COL FSAR Section 2.3.1 is within the scope of the ESP SSAR and adequately incorporates by reference Section 2.3.1 of the ESP SSAR. The information is therefore acceptable to the staff. The staff evaluated additional information related to NAPS ESP VAR 2.3-1 as discussed in “Tornado Characteristics,” above. The staff found this information to be correct and acceptable for the North Anna 3 site. In addition, the staff compared the additional COL information in the application to the relevant NRC regulations and acceptance criteria defined in Section 2.3.1of NUREG-0800. The staff concluded that the COL applicant is in compliance with the relevant requirements of 10 CFR Parts 52 and 100. The staff finds that COL item 2.0-7-A has been adequately addressed by the applicant and can be considered closed.

2.3.2 Local Meteorology

2.3.2.1 Introduction

North Anna 3, “Local Meteorology,” addresses the local (site) meteorological characteristics, the assessment of the potential influence of the proposed plant and its facilities on local meteorological conditions and the impact of these modifications on plant design and operations, and a topographical description of the site and its environs.

2.3.2.2 Summary of Application

Section 2.3.2, “Local Meteorology,” of the North Anna 3 COL FSAR, Revision 9, incorporates by reference Section 2.3.2 of the ESBWR DCD, Revision 10 and Section 2.3.2 of the North Anna 3 ESP SSAR.

In addition, in North Anna 3 COL FSAR Section 2.3, the COL applicant provided the following:

COL Items:

- NAPS COL 2.0-8-A

The COL applicant provided information in NAPS COL 2.0-8-A to address site-specific information relating to regional climatology, site-specific meteorology, and the onsite meteorological measurements program.

- NAPS ESP COL 2.3-1

The staff reviewed the resolution to NAPS ESP COL 2.3-1, related to the potential impact on the design or operation of the proposed unit(s) of any cooling tower-induced local increase in: (1) ambient air temperature; (2) ambient air moisture content; or (3) moisture and salt deposition. The COL applicant responded to this COL item by providing supplemental information on the potential impact of the North Anna 3 cooling towers on North Anna 3 plant design and operation due to salt deposition, fogging, icing, and local ambient air temperature increases.

2.3.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in the FSER related to the DCD.

In addition, the acceptance criteria associated with the relevant requirements of the Commission regulations for local meteorology are given in Section 2.3.2 of NUREG-0800.

The applicable regulatory requirements for identifying local meteorology are:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c)(2), and 10 CFR 100.21(d) as it relates to the consideration given to the local meteorological characteristics of the site.

The related acceptance criteria from Section 2.3.2 of NUREG-0800 are as follows:

- Local summaries of meteorological data based on onsite measurements in accordance with RG 1.23, Revision 1, and NWS station summaries or other standard installation summaries from appropriate nearby locations (e.g., within 80 km (50 mi)) should be presented as specified in RG 1.206, Section 2.3.2.1.

- A complete topographical description of the site and environs out to a distance of 80 km (50 mi) from the plant, as described in RG 1.206, Section 2.3.2.2, should be provided.

- A discussion and evaluation of the influence of the plant and its facilities on the local meteorological and air quality conditions should be provided. COL applicants should also identify potential changes in the normal and extreme values, resulting from plant construction and operation. The acceptability of the information is determined through comparison with standard assessments.

- The description of local site airflow should include wind roses and annual joint frequency distributions (JDF) of wind speed and wind direction by atmospheric stability for all measurement levels using the criteria provided in RG 1.23, Revision 1.

2.3.2.4 Technical Evaluation

The staff reviewed Section 2.3.2 of the North Anna 3 COL FSAR and checked the referenced ESP SSAR, Revision 9. The staff's review confirmed that the information contained in the North Anna 3 COLA and incorporated by reference to Section 2.3.2 of the ESP SSAR addresses the relevant information related to the local meteorology. The staff's technical evaluation of the information incorporated by reference to the ESP SSAR related to local meteorology is documented in NUREG-1835.

The staff's technical evaluation of this application subsection is limited to reviewing: (1) the resolution of COL item NAPS COL 2.0-8-A, and (2) the resolution of COL Action Item NAPS ESP COL 2.3-1.

COL Items:

- NAPS COL 2.0-8-A

- NAPS ESP COL 2.3-1

The staff reviewed the resolution to NAPS COL 2.0-8-A and NAPS ESP COL 2.3-1 related to local meteorology. The staff found that the COL applicant had appropriately supplied site-specific local meteorological information by incorporating by reference Revision 9 to the North Anna ESP SSAR Section 2.3.2. The staff's review of the COL applicant's supplemental information regarding the North Anna 3 cooling tower impact on North Anna 3 plant design and operation is discussed below.

Potential Influence of the Plant and the Facilities on Local Meteorology

The COL applicant states that the cooling towers are positioned at a location that attempts to reduce or eliminate the potential for plume interference effects on the same-unit and adjacent-unit components and systems that are important to safety. The COL applicant provided a discussion of the effects of salt and moisture deposition on the North Anna 3 transformers, switchyard equipment, or transmission lines. The COL applicant provided an electronic copy of the input and output files from the Seasonal/Annual Cooling Tower Impact (SACTI) computer model. The staff reviewed the model input files to assure that the COL applicant made conservative assumptions. The SACTI results indicate that a highest deposition rate of salt accumulation would result in 0.00015 milligrams per cubic centimeter per month (mg/cm^2-month) near the North Anna 3 transformers during the winter months. This accumulation rate is below the lower end of the "Light Contamination Level" range of 0.03 – 0.08 mg/cm^2 defined by the Institute of Electrical and Electronic Engineers (IEEE) standard[2]. The staff has independently verified the source cited by the COL applicant. The staff agrees that total accumulation reaching amounts that require mitigation is highly unlikely due to local precipitation removing any salt deposits before it reaches a level of concern.

The COL applicant states that the plume from the CIRC hybrid cooling towers is unlikely to affect any heating, ventilation, and air conditioning systems due to the location of the CB being over 1600 ft away. This assures sufficient mixing between the exhaust plume and the surrounding air to minimize any significant increases in wet bulb or dry bulb temperature above local ambient values. The staff agrees with this assessment and finds that the COL applicant has given adequate consideration to whether cooling towers may adversely impact local temperatures, humidity, and other hazards posed by cooling towers.

2.3.2.5 Post Combined License Activities

There are no post COL activities associated with this subsection.

2.3.2.6 Conclusion

The staff reviewed the application and checked the referenced North Anna ESP SSAR. The staff finds that the COLA includes all the required information relevant to this section, and the staff confirmed that there is no outstanding information that remains to be addressed in the COL FSAR related to this Section.

The staff concluded that the information pertaining to North Anna 3 COL FSAR, Section 2.3.2 is within the scope of the ESP and adequately incorporates by reference Section 2.3.2 of the ESP SSAR. Therefore the information is acceptable to the staff. In addition, the staff compared the additional COL information in the application to the relevant NRC regulations and acceptance

[2] IEEE Guide for Application of Power Apparatus Bushings, IEEE Standard C.57.19.100-1995, Aug 1995.

criteria defined in Section 2.3.2 of NUREG-0800 and concluded that the COL applicant is in compliance with the relevant requirements of 10 CFR Parts 52 and 100. COL item NAPS COL 2.0-8-A and COL Action Item NAPS ESP COL 2.3-1 have been adequately addressed by the COL applicant and can be considered closed.

2.3.3 Onsite Meteorological Measurement Programs

2.3.3.1 Introduction

The North Anna 3 onsite meteorological measurement program addresses the need for onsite meteorological monitoring and the resulting data. The staff review covers the following specific areas: (1) meteorological instrumentation, including siting of sensors, sensor type and performance specifications, methods and equipment for recording sensor output, the quality assurance program for sensors and recorders, data acquisition and reduction procedures, and special considerations for complex terrain sites; and (2) the resulting onsite meteorological database, including consideration of the period of record and amenability of the data for use in characterizing atmospheric dispersion conditions.

2.3.3.2 Summary of Application

Section 2.3 of the North Anna 3 COL FSAR, Revision 9, incorporates by reference Section 2.3.3 of the ESBWR DCD, Revision10 and Section 2.3.3 of the North Anna 3 ESP SSAR, Revision 9.

COL Item:

- NAPS COL 2.0-9-A

The COL applicant provided information in NAPS COL 2.0-9-A to address site-specific information relating to regional climatology, site-specific meteorology, and the onsite meteorological measurements program

2.3.3.3 Regulatory Basis

The regulatory basis for incorporating information by reference to the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP, provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP.

The regulatory basis for the information presented in the ESP SSAR is addressed in the FSER related to the ESP SSAR (i.e., NUREG-1835).

The acceptance criteria for the adequacy of distances from the North Anna 3 to the onsite meteorological measurements program are in RG 1.23. NUREG-0800, Section 2.3.3, states that guidance on a suitable onsite meteorological monitoring program is in RG 1.23, Revision 1.

2.3.3.4 Technical Evaluation

The staff reviewed Section 2.3.3 of the North Anna 3 COL FSAR and checked the referenced ESP SSAR. The staff's review confirmed that the information contained in the North Anna 3

COLA and incorporated by reference to Section 2.3.3 of the ESP SSAR, Revision 9, addresses the relevant information related to the onsite meteorological measurements program. The staff's technical evaluation of the information incorporated by reference to the ESP SSAR related to the onsite meteorological measurements program is documented in the corresponding SER (i.e., NUREG-1835).

The staff's technical evaluation of this application subsection is limited to reviewing the resolution of COL Item NAPS COL 2.0-9-A. There are no site parameters or site characteristics associated with this FSAR subsection.

COL Item:

- NAPS COL 2.0-9-A

The staff reviewed the resolution to NAPS COL 2.0-9-A related to the onsite meteorological measurements program. The staff found that the COL applicant had appropriately supplied site-specific onsite meteorological measurements program information by incorporating by reference North Anna 3 ESP SSAR Section 2.3.3.

The staff also reviewed the information provided by the COL applicant in North Anna 3 COL FSAR Section 2.3.3.1.2, concerning the distance between the onsite meteorological towers and the North Anna 3 structures. The COL applicant stated that the highest building at the North Anna 3 site is the Turbine Building (TB) at 52 m (170.6 ft). The primary and backup meteorological towers are approximately 733.4 m (2,406 ft) and 744 m (2,440 ft), respectively, from the plant facility boundary. Because the primary and backup meteorological towers are more than 10 building heights away from the tallest building at the North Anna 3 site, the COL applicant concluded that the North Anna 3 TB does not influence the meteorological measurements. The staff concurred with this assessment because the COL applicant had met the RG 1.23, Revision 1 guidance. RG 1.23, Revision 1 states that obstructions to wind measurements should be at a distance of at least 10 times their height from the wind sensors. The staff noted that the tallest cooling tower is the CWS hybrid cooling tower, which, at 55 m (180 ft), is slightly taller than the TB, but is located further from the primary and backup meteorological towers. Therefore, the staff concluded that the building wake from the cooling tower structures would not influence the meteorological measurements.

2.3.3.5 Post Combined License Activities

Part 10 of the COLA describes proposed COL conditions, including ITAAC. Part 10, Table 2.3-1 of the COLA contains the emergency planning (EP) ITAAC. The following EP ITAAC involve demonstrating that the operational onsite meteorological monitoring program appropriately supports the North Anna 3 emergency plan:

- EP Program Element 6.3: The means exist to continuously assess the impact of the release of radioactive materials to the environment, accounting for the relationship between effluent monitor readings, and onsite and offsite exposures and contamination for various meteorological conditions.

- EP Program Element 6.4: The means exist to acquire and evaluate meteorological information.

- The North Anna 3 EP, including EP ITAAC are addressed in SER Section 13.3, "Emergency Planning."

2.3.3.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff finds that the COLA includes all the information relevant to this subsection, and the staff confirmed that there is no outstanding information that remains to be addressed in the COL FSAR related to this subsection.

The staff concluded that the information pertaining to North Anna 3 COL FSAR Section 2.3.3 is within the scope of the ESP SSAR and adequately incorporates by reference Section 2.3.3 of the North Anna 3 ESP SSAR. The information is therefore acceptable to the staff. In addition, the staff has compared the additional COL information within the application to the relevant NRC regulations and acceptance criteria defined in NUREG-0800, Section 2.3.3, and concludes that the COL applicant is in compliance with the 10 CFR Parts 52 and 100 as described in RG 1.23 and SRP Section 2.3.3. Therefore, NAPS COL Item 2.0-9-A has been adequately addressed by the COL applicant and can be considered closed.

2.3.4 Short-Term Diffusion Estimates (Related to RG 1.206, Section C.III.1, Chapter 2, C.I.2.3.4, "Short-Term Atmospheric Dispersion Estimates for Accident Releases")

2.3.4.1 Introduction

The short-term diffusion estimates are used to determine the amount of airborne radioactive materials expected to reach a specific location during an accident situation. The diffusion estimates address the requirement for conservative atmospheric dispersion (relative concentration) factor (χ/Q value) estimates at the EAB, the outer boundary of the LPZ, and at the control room for postulated design-basis accidental radioactive airborne releases. The staff's review covers the following specific areas: (1) atmospheric dispersion models to calculate atmospheric dispersion factors for postulated accidental radioactive releases; (2) meteorological data and other assumptions used as input to atmospheric dispersion models; (3) derivation of diffusion parameters (e.g., σ_y and $o_{z.}$); (4) cumulative frequency distributions of χ/Q values; (5) determination of conservative χ/Q values used to assess the consequences of postulated design-basis atmospheric radioactive releases to the EAB, LPZ, and control room; and (6) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.3.4.2 Summary of Application

North Anna 3 COL FSAR, Revision 9, Section 2.3.4 addresses site-specific information on short-term atmospheric dispersion estimates for accident releases. The COL applicant addressed the information as follows:

COL Item:

- NAPS COL 2.0-10-A

This COL item states that the COL applicant should provide conservative factors as described in Section 2.3.4 of NUREG-0800.

- NAPS ESP COL 2.3-2

This COL action item states that the COL applicant should assess dispersion of airborne radioactive materials to the control room. The COL applicant responded to this COL action item by providing details regarding the source and receptor information needed to determine χ/Q values at the ESBWR control room. The χ/Q values calculated through the use of the ARCON96 computer program are provided in North Anna 3 COL FSAR Table 2.0-201. Tables 2.3-201 through 2.3-204, Table 2.3-206, and Table 2.3-207.

2.3.4.3 Regulatory Basis

The regulatory basis for incorporating information by reference to the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP, provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP.

The regulatory basis for the information presented in the ESP SSAR is addressed in the FSER related to the ESP SSAR (i.e., NUREG-1835).

The acceptance criteria for the additional accidental atmospheric dispersion estimates presented in the North Anna 3 COL FSAR, beyond those presented in the ESP SSAR, are based on meeting the relevant requirements of 10 CFR Part 50. The staff considered the following regulatory requirements in reviewing the COL applicant's discussion of control room atmospheric dispersion analyses:

- 10 CFR Part 50, Appendix A, GDC 19, "Control Room," as it relates to the meteorological considerations used to evaluate the personnel exposures inside the control room during radiological accident conditions.

- 10 CFR Part 50, Appendix E, Paragraph IV.E.8, as it relates to providing an onsite technical support center (TSC) from which effective direction can be given and effective control can be exercised during an emergency.

The related acceptance criteria from Section 2.3.4 of NUREG-0800 are as follows:

- A description of the atmospheric dispersion models used to calculate χ/Q values for accidental releases of radioactive materials into the atmosphere.

- Meteorological data used for the evaluation (as input to the dispersion models), which represent annual cycles of hourly values of wind direction, wind speed, and atmospheric stability for each mode of accidental release.

- A discussion of atmospheric diffusion parameters, such as lateral and vertical plume spread (σ_y and $o_{z.}$) as a function of distance, topography, and atmospheric conditions, should be related to measured meteorological data.

- Hourly cumulative frequency distributions of χ/Q values from the effluent release point(s) to the EAB and LPZ should be constructed to describe the probabilities of these χ/Q values being exceeded.

- Atmospheric dispersion factors used for the assessment of consequences related to atmospheric radioactive releases to the control room for design-basis and other accidents should be provided.

- For control room habitability analysis, a site plan drawn to scale should be included showing true North and potential atmospheric accidental release pathways, control room intake, and unfiltered inleakage pathways.

Section 15.0.3 of NUREG-0800 specifies (in part) that an application meets 10 CFR Part 50, Appendix E, TSC radiological habitability requirements if the total calculated radiological consequences for postulated accidents fall within the exposure acceptance criteria specified for the control room.

The following RGs are applicable to this section:

- RG 1.78, Revision 1;

- RG 1.145, “Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants,” Revision 1; and

- RG 1.194, “Atmospheric Relative Concentrations for Control Room Radiological Habitability Assessments at Nuclear Power Plants.”

2.3.4.4 Technical Evaluation

The staff reviewed North Anna 3 COL FSAR Section 2.3.4 and checked the referenced ESP SSAR, Revision 9. The staff’s review confirmed that the information contained in the North Anna 3 COLA and incorporated by reference to Section 2.3.4 of the ESP SSAR, addresses the relevant information related to short-term atmospheric diffusion estimates for accident releases. The staff’s technical evaluation of the information incorporated by reference to the ESP SSAR related to long-term atmospheric dispersion estimates for routine releases is documented in the corresponding FSER (i.e., NUREG-1835).

The staff’s technical evaluation of this subsection is limited to reviewing: (1) the resolution of COL item NAPS COL 2.0-10-A; (2) the resolution of COL Action Item NAPS ESP COL 2.3-2; and (3) whether the North Anna 3 short-term atmospheric diffusion site characteristics fall within the ESBWR DCD short-term atmospheric diffusion site parameter values.

EAB and LPZ χ/Q Values

The staff found the continued use of the North Anna 3 ESP SSAR accident EAB and LPZ χ/Q values acceptable for the following reasons:

- Section 2.3.4 of NUREG-0800, states that a COLA referencing an ESP need not include a re-investigation of the site characteristics that have been previously accepted in the referenced ESP.

- The North Anna 3 site layout shown in North Anna 3 COL FSAR Figure 2.0-205, "Unit 3 Power Block Building Locations Within the ESP Proposed Facility Boundary," is the same layout shown in North Anna 3 ESP Figure 1.2-4 and the definitions of the North Anna 3 COL FSAR EAB and LPZ are the same as the North Anna 3 ESP definitions. Consequently, the downwind distances used in the North Anna 3 ESP SSAR to calculate the EAB and LPZ χ/Q site characteristic values are applicable to the North Anna 3 COLA.

Other input assumptions used to derive the North Anna 3 ESP SSAR EAB and LPZ accident χ/Q site characteristic values remain bounding for North Anna 3. For example, all release points are as ground level releases and the COL applicant did not take credit for building wake effects. Ignoring building wake effects for a ground-level release decreases the amount of atmospheric turbulence assumed to be in the vicinity of the release point, resulting in higher (more conservative) χ/Q values.

The staff concluded that the input assumptions used to model the North Anna 3 ESP SSAR accident EAB and LPZ χ/Q values bound the actual North Anna 3 plant and site characteristics and the use of one set of accident χ/Q values to model all potential accident release points is appropriate. Therefore, the staff finds that the COL applicant's use of the North Anna 3 ESP SSAR EAB and LPZ χ/Q values for North Anna 3 is appropriate.

Control Room and TSC χ/Q Values for North Anna 3 Releases

The COL applicant used the computer code ARCON96 (NUREG/CR-6331, "Atmospheric Relative Concentrations in Building Wakes") to estimate χ/Q values at the control room for potential accidental releases of radioactive material. The ARCON96 model implements the methodology outlined in RG 1.194.

The ARCON96 code estimates χ/Q values for various time-averaged periods ranging from 2 hours to 30 days. The meteorological input to ARCON96 consists of hourly values of wind speed, wind direction, and atmospheric stability class. The χ/Q values calculated through ARCON96 are based on the theoretical assumption that material released to the atmosphere will be normally distributed (Gaussian) about the plume centerline. A straight-line trajectory is assumed between the release points and receptors. The diffusion coefficients account for enhanced dispersion under low wind speed conditions and in building wakes.

The hourly meteorological data are used to calculate hourly relative concentrations. The hourly relative concentrations are then combined to estimate concentrations ranging in duration from 2 hours to 30 days. Cumulative frequency distributions are prepared from the average relative concentrations and the relative concentrations that are exceeded no more than 5 percent of the time for each averaging period is determined.

The meteorological input to ARCON96 used by the COL applicant consisted of wind speed, wind direction, and atmospheric stability data based on hourly onsite data from a 3-year period from January 1, 1996 through December 31, 1998. The wind data were obtained from the 10-m and 48.4 m levels of the onsite meteorological tower, and the stability data were derived from the vertical temperature difference (delta-temperature) measurements taken between the 48.4-m and 10-m levels on the onsite meteorological tower.

The following sources were used as the necessary input to ARCON96:

Onsite Hourly Meteorological Data: ----------- January 1, 1996 – December 31, 1998
ESBWR DCD Figure 2A-1:-----------------------Site Plan with Release and Intake Locations
ESBWR DCD Table 2A-1 to 2A-4:------------- CR and TSC Source/Receptor Data
North Anna 3 COL FSAR Figure 2.1-201:----Plant Layout on the North Anna 3 Site

North Anna 3 COL FSAR Section 2.4.2.3 states that for North Anna 3 Units 3, the plant orientation is rotated 23.54 degrees clockwise from true north. ARCON96 modeling was conducted by the COL applicant to evaluate impacts at the Control Room emergency intakes.

North Anna 3 COL FSAR Table 2.3-201 through 2.3-207 lists the atmospheric dispersion estimates that the COL applicant derived from its ARCON96 modeling run results. In accordance with the ESBWR DCD, North Anna 3 COL FSAR Table 2.0-201 compared the site-specific control room χ/Q values to the corresponding site parameters provided in the DCD. This comparison showed that the ESBWR control room values conservatively bounded the site-specific values.

RAI 02.03.04-2 requested the COL applicant provide a copy of the ARCON96 input and output files used to determine the control room and TSC χ/Q values. As part of the response to RAI 02.03.04-2 dated January 10, 2011 (ADAMS Accession No. ML110140131), the COL applicant committed to updating the FSAR to include a comparison of the site χ/Q values against Revision 3 of the US-APWR DCD. The staff confirmed the COL applicant's atmospheric dispersion estimates for the 1996-1998 data by running the ARCON96 computer model and obtaining similar results (i.e., values on average within ± 2.5 percent). Both the staff and COL applicant used a ground-level release assumption for each of the release/receptor combinations as well as other conservative assumptions. In light of the foregoing, the staff accepts the control room χ/Q values presented by the COL applicant and determines that RAI 02.03.04-2 is resolved and closed. The licensee later submitted ARCON96 input and output files to support the control room and TSC χ/Q values for the ESBWR DCD.

2.3.4.5 Post Combined License Activities

There are no post COL activities associated with this subsection.

2.3.4.6 Conclusion

The staff reviewed the application and checked the referenced DCD and the North Anna 3 ESP SSAR. The staff finds that the COLA includes all the required information related to short-term diffusion estimates, and the staff confirmed that there is no outstanding information that remains to be addressed in the North Anna 3 COL FSAR related to this subsection. The staff's technical evaluation of the information incorporated by reference to the ESP SSAR related to local meteorology is documented in NUREG-1835.

In addition, the staff has compared the additional COL information in the application to the relevant regulations and acceptance criteria defined in NUREG-0800, Section 2.3.4. The staff concludes that the COL applicant is in compliance with the relevant requirements of 10 CFR Parts 50, 52, and 100.

2.3.5 Long-Term Diffusion Estimates (Related to RG 1.206, Section C.III.2, Chapter 2, C.I.2.3.5, "Long Term Atmospheric Dispersion Estimates for Routine Releases")

2.3.5.1 Introduction

The long-term diffusion estimates are used to determine the amount of airborne radioactive materials expected to reach a specific location during normal operations. The diffusion estimates address the requirement concerning atmospheric dispersion and dry deposition estimates for routine releases of radiological effluents to the atmosphere. The review covers the following specific areas: (1) atmospheric dispersion and deposition models used to calculate concentrations in air and amount of material deposited as a result of routine releases of radioactive material to the atmosphere; (2) meteorological data and other assumptions used as input to the atmospheric dispersion models; (3) derivation of diffusion parameters (e.g., σ_z); (4) atmospheric dispersion (relative concentration) factors (χ/Q values) and deposition factors (D/Q values) used for assessment of consequences of routine airborne radioactive releases; (5) points of routine release of radioactive material to the atmosphere, the characteristics of each release mode, and the location of potential receptors for dose computations; and (6) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.3.5.2 Summary of Application

North Anna 3 COL FSAR, Section 2.3.5 addresses site-specific information on long-term atmospheric dispersion estimates for routine releases. The COL applicant addressed the information as follows:

<u>*COL Items:*</u>

- NAPS COL 2.0-11-A

This COL information item states that the COL applicant should characterize the atmospheric transport and diffusion conditions necessary for estimating radiological consequences of the routine release of radioactive materials to the atmosphere, and provide realistic estimates of annual average χ/Q values and D/Q values as described in Section 2.3.5 of NUREG-0800.

- NAPS ESP COL 2.3-3

This COL item states that the COL applicant should verify specific release point characteristics and specific locations of receptors of interest used to generate the ESP SSAR long-term (routine release) atmospheric dispersion site characteristics. The COL applicant responded to this COL action item by recalculating site-specific, long-term χ/Q and D/Q values at specific receptors of interest using: (1) the land-use census results reported in the Dominion North Anna 3 2006 Annual Radiological Environmental Operating Report (AREOR), and (2) ESBWR-specific vent building height and building cross-sectional area data. These new North Anna 3 long-term χ/Q and D/Q values at specific receptors of interest are in North Anna 3 COL FSAR Table 2.3-16R. The COL applicant recalculated long-term χ/Q and D/Q values at the site boundary; however, χ/Q and D/Q values from the ESP SSAR are used because the COL applicant had determined that the ESP SSAR values for the site boundary are bounding.

Early Site Permit Variances:

- NAPS ESP VAR 2.0-1a

The COL applicant proposed variance NAPS ESP VAR 2.0-1a from the ESP SSAR. This variance recalculated North Anna 3 maximum long-term (routine release) χ/Q and D/Q values for the RW ventilation stack to replace corresponding values presented in the ESP SSAR.

2.3.5.3 Regulatory Basis

The regulatory basis for incorporating information by reference to the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP, provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP.

The regulatory basis for the information presented in the ESP SSAR is addressed in the FSER related to the ESP SSAR (i.e., NUREG-1835).

The acceptance criteria for the additional long-term atmospheric dispersion estimates presented in North Anna 3 COL FSAR Section 2.3.5, beyond those presented in the ESP SSAR, are based on meeting the relevant requirements of 10 CFR Parts 20, "Standards for Protection Against Radiation," 50, and 100. The staff considered the following regulatory requirements in reviewing the COL applicant's discussion of long-term atmospheric dispersion and deposition estimates:

- 10 CFR Part 20, Subpart D, as it relates to establishing atmospheric dispersion site characteristics for demonstrating compliance with dose limits for individual members of the public.
- 10 CFR 50.34a, "Design objectives for equipment to control releases of radioactive material in effluents – nuclear power reactors," and Sections II.B, II.C, and II.D of Appendix I, "Numerical Guides for Design Objectives and Limiting Conditions for Operation to Meet the Criterion 'As Low as is Reasonably Achievable' for Radioactive Material in Light-Water-Cooled Nuclear Power Reactor Effluents," of 10 CFR Part 50, as they relate to establishing atmospheric dispersion site characteristics for operation to meet the requirements that radioactive material in effluents released to unrestricted areas be kept as low as is reasonably achievable.
- 10 CFR 100.21(c)(1), as it relates to establishing atmospheric dispersion site characteristics such that radiological effluent release limits associated with normal operation can be met for any individual located offsite.

The related acceptance criteria from Section 2.3.5 of NUREG-0800 are as follows:

- A detailed description of the atmospheric dispersion and deposition models used by the COL applicant to calculate annual average concentrations in air and amount of material deposited as a result of routine releases or radioactive materials to the atmosphere.
- A discussion of atmospheric diffusion parameters, such as vertical plume spread ($\sigma_{z.}$) as a function of distance, topography, and atmospheric conditions.

- Meteorological data summaries (onsite and regional) used as input to the dispersion and deposition models.

- Points of routine release of radioactive material to the atmosphere, including the characteristics (e.g., location, release mode) of each release point.

- The specific location of potential receptors of interest (e.g., nearest vegetable garden, nearest resident, nearest milk animal, and nearest meat cow in each 22½ degree direction sector within a 5-mi [8-km] radius of the site).

- The χ/Q and D/Q values to be used for assessment of the consequences of routine airborne radiological releases as described in and Section 2.3.5.2 of RG 1.206: (1) Maximum annual average χ/Q values and D/Q values at or beyond the site boundary and at specified locations of potential receptors of interest utilizing appropriate meteorological data for each routine venting location; and (2) estimates of annual average χ/Q values and D/Q values for 16 radial sectors to a distance of 50 mi (80 km) from the plant using appropriate meteorological data.

The following RGs are applicable to this section:

- RG 1.23, Revision 1;

- RG 1.109, "Calculation of Annual Doses to Man from Routine Releases of Reactor Effluents for the Purpose of Evaluating Compliance with 10 CFR Part 50, Appendix I," Revision 1;

- RG 1.111, "Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors," Revision 1; and

- RG 1.112, "Calculation of Releases of Radioactive Materials in Gaseous and Liquid Effluents from Light-Water-Cooled Power Reactors," Revision 1.

2.3.5.4 Technical Evaluation

The staff reviewed North Anna 3 COL FSAR Section 2.3.5 and checked the referenced ESP SSAR, Revision 9. The staff's review confirmed that the information contained in the North Anna 3 COLA and incorporated by reference to Section 2.3.5 of the ESP SSAR, addresses the relevant information related to long-term atmospheric dispersion and deposition estimates for routine releases. The staff's technical evaluation of the information incorporated by reference to the ESP SSAR related to long-term atmospheric dispersion estimates for routine releases is documented in the corresponding FSER (i.e., NUREG-1835).

The staff's technical evaluation of this subsection is limited to reviewing: (1) the resolution of COL Item NAPS COL 2.3-3, (2) the resolution of COL Action Item NAPS ESP COL 2.3-3, (3) variance NAPS ESP VAR 2.0-1 (Long-Term Dispersion Value (D/Q) Estimate), and (4) whether the North Anna 3 long-term atmospheric dispersion and deposition site characteristics fall within the ESBWR DCD long-term atmospheric dispersion and deposition site parameter values.

Atmospheric Dispersion Model

The COL applicant used the NRC-sponsored computer code XOQDOQ (described in NUREG/CR-2919, "XOQDOQ Computer Program for the Meteorological Evaluation of Routine Effluent Releases at Nuclear Power Stations") to estimate χ/Q and D/Q values resulting from routine releases. The XOQDOQ model implements the constant mean wind direction model methodology outlined in RG 1.111, Revision 1.

The XOQDOQ model is a straight-line Gaussian plume model based on the theoretical assumption that material released to the atmosphere will be normally distributed (Gaussian) about the plume centerline. In predictions of χ/Q and D/Q values for long time periods (i.e., annual averages), the plume's horizontal distribution is assumed to be evenly distributed within the downwind direction sector (e.g., "sector averaging"). A straight-line trajectory is assumed between the release point and all receptors.

Release Characteristics and Receptors

The COL applicant modeled two ground-level release points and two mixed-mode release points. Releases from the TB and the RB assumed a minimum building cross-sectional area of 3,098 m^2, a building height of 46.1 m, and release heights of 71.3 m (TB) and 52.77 m (RB). Releases from the RW assume a building minimum building cross-sectional area of 3,098 m^2, a building height of 46.1 m, and a release height of 0.0 m. Releases from the CIRC Cooling Tower assume a height of 0.0 m for both building height and release height and a minimum cross-sectional area of 0.0 m^2. The COL applicant assumed a mixed-mode release for releases from the RB ventilation stack and the TB ventilation stack. Ground-level releases are used to model routine releases from the RW and the CIRC Cooling Tower.

The staff found that the ESBWR DCD assumed a ground-level release for releases from the RW, while mixed-mode releases were considered for releases from the RB/ FB stack and the TB stack based on the criteria set forth in RG 1.111. Revision 8 of the North Anna 3 FSAR stated that the vent stacks on the RB/FB, TB, and RW are all modeled as mixed-mode releases. On September 9, 2014, the staff issued RAI 02.03.05-5, which asked the applicant to update the FSAR to include a justification for modeling the RW vent stack (RW-VS) as a mixed-mode release or update the FSAR to implement the ground-level source configuration guidance provided in RG 1.111 for the RW-VS releases. The applicant submitted a response to RAI 02.03.05-5 on October 17, 2014 (ADAMS Accession No. ML14295A659), which updated the FSAR to reflect the RW-VS source as a ground-level release. The RAI response also updated FSAR Section 2.3.5.1, Table 2.3-16R, Tables 2.3-208 through 2.3-215, and Table 2.0-201. The staff confirmed the applicant's changes to the release point characteristics by comparing the release details against the ESBWR DCD. The staff performed an independent confirmatory analysis of the release sources using the XOQDOQ model and the provided onsite meteorological database. The staff has confirmed the assumptions and revised χ/Q and D/Q values provided in the RAI response. Therefore, the staff considers RAI 02.03.05-5 to be closed. The staff verified that the appropriate changes are incorporated into FSAR Section 2.3.5, Revision 9, and, therefore, Confirmatory Item 2.3.5-1 from the staff's advanced SER for North Anna 3 is resolved and closed. The use of mixed-mode releases and ground-level releases is acceptable to the staff because it follows the guidance provided in RG 1.111, Revision 1, and the methodology used in the ESBWR DCD.

The distance to the receptors of interest (i.e., the EAB, nearest residence, nearest vegetable garden, and nearest meat animal) were presented in North Anna 3 COL FSAR Table 2.3-15R. For the evaluation of each of the receptors (with the exception of the EAB), the COL applicant conservatively assumed that the location of the closest receptor is the distance to each of the receptors. The closest receptor was determined to be a residence in the NW direction at a distance of 1.2 km. Therefore, for the purposes of the atmospheric dispersion calculations, each receptor was assigned a distance of 1.2 km for each radial direction. For releases from the CIRC Cooling Tower, which lies outside of the plant facility boundary, distances from the CIRC Cooling Tower to the EAB in each sector were used to calculate separate χ/Q and D/Q values. Because the COL applicant chose to use the closest distance for each of the receptors, these assumptions are conservative and are therefore acceptable to the staff.

Meteorological Data Input

The meteorological input to XOQDOQ used by the COL applicant consisted of a JFD of wind speed, wind direction, and atmospheric stability based on hourly onsite data from a 3-year period from January 1, 1996 through December 31, 1998. The wind data were obtained from the 10-m level of the onsite meteorological tower, and the stability data were derived from the vertical temperature difference (delta-temperature) measurements taken between the 48.4-m and 10-m levels on the onsite meteorological tower. As discussed in SER Section 2.3.3, the staff considers the January 1, 1996 through December 31, 1998 onsite meteorological database suitable for input to the XOQDOQ model.

Diffusion Parameters

The COL applicant chose to implement the diffusion parameter assumptions outlined in RG 1.111, Revision 1 for the XOQDOQ model runs. The staff evaluated the applicability of the XOQDOQ diffusion parameters and concluded that no unique topographic features preclude the use of the XOQDOQ model for the North Anna 3 site. Therefore, the staff finds that the COL applicant's use of diffusion parameter assumptions, as outlined in RG 1.111, Revision 1 is acceptable.

Resulting Relative Concentration and Relative Deposition Factors

North Anna 3 COL FSAR Table 2.3-16R, "XOQDOQ Predicted Maximum χ/Q and D/Q Values at Specific Points of Interest," lists the maximum long-term atmospheric dispersion and deposition estimates for the special receptors of interest that the COL applicant derived from its XOQDOQ modeling results. North Anna 3 COL FSAR Table 2.3-208 through 2.3-223 lists the COL applicant's long-term atmospheric dispersion and deposition estimates for 16 radial sectors from the site boundary, to a distance of 50 mi from the proposed facility.

The χ/Q values presented in North Anna 3 COL FSAR Table 2.3-16R reflect several plume radioactive decay and deposition scenarios. Section C.3 of RG 1.111, Revision 1 states that radioactive decay and dry deposition should be considered in radiological impact evaluations of potential annual radiation doses to the public, resulting from routine releases of radioactive materials in gaseous effluents. Section C.3.a of RG 1.111, Revision 1 states that an overall half-life of 2.26 days is acceptable for evaluating the radioactive decay of short-lived noble gases and an overall half-life of 8 days is acceptable for evaluating the radioactive decay for all iodine's released to the atmosphere. Definitions for the χ/Q categories listed in the headings of North Anna 3 COL FSAR Table 2.3-16R are as follows:

- Undepleted/No Decay χ/Q values are χ/Q values used to evaluate ground-level concentrations of long-lived noble gases, tritium, and carbon-14. The plume is assumed to travel downwind, without undergoing dry deposition or radioactive decay.

- Undepleted/2.26-Day Decay χ/Q values are χ/Q values used to evaluate ground-level concentrations of short-lived noble gases. The plume is assumed to travel downwind, without undergoing dry deposition, but is decayed, assuming a half-life of 2.26 days, based on the half-life of xenon-133.

- Depleted/8.00-Day Decay χ/Q values are χ/Q values used to evaluate ground-level concentrations of radioiodine and particulates. The plume is assumed to travel downwind, with dry deposition, and is decayed, assuming a half-life of 8.00 days, based on the half-life of iodine-131.

Using the information provided by the COL applicant, including the 10-m level JFDs of wind speed, wind direction, and atmospheric stability presented received during the North Anna 3 ESP SSAR review, the staff confirmed the COL applicant's χ/Q and D/Q values by running the XOQDOQ computer code. Although the staff's χ/Q and D/Q values differed from the COL applicants, the values presented in the North Anna 3 COL FSAR were consistently more conservative than those calculated by the staff. The applicant provided information related to NAPS ESP VAR 2.0-1, which requests the use the North Anna 3 maximum long-term deposition value (D/Q) estimate provided in North Anna 3 FSAR Table 2.3-16R for the maximum annual average meat animal D/Q value in the South direction for releases from the RW ventilation stack rather than the corresponding ESP value in FSER Supplement 1, Appendix A and in ESP SSAR Table 2.3-16. Both the COL applicant and the staff calculated χ/Q and D/Q (including those provided as part of NAPS ESP VAR 2.0-1) values were within bounds of the ESBWR DCD χ/Q and D/Q site parameter values, and are, therefore, acceptable to the staff.

2.3.5.5 Post Combined License Activities

There are no post-COL activities related to this section.

2.3.5.6 Conclusion

The staff reviewed the application including NAPS COL 2.3-3 and checked the referenced DCD and the North Anna 3 ESP SSAR. The staff finds that the COLA includes all the required information relating to long-term diffusion estimates, and the staff confirmed that there is no outstanding information that remains to be addressed in the North Anna 3 COL FSAR related to this subsection. The staff evaluated additional information related to NAPS ESP VAR 2.0-1 as discussed in "Resulting Relative Concentration and Relative Deposition Factors," above. The staff found this information to be correct and acceptable for use in the FSAR. The staff's technical evaluation of the information incorporated by reference to the ESP SSAR related to local meteorology is documented in NUREG-1835.

ESBWR DCD, Section 2.3.6.5 states that a COL applicant shall characterize the atmospheric transport and diffusion conditions necessary for estimating radiological consequences of the routine release of radioactive materials to the atmosphere, and provide realistic estimates of annual average χ/Q values and D/Q values as described in Section 2.3.5 in NUREG-0800. Based on the meteorological data provided by the COL applicant and an atmospheric dispersion model that is appropriate for the characteristics of the site and release points, the staff concludes that representative atmospheric dispersion and deposition factors have been calculated for 16 radial sectors from the site boundary to a distance of 50 mi (80 km), as well as for specific locations of potential receptors of interest. The characterization of atmospheric dispersion and deposition conditions are acceptable to meet the criteria described in RG 1.111, Revision 1 and are appropriate for the evaluation to demonstrate compliance with the numerical guides for doses in Subpart D of 10 CFR Part 20 and Appendix I to 10 CFR Part 50. The staff finds that the COL applicant has provided sufficient information to meet the requirements of the ESBWR DCD.

2.4 <u>Hydrology</u>

This section of the SER addresses the North Anna 3 COL FSAR, Revision 9, site-specific hydrological site parameters and site characteristics identified in Chapter 5 of Tier 1 and Chapter 2 of Tier 2 of the ESBWR DCD, Revision 10.

2.4.1 Hydrologic Description

2.4.1.1 Introduction

The hydrologic description of the nuclear power plant site includes the interface of the plant with the hydrosphere, hydrological causal mechanisms, surface and groundwater uses, hydrologic data, and alternate conceptual models. The review covers the following specific areas: (1) interface of the plant with the hydrosphere including descriptions of site location, major hydrological features in the site vicinity, surface- and groundwater related characteristics, and the proposed water supply to the plant; (2) hydrological causal mechanisms that may require special plant design bases or operating limitations with regard to floods and water supply requirements; (3) current and likely future surface and groundwater uses by the plant and water users in the vicinity of the site that may impact safety of the plant; (4) available spatial and temporal data relevant for the site review; (5) alternate conceptual models of the hydrology of the site that reasonably bound hydrological conditions at the site; (6) potential effects of seismic and nonseismic data on the postulated design bases and how they relate to the hydrology in the vicinity of the site and the site region; and, (7) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.1.2 Summary of Application

North Anna 3 COL FSAR Section 2.4.1, "Hydrologic Description," describes the site from the standpoint of hydrologic considerations. This section also provides topographic and regional maps showing proposed changes to the site's natural drainage features and major hydrological features.

The COL applicant addressed the ESBWR DCD and ESP information as follows:

<u>COL Item:</u>

- NAPS COL Item 2.0-12-A — Hydraulic Description, COL Applicant to provide information in accordance with SRP 2.4.1

The COL applicant incorporated by reference ESP SSAR Section 2.4.1 to address COL Item 2.0-12-A.

The COL applicant provided updated site-specific information to supplement ESP SSAR, Section 2.4.1.1, "Site and Facilities," by stating that the design plant grade elevation is 88.39 m (290.0 ft) North American Vertical Datum 1988 (NAVD88) and that the layout will affect a few small wetlands and the upper portion of two small unnamed streams that flow into Lake Anna northwest of the powerblock. In these areas, drainage will be directed into drainage swales and a stormwater management system and then rejoined with the two small streams.

- NAPS ESP COL 2.4-1 Intake and Discharge Tunnels Layout

The NAPS ESP COL 2.4-1 item provides a site-specific layout of intake and discharge tunnels for plant service water (SW) and circulating water systems.

- NAPS ESP COL 2.4-2 Shut Down Water Level

The NAPS ESP COL 2.4-2 item describes the Lake Anna required shutdown water level.

- NAPS ESP COL 2.4-6 UHS Reservoir Design

The NAPS ESP COL 2.4-6 item provides the basis for emergency cooling capability.

- NAPS ESP COL 2.4-7 UHS Storage Basins Sufficient for 30-Day Emergency Cooling Water Needs

The NAPS ESP COL 2.4-7 item provides the North Anna 3 UHS for the passive ESBWR design.

- NAPS ESP COL 2.4-8 Use of Lake Anna or the Waste Heat Treatment Facility (WHTF) for Safety-Related Water Withdrawals

The NAPS ESP COL 2.4-8 item describes that the Isolation Condenser/Passive Containment Cooling System (IC/PCCS) pools have their own water in place during North Anna 3 operation for safety-related cooling in the event that use of the UHS is required.

Early Site Permit Condition:

ESP Permit Condition 3.E(2), Second New Unit Shall Use A Dry Cooling System.

Early Site Permit Variance:

The following variances from the ESP SSAR is discussed in Section 2, “Variances,” of Part 7 to the COLA:

- NAPS ESP VAR 2.4-4 Lake Level Increase

The COL applicant requested VAR 2.4-4 to the ESP SSAR to use a higher value for the normal elevation of Lake Anna. The COL applicant supplemented ESP SSAR Section 2.4.1.3, “Existing and Proposed Water Control Structures,” by stating that, with the addition of North Anna 3, the normal pool elevation will be increased by 7.6 cm (3 in) to a level of 76.01 m (249.39 ft) NAVD88.

In addition, the COL applicant supplemented North Anna 3 COL FSAR Section 2.4.1 with a statement that the flood surcharge capacity of Lake Anna is 4.50 m (14.75 ft) above the normal pool elevation and included information on Lake Anna storage allocations in North Anna 3 COL FSAR Table 2.4-1R.

- NAPS ESP VAR 2.0-7 Coordinates/Removal of abandoned mat foundations

This variance is discussed in the Variances Section of the Departures Report (Part 7) of the COLA and contains two parts as discussed below:

The COL applicant requested a variance from one of the coordinate systems that define the "ESP Plant Parameter Envelope" shown in the ESP, Appendix A, Figure 1 which lists the coordinates of the site in State NAD 83 South Zone, as well as in the North Anna 3 site Grid coordinates. In the variance, the COL applicant requested to use the values given in North Anna 3 COL FSAR Figure 2.0-205 as "COORDINATES (STATE PLANE NAD 83 VA SOUTH ZONE)," to replace those in the ESP given as "Coordinates (State NAD 83 South Zone)." The review of this part of the variance (site Grid coordinates) request is discussed below.

The COL applicant in addition requested a variance from ESP, Appendix A, Figure 1, Note 2, which states, "Abandoned Unit 3 and 4 Reactor Building Mat Foundations are to be removed." The applicant requests to not remove the abandoned mat foundations for the originally planned North Anna Units 3 and 4 unless a Unit 3 Seismic Category I or II structure would be located above an abandoned foundation. The review of this part of the variance request is discussed above in Section 2.0.

2.4.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835 the FSER related to the North Anna 3 ESP. In addition, guidance relevant to the Commission's regulations for the hydrologic descriptions, and the associated acceptance criteria, with the relevant requirements of the NRC regulations for site hydrology are described in Section 2.4.1 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 site hydrologic information presented in the FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item 2.0-12-A and NAPS ESP VAR 2.4-4), are based on meeting the following relevant requirements of 10 CFR Parts 52 and 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

The hydrological information assembled in compliance with the above regulatory requirements are necessary to determine a proposed facility's compliance with the following requirements in Appendix A of 10 CFR Part 50:

- GDC 2, which requires that SSCs important to safety be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions.

The related acceptance criteria from Section 2.4.1 of NUREG-0800 SRP are as follows:

- Interface of the Plant with the Hydrosphere: The application should provide a description of hydrology in the vicinity of the site and site regions and of how the plant interfaces with the hydrosphere.

- Hydrological Causal Mechanisms: The application should provide a description of hydrological causal mechanisms that affect the safety of the plant.

- Surface and Ground Water Uses: The application should provide a description of surface and ground water uses in the vicinity of the site that affect the safety related water supply to the plant.

- Data: The application should provide a complete description of all spatial and temporal datasets used by the applicant in support of its conclusions regarding safety of the plant.

- Alternate Conceptual Models: The application should provide a description of alternate conceptual models of site hydrology.

- Consideration of Other Site-Related Evaluation Criteria: The application should demonstrate that the potential effects of site-related proximity and of seismic and non-seismic information as they relate to hydrologic description in the vicinity of the proposed plant site and site regions are appropriately taken into account.

The description of hydrologic characteristics should correspond to those of the United States Geological Survey (USGS), Natural Resources Conservation Service (NRCS), U.S. Army Corps of Engineers (USACE), or appropriate State and river basin agencies.

In addition, the hydrologic characteristics should be consistent with appropriate sections from: RG 1.27, RG 1.29, “Seismic Design Classification,” RG 1.59, “Flood Design Basis for Nuclear Power Plants,” as supplemented by best current practices, and RG 1.102, “Flood Protection for Nuclear Power Plants.”

2.4.1.4 Technical Evaluation

As documented in Section 2.4.1 of NUREG-1966 and Section 2.4.1 of NUREG-1835, the staff reviewed and approved information related to hydrologic description for the certified ESBWR DCD, Revision 10, and Section 2.4.1 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.1 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic. The staff’s review confirms that the information in the application and the information incorporated by reference address the required information related to “Hydrologic Description.”

The staff’s review of the additional information and ESP variances contained in the North Anna 3 COL FSAR is as follows.

The staff’s technical review of this application includes the supplemental information pertaining to NAPS COL 2.0-12-A and NAPS ESP VAR 2.4-4. This review also includes staff evaluation of additional items discussed in the ESP and the North Anna 3 COL FSAR, as described below.

COL Items:

- NAPS COL 2.0-12-A Hydraulic Description

The COL applicant's updated design plant grade elevation for North Anna 3 is 88.39 m (290.0 ft) NAVD88 which is 6.36 m (20.86 ft) above the flood elevation site characteristic (82.03 m [269.14 ft] NAVD88). The COL applicant provided North Anna 3 COL FSAR Figure 2.1-201 showing the layout of the external structures and components of North Anna 3.

The COL applicant stated that small changes to natural drainage features would be required to accommodate North Anna 3, including a few small wetlands and the upper ends of two intermittent streams that discharge to Lake Anna. Drainage from filled areas will be directed into swales before entering the streams. North Anna 3 COL FSAR Section 2.4.2.3 discusses drainage during the local probable maximum precipitation (PMP). The staff finds that the additional information is consistent with the information in the ESP SSAR, which has already been accepted by the staff as documented in the North Anna ESP FSER (NUREG-1835).

- NAPS ESP COL 2.4-1 Intake and Discharge Tunnels Layout

ESP COL Action Item 2.4-1 considers the layout of intake and discharge tunnels for plant SW and circulating water systems. North Anna 3 COL FSAR Section 1.12 discusses hazards to existing units from construction, and it is stated that piping plans for intake and discharge structures will be provided to NRC 60 days prior to construction of the piping.

Based on the description of the UHS in ESBWR DCD Section 9.2.5 and North Anna 3 COL FSAR Section 9.2.5, staff have determined that intake and discharge piping does not provide safety-related functions. The maximum flood and the maximum groundwater elevations are below the ESBWR DCD site parameters for hydrologic characteristics; therefore, ESP COL Action Item 2.4-1 is considered closed.

- NAPS ESP COL 2.4-2 Shut Down Water Level

Although Appendix C of the North Anna ESP discusses Action Item 2.4-2 in ESP FSER Section 2.4.1, the COL applicant chose to discuss this item in North Anna 3 COL FSAR Section 2.4.14. This report follows the North Anna 3 COL FSAR convention, and staff's review of NAPS ESP COL 2.4-2 can be found in Section 2.4.14.

- NAPS ESP COL 2.4-6 UHS Reservoir Design

- NAPS ESP COL 2.4-7 UHS Storage Basins Sufficient for 30-Day Emergency Cooling Water Needs

- NAPS ESP COL 2.4-8 Use of Lake Anna or the Waste Heat Treatment Facility (WHTF) for Safety-Related Water Withdrawals

ESBWR DCD Section 9.2.5 and North Anna 3 COL FSAR Section 9.2.5 describe the UHS. The UHS is provided by the IC/PCCS pools, with makeup from the equipment storage pool and Reactor Well sufficient during the initial 72 hours of an accident. ESBWR DCD Section 9.2.5 states that a separate safety-related reservoir is not required. The Fire Protection System, described in ESBWR Section 9.5.1, provides onsite makeup to the UHS from 72 hours to 7 days through a connection to safety-related components of the Fuel and Auxiliary Pools Cooling System, described in ESBWR DCD Section 9.1.3. ESBWR DCD Section 9.2.5 states that the makeup water source beyond 7 days post-accident is not required to be safety-related.

The COL applicant supplemented North Anna 3 COL FSAR Section 2.4.8 to state that Lake Anna and the WHTF are not used for safety-related cooling.

Based on the description of the UHS, staff have determined that no underground reservoirs are included in the design of the ESBWR UHS and no external source of safety-related makeup water is required for the UHS. Accordingly, ESP COL Action Items 2.4-6, 2.4-7, and 2.4-8 are considered closed.

Early Site Permit Condition:

- ESP Permit Condition 3.E(2) Second New Unit Shall Use A Dry Cooling System

In North Anna 3 COL FSAR Table 1.10-202, the COL applicant states that Permit Condition 3 is not applicable to North Anna 3.

The North Anna 3 COL FSAR describes the construction of a single new unit. Therefore, ESP Permit 3.E(2), which states that a second new unit shall use a dry cooling tower system to remove waste heat from the working fluid passed through the turbine/generator set during normal operations, does not apply to this licensing action.

Early Site Permit Variance:

- NAPS ESP VAR 2.4-4 Lake Level Increase

With the addition of North Anna 3, the normal pool elevation is to be held at 76.01 m (249.39 ft) NAVD88, which is 0.08 m (0.25 ft) higher than prior to the addition of North Anna 3. The higher water level is to improve water availability to downstream users during drought conditions. The COL applicant analyzed the effect of the lake level increase on the maximum elevation from the probable maximum flood (PMF) in North Anna 3 COL FSAR Section 2.4.3 and the effect on water balance and minimum water level in North Anna 3 COL FSAR Section 2.4.11. The staff's review of NAPS ESP VAR 2.4-4 can be found in those sections.

- NAPS ESP VAR 2.0-7 Coordinates/Removal of abandoned mat foundations

The COL applicant requested a variance from one of the coordinate systems presented in the ESP, Appendix A, Figure 1 which lists the coordinates of the site in State NAD 83 South Zone as well as in the North Anna 3 Grid coordinates. In the variance, the COL applicant stated that there is an error associated with the coordinates of the proposed facility boundaries, which are coordinated of the eight points that define "ESP Plant Parameter Envelope." The applicant requested to use the values given in North Anna 3 COL FSAR Figure 2.0-205 as "COORDINATES (STATE PLANE NAD 83 VA SOUTH ZONE)," to replace those in the ESP given as "Coordinates (State NAD 83 South Zone)." The coordinates provided in the North Anna Grid coordinates in the ESP, Appendix A, Figure 1 remained unchanged; therefore, this variance request corrects an administrative error and is acceptable.

The COL applicant requested a variance from ESP, Appendix A, Figure 1, Note 2 that states, “Abandoned Unit 3 and 4 Reactor Building Mat Foundations are to be removed.” The applicant requests to not remove the abandoned mat foundations for the originally planned North Anna Units 3 and 4 unless a Unit 3 Seismic Category I or II structure would be located above on an abandoned foundations. The review of this part of the variance request is discussed above in Section 2.0.

2.4.1.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.1.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff’s review confirmed that the COL applicant has addressed the relevant information and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.1 of NUREG–0800, and NRC RGs. The staff’s review concludes that the applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the applicant has adequately addressed NAPS COL 2.0-12-A as it relates to the hydrologic description.

As set forth above, the COL applicant has presented and substantiated information relative to the hydrologic description in the vicinity of the site and site regions important to the design and siting of this plant. The staff reviewed the available information provided. For the reasons given above, the staff concluded that the identification and consideration of the hydrology in the vicinity of the site and site regions are acceptable and meet the requirements of GDC 2, 10 CFR Part 50, 10 CFR 52.79, and 10 CFR 100.20(c), with respect to determining the acceptability of the site for the ESBWR design.

The staff finds that the COL applicant has considered the appropriate site phenomena for establishing the design bases for SSCs important to safety. The staff accepted the methodologies used to determine the hydrologic description in the vicinity of the site and site regions reflected in site characteristics documented in the ESP FSER. Accordingly, the staff concluded that the use of these methodologies results in site characteristics containing sufficient margins for the limited accuracy, quantity, and period of time in which the data have been accumulated. The staff concluded that the identified site characteristics meet the requirements of 10 CFR 52.79 and 10 CFR 100.20(c), with respect to establishing the design basis for SSCs important to safety.

2.4.2 Floods

2.4.2.1 Introduction

This section discusses the historical flooding at the proposed site or in the region of the site. The information summarizes and identifies the individual types of flood-producing phenomena, and combinations of flood-producing phenomena, considered in establishing the flood design bases for safety-related plant features. The discussion also covers the potential effects of local intense precipitation. The flood history and the potential for flooding are reviewed for the sources and events described below. Factors affecting potential runoff (such as urbanization, forest fire, changes in agricultural use, erosion, and sediment deposition) are considered in the review. In addition to describing flood history, this section also determines the local intense precipitation on the site used to estimate localized flooding and sheet flow. Local intense precipitation is reported as a site characteristic used in site grading design.

2.4.2.2 Summary of Application

North Anna 3 COL FSAR, Revision 9, Section 2.4.2, "Floods," describes the site from the standpoint of flooding considerations.

The COL applicant addressed the ESBWR DCD and ESP information as follows:

COL Items:

- NAPS COL Item 2.0-13-A — Floods, COL Applicant to provide information in accordance with SRP 2.4.2

The COL applicant incorporated by reference ESP SSAR Section 2.4.2 to address NAPS COL 2.0-13-A. The COL applicant also supplemented the site-specific information of ESP SSAR Section 2.4.2.2, "Flood Design Consideration," indicating that the design plant grade elevation of 89.39 m (290 ft) NAVD88 for safety-related SSCs is below the localized sheet flow levels at specific locations of the site due to the local intense precipitation event. As indicated in the discussion in SER Section 2.4.2, the staff issued RAI 02.04.02-8 (ADAMS Accession Number No. ML110970719) dated April 07, 2011, and RAI 02.04.02-10 through 02.04.02-15 dated December 11, 2014 (ADAMS Accession No. ML14345B075), which asked for clarification of the design sheet flow levels due to the local precipitation event. The applicant's response (ADAMS Accession Nos. ML11124A154, ML15022A199, and ML16229A451) dated May 03, 2011, January 19, 2015, and June 12, 2015, respectively, stated that the local PMP sheet flow flood elevation is above the plant grade elevation in three specific areas of the site. As detailed in SER Section 2.4.10, the applicant committed to providing flood protection features for the impacted site areas.

- NAPS ESP COL 2.4-3

Appendix C of the North Anna ESP states that NAPS ESP COL 2.4-3 is not used. Therefore, a sequential gap exists between NAPS ESP COL 2.4-2, which is discussed in North Anna 3 COL FSAR Section 2.4.14, and NAPS ESP COL 2.4-4, which is discussed in North Anna 3 COL FSAR Section 2.4.2.

- NAPS ESP COL 2.4-4 and 2.4-5

The COL applicant provided updated site-specific information to supplement ESP SSAR Section 2.4.2.3, "Effects of Local Intense Precipitation," to address ESP COL Action Items 2.4-4 and 2.4-5. The applicant provided four figures, with the first (North Anna 3 COL FSAR Figure 2.4-201) showing the site layout and sub-basin drainage areas, the second (North Anna 3 COL FSAR Figure 2.4-202) showing the site's PMP duration-intensity curve, the third (North Anna 3 COL FSAR Figure 2.4-203) showing the location of ditch cross sections used for the HEC-RAS model analysis (ADAMS Accession No. ML16229A451), and the fourth (North Anna 3 COL FSAR Figure 2.4-221) showing the location of supercritical flow and hydraulic jumps from the HEC-RAS model analysis.

2.4.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP. In addition, guidance relevant to the Commission's regulations for flooding descriptions, and the associated acceptance criteria, with the relevant requirements of the NRC regulations are described in Section 2.4.2 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 site floods information presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Items 2.0-13-A, and NAPS ESP COL 2.4-3, 2.4-4 and 2.4-5), are based on meeting the following relevant requirements of 10 CFR Parts 52 and 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

The following related acceptance criteria are summarized from SRP Section 2.4.2:

Local Flooding on the Site and Drainage Design: The application should include an estimate of local intense precipitation or local PMP and a determination of the capacity of site drainage facilities (including drainage from the roofs of buildings and site ponding).

- Stream Flooding: The application should include documentation of the potential sources of flood and flood response characteristics.

- Surges: The application should include the complete history of storm surges in the vicinity of the site.

- Seiches: The application should include the complete history of seiches in the vicinity of the site.

- Tsunami: The application should include the complete history of tsunami in the vicinity of the site.

- Seismically Induced Dam Failures (or Breaches): The application should include the flooding hazard at the plant site resulting from seismically induced dam failure upstream of the site location.

- Flooding Caused by Landslides: The application should include the flooding hazard at the plant site from flood waves induced by landslides and backwater effects due to stream blockage from landslides.

- Effects of Ice Formation in Water Bodies: The application should include information concerning potential flooding at the plant site due to flood waves resulting from the collapse of an ice dam or backwater effects due to stream blockage due to an ice dam or an ice jam downstream of the plant site.

- Combined Events Criteria: The application should include information concerning design basis flooding at the plant site, including consideration of appropriate combinations of individual flooding mechanisms in addition to the most severe effects from individual mechanisms themselves.

- Consideration of Other Site-Related Evaluation Criteria: The application should demonstrate that the potential effects of site-related proximity, seismic, and nonseismic information as they relate to hydrologic description in the vicinity of the proposed plant site and site regions are appropriately taken into account.

In addition, the hydrologic characteristics should be consistent with appropriate sections in RGs 1.27, 1.29, 1.59, as supplemented by best current practices and in RG 1.102.

2.4.2.4 Technical Evaluation

As documented in Section 2.4.2 of NUREG-1966 and Section 2.4.2 of NUREG-1835, the staff reviewed and approved information related to floods for the certified ESBWR DCD, Revision 10, and Section 2.4.2 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.2 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic. The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Floods."

In addition the staff reviewed Section 2.4.2 of the North Anna 3 COL FSAR, Revision 9, related to flood history, flood design, and the effects of the PMP as follows:

COL Items:

- NAPS COL 2.0-13-A Floods

The staff reviewed the resolution to NAPS COL 2.0-13-A, related to historical flooding at the proposed site or in the region of the site, and included in North Anna 3 COL FSAR Section 2.4.2. The staff's technical review of this application was limited to reviewing the supplemental information pertaining to NAPS COL 2.0-13-A and ESP COL Action Items 2.4-4 and 2.4-5, as addressed below:

The staff reviewed the North Anna 3 COL FSAR, Revision 9, the applicant's responses to RAI 02.04.02-10 through 02.04.02-15, and checked the referenced ESP SSAR. The staff's review confirmed that the information contained in the application and in the responses to RAIs, and incorporated by reference addresses the relevant information related to this section. Based on a review of the North Anna 3 site grading plan, the design plant grade elevation is 88.39 m (290.0 ft) NAVD88. As discussed in the ESP FSER, the flooding site characteristic is produced by the PMF in Lake Anna's watershed, the simultaneous failure of upstream storage reservoirs, and coincident wave action, which produces a water surface elevation of 82.03 m (269.14 ft) NAVD88. However, for the North Anna 3 COLA, the applicant provided supplemental information from the analysis of local intense precipitation that produces localized sheet flow levels that are above site grade. According to the COL applicant's analysis, the sheet flow level resulting from the local intense precipitation is a maximum of 0.15 m (0.5 ft) above the design plant grade.

The staff checked ESP FSER Section 2.4.2.3 and supplemented the ESP safety evaluation with an independent confirmation of the applicant's steady-state HEC-RAS numerical modeling analysis of site drainage during local intense precipitation. The ESBWR DCD site parameter Maximum Flood (or Tsunami) Level is 1 ft below plant grade. The design plant grade elevation is 88.39 m (290.0 ft) NAVD88. As stated above, the maximum sheet flow flood level at the site, during a local intense precipitation event, is 88.54 m (290.5 ft) NAVD88 which is (0.15 m) 0.5 ft above the design plant grade. By definition, sheet flow due to local intense precipitation will always be above plant grade; therefore, the ESBWR DCD site parameter Maximum Flood (or Tsunami) Level does not apply to localized sheet flow. However, local intense precipitation-generated sheet flow is included in determination of the design-basis event and any necessary flood protection as discussed below.

- NAPS ESP COL 2.4-4 and 2.4-5

The COL applicant provided to the staff the input files of the numerical model HEC-RAS that were used to analyze runoff from local intense precipitation for site drainage of North Anna 3 with the ESBWR reactor. HEC-RAS is a numerical model developed by the USACE, Hydrologic Engineering Center (USACE 2010a). The model is widely used within the engineering community and is accepted as a standard engineering-practice tool for the analysis of flooding. Figure 2.4.2-1 shows the site drainage plan provided by the COL applicant in the North Anna 3 COL FSAR and includes additional identifying information. The staff determined that the site drainage plan satisfies the requirements of ESP COL Action Item 2.4-4 and ESP COL Action Item 2.4-5. The staff also reviewed the supplemental information provided in North Anna 3 COL FSAR Section 2.4.2 and the HEC-RAS hydraulic model provided by the COL applicant, and also conducted sensitivity tests on the hydraulic model.

Information Submitted by Applicant:

In North Anna 3 COL FSAR Section 2.4.2.2 the COL applicant provides supplemental information on the local intense precipitation flooding which is reported as being a maximum of 0.15 m (0.5 ft) above the design plant grade of 88.39 m (290.0 ft) NAVD88. In addition to the design plant grade and elevations of safety-related buildings (corresponding to the floor and entrance elevations), the COL applicant stated that the ground level elevations outside the buildings is 88.24 m (289.5 ft) NAVD88.

The site drainage plan consists of three drainage channels (labeled east ditch, south ditch, and west ditch in Figure 2.4.2-1), a stormwater management pond, and an outfall channel. Figure 2.4.2-1 also shows the layout of drainage basins used in the estimation of local intense precipitation-generated runoff. For the analysis of local intense precipitation flooding, the culverts were assumed to be blocked where the ditches passed under the plant access roads. In the HEC-RAS model of the drainage system, the roads crossing the ditches were treated as broad-crested weirs. As noted in Figure 2.4.2-1, these weirs are located in the south and west ditches. The east ditch has no weirs. Figure 2.4.2-2 shows the layout of HEC-RAS cross sections with respect to the ditches, stormwater management pond, and outfall channel. Figure 2.4.2-2 also shows the locations of blocked culverts, which were simulated as inline weirs.

Because channel linings consist of rip-rap (stone used for erosion protection), the COL applicant set up the HEC-RAS hydraulic model using Manning's roughness values of 0.035 for all cross sections. The COL applicant generally used a contraction coefficient of 0.1 and an expansion coefficient of 0.3 for most cross sections, which assume a gradual transition between adjacent cross sections. However, for cross sections 900 in the east ditch, 500, 390, and 100 in the outfall, and 490 to 195 in the south ditch (Figure 2.4.2-2), the COL applicant used a contraction coefficient of 0.3 and an expansion coefficient of 0.5. The COL applicant did not explain how these values were determined. Therefore, in RAI 02.04.02-13, the staff requested that the COL applicant provide a description of the basis for selection of expansion and contraction coefficients. The COL applicant's response dated January 19, 2015 (ADAMS Accession No. ML15022A199), and the staff's independent confirmatory evaluation are described in the staff's technical evaluation section of this SER below.

The staff found in its examination of the HEC-RAS input files provided by the COL applicant that the downstream boundary condition assigned by the COL applicant to the HEC-RAS model was the water surface elevation of Lake Anna, which the COL applicant assigned a constant elevation of 80.77 m (265 ft) NAVD88.

The precipitation intensity used by the COL applicant for the local intense precipitation analysis was taken from ESP SSAR Table 2.4.3, which is shown in Table 2.4.2-1. The COL applicant divided the drainage area into subbasin areas (Table 2.4.2-2) for use in estimating precipitation runoff and distribution of runoff to the drainage channel system.

Table 2.4.2-1 Local intense precipitation depths for durations less than 6 hours and over a 2.59-km^2 (1-mi^2) area. (Derived from ESP SSAR Table 2.4-3)

Duration	Precipitation Depth (in)	Precipitation Depth (cm)
6-hr	27.9	70.9
1-hr	18.3	46.5
30-min	13.7	34.8
15-min	9.6	24.4
5-min	6.1	15.5

The COL applicant estimated discharge from local intense precipitation using the rational method, combined with the areas of the drainage basins and assumptions about the runoff coefficient (representing precipitation infiltration). The COL applicant's subbasin areas were provided in Table 2.4.2-2. The COL applicant assumed that vegetated areas have a runoff coefficient of 0.9 and that other areas have a runoff coefficient of 1.0, reflecting their imperviousness resulting in composite runoff coefficients ranging from 0.93 to 1.0. The COL applicant computed the time of concentration of a subbasin to determine the appropriate rainfall intensity for use in calculating subbasin discharges from local intense precipitation. The COL applicant estimated the time of concentration for each of the subbasins using the methods of the US Natural Resource Conservation Service (1986). To account for non-linear response to large storms, the COL applicant also included a 25 percent reduction of the times of concentration based on guidance from USACE (1994). Table 2.4.2-1 provided the duration-intensity data for local intense precipitation at the North Anna 3 site. Table 2.4.2-2 provided characteristics of the subbasins provided by the COL applicant including the cumulative drainage area along each reach, the runoff coefficients, the times of concentration, the precipitation intensities corresponding to the times of concentration, and the discharge estimates for cumulative drainage areas. Generally, the times of concentration and discharges increased with increasing cumulative drainage area. The COL applicant-provided information supplemental to the North Anna 3 COL FSAR provided detail of the methods used to calculate the time of concentration, precipitation intensity, and runoff. However, the staff determined that the North Anna 3 COL FSAR contained little discussion of the methods and results for computation of subbasin discharges. Therefore, in RAI 02.04.02-11, the staff requested that the COL applicant provide a description of the estimation of subbasin discharges including the estimation of flow type lengths, Manning's roughness coefficients, and times of concentration. The COL applicant's response dated January 19, 2015 (ADAMS Accession No. ML15022A199), and the staff's evaluation are described in the staff's technical evaluation section below.

Table 2.4.2-2. Subbasin characteristics used to estimate discharge during the local intense precipitation. (Derived from COL FSAR Tables 2.4-201, 2.4-202, and 2.4-203.)

Subbasin	Areas m^2 (ft^2)	Contributing Subbasins	Cumulative Area ha (ac)	Runoff Coefficient	Time of Concentration (min)	Precipitation Intensity cm/hr (in/hr)	Discharge m^3/s (cfs)
B	35,193 (378,813)	All	24.38 (60.24)	0.98	20.4	31.7	52.99 (1871.4)

N/A – not available

According to the COL applicant's HEC-RAS model analysis, the highest predicted water surface elevation of 89.70 m (294.3 ft) NAVD88 occurred at the upstream end of the west ditch (ADAMS Accession No. ML16229A451). However, this portion of the west ditch is upstream of the powerblock, and it is tributary to the drainage system surrounding the powerblock (Figure 2.4.2-1). In the drainage channels surrounding the powerblock, the highest predicted water surface elevations occurred at the upstream ends of the south and east ditches. These computed water surface elevations were 87.92 m (288.45 ft) NAVD88 (south ditch) and 87.84 m (288.2 ft) NAVD88 (east ditch) and were on opposite sides of the Administration Building (Figure 2.4.2-1). Consequently, the maximum water surface elevation computed by the COL applicant in the site drainage ditches adjacent to the powerblock was in the south ditch. Note that in the North Anna 3 COL FSAR, the COL applicant rounded the water surface elevations to one-tenth of a foot and reported the maximum elevation as 87.90 m (288.4 ft) NAVD88, 0.18 m (0.6 ft) below the North Anna 3 ESBWR DCD's Maximum Flood (or Tsunami) Level site parameter value of 88.09 m (289.0 ft) NAVD88 (North Anna 3 COL FSAR Table 2.0-1).

The COL applicant assumed that the roads crossing the west and south ditches and the outfall from the stormwater management pond were completely blocked and functioned as weirs during the flooding from local intense precipitation (Figures 2.4.2-1 and 2.4.2-2). As found in the COL applicant's HEC-RAS input files, inline weirs were designated as broad-crested weirs with discharge coefficients specified as either 2.6 or 2.4. Because the COL applicant did not provide a justification for choosing the lower of these two discharge coefficient values, in RAI 02.04.02-14, the staff requested that the COL applicant provide a discussion of the basis for selecting weir discharge coefficients. The COL applicant's response dated January 19, 2015 (ADAMS Accession No. ML15022A199), and the staff's evaluation are described in the staff's technical evaluation section below in this SER.

According to North Anna 3 COL FSAR, Revision 9, Figures 2.4-201 and 2.4-203, the discharge from the west ditch was combined with the outflow from the stormwater management pond. However, according to the geometry of the HEC-RAS model provided by the COL applicant, the staff discovered that the discharge from the west ditch entered the stormwater management pond. Therefore, in RAI 02.04.02-12, the staff requested that the COL applicant provide an explanation for the disagreement between the North Anna 3 COL FSAR figures and the HEC-RAS input files and any necessary corrections. The COL applicant's response dated January 19, 2015 (ADAMS Accession No. ML15022A199), and the staff's evaluation are described in the staff's technical evaluation section below in this SER.

A drainage divide is located between the North Anna 3 stormwater management pond and the existing Unit 2 site at an elevation of 82.91 m (272.0 ft) NAVD88. As indicated in Figure 2.4.2-1, the stormwater management pond received flow from the east and west ditches. Discharge was routed from the stormwater management pond by overtopping the main access road, which was simulated in the HEC-RAS model as a broad-crested weir. The maximum water surface elevation computed by the COL applicant in the stormwater management pond was 82.84 m (271.8 ft) NAVD88 resulting in a freeboard of 0.06 m (0.2 ft). The COL applicant concluded that flows in North Anna 3 site would not affect the existing Units 1 and 2. Although the staff found references to Subbasin U1&2 in North Anna 3 COL FSAR Tables 2.4-201 and 2.4-202 (Table 2.4.2-2), the COL applicant did not adequately explain how Subbasin U1&2 derived flow from the existing Units 1 and 2 area. In RAI 02.04.02-10, the staff requested that the COL applicant provide additional details regarding how the rational method was applied to estimate peak discharges, particularly from Subbasin U1&2 (ML14345B075). The COL applicant's response dated January 19, 2015 (ADAMS Accession No. ML15022A199), and the staff's evaluation are described in the staff's technical evaluation section below in this SER.

Based on the staff's examination of the COL applicant's HEC-RAS analysis results, supercritical flow was found to occur in the east and west ditches during flooding from local intense precipitation. In these locations, the water velocities ranged from 2.1 m/s (7.0 fps) to 4.5 m/s (14.7 fps) with Figure 2.4.2-3 showing the locations of supercritical flow based on the HEC-RAS analysis. In North Anna 3 COL FSAR Section 2.4.2.3, the COL applicant stated that:

- The locations where supercritical flow regimes were predicted to occur would be protected against possible erosive forces arising from large velocities and potential hydraulic jumps using linings and hardened surface protections;

- Grading near safety-related SSCs will slope away from the structures so that ground and roof runoff during a local intense precipitation event will sheet flow towards drainage ditches;

- During the construction phase for North Anna 3, the construction and as-built drawings will be checked against site topography, surface type, and channel linings that were used for the for local intense precipitation analysis and the associated HEC-RAS modeling;

- During operation of North Anna 3 the drainage system will be monitored to ensure consistency with the assumptions used in the flood analysis for local intense precipitation and associated HEC-RAS modeling analysis;

- Drainage facilities will be inspected during construction at least once every two weeks; and

- Site inspections will be done quarterly to inspect areas with erosion potential.

During review of the COL applicant's local intense precipitation flood analysis, the staff noted that the COL applicant analyzed runoff from building roofs in the powerblock area as sheet flow. The staff located additional details of the analysis in the COL applicant's Calculation Package 25161-G-012. From the information provided by the COL applicant on the sheet flow analysis, the staff could not determine how the COL applicant partitioned roof runoff from adjacent roofs and direct precipitation in passageways between safety-related buildings. It was also unclear to the staff if the COL applicant's approach to sheet flow analysis was consistent with guidance provided in ANSI/ANS-2.8-1992, Section 11.4 (ANS 1992). Therefore, in RAI 02.04.02-15, the staff requested that the COL applicant provide: (1) a discussion of the effects of roof drainage and direct precipitation during local intense precipitation on flood water surface elevations along passageways between buildings and structures important for safety; (2) a comparison of these flood water surface elevations or depths to the elevations of any penetrations or openings housing safety-related SSCs; and, (3) an update to the FSAR to include this information. The COL applicant's responses dated January 19, 2015 and June 12, 2015 (ADAMS Accession Nos. ML15022A199 and ML16229A451, respectively), as well as the staff's evaluation are described in the staff's technical evaluation section below in this SER.

In response to staff's RAI 02.04.02-10 through 02.04.02-15, the COL applicant proposed updating the North Anna 3 COL FSAR in a future revision (ADAMS Accession Nos. ML15022A199 and ML16229A451). The staff verified that the appropriate updates are incorporated into the FSAR, Revision 9, and, therefore Confirmatory Items 2.4.2-1 to 2.4.2-6 from the staff's advanced SER for North Anna 3 are resolved and closed.

The Staff's Technical Evaluation

The staff reviewed the application and verified information discussed in this section.

The North Anna 3 COL FSAR states that the design plant grade for the safety-related SSCs for North Anna 3 is 88.39 m (290.0 ft) NAVD88. The maximum flood level reported in North Anna 3 COL FSAR from local intense precipitation sheet flow was 88.54 m (290.5 ft) NAVD88 which is 0.15 m (0.5 ft) above the design plant grade. The staff's examination of the HEC-RAS model provided by the applicant showed that the maximum flood level in the drainage ditches adjacent to the powerblock was 87.92 m (288.45 ft) NAVD88, reported in the North Anna 3 COL FSAR to the nearest tenth foot, or 87.90 m (288.4 ft) NAVD88.

In RAI 02.04.02-8, the staff requested that the COL applicant provide clarification as to why the reported design basis flood elevation was lower than the maximum flood elevation resulting from the local PMP. The COL applicant provided a response dated May 3, 2011 (ADAMS Accession No. ML11124A154), which clarified the issue. The staff noted that the information provided in the response is included in the current revision of the North Anna 3 COL FSAR. Accordingly, the staff considers RAI 02.04.02-8, resolved and closed.

The staff checked the COL applicant's precipitation depths and durations for the local intense precipitation (Table 2.4.2-1) and confirmed that they matched the values of the ESP (Dominion 2006). The staff also compared the 1-hour and 5-minute precipitation intensities (46.5 cm/hr [18.3 in/hr] and 15.5 cm/5 min [6.1 in/5 min], respectively) provided by the COL applicant against the ESBWR DCD and found that they were below the ESBWR DCD site parameter values of 49.3 cm/hr (19.4 in/hr) and 15.7 cm/5 min (6.2 in/5 min) for roof design. Therefore, the staff concluded that the ESBWR standard plant site parameters for precipitation bound the site-specific local intense precipitation.

The staff independently checked and confirmed the subbasin areas (Table 2.4.2-2) reported in the North Anna 3 COL FSAR. Although the staff did not obtain the exact subbasin areas as reported by the COL applicant, the staff's estimates were within 2 percent of the COL applicant's available area estimates. The staff considers this difference reasonable. The subbasin areas were used by the COL applicant to estimate runoff using the rational method. The COL applicant's use of the rational method to estimate runoff during the local intense precipitation is a conservative method because it assumes steady-state runoff using maximum precipitation depths over precipitation periods corresponding to the time of concentration. This approach results in the assumption that the whole subbasin was contributing runoff at the furthest downstream point. The staff determined that the rational method produced conservative estimates of discharge for use in steady-state analyses provided that the conservative times of concentration and precipitation data are used.

The staff noted that the North Anna 3 COL FSAR does not discuss North Anna 1 and 2 discharges, which was mentioned only in North Anna 3 COL FSAR Tables 2.4-201 and 2.4-202 (combined into Table 2.4.2-2). No value was provided in the FSAR for discharge from Subbasin U1&2 into the stormwater management pond; however, using the HEC-RAS input files provided by the applicant, the staff estimated that a discharge of 5.48 m^3/s (193.7 cfs) was used. In RAI 02.04.02-10, the staff requested that the COL applicant provide additional details regarding how the rational method was applied to estimate peak discharges, particularly from North Anna 1 and 2 Subbasin. In response to RAI 02.04.02-10 (ADAMS Accession No. ML15022A199), the COL applicant stated that a peak discharge specifically for Unit 1 and Unit 2 Subbasin was not calculated because it contributes flow to Subbasin B and was included in the calculation for Subbasin B (ADAMS Accession No. ML15022A199). The COL applicant provided proposed updated North Anna 3 COL FSAR text in the North Anna 3 COL FSAR, Revision 9, and the staff confirmed its inclusion. The staff reviewed the COL applicant's response and determined that the area of Subbasin B, including that of Subbasin U1&2 would be higher than that of North Anna 1 and 2 Subbasin itself and therefore the peak discharge estimated for Subbasin B would be slightly less than the peak discharge estimated for Subbasin U1&2 only. Therefore, it remained possible that the discharge for the outfall segment of the local drainage network could be slightly greater if North Anna 1 and 2 Subbasin were to be treated separately. However, the staff determined that the increase in discharge to be minor because the North Anna 1 and 2 Subbasin discharge occurs directly to the stormwater pond and would not significantly affect water-surface elevations in the powerblock area. Therefore, the staff determined that the COL applicant's response was adequate and RAI 02.04.02-10, was resolved and closed. The verified that all appropriate text changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.2-1 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff independently computed the times of concentration using Figure 2.4.2-1 for areas, distances, and slopes, and by using WinTR-55 software (SCS 1986, NRCS 2009). The TR-55 methodology includes three types of flow: overland (sheet) flow, concentrated flow, and channel flow. For sheet flow, the staff used Manning's roughness coefficients as provided in NRCS (2003). As indicated in the North Anna 3 COL FSAR, there are two land cover types: graveled areas and grass covered areas. For sheet flow over graveled areas, NRCS (2003) recommends a Manning's roughness of 0.02, while for sheet flow through dense-grass coverage a value of 0.24 is recommended. The WinTR-55 software provides drop-down lists for selection of surface type (as described by Manning's roughness values). For sheet flow, a 0.02 value for graveled areas is not provided in WinTR-55, so the staff used the next largest available value of 0.05. The staff assumed a 1 percent surface slope as indicated in Figure 2.4.2-1, though the staff expects that between buildings surface slopes would be smaller. Estimating the distance that sheet flow will occur is problematic without detailed information. The staff used a distance of 30.48 m (100 ft), which is the maximum distance that sheet flow could occur according to NRCS (2003). Comparing the staff-computed values with those provided by the applicant showed that for the east drainage areas the times of concentration are similar, though the staff's estimates are short by 1 to 2 minutes. However, the staff-computed times of concentration for the west and south drainage areas are shorter than those computed by the COL applicant, for example 10.4 min versus 20.4 min. Examination of additional information pertaining to the COL applicant's computation of times of concentration indicates the COL applicant used higher Manning's roughness coefficients for sheet flow and smaller slopes than used by the staff. The staff noted that in Subbasin S2, the applicant's estimated time of concentration for sheet flow accounts for over 60 percent of the subbasin's response time. Consequently, the COL applicant's basis for estimating sheet flow was needed.

The staff independently developed an exponential curve fit to estimate precipitation intensities for intermediate durations using the COL applicant's precipitation duration-depth data for 1-hr, 30-min, 15-min, and 5-min durations. The staff then used the independently estimated times of concentrations to compute precipitation intensities and discharges for the contributing areas. The staff used the same runoff coefficients for the Rational Method as those estimated by the COL applicant. The staff-computed discharges are higher than those estimated by the COL applicant because of higher estimated precipitation intensities. In RAI 02.04.02-11 (ADAMS Accession No. ML14345B075) dated December 11, 2014, the staff requested that the COL applicant provide a description of the assumptions made in estimation of subbasin discharges and include a discussion of the estimation of flow type lengths, Manning's roughness coefficients, times of concentration, and discharges.

In response to RAI 02.04.02-11 dated January 19, 2015 (ADAMS Accession No. ML15022A199), the COL applicant described the process used to estimate times of concentration for each subbasin. The COL applicant also described the basis for selection of Manning's roughness coefficients and the use of USACE guidance to reduce values of times of concentration for PMF events. The COL applicant provided proposed updated North Anna 3 COL FSAR text in the North Anna 3 COL FSAR, Revision 9, and the staff confirmed its inclusion. The staff reviewed the COL applicant's response and determined that the COL applicant appropriately followed current engineering practices and guidance applicable to PMF computations. The staff's higher estimates of discharges were related to differences in Manning's roughness coefficients and slopes. The staff determined that the COL applicant has appropriately used these parameters for the site-specific conditions. Therefore, the staff determined that the COL applicant's response was adequate and RAI 02.04.02-11 was resolved and closed. The staff verified that the appropriate text changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.2-2 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff received an updated set of HEC-RAS model input files from the COL applicant for the local intense precipitation flooding analysis (ADAMS Accession No. ML14013A113). The updated model files reflected the current North Anna 3 site design for the ESBWR.
The staff examined the COL applicant-provided HEC-RAS files and found the input consistent with the site plan shown in North Anna 3 COL FSAR Figure 2.4.2-203 (shown in Figure 2.4.2-1). In addition to the elevations computed by the HEC-RAS model, the staff examined the output from the COL applicant's analysis for supercritical flow. Locations with supercritical flow are noted in Figure 2.4.2-3. A transition from supercritical to subcritical flow regime is expected to produce a hydraulic jump. The staff examined the results from the COL applicant's HEC-RAS analysis for hydraulic jumps and found that the COL applicant correctly identified locations within the drainage ditches where supercritical to subcritical transitions would be predicted.

The staff noted that the downstream boundary condition in the HEC-RAS model is 80.77 m (265.0 ft) and noted that the boundary value was set 0.26 m (0.86 ft) higher than the maximum flood storage elevation in Lake Anna. The staff determined that the COL applicant used a conservative boundary condition which would result in conservative flood water surface elevations near safety-related SSCs during a local intense precipitation event.

The staff noted that the applicant's HEC-RAS input file geometry was inconsistent with the connectivity of the west ditch for the storm water management pond. In RAI 02.04.02-12, the staff requested that the COL applicant explain the apparent disagreement between the HEC-RAS input files and North Anna 3 COL FSAR Figures 2.4.201 and 2.4.203 which illustrate the connection of the west ditch to the stormwater management pond. In response to RAI 02.04.02-12 (ADAMS Accession No. ML15022A199), the COL applicant stated that as the west ditch approaches the stormwater management pond, water will flow in three directions: a portion will flow north into an area adjacent to the intake channel, another portion will flow south into the stormwater management pond, and a third portion will continue flowing along the west ditch towards the stormwater management pond outlet and into Lake Anna. The COL applicant chose to direct all flow from the west ditch into the stormwater management pond because the calculated water surface elevation would then be conservatively higher in Subbasin B. The COL applicant proposed updating North Anna 3 COL FSAR Figures 2.4-201 and 2.4-203 to correctly depict the discharge from the west ditch into the stormwater management pond, consistent with the HEC-RAS model setup. The staff determined that the COL applicant's response was adequate and verified that the appropriate updates to Figures 2.4-201 and 2.4-203 are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.2-3 from the staff's advanced SER for North Anna 3 is resolved and closed.

The HEC-RAS model requires specification of contraction and expansion coefficients. Typical contraction and expansion coefficient values are 0.1 and 0.3, respectively, for gradual transitions, 0.3 and 0.5 for typical bridge sections, respectively, and a maximum of 0.6 and 1.0 for abrupt transitions, respectively (USACE, 2010). The staff noted in the review of the COL applicant's HEC-RAS model that several cross sections were specified with contraction and expansion coefficients at the default value of 0.1 and 0.3, respectively, but others had values of 0.3 and 0.5, respectively. While staff acknowledged that these higher values are conservative, there was no discussion in the North Anna 3 COL FSAR concerning the selection of the higher values. In RAI 02.04.02-13, the staff requested that the COL applicant provide a discussion of the basis for selection of contraction and expansion coefficient values of 0.3 and 0.5, respectively. In response to RAI 02.04.02-13 (ADAMS Accession No. ML15022A199), the COL applicant explained that contraction and expansion coefficient values of 0.3 and 0.5, respectively, were specified at cross sections located upstream and downstream of inline weirs where flow transitioning was expected to be less gradual and act more similarly to flow transitions near bridges. The COL applicant provided proposed updated North Anna 3 COL FSAR text in the North Anna 3 COL FSAR, Revision 9, and the staff confirmed its inclusion. In the COL applicant's HEC-RAS model input geometry, the staff identified and confirmed the presence of inline weirs that were used in place of culverts and were used to represent fully blocked culverts. The staff reviewed the COL applicant's justification for using contraction and expansion coefficient values of 0.3 and 0.5, respectively, at these locations and determined the values and associated justification adequate. Therefore, the staff determined that the COL applicant's response was adequate and verified that the appropriate text changes are incorporated in the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.2-4 from the staff's advanced SER for North Anna 3 is resolved and closed.

During the review of the inline weirs used in the COL applicant's HEC-RAS model, the staff noted that weir coefficients in the model were set to either 2.6 or 2.4. The staff found no discussion of the basis for these values in the North Anna 3 COL FSAR. Therefore, in RAI 02.04.02-14, the staff requested that the COL applicant provide a discussion of the basis and the method used to specify the weir coefficients used in the HEC-RAS model. In response to RAI 02.04.02-14 (ADAMS Accession No. ML15022A199), the COL applicant described the basis for selection of the weir coefficients. The COL applicant stated that all inline weirs in the HEC-RAS model acted as broad-crested weirs and that the selected weir coefficient values of 2.4 and 2.6 were fairly low values for broad-crested weirs. These low values would produce higher water-surface elevations over the weirs, which would result in more conservative water-surface elevations in the ditches. The staff reviewed the typical weir coefficient values used in currently accepted engineering practice (Chow 1959) and determined that the COL applicant's conclusion was reasonable. The COL applicant stated that a weir coefficient of 2.4 was used for weirs at the outfall and at a south ditch cross section to account for additional hydraulic loss because of the presence of security barriers at these locations. The COL applicant used an iterative calculation to estimate the weir coefficient value of 2.4 at these locations. The COL applicant provided proposed updated North Anna 3 COL FSAR text in the North Anna 3 COL FSAR, Revision 9, and the staff confirmed its inclusion. The staff reviewed the COL applicant's method for estimating the weir coefficient at locations that have security barriers and concluded that the applicant has appropriately analyzed the flow at these locations. Therefore, the staff determined that the COL applicant's response was adequate and verified that appropriate text changes are incorporated in the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.2-5 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff checked the reference (Chow 1959) used by the applicant to select the Manning's roughness coefficient value. In the North Anna 3 COL FSAR, the applicant explained that the channel linings consist of riprap and used a Manning's roughness coefficient of 0.035 for all cross sections. According to Chow (1959), this value is for a channel with a gravel bottom with riprap sides. A slightly higher value might be expected if the channel was completely lined with riprap rather than just on its sides. The COL applicant set Manning's roughness coefficients for all cross sections in the HEC-RAS model input to 0.035, which represents a channel lined with riprap. To test the effect of a slightly higher Manning's roughness coefficient, the staff examined the effect on water surface elevations using a value of 0.040 for Manning's roughness coefficient. The staff determined that the water-surface elevation increased 0.06 m (0.2 ft) in the east ditch compared to that from the COL applicant's estimate, while for the south ditch the water surface elevation was the same as the COL applicant's estimate. Because these changes in water-surface elevations are minor and remained significantly below the design plant grade, the staff concluded that the COL applicant's use of a Manning's roughness coefficient value of 0.035 was acceptable.

The staff noted that the COL applicant's Calculation Package 25161-G-012 included an analysis of runoff and flood water depths between buildings during a local intense precipitation event. In this calculation, the COL applicant determined that a depth up to 12.7 cm (5 in) could be expected to occur in at least one location (between the Hot Machine Shop and Auxiliary Diesel Building). The staff also noted that the North Anna 3 COL FSAR did not include a discussion of drainage and flood discharge between buildings. The staff consider the guidance provided by ANSI/ANS-2.8-1992 Section 11.4 for consideration of roof drainage during local intense precipitation events an important aspect of the safety analysis. The North Anna 3 COL FSAR Revision 7 did not provide a description of this aspect of local intense precipitation flooding. Therefore, in RAI 02.04.02-15, the staff requested that the COL applicant provide the following:

- A discussion of the effects of roof drainage and direct precipitation on water-surface elevations or depths along passageways between buildings and structures important for safety;

- A comparison of these estimated water-surface elevations with the elevations of any penetrations or openings housing safety-related SSCs; and

- Appropriate updates to the North Anna 3 COL FSAR.

In response to RAI 02.04.02-15 (ADAMS Accession No. ML15022A199), the COL applicant provided details of the analysis in Calculation Package 25161-G-012.

The staff's review of the COL applicant's response revealed that some narrow alleyways between buildings in the powerblock area may not have been fully analyzed. In a revised response to RAI 02.04.02-15 (ADAMS Accession No. ML16229A451), the COL applicant provided an updated analysis of runoff between buildings during a local intense precipitation event. The COL applicant assumed that all roof drains will be clogged during a local intense precipitation event. The COL applicant also stated that scuppers in the parapets of the Reactor, Fuel, Control, Turbine, and Service Buildings will be sized to pass the peak discharge from the local intense precipitation and will be designed to prevent clogging. The COL applicant described its analysis (ADAMS Accession No. ML16229A451) of sheet flow within four key areas of relatively narrow passages within the powerblock:

- Area 1, the area located between the Hot Machine Shop and the Ancillary Diesel Building, south of the FB;

- Area 2, the area south of the CB, north of the Service Building, and east of the RB;
- Area 3, the area between the north end of the CB, the southeast corner or the TB, and east of the RB; and
- Area 4, the alleyway north of the RB and south of the TB.

The COL applicant estimated the drainage area that would contribute runoff to these four areas, including adjacent building roof areas. The COL applicant stated that building scuppers would be designed to direct roof drainage in specific directions. The COL applicant used the rational equation to estimate the peak sheet flow discharge for each of the four areas using a runoff coefficient of 1.0 and using a 5-minute time of concentration that results in a local intense precipitation intensity of 185.9 cm (73.2 in) /hr. The COL applicant estimated peak sheet flow discharges for Areas 1 through 4 as 0.83, 0.52, 0.60, and 0.10 m^3/s (29.3, 18.3, 21.2, and 3.7 cfs), respectively.

For Area 1, the COL applicant estimated a sheet-flow depth of 0.12 m (0.4 ft) using an estimated flow width of 9.14 m (30 ft), a channel slope of 0.4 percent, and a Manning's roughness coefficient of 0.02 to represent shallow flow over a paved surface. Therefore, the COL applicant estimated that the maximum flood water-surface elevation in this area to be 88.36 m (289.9 ft) NAVD88 (i.e., the site grade of 88.24 m [289.5 ft] NAVD88 plus a maximum sheet-flow depth of 0.12 m [0.4 ft]).

Similarly, for Area 2, the COL applicant estimated a maximum flow depth of 0.24 m (0.8 ft) that, when added to the site grade resulted in a maximum flood water-surface elevation of 88.48 m (290.3 ft) NAVD88. In addition, the COL applicant also estimated the sheet-flow water-surface elevation on top of the access tunnel roof because the access tunnel roof is 15.2 cm (6 in) above the site grade and therefore water will discharge as weir flow over the roof into the alleyway. The COL applicant determined that the weir would be submerged. However, because the depth of submergence would be small, the COL applicant used a free fall weir discharge equation to estimate a weir flow water depth of 0.15 m (0.5 ft) with a corresponding maximum sheet-flow elevation of 88.54 m (290.5 ft) NAVD88 in this area.

For Area 3, the COL applicant estimated a maximum flow depth of 0.12 m (0.4 ft) that, when added to the site grade outside the CB downstream of the access tunnel resulted in a maximum flood water-surface elevation of 88.36 m (289.9 ft) NAVD88. Similar to the second sheet-flow area analysis, the COL applicant estimated the weir flow water depth of 0.12 m (0.4 ft) with a corresponding maximum sheet-flow elevation of 88.51 m (290.4 ft) NAVD88 in this area.

For Area 4, the COL applicant estimated the weir flow depth passing over the tunnel to be 0.06 m (0.2 ft) with a corresponding maximum sheet-flow elevation of 88.45 m (290.2 ft) NAVD88.

Because of the revisions to the scupper design that would direct flow off building roofs in certain areas, the COL applicant stated that subbasin areas for the HEC-RAS analysis changed. The COL applicant updated the HEC-RAS analysis to reflect these changes. The staff's description in the *Information Submitted by Applicant* section above reflected these changes.

Comparing the safety-related floor and doorway elevations in Area 2 with estimated maximum sheet-flow elevations at the same locations, the COL applicant determined that the elevation of the CB south stairway landing adjacent to the emergency exit door, 88.39 m (290.0 ft) NAVD88, was below the estimated maximum sheet-flow elevation of 88.48 m (290.3 ft) NAVD88.

Therefore, the COL applicant stated that flood protection measures will be provided by installing a curb at the door entrance or by ensuring that the door threshold is above an elevation of 88.48 m (290.3 ft) NAVD88.

Comparing the safety-related floor and doorway elevations in Area 3 with estimated maximum sheet-flow elevations at the same locations, the COL applicant determined that the elevation of the CB north stairway landing adjacent to the emergency exit door, 88.39 m (290.0 ft) NAVD88, was below the estimated maximum sheet-flow elevation of 88.51 m (290.4 ft) NAVD88. Therefore, the COL applicant stated that flood protection measures will be provided by installing a curb at the door entrance or by ensuring that the door threshold is above an elevation of 88.51 m (290.4 ft) NAVD88.

Comparing the safety-related floor and doorway elevations in Area 4 with estimated maximum sheet-flow elevations at the same locations, the COL applicant determined that the elevation of the RB floor adjacent to the equipment access door on the north side of the RB, 88.39 m (290.0 ft) NAVD88, was below the estimated maximum sheet-flow elevation of 88.45 m (290.2 ft) NAVD88. Therefore, the COL applicant stated that flood protection measures will be provided by installing a curb at the door entrance or by ensuring that the door threshold is above an elevation of 88.45 m (290.2 ft) NAVD88.

The COL applicant proposed changes to North Anna 3 COL FSAR Section 2.4.2.3 to describe the effects of sheet flow including a comparison of estimated sheet-flow elevations to floor and door elevations of safety-related SSCs; updates to North Anna 3 COL FSAR Tables 2.4-201 through 2.4-204 to reflect revised subbasin drainage areas, peak discharges, and water-surface elevations; and, updates to North Anna 3 COL FSAR Figures 2.4-201 and 2.4-203 to reflect revised subbasin drainage areas and to show the locations of the access and radwaste tunnels. In addition, the COL applicant proposed revisions to North Anna 3 COL FSAR Section 2.4.10 to describe flood protection measures described above.

The staff reviewed the COL applicant’s response to RAI 02.04.02-15 and determined that the COL applicant’s sheet-flow analysis appropriately followed ANSI/ANS-2.8-1992 Section 11.4 guidance and used current engineering practice methods with conservative assumptions that maximize sheet-flow water-surface elevations adjacent to safety-related SSCs. The COL applicant proposed changes to the North Anna 3 COL FSAR that included a description of the design roof drainage directions, a description of the sheet flow analysis comparisons of safety-related floor and door elevations with maximum sheet-flow elevations, and locations of required flood protection measures. Therefore, the staff determined that the COL applicant’s response was adequate and verified that the appropriate text revisions are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.2-6 from the staff’s advanced SER for North Anna 3 is resolved and closed.

In evaluating the effects of local intense precipitation, the staff relied on the following statements on the part of the COL applicant:

- Locations where supercritical flow regimes are predicted to occur will be provided with linings and hardened surface protection;
- Grading in the vicinity of safety-related SSCs will slope away from the structures to provide sheet flow to drainage ditches;
- No storm drain inlets or depressed areas are located near safety-related buildings;

- During North Anna 3 construction, as-built drawings will be checked against site topography, surface conditions, and channel linings represented in the local intense precipitation flooding HEC-RAS analyses;

- During North Anna 3 construction, drainage facilities will be inspected at least once every two weeks;

- During North Anna 3 operation, the storm water drainage system will be monitored and maintained to ensure consistency with the design conditions represented in the HEC-RAS analyses;

- During North Anna 3 operation, the drainage system will be inspected quarterly for areas with potential for erosion; and

- The scuppers in the parapets of Reactor, Fuel, Control, Turbine, and Service Buildings will be sized to pass the peak discharge from a local intense precipitation and will be designed to prevent clogging.

The Staff’s Independent Review Related to the Previous COLA Reactor Design

Preceding the RAIs discussed above and over the course of the staff’s review, several RAIs were issued by the staff to resolve questions corresponding to earlier versions of the North Anna 3 COL FSAR referencing the APWR design. These earlier versions under the APWR reactor design used a different drainage system design; however, for completeness, these RAIs and their applicability and resolution are discussed below.

In RAI 02.04.02-1 dated August 21, 2008 (ADAMS Accession No. ML082340933), the staff requested additional information from the applicant regarding the local intense precipitation analysis. Specifically in RAI 02.04.02-1, the staff requested that the COL applicant provide the following items:

- Assurance that the “as-built” site topography will match values provided in the HEC-RAS cross sections (locations shown in North Anna 3 COL FSAR Figure 2.4-203) and that this topography will remain static (or is a conservative assumption), considering the length of the North Anna 3 licensing period;

- A description of provisions to prevent placement of obstructions or other channel blockages in key drainage canals throughout the North Anna 3 licensing period and hence, to justify the selected HEC-RAS model parameters (e.g., contraction and expansion coefficients, channel roughness, and channel geometry values); and,

- A description of how runoff from each building and parking lot in North Anna 3 COL FSAR Figure 2.4-201 has been captured in the HEC-RAS model and hence, is correctly represented in the subbasin drainage boundaries in North Anna 3 COL FSAR Figure 2.4-201.

On September 16, 2008, the COL applicant responded to RAI 02.04.02-1 dated September 16, 2008 (ADAMS Accession No. ML082680033). Additionally, North Anna 3 COL FSAR Revision 3, Section 2.4.2 includes statements that address RAI 02.04.02-1.

Specifically concerning RAI 02.04.02-1(a), the applicant stated in North Anna 3 COL FSAR Section 2.4.2 that during construction of North Anna 3, construction and as-built drawings will be checked against site topography, surface type, and channel linings as provided for the local PMP flood analysis including the HEC-RAS modeling analysis.

Specifically concerning RAI 02.04.02-1(b), the applicant stated in North Anna 3 COL FSAR Section 2.4.2 that construction and as-built drawings will be checked against site topography, surface type, and channel linings as provided for the local PMP flood analysis including the HEC-RAS modeling analysis. The applicant also stated in North Anna 3 COL FSAR Section 2.4.2 that during operation of North Anna 3 the drainage system will be monitored so it continues to be consistent with the local PMP flood analysis including the HEC-RAS modeling analysis. Site inspections will be done quarterly to inspect areas with erosion potential.

Specifically concerning RAI 02.04.02-1(c), the applicant provided in North Anna 3 COL FSAR Section 2.4.2 a description of the site grading near the safety-related SSCs and described how ground and roof runoff reaches the drainage system. The applicant provided information on the imperviousness as included in the composite runoff coefficient. The staff addressed its concerns with the local intense precipitation analysis in RAI 02.04.02-10 through 02.04.02-15. As described previously herein, the staff described the resolution of these concerns.

In RAI 02.04.02-2 the staff requested information that was a follow-on to RAI 02.04.02-1 per the following items:

a. This item was a request for revised HEC-RAS model input files;

b. This item was a request that the COL applicant describe in the North Anna 3 COL FSAR a structure in the HEC-RAS model that results in overland flow from the ditch draining into the stormwater management pond;

c. This item requested a map be provided that identifies the locations where supercritical flows and hydraulic jumps are likely to occur in the drainage ditches. Additionally, the question requested the locations where flood events produce velocities higher than the design velocity for the channel bed material. A portion of the item concerned overland flow from the ditch draining into the stormwater management pond. This included the request for a description of how a potential failure of these drainage features could degrade any safety-related SSCs, or structures that satisfy RTNSS criteria; and,

d. This item requested controls and requirements needed to ensure the ditches and outfall canal would remain clear of obstructions, the side-slopes would remain stable, and the site drainage system would function as described in the North Anna 3 COL FSAR Section 2.4.2 for the length of the North Anna 3 licensing period. The item also requested that the COL applicant provide additional detail regarding Administrative Controls or surveillance requirements including the frequencies at which surveys will be conducted.

Specifically concerning RAI 02.04.02-2(a) dated March 06, 2009 (ADAMS Accession No. ML090680312), the applicant provided HEC-RAS files based on the current site storm water management system for the ESBWR reactor design. Therefore, this question item was resolved and closed.

Specifically concerning RAI 02.04.02-2(b), because the storm water management system was modified, the current design and HEC-RAS analysis does not include the referenced structure. Therefore, this question item no longer applied.

Specifically concerning RAI 02.04.02-2(c), because the storm water management system was modified, the current design and HEC-RAS analysis does not include overland flow and the erosion potential that would result from overflows from the ditch draining. Therefore, this portion of the RAI (item c) no longer applied. For the applicable remaining portion of the RAI (item d), the applicant had not provided a map of the potential locations of supercritical velocity and hydraulic jumps for the current storm water management system design. Therefore, in RAI 02.04.02-9, the staff requested that the COL applicant provide a map identifying locations with supercritical velocities and hydraulic jumps. The COL applicant provided a map in the current revision of the North Anna 3 COL FSAR with the locations of supercritical velocities and hydraulic jumps identified from HEC-RAS analyses (Figure 2.4.2-3). Therefore, the staff considered RAI 02.04.02-9, resolved and closed.

Specifically concerning RAI 02.04.02-2(d), the COL applicant committed to implementation of administrative controls and a quarterly monitoring program to inspect locations with erosion potential, as summarized above in this SER section titled “Information Submitted by Applicant.” Additionally, the COL applicant committed to corrective action if erosion were to occur. Therefore, the staff considered RAI 02.04.02-2(d) resolved and closed.

In RAI 02.04.02-3, the staff requested that the COL applicant provide information concerning the hydraulic characteristics created by an access road crossing a ditch with a drop culvert used for floodwater conveyance. This design produced flood elevations capable of affecting the Units 1 and 2 site. This road crossing was not included in the current design for the ESBWR North Anna 3 site. Therefore, RAI 02.04.02-3 no longer applied.

In RAI 02.04.02-4 dated July 28, 2009 (ADAMS Accession No. ML092090567), the staff requested that the COL applicant provide information concerning the construction and maintenance of the storm water drainage system, specifically asking for this information to be added to the North Anna 3 COL FSAR. The requested information included (1) that channels and overbanks be checked prior to use and (2) that channels and overbanks be maintained over the licensing period in the same condition as represented in the updated HEC-RAS model. As summarized above in the SER section titled “Information Submitted by Applicant,” this information has been included in the North Anna 3 COL FSAR. Therefore, the staff considered RAI 02.04.02-4 resolved and closed.

In RAI 02.04.02-5 dated July 28, 2009 (ADAMS Accession No. ML092090567), the staff requested that the COL applicant provide information concerning the construction and maintenance of the storm water drainage system, specifically asking for this information to be added to the North Anna 3 COL FSAR. Noting that the ditch identities below correspond to a previous version of the storm water drainage system, the previously requested information included the following items:

a. All drainage ditches, overflow area and embankments at North Anna 3 will be protected to withstand the predicted flood flow velocities resulting from the local PMP event for the North Anna 3 site;

b. The lining for the south drainage ditch at the location of the hydraulic jump will be designed to withstand the erosive forces generated by the hydraulic jump during the local PMP event;

c. The lining of the north ditch and storm water management basin side slopes in the vicinity of the north ditch will be designed to withstand the erosive forces of the hydraulic jump at the inlet to the storm water management basin; and,

d. The embankment for the outfall channel will be provided with hardened surface protection designed to withstand the erosive forces associated with the supercritical flow and the potential occurrence of a hydraulic jump at the embankment section.

As stated, the current North Anna 3 COL FSAR has different identities for the drainage ditches than was used in this early RAI above. As summarized above in the SER section titled “Information Submitted by Applicant,” this information has been incorporated in the North Anna 3 COL FSAR. Therefore, the staff considered RAI 02.04.02-5 resolved and closed.

In RAI 02.04.02-6 dated July 28, 2009 (ADAMS Accession No. ML092090567), the staff requested that the COL applicant provide information concerning the construction and maintenance of the storm water drainage system, specifically asking for this information to be added to the North Anna 3 COL FSAR. The requested information included surveillance and monitoring requirements, with the frequencies at which the surveys will be conducted. In addition, staff requested that this information not be tied to permits issued by the Commonwealth of Virginia. As summarized above in the staff SER section titled “Information Submitted by Applicant,” this information was included in the North Anna 3 COL FSAR. Additionally, the North Anna 3 COL FSAR does not include text that would tie this information to state issued permits. Therefore, the staff considered RAI 02.04.02-6 resolved and closed.

In RAI 02.04.02-7 dated July 28, 2009 (ADAMS Accession No. ML092090567), the staff requested that the COL applicant provide information concerning the hydraulic characteristics created by an access road crossing a ditch with a drop culvert used for floodwater conveyance. This design produced flood elevations capable of affecting the Units 1 and 2 site. This road crossing was not included in the current design for the ESBWR North Anna 3 site. Therefore, RAI 02.04.02-7 no longer applied.

2.4.2.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.2.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR and staff’s ESP FSER (NUREG-1835). The staff’s review confirmed that the COL applicant has addressed the required information, and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.2 of NUREG–0800, and NRC RGs. The staff’s review concluded that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the COL applicant has adequately addressed NAPS COL Item 2.0-13-A as it relates to floods.

As set forth above, the COL applicant has presented and substantiated information relative to the floods important to the design and siting of this plant. The staff reviewed the available information provided. For the reasons given above, the staff concludes that the identification and consideration of the floods at the site and in the surrounding area are acceptable and meet the requirements of 10 CFR 52.79(a)(31) and 100.20(c), with respect to determining the acceptability of the site for the ESBWR design.

The staff finds that the COL applicant has considered the appropriate site phenomena in establishing the design bases for SSCs important to safety. The staff accepts the methodologies used to determine the locally intense precipitation flood event. Accordingly, the staff concludes that the use of these methodologies results in design bases containing a sufficient margin for the limited accuracy, quantity, and period of time in which the data have been accumulated. The staff concludes that the identified design bases meet the requirements of 10 CFR 100.20(c) with respect to establishing the design basis for SSCs important to safety.

2.4.3 Probable Maximum Flood on Streams and Rivers

2.4.3.1 Introduction

The PMF on streams and rivers is used to determine the extent of any flood protection required for those safety-related SSCs necessary to ensure the capability to shut down the reactor and maintain it in a safe shutdown condition. The specific areas of review are as follows: (1) design basis for flooding in streams and rivers; (2) design basis for site drainage; (3) consideration of other site-related evaluation criteria; and, (4) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.3.2 Summary of Application

North Anna 3 COL FSAR Section 2.4.3, "Probable Maximum Flood on Streams and Rivers," addresses the need for information on site-specific PMF on streams and rivers.

The COL applicant addressed the ESBWR DCD and ESP information as follows:

COL Item:

- NAPS COL 2.0-14-A — Probable Maximum Flood on Streams and Rivers, COL Applicant to supply site-specific information in accordance with SRP 2.4.3

The COL applicant incorporated by reference ESP SSAR Section 2.4.3 to address ESBWR DCD COL Item 2.0-14-A and provided updated site-specific information to supplement ESP SSAR Sections 2.4.3.

Early Site Permit Variance:

The following variance from the ESP SSAR are discussed in Section 2, "Variances," of Part 7 to the COLA:

- NAPS ESP VAR 2.4-4

As described in Section 2.4.1, the COL applicant stated that, to improve water availability to downstream users during drought conditions, the normal pool elevation of Lake Anna is to be raised 0.08 m (0.25 ft) to 76.01 m (249.39 ft) NAVD88.

- NAPS ESP VAR 2.4-5

The COL applicant supplemented the ESP SSAR Section 2.4.3 with a revised PMF analysis for Lake Anna using the increased normal pool elevation, and also updated the model to use the USACE HEC-HMS code (USACE, 2010b) and USACE guidance on the use of peaked hydrographs to account for a nonlinear response to large storms. The COL applicant stated that the PMF for streams and rivers is at an elevation of 81.25 m (266.56 ft) NAVD88, which is 7.14 m (23.44 ft) below the design plant grade for safety-related components and structures.

2.4.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP. In addition, the guidance relevant to the Commission's regulations for the PMF on streams and rivers, and the associated acceptance criteria, are contained in Section 2.4.3 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 PMF on streams and rivers presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item NAPS COL 2.0-14-A, and NAPS COL VARs 2.4-4 and 2.4-5), are based on meeting the following relevant requirements of 10 CFR Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d), sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves at the site.

The following related acceptance criteria are summarized from SRP Section 2.4.3:

- Design Bases for Flooding in Streams and Rivers: To meet the requirements of 10 CFR Part 100, estimates of the following characteristics are needed, and should be based on conservative assumptions of hydrometeorologic characteristics in the drainage area: (a) the area of the watershed used to estimate flooding in streams and rivers, (b) the total depth of PMP and the PMP hyetograph, (c) the maximum PMF water surface elevation in streams and rivers with coincident wind-waves, and (d) hydraulic characteristics that describe dynamic effects of PMF on SSC important to safety. If a potential hazard to SSC important to safety exists, the applicant should document and justify the design bases of affected facilities.

- Design Bases for Site Drainage: To meet the requirements of 10 CFR Part 100, estimates of the following characteristics are needed: the runoff from the immediate site area and the drainage from areas adjacent to the site, including the roofs of safety-related structures. Flood response characteristics should be identified to estimate flooding adjacent to and on the plant site. The effects of erosion and sedimentation during the flooding should be identified and their effects on SSC important to safety should be determined. If a potential hazard to SSC important to safety exists, the applicant should document and justify the design bases of affected facilities.

- Consideration of Other Site-Related Evaluation Criteria: To meet the requirements of 10 CFR Part 100 information about the potential effects of site related proximity, seismic, and non-seismic information as they relate to flooding in streams and rivers and local flooding adjacent to and on the plant site is needed.

In addition, the hydrologic characteristics should be consistent with appropriate sections from RGs:

- RG 1.27, describes the applicable UHS capabilities.

- RG 1.29, identifies seismic design bases for SSC important to safety.

- RG 1.59, as supplemented by current best practices provides guidance for developing the hydrometeorological design bases.

- RG 1.102, describes acceptable flood protection to prevent the safety-related facilities from being adversely affected.

2.4.3.4 Technical Evaluation

As documented in Section 2.4.3 of NUREG-1966 and Section 2.4.3 of NUREG-1835, the staff reviewed and approved information related to PMF for the certified ESBWR DCD, Revision 10, and Section 2.4.3 of the North Anna ESP, respectively. The staff reviewed Section 2.4.3 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic. The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Probable Maximum Flood on Streams and Rivers."

The staff's technical review in this section is limited to reviewing the supplemental information pertaining to NAPS COL 2.0-14-A, NAPS ESP VAR 2.4-4, and NAPS ESP VAR 2.4-5 as addressed below.

Information Submitted by COL Applicant:

The current design for the site calls for an increase in the normal pool elevation of Lake Anna by 7.62 cm (3 inches) from 75.94 m (249.14 ft) NAVD88 to 76.01 m (249.39 ft) NAVD88 to increase water availability downstream of Lake Anna during drought conditions when North Anna 3 is operational. With the change in normal pool elevation, the COL applicant updated the PMF analysis, which included an update to the model to use the USACE HEC-HMS code, rather than the HEC-1 code used for the ESP SSAR.

The initial HEC-HMS simulation used the lower normal pool elevation and the same input data used in the ESP SSAR HEC-1 analysis. However, the input parameters for the Coefficient Ratio (CR) and the Recession Ratio (RC) were adjusted so that the HEC-HMS analysis matched the stillwater PMF elevation of 80.23 m (263.21 ft) NAVD88 as developed in the ESP SSAR.

For the North Anna 3 COL FSAR, the COL applicant revised the initial Lake Anna elevation and the stage-discharge relationship to reflect the 0.08 m (0.25 ft) increase in the normal pool elevation. The COL applicant also applied the peaked unit hydrograph. The COL applicant stated that the revised PMF at Lake Anna dam was increased by 0.01 m (0.03 ft) compared to the ESP SSAR PMF elevation. The COL applicant stated that, because the increase in the PMF elevation at the dam was so small, backwater and wind-wave activity effects on the maximum flood elevation were not reanalyzed, but were kept at 1.01 m (3.32 ft) (i.e., 0.03 m [0.09 ft] for wave set-up, 0.92 m [3.03 ft] for wave run-up, and 0.06 m [0.20 ft] for backwater). The COL applicant stated that the PMF elevation for the North Anna 3 site is 81.25 m (266.56 ft) NAVD88 including these associated effects. Additionally, the COL applicant stated that the PMF elevation is 7.14 m (23.44 ft) below the North Anna 3 design plant grade and that all UHS SSCs and the Fire Water Service Complex (FWSC) (which provides makeup water to the UHS from 72 hr. to 7 days post-accident) are above the PMF elevation.

The Staff's Technical Evaluation:

The staff reviewed the North Anna 3 COL FSAR and the COL applicant-provided HEC-HMS files. The staff checked the ESP SSAR and compared the results with the current analysis. The COL applicant updated the method of analysis using HEC-HMS, while the analysis in the ESP SSAR used HEC-1, which was a predecessor to HEC-HMS. The staff finds it acceptable to update the analyses using standard modeling tools, especially because the USACE no long supports HEC-1.

The COL applicant set up a HEC-HMS model to reproduce the maximum water surface as obtained in the ESP SSAR HEC-1 analysis. The COL applicant adjusted two parameters of the HEC-HMS model, the CR used in precipitation loss and the RC. Otherwise, all other inputs were the same as used for the HEC-1 analysis. The COL applicant adjusted the value of CR to match the basin runoff found in the ESP SSAR analysis using HEC-1. The COL applicant computed the value of RC using a conversion formula from the HEC-HMS documentation (USACE, 2010b).

The staff checked the applicant-provided HEC-HMS model run used for conversion from HEC-1 to HEC-RAS and confirmed the stillwater PMF elevation of 80.23 m (263.21 ft) NAVD88 at Lake Anna Dam reported in the North Anna 3 COL FSAR. The staff found the stillwater PMF elevation to be consistent with the value reported in the ESP SSAR. The staff also checked the model run with an initial 7.62 cm (3 in or 0.25 ft) rise of the Lake Anna normal pool elevation and found that the HEC-HMS model produced a stillwater PMF elevation of 80.24 m (263.24 ft) NAVD88 at Lake Anna Dam, the same as reported in North Anna 3 COL FSAR Section 2.4.3.

The COL applicant set the CR and RC parameters to 11.055 and 0.72482, respectively. The staff conducted sensitivity analyses of the adjusted parameters. CR values ranging from 1.0 to 100 produced an elevation change from 80.00 m (262.47 ft) NAVD88 to 80.30 m (263.45 ft) NAVD88. RC values ranging from 0.1 to 1.0 produced an elevation range from 79.92 m (262.19 ft) NAVD88 to 80.24 m (263.27 ft) NAVD88. The staff finds that the model sensitivity to these parameters is at most ±0.15 m (±0.5 ft) which is small in comparison to the 7.14 m (23.44 ft) difference between the PMF elevation and the design plant grade elevation.

The ESP SSAR reports a backwater effect at the North Anna 3 site of 0.06 m (0.2 ft). The ESP SSAR also reports the effect of wind wave activity as 0.03 m (0.09 ft) for wind set-up and 0.92 m (3.03 ft) for wave run-up. Because the increase in the stillwater PMF elevation from the ESP SSAR was only 0.01 m (0.03 ft), the staff finds acceptable for the North Anna 3 COL FSAR the backwater and wind wave effects used in the ESP SSAR. The staff computed a final PMF elevation for the North Anna 3 site of 81.25 m (266.56 ft) NAVD88, which agrees with the PMF elevation reported in the North Anna 3 COL FSAR. Accordingly, the staff accepted NAPS ESP VAR 2.4-4 and NAPS ESP VAR 2.4-5.

2.4.3.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.3.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR and staff's ESP FSER. The staff's review confirmed that the applicant has addressed the relevant information, and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.3 of NUREG–0800, and NRC RGs. The staff's review concludes that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the applicant has adequately addressed COL Item NAPS 2.0-14-A as it relates to the PMF on streams and rivers.

As set forth above, the applicant has presented and substantiated information relative to the PMF on streams and rivers important to the design and siting of this plant. The staff reviewed the available information provided. For the reasons given above, the staff concluded that the identification and consideration of the PMF on streams and rivers at the site and in the surrounding area are acceptable and meet the requirements of 10 CFR 52.79 and 10 CFR 100.20(c), with respect to determining the acceptability of the site for the ESBWR design.

The staff finds that the applicant has considered the appropriate site phenomena in establishing the design bases for SSCs important to safety. The staff accepted the methodologies used to determine the PMF on streams and rivers. Accordingly, the staff concluded that the use of these methodologies results in design bases containing a sufficient margin for the limited accuracy, quantity, and period of time in which the data have been accumulated. The staff concludes that the identified design bases meet the requirements of 10 CFR 100.20(c) with respect to establishing the design basis for SSCs important to safety.

2.4.4 Potential Dam Failures

2.4.4.1 Introduction

The potential dam failures are addressed to ensure that any potential hazard to the safety-related facilities due to the failure of onsite, upstream, and downstream water control structures is considered in the plant design. The specific areas of review are as follows: (1) flood waves resulting from a dam breach or failure, including those due to hydrologic failure as a result of overtopping for any reason, routed to the site and the resulting highest water surface elevation that may result in the flooding of SSCs important to safety; (2) successive failures of several dams in the path to the plant site caused by the failure of an upstream dam due to plausible reasons, such as a PMF, landslide-induced severe flood, earthquakes, or volcanic activity and the effect of the highest water surface elevation at the site under the cascading failure conditions; (3) dynamic effects of dam failure-induced flood waves on SSCs important to safety; (4) failure of a dam downstream of the plant site that may affect the availability of a safety-related water supply to the plant; (5) effects of sediment deposition or erosion during dam failure-induced flood waves that may result in blockage or loss of function of SSCs important to safety; (6) failure of onsite water control or storage structures such as levees, dikes, and any engineered water storage facilities that are located above site grade and may induce flooding at the site; (7) the potential effects of seismic and nonseismic data on the postulated design bases and how they relate to dam failures in the vicinity of the site and the site region; and, (8) any additional information requirements prescribed in the “Contents of Application” sections of the applicable subparts to 10 CFR Part 52.

2.4.4.2 Summary of Application

North Anna 3 COL FSAR Section 2.4.4,”Potential Dam Failures,” addresses the need for site-specific information on potential dam failures. The COL applicant addressed the information as follows:

COL Items:

- NAPS COL 2.0-15-A — Potential Dam Failures, COL Applicant to supply site-specific information in accordance with SRP 2.4.4. COL Applicant to demonstrate that failure of existing and potential upstream or downstream water control structures will not cause flooding to exceed 0.3 m (1 ft) below plant grade.

The COL applicant incorporated by reference ESP SSAR Section 2.4.4 to address ESBWR DCD COL Item 2.0-15-A.

- NAPS ESP COL 2.4-6

- NAPS ESP COL 2.4-7

The COL applicant provided updated site-specific information to supplement ESP SSAR Section 2.4.4 to address ESP COL Action Items 2.4-6 and 2.4-7, indicating that the UHS described in ESBWR DCD Section 9.2.5 addresses NRC’s requirements to provide sufficient emergency cooling capability.

2.4.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP. In addition, the guidance relevant to the Commission’s regulations for the potential dam failures, and the associated acceptance criteria, are contained in Section 2.4.4 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 description of potential dam failures presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item NAPS COL 2.0-15-A, and NAPS ESP COL Items 2.4-6 and 2.4-7), are based on meeting the following relevant requirements of 10 CFR Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d), sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves at the site.

The related acceptance criteria from SRP Section 2.4.4 are as follows:

- Flood Waves from Severe Breaching of an Upstream Dam: To meet the requirements of 10 CFR Part 100 and 10 CFR 100.23(d), estimates of the following characteristics are needed, and should be based on conservative assumptions of hydrometeorological, geological, and seismic characteristics in the drainage area: (a) modes of assumed dam breaches or failures, (b) consideration of flood control reservoirs at full pool level, and (c) conservatism of coincident flow rates and water surface elevations.

- Domino-Type or Cascading Dam Failures: To meet the requirements of 10 CFR Part 100 and 10 CFR 100.23(d), an appropriate configuration of the cascade of dam failures and its potential to produce the largest flood adjacent to the plant site is needed.

- Dynamic Effects on Structures: To meet the requirements of 10 CFR Part 100, an estimate of dynamic effects of flood waves, such as velocities and momentum fluxes, on SSC important to safety is needed.

- Loss of Water Supply Due to Failure of a Downstream Dam: To meet the requirements of 10 CFR Part 100 and 10 CFR 100.23(d), an assessment regarding loss of safety-related water supply to the plant caused by failure of a downstream dam is needed.

- Effects of Sediment Deposition and Erosion: To meet the requirements of 10 CFR Part 100 and 10 CFR 100.23(d), an assessment is needed regarding loss of functionality of safety-related water supply to the plant caused by blockages due to sediment deposition or erosion during the dam failure-induced flood event.

- Failure of Onsite Water Control or Storage Structures: To meet the requirements of 10 CFR Part 100, an assessment is needed regarding the failure of any onsite water control or storage structures that may cause flooding of SSC important to safety.

- Consideration of Other Site-Related Evaluation Criteria: The potential effects of site-related proximity, seismic, and non-seismic information as they relate to flooding due to upstream dam failures and loss of safety-related water supply due to blockages and failures of downstream dam failures adjacent to and on the plant site and site regions are needed to meet the requirements of 10 CFR Part 100.

In addition, the hydrologic characteristics should be consistent with appropriate sections from: RGs 1.27, 1.29, 1.59, as supplemented by best current practices, and RG 1.102.

2.4.4.4 Technical Evaluation

As documented in Section 2.4.4 of NUREG-1966 and Section 2.4.4 of NUREG-1835, the staff reviewed and approved information related to potential dam failures for the certified ESBWR DCD, Revision 10, and Section 2.4.4 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.4 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic.

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Potential Dam Failures."

The elevation of the design plant grade is 88.39 m (290.0 ft) NAVD88, which is 20.86 ft above the maximum flood level at the site resulting from a PMF in Lake Anna's watershed, the simultaneous failure of upstream storage reservoirs, and coincident wave action, as described in the ESP FSER.

The staff's technical review of this application is limited to the supplemental information pertaining to NAPS COL 2.0-15-A and NAPS ESP COL Action items 2.4-6 and 2.4-7, as addressed below.

The staff reviewed the resolution to DCD COL Item 2.0-15-A, related to any potential hazard to the safety-related facilities due to the failure of onsite, upstream, and downstream water control structures. These potential hazards are considered in the plant design included in North Anna 3 COL FSAR Section 2.4.4. The staff finds that the additional information was consistent with the information in the ESP SSAR, which has already been accepted in the ESP FSER.

As described in Section 2.4.1 of this SER, the staff determined that no underground reservoirs are included in the design of the ESBWR UHS and no external source of safety-related makeup water is required for the UHS. Because the predicted flood elevation from dam failure was well below the design plant grade for North Anna 3 and the UHS does not depend on Lake Anna, the staff concludes that dam failure would not affect the North Anna 3 UHS.

2.4.4.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.4.6 Conclusion

The staff reviewed the COLA and checked the referenced ESP SSAR and staff's ESP FSER. The staff's review confirmed that the COL applicant has addressed the relevant information and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.4 of NUREG–0800, and NRC RGs. The staff's review concludes that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the applicant has adequately addressed COL Item NAPS 2.0-15-A as it relates to potential dam failure.

As set forth above, the applicant has presented and substantiated information relative to the effects of dam failures important to the design and siting of this plant. The staff reviewed the available information provided. For the reasons given above, the staff concluded that the identification and consideration of the effects of dam failures at the site and in the surrounding area are acceptable and meet the requirements of 10 CFR 52.79, 10 CFR 100.23(d), and 10 CFR 100.20(c).

The staff finds that the applicant has considered the appropriate site phenomena in establishing the design bases for SSCs important to safety. The staff accepted the methodologies used to determine the effects of dam failures reflected in the site characteristics documented in the ESP SER. Accordingly, the staff concludes that the use of these methodologies results in design bases containing a sufficient margin for the limited accuracy, quantity, and period of time in which the data have been accumulated. The staff concludes that the identified design bases meet the requirements of 10 CFR 100.23(d) and 10 CFR 100.20(c), with respect to establishing the design basis for SSCs important to safety.

2.4.5 Probable Maximum Surge and Seiche Flooding

The probable maximum surge and seiche flooding are addressed to ensure that any potential hazard to the safety-related facilities due to the effects of probable maximum surge and seiche is considered in plant design. The specific areas of review are as follows: (1) probable maximum hurricane (PMH) that causes the probable maximum surge as it approaches the site along a critical path at an optimum rate of movement; (2) probable maximum wind storm (PMWS) from a hypothetical extratropical cyclone or a moving squall line that approaches the site along a critical path at an optimum rate of movement; (3) a seiche near the site, and the potential for seiche wave oscillations at the natural periodicity of a water body that may affect flood water surface elevations near the site or cause a low water surface elevation affecting safety-related water supplies; (4) wind-induced wave run-up under a PMH or PMWS winds; (5) effects of sediment erosion and deposition during a storm surge and seiche-induced waves that may result in blockage or loss of function of SSCs important to safety; (6) the potential effects of seismic and nonseismic information on the postulated design bases and how they relate to a surge and seiche in the vicinity of the site and the site region; and, (7) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

The COL applicant incorporated by reference ESP SSAR Section 2.4.5 to address DCD COL Item 2.0-16-A, related to probable maximum surge and seiche flooding. The staff reviewed the COLA and checked the referenced ESP SSAR and the staff's ESP FSER. The staff confirmed that no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

2.4.6 Probable Maximum Tsunami Hazards

The probable maximum tsunami (PMT) hazards are addressed to ensure that any potential tsunami hazards to the SSCs important to safety are considered in plant design. The specific areas of review are as follows: (1) historical tsunami data, including paleotsunami mappings and interpretations, regional records and eyewitness reports, and more recently available tide gauge and real-time bottom pressure gauge data; (2) PMT that may pose hazards to the site; (3) tsunami wave propagation models and model parameters used to simulate the tsunami wave propagation from the source toward the site; (4) extent and duration of wave run-up during the inundation phase of the PMT event; (5) static and dynamic force metrics including the inundation and drawdown depths, current speed, acceleration, inertial component, and momentum flux that quantify the forces on any safety-related SSCs that may be exposed to the tsunami waves; (6) debris and water-borne projectiles that accompany tsunami currents and may impact safety-related SSCs; (7) effects of sediment erosion and deposition caused by tsunami waves that may result in blockage or loss of function of safety-related SSCs; and, (8) potential effects of seismic and nonseismic information on the postulated design bases and how they relate to tsunami in the vicinity of the site and the site region; (9) any additional information requirements prescribed in the “Contents of Application” sections of the applicable subparts to 10 CFR Part 52.

The COL applicant incorporated by reference ESP SSAR Section 2.4.6 to address DCD COL Item 2.0-17-A related to PMT flooding. The staff reviewed the COLA and checked the referenced ESP SSAR and the staff’s ESP FSER. The staff confirmed that no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

2.4.7 Ice Effects

2.4.7.1 Introduction

The ice effects are addressed to ensure that safety-related facilities and water supply are not affected by ice-induced hazards. The specific areas of review are as follows: (1) regional history and types of historical ice accumulations (i.e., ice jams, wind-driven ice ridges, floes, frazil ice formation, etc.); (2) potential effects of ice-induced, high- or low-flow levels on safety-related facilities and water supplies; (3) potential effects of a surface ice-sheet to reduce the volume of available liquid water in safety-related water reservoirs; (4) potential effects of ice to produce forces on, or cause blockage of, safety-related facilities; (5) potential effects of seismic and nonseismic data on the postulated worst-case icing scenario for the proposed plant site; and, (6) any additional information requirements prescribed in the “Contents of Application” sections of the applicable subparts to 10 CFR Part 52.

2.4.7.2 Summary of Application

The North Anna 3 COL FSAR, Revision 9, Section 2.4.7, “Ice Effects,” addresses site-specific ice effects. The COL applicant addressed the information as follows:

<u>*COL Item:*</u>

- NAPS COL 2.0-18-A — Ice Effects, COL Applicant to supply site-specific information in accordance with SRP 2.4.7

The COL applicant incorporated by reference ESP SSAR Section 2.4.7 to address DCD COL Item 2.0-18-A and provided updated site-specific information to supplement ESP SSAR Section 2.4.7. The COL applicant described the potential for ice formation at the North Anna 3 station water intake building and at the intake trash racks or intake screens. The COL applicant stated that the emergency cooling water for North Anna 3 is provided from the UHS, which is not affected by ice conditions, and that the normal cooling systems for North Anna 3 are not safety-related systems. The COL applicant further clarified that the water intake and associated pumps for North Anna 3 do not perform safety-related functions and that the makeup water supply from the North Anna 3 intake is not safety-related.

2.4.7.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP. In addition, the guidance relevant to the Commission’s regulations related to ice effects, and the associated acceptance criteria, are contained in Section 2.4.7 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 ice effects presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item 2.0-18-A), are based on meeting the following relevant requirements of 10 CFR Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

The related acceptance criteria from SRP Section 2.4.7 are as follows:

- Historical Ice Accumulation: The application should include a complete history of ice formation at and in the vicinity of the site.

- High and Low Water Levels: The application should include estimates of water levels resulting from potential ice flooding or low flows.

- Ice Sheet Formation: The application should include estimates of the most severe ice sheet formation in water storage reservoirs.

- Ice-induced Forces and Blockages: The application should provide estimates of the most severe ice-induced forces on safety-related SSC.

- Consideration of Other Site-Related Evaluation Criteria: The application should demonstrate that the potential effects of site-related proximity, seismic, and nonseismic information as they relate to worst-case icing scenarios adjacent to and on the plant site and site regions are appropriately take into account.

In addition, the hydrologic characteristics should be consistent with appropriate sections from: RGs 1.27, 1.29, 1.59, as supplemented by best current practices, and RG 1.102.

2.4.7.4 Technical Evaluation

As documented in Section 2.4.7 of NUREG-1966 and Section 2.4.7 of NUREG-1835, the staff reviewed and approved information related to ice effects for the certified ESBWR DCD, Revision 10, and Section 2.4.7 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.7 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic.

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Ice Effects."

The staff's technical review of this application is limited to reviewing the supplemental information pertaining to ESBWR DCD COL 2.0-18-A, as addressed below:

The applicant incorporated by reference ESP SSAR Section 2.4.7 to address DCD COL Item 2.0-18-A and provided updated site-specific information to supplement ESP SSAR Section 2.4.7, related to ice effects. As stated in Section 2.4.1 of this SER, the staff confirmed that neither Lake Anna nor the WHTF will be used for safety-related withdrawals, and that the

UHS does not require an external source of safety-related makeup water. Therefore, the staff concludes that no safety-related systems or water supplies are affected by ice.

The staff also reviewed the additional information concerning surface ice and roof loads provided in the North Anna 3 COL FSAR, which states that the snow depths and winter PMP was discussed in North Anna 3 COL FSAR Section 2.3.1.3.4. The staff determined that the additional information was consistent with the information in the ESP SSAR, which has already been accepted in the ESP FSER (NUREG-1835).

2.4.7.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.7.6 Conclusion

The staff reviewed the application and checked the referenced North Anna ESP SSAR and staff's ESP FSER (NUREG-1835). The staff's review confirmed that the applicant has addressed the relevant information and there is no outstanding information expected to be addressed in the North Anna 3 COL FSAR related to this section.

As set forth above, the applicant has presented and has substantiated information relative to the ice effects important to the design and siting of this plant. The staff reviewed the available information provided. For the reasons given above, the staff concluded that the identification and consideration of the potential for ice flooding, ice blockage of water intakes, ice forces on structures, and the minimum low water levels (from an upstream ice blockage) are acceptable and meet the requirements of 10 CFR 52.79 and 10 CFR 100.20(c), with respect to determining the acceptability of the site for the ESBWR design.

The staff finds that the applicant has considered the appropriate site phenomena for establishing the design basis for SSCs important to safety. The staff accepted the methodologies used to determine the potential for ice formation and blockage reflected in the site characteristics documented in the ESP FSER. Accordingly, the staff concluded that the use of these methodologies results in site characteristics containing a sufficient margin for the limited accuracy, quantity, and period of time in which the data have been accumulated. The staff concluded that the identified site characteristics meet the requirements of 10 CFR 52.79 and 10 CFR 100.20(c), with respect to establishing the design basis for SSCs important to safety.

2.4.8 Cooling Water Canals and Reservoirs

2.4.8.1 Introduction

The cooling water canals and reservoirs used to transport and impound water supplied to the SSCs important to safety are reviewed to verify their hydraulic design basis. The specific areas of review are as follows: (1) design bases postulated and used by the applicant to protect structures such as riprap, inasmuch as they apply to safety-related water supply; (2) design bases of canals pertaining to capacity, protection against wind waves, erosion, sedimentation, and freeboard and the ability to withstand a PMF (surges, etc.), inasmuch as they apply to a safety-related water supply; (3) design bases of reservoirs pertaining to capacity, PMF design basis, wind wave and run-up protection, discharge facilities (e.g., low-level outlet, spillways, etc.), outlet protection, freeboard, and erosion and sedimentation processes inasmuch as they apply to a safety-related water supply; (4) potential effects of seismic and nonseismic information on the postulated hydraulic design bases of canals and reservoirs for the proposed plant site; and, (5) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.8.2 Summary of Application

North Anna 3 COL FSAR Section 2.4.8, "Cooling Water Canals and Reservoirs," addresses the need for site-specific information on the use of cooling water canals and reservoirs. The COL applicant addressed the information as follows:

<u>*COL Items:*</u>

• NAPS COL 2.0-19-A	Cooling Water Canals and Reservoirs, COL Applicant to supply site-specific information in accordance with SRP 2.4.8

The COL applicant incorporated by reference ESP SSAR Section 2.4.8 to address ESBWR DCD COL Item 2.0-19-A.

- NAPS ESP COL 2.4-8

The COL applicant provided updated site-specific information to supplement ESP SSAR Section 2.4.8 to confirm that the North Anna Reservoir and WHTF, which comprise Lake Anna, are not used for safety-related water withdrawals for North Anna 3. The emergency cooling water for North Anna 3 comes from the UHS, as described in ESBWR DCD Section 9.2.5 and North Anna 3 COL FSAR Section 9.2.5.

2.4.8.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP. In addition, the guidance relevant to the Commission's regulations related to cooling water canals and reservoirs, and the associated acceptance criteria, are contained in Section 2.4.8 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 cooling water canals and reservoirs presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item 2.0-19-A and NAPS ESP COL Item 2.4-8), are based on meeting the following relevant requirements of 10 CFR Parts 52 and 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d) sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves the site.

The related acceptance criteria from SRP Section 2.4.8 are as follows:

- Hydraulic Design Bases for Protection of Structures: To meet the requirements of 10 CFR Part 100, a complete description of the hydraulic design bases for protection of structures is needed.

- Hydraulic Design Bases of Canals: To meet the requirements of 10 CFR Part 100, a complete description of the hydraulic design bases related to the capacity, protection against wind waves, erosion, sedimentation, and freeboard, and the ability to withstand a PMF, surges, etc., is needed.

- Hydraulic Design Bases of Reservoirs: To meet the requirements of 10 CFR Part 100, a complete description of the design bases of safety-related reservoirs related to their capacity, PMF design basis, wind wave and run-up protection, discharge facilities (e.g., low-level outlet, spillways, etc.), outlet protection, freeboard, and erosion and sedimentation processes is needed.

- Consideration of Other Site-Related Evaluation Criteria: To meet the requirements of 10 CFR Part 100, a complete description of the potential effects of site-related proximity, seismic, and non-seismic information on the postulated design bases of safety-related canals and reservoirs is needed.

In addition, the hydrologic characteristics should be consistent with appropriate sections from RGs 1.27, 1.29, 1.59, as supplemented by best current practices, RG 1.102, and RG 1.125, "Physical Models for Design and Operation of Hydraulic Structures and Systems for Nuclear Power Plants."

2.4.8.4 Technical Evaluation

As documented in Section 2.4.8 of NUREG-1966 and Section 2.4.8 of NUREG-1835, the staff reviewed and approved information related to cooling water canals and reservoirs for the certified ESBWR DCD, Revision 10, and Section 2.4.8 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.8 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR that represent the complete scope of information relating to this review topic.

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Cooling Water Canals and Reservoirs."

The staff's technical review of this application was limited to reviewing the supplemental information pertaining to NAPS COL 2.0-19-A and ESP COL Action Item 2.4-8, as addressed below:

The COL applicant incorporated by reference ESP SSAR Section 2.4.8 to address ESBWR DCD COL Item 2.0-19-A, related to cooling water canals and reservoirs. The staff determined that the additional information is consistent with the information provided in the ESP SSAR, which has already been accepted in the ESP FSER (NUREG-1835).

As described in Section 2.4.1 of this SER, the staff confirmed that the North Anna Reservoir and WHTF are not used for safety-related water withdrawals for North Anna 3.

2.4.8.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.8.6 Conclusion

The staff reviewed the COLA and checked the referenced ESP SSAR and the staff's ESP FSER. The staff's review confirmed that the COL applicant has addressed the required information and no outstanding information remains to be addressed in the COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.8 of NUREG–0800, and NRC RGs. The staff's review concludes that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the COL applicant has adequately addressed COL Item NAPS 2.0-19-A as it relates to cooling water canals and reservoirs.

As set forth above, the COL applicant has presented and substantiated information relative to the design bases of canals and reservoirs important to the design and citing of this plant. The staff has reviewed the available information provided and for the reasons given above, concludes that the identification and consideration of the design bases of canals and reservoirs is acceptable and meets the requirements of 10 CFR 52.79(a)(1)(iii), 10 CFR 100.20(c), and 10 CFR 100.23(d), with respect to determining the acceptability of the site.

2.4.9 Channel Diversions

Plant and essential water supplies used to transport and impound water supplies were evaluated to ensure that they will not be adversely affected by stream or channel diversions. The review includes stream channel diversions away from the site (which may lead to a loss of safety-related water) and stream channel diversions toward the site (which may lead to flooding). In addition, in such an event, the applicant needs to show that alternate water supplies are available to safety-related equipment. The specific areas of review are as follows: (1) historical channel migration phenomena including cutoffs, subsidence, and uplift; (2) regional topographic evidence that suggests a future channel diversion may or may not occur (used in conjunction with evidence of historical diversions); (3) thermal causes of channel diversion, such as ice jams, which may result from downstream ice blockages that may lead to flooding from backwater or upstream ice blockages that can divert the flow of water away from the intake; (4) potential for forces on safety-related facilities or the blockage of water supplies resulting from channel migration-induced flooding (flooding not addressed by hydrometeorological-induced flooding scenarios in other sections); (5) potential of channel diversion from human-induced causes (i.e., land-use changes, diking, channelization, armoring, or failure of structures); (6) alternate water sources and operating procedures; (7) potential effects of seismic and nonseismic information on the postulated worst-case channel diversion scenario for the proposed plant site; and, (8) any additional information requirement prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

The COL applicant incorporated by reference ESP SSAR Section 2.4.9 with no supplement or departure to address DCD COL Item 2.0-20-A, related to channel diversions. The staff reviewed the COLA and checked the referenced ESP SSAR and the staff's ESP FSER. The staff confirmed that no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

2.4.10 Flooding Protection Requirements

2.4.10.1 Introduction

The flooding protection requirements address the locations and elevations of safety-related facilities and those of structures and components required for protection of safety-related facilities. These requirements are then compared with design-basis flood conditions to determine whether flood effects need to be considered in the plant's design or in emergency procedures. The specific areas of review are as follows: (1) safety-related facilities exposed to flooding; (2) type of flood protection (e.g., "hardened facilities," sandbags, flood doors, bulkheads, etc.) provided to the SSCs exposed to floods; (3) emergency procedures needed to implement flood protection activities and warning times available for their implementation reviewed by the organization responsible for reviewing issues related to plant emergency procedures; (4) potential effects of seismic and nonseismic information on the postulated flooding protection for the proposed plant site; and, (5) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.10.2 Summary of Application

The North Anna 3 COL FSAR Section 2.4.10, "Flooding Protection Requirements," address the needs for site-specific information on flooding protection. The COL applicant addressed the information as follows:

COL Items:

- NAPS COL 2.0-21-A — Flooding Protection Requirements, COL Applicant to supply site-specific information in accordance with SRP 2.4.10

The COL applicant incorporated by reference ESP SSAR Section 2.4.10 to address ESBWR DCD COL Item 2.0-21-A and provided updated site-specific information to supplement ESP SSAR Section 2.4.10. The COL applicant described the results of the local PMP drainage analysis presented in North Anna 3 COL FSAR Section 2.4.2.3. The COL applicant stated that the maximum water-surface elevation within drainage ditches in the powerblock area would be 87.90 m (288.4 ft) NAVD88 or 0.49 m (1.6 ft) below the plant grade of 88.39 m (290.0 ft) NAVD88. In response to staff's RAI 02.04.02-15 (ADAMS Accession Nos. ML15022A199 and ML16229A451), the COL applicant stated that an analysis of sheet flow resulting from local intense precipitation between buildings in the powerblock area indicated that water levels would exceed the floor elevations of safety-related SSCs at three entrance locations. To prevent sheet flow from entering the RB and CB, the COL applicant committed to installing curbs at the entrances or to ensure that the door thresholds would be above the maximum sheet-flow elevations. The COL applicant proposed revisions to North Anna 3 COL FSAR Section 2.4.10 to describe flood protection measures. The staff verified that the appropriate text changes are incorporated in the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.10-1 from the staff's advanced SER for North Anna 3 is resolved and closed.

- NAPS ESP COL 2.4-9 Slope Embankment Protection

The COL applicant provided updated site-specific information to supplement ESP SSAR Section 2.4.10 to address ESP COL Action Item 2.4-9. The COL applicant indicated that the North Anna 3 water intake building will be separated from Lake Anna by an elevated berm that will protect it from flood events up to a 100-year flood on the lake. Rip-rap protection of the slope embankment is provided to protect against local erosion near the intake structure. The COL applicant noted that the North Anna 3 water intake is not a safety-related structure.

2.4.10.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835 the FSER related to the North Anna 3 ESP. In addition, the guidance relevant to the Commission's regulations related to flood protection requirements, and the associated acceptance criteria, are given in Section 2.4.10 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 flooding protection requirements presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item NAPS COL 2.0-21-A and NAPS ESP COL Item 2.4-9), are based on meeting the following relevant requirements of 10 CFR Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d) sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves the site.

The related acceptance criteria from SRP Section 2.4.10 are as follows:

- Safety-related Facilities Exposed to Flooding: To meet the requirements of 10 CFR Part 100, identification of all SSC exposed to flooding is needed.

- Type of Flood Protection: To meet the requirements of 10 CFR Part 100, an evaluation of the applicant's proposed flood protection measures is needed.

- Emergency Procedures: To meet the requirements of 10 CFR Part 100, a listing of proposed emergency procedures is needed.

- Consideration of Other Site-Related Evaluation Criteria: To meet the requirements of 10 CFR Part 100, an assessment regarding the potential effects of site-related proximity, seismic, and non-seismic information on the postulated flooding protection is needed.

In addition, the hydrologic characteristics should be consistent with appropriate sections from: RGs 1.29, 1.59, as supplemented by best current practices, and RG 1.102.

2.4.10.4 Technical Evaluation

As documented in Section 2.4.10 of NUREG-1966 and Section 2.4.10 of NUREG-1835, the staff reviewed and approved information related to flooding protection requirements for the certified ESBWR DCD, Revision 10, and Section 2.4.10 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.10 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic. The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Flooding Protection Requirements."

The elevation of the design plant grade for North Anna 3 is 88.39 m (290.0 ft) NAVD88. This elevation is approximately 6.10 m (20 ft) above the maximum flood level at the site resulting from a PMF in Lake Anna's watershed, the simultaneous failure of upstream storage reservoirs, and coincident wave action (82.30 m [270 ft] NAVD88).

The staff's technical review in this section was limited to the supplemental information pertaining to ESBWR DCD COL Item 2.0-21-A and ESP COL Action Item 2.4-9, and to the flooding protection described in the response to RAI 02.04.02-15, as addressed below.

The staff reviewed the resolution to the ESBWR DCD COL Item 2.0-21-A, related to flooding protection requirements, and the comparison with design-basis flood conditions to determine whether flood effects need to be considered in the plant's design or in emergency procedures included under North Anna 3 COL FSAR Section 2.4.10. As described in Section 2.4.2 of this SER, the COL applicant stated in the response to RAI 02.04.02-15 (ADAMS Accession Nos. ML15022A199 and ML16229A451), that the maximum flood elevation resulting from local intense precipitation exceeds the entrance elevations to some safety-related structures. The COL applicant will take action to provide flood protection measures at the following locations (the floor elevation at all three locations is 88.39 m [290.0 ft] NAVD88):

- CB south stairway emergency exit, maximum water surface elevation of 88.48 m (290.3 ft) NAVD88 (Area 2);

- CB north stairway emergency exit, maximum water surface elevation of 88.51 m (290.4 ft) NAVD88 (Area 3); and

- RB north wall equipment access door, maximum water surface elevation of 88.45 m (290.2 ft) NAVD88 (Area 4).

The COL applicant stated that the flood protection would be provided by installing curbs at the door entrances or by ensuring that door thresholds are above the maximum water surface elevations. The staff reviewed the COL applicant's response to RAI 02.04.02-15 (ADAMS Accession Nos. ML15022A199 and ML16229A451), and concluded that the proposed measures provide the required flood protection. The staff verified that the appropriate text changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.10-1 from the staff's advanced SER for North Anna 3 is resolved and closed.

As described in Section 2.4.1 of this SER, the UHS design for the ESBWR relies on an internal makeup water supply during the initial 7 days following an accident and the makeup water source beyond 7 days is not required to be safety-related. In addition, the staff confirmed that

Lake Anna will not be used for safety-related UHS withdrawals. Accordingly, the staff determined that the intake structure is not a safety-related structure and is not credited for safety-related functions. However, the structure has protection features that the applicant addressed in ESP COL Action Item 2.4-9 as applicable.

2.4.10.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.10.6 Conclusion

The staff reviewed the COLA and checked the referenced North Anna ESP SSAR and staff's ESP FSER. The staff's review confirmed that the COL applicant has addressed the required information and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.10 of NUREG–0800, and NRC RGs. The staff's review concludes that the applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the applicant has adequately addressed COL Item NAPS 2.0-21-A as it relates to flooding protection requirements.

As set forth above, the applicant has presented and substantiated information relative to the flood protection measures important to the design and siting of this plant. The staff has reviewed the available information provided and for the reasons given above, concludes that the identification and consideration of the flood protection measures is acceptable and meets the requirements of 10 CFR 52.79(a)(1)(iii), 100.20(c), and 100.23(d), with respect to determining the acceptability of the site.

2.4.11 Low Water Considerations

2.4.11.1 Introduction

The low water considerations address natural events that may reduce or limit the available safety-related cooling water supply. The applicant ensures that an adequate water supply will exist to shut down the plant under conditions requiring safety-related cooling. The specific areas of review are as follows: (1) worst drought considered reasonably possible in the region; (2) effects of low water surface elevations caused by various hydrometeorological events and a potential blockage of intakes by sediment, debris, littoral drift, and ice because they can affect the safety-related water supply; (3) effects on the intake structure and pump design bases in relation to the events described in North Anna 3 COL FSAR Sections 2.4.7, 2.4.8, 2.4.9, and 2.4.11, which consider the range of water supply required by the plant (including minimum operating and shutdown flows during anticipated operational occurrences and emergency conditions) compared with availability (considering the capability of the UHS to provide adequate cooling water under conditions requiring safety-related cooling); (4) use limitations imposed or under discussion by Federal, State, or local agencies authorizing the use of the water; (5) potential effects of seismic and nonseismic information on the postulated worst-case low water scenario for the proposed plant site; and, (6) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.11.2 Summary of Application

The North Anna 3 COL FSAR Section 2.4.11, “Low Water Considerations,” addresses the impacts of low water on site water supply. The COL applicant addressed the information as follows:

<u>COL Items:</u>

- NAPS COL 2.0-22-A — Cooling Water Supply, COL Applicant to supply site-specific information in accordance with SRP 2.4.11.

The COL applicant incorporated by reference ESP SSAR Section 2.4.11 to address DCD COL Item 2.0-22-A.

- NAPS ESP COL 2.4-10

The COL applicant provided updated site-specific information to supplement ESP SSAR Sections 2.4.11.5, “Plant Requirements,” and 2.4.11.6, “Heat Sink Dependability Requirements,” to address ESP COL Action Item 2.4-10.

<u>Early Site Permit Variances:</u>

- NAPS ESP VAR 2.4-4

The COL applicant provided updated site-specific information to supplement ESP SSAR Sections 2.4.11.1, “Low Flow in Streams,” which states that the operating level of Lake Anna will be 76.01 m (249.39 ft) NAVD88 with the addition of Unit 3. In addition, ESP SSAR Section 2.4.11.4, “Future Controls,” provides supplemental information on the water budget and low water levels with the operation of North Anna 3.

2.4.11.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP. In addition, the guidance relevant to the Commission’s regulations related to low water considerations, and the associated acceptance criteria, are contained in Section 2.4.11 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 low water consideration requirements is presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item NAPS COL 2.0-22-A, NAPS ESP VAR 2.4-4 and NAPS ESP COL Item 2.4-10), are based on meeting the following relevant requirements of 10 CFR Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d) sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves the site.

The related acceptance criteria from SRP Section 2.4.11 are as follows:

- Low Water from Drought: To meet the requirements of 10 CFR Part 100, a complete history of low water conditions at and in the vicinity of the site is needed.

- Low Water from Other Phenomena: To meet the requirements of 10 CFR Part 100, a complete history of low water conditions, caused by phenomena other than a drought, at and in the vicinity of the site is needed.

- Effect of Low Water on Safety-Related Water Supply: To meet the requirements of 10 CFR Part 100, a thorough description of all safety-related water supply requirements and the effects of the most severe low water event reasonably possible at or in the vicinity of the site is needed.

- Water Use Limits: To meet the requirements of 10 CFR Part 100, a thorough description of water use and discharge limitations (both physical and legal), already in effect or under discussion by responsible Federal, regional, State, or local authorities, that may affect water supply at the plant that have been considered and are substantiated by reference to reports of the appropriate agencies is needed.

- Consideration of Other Site-Related Evaluation Criteria: To meet the requirements of 10 CFR Part 100, the applicant should provide an assessment of the potential effects of site-related proximity, seismic, and non-seismic information on the postulated worst-case low-flow scenario for the proposed plant site

2.4.11.4 Technical Evaluation

As documented in Section 2.4.11 of NUREG-1966 and Section 2.4.11 of NUREG-1835, the staff reviewed and approved information related to low water considerations for the certified ESBWR DCD, Revision 10, and Section 2.4.11 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.11 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic.

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Low Water Considerations."

The staff's technical review of this application is limited to the supplemental information pertaining to DCD COL 2.0-22-A, NAPS ESP COL Action Item 2.4-10, and NAPS ESP VAR 2.4-4 as addressed below.

<u>*COL Items:*</u>

- NAPS COL 2.0-22-A — Cooling Water Supply, COL Applicant to supply site-specific information in accordance with SRP 2.4.11.

The staff reviewed the resolution to ESBWR DCD COL Item 2.0-22-A, related to low water considerations to ensure that an adequate water supply will exist to shut down the plant under conditions requiring safety-related cooling, included under North Anna 3 COL FSAR Section 2.4.11. The applicant provided supplemental information in North Anna 3 COL FSAR Section 2.4.11.4, in which the water budget for Lake Anna was updated using the ESBWR operational cooling requirements. The staff finds that the additional information is consistent with the information in the ESP SSAR as accepted in the ESP FSER.

- NAPS ESP COL 2.4-10

The COL applicant indicated that the North Anna 3 CWS has two modes of operation: energy conservation (when Lake Anna water level is at or above an elevation of 75.94 m (249.14 ft) NAVD88 at the North Anna Dam), and maximum water conservation (when the water level is below an elevation of 75.94 m (249.14 ft) NAVD88 and is not restored within a reasonable period of time). The COL applicant stated that North Anna 3 will be required to shut down when the Lake Anna water elevation decreases below 73.50 m (241.14 ft) NAVD88. The COL applicant stated that the North Anna 3 UHS does not rely on Lake Anna as a safety-related water source and staff determined that ESP COL Action Item 2.4-10 was addressed by the applicant as required.

Early Site Permit Variances:

- NAPS ESP VAR 2.4-4

As described in Section 2.4.1 of this SER, the staff confirmed that neither Lake Anna nor the WHTF will be used for safety-related withdrawals, and that the UHS does not require an external source of safety-related makeup water. Based on the UHS cooling system design specified in North Anna 3 COL FSAR Section 9.2.5, the staff accepted NAP ESP VAR 2.4-4.

2.4.11.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.11.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR and staff's ESP FSER (NUREG-1835). The staff's review confirmed that the applicant has addressed the required information, and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.11 of NUREG–0800, and NRC RGs. The staff's review concludes that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the applicant has adequately addressed COL Item NAPS 2.0-22-A as it relates to low water considerations.

As set forth above, the applicant has presented and substantiated information relative to the low water effects important to the design and siting of this plant. The staff reviewed the available information provided and for the reasons given above, concludes that the identification and consideration of the potential for low water conditions are acceptable and meet the requirements of 10 CFR 52.79(a)(1)(iii), 10 CFR 100.20(c), and 10 CFR 100.23(d), with respect to determining the acceptability of the site.

The staff finds that the applicant has considered the appropriate site phenomena in establishing the design bases for SSCs important to safety. The staff accepted the methodologies used to determine the potential for low water conditions reflected in the site characteristics documented in the ESP FSER. Accordingly, the staff concluded that the use of these methodologies results in design bases containing a sufficient margin for the limited accuracy, quantity, and period of time in which the data have been accumulated. The staff concluded that the identified design bases meet the requirements of 10 CFR 100.20(c) with respect to establishing the design basis for SSCs important to safety.

2.4.12 Groundwater

2.4.12.1 Introduction

This section describes the hydrogeological characteristics of the site. One of the key objectives of groundwater investigations and monitoring at this site is to evaluate the maximum groundwater-surface elevation at the site, which is used in Section 2.5 of this report to determine the effects of groundwater on the stability of plant foundations and slopes. The evaluation is performed to ensure that the maximum groundwater-surface elevation remains less than the ESBWR DCD site parameter value of 0.61 m (2 ft) below plant grade. Other significant objectives are to examine whether groundwater provides any safety-related water supply, to determine whether dewatering systems are required to maintain groundwater-surface elevations below the required elevation, and to describe subsurface pathways for potential groundwater contaminants.

The specific areas of review are as follows: (1) identification of the aquifers, types of onsite groundwater use, sources of recharge, present withdrawals and known and likely future withdrawals, flow rates, travel time, gradients and other properties that affect the movement of accidental contaminants in groundwater, groundwater-surface elevations beneath the site, seasonal and climatic fluctuations, monitoring and protection requirements, and man-made changes that have the potential to cause long-term changes in local groundwater regime; (2) effects of groundwater-surface elevations and other hydrodynamic effects of groundwater on design bases of plant foundations and those of other SSCs important to safety; (3) reliability of groundwater resources and related systems used to supply safety-related water to the plant; (4) reliability of dewatering systems to maintain groundwater conditions within the plant's design bases; (5) potential effects of seismic and nonseismic information on the postulated worst-case groundwater conditions for the proposed plant site; and, (6) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.12.2 Summary of Application

The North Anna 3 COL FSAR Section 2.4.12, "Groundwater," incorporates by reference ESBWR DCD Tier 2 Chapter 2, "Site Characteristics." This section of the North Anna 3 COL FSAR addresses the groundwater in terms of effects on structures and water supply. All elevations in this SER here and elsewhere are referenced to the NAVD88.

In addition, in North Anna 3 COL FSAR Section 2.4.12, the COL applicant addressed the following COL items:

COL Item:

- COL Item 2.0-12-A — Hydraulic Description Maximum Ground Water Level, per ESBWR DCD Tier 2, Table 2.0-1, 0.61 m (2 ft) below plant grade.

- COL Item 2.0-23-A — Groundwater, COL applicant to supply site-specific information in accordance with SRP 2.4.12.

To address these COL Items, the COL applicant incorporated by reference ESP SSAR Section 2.4.12. The COL applicant provided updated site-specific information to supplement or replace ESP SSAR sections as follows:

- The COL applicant described the local hydrogeology of the site, including the saprolite and bedrock hydrogeologic units, groundwater level measurements, hydraulic gradients, groundwater flow directions, hydraulic conductivity data, porosity data, and groundwater velocity. The COL applicant stated that the saprolite and bedrock are hydrologically connected. The COL applicant estimated a groundwater velocity of 0.11 m/d (0.35 ft/d) and a groundwater travel time to the Lake Anna shoreline of 7.8 yr. from the radwaste building and 6 yr. from the condensate storage tank (CST);

- The COL applicant stated that groundwater from six wells is currently used to supply water for North Anna Units 1 and 2, the North Anna Nuclear Information Center (NANIC), the security training building, and the Meteorology/Environmental Laboratory. The COL applicant provided well capacities and monthly usage data for the wells serving Units 1 and 2, and stated that groundwater will not be used for safety-related purposes for North Anna 3;

- The COL applicant described the groundwater monitoring for the ESP and COL subsurface investigations, and stated that groundwater levels will be monitored monthly during any dewatering activities, quarterly for two years after completion of construction, and semi-annually or annually during operation; and

- The COL applicant described the site characteristics, including the maximum operational groundwater-surface elevation, for groundwater-induced hydrostatic loadings on subsurface portions of safety-related SSCs. The COL applicant developed and applied a groundwater model of the North Anna 3 site and the surrounding area to evaluate post-construction groundwater-surface elevations. The COL applicant stated that the maximum groundwater elevation around seismic Category 1 structures was 86.1 m (282.6 ft), or 2.3 m (7.4 ft) below the North Anna 3 plant grade of 88.39 m (290 ft). The COL applicant stated that, based on the groundwater design bases described in ESBWR DCD Section 3.4 and comparison with the ESBWR DCD site parameter value for maximum groundwater level, a permanent dewatering system is not required.

Early Site Permit Variances

The following variances from the ESP SSAR are discussed in Section 2, “Variances,” of Part 7 to the COLA:

- NAPS ESP VAR 2.0-2 Hydraulic Conductivity

The COL applicant requested VAR 2.0-2 to the ESP SSAR hydraulic conductivity value and used higher maximum and geometric mean values in FSAR Section 2.4.12.1.2.

- NAPS ESP VAR 2.0-3 Hydraulic Gradient

The COL applicant requested VAR 2.0-3 to the ESP SSAR hydraulic gradient value and used a higher value in FSAR Section 2.4.12.1.2.

- NAPS ESP VAR 2.4-1 Void Ratio, Porosity, and Seepage Velocity

The COL applicant requested VAR 2.4-1 to the ESP SSAR values for void ratio, porosity (total and effective), and seepage velocity and estimated lower values for void ratio and porosity, and a higher value for seepage velocity, in FSAR Section 2.4.12.1.2.

- NAPS ESP VAR 2.4-2 NAPS Water Supply Well Information

The COL applicant requested VAR 2.4-2 to use revised information for the water supply well information and provided FSAR Table 2.4-17R to correct certain information in the ESP SSAR Table 2.4-17.

- NAPS ESP VAR 2.4-3 Well Reference Point Elevation

The COL applicant requested VAR 2.4-3 to use revised information for the reference point elevation of observation well WP-3 and provided FSAR Table 2.4-15R to correct groundwater level information for this well originally appearing in ESP SSAR Table 2.4-15.

2.4.12.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835 the FSER related to the North Anna ESP. In addition, the guidance relevant to the Commission's regulations related to ground water considerations, and the associated acceptance criteria, are contained in Section 2.4.12 of NUREG-0800 SRP.

The acceptance criteria for the North Anna 3 ground water consideration requirements presented in the North Anna 3 COL FSAR, beyond that presented in the ESP SSAR (i.e., NAPS COL Item NAPS COL 2.0-12-A, 2.0-23-A, NAPS ESP VAR 2.0-2, 2.0-3, 2.4-1, 2.4-2, and 2.4-3), are based on meeting the following relevant requirements of 10 CFR) Part 52 and 10 CFR Part 100:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d) sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves the site.

The related acceptance criteria from SRP Section 2.4.12 are as follows:

- Local and Regional Groundwater Characteristics and Use: To meet the requirements of 10 CFR 50.55a, “Codes and Standards,” 10 CFR 100.20(c)(3), 10 CFR 100.23(d), and 10 CFR 100.20(c), a complete description of regional and local groundwater aquifers, sources, and sinks, local and regional groundwater use, present and known and likely future withdrawals, regional flow rates, travel time, gradients, and velocities, subsurface properties that affect movement of contaminants in the groundwater, groundwater levels including their seasonal and climatic fluctuations, groundwater monitoring and protection requirements, and any manmade changes with a potential to affect regional groundwater characteristics over a long period of time is needed.

- Effects on Plant Foundations and other Safety-Related SSCs: To meet the requirements of 10 CFR 50.55a, 100.20(c)(3), 100.23(d), and 100.20(c), a complete description of the effects of groundwater levels and other hydrodynamic effects on the design bases of plant foundations and other SSC important to safety is needed.

- Reliability of Groundwater Resources and Systems Used for Safety-Related Purposes: To meet the requirements of 10 CFR 50.55a, 100.20(c)(3), 100.23(d), and 100.20(c), a complete description of all SSC important to safety that depend on groundwater is needed.

- Reliability of Dewatering Systems: To meet the requirements of 10 CFR 50.55a, 100.20(c)(3), 100.23(d), and 100.20(c), a complete description of the site dewatering system, including its reliability to maintain the groundwater conditions within the groundwater design bases of SSC important to safety is needed.

2.4.12.4 Technical Evaluation

As documented in Section 2.4.12 of NUREG-1966 and Section 2.4.12 of NUREG-1835, the staff reviewed and approved information related to groundwater for the certified ESBWR DCD, Revision 10, and Section 2.4.12 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.12 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic.

The staff’s review confirms that the information in the application and the information incorporated by reference address the required information related to “Groundwater.”

The staff’s technical review of this application was limited to reviewing the supplemental information pertaining to COL Items 2.0-12-A and 2.0-23-A and to variances NAPS ESP VAR 2.0-2, NAPS ESP VAR 2.0-3, NAPS ESP VAR 2.4-1, NAPS ESP VAR 2.4-2, and NAPS ESP VAR 2.4-3 as addressed below.

The staff’s discussion of groundwater characteristics is organized into technical areas as described below. Variances are described where appropriate within these areas.

General Hydrogeological Characteristics of the Site

Information Submitted by COL Applicant:

The COL applicant's description of the regional hydrogeology and groundwater conditions was described in ESP SSAR Section 2.4.12 and is incorporated by reference into the North Anna 3 COL FSAR with no supplements or variances.

The COL applicant's description of the site hydrogeology and groundwater conditions was supplemented based on the results of a North Anna 3 subsurface field investigation conducted from August to November of 2006 and two supplemental investigations conducted from September to October of 2009, as described in North Anna 3 COL FSAR Section 2.5.4.2.3. This investigation included 93 exploratory borings and the installation of seven observation wells.

The North Anna 3 COL FSAR used the same classification of subsurface materials as in the ESP SSAR. The COL applicant classified subsurface materials as crystalline parent bedrock, weathered rock, saprolite of 10 to 50 percent core stone, saprolite of less than 10 percent core stone, residual soil, and fill. The COL applicant stated that the borings described in the ESP SSAR and the North Anna 3 COL FSAR penetrated saprolite with a maximum thickness of 34.7 m (114 ft) and a median thickness of 11.3 m (37 ft). The COL applicant stated that groundwater at the site occurs in the saprolite and in the fractures of the bedrock. Of the seven wells installed as part of the North Anna 3 subsurface field investigation, the COL applicant stated that four were completed in rock and three were completed in soil/weathered rock. The COL applicant stated that the bedrock and saprolite are hydraulically connected, that groundwater heads observed in well pairs completed at different elevations were nearly equal, that the water table at the site reflects the ground surface topography, and that the groundwater flow at the site is toward areas of lower ground surface elevation.

The Staff's Technical Evaluation:

The staff reviewed the supplemental information provided in the North Anna 3 COL FSAR regarding site hydrogeology and groundwater conditions. The staff determined that the methods used were appropriate, and that the supplemental information was consistent with the overall picture of site conditions presented in the ESP SSAR.

The staff evaluated the site groundwater head measurements provided in North Anna 3 COL FSAR Table 2.4-15R and illustrated in North Anna 3 COL FSAR Figure 2.4-205 and North Anna 3 COL FSAR Figures 2.4-207 through 2.4-214. The staff determined that the data obtained in 2006 and 2007 were consistent with earlier measurements. Groundwater flow direction from the North Anna 3 reactor area is generally to the northeast toward Lake Anna. Three of the wells installed as part of the North Anna 3 subsurface field investigation were located adjacent to and deeper than existing wells, providing a total of four well pairs that the staff used to evaluate vertical groundwater head gradients at the site. The staff determined that vertical groundwater head gradients were small and upward for three of the well pairs, but were higher and downward for the well pair located near the North Anna 3 intake (observation wells OW-848 and OW-950). Based on the observed vertical gradients in the well pairs, the staff concluded that the shallow bedrock and saprolite units are hydraulically connected, with vertical gradients between the units generally small, but significant at some locations.

Plant Groundwater Use

Information Submitted by COL Applicant:

The COL applicant stated that any groundwater required will not be used for safety-related functions at North Anna 3 (North Anna 3 COL FSAR Section 2.4.12.1.3, “Plant Groundwater Use”).

The Staff’s Technical Evaluation:

The staff determined that the groundwater supply’s lack of safety function is consistent with the uses stated for groundwater and with provisions for safety-related water supply from other sources, as described in the North Anna 3 COL FSAR.

Hydraulic Conductivity (NAPS ESP VAR 2.0-2)

Information Submitted by COL Applicant:

The COL applicant conducted slug tests in four of the seven wells installed as part of the North Anna 3 subsurface field investigation (three soil/weathered rock wells and one bedrock well) to supplement the existing data used to estimate hydraulic conductivities in the saprolite and the shallow bedrock. The COL applicant conducted packer tests in a borehole adjacent to one of the bedrock wells to estimate the hydraulic conductivity of the shallow bedrock. Using these supplemental data, the COL applicant estimated hydraulic conductivity for the saprolite of 0.076 to 3.017 m/d (0.25 to 9.9 ft/d) with a geometric mean of 0.53 m/d (1.74 ft/d) (as compared to a range of 0.06 to 1.04 m/d and a geometric mean of 0.40 m/d from the ESP SSAR). The COL applicant estimated hydraulic conductivity for the shallow bedrock of 0.152 to 1.920 m/d (0.5 to 6.3 ft/d) with a geometric mean of 0.625 m/d (2.05 ft/d) (compared to a range of 0.61 to 0.91 m/d from the ESP SSAR).

The maximum hydraulic conductivity of 3.0 m/d in North Anna 3 COL FSAR Section 2.4.12.1.2 is higher than the hydraulic conductivity site characteristic in Appendix A of the North Anna ESP. The ESP site characteristic hydraulic conductivity of 1.0 m/d was based on the data obtained during the ESP subsurface field investigation. The additional hydraulic conductivity data obtained during the North Anna 3 field investigation resulted in a higher estimate of the maximum hydraulic conductivity.

In the COL Application Departures Report, the COL applicant identified the hydraulic conductivity variance (NAPS ESP VAR 2.0-2) and requested to use the North Anna 3 COL FSAR value of 3.0 m/d instead of the 1.04 m/d value in the ESP SSAR. The COL applicant provided the following two justifications for the request:

1) The COL applicant used a hydraulic conductivity value of 3.0 m/d in the groundwater transport analysis of North Anna 3 COL FSAR Section 2.4.13 and demonstrated compliance with the requirements of 10 CFR Part 20. The COL applicant stated that the radionuclide concentrations and associated doses calculated in North Anna 3 COL FSAR 2.4.13 are conservative because the hydraulic conductivity 3.0 m/d is the maximum observed at the North Anna 3 site; and

2) The groundwater flow model used in COL FSAR Section 2.4.12 to evaluate the maximum post-construction groundwater-surface elevation incorporated the data from the North Anna 3 subsurface field investigation, and the resulting maximum

groundwater-surface elevation satisfied the ESBWR DCD site characteristic on maximum groundwater level.

The Staff's Technical Evaluation:

The staff reviewed the supplemental slug test and packer test data in North Anna 3 COL FSAR Appendix 2.5.4AA and the resulting saturated hydraulic conductivities in North Anna 3 COL FSAR Table 2.4-16R. The staff determined that the methods used were appropriate and that the estimated conductivities were consistent with the previous estimates in the ESP SSAR. The supplemental data expanded the range of observed saturated hydraulic conductivity for both the saprolite and shallow bedrock, resulting in higher maximum hydraulic conductivity estimates than were provided in the ESP SSAR: 3.0 m/d for the saprolite and 1.9 m/d for the shallow bedrock. Because a saturated hydraulic conductivity value of 3.0 m/d is based on site-specific observations and is conservative, the staff concludes that this value is an appropriate site characteristic and accepts NAPS ESP VAR 2.0-2.

Hydraulic Gradient (NAPS ESP VAR 2.0-3)

Information Submitted by COL Applicant:

The maximum hydraulic gradient of 0.05 provided in FSAR Section 2.4.12.1.2 is higher than the hydraulic gradient site characteristic provided in Appendix A of the North Anna ESP. The ESP hydraulic gradient of 0.03 was based on the groundwater head measurements obtained during the ESP subsurface field investigation. The additional groundwater head measurements obtained during the North Anna 3 field investigation resulted in higher estimates of the maximum groundwater hydraulic gradient.

In the COL Application Departures Report, the COL applicant identified the hydraulic gradient variance (NAPS ESP VAR 2.0-3) and requested to use the North Anna 3 COL FSAR value of 0.05 instead of the value of 0.03 in the ESP SSAR. The COL applicant justified the use of the higher hydraulic gradient by demonstrating compliance with the 10 CFR Part 20, Appendix B, Table 2 concentration limits using the North Anna 3 COL FSAR hydraulic gradient value of 0.05 in the groundwater transport analysis of North Anna 3 COL FSAR Section 2.4.13.

The Staff's Technical Evaluation:

The staff evaluated horizontal groundwater head gradients at the North Anna 3 site using the groundwater head measurements provided in North Anna 3 COL FSAR Table 2.4-15R. The COL applicant used the maximum head at observation well OW-901 and the minimum head at well OW-950 to estimate the horizontal groundwater gradient between the RB and Lake Anna. Based on the observed heads, the staff concluded that although the local gradient at the RB is likely to be higher, 0.05 is a conservative estimate of the average gradient between the RB and Lake Anna. This value is conservative because the actual groundwater flow path would be longer than the straight-line distance between wells OW-901 and OW-950 used to compute the gradient. Because a groundwater hydraulic gradient of 0.05 is based on site-specific observations and is conservative, the staff concluded that this value was an appropriate site characteristic and accepts NAPS ESP VAR 2.0-3.

Void Ratio, Porosity, and Seepage Velocity (NAPS ESP VAR 2.4-1)

Information Submitted by COL Applicant:

The COL applicant used samples from the North Anna 3 field investigation boreholes to supplement the moisture content and specific gravity data used to estimate the void ratio and porosity. Based on laboratory tests of saprolite samples, the COL applicant determined that the median moisture content was 17 percent and the median specific gravity was 2.65. Using these values, the COL applicant estimated a void ratio of 0.45 with a resulting total porosity of 0.31. (The ESP SSAR estimated values of 26 percent for the average moisture content and 2.68 for the specific gravity, resulting in estimates of 0.7 for the void ratio and 0.41 for the porosity.) The COL applicant assumed the effective porosity was 80 percent of the total porosity, or 0.25. (This assumption was also made in determining the ESP SSAR effective porosity of 0.33.)

The COL applicant used the geometric mean saprolite hydraulic conductivity (0.53 m/d), the site characteristic hydraulic gradient of 0.05, and the effective porosity (0.25) to compute a groundwater seepage velocity of 0.11 m/d (0.35 ft/d) (compared to the ESP SSAR groundwater velocity of 0.037 m/d). Based on this velocity and a travel distance of 304.8 m between the radwaste building and Lake Anna, the COL applicant estimated a groundwater travel time of 7.8 yr. (as compared to the travel time of 40 yr. in the ESP SSAR for a distance of 549 m). Using a distance of 234.7 m (770 ft) from CST to Lake Anna, the COL applicant estimated a groundwater travel time of 6 yr.

In the COL Application Departures Report, the COL applicant identified the void ratio, porosity, and seepage velocity variance (NAPS ESP VAR 2.4-1) and requested to use the North Anna 3 COL FSAR values instead of the values in the ESP SSAR. The COL applicant justified the use of the North Anna 3 COL FSAR values by demonstrating compliance with the 10 CFR Part 20, Appendix B, Table 2 concentration limits in the groundwater transport analysis of North Anna 3 COL FSAR Section 2.4.13.

The Staff's Technical Evaluation:

The staff reviewed the data on gravimetric water content described in North Anna 3 COL FSAR Section 2.5.4 and the COL applicant's computation of porosity. While using conservative values (i.e., maximum observed) for the site characteristic hydraulic gradient and saturated hydraulic conductivity, the applicant used an average value for the site characteristic porosity. The staff reviewed the gravimetric water content data in Table 3.1 of North Anna 3 COL FSAR Appendix 2.5.4AA. Using a specific gravity of 2.65 as in North Anna 3 COL FSAR Section 2.4.12, the staff calculated average and minimum porosities for samples with less than 10 percent gravel and for samples with more than 10 percent gravel. Results are in Table 2.4.12-1 (compared to the applicant's total porosity estimate of 0.31, as presented in North Anna 3 COL FSAR Section 2.4.12.1.2). The staff determined that the large number of samples provides confidence in the median porosity value used by the COL applicant, and that the samples with lower average porosity (i.e., those with gravel greater than 10 percent) were few in number, not contiguous, and therefore unlikely to be evidence of a low porosity and high velocity pathway. Therefore the staff concluded that a total porosity estimate of 0.31 is appropriate for the groundwater transport analysis at the North Anna 3 site.

Table 2.4.12-1 Average and minimum porosity for soil samples with percentage of gravel greater than and less than 10 percent

	Gravel < 10%	Gravel > 10%
Number of Samples	102	7
Average Porosity	0.328	0.244
Minimum Porosity	0.129	0.053

The staff reviewed the computation of groundwater velocity using the COL applicant's site characteristic values of hydraulic gradient and effective porosity and the geometric mean saturated hydraulic conductivity for saprolite. The staff confirmed the COL applicant's groundwater velocity of 0.11 m/d provided in North Anna 3 COL FSAR Section 2.4.12.1.2. The staff also computed a more conservative groundwater velocity of 0.6 m/d using the COL applicant's maximum observed hydraulic conductivity (3.0 m/d). The staff determined that the higher groundwater velocity (3.0 m/d) was used by the COL applicant in the groundwater transport analysis of North Anna 3 COL FSAR Section 2.4.13. Although the staff determined that the available data do not provide evidence for a high permeability pathway between either the RW or the CST and Lake Anna, the staff concluded that the COL applicant's use of the maximum observed hydraulic conductivity in the transport analysis provided conservative estimates of accidental release concentrations and doses. Therefore, the staff accepts NAPS ESP VAR 2.4-1.

NAPS Water Supply Well Information (NAPS ESP VAR 2.4-2)

Information Submitted by COL Applicant:

Corrected and supplemental information was provided on the location and pumping rates for existing onsite groundwater supply wells in North Anna 3 COL FSAR Tables 2.4-17R and 2.4-205. The applicant stated that any groundwater used for North Anna 3 will not be safety-related. In the COL Application Departures Report, the applicant identified a variance in the plant water supply well information (NAPS ESP VAR 2.4-2). The variance arose from the use of incorrect information in the ESP SSAR and new information obtained on plant water supply wells. The COL applicant justified the North Anna 3 COL FSAR water supply well information (see North Anna 3 COL FSAR Table 2.4-17R) because it better reflected current plant water supply well conditions, and because it supported the ESP SSAR conclusion that future groundwater withdrawals will likely be from the existing wells or from new wells drilled onsite, and any future additional groundwater use is not expected to impact offsite wells.

The Staff's Technical Evaluation:

The staff reviewed the corrected information provided in the North Anna 3 COL FSAR describing the existing groundwater supply wells and groundwater use and accepted NAPS ESP VAR 2.4-2. The staff also evaluated the potential for a groundwater transport pathway to the well located at the NANIC, which supplies potable water. The staff reviewed the maps of groundwater head and the information provided on the NANIC well construction and operation. The staff determined that the NANIC well is located approximately 0.9 kilometers (0.4 miles) up gradient of the radionuclide source used in the North Anna 3 COL FSAR Section 2.4.13 accidental release analysis, the groundwater head at the NANIC well is approximately 12.2 m (40 ft) higher than at the source location, the NANIC well is finished in bedrock at a depth of 79.2 m (260 ft) (much deeper than the source), and the current groundwater hydraulic heads reflect pumping from the well so future changes in hydraulic gradients are not expected. Therefore, the staff concluded that an accidental release pathway to the NANIC water supply well is implausible.

Well Reference Point Elevation (NAPS ESP VAR 2.4-3)

Information Submitted by COL Applicant:

Supplemental information was provided in the North Anna 3 COL FSAR on the groundwater monitoring programs required during and following plant construction. The COL applicant stated that seven new observation wells were installed during subsurface investigations for North Anna 3, and that these have been monitored in addition to continued monitoring of wells installed previously. The COL applicant stated that some observation wells may need to be closed prior to site earthwork activities and that an evaluation will be conducted to determine whether new wells will be required to provide adequate evaluation of construction impacts on site groundwater levels. Regarding the frequency of monitoring, the COL applicant stated that groundwater levels will be measured monthly during any construction-related dewatering, quarterly for two years following the completion of construction, and semi-annually or annually during plant operations. In the COL Application Departure Report, the applicant identified a variance in the reference point elevation for observation well WP-3 (NAPS ESP VAR 2.4-3). The variance arose from using an un-surveyed vertical coordinate originating from a label attached to the well casing as the basis for the well reference elevation in the ESP SSAR. The COL applicant completed a field survey in 2009 to provide a corrected well reference elevation. The COL applicant justified the North Anna 3 COL FSAR well reference elevation because it was a corrected value and did not materially change the estimates of groundwater flow, post-construction groundwater head, or the analysis of accidental release of liquid effluents to groundwater. The COL applicant provided the corrected well reference elevation and corrected groundwater level measurements in North Anna 3 COL FSAR Table 2.4-15R and updated the groundwater head contour maps in North Anna 3 COL FSAR Figures 2.4-207 to 2.4-214.

The Staff's Technical Evaluation:

The staff reviewed the supplemental information provided in the North Anna 3 COL FSAR regarding groundwater monitoring programs. The staff recognizes that groundwater monitoring would be an ongoing activity, and that existing monitoring wells may need to be abandoned and new wells installed because of changing site access conditions during construction. The staff agrees that further evaluation and the possible installation of new wells will be necessary to assure that groundwater-surface levels will be adequately monitored as site conditions change. The staff determined that the frequency of monitoring proposed by the COL applicant was reasonable for monitoring the effects of construction on, and natural variation of, groundwater-surface levels.

The staff reviewed the groundwater head observations and associated contour maps based on the corrected well reference elevation for observation well WP-3 and verified that the corrected data was used by the COL applicant in the groundwater flow modeling carried out to support the post-construction estimate of maximum groundwater head.

Design Bases for Subsurface Hydrostatic Loading

Information Submitted by COL Applicant:

The design plant grade elevation is specified in the North Anna 3 COL FSAR as 88.39 m (290 ft) NAVD88. The COL applicant stated that construction of North Anna 3 will require cut and fill on the site, which will modify the existing groundwater elevations in the power block area. The ESBWR DCD site parameter for the maximum groundwater level is 0.61 m (2 ft) below plant grade (North Anna 3 COL FSAR Table 2.0-201), which corresponds to a maximum groundwater-surface elevation of 87.78 m (288 ft) NAVD88 at the North Anna 3 site. ESBWR DCD Table 2.0-1 (Note 1) indicates that the maximum groundwater level site parameter applies at seismic Category I, II, and Radwaste Building structures. The COL applicant developed and applied a groundwater flow model of the North Anna 3 site to evaluate post-construction groundwater-surface levels. The COL applicant revised the groundwater flow model in response to RAI 02.04.12-1 dated August 08, 2008 (ADAMS Accession No. ML082210547), and RAI 02.04.12-2 dated March 25, 2009 (ADAMS Accession No. ML090840271). In Enclosure 7 of a letter dated December 18, 2013 (ADAMS Accession No. ML14013A113), the COL applicant provided a response to these RAIs that superseded all prior responses. Enclosure 7 of the COL applicant's letter documented the development and application of a groundwater model of the NAPS site. The COL applicant used results from this model as the basis for the discussion of site characteristics for subsurface hydrostatic loading and dewatering in North Anna 3 COL FSAR, Section 2.4.12.4. The COL applicant provided the groundwater model input and output files in a letter dated August 19, 2014 (ML14238A018).

Based on the results of the groundwater modeling, the COL applicant concluded that the maximum post-construction groundwater-surface elevation in the power block area ranges from 82.30 to 86.56 m (270 to 284 ft) NAVD88 with a maximum of 86.14 m (282.6 ft) NAVD88 at Seismic Category 1 structures. Because the maximum groundwater elevation is less than the DCD site parameter value of 0.61 m (2 ft) below plant grade (87.78 m or 288 ft NAVD88), the COL applicant concluded that a permanent dewatering system is not needed for safe operation of North Anna 3.

The maximum post-construction groundwater elevation provided in North Anna 3 COL FSAR Section 2.4.12.4 is higher than the Maximum Elevation of Groundwater site characteristic provided in Appendix A of the North Anna ESP. In the response to RAI 02.04.12-3 dated October 23, 2012 (ADAMS Accession No. ML12307A196), the COL applicant stated that the ESP site characteristic was relative to the site grade. The ESP maximum groundwater elevation of 82.03 m (269.14 ft) NAVD88 was based on a proposed site grade of 82.34 m (270.14 ft) NAVD88 and a prior estimate of maximum groundwater elevation for the existing units. Because the North Anna 3 COL FSAR design plant grade is higher than the ESP proposed site grade, the North Anna 3 COL FSAR maximum groundwater elevation is also higher than the ESP value, but still less than the ESBWR DCD site parameter for maximum groundwater level.

The Staff's Technical Evaluation:

In RAI 02.04.12-1 the staff requested: (1) a description of the technical basis for the assumptions, parameter values, and boundary conditions used by the COL applicant in the groundwater flow model; (2) a discussion of the discrepancy between the observed and model-simulated groundwater heads at the location of the North Anna 3 RB; and, (3) the technical basis for confidence in model predictions of post-construction groundwater heads. The COL applicant's response to RAI 02.04.12-1 dated December 18, 2013 (ADAMS Accession No. ML14013A113), contained the technical basis for the assumptions, parameter values, and boundary conditions of the groundwater flow model. The COL applicant developed a steady-state, two-layer model, with the upper layer representing the saprolite and the lower layer representing the shallow bedrock. The upper layer reflected the ground-surface topography. The COL applicant based the elevation of the contact between the layers on data from the ESP and COL site investigations geotechnical borings. The COL applicant placed the lower, no-flow boundary at a depth of 38.10 m (125 ft) below the ground surface, reflecting the conceptual model in which the occurrence of water-bearing fractures decreases with depth. The COL applicant placed lateral and internal boundaries to represent the locations of drainages, ponds, and Lake Anna, including the WHTF. The COL applicant treated intermittent streams as drain boundaries and Lake Anna and the WHTF as constant head boundaries. The COL applicant assumed recharge was zero at the location of buildings and paved surfaces, relatively large at the Units 1 and 2 SW reservoir, and uniform over the remainder of the model domain (this latter assumption was tested by the COL applicant via simulation). The COL applicant used two saturated hydraulic conductivity zones defined by differences in the observed values of conductivity from slug tests and by the location of a fault identified in ESP SSAR, Figure 2.5-18. The COL applicant assumed hydraulic conductivities were the same in the two model layers and were isotropic everywhere. These assumptions were tested by the applicant via simulation. The staff reviewed the model assumptions and boundary conditions and concluded that they were appropriate and consistent with the site data and conceptual model presented by the COL applicant.

The COL applicant adjusted the recharge and saturated hydraulic conductivity to fit groundwater heads observed during May 2007. The COL applicant's calibrated recharge values were 28 cm/yr. (11.0 in/yr) over the majority of the domain and 37 cm/yr. (14.5 in/yr) over the SW reservoir. Calibrated hydraulic conductivity values were 0.35 m/d (1.14 ft/d) in the northern zone and 0.13 m/d (0.43 ft/d) in the southern zone. The COL applicant stated that all calibration criteria were met. In RAI 02.04.12-1, the staff noted that the observed head at well OW-901, located at the position of the North Anna 3 RB, was about 4 ft higher than the model simulation. This concerned the staff because of the potential for errors of similar magnitude in the post-construction maximum groundwater head in the reactor area estimated from the model. In response to RAI 02.04.12-1 (ADAMS Accession No. ML14013A113), the COL applicant stated that the model was unable to reproduce the steep gradient in groundwater head observed in the power block area, and that the model calibration therefore underestimated the highest heads and overestimated the lowest heads observed in the power block wells. The COL applicant also completed an alternative calibration in which the general recharge rate was increased to 32.3 cm/yr. (12.7 in/yr) in order to fit the observed head at OW-901. However, the COL applicant stated that the increased recharge resulted in unacceptable errors in the simulated groundwater levels at other wells.

The COL applicant conducted predictive simulations of post-construction groundwater heads using the calibrated model described above. In these simulations, the COL applicant modified the ground surface topography of the model to reflect the final site grading, made model cells inactive where deep building foundations will occur, and increased the constant head boundary conditions for Lake Anna and the WHTF to reflect an 8 cm (3 in) increase in the normal operating lake level. In addition, the COL applicant used a backfill zone with a hydraulic conductivity of 0.86 m/d (2.83 ft/d) in the area around the power block, applied a recharge rate of zero where buildings and paved areas will be located, and included model drain cells to represent the surface drainage ditches planned for controlling surface runoff around the power block and the cooling tower. The COL applicant assumed the May 2007 groundwater observations were close to historic maximum levels and presented data on precipitation and regional water conditions to support this assumption. The COL applicant completed a base case simulation with the model and presented results for this analysis in North Anna 3 COL FSAR Figure 2.4-216. The COL applicant compared the model-simulated heads at a set of 16 points around the power block buildings to the ESBWR DCD maximum groundwater elevation. The maximum groundwater head of 86.53 m (283.9 ft) NAVD88 occurred at the Ancillary Diesel Building and was 1.86 m (6.1 ft) below the design plant grade.

Input files for all the simulations described in the groundwater modeling report were used in the staff's review and confirmatory simulations. The staff concluded that the groundwater model developed by the COL applicant appropriately represented the site characterization data and the conceptual understanding of site groundwater flow. However, the staff was concerned with errors in the model's representation of observed groundwater heads in the power block area and the potential that these errors could be carried through to the model predictions of post-construction groundwater conditions.

The 88.39 m (290 ft) NAVD88 grade for the North Anna 3 power block will be created by excavating the existing soil and rock materials at the site. A significant cut-slope will be created on the southwest and southeast sides of the power block area, as shown on North Anna 3 COL FSAR Figure 2.4-201. As a result of groundwater flow from the upland areas towards the lake, the groundwater heads will be higher than plant grade above the cut-slope. Surface drainage ditches around the power block will be depended upon to also drain groundwater, increasing the groundwater head gradients around the power block and lowering the groundwater heads throughout the power block area. This effect can be seen in the model simulation results of North Anna 3 COL FSAR Figure 2.4-216, where the drainage ditches are shown in yellow.

Based on a set of confirmatory simulations, the staff determined that the groundwater elevations predicted by the COL applicant's groundwater model were strongly dependent on the characteristics of the model drain cells that represent the site surface water drainage system surrounding the power block. For the groundwater model used by the COL applicant, groundwater discharge to a model drain cell is proportional to the conductance parameter, the value of which is unknown, but is related to the effective hydraulic conductivity over the drainage pathway, the geometry of the drain, and the dimensions of the model grid cell. The COL applicant assigned a drain conductance value of 2.32 m^2/day (25 ft^2/day) based on a hydraulic conductivity of 0.35 m/day (1.14 ft/day). The hydraulic conductivity of the model cells within which the drains are located is about one-third of this value along eastern portions of the drainage ditches. Based on this observation, and on geometric considerations, the staff concluded that values of drain conductance less than 2.32 m^2/day (25 ft^2/d) were plausible. The staff requested additional information to resolve this issue in RAI 02.04.12-2.

In response to RAI 02.04.12-2 dated December 18, 2013 (ADAMS Accession No. ML14013A113), the COL applicant provided results of model simulations to evaluate the effect of the drain cell conductance on the groundwater heads in the power block area. In particular, the COL applicant evaluated groundwater heads in the power block area using a smaller drain conductance value of 0.23 m^2/day (2.5 ft^2/d) and reported that this increased the maximum groundwater head to 87.66 m (287.6 ft) NAVD88. Using groundwater model input files provided by the COL applicant, the staff evaluated groundwater heads in the power block area using a drain conductance value of 0.093 m^2/day (1.0 ft^2/d) and found that the simulated maximum groundwater head could exceed 87.78 m (288 ft) at this low conductance value. In RAI 02.04.12-4 dated November 21, 2014 (ADAMS Accession No. ML14325A831), the staff requested documentation in the North Anna 3 COL FSAR of the drainage ditch design, construction methods, and materials, and the function of the drainage ditches in maintaining groundwater levels. In the response to RAI 02.04.12-4 dated January 08, 2015 (ADAMS Accession No. ML15009A237), the COL applicant provided proposed updated North Anna 3 COL FSAR text in the North Anna 3 COL FSAR, Revision 9, and the staff confirmed its inclusion. Based on the description of the ditches provided by the COL applicant the staff determined that drainage ditch materials and construction would not impede the discharge of groundwater into the ditches. Therefore, the staff concluded that drain conductance values of 0.23 m^2/day (2.5 ft^2/d) and lower are unlikely and that a drain conductance value of 2.32 m^2/day (25 ft^2/day) is appropriate and conservative. The staff verified that the appropriate revisions are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.4.12-1 from the staff's advanced SER for North Anna 3 is resolved and closed.

Evaluation of the maximum groundwater elevation using the groundwater model depends on the ability of the model to accurately represent the groundwater system. Examination of the simulation results showed that the model predicted flooding (i.e., steady-state groundwater heads above the surface elevations) at a number of locations across the site, for both the pre-construction and post-construction models. The staff used groundwater head observations to evaluate whether the predicted flooding indicated a model bias.

The COL applicant used groundwater head observations from May 30, 2007 to develop and evaluate the pre-construction groundwater model. The staff plotted these observations as a function of the ground surface elevation at the observation well locations, as shown in Figure 2.4.122-1[3]. As described above, the observations from well pairs at different depths indicated that generally minor vertical gradients exist at the site. The groundwater heads in this shallow unconfined system were therefore interpreted as water table elevations. The staff determined that observed groundwater levels were related to ground surface topography; the envelope of maximum observed groundwater levels was well-represented as a linear function of the ground surface elevation (with a slope of 0.75), as shown in Figure 2.4.12-1. Based on this relationship, maximum observed groundwater levels were close to ground surface at lower elevations (e.g., at the Lake Anna elevation of 76.20 m [250 ft] NAVD88), and progressively deeper as the ground surface elevation increased (e.g., maximum groundwater level was 6.10 m [20 ft] deep at a ground surface elevation of 100.58 m [330 ft] NAVD88).

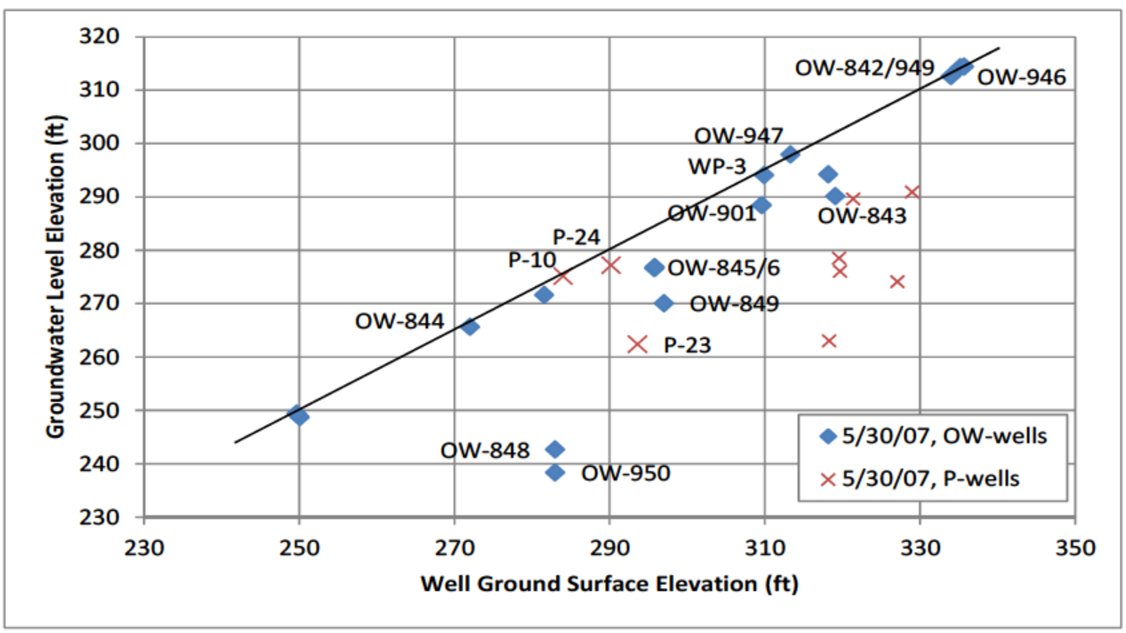

Figure 2.4.122-1. NAPS Unit 3 groundwater head observations on 5/30/2007 as a function of ground surface elevation at the well

[3] For most of the P-series wells surrounding the Units 1 and 2 UHS impoundment, the well stick-up was not specified; these head observations are plotted against the well reference point elevations.

While no observations fall significantly above the envelope line in Figure 2.4.12-1, a number of observations fall significantly below the line. The staff examined the current site topography, as shown on FSAR Figure 2.4-206, and determined that the wells with observations below the line in Figure 2.4.12-1 tended to be located above and near a significant topographic slope. For example, OW-848 and OW-950 are on the bluff above the proposed North Anna 3 intake bay, and OW-849 and OW-843 are above the cut-slope for the switch yard. In contrast, the observations that lie close to the line in Figure 2.4.12-1 tended to be in areas of relatively flat topography, or near the bottom of topographic slopes. For example, OW-844 lies just below the cut-slope down to the Unit 1/2 operations level.

The COL applicant's pre-construction model, calibrated using the May 30, 2007 groundwater observations, resulted in groundwater heads at several observation wells that were above the envelope line shown in Figure 2.4.12-1. The greatest deviations were at wells OW-945, a relatively low-lying area where the model produced flooded conditions, and OW-844, located at the bottom of a cut-slope. The deviation at OW-844 was about 1.22 m (4 ft). Based on the observations shown in Figure 2.4.12-1, the staff concluded that groundwater head measured in a well located at a surface elevation of 88.39 m (290 ft) (the North Anna 3 design plant grade) would be unlikely to exceed 85.34 m (280 ft). The COL applicant's post-construction model predicted heads about 1.22 m (4 ft) greater than this in the power block area: 86.53 m (283.9 ft) at the Ancillary Diesel Building, located near the cut-slope down to the power block. The staff concluded that the COL applicant's groundwater model will tend to over-estimate groundwater heads below a cut-slope such as that planned around the North Anna 3 power block area.

Conclusions about the maximum groundwater heads at the North Anna 3 site that are based on the observed groundwater heads on May 30, 2007, assume that these observations represent maximum historical values. The staff evaluated this assumption by examining the historical record of water level in a USGS well in Louisa County, approximately 11.5 mi from the North Anna 3 site and completed in the fractured rock aquifer[4]. The staff determined that water levels in this USGS well, interpolated to the North Anna 3 observation well sampling dates, were correlated with North Anna 3 well OW-842 observed water levels (correlation coefficient of 0.85). Water levels for the two wells, shown in Figure 2.4.122-2, indicate that the North Anna 3 sampling times may not have coincided with the maximum groundwater levels at the North Anna 3 site. The maximum groundwater level in the USGS well occurred in April 2010. Given the correlation between the water levels in the two wells, the staff determined that the maximum groundwater elevation in well OW-842 may be several feet higher than the elevation observed on May 30, 2007. This implies that the upper end of the envelope line in Figure 2.4.12-1, would increase several feet; the increase at a ground surface elevation of 88.39 m (290 ft) would be less.

Given the staff's independent evaluation of the available data and the staff's confirmatory analysis of the COL applicant's model results, the staff determined that the COL applicant's groundwater model provided conservative estimates of post-construction maximum groundwater elevation in the power block area. Because the model predicted a maximum head in the power block that is well below the DCD requirement, the staff concluded that the applicant's maximum groundwater elevation site characteristic of 86.53 m (283.9 ft) NAVD88 is conservative and acceptable. Accordingly, the staff considers RAI 02.04.12-1 and RAI 02.04.12-2 resolved and closed.

---

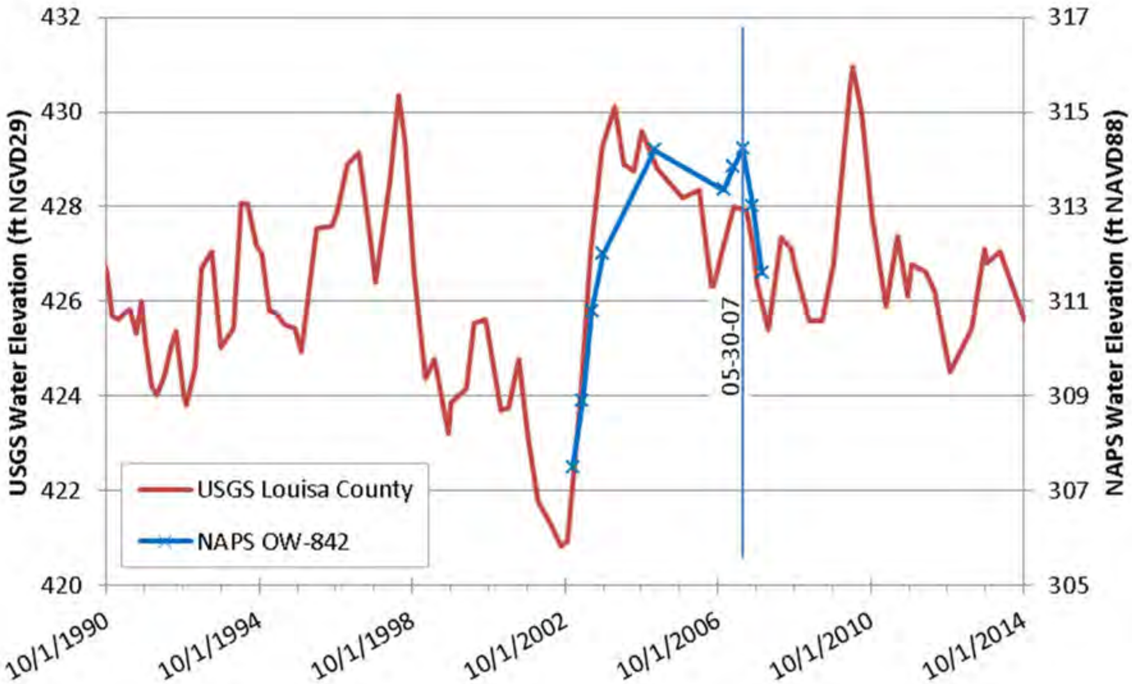

Figure 2.4.122-2. Water levels for the USGS Louisa County well and NAPS Unit 3 well OW-842

Regarding seismic effects, SRP Section 2.4.12 states that seismic criteria should be evaluated to determine whether they should be used in postulating worst-case groundwater effects at a site. In North Anna 3 COL FSAR Section 2.5, the applicant submitted information on seismic risks and the potential effects of earthquakes on structures and foundations. Also in Section 2.5, the applicant discussed groundwater conditions in relation to construction and foundation stability (see Section 2.5.4.6).

While the applicant did not submit specific information on potential effects of seismic events on worst-case groundwater conditions, the staff reviewed available literature on seismic effects on groundwater-surface elevations (e.g., Montgomery and Manga 2003; Wang and Manga 2010; Roeloffs 1996; Bredehoeft 1967) and considered North Anna 3 site-specific conditions. Groundwater in the power block area is unconfined, transmissive depth is from 30 to 100 m (98 to 328 ft) below ground surface, with an estimated effective porosity of 0.25. The staff considered the design earthquakes given in North Anna 3 COL FSAR Table 2.5.2-218, "Mean Magnitude and Distance for LF and HF Response Spectra for Three MAFEs," and used the idealized unconfined aquifer analysis of Bredehoeft (1967) to estimate a maximum increase in groundwater-surface elevation of 0.30 m (1 ft). Given the margin in the maximum groundwater elevation estimated by the COL applicant using the groundwater model discussed above, the staff concluded that no plausible scenarios present conditions in which seismic events could have significant effects on groundwater-surface elevations at this site.

2.4.12.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.12.6 Conclusion

The staff reviewed the application and confirms that the COL applicant addressed the required information as it relates to groundwater, and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.12 of NUREG-0800 SRP, and other NRC RGs. The staff's review concludes that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the COL applicant has adequately addressed COL Items 2.0-12-A and 2.0-23-A as they relate to groundwater.

As set forth above, the applicant presented and substantiated information relative to the groundwater effects important to the design and siting of this plant. The staff has reviewed the available information provided and, for the reasons given above, concludes that the identification and consideration of the potential effects of groundwater in the vicinity of the site are acceptable and meet the requirements of 10 CFR 50.55, "Conditions of construction permits, early site permits, combined licenses, and manufacturing licenses," 10 CFR 50.55a, 10 CFR 100.20(c)(3), 10 CFR 100.23(d), and 10 CFR 100.20(c), with respect to determining the acceptability of the site.

2.4.13 Accidental Release of Radioactive Liquid Effluent in Ground and Surface Waters

2.4.13.1 Introduction

This section provides a characterization of the attenuation, retardation, dilution, and concentrating properties governing transport processes in the surface-water and groundwater environment at the site. This section's goal is not to provide an assessment of the impacts of a specific release scenario but to provide a suitable conceptual model of the hydrological environment for other assessments. Since it would be impractical to characterize all the physical and chemical properties (e.g., hydraulic conductivities, porosity, mineralogy, etc.) of a time-varying and heterogeneous environment, this section characterizes the environment in terms of the projected transport of a postulated release of radioactive waste. The accidental release of radioactive liquid effluents in ground and surface waters is evaluated using information on existing uses of groundwater and surface water and the known and likely future uses as the basis for selecting a location to summarize the results of the transport calculation. The source term from a postulated accidental release is reviewed under Section 11.2 of NUREG-0800 following the guidance in Branch Technical Position (BTP) 11-6, "Postulated Radioactive Releases Due to Liquid-Containing Tank Failures" and ISG DC/COL-ISG-013, "Assessing the Radiological Consequences of Accidental Releases of Radioactive Materials from Liquid Waste Tanks for Combined License Applications." The source term is determined from a postulated release from a single tank outside of the containment. The results of a consequence analysis are evaluated against SRP Section 11.2 and BTP 11-6 guidance and the effluent concentration limits (ECLs) of Table 2, Column 2 in 10 CFR Part 20, Appendix B, as SRP acceptance criteria. Under SRP guidance, the ECLs of 10 CFR Part 20, Appendix B are applied as acceptance criteria and are not intended for demonstrating compliance with ECLs.

The following specific areas are reviewed by the staff: (1) alternative conceptual models of the hydrology at the site that reasonably bound hydrogeological conditions at the site inasmuch as these conditions affect the transport of radioactive liquid effluent in the ground and surface water environment; (2) a bounding set of plausible surface and subsurface pathways from potential points of an accidental release to determine the critical pathways that may result in the most severe impact on existing uses and known and likely future uses of ground and surface water resources in the vicinity of the site; (3) the ability of the groundwater and surface water environments to delay, disperse, dilute, or concentrate accidentally released radioactive liquid effluents during transport; and, (4) the assessment of scenarios wherein an accidental release of radioactive effluents is combined with potential effects of seismic and non-seismic events.

2.4.13.2 Summary of Application

North Anna 3 COL FSAR Section 2.4.13, Revision 9, "Accidental Releases of Liquid Effluents to Ground and Surface Waters," incorporates by reference ESP SSAR, Revision 9, Section 2.4.13, "Accidental Releases of Liquid Effluents to Ground and Surface Waters." This section of the North Anna 3 COL FSAR addresses the accidental release of radioactive liquid effluents in ground and surface waters.

In addition, in North Anna 3 COL FSAR Section 2.4.13, the COL applicant addressed COL item 2.0-24-A identified in ESBWR DCD Tier 2, Revision 10, Table 2.0-2 and ESP Permit Condition 3.E(3).

COL Item:

- COL Item 2.0-24-A — COL Applicant to Address SRP 2.4.13

Permit Condition:

- ESP Permit Condition 3.E(3) — Features to Preclude Radioactive Releases into any Potential Liquid Pathway

The COL applicant addressed these issues by including in North Anna 3 COL FSAR, Revision 9 Section 2.4.13 the following information as a supplement to ESP SSAR Section 2.4.13:

The COL applicant described the accident scenario and resulting source term. For the source term, the COL applicant considered tanks that are part of the Liquid Waste Management System (LWMS) and the Condensate Storage and Transfer System (CSTS). The COL applicant described design features of these systems intended to preclude accidental releases into potential liquid pathways, consistent with ESP Permit Condition 3.E (3). The COL applicant nevertheless considered rupture of the CST as the postulated source, because this tank is the largest above-grade tank located outside of containment. The CST is described in ESBWR DCD Section 9.2.6.2. The tank was postulated to instantaneously release 80 percent of its volume to the unconfined aquifer.

The COL applicant determined that a direct surface water pathway would be precluded by design, and identified a groundwater pathway from the CST to the North Anna 3 intake basin. The COL applicant described two conceptual models: a primary conceptual model with North Anna 3 not operating and an alternative conceptual model with North Anna 3 operating. Groundwater travel time was estimated using site data.

The COL applicant described a radionuclide transport analysis, including the calculation of radionuclide concentrations and doses, and comparison with acceptance criteria based on 10 CFR Part 20. The COL applicant's transport analysis was primarily based on a method of characteristics solution to the one-dimensional advection-dispersion equation with first-order decay and linear equilibrium adsorption. The transport analysis was conducted using three stages. The initial stage of the transport analysis considered advection and radioactive decay only. The second stage of the COL applicant's analysis included the effect of advection, radionuclide decay, and adsorption in computing radionuclide concentrations at the groundwater discharge location. The third stage of the COL applicant's analysis included the effect of dilution of groundwater discharged to the North Anna 3 intake basin, and considered the effect of the two conceptual models on dilution.

The COL applicant computed doses to an individual from consumption of water, consumption of fish and invertebrates, and from swimming, boating, and shoreline activities. The COL applicant estimated that the total body dose to a child from all exposure pathways would be 28 mrem.

Early Site Permit Variance:

The following variance from the ESP SSAR is discussed in Section 2, "Variances," of Part 7 to the COLA:

- NAPS ESP VAR 2.0-5 Distribution Coefficients (Kd)

The COL applicant requested VAR 2.0-5 to use the distribution coefficients provided in North Anna 3 COL FSAR Table 2.4-206 rather than the corresponding values in ESP SSAR Tables 1.9-1 and 2.4-20.

2.4.13.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to ESBWR DCD, and in NUREG-1835, the FSER related to the North Anna ESP.

The relevant requirements of NRC regulations for the pathways of liquid effluents in ground and surface waters, and the associated acceptance criteria, are specified in Section 2.4.13 in NUREG-0800 SRP and ISG DC/COL-ISG-014, "Assessing the Radiological Consequences of Accidental Releases of Radioactive Materials from Liquid Waste Tanks in Ground and Surface Waters for Combined License Applications." The applicable regulatory requirements are as follows:

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity, and time in which the historical data have been accumulated.

- 10 CFR 100.20(c), as it relates to the consideration given to the hydrological characteristics of the site.

- 10 CFR 100.23(d) sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves the site.

The related acceptance criteria from SRP Section 2.4.13 are as follows:

- Alternate Conceptual Models: Alternate conceptual models of hydrology in the vicinity of the site are reviewed.

- Pathways: The bounding set of plausible surface and subsurface pathways from the points of release are reviewed.

- Characteristics that Affect Transport: Radionuclide transport characteristics of the groundwater environment with respect to existing and known and likely future users should be described.

- Consideration of Other Site-Related Evaluation Criteria: The applicant's assessment of the potential effects of site-proximity hazards, seismic, and nonseismic events on the radioactive concentration from the postulated tank failure related to accidental release of radioactive liquid effluents to ground and surface waters for the proposed plant site is needed.

BTP 11-6 provides guidance in assessing a potential release of radioactive liquids following the postulated failure of a tank and its components, located outside of containment, and impacts of the release of radioactive materials at the nearest potable water supply, located in an unrestricted area, for direct human consumption or indirectly through animals, crops, and food processing.

In addition, the hydrologic characteristics should be consistent with appropriate sections from RG 1.113, "Estimating Aquatic Dispersions of Effluents from Accidental and Routine Reactor Releases for the Purpose of Implementing Appendix I."

2.4.13.4 Technical Evaluation

As documented in Section 2.4.13 of NUREG-1966 and Section 2.4.13 of NUREG-1835, the staff reviewed and approved information related to accidental release of radioactive liquid effluent in ground and surface waters for the certified ESBWR DCD, Revision 10, and Section 2.4.13 of the North Anna ESP SSAR, respectively. The staff reviewed Section 2.4.13 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR represent the complete scope of information relating to this review topic.

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Accidental Release of Radioactive Liquid Effluent in Ground and Surface Waters."

The staff's technical review of this application was limited to the supplemental information pertaining to COL item 2.0-24-A and ESP Permit Condition 3.E(3), as addressed in the following sections. Also discussed within this context are RAIs and variance NAPS ESP VAR 2.0-5.

Radionuclide Transport Analysis

Information Submitted by COL Applicant:

The COL applicant described the accidental radionuclide release source in North Anna 3 COL FSAR Section 2.4.13.1, and stated that tanks from the LWMS and the CSTS were evaluated. The COL applicant described design features of these systems intended to preclude accidental releases into potential liquid pathways, consistent with ESP Permit Condition 3.E(3). The COL applicant nevertheless considered rupture of the CST as the postulated source, because this tank is the largest above-grade tank located outside of containment. In RAI 02.04.13-6 dated January 07, 2015 (ADAMS Accession No. ML14347A004), the staff requested the basis for the source term concentrations provided in North Anna 3 COL FSAR Table 2.4-206. In response to RAI 02.04.13-6 dated January 27, 2015 (ADAMS Accession No. ML15028A392), the COL applicant described the input streams to the CST and referred to the ESBWR DCD tables from which concentrations of these input streams were derived. The COL applicant stated that the North Anna 3 COL FSAR 2.4.13 analysis used a bounding CST concentration for each radionuclide based on the largest of the LWMS and CSTS input streams. Resolution of RAI 02.04.13-6 is discussed in Section 11.2 of this SER.

The COL applicant described the accidental release scenario, rupture of the CST, in North Anna 3 COL FSAR Section 2.4.13.2. The CST selected as the source is located at a grade elevation of 88.24 m (289.5 ft) NAVD88 and has a volume of 4885 m^3 (172,512 ft^3). The COL applicant postulated that the tank instantaneously releases 80 percent of its volume, 3908 m^3 (138,010 ft^3), to the unconfined aquifer, consistent with BTP 11-6.

The COL applicant stated that the basin surrounding the CST precludes an uncontrolled release directly to the ground surface. On this basis, the COL applicant did not consider a surface water pathway.

Based on observed groundwater head contour maps, the COL applicant identified the groundwater transport pathway to be north-northeast toward the cove used for the North Anna 3 intake in Lake Anna. The COL applicant assumed transport would occur along a straight-line path between the CST and the cove, a distance of 234.70 m (770 ft). The COL applicant stated that the existing groundwater supply well in the power block area will be closed before North Anna 3 construction, and as a result, groundwater from the postulated release will discharge to the Lake Anna cove that constitutes the North Anna 3 water supply intake.

The COL applicant described a primary conceptual model in which North Anna 3 is not operating, so that groundwater discharged to Lake Anna would be diluted by water in the North Anna 3 intake cove. For the primary conceptual model, the COL applicant adopted the culverts that connect the intake cove to the main body of Lake Anna as the release point for demonstrating compliance with 10 CFR Part 20, Appendix B, Table 2 radionuclide concentration limits. The COL applicant also described an alternate conceptual model in which North Anna 3 is operating, so that groundwater discharged to Lake Anna would be diluted with lake water before being pumped back into the North Anna 3 facility as makeup water, and ultimately be discharged with cooling tower blowdown to the discharge canal. The COL applicant adopted the end of the discharge canal as the release point for compliance with the 10 CFR Part 20, Appendix B, Table 2 radionuclide concentration limits.

The COL applicant based the groundwater radionuclide transport analysis on a method of characteristics solution to the one-dimensional advection-dispersion equation with first-order decay and linear equilibrium adsorption. The COL applicant neglected dispersion in deriving the analytical solutions for parent and progeny radionuclides. The COL applicant conducted the analysis using three stages of progressive refinement. At the first two stages, the COL applicant considered in the following stage only radionuclides whose concentrations were greater than 1×10^{-6} times the applicable concentration limit. The COL applicant provided calculated concentrations in groundwater in FSAR Table 2.4-206.

The COL applicant’s first stage of analysis considered radioactive decay only, and computed radionuclide concentrations at the groundwater discharge location. The COL applicant computed a groundwater travel time of 1.07 yr. using a hydraulic conductivity of 3.02 m/day

(9.9 ft/day), a hydraulic gradient of 0.05, and an effective porosity of 0.25. The COL applicant included in the next stage of the analysis the 21 radionuclides for which the resulting concentrations were greater than $1x10^{-6}$ times the 10 CFR Part 20, Appendix B, Table 2 values. The second stage of the COL applicant's analysis included the effect of radionuclide decay and adsorption in computing radionuclide concentrations at the groundwater discharge location. The COL applicant stated that chelating agents, which could reduce radionuclide adsorption, are neither required nor planned for use in North Anna 3.

The COL applicant used site-specific distribution coefficient (K_d) values obtained in the laboratory using soil samples from 12 borings and water from the unconfined aquifer, with results listed in North Anna 3 COL FSAR Table 2.4-207. The COL applicant used the minimum observed value in the transport analysis. The COL applicant assumed the distribution coefficient of yttrium isotopes to be that of Sr-90. For those radioactive daughter products without measured values the COL applicant assigned the distribution coefficient values of the parent radionuclides. The COL applicant assumed Te-129m, Zr-95, Nb-95, and H-3 to be unaffected by adsorption. The COL applicant computed retardation factors using an effective porosity of 0.25 and a bulk density of 1.83 g/cm^3 (based on an assumed particle specific gravity of 2.65 g/cm^3 and a total porosity of 0.31). The COL applicant included in the next stage of the analysis the 10 radionuclides for which the resulting concentrations were greater than $1x10^{-6}$ times the 10 CFR Part 20, Appendix B, Table 2 values, these being H-3, Co-60, Ni-63, Sr-90, Y-90, Zr-95, Nb-95, Te-129m, Cs-137, and Pu-239.

The approach to selecting distribution coefficients described above represents a variance from the distribution coefficients as discussed in the ESP SSAR. The COL applicant formally stated this variance in the COL Application Departures Report as NAPS ESP Var 2.0-5. The values reported in ESP SSAR Table 2.4.20 were based on Sheppard and Thibault (1990) and the EPA (1999). The values used in FSAR Table 2.4-207 were based on site-specific measurements. The COL applicant justified the use of the North Anna 3 COL FSAR Table 2.4-206 distribution coefficient values because they were based on site-specific measurements, and compliance with the 10 CFR Part 20, Appendix B, Table 2 concentration limits was demonstrated using the North Anna 3 COL FSAR distribution coefficient values in the North Anna 3 COL FSAR Section 2.4.13 analysis of groundwater release.

The third stage of the COL applicant's analysis included the effect of decay, adsorption, and dilution of groundwater discharged to surface water under two conceptual models. The COL applicant's primary conceptual model assumed North Anna 3 was not operating and diluted the tank release volume in the volume of the Lake Anna cove, using the radionuclide groundwater concentrations from the second stage analysis. The COL applicant calculated a dilution factor of 26 for the primary conceptual model. The COL applicant's alternate conceptual model assumed North Anna 3 was in operation and diluted the groundwater discharge rate to the North Anna 3 intake cove by the total water withdrawal rate from Lake Anna for North Anna 3 operation, with the dilution factor reduced by the cycles of concentration. The COL applicant calculated a dilution factor of 38 for the alternate conceptual model using the maximum cycles of concentration (9). The COL applicant evaluated the "sum of fractions approach" described in 10 CFR Part 20 using the diluted concentrations and found the sum of fractions to be less than 1.0 under both scenarios.

The COL applicant computed doses to an individual from consumption of water, consumption of fish and invertebrates, and from swimming, boating, and shoreline activities using diluted concentrations from the primary conceptual model. The COL applicant estimated that the total body dose to a child from all exposure pathways would be 28 mrem.

The Staff's Technical Evaluation:

In RAI 02.04.13-1 dated August 19, 2008, (ADAMS Accession No. ML082320133), the staff requested information on the presence of chelating agents in the tank used for the source in the accidental release analysis. In North Anna 3 COL FSAR, Revision 9, Section 2.4.13.3.2.2, the COL applicant stated that chelating agents are neither required nor planned to be used. As a result, the staff considers RAI 02.04.13-1 resolved and closed.

The COL applicant assumed that there were no differences in the flow and transport characteristics between the saprolite and the shallow bedrock. The staff determined that this assumption is consistent with the hydrogeological conceptual model in North Anna 3 COL FSAR Section 2.4.12.

The staff verified that the groundwater transport analysis in North Anna 3 COL FSAR Section 2.4.13 used a hydraulic conductivity value that was the maximum observed value (3.02 m/day) from the site slug tests. In RAI 02.04.13-3 dated August 19, 2008 (ADAMS Accession No. ML082320133), the staff requested additional information about the consistency between the MODFLOW model used to model groundwater levels in North Anna 3 COL FSAR Section 2.4.12 and the contaminant transport model. The issue was that these two models used different values of hydraulic conductivity. In response to RAI 02.04.13-3 dated October 02, 2008 (ADAMS Accession No. ML082810405), the COL applicant provided a comparison between the values of hydraulic conductivity used in the two models. The COL applicant also provided a comparison between the groundwater travel times calculated using the different values of hydraulic conductivity. The staff reviewed these calculations and concluded that the COL applicant's contaminant transport model was not consistent with the MODFLOW model because higher, more conservative values of hydraulic conductivity were used in North Anna 3 COL FSAR 2.4.13. The staff concluded that using conservative values in transport modeling was appropriate because it was desirable to calculate groundwater travel times in a conservative manner. The staff also concluded that it was not necessary for the transport model and the MODFLOW groundwater flow model to use the same values of hydraulic conductivity, because the two modeling efforts had different intended objectives.

In RAI 02.04.13-3, the staff requested additional information on alternative groundwater transport pathways considered by the COL applicant. In an October 2, 2008, response to RAI 02.04.13-3 (ADAMS Accession No. ML082810405), the COL applicant identified and considered the following five alternative transport pathways which were designated as follows:

a. Flow north-northeast in the saprolite to the North Anna 3 intake forebay (the selected pathway);

b. Flow northeast in the saprolite to the Units 1 and 2 intake bay;

c. Flow southeast in the saprolite to the discharge canal;

d. Flow north in the saprolite to Lake Anna; and

e. Flow in fractured bedrock to the North Anna 3 intake forebay.

The COL applicant concluded that, compared to the selected pathway, the other saprolite pathways were longer and less plausible when evaluated against the observed groundwater heads and the post-construction MODFLOW model results. The COL applicant stated that the selected pathway was more conservative than the bedrock pathway, because the hydraulic conductivity in the bedrock generally decreased with depth due to a decrease in the number and extent of fractures. The staff noted that effective porosity was also expected to decrease with depth, which would tend to increase groundwater velocity. Based on the slug and pressure test data for the shallow bedrock, the staff determined that the hydraulic conductivity of the shallow bedrock was comparable to that of the saprolite. The staff also determined that there was no site-specific information on which to base an effective porosity estimate for the shallow bedrock. The staff concluded that it was appropriate to base a conservative transport analysis on the site-specific properties of the saprolite. The staff evaluated the alternative transport pathways described by the COL applicant and determined that the selected pathway (pathway a. above) was conservative. This pathway was used by the COL applicant in FSAR Section 2.4.13 and by the staff in its independent confirmatory analysis. The staff finds the discussion of alternative transport pathways acceptable. Accordingly, the staff considers RAI 02.04.13-3 resolved and closed.

The COL applicant made laboratory measurements of adsorption coefficient (K_d) values for the transport analysis on 20 soil and weathered rock samples. The staff reviewed a report documenting the laboratory measurements of K_d for the transport analysis and determined that the K_d values were highly variable with ranges between one and four orders of magnitude for individual radionuclides. Measurements were conducted on the less than 2 millimeter-size fraction of the samples, with the fraction greater than 2 millimeters reported as zero for most of the samples. Given the reported presence of rock fragments in the saprolite and their potential effect on radionuclide adsorption, in RAI 02.04.13-2 the staff requested information on the technical basis for neglecting this effect in a conservative analysis. The staff also noted that a wide range of pH values was measured in the soil samples used in the K_d measurements and that there was an apparent relationship between the measured K_d values and the measured pH values. In RAI 02.04.13-2, the staff also requested information on the technical basis for neglecting this effect in a conservative analysis. In response to both of these issues (ADAMS Accession No. ML082810405), the COL applicant argued that the use of conservative K_d values (the COL applicant used the minimum measured K_d values) implicitly considered the effects of rock fragments and pH, both of which could act to reduce K_d values. Given the wide range of measured K_d values and the lack of a plausible low-pH pathway, the staff concluded that the use of minimum measured K_d values was demonstrably conservative with respect to the effect of the pH on adsorption. Although the staff considers that a pathway containing significant gravel is plausible (e.g., a pathway through Zone IIb/III in North Anna 3 COL FSAR Figure 2.4-217), the staff determined that the impact of gravel on K_d would be small compared to the wide range of K_d values measured by the COL applicant. The staff therefore concludes that a transport analysis using minimum, site-specific measured K_d values is demonstrably conservative, and considers RAI 02.04.13-2 resolved.

The staff reviewed the COL applicant's transport analysis as described in North Anna 3 COL FSAR Section 2.4.13. The staff completed a confirmatory analysis that computed radionuclide concentrations and the limiting value of the radionuclide mixture (as described in 10 CFR Part 20, Appendix B, Table 2, Note 4) without regard to the time of arrival of each radionuclide at the accessible environment, thereby maximizing the value of the sum. For this analysis, the staff computed conservative radionuclide transport times using maximum observed hydraulic conductivity and radionuclide-specific K_d values determined as the smaller value of the minimum measured K_d and the 0.01 quantile[5] estimated from the measured values. Radionuclides without measurements were assigned a K_d value of the 0.1 quantile estimated from the mean and standard deviation from NUREG/CR-6697, Development of Probabilistic RESRAD 6.0 and

[5] Estimated using the method of moments from the measured $\ln(K_d)$ values. The 0.01 quantile is expected to be exceeded by 99% of measured Kd values.

RESRAD-BUILD 3.0 Computer Codes" (ADAMS Accession Number: ML010090284), Attachment C, Table 3.9-1 (Yu et al. 2000). Radionuclide concentrations in groundwater at the discharge location were computed based on these transport times. The staff considered the two surface water dilution scenarios described by the COL applicant in North Anna 3 COL FSAR Section 2.4.13 and concluded that dilution in the volume of the North Anna 3 intake basin cove without North Anna 3 operating (the COL applicant's primary conceptual model) was a bounding approach. The staff verified that the COL applicant's alternative conceptual model (recirculation with North Anna 3 operating, and dilution in the discharge canal) resulted in greater dilution. The staff computed a dilution factor of 0.037 by assuming the entire source release was uniformly mixed with the North Anna 3 intake basin cove. The staff computed the mixture sum by dividing each concentration by its 10 CFR Part 20, Appendix B, Table 2 limit and summing over all radionuclides. This conservative approach resulted in a sum of 0.86, of which 0.35 was due to H-3, 0.04 to Sr-90, and 0.47 to Cs-137. This value was less than the 10 CFR Part 20, Appendix B, Table 2 limit for a radionuclide mixture (1.0).

The transport analysis described above assumed constant K_d values along the transport pathway. The measured K_d values reported by the applicant were obtained on small samples of soil/rock taken from locations across the site. The staff evaluated the degree of conservatism in assuming that the minimum K_d value measured in a small-scale sample represented the average K_d along the transport pathway. This analysis was completed for the Sr-90 and Cs-137 K_d data (the most significant sorbing contributors to the radionuclide mixture sum) using the methods described in NUREG/CR-6565 (Meyer et al. 1997). The results indicated that there is less than a 1 percent chance that the average Sr-90 and Cs-137 K_d values at the site are as low as the minimum measured values.

No accidental releases directly to surface water are described in North Anna 3 COL FSAR Sections 2.4.13 and 11.2.3.2. Surface water releases considered in the North Anna 3 COL FSAR were due to groundwater transport and discharge to surface water features as described above. Based on the COL applicant's description of the design features intended to preclude the release of radioactive liquid effluents, the staff concludes that a direct release to surface water is not plausible.

In RAI 02.04.13-4 dated March 29, 2009 (ADAMS Accession No. ML090840271), the staff requested information demonstrating that the accidental release analysis described in North Anna 3 COL FSAR Section 2.4.13 is bounding. Based on the information provided in North Anna 3 COL FSAR Section 2.4.13, described above, and on the staff's independent confirmatory analyses, the staff concludes that the transport analysis described in North Anna 3 COL FSAR Section 2.4.13 constitutes a bounding analysis. Accordingly, the staff considers RAI 02.04.13-4 resolved and closed.

Section 11.2.4 of this SER provides the staff findings associated with the COL applicant's radiological dose analysis and associated RAIs.

2.4.13.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.13.6 Conclusion

The staff reviewed the COLA and confirmed that the COL applicant addressed the relevant information and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section.

In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 2.4.13 of NUREG–0800, and NRC RGs. The staff's review concludes that the COL applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the COL applicant has adequately addressed NAPS COL Item 2.0-24-A as it relates to accidental releases of liquid effluents in ground and surface waters. The staff notes that mitigating design features described in the North Anna 3 COL FSAR would further bound groundwater or surface water releases described above.

The review confirms that the COL applicant has satisfactorily addressed the potential for radionuclides to impact receptors under five alternative groundwater transport pathways. The release scenario considered was a worst-case release to groundwater resulting from a catastrophic release of the contents of the CST, the largest above-grade tank located outside containment. Conservative assumptions (i.e., promoting transport and high concentrations) were used in an approach to determine the activity concentrations of radionuclides at locations of groundwater discharge to surface water, relative to the ECLs specified in 10 CFR Part 20, Appendix B, Table 2, Column 2. As described above, the calculated activity concentrations satisfied the ECLs and sum-of-fractions criteria at the groundwater discharge locations using conservative dilution assumptions. The staff concludes that the analysis and its results provide sufficient information to satisfy the requirements of 10 CFR 100.20(c), 10 CFR 100.23(d), and 10 CFR 52.79(a)(1)(iii).

2.4.14 Technical Specification and Emergency Operation Requirements

2.4.14.1 Introduction

The technical specifications (TSs) and emergency operation requirements described here implement protection against floods for safety-related facilities to ensure that an adequate supply of water for shutdown and cool-down purposes is available. The specific areas of review are: (1) controlling hydrological events, as determined in previous hydrology sections of the SAR, to identify bases for emergency actions required during these events; (2) the amount of time available to initiate and complete emergency procedures before the onset of conditions while controlling hydrological events that may prevent such action; (3) reviewing TSs related to all emergency procedures required to ensure adequate plant safety from controlling hydrological events by the organization responsible for the review of issues related to TSs; (4) potential effects of seismic and nonseismic information on the postulated TSs and emergency operations for the proposed plant site; and, (5) any additional information requirements prescribed in the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.4.14.2 Summary of Application

This section of the North Anna 3 COL FSAR addresses TSs and emergency operation requirements. The COL applicant addressed the information as follows:

<u>*COL Items:*</u>

- NAPS COL 2.0-25-A — Technical Specification and Emergency Operation Requirements, COL Applicant to provide site-specific information in accordance with SRP 2.4.14

The COL applicant provided North Anna 3 COL FSAR Section 2.4.14 to address ESBWR DCD COL Item 2.0-25-A and referenced Sections 2.4.2 and 2.4.12 of the North Anna 3 COL FSAR regarding design basis floods and maximum groundwater elevation and their impacts on safety-related SSCs. The COL applicant concluded that the combination of the ESBWR DCD design and the plant grade elevation do not necessitate emergency procedures or TSs to prevent hydrological phenomena from degrading the UHS.

- NAPS ESP COL 2.4-2		Shut Down Water Level

The COL applicant provided site-specific information in North Anna 3 COL FSAR Section 2.4.14 to address ESP COL Action Item 2.4-2. The COL applicant stated that North Anna 3 will be shut down when the water level in Lake Anna drops below the elevation of 73.50 m (241.14 ft) NAVD88. The COL applicant added that this operational restriction is not related to the protection of safety-related SSCs or degradation of the UHS and is therefore not a TS limiting condition for operation (LCO).

2.4.14.3 Regulatory Basis

The relevant requirements of the Commission regulations for the TSs and emergency operation requirements, and the associated acceptance criteria, are in Section 2.4.14 of NUREG–0800. The applicable regulatory requirements are as follows:

- 10 CFR Part 100, as it relates to identifying and evaluating hydrological features of the site. The requirements to consider physical site characteristics in site evaluations are specified in 10 CFR 100.20(c).

- 10 CFR 100.23(d), sets forth the criteria to determine the citing factors for plant design bases with respect to seismically induced floods and water waves at the site.

- 10 CFR 52.79(a)(1)(iii), as it relates to identifying hydrologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding areas and with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR 50.36, "Technical Specifications," as it relates to identifying limiting conditions on TSs for safe operation of the plant.

The following related acceptance criteria are summarized from SRP Section 2.4.14:

- Bases for Emergency Actions: To meet the requirements of 10 CFR 50.36 and 10 CFR Part 100, an assessment of the hydrological bases for emergency actions is needed.

- Available Response Time: To meet the requirements of 10 CFR 50.36 and 10 CFR Part 100, estimates of available response times to initiate and complete emergency procedures are needed.

- Technical Specifications: To meet the requirements of 10 CFR 50.36 and 10 CFR Part 100, the applicant's proposed TSs related to emergency procedures are reviewed.

- Consideration of Other Site-Related Evaluation Criteria: To meet the requirements of 10 CFR 50.36 and 10 CFR Part 100, the applicant's assessment of the potential effects of site-related proximity, seismic, and non-seismic information on the postulated TSs and emergency operations is needed.

In addition, the hydrologic characteristics should be consistent with appropriate sections from: RGs 1.29, 1.59, and 1.102.

2.4.14.4 Technical Evaluation

As documented in Section 2.4.14 of NUREG-1966, the staff reviewed and approved information related to TSs and emergency operation requirements for the certified ESBWR DCD, Revision 10. The staff reviewed Section 2.4.13 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD and the North Anna ESP SSAR to ensure that the combination of the information in the North Anna 3 COL FSAR and the information in the ESBWR DCD and ESP SSAR that represent the complete scope of information relating to this review topic.

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to "Accidental Release of Radioactive Liquid Effluent in Ground and Surface Waters."

In addition the staff reviewed the resolution to ESBWR DCD COL Item 2.0-25-A, related to the TSs and emergency operation requirements that implement protection against floods for safety-related facilities to ensure that an adequate supply of water for shutdown and cool-down purposes is available. Based on the ESBWR DCD design, the COL applicant's selection of design basis plant grade, and the flood protection measures described in Section 2.4.10 of this SER, no emergency procedures or TSs are necessary to prevent hydrological phenomena from degrading the UHS.

Appendix A of the North Anna ESP specifies that the minimum lake water level for operation of North Anna 1, 2, and 3 is elevation 73.50 m (241.14 ft) NAVD88. In North Anna 3 COL FSAR Section 2.4.14 the COL applicant committed to shut down North Anna 3 when the water level in Lake Anna drops below elevation 73.50 m (241.14 ft) NAVD88. Because of the UHS design, this operational restriction is not related to protection of safety-related SSCs or degradation of the UHS.

2.4.14.5 Post Combined License Activities

There are no post COL activities related to this section.

2.4.14.6 Conclusion

The staff reviewed the application and checked the referenced DCD and confirms that the COL applicant has addressed the required information, and no outstanding information remains to be addressed in the North Anna 3 COL FSAR related to this section. The review confirmed that no emergency procedures or TSs are necessary to prevent hydrological phenomena from degrading the UHS.

In addition, the staff compared the additional information in the COL to the relevant NRC regulations, the guidance in Section 2.4.14 of NUREG–0800, and NRC RGs. The staff's review concludes that the applicant has provided sufficient information to satisfy the requirements of NRC regulations. The staff has determined that the applicant has adequately addressed NAPS COL Item 2.0-25-A as it relates to TSs and emergency operation requirements.

As set forth above, the applicant has presented and substantiated information relative to the TSs and emergency operations important to the design and siting of this plant. The staff has reviewed the available information provided and for the reasons given above, concludes that the identification and consideration of the TSs and emergency operations is acceptable and meets the requirements of 10 CFR 50.36, 10 CFR 52.79(a)(1)(iii), 10 CFR 100.20(c), and 10 CFR 100.23(d) with respect to determining the acceptability of the site.

2.5 Geology, Seismology, and Geotechnical Engineering

In Section 2.5, "Geology, Seismology, and Geotechnical Engineering," of the North Anna 3 FSAR, the applicant described the geologic, seismic, and geotechnical engineering properties of the North Anna 3 COLA site.

FSAR Section 2.5.1, "Basic Geologic and Seismic Information," presents information on geologic and seismic characteristics of the COL site and region surrounding the site. FSAR Section 2.5.2, "Vibratory Ground Motion," describes the vibratory ground motion assessment for the COL site through a Probabilistic Seismic Hazard Analysis (PSHA) and develops the Safe Shutdown Earthquake (SSE) ground motion. FSAR Section 2.5.3, "Surface Faulting," evaluates the potential for surface tectonic and non-tectonic deformation at the COL site. FSAR Sections 2.5.4, "Stability of Subsurface Materials and Foundations," and 2.5.5, "Stability of Slopes," describe foundation and subsurface material stability at the COL site. FSAR Section 2.5.6, "Embankments and Dams," describes the embankments and dams in the site area.

The FSAR incorporates by reference the information contained in Revision 9 of the ESP SSAR and ESBWR DCD Revision 10; and adds new information to address DCD and ESP COL items, to satisfy ESP permit conditions, and to resolve variances from the ESP. The applicant defined three zones around the site: the region within 320 km (200 miles), a vicinity within 40 km (25 miles), and an area within 8 km (5 miles). The COL site is in the area within 1 km (0.6 mile) of the site location adjacent to North Anna 1 and 2, abandoned foundation mats for Units 3 and 4, and the independent spent fuel storage installation (ISFSI).

The COL FSAR, Section 2.5, provides variances to the ESP SSAR based on new information regarding: (a) the **M**5.8 earthquake that occurred on August 23, 2011, in Mineral, Louisa County, Virginia, and the results of a geological reconnaissance to investigate any surface features associated with the earthquake in the site vicinity; (b) incorporation of the CEUS-SSC model (NUREG-2115); and (c) additional borings to support North Anna 3 ESBWR investigation. The COL FSAR Section 2.5 provides information to satisfy ESP permit conditions (conditions 4, 5, 6, 7); ESP VARs 2.5-2, 2.5-4, 2.5-7; and ESP COL Action 2.5-1. The staff has previously reviewed Section 2.5 of the North Anna 3 ESP SSAR and its findings are documented in NUREG-1835.

The staff reviewed North Anna 3 COL FSAR Section 2.5, interacted with the applicant during public meetings, and issued RAIs to confirm the assertions made by the applicant in the North Anna 3 COL FSAR. In early versions of the North Anna 3 COL FSAR, the applicant used seismic source models developed in 1986 and 1989 by the EPRI, as the starting point for characterizing potential regional seismic sources and resulting vibratory ground motion, and then updated these seismic source models in light of more recent data and evolving knowledge. The applicant later replaced the original EPRI (1989) ground motion models (GMM) with more recent EPRI models (2013), and applied the performance-based approach described in RG 1.208, "A Performance-Based Approach to Define the Site-Specific Earthquake Ground Motion," which incorporates PSHA, to develop ground motion response spectra (GMRS) for the site. The applicant subsequently replaced those models with the new seismic source characterization model for the central and eastern United States (CEUS-SSC) published in NUREG-2115, “Central and Eastern United States Seismic Source Characterization for Nuclear Facilities” in response to RAI 02.05.02-4 dated February 13, 2012 (ADAMS Accession No. ML12048A096), which requested the applicant to evaluate the seismic hazard in light of the August 23, 2011, Mineral, Virginia, earthquake.

Further, following the 2011 Fukushima Dai-Ichi nuclear power plant accident in Japan, which occurred as a result of the Great Tohoku earthquake and the subsequent tsunami, the NRC Near-Term Task Force (NTTF) issued a series of recommendations for reevaluating and improving nuclear power plant safety in the U.S. Consequently, on March 12, 2012, the NRC issued an information letter requesting that licensees of all operating nuclear power plants in the U.S. reevaluate the seismic hazard at their respective plants using the most recent data and evaluation methodologies available. That information letter also requested that licensees of operating plants in the CEUS use the seismic source model provided in NUREG-2115 to characterize seismic hazard at their respective plants. Consistent with existing guidance in RG 1.208, pertaining to the need to consider the latest information in the evaluation of seismic hazard, the NRC also requested that all COL and ESP applicants in the CEUS address seismic hazard for their respective proposed plant sites using information in NUREG-2115 and modify the GMRS, if needed. The staff issued this request to North Anna 3 in RAI 01.05-1 dated June 25, 2012 (ADAMS Accession No. ML12214A593).

In a December 18, 2013, response to RAI 01.05-1 (ADAMS Accession No. ML14013A113), the applicant stated that RAI 01.05-1 is no longer applicable to the North Anna 3 site, because it replaced the previous EPRI seismic source models with the CEUS-SSC model presented in NUREG-2115 as the starting point for developing GMRS for the North Anna 3 site in response to RAI 02.05.02-4 dated February 13, 2012 (ADAMS Accession No. ML12048A096).

With this change in the base seismic source model, some of the RAIs the staff previously asked of the applicant became unnecessary, as described in SER Section 2.5.2.4. Therefore, this SER references only the most recent version of the North Anna 3 COL FSAR and the staff’s technical evaluation of that version without discussing the replaced portions of the previous North Anna 3 COL FSAR and some of the staff’s earlier RAIs, which are now unnecessary and closed without specific resolution. The following sections of this report discuss the RAIs that remain applicable to the staff’s review following the change in the base seismic source model, along with the new RAIs related to the most recent version of the North Anna 3 COL FSAR.

2.5 Geology, Seismology, and Geotechnical Engineering

2.5.1 Basic Geologic and Seismic Information

2.5.1.1 Introduction

Section 2.5.1 of this SER provides the basic geologic and seismic information related to the North Anna 3 site. Section 2.5.1.2 of this SER summarizes the relevant geologic and seismic information in FSAR Section 2.5.1 of the North Anna 3 COLA. SER Section 2.5.1.3 summarizes the regulations and guidance used by the applicant to perform the investigation. SER Section 2.5.1.4 reviews the staff’s evaluation of FSAR Section 2.5.1, including any RAIs, open items, and confirmatory analyses performed by the staff. SER Section 2.5.1.5 discusses any post COL activities. Finally, SER Section 2.5.1.6 provides an overall summary of the applicant’s conclusions, as well as the staff’s conclusions; restates any bases covered in the application; and confirms that regulations were met or fulfilled by the applicant.

COL FSAR Section 2.5.1, and by reference the ESP SSAR Section 2.5.1, describes the geologic information that the COL applicant collected during site investigations to address regional and site-specific geologic characteristics derived from previous work and from surface and subsurface investigations. The COL applicant stated it reviewed previous site investigations for North Anna 1 and 2, and abandoned Units 3 and 4 for the geologic properties of the COL site. Additionally, COL FSAR Section 2.5.1, and by reference the ESP SSAR Section 2.5.1, includes newly published information and the recent geologic, seismic, geophysical and geotechnical investigations conducted for North Anna 3. Finally, COL FSAR Section 2.5 includes information on the **M**5.8 earthquake that occurred on August 23, 2011, in Mineral, Louisa County, Virginia, and the results of the geological field reconnaissance program to investigate any surface features associated with the earthquake in the site vicinity.

The COL applicant conducted these investigations to assess geologic and seismic suitability of the site, to determine whether new geologic or seismic data exist that could significantly impact seismic design based on the results of PSHA, and to provide the geologic and seismic data appropriate for plant design.

2.5.1.2 Summary of the Application

Section 2.5.1 of the North Anna 3 COL FSAR, incorporates by reference Section 2.5.1 of the North Anna ESP SSAR, Revision 9. In addition, in FSAR Section 2.5.1, the applicant provided supplemental information to address the geologic and geotechnical data collected as part of the additional North Anna 3 site borings. This information included additional descriptions of the Ta River Metamorphic Suite and the saprolite and artificial material encountered in the site subsurface. The applicant also supplied additional details on the engineering geology of the soil and rock at the site. Finally, the applicant provided information to satisfy permit conditions 5 through 7 from the North Anna ESP.

This COL FSAR section also addresses COL Item 2.0-26-A from Revision 5 to the ESBWR DCD; ESP COL Action Item 2.5-1; and permit conditions identified in the North Anna 3 ESP SER (NUREG-1835) and summarized in Part 3, Section E of the North Anna ESP (ADAMS Accession No. ML073180440).

COL Items, ESP Variances, and ESP Permit Conditions:

- NAPS COL 2.0-26-A

The applicant incorporated by reference Section 2.5.1 of the North Anna 3 ESP SSAR to address NAPS COL 2.0-26-A (ESBWR DCD COL Item 2.0-26-A) which requires that a COL applicant referencing the ESBWR design to provide basic geologic and seismic information for the site in accordance with SRP 2.5.1.

- NAPS ESP VAR 2.0-4

The applicant provided additional information to address ESP COL Action Item 2.5-9, which states that the COL applicant should determine that the average shear wave velocity (V_s) of the material underlying the foundation for the reactor containment equals or exceeds that of the chosen design.

- NAPS ESP COL 2.5-1

The applicant provided additional information to address ESP COL Action Item 2.5-1, which states that the COL applicant should perform additional borings in the subsurface to identify any weathered or fractured rock beneath the new foundations.

- ESP Permit Condition 3.E(4)

The applicant provided additional information to address ESP Permit Condition 3.E(4), which requires the replacement of weathered or fractured rock at the foundation level with lean concrete before initiation of foundation construction.

- ESP Permit Condition 3.E(5)

The applicant provided additional information to address ESP Permit Condition 3.E(5), which prohibits the applicant from using engineered fill with high compressibility and low maximum density, such as saprolite, in the construction of North Anna 3.

- ESP Permit Condition 3.E(6)

The applicant provided additional information to address ESP Permit Condition 3.E(6), which requires the applicant to provide geologic mapping information for future excavations of safety-related structures and to evaluate unforeseen geologic features that are encountered. The applicant should notify the NRC no later than 30 days before any excavations for safety-related structures are open for NRC's examination and evaluation.

Regional Tectonic Setting

COL FSAR Section 2.5.1.1.4 describes the new PSHA based on the CEUS-SSC model described in NUREG-2115. The CEUS-SSC model (NRC, 2012) replaces the previous PSHA based on the Electric Power Research Institute–Seismicity Owners Group (EPRI-SOG) model (EPRI, 1988, 1989) and the Lawrence Livermore National Laboratory model (LLNL, 1993, NUREG/CR-5250, "Seismic hazard characterization of 69 nuclear plant sites east of the Rocky Mountains."). The applicant described the Extended Continental Crust-Atlantic Margin Zone (ECC-AM) as the CEUS-SSC host source for the North Anna 3 site.

Principal Tectonic Structures

COL FSAR Section 2.5.1.1.4.c indicates that the host seismotectonic zone for the site is the ECC AM (Figure 2.5.1-1 of this report) and that this zone includes Mesozoic extensional structures formed during the opening of the Atlantic Ocean. The COL applicant stated that no basin-margin faults have been reactivated during the Quaternary in the site region and that any reactivation of faults bordering or beneath Mesozoic basins is addressed in the CEUS-SSC model. The Stafford fault system, a Tertiary tectonic structure and also located within the ECC-AM, does not reveal any geologic or geomorphic evidence of Quaternary activity based on the COL applicant's field and aerial reconnaissance. The COL applicant indicated that the Stafford fault system is not included as a Quaternary structure in Crone and Wheeler (2000) and thus concluded that it is not a capable tectonic source. In the Quaternary Tectonic Features Section, the COL applicant explained that aftershock data from the August 23, 2011, **M**5.8 Mineral earthquake delineates a previously unmapped geologic structure named the "Quail fault" (Horton et al. 2012, 2014, 2015). The COL applicant concluded that this structure does not fit the criteria for a repeated large magnitude earthquake (RLME) source per NUREG-2115. The FSAR provides information regarding other tectonic features in the site region that have been considered as possibly

Quaternary age such as the paleoliquefaction sites of Obermeier and McNulty, the Everona-Mountain Run Fault Zone, and the East Coast Fault System. None of these tectonic features fit the criteria for a RLME source. Each of these features is considered within the ECC-AM source zone in the CEUS-SSC model.

Seismic Sources Defined by Regional Seismicity

COL FSAR Section 2.5.1.1.4.d describes modifications made to seismic sources defined by regional seismicity based on new data and information in CEUS-SSC model. The Central Virginia Seismic Zone (CVSZ) is located within the ECC-AM seismotectonic source zone of the CEUS-SSC model and includes the August 23, 2011, Mineral, Virginia, earthquake (Figure 2.5.1-1 of this report). The COL applicant stated that the **M**5.8 Mineral earthquake main shock is included in the updated seismicity catalog and indicates reverse motion at a final depth of 6.0 km (4 mi). The COL applicant modeled a possible rupture plane based on aftershock data (Figure 2.5.1-2 of this report). Researchers investigating the epicentral area immediately after the earthquake described several liquefaction features associated with the earthquake.

The COL FSAR also describes the Giles County Seismic Zone located within the Paleozoic extended zone (PEZ) seismotectonic source zone and that the maximum magnitudes (M_{max}) for the Giles County Seismic Zone and Eastern Tennessee Seismic Zone (ETSZ) sources were incorporated into the CEUS-SSC model. The COL applicant used the Charleston and New Madrid Seismic Zones as RLME sources from the CEUS-SSC model to predict seismic hazard at the North Anna 3 site. See specific details regarding the sensitivity analysis of these RLME sources in SER Section 2.5.2.

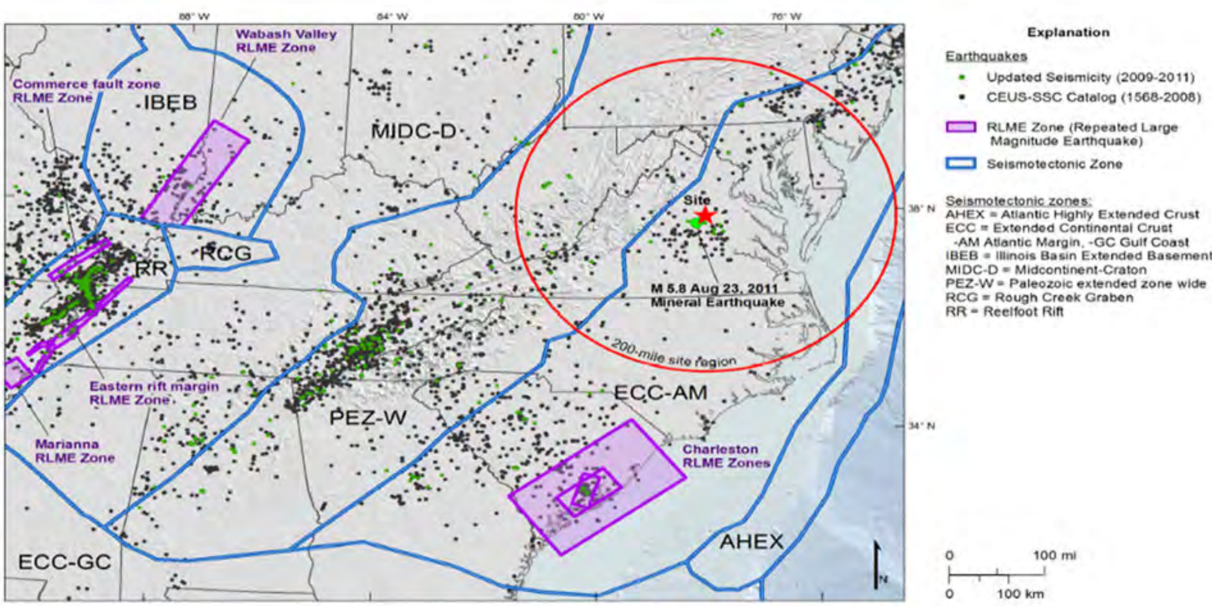

Figure 2.5.1-1. NAPS site region with seismotectonic source zones and the August 2011 Mineral, Virginia, earthquake (from FSAR Figure 2.5.1-202, Rev. 8)

Geologic Bases for Defining Relevant Source Zones

COL FSAR Section 2.5.1.1.6 details the geologic bases for defining relevant source zones. The North Anna 3 site is located within the ECC-AM seismotectonic source zone, a region comprised of rifted and extended continental crust that developed from the Mesozoic rifting that created the Atlantic Ocean and an older basal detachment fault that separates the over-thrusted Appalachian terranes from underlying Precambrian rocks of the North American craton. The COL applicant explained that a global study of earthquakes in stable continental regions (SCRs) (Johnston et al., 1994) and the CEUS-SSC model indicate that Mesozoic and younger extended crust has produced all M ≥ 7 stable craton earthquakes worldwide. The Paleozoic extended crust source zone, located immediately west of the ECC-AM, is comprised of terrane rifted during the Iapetan crustal extension. The COL applicant stated that normal faults formed during the opening of the Iapetus Ocean in this zone created zones of crustal weakness that exhibit a higher rate of seismicity and appear to coincide with the Giles County and the ETSZs.

Information on the August 23, 2011 Mineral, Virginia, Earthquake

The North Anna 3 site is located within the CVSZ, an area of persistent, low-level seismicity in the Piedmont Province and the ECC-AM seismotectonic zone. COL FSAR Section 2.5.1.1.7 describes the seismicity characteristics of the Mineral earthquake and the geologic field reconnaissance completed by the COL applicant to evaluate and document surface deformation from the Mineral earthquake. The COL applicant delineated a zone of possible surface deformation from the Mineral earthquake by fitting a rupture plane to aftershocks relocated by McNamara et al. (2014) and projecting this plane up-dip to the surface (Figure 2.5.1-2 of this report). The rupture plane strikes approximately N30ºE, dipping 45-50º SE with a length of ~6.2 mi (10 km) between the town of Quail, Virginia, and the headwaters of Despar Creek. The COL applicant indicated that the Mineral earthquake was a reverse faulting event that ruptured at a shallow depth (6.0 ± 3.1 km) and the up-dip surface projection of its rupture plane is located within the Chopawamsic Formation (Figure 2.5.1-3) (Burton et al. 2014).

The COL applicant performed a geologic reconnaissance field program (FSAR Section 2.5.1.1.7b) and acquired and processed Light Detection and Ranging (LiDAR) data covering a region encompassing the rupture plane of the Mineral earthquake and the proposed North Anna North Anna 3 site (Figure 2.5.1-4). The COL applicant used LiDAR as a basis for its geomorphic evaluation to document any coseismic surface rupture or other visible deformation at the surface in the Mineral earthquake epicentral region. The LiDAR package included a bare earth Digital Elevation Model (DEM), hillshade, slope and contour maps and orthophotography. The COL FSAR describes the search for evidence of regional fault-related geomorphic features, including geomorphic lineaments caused by active faulting, stream gradient changes or offsets, and contrasting large topographic features. On the ground field reconnaissance by the COL applicant included a search for ground fissures or compressional ground buckling, springs or artesian conditions, changes in vegetation growth, minor fault scarps, fault controlled drainages, and cracked or offset pavement along roads that might indicate surface deformation.

The COL applicant identified strong topographic lineaments in the LiDAR data and suggested that the lineaments reveal contrasts in erosion susceptibility between different geologic units. No liquefaction features were found during the field reconnaissance; however, the COL applicant stated that a few liquefaction features generated by the Mineral earthquake are described by researchers who investigated the epicentral area immediately following the earthquake. The COL applicant concluded that the **M**5.8 earthquake did not produce any discernible rupture or deformation at the ground surface and the Mineral earthquake did not rupture on a previously mapped fault.

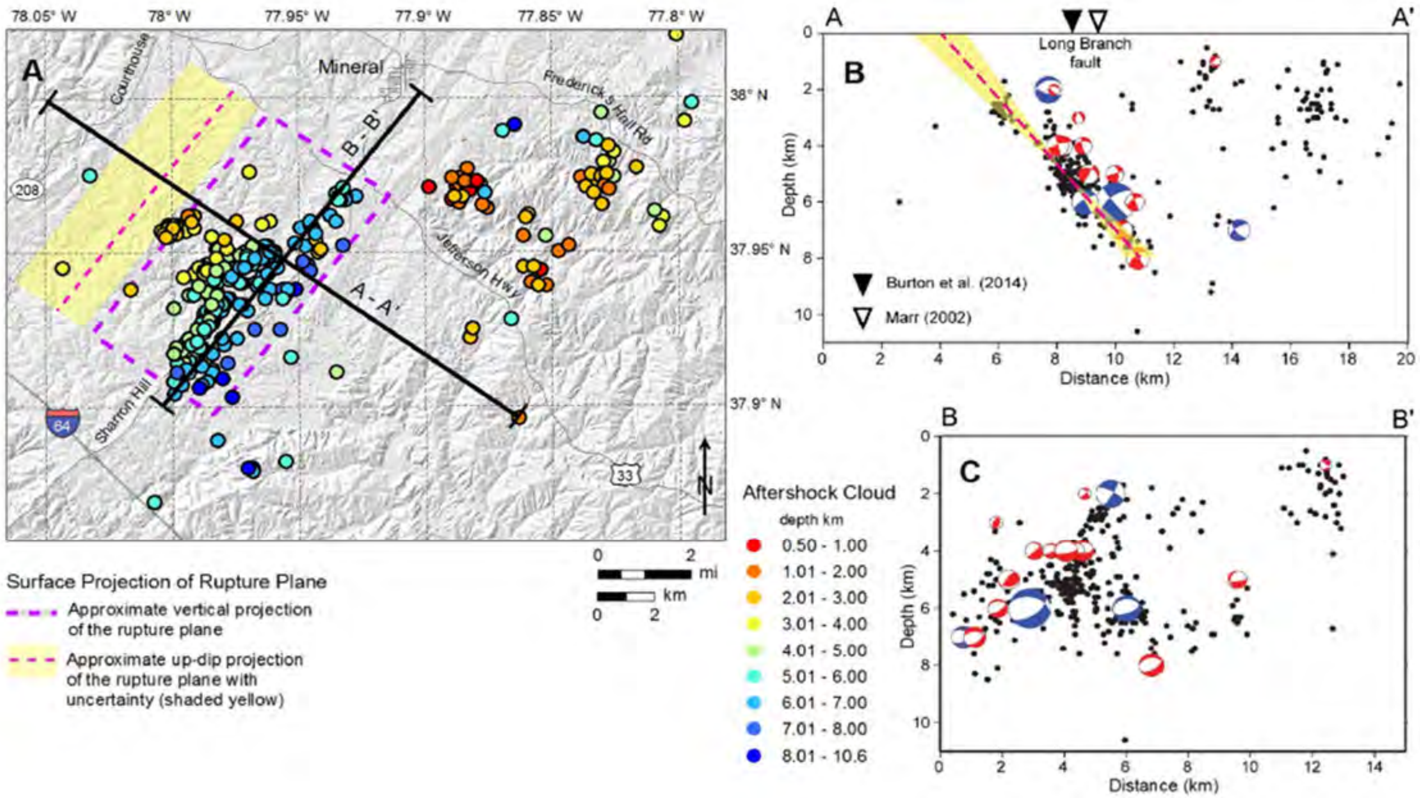

Figure 2.5.1-2. August 2011 Mineral, VA, earthquake aftershocks map and cross-sections illustrating subsurface rupture plane (from McNamara et al. (2014) taken from FSAR Figure 2.5.1-209, Rev. 9

Site Area Stratigraphy

COL FSAR Section 2.5.1.2.3 presents additional information based on supplemental borings collected at the North Anna 3 site in support of the ESBWR DCD, which include 93 borings, 23 cone penetrometer tests (CPTs), along with test pits, borehole geophysical logging, shear wave suspension loggings, and electrical resistivity tests. Details of this subsurface investigation are in FSAR Section 2.5.4 and in appendices 2.5.4 AA, 2.5.4 BB, 2.5.4 CC. The COL applicant briefly described the extent of various zones of fresh to weathered rock, including saprolite, as modified by the supplemental boring program.

The COL FSAR Section 2.5.1.2.3 also adds new information regarding the Ellisville pluton, based on new geologic mapping at the 1:24,000 scale in the northern half of the Ferncliff, Virginia, 7.5 minute quadrangle that suggests that the Ellisville pluton (approximately 440 Ma) cross-cuts and post-dates the Chopawamsic thrust fault (Hughes and Hibbard, 2012).

Site Area Structural Geology

The previous ESP SSAR Section 2.5.1.2.4 lists seven bedrock faults identified within a 5-mile radius of the site: Spotsylvania thrust, Chopawamsic thrust, Long Branch thrust, Sturgeon Creek fault, Unnamed fault (“a”) traversing the North Anna 3 site, Unnamed fault (“b”) separating the Ta River Metamorphic Suite from the Quantico Formation, and Unnamed fault (“c”) separating the

Northeast Creek pluton from the Quantico Formation. In the COL FSAR Section 2.5.1.2.4, the COL applicant stated that none of these faults are capable tectonic sources per RG 1.208.

Site Engineering Geology Evaluation

The COL FSAR Section 2.5.1.2.6 briefly describes the engineering behavior of soil and rock quality designations (RQD) and references details in Appendices 2.5.4 AA, 2.5.4 BB, and 2.5.4 CC. The COL applicant stated that results from the previous geotechnical investigations (ESP SSAR References 7 and 8), and for both the ESP subsurface investigation (ESP SSAR Appendix 2.5.4 B) and the North Anna 3 subsurface investigation (Appendices 2.5.4AA, 2.5.4BB, and 2.5.4CC) indicate that Zone III, III-IV, and IV Rock are suitable bearing surfaces for founding seismic Category I structures and that the density and area extent of jointing and fracturing in these zones is not extensive enough to affect engineering behavior of the rock. The COL applicant also stated that weathered and fractured rock at the foundation level for safety-related features would be excavated and replaced with lean concrete before initiation of foundation construction. In addition, the COL applicant also stated that future excavations for safety-related structures would be geologically mapped in order to detect and evaluate unknown geologic features at the site.

2.5.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed within the FSER related to the ESBWR DCD and its supplements and in NUREG-1835.

The applicable regulatory requirements for reviewing the applicant's discussion of geologic and seismic information are:

10 CFR 52.79(a)(1)(iii), "Contents of applications; technical information in the final safety analysis report," relates to identifying geologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity and period of time in which the historical data have been accumulated.

10 CFR Part 100, Section 100.23, "Geologic and seismic siting criteria," provides the nature of the investigations required to obtain the geologic and seismic data necessary to determine site suitability and identify geologic and seismic factors required to be taken into account in the siting and design of nuclear power plants.

The related acceptance criteria are summarized from SRP Section 2.5.1:

Regional Geology: In meeting the requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17, 10 CFR 52.79 and 10 CFR 100.23 (c) and guidance in RGs 1.206, 1.208 and 4.7, the description of regional geology is acceptable if a complete and documented discussion is presented for the geologic setting, tectonic framework and conditions caused by human activities, that have the potential to affect the safe siting and design of the plant. This section should contain a review of regional stratigraphy, lithology, structural geology, geologic and tectonic history, tectonic features (with emphasis on the Quaternary period), seismology, geomorphology, paleoseismology, and physiography within the 320 km (200 mi) site region or beyond as necessary to provide a framework within which significance to safety can be evaluated concerning geology, seismology, and conditions caused by human activities. Geologic maps and cross-sections constructed at scales adequate to illustrate relevant regional features should be included in the application.

Site Geology: In meeting requirements of 10 CFR 52.79 and 10 CFR 100.23, and regulatory positions presented in RG 1.208, 1.206, and RG 4.7, the description of site geology is considered acceptable if it contains a description and evaluation of geologic (including tectonic and non-tectonic) features, geotechnical characteristics, seismic conditions, and conditions caused by human activities at appropriate levels of detail within areas defined by circles drawn around the site using radii of 40 km (25 mi) for site vicinity, 8 km (5 mi) for site area, and 1 km (0.6 mi) for site location. In addition, the geologic characteristics should be consistent with appropriate sections from; RG 1.208, and RG 1.206.

2.5.1.4 Technical Evaluation

The applicant incorporated by reference Section 2.5.1 of the ESP SSAR, Revision 9. The staff's technical evaluation of Section 2.5.1 of the ESP SSAR is documented in NUREG-1835.

The staff reviewed Section 2.5.1 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD, Revision 10 and the North Anna 3 ESP SSAR, to ensure that the combination of the DCD, the North Anna 3 ESP SSAR and the COLA represents the complete scope of information related to this review topic.[1]

The staff's review confirms that the information in the COL FSAR and incorporated by reference addresses the required information for geologic characterization information.

The staff's technical evaluation of COL FSAR Section 2.5.1 is limited to reviewing (1) the resolution of DCD COL Item 2.0-26-A and ESP Action 2.5-1; (2) adherence to Permit Condition Section(E)(6); (3) resolution of ESP VAR 2.0-4 and; (4) applicant's responses to RAIs, as addressed below.

COL Items, ESP Variances, and ESP Permit Conditions:

- NAPS COL 2.0-26-A

In accordance with DCD COL Item 2.0-26-A, the applicant provided additional information on the site stratigraphy, engineering geology evaluation, and groundwater conditions as determined from additional subsurface investigations conducted at the North Anna 3 site. This new information presented by the applicant supplements the information in the ESP SSAR and includes additional information and data obtained through the COL site investigations. The staff concludes that the applicant has included sufficient information from subsurface investigations to supplement ESP SSAR Section 2.5.1 and to resolve DCD COL Item 2.0-26-A.

- NAPS ESP COL 2.5-1

ESP COL Action Item 2.5-1 requires the applicant referencing the North Anna 3 ESP to provide additional boring data to identify any weathered or fractured rock that may be beneath the new foundations. In FSAR Section 2.5.1.2.3, the applicant stated that the borings completed for North Anna 3, the logs of which are included in Appendix 2.5.4AA of the FSAR, encountered weathered rock from the elevation of 62.7 to 86.8 m (206 to 285 ft) and again from 56.9 to 89.0 m (187 to 292 ft) and from 53.0 to 84.7 m (174 to 278 ft). The elevations corresponded too moderately to highly weathered Zone III rock, slightly too moderately weathered Zone II-IV rock, and slightly weathered to fresh Zone IV rock, respectively. Because the applicant identified the subsurface elevation where weathered rock occurs beneath the foundations, the staff concludes this information is sufficient to satisfy the requirements of ESP Action Item 2.5-1. Therefore, the staff considers ESP COL Action Item 2.5-1 to be resolved.

- ESP Permit Conditions 3.E(4) through 3.E(6)

Three permit conditions were identified in the ESP SER and summarized in Section E to Part 3 of the ESP. Permit Condition 3.E(4) requires the replacement of weathered and fractured rock at the foundation level with lean concrete before the initiation of foundation construction. The applicant stated in FSAR Section 2.5.1.2.6 that weathered or fractured rock encountered at the site will be excavated and replaced with lean concrete. The staff concluded that this planned action, in addition to the excavation plans summarized in SER Section 2.5.4.2.10, is acceptable and meets the criteria in Permit Condition 3.E(4).

Permit Condition 3.E(5) prohibits the applicant from using engineered fill with high compressibility and low maximum density, such as saprolite, in the construction of North Anna 3. FSAR Section 2.5.1.2.3 states that “engineered fill such as saprolite, will not be used as engineered fill to support or backfill seismic Category I or II structures.” The staff reviewed additional excavation and backfill plans in FSAR Section 2.5.4 and determined that the plans do not include the use of high compressibility and low maximum density materials such as engineered fill to support any seismic Category I or II structures.

Permit Condition 3(E)(6) requires the applicant to provide geologic mapping information for future excavations of safety-related structures and to evaluate any unforeseen geologic features that are encountered. The applicant is also required to notify the NRC no later than 30 days before any such excavation is open for NRC examination and evaluation. An applicant for a construction permit (CP) or COL referencing this ESP shall perform geologic mapping of any excavation for a safety-related structure, evaluate any unforeseen geologic features that are encountered, and notify the NRC no later than 30 days before any such excavation is open for NRC examination and evaluation. This permit condition has been carried forward as a license condition for future excavations of safety-related structures (Section 2.5.1.4, this report).

The North Anna 3 COL FSAR Section 2.5.1, “Basic Geologic and Seismic Information,” incorporates by reference the North Anna 3 SSAR Section 2.5.1. The staff reviewed the COL FSAR variance to the ESP SSAR (North Anna 3 ESP VAR 2.0-4) for the North Anna 3 FSAR Section 2.5.1 and submitted several RAIs. The staff's evaluation of this variance to the ESP SSAR in COL FSAR Section 2.5.1 and of the COL applicant's responses to staff RAIs is presented below.

Basic Geologic and Seismic Information

The COL FSAR Section 2.5.1, and by reference the ESP SSAR Section 2.5.1, includes newly published information and the recent geologic, seismic, geophysical, and geotechnical investigations conducted for North Anna 3. This includes information on the **M**5.8 earthquake that occurred on August 23, 2011, in Mineral, Louisa County, Virginia, and the results of the geological field reconnaissance program (FSAR Section 2.5.1.1.7b) to investigate any surface features associated with the earthquake in the site vicinity. In COL FSAR Section 2.5.1, Basic Geologic and Seismic Information, the COL applicant stated that they contacted the USGS, State geological survey organizations, and universities and identified relevant unpublished geologic literature, studies, and projects. Since a large part of this new information on the effects of the Mineral earthquake is not yet in peer reviewed publications, staff asked the applicant in RAI 02.05.01-1 dated April 22, 2014 (ADAMS Accession No. ML14112A156), to provide further details regarding research by others and to explain how they have considered the findings and interpretations of others in their characterization of the CVSZ and the effects of the Mineral earthquake.

In a May 21, 2014 response to RAI 02.05.01-1 (ADAMS Accession No. ML14143A239), the COL applicant provided a list of persons contacted within various organizations and a summary of the topics that were discussed. The COL applicant attended professional conferences, visited USGS and the Virginia Department of Mines, Minerals and Energy (DMME) offices and talked with geoscientists who were actively collecting and analyzing data from the Mineral earthquake including assessment of aftershock data, LiDAR analyses, geologic mapping and trenching, and investigation of liquefaction sites. This information guided the COL applicant in its own geologic reconnaissance of the epicentral area. The COL applicant used aftershock data analysis by M. Chapman of Virginia Tech to direct the field team to areas where surface effects from the Mineral earthquake would most likely have occurred. LiDAR data covering the epicentral area was subsequently obtained from interstate 64 to the northeast shore of Lake Anna. The COL applicant reviewed and compared various mapping products from USGS, DMME and NC State University researchers, included information from the ESP application and incorporated the information into the Geologic Reconnaissance Report. Key elements of the Geologic Reconnaissance Report are included in the revised FSAR Section 2.5.1 because of FSAR revisions made by the COL applicant in various RAI responses (RAI 02.05.01-4, 5, 02.05.01-8). The COL applicant provided a summary of the geologic reconnaissance program in FSAR Section 2.5.1.1.7b and c.

The staff reviewed the COL applicant's RAI response and also talked with geoscientists presenting recent research on the effects of the Mineral earthquake at the GSA southeastern section meeting in Blacksburg, VA, March 2014. In addition, staff audited the COL applicant's Geologic Reconnaissance Report in Frederick, MD on March 11, 2014. The staff's audit summary is available in ADAMS Accession No. ML14203A211. The Geologic Reconnaissance Report includes a compilation and evaluation of published information, communications with other researchers, and a geomorphic evaluation of LiDAR data acquired by Dominion for this project related to the potential for surface deformation in the site vicinity for North Anna Power Station North Anna 3. Based on the RAI response, staff's own contact with active investigators and staff's audit of the COL applicant's Geologic Reconnaissance Report, staff acknowledges that the COL applicant reached out to known active investigators to capture the breadth of scientific understanding currently available for the geologic effects of the Mineral earthquake. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-1 resolved and closed.

Regional Tectonic Setting

In FSAR Section 2.5.1.1.4, Regional Tectonic Setting, the COL applicant describes the orientation of tectonic stress in the site region. The staff notes that Mazzotti and Townend (2010) determined that the principle horizontal stress direction in the CVSZ is essentially east to west, rotated 48 degrees clockwise from the regional northeast to southwest stress direction. In RAI 02.05.01-2 dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to provide a discussion regarding the current local stress field within CVSZ and the focal mechanisms of the Mineral earthquake and aftershocks and the impact on suitably or susceptibly oriented faults in the area.

In a May 21, 2014, response to RAI 02.05.01-2 (ADAMS Accession No. ML14143A239), the COL applicant stated that the recently revised world stress map indicates an overall NE-SW maximum horizontal compressive stress orientation throughout the eastern and central US (Hurd and Zoback, 2012). This was based on borehole breakout tests and hydrofracturing, and to a lesser extent on earthquake focal mechanisms. The COL applicant stated that for the CVSZ specifically, Mazzotti and Townend (2010) based their findings on 13 earthquake focal mechanisms. Hurd and Zoback (2012) also report an E-W direction to stress for the CVSZ. The COL applicant concluded that this is strong corroborating evidence that the E-W stress field is real and deviates from the regional NE-SW stress direction. The E-W stress field is more consistent with the Mineral earthquake data than the regional NE-SW stress field. For the focal mechanisms of the Mineral earthquake, the COL applicant cited McNamara et al. (2014) who found that locations and focal mechanisms from the Mineral earthquake and aftershocks indicate a rupture plane striking approximately N36 degrees E, dipping 49 degrees ESE, with a reverse slip focal mechanism. The COL applicant stated that other NE to SW oriented structures, aligned with the regional tectonic fabric, are thus favorably oriented for reactivation within the local stress field.

The staff considered the RAI responses and reviewed the findings of Mazzotti and Townend (2010) and Hurd and Zoback (2012). The staff agrees with the COL applicant's conclusions in that the local stress field is consistent with the character of the Mineral earthquake and that other NE-SW striking structures are favorably oriented for reactivation in this area. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-2 resolved and closed. The COL applicant provided a proposed COL revision to include portions of the RAI response in a future revision of the North Anna 3 FSAR. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5.01 from the staff's advanced SER for North Anna 3 is resolved and closed.

Central Virginia Seismic Zone

The COL applicant stated in the section on the CVSZ, that researchers who investigated the epicentral area immediately following the 2011 Mineral earthquake describe several liquefaction features generated by the earthquake. In RAI 02.05.01-3 dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to provide additional details regarding these recent features as well as the paleoliquefaction features documented by Obermeier and McNulty (1998), all within 30 miles of North Anna 3. The staff asked the COL applicant to discuss the possible impact to the SSC of the eastern part of the CVSZ in light of new age determinations on the paleoliquefaction sites.

In a June 23, 2014, response to RAI 02.05.01-3 (ADAMS Accession No. ML14177A441), the COL applicant explained that immediately following the August 23, 2011, Mineral earthquake, an Earthquake Engineering Research Institute (EERI) Geotechnical Extreme Events Reconnaissance (GEER) team of engineers and geologists initiated a regional ground reconnaissance program and identified two sites along the South Anna River where liquefaction occurred (EERI 2011) (Yancey-3 & BOR-2 sites). The COL applicant plotted the locations on high-resolution topographic hill shade maps derived from LiDAR data to show the local geomorphic context for these sites. Both these sites are within the 25-mile radius of North Anna 3.

The Yancey-3 site is located within the incised South Anna river channel near the intersection of Yanceyville and Vigor Roads and the South Anna River. These sand boils are small and the ejected material is described as well-graded sand with silt and gravel (Green et al., 2014). The Bor-2 site is about 3 km northwest of the Yancey-3 site, in a tributary channel of the South Anna River. Material ejected is described as silt. The EERI team reported that even though the sand boils resulted from liquefaction, the material properties, stratigraphy and liquefaction source zone were less than ideal. The COL applicant stated that given the magnitude and period of the Mineral earthquake, widespread liquefaction would not be expected.

The applicant also provided information about 3 paleoliquefaction sites that lie just beyond the site vicinity (Obermeier and McNulty, 1998) and a new figure (FSAR Figure 2.5.1-225) showing the locations of both the paleoliquefaction and the Mineral earthquake liquefaction sites relative to North Anna 3. The paleoliquefaction sites that are located on the James, Rivanna, and South Anna Rivers reveal a few small clastic dikes in riverbank deposits. Radiocarbon dates for the James River site indicate an age of a few hundred years. The other sites might be early to late Holocene age based on the severe weathering of the clastic dikes. Recent radiocarbon and Optically Stimulated Luminescence dates suggest ages between 2,000 to 900 years before present (Harrison et al., 2014). These dates were presented in conference and the specific context of the samples could not be evaluated with respect to previous dates. The COL applicant concluded that both the paleoliquefaction and the recent liquefaction sites are consistent with a local moderate-magnitude earthquake, similar to the 2011 Mineral earthquake.

The staff considered the information and maps provided in the RAI response and notes that the Mineral earthquake would not likely cause widespread, numerous liquefaction features based on the size of the earthquake and the lack of ideal liquefaction conditions in the region. The staff also reviewed the information in the Obermeier and McNulty (1998) publication. The staff agrees with the COL applicant’s conclusion that the paleoliquefaction features likely reflect moderate-size earthquakes, possibly similar to the Mineral earthquake. The staff notes that the North Anna 3 and the CVSZ are located in the ECC-AM host zone of the CEUS-SSC model that includes a large Mmax distribution for the zone and recurrence parameters derived from the historical seismicity. The staff thus concludes that the CEUS-SSC adequately captures the current understanding of the CVSZ. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-3 resolved and closed. The COL applicant provided a proposed COL revision to include portions of the RAI response in a future revision of the North Anna 3 FSAR. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore Confirmatory Item 2.5-02 from the staff’s advanced SER for North Anna 3 is resolved and closed.

Mineral Virginia Earthquake

In COL FSAR Section 2.5.1.1.7, the staff reviewed new information regarding the 2011 Mineral Virginia Earthquake. The COL applicant stated that up-dip surface projections of aftershock data (now called Quail fault) served as a guide for geologic field reconnaissance to determine the possibility of surface deformation caused by the Mineral 2011 earthquake (Figure 2.5.1-2). In RAI 02.05.01-4a dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to comment on the uncertainty of the surface projection of the geophysical data and discuss other clusters of aftershocks located to the northeast of the main cluster that might align with other structures. The staff also asked the COL applicant regarding other possible expressions of surface deformation, such as deformation expressed as an uplifted area in the hanging wall of the Quail fault.

In a June 10, 2014, response to RAI 02.05.01-4a (ADAMS Accession No. ML14162A436), the COL applicant stated that the field program focused on evidence for surface deformation in the epicentral area and the possible surface rupture zone. The surface rupture trace is one possible zone and was used as guide for field and remote sensing investigation. The COL applicant used information from McNamara et al. (2014) that provides a catalog of 365 aftershocks. The map of aftershock data reveal three discrete clusters of concentrated seismicity surrounded by a broader region of diffuse seismicity. The largest cluster contains the main shock. The staff notes that many investigators evaluated these data and proposed best-fit planes, which are intended to represent the location and geometry of the Mineral earthquake source. Horton et al. (2012, 2015) name the large cluster with the main shock, the Quail fault. The COL applicant focused their field program in the area where this fault projects to the surface as well as in the epicentral area (Figure 2.5.1-4). The Quail fault rupture plane is approximately 10 km long, 6 km wide, strikes N30E, and dips SE 45-55 degrees at depths from 8 to 2 km.

The COL applicant stated that the other subsidiary clusters lie east of the main cluster, typically contain aftershocks with local magnitudes of 2.6 or less, and are located at shallow depths less than 4 km. No studies available at this time have defined rupture planes or characterized potential sources from these subsidiary clusters. Also, McNamara et al. (2014) describe only one focal mechanism for aftershocks outside the main cluster, and its orientation is significantly different than those of the main cluster. The COL applicant stated that these subsidiary clusters of aftershocks do not appear to be structurally linked with the main aftershock plane and likely represent minor triggered slip on multiple, minor shears of limited extent in a zone of otherwise highly deformed bedrock. The COL applicant provided an enhanced map and cross section of the McNamara et al. (2014) aftershock data with labels to indicate the location of known surface faults, focal plane mechanisms, and the projection of the rupture plane to the surface with uncertainty zones (Figure 2.5.1-2).

Based on the staff's examination of aftershock locations and in consideration of modeled best fit planes (Horton et al., 2015), the staff concludes that surface deformation associated with the Mineral earthquake would most likely be found in the surface projection zone defined by the main aftershock cluster, and within the boundaries of the COL applicant's field reconnaissance program. The staff also agrees with the COL applicant that fitting a plane to subsidiary aftershock clusters is inappropriate due to the diffuse distribution of hypocenters and the lack of focal mechanisms to constrain rupture orientation. The staff examined the waypoint stations and the extent of the stream profile evaluation and considered the analysis of aftershock data reported in McNamara et al. (2014). The staff determined that the scope of the field program covered the fault zone surface projection as well as the hanging wall area located above the epicentral area and concluded that this was the appropriate focus given the published aftershock data. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-4a resolved and closed. The COL applicant provided a proposed COL revision to include portions of the RAI response in a future revision of the North Anna 3. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5-03 from the staff's advanced SER for North Anna 3 is resolved and closed.

Chopawamsic Fault

The COL applicant concluded, in COL FSAR Section 2.5.1.1.7, that the Chopawamsic fault is the nearest mapped structural surface to the projected surface expression of Quail fault on which a fault could be located and is a possible candidate for the causative fault for the Mineral earthquake. The staff notes that there are issues and recent changes to the mapped traces of faults in this area including the Chopawamsic fault. In RAI 02.05.01-4b dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to provide more details regarding the location of the Chopawamsic fault.

In response to RAI 02.05.01-4b dated June 10, 2014 (ADAMS Accession No. ML14162A436), the COL applicant provided a revised history of mapping in the area and focused on the most recent mapping of Hughes and Hibbard, 2012 and (Burton et al. 2014) that place the Chopawamsic fault further northwest of previous interpretations. The staff notes that the

Chopawamsic fault, therefore, is most likely structurally below the aftershock cluster and the rupture plane of the Mineral earthquake and is not a source candidate for that earthquake.

Based on analysis of LiDAR based slope and relief maps, the COL applicant describes a NW facing and a SE facing pair of topographic scarps bounding the neck region of the Ellisville pluton, where granodiorite is in contact with the Chopawamsic Formation. (Burton et al. 2014) interpret both these contacts to be faulted and named the fault along the NW facing scarp the Harris Creek fault. The COL applicant suggests that the topographic scarps are likely an expression of erosion susceptibility differences between the granodiorite and the Chopawamsic Formation (metavolcanic, felsic to mafic compositions) rather than a tectonic expression. The applicant, using geologic and LiDAR derived elevation maps, points out that where the lithologic units divert from the trace of the fault, the scarp follows the lithologic contacts rather than the fault.

The staff notes that the NW facing topographic scarp is more or less coincident with the newly identified Harris Creek and Roundabout Farm faults and the surface projection of the Mineral earthquake rupture plane. The staff also note that the maps and figures (RAI 2.05.01-4b response, Figures 5A, 5B, and 6) provided for explaining the erosion susceptibility differences did not clearly support the observations stated in the text and that other interpretations were possible. Therefore, in a supplemental RAI 02.05.01-8 dated August 1, 2014 (ADAMS Accession No. ML14283A557), the staff asked the COL applicant to provide clarification and further justification that this is not a neotectonic signature in the landscape.

In a September 30, 2014, response to RAI 02.05.01-8a (ADAMS Accession No. ML14274A303), the COL applicant stated that the Harris Creek fault is largely coincident with the northwest-facing topographic scarp along approximately 10 km of the fault's mapped extent. The COL applicant provided several new figures (RAI response 02.05.01-8a, Figure 1B, 2A, 2B, 3A, and 3B) that illustrate the expression and extent of the topographic scarp and the geologic traces of the Harris Creek fault and Roundabout Farm faults. The staff observes, in the new figures, that the Harris Creek fault places Ellisville pluton granodiorite alongside Chopawamsic Formation for most of its extent and that the Harris Creek fault extends beyond or bifurcates from the topographic scarp to the SW and to the NE along the fault trace. There is a notable difference in erosion resistance between the granodiorite and the Chopawamsic formation lithology. The neck region of the Ellisville pluton is highly foliated (Burton et al., 2012) and susceptible to weathering and erosion whereas the Chopawamsic Formation, which includes mylonite, metafelsite, quartzite and schist, is more resistant to erosion. The Chopawamsic quartzite and schist (Ocqs map unit, Figure 2.5.1-3) is a relatively resistant unit within the Chopawamsic Formation and forms a series of linear ridges and topographic in the epicentral area. The COL applicant pointed out that the lineament, as characterized over most of its length, does not extend beyond Beaver Creek. The alignments of short, discontinuous and subtle landforms (i.e., ridges, spurs, small drainages) northeast of Beaver Creek do not match the continuity and prominence of the topographic scarp to the SW and are not coincident with the mapped trace of the Harris Creek fault. The staff notes that this difference is illustrated in RAI 02.05.01-8 dated August 1, 2014 (ADAMS accession No. ML14283A557), Figures 3A and 3B.

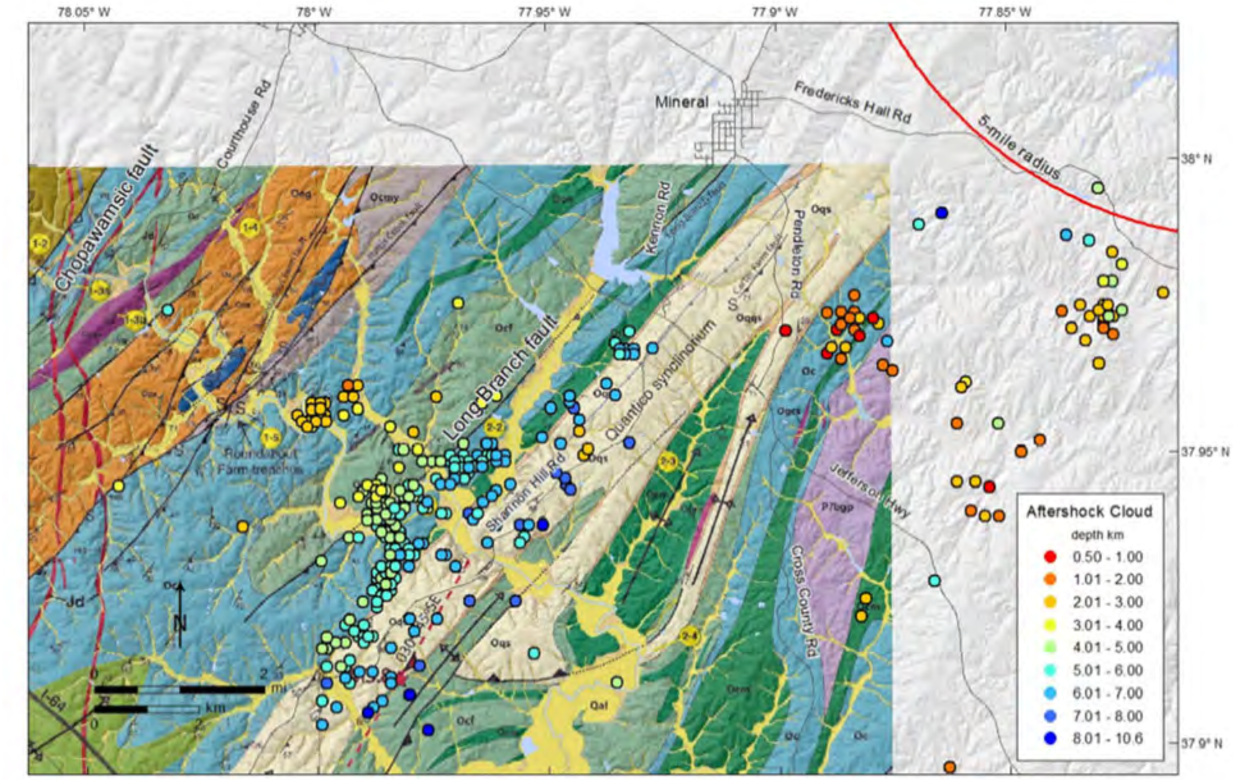

Figure 2.5.1-3. Recent geologic map (Burton et al. [2014]) and aftershocks (McNamara et al. 2014) in the 2011 Mineral, VA, earthquake epicentral area within 25 miles of the NAPS site (from FSAR Figure 2.5.1-210C, Rev. 9)

In supplemental RAI 02.05.01-8 dated August 1, 2014 (ADAMS Accession No. ML14283A557), the staff also asked the COL applicant for additional information regarding the tectonic significance high relief values concentrated in the up-dip projection of the Quail fault and the epicentral area in general as illustrated in Figure 6 of previous response to RAI 02.05.01-4, Part B.

In response, the COL applicant provided new map figures to provide a basis for their analysis regarding surface deformation related to the Mineral earthquake. Figure 2.5.1-5 shows a newly derived relief map using a linear color ramp to symbolize the local relief value across the epicentral area and to the NE, closer to North Anna 3. The staff notes that, in the area around the Ellisville pluton neck, high to low relief boundaries closely correspond to geologic map unit contacts. This supports the COL applicant's suggestion that the steep relief gradients are related to lithologic difference between map units rather than subtle tectonic uplift related to shallow earthquakes. The Chopawamsic Formation, to the NW and SE of the Ellisville pluton neck, is more erosion resistant than the Ellisville and, therefore, supports higher elevation and higher relief zones. In addition, staff notes, that the South Anna river system crosses the same geologic contacts by the Elllisville neck and the Mineral earthquake epicentral area. The river is a significant erosional agent in the area and lowers elevations in its basin but also contributes to the development of high local relief within its basin (Compare Figures 2.5.1-5 and 2.5.1-6). The staff also notes that high relief values diminish to the NE, near the basin divide between the South Anna and the North Anna river systems. The most continuous areas of low relief can be found along prominent drainage divides and areas of higher elevation, which represent areas farthest removed from the increased erosion rates associated with trunk streams. The staff agrees with the COL applicant that the landscape revealed in the new relief and elevation maps supports the interpretation that erosion rates increase toward the trunk of major drainages, and this enhances differential erosion rates associated with variable lithology. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-8a resolved and closed.

The COL applicant stated that the FSAR would be updated to reflect aspects of this response. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5-04 from the staff's advanced SER for North Anna 3 is resolved and closed.

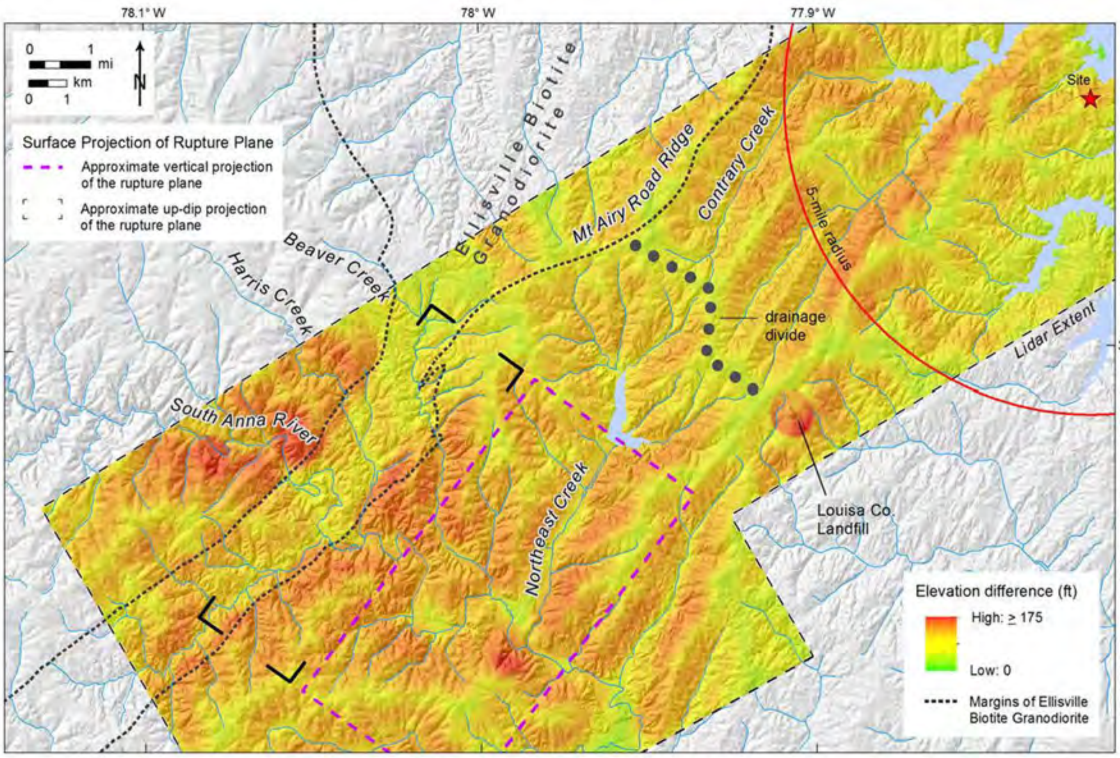

Figure 2.5.1-5. LiDAR-Derived Relief Map of the 2011 Mineral, VA, Earthquake Vicinity (from FSAR Figure 2.5.1-212A, Rev 9). Relief is represented as elevation difference within 0.5 km. The margin of Ellisville Biotite Granodiorite based on Burton et al. (2014) and Dicken et al. (2005)

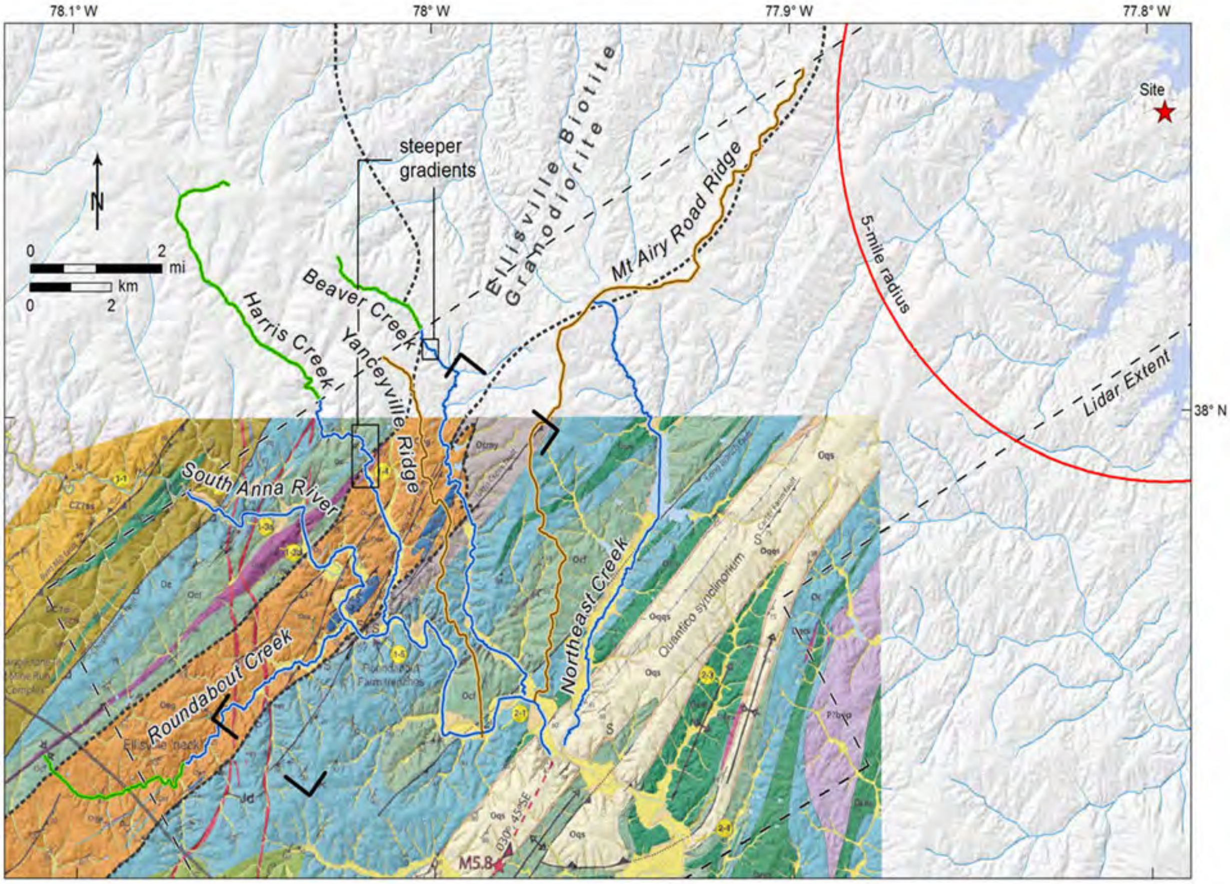

Figure 2.5.1-6. Stream and Ridge Topographic Profiles from FSAR Figure 2.5.1-216, Rev 9.0. The four brackets denote the approximate up-dip projection of the aftershock plane (Quail fault). Blue and green lines indicate locations of stream profiles from LiDAR and NED data, respectively. Brown lines indicate locations of profiles on ridgeline topographic profile

Long Branch Fault

The COL applicant stated that the Long Branch fault (LBF) as currently mapped is too far to the east of the surface projection of the Mineral earthquake rupture plane and thus dismiss it from consideration as an active structure in the Mineral earthquake. The staff notes that there are issues and recent changes to the mapped trace of the LBF. At least two groups of geoscientists have suggested the LBF might be an active structure in the Mineral EQ: Hughes and Hibbard (2012), and Harrison et al. (2011). In RAI 02.05.01-4c dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to discuss the relevance of the suggestions of other geologists regarding the SW extension of the LBF and the potential of LBF in conjunction with the geophysical data from the Mineral earthquake to have been active during this earthquake.

In a June 10, 2014, response to RAI 02.05.01-4c (ADAMS Accession No. ML14162A436), the COL applicant reviewed the geologic mapping of (Burton et al. 2014); Hughes and Hibbard (2012); Dicken et al. (2005); and Marr (2002). The LBF is not consistently located between these publications. However, the most recent mapping (Burton et al. 2014), mapped at 1:24,000, indicates the LBF strikes N35E, and is assumed to be dipping to the 40 to 50 degrees SE, congruent with foliation in the Chopawamsic Formation subunits. The COL applicant indicated that regardless of the specific interpretation for the location of LBF, all interpretations place the fault above deep aftershocks; therefore, the fault is structurally higher than the rupture plane of the Mineral earthquake and is not likely an active structure in the Mineral earthquake. The COL applicant added that there is no alignment of aftershock data in the main or subsidiary clusters that align with previously identified faults ‘a’ and ‘b’ in the North Anna 3 site area.

The COL applicant also stated that, based on the new mapping, the Chopawamsic fault is about 5 km northwest of the projected rupture plane (refer to previous RAI 02.05.01-4b) and the LBF is about 5 km southeast of it, placing the rupture plane of the Mineral earthquake in between these two faults in the subsurface. The COL applicant also pointed out that prior to the recent detailed geologic mapping (Burton et al., 2014), there were no faults previously mapped in the up dip projection of the Mineral earthquake rupture plane.

The COL applicant reviewed the LiDAR data and found a variety of topographic lineaments collinear with the southern extension of the LBF, consistent with the Burton et al. (2014) geologic map. However, the COL applicant interpreted this topographic expression to be bedrock structure exerting strong control on landscape morphology rather than geologically recent faulting.

The staff considered the COL applicant’s response and independently reviewed the geologic mapping of the LBF included in publications (Burton et al., 2014; Hughes and Hibbard, 2012; Dicken et al., 2005; and Marr, 2002) and concluded that, regardless of the particular investigator’s interpretation of the location of the LBF, the fault in all cases directly overlies deep aftershocks and must be structurally higher than the rupture plane of the Mineral earthquake. Therefore the fault is unlikely to be the seismic source of the Mineral earthquake. The staff notes that the earlier mapping efforts were completed at scales of 1:100,000. The most recent mapping completed by (Burton et al. 2014), was done at a 1:24,000 scale, which provides more detail or more resolution than the others and might be the most accurate geologic map of this structure to date. The staff concludes that current data indicate the LBF is not structurally involved with the Mineral earthquake rupture. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-4c resolved and closed. The COL applicant stated that a COL revision, that will include portions of this RAI response, will be included as part of the response to RAI 02.05.01-5 in a future revision of the North Anna 3 FSAR. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5-05 from the staff’s advanced SER for North Anna 3 is resolved and closed.

Geologic Reconnaissance Program

FSAR Section 2.5.1.1.7(b), Geologic Reconnaissance, provides information regarding the field reconnaissance program completed to evaluate potential surface deformation associated with the Mineral earthquake. The FSAR placed a special focus on the up dip projection of the Quail fault, evaluation of geomorphic features in the epicentral landscape, and a field map with routes and waypoints (Figure 2.5.1-4). The details of the field reconnaissance are reported in the Geologic Reconnaissance Report that staff audited on March 11, 2014. The summary of the staff’s audit can be reviewed in (ADAMS Accession No. ML14203A211). The COL applicant provided a summary of the geologic reconnaissance program in FSAR Section 2.5.1.1.7b and c. The report addressed the question of whether the August 23, 2011, Mineral earthquake did or did not cause surface faulting or surface deformation. The report detailed geologic field reconnaissance and geomorphic analyses performed using high-resolution LiDAR elevation data in the region of the August 2011 **M**5.8 Mineral, Virginia, earthquake’s epicentral region specifically acquired by Dominion for this field program. The report also included a compilation and evaluation of published information, communications with other researchers, all related to the potential for surface deformation in the site vicinity for North Anna Power Station North Anna 3. The staff issued an RAI relevant to the information found in this report. Thus in RAI 02.05.01-5 dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to provide additional details about the data analysis and the field program including:

a) At each waypoint, what was examined and what is its significance.

b) Provide a high resolution LiDAR map (scale ~1:10,000) for areas immediately west of North Anna 3 where fault ‘a’ might be located, such as waypoint sites 23, 24, and 25.

c) Discuss longitudinal stream profile analysis completed in the epicentral area. Discuss any anomalies revealed by this analysis that could indicate subtle tectonic deformation in the hanging wall of the Quail fault, such as gradient changes, offset stream terraces, elevated topography.

d) Explain how you evaluated the Quaternary geology of the epicentral area and the distribution, correlation and elevation of river terraces on the South Anna River. Discuss any indication of subtle surface uplift in river terraces on the hanging wall of Quail fault that might indicate prolonged or repeated surface deformation.

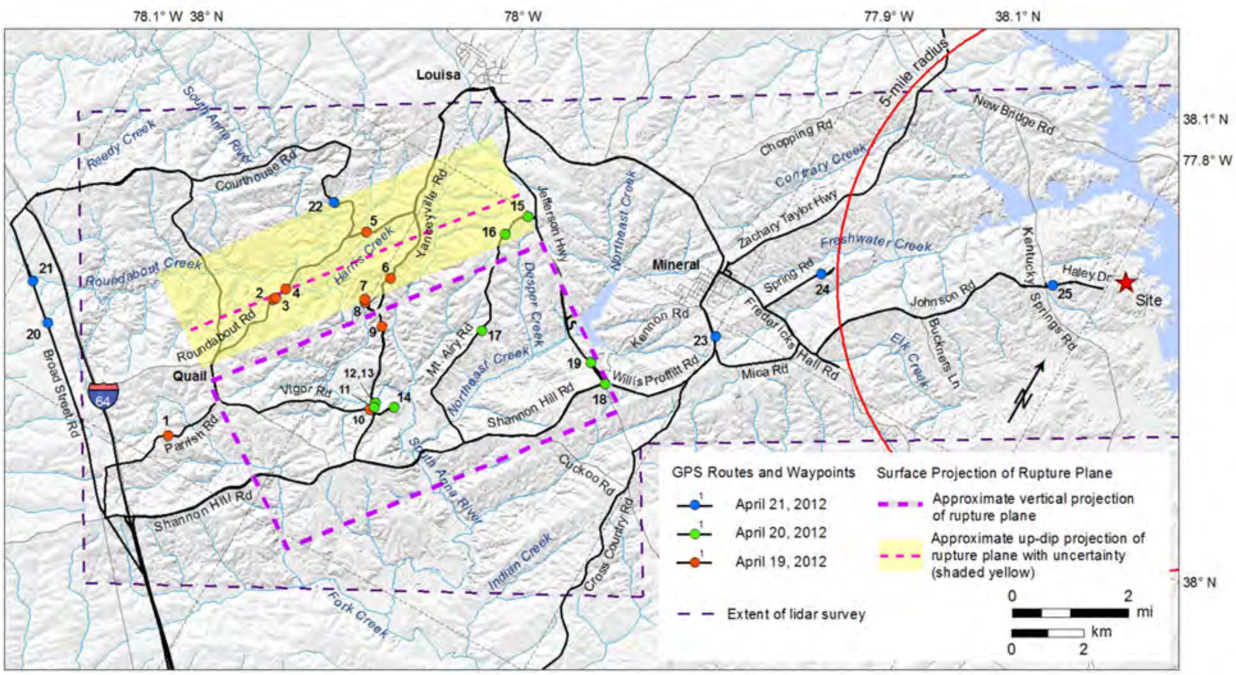

Figure 2.5.1-4. NAPS Geologic Field Reconnaissance after the 2011 Mineral, VA, earthquake showing traverse routes, waypoints and the LiDAR survey boundary (from FSAR Figure 2.5.1-204, Rev. 9)

In a June 10, 2014, response to RAI 02.05.01-5a and b (ADAMS Accession No. ML14177A441), the COL applicant provided a table with details for the significance of each waypoint visited during the field reconnaissance program. Observations at some of the waypoints confirm structural, geomorphic features or relationships previously published by others or observed by Dominion. The staff notes in particular that Waypoint 25, located just outside the plant boundary, is along the extended strike of fault ‘a’, as mapped by Mixon et al. (2000). The waypoint is located on a flat, broad ridge crest, with a deeply weathered soil profile. This ridge crest is likely one of the more stable landforms in this area and useful to evaluate potential deformation or activity on fault ‘a’. The COL applicant provided several detailed LiDAR-based elevation panels of the waypoints they examined to evaluate the possible extent of fault ‘a’. The staff notes that there are no anomalous features revealed in the detailed LiDAR-based elevation panels to indicated surface faulting or deformation. The COL applicant pointed out that the lack of expression of fault ‘a’ in this area support previous studies that determined fault ‘a’ to be pre-Quaternary.

During the May 8, 2014, site audit, as summarized in (ADAMS Accession No. ML14203A179), the staff visited several waypoint stations to fully understand how the LiDAR and field reconnaissance were used to verify geologic features, map contacts and geomorphic landforms. The staff talked with geologists David Fenster (Bechtel, Dominion contractor) and Scott Lindvall (LCI, Bechtel contractor) regarding the extent of fault ‘a’ across Lake Anna to the northeast and further to the southwest with respect to the locations of the 1970’s Dames and Moore exploratory trenches 1 through 3. The staff toured the site vicinity to examine the geomorphic landforms and geologic characteristics of the site vicinity especially with respect to possible surface deformation related to neotectonism in the site vicinity. The staff examined upland surfaces near the possible extension of fault ‘a’, at waypoint 25, and observed no evidence of anomalous deformation. The staff visited exposures of crystalline rock near the Chopawamsic fault and the Ellisville pluton neck and noted the foliation in the granodiorite. The staff also visited the possible exposure of the southeastward extension of the LBF and the location of the small, limited liquefaction related to the Mineral Virginia earthquake. The staff was able to verify the significance of the waypoint stations that the COL applicant examined within their field reconnaissance program after the Mineral earthquake. The staff also determined that the scope of the field reconnaissance was focused in the area where we would expect to see possible effects of the Mineral earthquake on the landscape.

In a June 23, 2014, response to RAI 02.05.01-5c and d (ADAMS Accession No. ML14177A441), the COL applicant provided a figure to indicate the five stream profiles derived from LiDAR data and discussed the analysis of longitudinal stream profiles in the epicentral area to determine if subtle anomalies in the profiles indicate possible surface deformation from the Mineral earthquake (Figure 2.5.1-7). Most profiles were vertically exaggerated 25 times. The analysis revealed several subtle anomalies such as gradient changes and knick points that could be related to many geologic conditions or processes but none that could unequivocally be attributed to tectonic deformation in the hanging wall of the Quail fault. The staff examined the stream profiles and agrees that the profiles show well-graded streams and that anomalies are observable only at great vertical exaggeration. The COL applicant concluded that there is no consistent relationship of anomalies in streams crossing the up-dip projection of the Mineral earthquake rupture plane. However, the COL applicant stated that there is a consistent relationship between lithology changes and stream profile anomalies.

In describing the South Anna River, the COL applicant suggested that, in addition to lithology changes along the stream profile, large increases in drainage area at the confluence of Roundabout, Harris, and Beaver Creeks likely drive a noticeable gradient change along that stretch of river. A dramatic increase in drainage area impacting a river implies an increase in stream power, which governs the ability of the river to incise its channel and modify the gradient. However, staff notes that it is not possible to verify that statement based on the figures provided. Therefore, in supplement RAI 02.05.01-8c dated August 1, 2014 (ADAMS Accession

No. ML14283A557), the staff asked the COL applicant for further clarification on the analysis of stream profiles and changes in stream power along the course of South Anna River.

In a September 30, 2014, response to RAI 02.05.01-8c (ADAMS Accession No. ML14274A303), the COL applicant stated that a subtle gradient change lies near a 20 percent increase in drainage area due to confluences of Roundabout and Harris Creeks, and upstream of a 17 percent increase in drainage area due to confluences of Beaver and Northeast Creeks and provided a new figure for the South Anna River profile with drainage area increases (RAI 02.05.01-8 Figure 11). The staff notes that Dominion considered and performed additional assessments on some profiles, such as stream gradient (SL) index (Hack, 1957), slope versus distance, and drainage basin versus distance (for South Anna River only) but these methods did not provide useful results for evaluating the subtle anomalies due in part to the extremely low gradient of the streams and the high-frequency (HF) data noise (Figure 2.5.1-8).

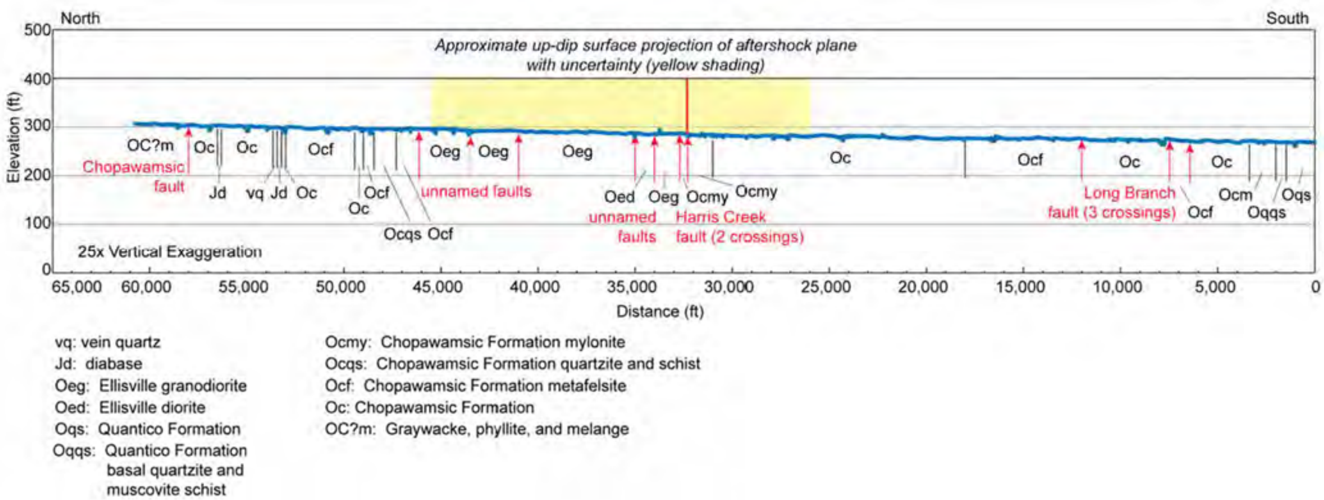

Figure 2.5.1-7. South Anna River Profile Showing Geology of Burton et al. (2014) from FSAR Figure 2.5.1-223, Rev. 9

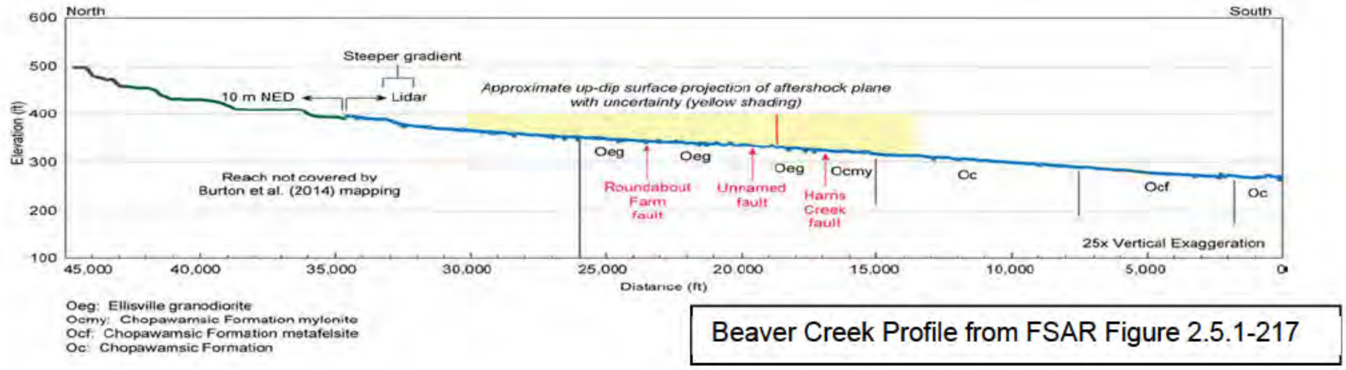

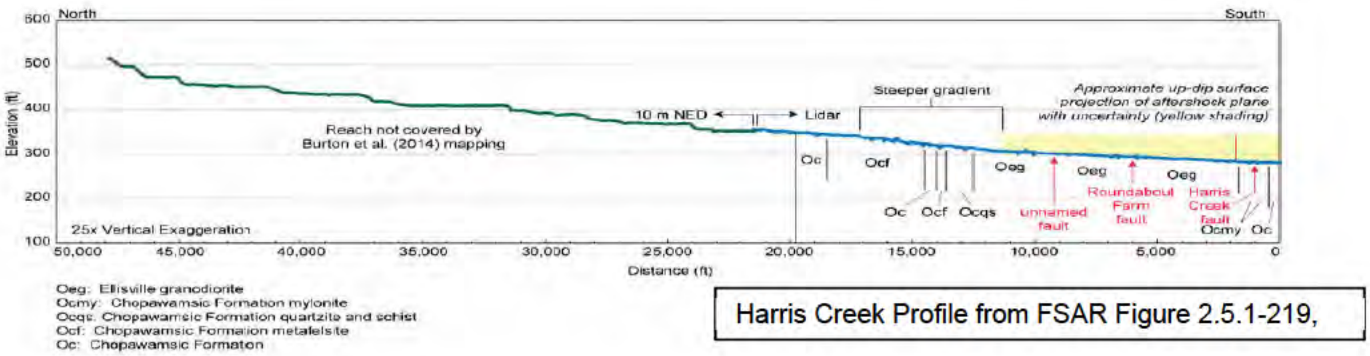

Figure 2.5.1-8. Stream Profiles with Geology of Burton et al. (2014) from FSAR Figure 2.5.1-217 and -219, Rev. 9

The stream profile analysis also reveals a series of possible river terraces along South Anna River. The river terraces were identified in the LiDAR data products but were not evaluated in the field program. The COL applicant stated many geologic conditions and processes could be in operation to drive river incision and the development and preservation of terrace surfaces such as: climate change, stream capture, changes in sediment influx, eustatic sea level change, and tectonic activity. The LiDAR data reveal several possible terrace surfaces along the South Anna River, and the COL applicant plotted representative elevation points along the South Anna River profile. The COL applicant stated that they have not correlated terrace sets along the profile. The staff notes that terraces are more abundant downstream of the surface projection of the Mineral earthquake rupture plane, at greater heights above the channel than in the upstream reach and also along the low-gradient reach of the river. This is the same reach of river where there is a sharp increase in stream drainage area. The COL applicant stated that an increase in drainage area increases the river's capacity to incise its channel and to keep pace with the impacts imposed by any of the geologic conditions or processes previously mentioned. Therefore, staff concludes that a greater number of terraces, at greater height above the channel on the low gradient reach of the South Anna River, is expected and does not uniquely indicate tectonic activity.

The staff noted that the geologic map used (assemblage of earlier geologic mapping) for the stream profile analysis is not the same as the more recent geologic map (Burton et al., 2014), used to respond to RAI 02.05.01-4 and features previously discussed such as the Harris Creek and Chopawamsic faults, lithologic contacts, and the topographic scarps are not the same or are not indicated on maps or on the various stream profiles provided in addressing RAI 2.5.1-5c.

Therefore in supplemental RAI 02.05.01-8b dated August 1, 2014 (ADAMS Accession No. ML14283A557), the staff asked the COL applicant to provide clarification and coordination between the discussions for topographic scarps and geologic faults in RAI 2.5.1- 5c with the analysis of stream profiles in RAI 2.5.1-4b.

In a September 30, 2014, response to RAI 02.05.01-8b (ADAMS Accession No. ML14274A303), the applicant stated that the profiles show that streams crossing the epicentral area are all very well graded (smoothly descending curve) and that the profiles do not show significant anomalies associated with the up-dip projection of the Mineral earthquake rupture plane or any of the faults mapped by (Burton et al. 2014), including the Harris Creek fault. The COL applicant provided new figures of these profiles on a geologic base map from (Burton et al. 2014). The staff notes that there are two slight anomalously steep gradients in the stream profiles of Harris and Beaver Creeks. The steep gradients do not correlate with the up-dip projection of the rupture plane, the Harris Creek fault, Roundabout Farm fault, or other faults. They are located on or near the Chopawamsic Formation contact with the Ellisville granodiorite, suggesting a lithologic correlation. The COL applicant stated that the steepened southeast facing gradient is likely not tectonic, because it is inconsistent with deformation produced by a southeast-dipping reverse fault, such as the Mineral earthquake rupture. The staff notes that the higher gradient reach of Harris Creek crosses five lithologic units in close succession, including Chopawamsic metafelsite (Ocf); Chopawamsic Formation undifferentiated (Oc), Chopawamsic metafelsite (Ocf), Chopawamsic quartzite and schist (Ocqs), and Ellisville granodiorite (Oeg) (FSAR Figure 2.5.1-219). The Chopawamsic quartzite and schist represents a relatively resistant unit that forms a series of linear ridges and topographic highs in the area so this characteristic could cause stream gradient anomalies. Based on the new figures and explanation provided by the COL applicant, staff's concerns are addressed. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-8b resolved and closed.

The COL applicant stated that the FSAR will be updated to focus on the two most prominent gradient changes in the profiles, eliminate some of the description of the very subtle features in the profiles that may be beyond the threshold of detection, and to include updated figures showing (1) relief and elevation from the LiDAR and (2) profiles annotated with the Burton et al. (2014) geology. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5-06 from the staff's advanced SER for North Anna 3 is resolved and closed.

Conclusions on Possible Surface Deformation Associated with the Mineral, Virginia Earthquake

Based on the forgoing discussions, the staff concludes that the topographic expression of a portion of the Harris Creek fault and the pattern of local relief in the area is best explained by differential erosion of contrasting lithologies and higher rates of erosion near the South Anna River, rather than neotectonic surface deformation. The staff also concludes that the updated stream profiles with the more recent geologic mapping of Burton et al. (2014) clarifies that only two of the observed river anomalies on Harris and Beaver Creeks are significant, and they are located on or along the major lithologic contact between the Chopawamsic Formation and the Ellisville granodiorite. Some of the potential stream anomalies originally identified are very subtle features and do not represent significant perturbations in the profiles and may in fact be artifacts from the LiDAR generated stream profiles.

Based on the COL applicant's field program in addition to fieldwork reported by USGS and other academic research teams that staff independently reviewed, the staff finds that there is no observable surface deformation associated with the **M**5.8 Mineral earthquake. Thus it is unlikely that any previous repeated events of a Mineral type earthquake in this area would be recorded in the landscape. Finally, staff concludes that larger magnitude events would likely be necessary to produce surface rupture or topographic expression in this landscape.

Site Area Stratigraphy

FSAR Section 2.5.1.2.3, Site Area Stratigraphy, the applicant described borings from the supplemental subsurface investigation described in greater detail in Section 2.5.4.3. In RAI 02.05.01-6 dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the applicant to provide further explanations of site area stratigraphy and subsurface conditions.

In RAI 02.05.01-6a dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant if the severely weathered and jointed intervals in Zone III-IV and Zone IV rock, described in site area borings, indicate the presence of a geologic structure or shear zone. In a June 23, 2014, response to RAI 02.05.01-6a (ADAMS Accession No. ML14177A441), the COL applicant stated that even though these weathered and jointed intervals are found in several borings, no systemic distribution of the zones between borings could be determined; therefore, the zone cannot be mapped. The true orientation of the zones, based on dip of foliation, could not be determined because the core was not oriented. The COL applicant pointed out that several intervals are encountered in each borehole, and the severe weathering was typically found in mafic intervals and the closely spaced, tight joints were found in the felsic, biotite quartz gneiss. Because there was not a systematic distribution of these zones between bore holes and within elevation intervals, the COL applicant concluded there was no indication for a single geologic structure.

The staff reviewed the COL applicant’s response to RAI 02.05.01-6a and also examined core at the North Anna 3 during a site audit conducted May 8, 2014, as documented in ADAMS Accession No. ML14203A179. The staff directly examined portions of several borings (W-1, -2, -3, -4, -5, -6, -7; M-1, M-27, B-905, B-920) to observe the severely weathered and jointed intervals within more competent Zone III-IV and Zone IV crystalline rock, as reported in the FSAR. The staff notes the essentially random distribution of these zones within each core and between cores. In addition, during the field trip portion of the audit, staff visited outcrops of the same rock formation and noted the same pattern of well-weathered intervals of mafic rock within fresher felsic gneiss. The staff agrees with the COL applicant’s position that there is little reason to conclude that this represents a single, mapable geologic structure. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-6a resolved and closed.

In RAI 02.05.01-6b dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant if the micro-shear zone identified in boring W-1, within Zone III-IV rock, is structurally associated with the severely weathered and jointed zone, or if this micro shear is structurally related to fault ‘a’, a previously identified fault and shear zone discovered during construction of Units 1 and 2 (fault ‘a’ observed in excavations for Units 1 and 2 and abandoned Units 3 and 4). In a June 23, 2014, response to RAI 02.05.01-6b (ADAMS Accession No. ML14177A441), the COL applicant replied that it does not think that the micro-shear zone is structurally associated with the severely weathered and jointed intervals discussed above based on the following reasons. The shear zone is found at elevation 210 ft in boring W-1 and at elevation 185.5 ft in boring W-5. In both borings, the shear zone is characterized by rock fragments, an indication of brittle deformation, mixed with yellow-brown clay and chlorite. The COL applicant stated that the material in the zone is characteristic of fault gouge. The COL applicant stated that the micro-shear zone in W-1 and W-5 is not associated with fault ‘a’ Dames and Moore (1973) trenched fault ‘a’ and determined the fault ‘a’ dipped 45 to 50 degrees NW.

Borings W-1 and W-5, located NW of fault ‘a’ would intersect fault ‘a’ at elevations much lower than where the micro-shear zone is located. The COL applicant looked for the micro-shear zone in adjacent borings and found no indication of this feature.
During the May 2014 site audit, as summarized in ADAMS Accession No. ML14203A179, the staff examined the micro-shear zone in W-1 and W-5 to understand the character and extent of the feature with respect to what was described in the FSAR. In the borings, the micro shear is a relatively thin layer. Furthermore, the micro-shear zone is not exposed at the surface in rock exposures in the site vicinity. The staff reviewed several Dames and Moore reports from the 1970’s regarding fault ‘a’ in addition to the findings in the ESP SER regarding fault ‘a’ (NUREG-1835). The micro-shear has similar features to fault ‘a’ but at a much less significant scale. Because the micro-shear zone in W-1 and W-5 is located NW of fault ‘a’ and likely also dips NW, it is structurally higher than fault ‘a’. The staff notes that significant structures such as fault ‘a’ typically have a zone of deformation and deformation fabric is not necessarily limited to a single fault plane so the micro-shear zone could be associated with fault ‘a’. Regardless of a structural association or not, the deformation associated with fault ‘a’ was determined to be geologically old, greater than 1 million years old. The staff considers the micro-shear zone in W-1 and W-5 likely to be the same age as fault ‘a’ and not a potential future surface deformation hazard to the site. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-6b resolved and closed.

The staff reviewed the previous ESP SER and the investigations completed by Dames and Moore in the early 1970’s and notes that North Anna 3 abandoned Units 3 and 4 excavations revealed fault 'a' and that this fault traces across the ESP parameter envelope. In RAI 02.05.01-6 d dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to describe what evaluation it completed to determine the potential for future surface deformation on fault ‘a’ in light of the Mineral earthquake and possible structural links to the Mineral earthquake epicentral area.

In a June 23, 2014, response to RAI 02.05.01-6d (ADAMS Accession No. ML14177A441), the COL applicant stated that Dames and Moore (1973) concluded that fault ‘a’ was pre-Quaternary and not a capable tectonic structure. The COL applicant provided a new figure on a LiDAR hillshade base with key North Anna 3 borings and the trace of fault ‘a’ as mapped by the Dames and Moore and as mapped by Mixon et al. (2000). Mixon et al. (2000) does not place fault ‘a’ at the same location as Dames and Moore. However, Dames and Moore explored the extent and character of fault ‘a’ in 3 onsite trenches so staff considers the Dames and Moore fault trace more accurate. The COL applicant stated that after the Mineral earthquake it initiated a geologic reconnaissance field program and acquired the high-resolution topographic LiDAR data. The purpose was to look for evidence of surface deformation from the Mineral earthquake. The COL applicant found no evidence for surface deformation along the extension of fault ‘a’ beyond the site boundaries, along Mixon et al.’s (2000) interpretation of the fault or the projection of the Dames and Moore’s mapped extent.

On March 11, 2014, the staff reviewed information supplied by the COL applicant in a reading room at the Bechtel Park Campus in Frederick, MD as summarized in (ADAMS Accession No. ML14203A211). The staff examined the LiDAR data and the geologic field reconnaissance Waypoints 23, 24, and 25 to specifically consider if LiDAR data revealed the presence of surface deformation along fault ‘a’. The staff also considered the COL applicant’s descriptions of Waypoints 23, 24, and 25 (previous RAI 02.05.01-5). The staff concludes that there is no obvious deformation revealed in the high-resolution LiDAR base maps. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-6d resolved and closed.

The COL applicant provided a proposed COL revision to include portions of the RAI response in a future revision of the North Anna 3 FSAR. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5-07 from the staff's advanced SER for North Anna 3 is resolved and closed.

In FSAR Section 2.5.1.2.4, Site Area Structural Geology, the COL applicant concluded that none of the faults in the site area are considered capable tectonic sources, as defined in RG 1.208, Appendix A. The staff notes that the capable tectonic source definition in RG 1.208 is not the sole criteria for staff's safety finding for the site area (SRP 2.5.1.2) and for surface deformation (SRP 2.5.3). As discussed in RG 1.208, a PSHA characterizes seismic potential through consideration of the historic and geologic record from the Quaternary Period. In addition, 10 CFR 100.23(d)(2) specifically requires the potential for surface tectonic and non-tectonic deformation to be determined. Therefore, in RAI 02.05.01-7 dated April 22, 2014 (ADAMS Accession No. ML14112A156), the staff asked the COL applicant to describe the analysis that it completed to determine the potential for future surface deformation, tectonic and non-tectonic, at the site and to state whether these findings have an impact on the PSHA for North Anna 3.

In response to RAI 02.05.01-7, dated June 23, 2014 (ADAMS Accession No. ML14177A441), the COL applicant described its analysis to determine the potential for future surface deformation at the site by referencing previous regional geologic studies and its own previous work for Units 1 and 2; referencing current regional geologic mapping studies and its own recent geologic reconnaissance program and concluded that the potential for tectonic deformation at the site is negligible based on the results these investigations:

Since original site studies in the early 1970's, no new information has been reported to substantiate the existence of a Quaternary fault near the site.
The 2011 Mineral earthquake prompted new research on the part of government and academic institutions that included detailed geologic mapping at scales more detailed than previous mapping projects.

Dominion initiated its own investigation to determine impacts of the Mineral earthquake with acquisition of high resolution topographic data (LiDAR) and subsequent geomorphic desk-top analysis in addition to a field reconnaissance study in the epicentral area of the Mineral earthquake.

The COL applicant acknowledges that the Mineral earthquake occurred on a previously unmapped subsurface fault zone within the site vicinity and provides details in FSAR Section 2.5.2.2 regarding why this fault is not an RLME seismic source and how this earthquake is incorporated into the updated PSHA.

With respect to potential for non-tectonic surface deformation, the COL applicant discussed:

- The negligible impact of Quaternary glaciation;
- The lack of carbonate or evaporite rock in the metamorphic and igneous geology in the site vicinity;
- The lack of growth faulting in this area's geologic setting;
- The lack of Quaternary age volcanic centers within 200 mile radius of site;

- No oil or gas resources are expected to be found in the site area; and
- No mining of commercial value.

The COL applicant stated that an additional FSAR subsection would be added to FSAR Section 2.5.3 to describe the analysis completed to determine the potential for future tectonic and non-tectonic surface deformation at the site.

In consideration of the COL applicant’s response to RAI 02.05.01-7, the staff independently reviewed several documents from previous North Anna 3 investigations completed in the early 1970’s for the licensing of Units 1 and 2 (Virginia Electric and Power Company (VEPCO),1974 and 1973) and the material provided by the COL applicant in the ESP SSAR. These studies provide one basis for the applicant’s analysis for future surface deformation potential. Geologic faulting discovered at the site during excavation of Units 1 through 4 was determined to be geologically old and unlikely to cause a future surface deformation problem for the site. The details of those studies are found in the ESP SSAR and the numerous Dames and Moore reports and letters to the NRC from the 1970’s. The staff has also independently considered the findings in the current literature regarding the local impact of the Mineral earthquake and the possible impact on future surface deformation potential for the North Anna 3 site including but not limited to: Burton et al., 2014; Green et al. (2012); Harrison et al. (2014); Horton et al. (2012); Hughes and Hibbard, 2012; and Spears and Gilmer (2012). To date there has been no surface rupture related to the Mineral earthquake reported in publications or in conference presentations. The staff reviewed the COL applicant’s geologic reconnaissance report in an audit in March 2014 as summarized in (ADAMS Accession No. ML14203A211), and considered the scope of that investigation with respect to how the COL applicant would determine the potential for tectonic deformation at the site. The staff concludes that the COL applicant executed what would be a typical geomorphic study designed to investigate questions of neotectonism in the landscape. The evaluation of longitudinal stream profiles, examination of geologic maps relative to high resolution topographic data (LiDAR), and field traverses to check the position of lithologic contacts and fault locations are part of such a typical investigative program.

The staff considered the COL applicant’s analysis for non-tectonic surface deformation in conjunction with the regional and local geology of Appalachian Piedmont geology, where North Anna 3 is located. The staff find that non-tectonic hazards such as subsurface dissolution leading to surface collapse and volcanic hazard are not present and do not contribute to the future surface deformation hazard. The staff agrees with the COL applicant’s response that oil and gas reserves are not likely in this geologic environment and therefore would not cause a man-made surface deformation hazard.

Based on the foregoing considerations for tectonic, non-tectonic and man-made surface deformation, the staff agrees with the COL applicant’s findings that the potential for tectonic and non-tectonic deformation at the site is negligible. Accordingly, and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-7 resolved and closed. The COL applicant provided a proposed COL revision to include portions of the RAI response in a future revision of the North Anna 3 FSAR. The staff finds the proposed COL FSAR changes acceptable and verified that the appropriate changes are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5-08 from the staff’s advanced SER for North Anna 3 is resolved and closed.

2.5.1.5 Post Combined License Activities

The staff identified the following licensing condition as the responsibility of the COL licensee. This License Condition relates to geologic mapping of both tectonic and non-tectonic surface deformation features at the site. This geologic license condition replaces ESP Permit Condition 3(E)(6).

> **License Condition 2.5.1-1.** The licensee shall (1) perform detailed geologic mapping of future excavations for North Anna 3 nuclear island structures; (2) examine and evaluate geologic features discovered in excavations for safety-related structures; and (3) notify the Director of the Office of New Reactors, or the Director's designee, once excavations for North Anna 3 safety-related structures are open for examination by staff.

2.5.1.6 Conclusion

The staff reviewed the COL FSAR, Revision 8, and considered the referenced ESP SSAR, Revision 9. The staff also considered the ESP FSER (NUREG-1835) in the review of the COL FSAR. The staff's review confirms that the applicant has addressed the relevant information to support 10 CFR 100.23 and 10 CFR 52.79 and there is no outstanding information to be addressed in the COL FSAR related to Section 2.5.1. The staff concludes that the information pertaining to North Anna 3 COL FSAR Section 2.5.1 is within the scope of the ESP and adequately incorporates by reference Section 2.5.1 of the North Anna ESP SSAR and is thus acceptable. In addition, the staff compared the additional COL information in the application to the relevant NRC regulations and acceptance criteria defined in NUREG-0800 and concludes that the applicant is in compliance with the relevant requirements of 10 CFR Parts 52 and 100. The staff also concludes that COL Action Item 2.0-26-A has been adequately addressed by the applicant and can be considered closed. The staff further concludes that the criteria in Permit Conditions 3.E(4) through (6) of the ESP have been met and that VAR 2.0-4 is acceptable.

On the basis of the foregoing, the staff concludes that the applicant has provided a thorough and accurate characterization of the geologic and seismic characteristics of the site as required by 10 CFR 52.17(a)(1)(vi), 10 CFR 100.23(c), and 10 CFR 100.23(d). Therefore, the staff concludes that the site is suitable with respect to the geologic and seismic siting criteria for new nuclear power plants.

2.5.2 Vibratory Ground Motion

2.5.2.1 Introduction

Section 2.5.2 of this SER provides information on the vibratory ground motion at the North Anna 3 site. Section 2.5.2.2 of this SER provides a summary of relevant geologic and seismic information in FSAR Section 2.5.2 of the North Anna 3 COLA. SER Section 2.5.2.3 summarizes the regulations and guidance used by the applicant to perform the investigation. SER Section 2.5.2.4 reviews the staff's evaluation of FSAR Section 2.5.2, including any RAIs, open items, and confirmatory analyses performed by the staff. SER Section 2.5.2.5 discusses post COL activities. Finally, SER Section 2.5.2.6 provides an overall summary of the applicant's conclusions, as well as the staff's conclusions, restates any base covered in the application, and confirms that regulations have been met or fulfilled by the applicant.

North Anna 3 COL FSAR Section 2.5.2 presents the applicant's evaluation of the vibratory ground motion that relates to the North Anna 3 site. The vibratory ground motion is evaluated based on seismological, geological, geophysical, and geotechnical investigations carried out to determine the site-specific ground motion response spectrum (GMRS), which must meet the regulations for the SSE provided in 10 CFR 100.23. The GMRS is defined as the free-field horizontal and vertical response spectra at the plant site. The development of the GMRS is based on a detailed evaluation of earthquake potential, taking into account the regional and local geology, Quaternary tectonics, seismicity, and site-specific geotechnical engineering characteristics of the site subsurface material. The specific investigations necessary to determine the GMRS include the seismicity of the site region and the correlation of earthquake activity with seismic sources. Seismic sources are identified and characterized, including the rates of occurrence of earthquakes associated with each seismic source. Seismic sources that have any part within 320 km (200 miles) of the site must be identified. More distant sources that have a potential for earthquakes large enough to affect the site must also be identified. Seismic sources can be capable tectonic sources or seismogenic sources. The review covers the following specific areas: (1) seismicity, (2) geologic and tectonic characteristics of the site and region, (3) correlation of earthquake activity with seismic sources, (4) PSHA and controlling earthquakes, (5) seismic wave transmission characteristics of the site, (6) site-specific GMRS, and (7) any additional information requirements prescribed within the "Contents of Application" sections of the applicable subparts to 10 CFR Part 52.

2.5.2.2 Summary of Application

Section 2.5.2 of the North Anna 3 COL FSAR, incorporates by reference Section 2.5.2 of the North Anna 3 ESP SSAR, Revision 9. In addition, in FSAR Section 2.5.2, the applicant provided supplemental information on additional subsurface details discovered during the COL site investigations.

This COL FSAR section also addresses COL Item 2.0-27-A from Revision 10 of the ESBWR DCD as follows:

<u>*COL Items:*</u>

- NAPS COL 2.0-27-A

NAPS COL 2.0-27-A addresses the information provided in accordance with SRP Section 2.5.2 and requires confirmatory information to ensure that the RB and FB, CB, and FWSC foundation input response spectra (FIRS) are enveloped by the ESBWR certified seismic design response spectra (CSDRS) referenced at the foundation level. In FSAR Section 2.5.2, the applicant provided site-specific information in accordance with SRP Section 2.5.2 to address COL Item North Anna 3 COL 2.0-27-A, and to resolve item 2.5-3, which addresses the provision for performing site-specific evaluations if the site-specific GMRS at foundation level exceeds the ESBWR DCD design response spectra referenced at the foundation level.

- NAPS ESP VAR 2.0-4

In response to the August 23, 2011, **M**5.8 earthquake that occurred in the town of Mineral, Virginia, of Louisa County, the applicant updated its selection of seismic source model. In NAPS ESP VAR 2.0-4, the applicant selected the new SSC model for CEUS published in NUREG-2115, hereafter referred to as the CEUS-SSC model, for conducting its PSHA, rather than the EPRI-SOG model (EPRI, 1986) used in developing the site ground motion for the ESP. In addition, the applicant requested that the North Anna 3 horizontal and vertical GMRS be defined at Elevation 68.3 m (224 ft) which corresponds to the deepest excavation at the site and lies on competent material rather than Elevation 76.2 m (250 ft). The applicant developed the

GMRS using the performance-based approach recommended in RG 1.208. The applicant then updated its selection of GMM from the EPRI (2004, 2006) model to the most recent EPRI (2013) model. Based on the evaluation, the applicant presented the following details related to the vibratory ground motion information for the North Anna 3 site.

Seismicity

FSAR Section 2.5.2.1 states that the applicant used the most recent earthquake catalog published as part of the CEUS-SSC model in its seismic hazard assessment at the North Anna 3 site. The CEUS-SSC earthquake catalog covers earthquakes in the CEUS region from 1568 through 2008. The applicant stated that the CEUS-SSC catalog is the starting point for developing an updated earthquake catalog for the North Anna 3 site. The applicant developed the updated catalog for the entire region covered by the CEUS-SSC for the period from January 1, 2009, through mid-December 2011. This period includes the August 23, 2011, Mineral, Virginia, earthquake, hereafter referred to as the Mineral earthquake, which occurred within the North Anna 3 site vicinity. The applicant followed the process used in the CEUS-SSC for developing an earthquake catalog. Consistent with the CEUS-SSC catalog, E[**M**] is the expected value of the true moment magnitude (**M**) and was calculated for all post-CEUS-SSC catalog earthquakes in the updated catalog.

The applicant reported 141 additional mainshock earthquakes with **M** greater than or equal to 2.9 in the 320 km (200 mi) site region and that the 2011 **M**5.8 Mineral earthquake was the most significant earthquake identified in the 2009 to 2011 earthquake catalog update. SER Figure 2.5.2-1 shows the seismicity of the North Anna 3 site region within the surrounding CEUS. The applicant also noted that a few moment magnitude values in the CEUS-SSC report were incorrect due to a period of manual processing of earthquake data at Saint Louis University and reported that in general these differences were small and had a negligible impact on any analysis performed in the CEUS-SSC report.

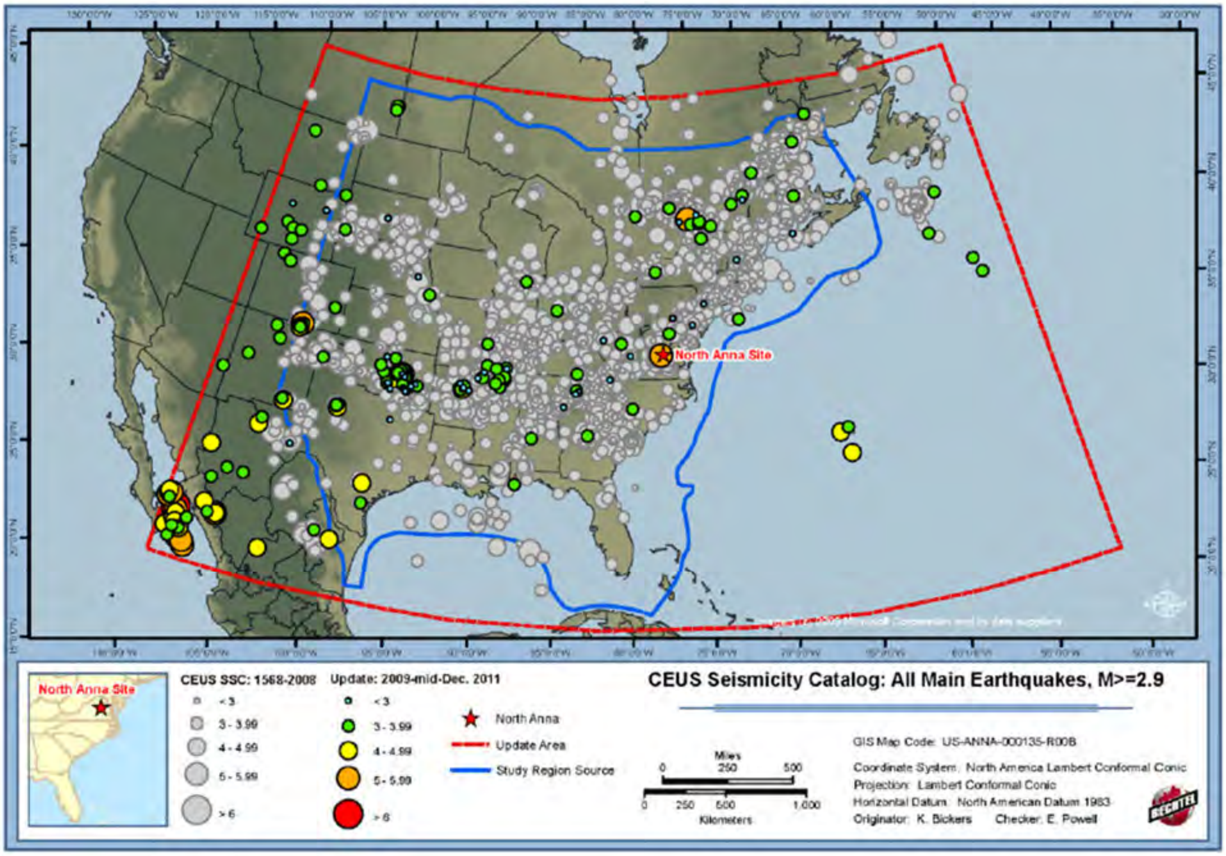

Figure 2.5.2-1. **Map Showing the COL Applicant's Updated Seismicity Catalog for the CEUS-SSC Region (FSAR Figure 2.5.2-202, Rev. 8)**

Seismic Information Related to the Mineral Earthquake

The applicant stated that the August 23, 2011, Mineral earthquake had a hypocenter located at latitude 37.936°N, longitude 77.933°W, and depth 6 km (3.7 mi), or approximately 18 km (10.8 mi) southwest of the North Anna 3 site. The applicant described the earthquake as occurring on a reverse fault within the CVSZ, a previously recognized zone of moderate seismicity. FSAR Section 2.5.2.1.3 states that the Mineral earthquake is the largest instrumentally recorded earthquake in eastern North America since the 1988 M5.9 Saguenay, Canada earthquake and that shaking was felt across a large area of the eastern U.S. including Washington, D.C., Philadelphia, PA, and portions of New York.

FSAR Section 2.5.2.1.3 states that there are different estimates of moment magnitude for the Mineral earthquake, ranging from M5.65 to **M**5.8. Following procedures outlined in the CEUS-SSC, the applicant determined that the best estimate (BE) uniform magnitude for the event was E[M]5.71.

The applicant stated that prior to the Mineral earthquake the largest earthquakes to occur in the CVSZ were an 1875 M4.8 and a 2003 M4.5 event that occurred in Goochland County, Virginia, south of the Mineral earthquake's epicenter.

The applicant stated that aftershocks of the Mineral earthquake ranged in depth from 1 to 7.5 km (0.6 to 4.5 mi), with magnitudes up to M3.9. Additionally, the applicant stated that global and USGS moment tensor solutions and the location of aftershocks for the Mineral earthquake defined a rupture plane 10 km (6.2 mi) in length striking approximately N26º – 30ºE and dipping 37º – 55ºSE (FSAR Table 2.5.2-204). The applicant used the up-dip projection of the rupture plane defined by aftershocks to highlight a zone on the surface that may have been susceptible to ground deformation from the mainshock. As discussed in SER Section 2.5.1.1.3, the applicant stated that field reconnaissance in the epicentral region of the Mineral earthquake revealed no discernable surface rupture or ground deformation.

The applicant discussed the two sets of three-component strong ground motion accelerograms of the **M**5.8 Mineral earthquake recorded at the North Anna 1 structure. One recording was located at the containment mat foundation approximately 16 m (54 ft) below plant grade and the second recording was at the containment operating deck approximately 6 m (20 ft) above plant grade. The applicant stated that the largest acceleration recorded at the foundation was 0.26 g, and the largest horizontal acceleration recorded at the operating deck level was 0.4 g. The applicant reported that these records are the closest available strong motion recordings of the Mineral earthquake. Based on the analysis of strong-motion recordings collected by the Center for Engineering Strong-Motion Data obtained at different distances from the Mineral earthquake, the applicant concluded that recorded ground motions correlated well with ground motion prediction equations for the CEUS at high frequencies (peak ground acceleration (PGA), 5 Hz but were lower than predicted at low frequency (1 Hz).

Geologic and Tectonic Characteristics of the Site and Region

FSAR Section 2.5.2.2 describes the seismic sources and seismic model parameters that the applicant used to calculate the seismic ground motion hazard at the North Anna 3 site. The applicant used the CEUS-SSC as a starting point for its hazard calculations rather than the EPRI-SOG model used in the ESP SSAR. Published in January 2012, the CEUS-SSC was developed following the Senior Seismic Hazard Analysis Committee (SSHAC) Level 3 procedures as outlined in NUREG/CR-6372, "Recommendations for Probabilistic Seismic Hazard Analysis: Guidance on Uncertainty and Use of Experts." It is a regional seismic source model to be used as a starting model in seismic hazard calculations for nuclear facilities in the CEUS region. The applicant stated that it conducted a review of the CEUS-SSC model to identify whether there was a need to update any of the seismic sources.

Summary of the Central and Eastern United States – Seismic Source Characterization Model

The applicant stated that the CEUS-SSC model contains two types of seismic sources: distributed seismicity sources and RLME sources. While the distributed seismicity sources were developed based on available earthquake locations and regional geologic and tectonic characterizations, the RLME sources were based on paleo- and historic earthquake records. The RLME sources represent the zones of repeated (two or more) RMLEs (M>6.5) in the CEUS region.

The CEUS-SSC model categorizes the distributed seismicity sources into two subgroups: maximum magnitude (M_{max}) zones and seismotectonic zones. These subgroups represent uncertainties in source characterizations and differences of opinions in seismic source identification in the region. In hazard estimates, the M_{max} and seismotectonic sources are weighted by 40 percent and 60 percent, respectively, to determine their contributions to the total seismic hazard at the site. The M_{max} zones are broad seismic sources identified based on limited tectonic information and represent potential seismic sources of future earthquakes. The seismotectonic sources are those developed by extensive analyses of regional geology and geophysics, tectonics, and seismicity in the CEUS region. Both the M_{max} and the seismotectonic zones also include alternative source geometries, accommodating inherent uncertainty in SSC. RLME sources are superimposed on the distributed seismicity sources when calculating total site hazard.

In FSAR Sections 2.5.2.2.2 and 2.5.2.2.3, the applicant stated that the PSHA conducted for the North Anna 3 site includes the contributions from all or parts of each distributed seismicity model (i.e. M_{max} and seismotectonic source zones) that lie within 1,000 km (620 mi) of the site. As a result, the applicant used the following alternative seismic source configurations for the M_{max} zones where Mesozoic-aged tectonic extension occurred (MESE) and did not occur (NMESE): MESE-N, MESE-W, NMESE-N, NMESE-W, and the Study Region. The Study Region is the largest seismic source in the CEUS-SSC model, and it represents the entire area of the CEUS region with no division between MESE and NMESE. The applicant considered narrow (N) and wide (W) extensions to represent varying alternative geometries of the MESE and NMESE sources resulting in four alternative configurations of the two overall classifications: MESE-N, MESE-W, NMESE-N, and NMESE-W. The applicant noted that the North Anna 3 site is located in the MESE M_{max} source zone in both interpretations. The applicant included the following seismotectonic source zones in the seismic hazard model for the North Anna 3 site: Atlantic Highly Extended (AHEX) Crust; Extended Continental Crust-Atlantic Margin (ECC-AM), PEZ including PEZ-N and PEZ-W; Midcontinent-Craton (MidC) including MidC-A, MidC-B, MidC-C, and MidC-D; St. Lawrence Rift (SLR); and Illinois Basin Extended Basement (IBEB) (SER Figure 2.5.2-2).

The applicant indicated that AHEX, ECC-AM, PEZ, and MIDC seismic sources were located within 320 km (200 mi) of the North Anna 3 site, and the North Anna 3 site itself is located within the ECC-AM seismic source. The applicant described the ECC-AM seismic source as a zone that encompasses portions of the Piedmont, Coastal Plain, and Continental Shelf physiographic provinces that experienced Mesozoic and younger extension. The applicant noted that the ECC-AM seismic zone is defined by the observation that earthquakes greater than M7 in SCRs occur within crust extended during the Mesozoic and younger period. Magnetic and gravity anomalies define the boundaries of the ECC-AM seismic zone near the North Anna 3 site.

The applicant stated that the AHEX seismic source lies offshore along the continental shelf at the eastern edge of the 320 km (200 mi) site radius. The applicant characterized the AHEX seismic source as a zone of thinned mafic oceanic crust extended during the Mesozoic. The third seismotectonic zone used, PEZ, represents the seismic zone in the western part of the North Anna 3 site region. Because the western boundary of this zone is not well constrained, the CEUS-SSC model has two alternative source geometries for this source representing a wide (W) or narrow (N) geometry: PEZ-W and PEZ-N. The applicant stated that the last seismotectonic zone, MidC, is a large areal zone encompassing the continental interior where very little or no significant tectonic deformation took place in the past several hundred million years. Since the MidC zone boundaries are also uncertain, this zone is defined by four alternatives: MidC-A; MidC-B; MidC-C; and MidC-D. The applicant stated that, although only MidC-A and MidC-B configurations are within the 320 km (200 mi) site radius, all four model alternatives were included in the baseline hazard calculation.

In FSAR Sections 2.5.2.2.4, the applicant summarized the RLME sources used in the North Anna 3 seismic hazard calculations. The CEUS-SSC model requires contributions from the RLME sources to be added to the seismic hazard estimates obtained from the distributed seismicity models. Figure 2.5.2-3 in this SER shows the locations of the RLME sources characterized in the CEUS-SSC model. The applicant stated that the RLME sources that contribute significantly to seismic hazard at the North Anna 3 site are Charleston, New Madrid Fault System, and the Wabash Valley sources.

Figure 2.5.2-2. **Map Showing the CEUS-SSC Seismotectonic Zones for One of the Four Alternative Models for the MidC Seismotectonic Zone (FSAR Figure 2.5.2-215, Rev. 8)**

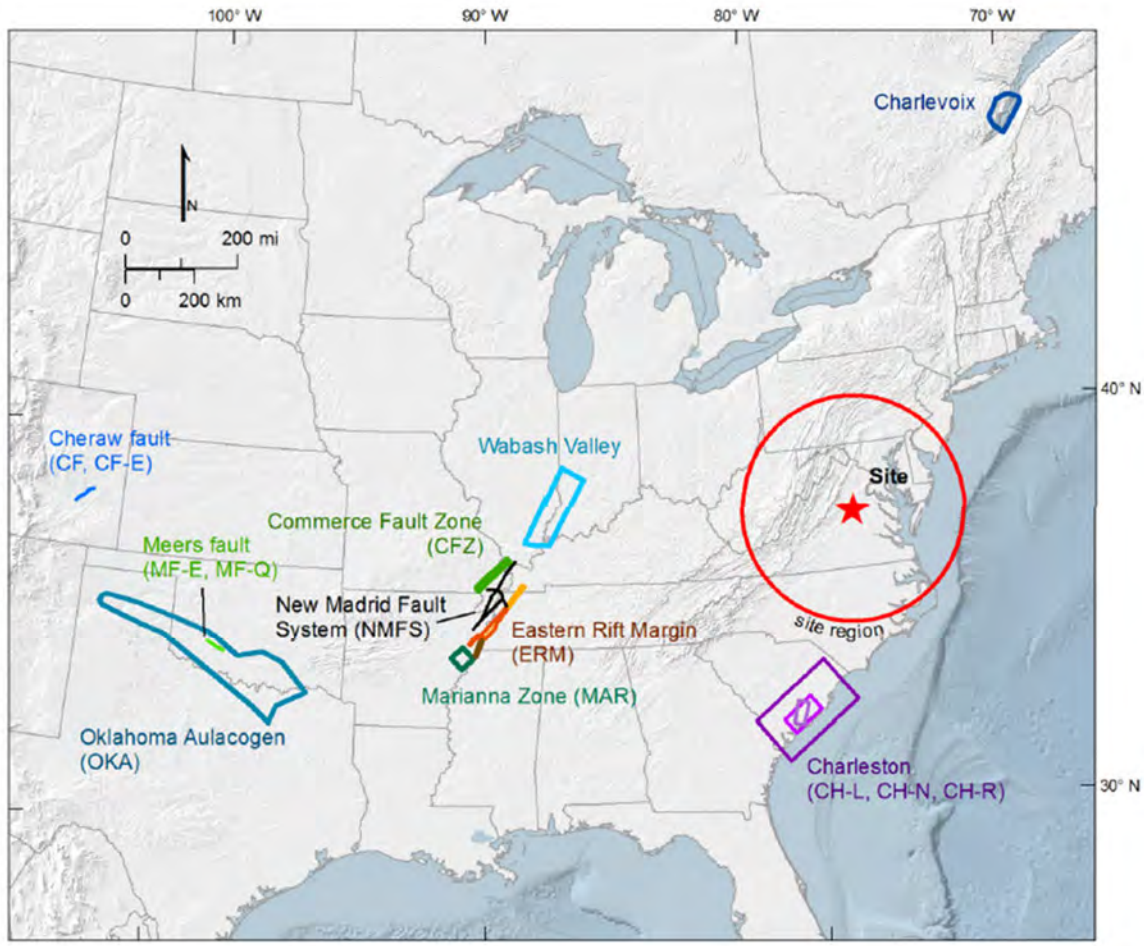

Figure 2.5.2-3. Map Showing the Repeated Large Magnitude Earthquake (RLME) Sources in the CEUS-SSC Model (FSAR Figure 2.5.2-218, Rev. 8)

Post-Central and Eastern United States – Seismic Source Characterization Studies

In FSAR Section 2.5.2.2.5, the applicant described geologic and seismic investigations of the North Anna 3 site region used to evaluate and potentially update the CEUS-SSC model. The applicant performed sensitivity studies to determine the impact of the Mineral earthquake on the M_{max} and earthquake recurrence distributions for the ECC-AM, MESE-N, MESE-W, and Study Region seismic sources. The applicant stated that because earthquakes in background zones are modeled as finite ruptures on randomly oriented faults, a future earthquake similar to the Mineral earthquake is included within the updated CEUS-SSC model.

In FSAR Section 2.5.2.2.3.1, the applicant noted that the E[M]5.71 Mineral earthquake, which occurred after the development of the CEUS-SSC earthquake catalog, is now the second largest earthquake not associated with an RLME in the ECC-AM. Based on sensitivity studies, the applicant increased the minimum M_{max} in the ECC-AM region from 6.0 to 6.1 (FSAR Table 2.5.2-211). The applicant performed a SSHAC Level 2 assessment to determine if incorporating the rupture plane of the Mineral earthquake as a new fault source was appropriate (FSAR Section 2.5.2.4). The applicant stated that although a potentially causative structure for the Mineral earthquake is defined, there are no constraints on slip rate, recurrence, and M_{max}. Therefore, the applicant incorporated the Mineral earthquake in the PSHA for the North Anna 3 site by increasing the M_{max} distribution for the ECC-AM zone. The applicant also indicated that it did not include the rupture plane of the Mineral earthquake as an RLME source since RLME sources are defined as locations of repeated large-magnitude (M≥6.5) earthquakes.

The applicant also discussed the impact of recent paleoseismic studies in the ETSZ. The applicant did not represent the ETSZ as an RLME since these studies did not provide information on earthquake recurrence interval or magnitude parameters for the ETSZ.

Correlation of Earthquake Activity with Seismic Sources

FSAR Section 2.5.2.3 describes the correlation of updated seismicity with the CEUS-SSC seismotectonic zones and RLME sources significant to the site (SER Section 2.5.2.2.2). The applicant discussed correlations of seismicity in the updated catalog with the Charleston, New Madrid Fault System, and Wabash Valley RLME sources (FSAR Figures 2.5.2-223 and 2.5.2-226), but identified no significant deviations from zones or faults defined within these sources. The applicant concluded that seismicity in the updated catalog was consistent with the patterns of seismicity for the PEZ, AHEX, SLR, and IBEB seismotectonic zones defined in the CEUS-SSC model.

Within the ECC-AM seismotectonic zone, the applicant identified elevated rates of seismicity in the CVSZ and the New York-Philadelphia region. The applicant noted that these zones are not RLMEs as there is no evidence for repeated, large-magnitude earthquakes or discrete faults associated with seismicity. The applicant indicated that while the 2011 Mineral earthquake and its aftershocks defined a northeast-striking and southeast-dipping rupture plane, there is not sufficient information to designate the rupture plane of the Mineral earthquake as an RLME. The magnitude of the Mineral earthquake, E[M]5.71, is less than the maximum magnitude for the ECC-AM (M_{max} = 6.5), its host seismotectonic zone. The applicant suggested that the largest earthquake possibly recorded in the ECC-AM is the 1755 Cape Ann, Massachusetts E[M]6.10 earthquake. However, the uncertainty in the location of the Cape Ann earthquake could place its epicenter in the Northern Appalachian (NAP) seismotectonic zone instead of the ECC-AM. Therefore, the applicant stated that if the Cape Ann earthquake occurred in the NAP, the largest event in the ECC-AM would then be the 2011 Mineral E[M]5.71 earthquake. The applicant noted that including the Mineral earthquake and other post-2008 seismicity in the updated CEUS-SSC catalog caused minor increases in seismicity rates (*a*-values) in the ECC-AM.

Probabilistic Seismic Hazard Analysis and Controlling Earthquake

FSAR Section 2.5.2.4 describes the applicant's PSHA calculations for the North Anna 3 site. The hazard curves generated by the applicant's PSHA represent the hazard calculated for generic hard rock conditions characterized by a shear wave (S-wave) velocity of 2.8 km/s (9,200 fps). In accordance with RG 1.208, FSAR Section 2.5.2.4 also describes the earthquake potential for the North Anna 3 site in terms of the most likely earthquake magnitudes and source-to-site distances, which are referred to as 'controlling earthquakes' at low-frequency (LF) (1 and 2.5 Hz) and HF (5 and 10 Hz) at the 10^{-4} and 10^{-5} mean annual frequencies of exceedance levels.

Probabilistic Seismic Hazard Analysis Inputs

The applicant's PSHA calculations used the CEUS-SSC model updated to include seismicity through December 2011 and the GMM described in EPRI Technical Report 3002000717,"Ground-Motion Model (GMM) Review Project, (EPRI, 2013)."

Seismic Source Model

The applicant stated that the PSHA inputs for the North Anna 3 site consist of the distributed seismicity sources (M_{max} and seismotectonic zones) or portions of these zones that are within 1,000 km (620 mi) of the North Anna 3 site. The applicant conducted PSHA sensitivity calculations to aid in the selection of an appropriate set of RLME sources to include in the PSHA from the CEUS-SSC model. Based on these results, the applicant included the Charleston, New Madrid Fault System, and Wabash Valley RLME sources because they contribute close to or greater than 1 percent to the total mean hazard at the North Anna 3 site. The seismic sources used in the PSHA calculations are summarized earlier in SER Section 2.5.2.2.2.

Ground Motion Models

The applicant used the EPRI (2013) GMM to calculate seismic hazard. The GMM developed by EPRI characterize the range of expected ground motions from a seismic source at seven oscillator frequencies; 0.5, 1, 2.5, 5, 10, 25, and 100 Hz. The applicant applied two different sets of GMMs depending on the seismic source under consideration: the 9 general, non-rift EPRI (2013) GMM relationships for the Midcontinent region were applied to all background seismic sources, and the 12 non-general, rift EPRI (2013) GMM relationships for the Midcontinent region were applied to all RLME sources.

Probabilistic Seismic Hazard Analysis Methodology and Calculation

Using the modified CEUS-SSC, with modified M_{max}, recurrence, and rate distributions described in FSAR Section 2.5.2.4.3 and summarized in this SER, and EPRI GMM (2013), the applicant performed the PSHA calculations using a fixed lower bound magnitude of M5.0 and modeled earthquakes occurring in the CEUS-SSC-distributed seismicity sources as point sources. The applicant applied the EPRI (2013) models for distance adjustment and additional aleatory variability resulting from the use of point sources (epicenter to model earthquakes) for distributed seismicity. The models assumed a random rupture location with respect to the epicenter. The applicant modeled earthquakes occurring in the RLME sources as extended ruptures and did not apply the distance adjustment and additional aleatory variability models to these sources.

The applicant performed the above PSHA calculations for ground motion frequencies of 0.5, 1, 2.5, 5, 10, 25 Hz, and PGA as described in RG 1.208. FSAR Figures 2.5.2-230 through 2.5.2-236 show the mean and fractile hazard curves for the seven oscillator frequencies.

Probabilistic Seismic Hazard Analysis Results

In order to determine which earthquakes are most significant to hazard at the North Anna 3 site, the applicant performed deaggregation for LF and HF ground motions. These earthquakes, termed controlling earthquakes, were determined by averaging the deaggregated impact of distance and magnitude on hazard at 1 and 2.5 Hz for LF and 5 and 10 Hz for HF following procedures outlined in RG 1.208, Appendix D. The applicant deaggregated the PSHA results at target mean annual frequencies of exceedance levels to determine the controlling earthquakes in terms of magnitude and site-to-source distance. SER Figure 2.5.2-4 shows the deaggregation plots for HF and LF 10^{-4} mean annual frequencies of exceedance hazard results. Following RG 1.208, the applicant selected the controlling earthquake for LF ground motions from the distance calculation of greater than 100 km (62 mi).

The applicant followed Approach 2A described in NUREG/CR-6728, “Technical Basis for Revision of Regulatory Guidance on Design Ground Motions: Hazard- and Risk-Consistent Ground Motion Spectra Guidelines.” As part of Approach 2A, the applicant determined the site response analysis input ground motion by calculating spectral shapes based on NUREG/CR-6728 for HF and LF ground motions at 10^{-4}, 10^{-5}, and 10^{-6} mean annual frequencies of exceedance. The applicant anchored HF input ground motions at the PSHA values for frequencies of 2.5 Hz and higher and the LF input ground motions at the PSHA values for frequencies of 2.5 Hz and lower. FSAR Figure 2.5.2-257 shows the Uniform Hazard Response Spectrum (UHRS) that the applicant determined by enveloping the LF and HF input motions.

Table 2.5.2-1 Mean Magnitude and Distance for LF and HF Response Spectra for Three MAFEs (Table 2.5.2-218, Rev 9)

MAFE	**10^{-4}**	**10^{-5}**	**10^{-6}**
Low Frequency M	7.1	6.4	6.7
Low Frequency R (km)	340	21	16
High Frequency M	5.9	6.1	6.4
High Frequency R (km)	22	15	13

LF: low frequency, 1 to 2.5 Hz
HF: high frequency, 5 to 10 Hz
MAFE: mean annual frequency of exceedance

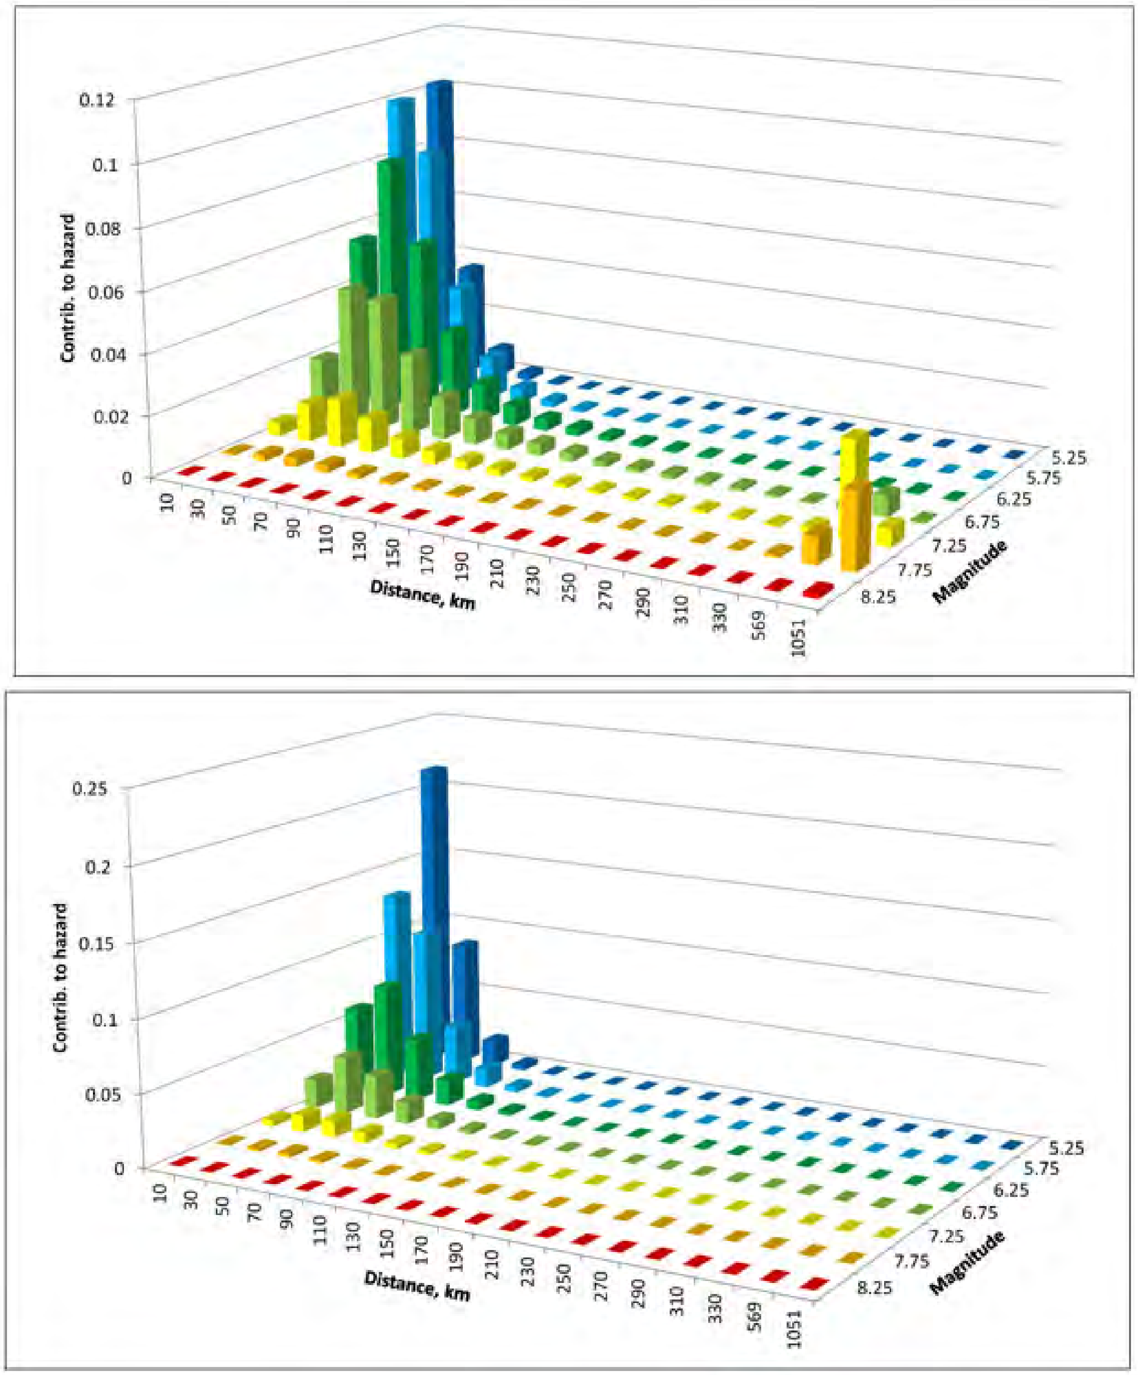

Figure 2.5.2-4. Deaggregation Results for LF (Upper) and HF (Lower) at the 10-4 Mean Annual Frequency of Exceedance Level (Figure 2.5.2-250 and Figure 2.5.2-251, Rev. 9)

Seismic Wave Transmission Characteristics of the Site

FSAR Section 2.5.2.5 describes the procedure the applicant used to assess the effects of soils on seismic wave transmission beneath the North Anna 3 site. The PSHA calculates hazard curves for generic hard rock conditions, characterized by S-wave velocity of 2.8 km/s (9,200 fps). For the North Anna 3 site, these hard rock conditions exist at depths ranging from 47.3 to 50.3 m (155 to 165 ft) below surface elevation 88.4 m (290 ft) NAVD88. To determine the near-surface soil UHRS, the applicant first developed soil/rock profile models for the North Anna 3 site; selected representative hard rock ground motions based on a hard rock seismic hazard calculations; and performed site response analysis to obtain the free-field soil UHRS at the elevation of the competent layer beneath the North Anna 3 site.

In FSAR Section 2.5.2.5, the applicant described two sets of site response analyses. The applicant used one analysis to develop the site-specific GMRS and the second analysis to perform the soil structure interaction (SSI) analyses. For the SSI analyses inputs, the applicant developed the performance-based surface response spectra (PBSRS) and FIRS. While the applicant described development of PBSRS and FIRS in FSAR Section 2.5.2.5, the summary and evaluation of the PBSRS, FIRS, and SSI analysis are discussed in SER Section 3.7.1.

The applicant stated that the geology of the site is complex, consisting of undulating layers of saprolite and rock of varying degrees of weathering. In order to account for the uncertainty in the material properties of the rock at the GMRS elevation across the footprint of the plant, the applicant developed BE velocity profiles for the GMRS elevation based on borings (B-901, B-907, and B-909) within the footprint of the RB/FB and the CB. The applicant developed separate models for the two buildings at the GMRS Elevation 68.3 m (224 ft) NAVD88 and enveloped the resulting response spectra to determine the site GMRS.

Site Response Model

According to the applicant, the geology at the North Anna 3 site consists of layers of saprolite overlying rocks of the Ta River Metamorphic suite that have varying degrees of weathering and fracturing. The applicant subdivided the saprolite and weathered rock layers into zones termed Zone I-IV based on physical characteristics. The applicant proposed to locate the GMRS at Elevation 68.3 m (224 ft) NAVD88 in the rock layer termed Zone IV, a layer of competent rock material. The applicant encountered CEUS generic hard rock conditions (i.e., an S-wave velocity of about 2.8 km/s [9,200 fps]) at a depth of approximately 47.2 m (155 ft) (Elevation 41.2 m [135 ft]).

In addition to the S-wave velocity profile, the applicant noted that the other material parameters used as inputs to the site response analysis include material unit weight, shear modulus, and damping. The applicant obtained soil and rock unit weights for the site response profile from laboratory test results and site characterization analysis. The applicant stated that unit weights for the rock units beneath the site range from 2,000 to 2,600 kg/m^3 (125 to 164 pounds per cubic foot).

The applicant determined that for saprolite and Zone III rock, strain dependent damping and shear modulus reduction curves were appropriate. For Zone III-IV and Zone IV rock, the applicant stated that the materials were expected to behave linearly, so no shear modulus reduction curve was required and a constant damping value was used.
The applicant modeled the variability in the site data by randomizing the S-wave velocity profile, the layer thickness, and the shear modulus reduction and damping relationships for the soil. In order to consider the appropriate level of variability in calculating soil profiles, the applicant

considered measurements beneath both the RB/FB and the CB when determining the standard deviation used in randomizing the soil profile. The applicant generated randomized profiles using the S-wave velocity correlation model developed by Silva et al. (1996). The applicant also randomized the shear modulus reduction and damping in the saprolite and Zone III rock. These artificial profiles represent the soil column from the top of the bedrock (rock with an S-wave velocity equal to that of reference rock [2.8 km/s (9,200 fps)]) to Elevation 68.3 m (224 ft) for calculating the GMRS. The applicant used these randomized profiles as input to the site response calculations, which are summarized below.

The applicant separately developed soil profiles for the RB/FB and the CB based on closest downhole measurements. The applicant randomized each of these profiles and calculated the expected site response at the GMRS elevation. In order to account for observed variability in physical characteristics across the site, the applicant enveloped the site response curves for RB/FB and CB profiles when calculating the GMRS. SER Figure 2.5.2-5 shows the input S-wave velocity profiles for the RB/FB and the CB.

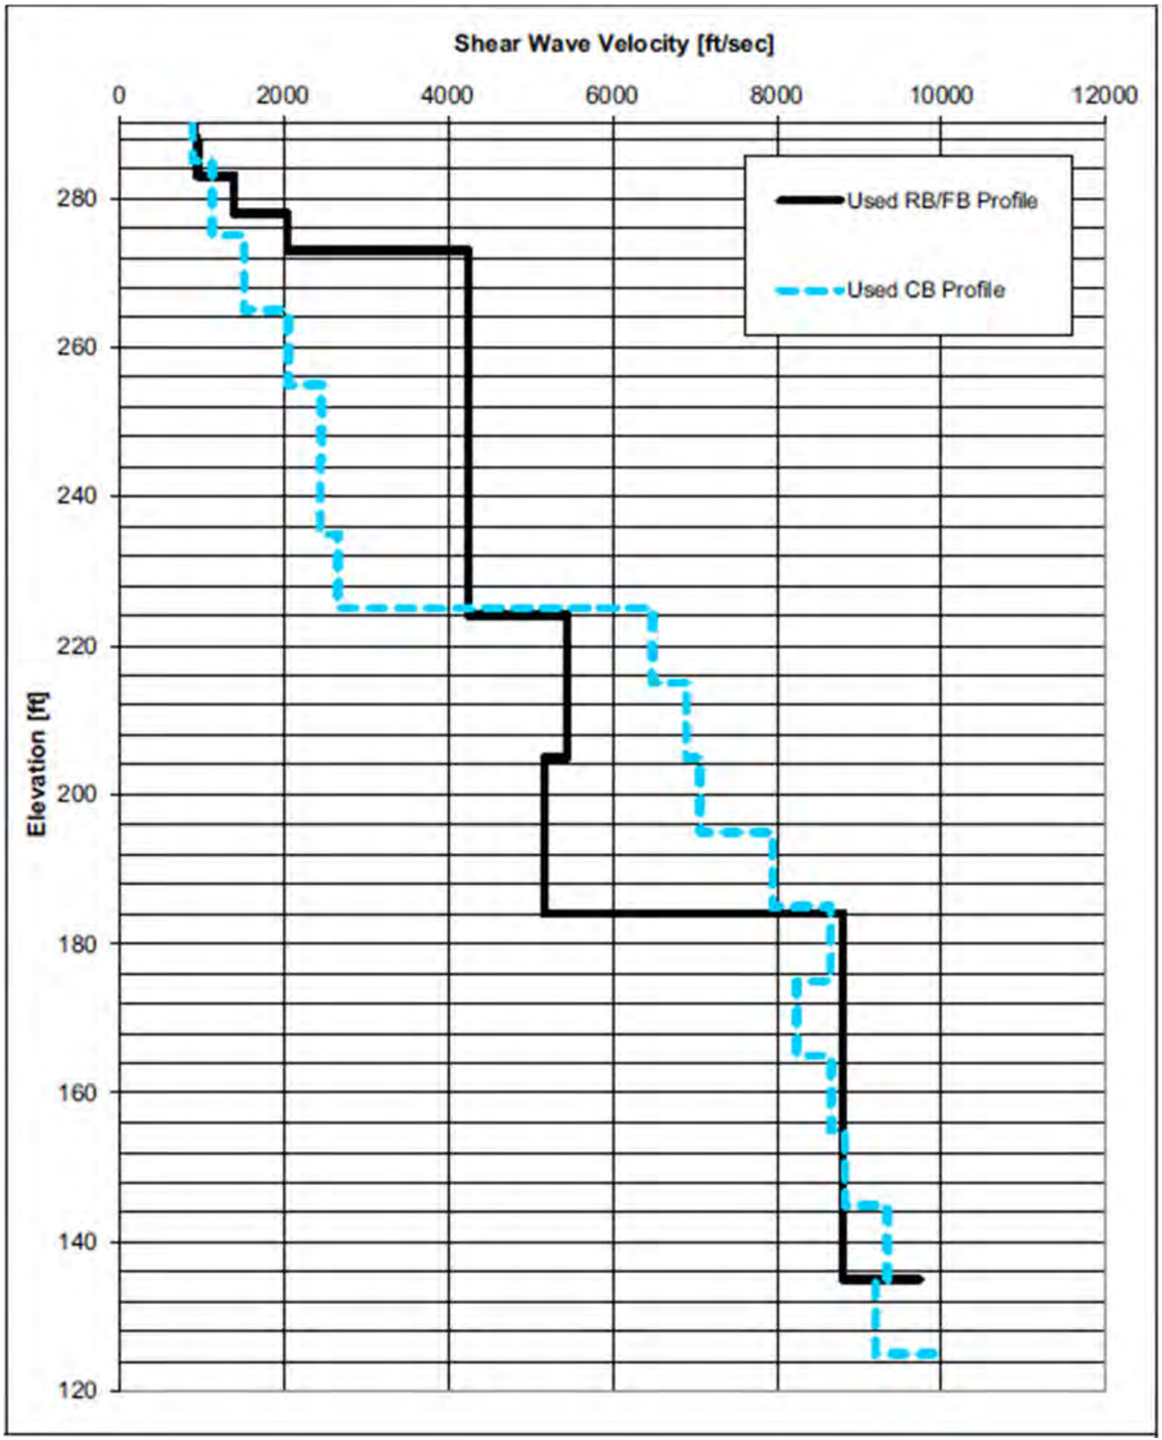

Figure 2.5.2-5. **Input Shear-wave Velocity Profiles for the RB/FB and CB Buildings Used for Site Response Calculations (FSAR Figure 2.5.2-259, Rev. 8)**

Site Response Methodology and Results

In FSAR Section 2.5.2.5.3, the applicant described its approach to developing site response analysis input and methodology. The applicant used the computer program P-SHAKE to calculate site response at the North Anna 3 site. The P-SHAKE program uses equivalent-linear site-response formulations in combination with Random Vibration Theory (RVT) to produce site response input at the reference rock/soil boundary that is propagated through the soil profile. The program takes input response spectra calculated using equations in NUREG/CR-6728 scaled to the hard rock UHRS and converts them to an acceleration power spectral density (PSD). The program calculates a transfer function for shear strain in each soil layer and convolves this with the PSD to calculate an effective strain that is used as input in the next iteration. The program iterates until convergence when the amplitude response spectrum (ARS) at each layer interface can be calculated from the PSD of the solution using the RVT approach.

The RVT method requires additional inputs, particularly strong-motion duration and effective strain ratio. The applicant used NUREG/CR-6728 to calculate strong-motion duration based on the HF and LF controlling earthquakes at the 10^{-4} and 10^{-5} annual frequencies of exceedance. The applicant determined the effective strain ratio using equation 2.5.2.5-1 in the FSAR.

To calculate the final site amplification effects of the soil, the applicant divided the response spectrum for the computed surface motion by the corresponding response spectrum for the hard rock input motion. The applicant calculated the ARS for each of the 60 site profiles and took the arithmetic mean to define the amplification function. The applicant performed the analysis for the HF and LF spectra at the 10^{-4} and 10^{-5} exceedance frequencies and enveloped the resulting ARS to determine the UHRS at the GMRS elevation. FSAR Figures 2.5.2-286 and 2.5.2-287 show the amplification functions determined by the applicant for the 10^{-4} and 10^{-5} exceedance frequencies respectively.

Ground Motion Response Spectra

FSAR Section 2.5.2.6 describes the method the applicant used to develop the horizontal and vertical site-specific GMRS. To obtain the horizontal GMRS, the applicant used the performance-based approach described in RG 1.208 and in ASCE/SEI Standard 43-05, "Seismic Design Criteria for Structures, System, and Components in Nuclear Facilities" (ASCE/SEI, 2005). The applicant developed the vertical GMRS using site-specific vertical to horizontal (V/H) response spectral ratios developed using guidance provided in NUREG/CR-6728 for CEUS sites.

Horizontal Ground Motion Response Spectra

The applicant calculated a horizontal, site-specific, performance-based GMRS using the method described in RG 1.208. The performance based method achieves the annual target performance goal (P_F) of 10^{-5} per year for the frequency of onset of significant inelastic deformation. This damage state (i.e., deformation) represents a minimum structural damage state – or essentially elastic behavior – and falls well short of the damage state that would interfere with functionality. The GMRS was calculated using the following relationship:

$$GMRS = DF * UHRS(10^{-4})$$

Where:

$$DF = max\{1.0, 0.6 * (A_R)^{0.8}\}$$
$$A_R = UHRS(10^{-5})/UHRS(10^{-4})$$

The applicant noted that when the value of A_R exceeds 4.2, RG 1.208 specifies that it is appropriate to use a GMRS value equal to 45 percent of the mean 10^{-5} UHRS. The applicant calculated a GMRS using the above approach for both the RB/FB and the CB at Elevation 68.3 m (224 ft) NAVD88 and enveloped them to determine the site-specific performance-based GMRS. SER Figure 2.5.2-6 shows the resulting horizontal GMRS.

Vertical Ground Motion Response Spectra

The applicant obtained the vertical GMRS by calculating site-specific V/H ratios and applying them to the horizontal GMRS. The applicant used information provided in NUREG/CR-6728 and velocities at the GMRS elevation to calculate a site-specific V/H ratio. SER Figure 2.5.2-6 shows the vertical GMRS for the North Anna 3 site using the V/H ratio shown in FSAR Figure 2.5.2-320.

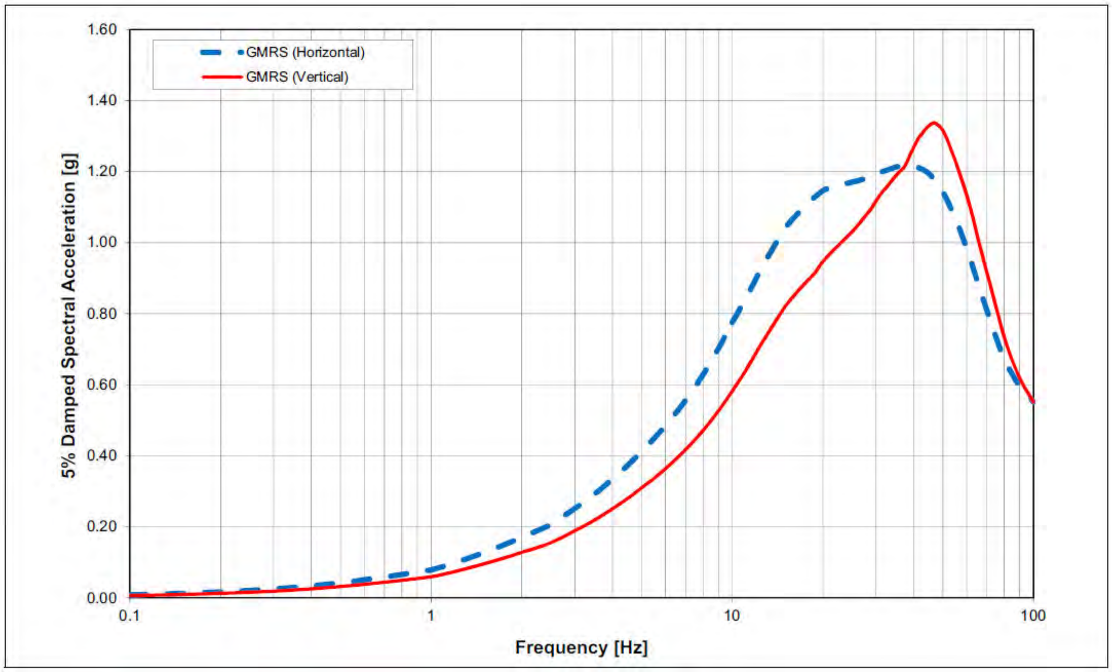

Figure 2.5.2-6. Horizontal and Vertical GMRS for the North Anna 3 Site at Elevation 68.28 m (224 ft) (FSAR Figure 2.5.2-313, Rev. 9)

2.5.2.3 Regulatory Basis

The regulatory basis for incorporating information by reference to the ESP SSAR is 10 CFR 52.79(b), which states (in part) that if a COLA references an ESP, then the FSAR need not contain information or analyses submitted to the Commission in connection with the ESP provided that the FSAR must either include or incorporate by reference the ESP SSAR and must contain, in addition to the information and analyses otherwise required, information sufficient to demonstrate that the design of the facility falls within the site characteristics and design parameters specified in the ESP. Full descriptions of the applicable regulatory and acceptance criteria, and related NRC guidance, are provided in SRP Section 2.5.2 (NUREG-0800).

The regulatory basis for the information incorporated by reference is addressed in the SER related to the North Anna 3 ESP (NUREG-1835).

The applicable regulatory requirements for reviewing the applicant's discussion of vibratory ground motion are:

- 10 CFR 100.23, with respect to obtaining geologic and seismic information necessary to determine site suitability and ascertain that any new information derived from site-specific investigations does not impact the GMRS derived by a PSHA. The site-specific GMRS satisfies the requirements of 10 CFR 100.23 with respect to development of the SSE. In complying with this regulation, the applicant also meets guidance in RG 1.132, "Site Investigations for Foundations of Nuclear Power Plants," Revision 2; and RG 1.208.

- 10 CFR 52.79(a)(1)(iii), as it relates to consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity and period of time in which the historical data have been accumulated.

The related acceptance criteria summarized from NUREG-0800 Section 2.5.2 are as follows:

- **Seismicity**: To meet the requirements in 10 CFR 100.23, this section is accepted when the complete historical record of earthquakes in the region is listed and when all available parameters are given for each earthquake in the historical record.

- **Geologic and Tectonic Characteristics of Site and Region:** Seismic sources identified and characterized by the LLNL and the EPRI were used for studies in the CEUS in the past.

- **Correlation of Earthquake Activity with Seismic Sources:** To meet the requirements in 10 CFR 100.23, acceptance of this section is based on the development of the relationship between the history of earthquake activity and seismic sources of a region.

- **Probabilistic Seismic Hazard Analysis and Controlling Earthquakes:** For CEUS sites relying on LLNL or EPRI methods and databases, the staff will review the applicant's PSHA, including the underlying assumptions and how the results of the site investigations are used to update the existing sources in the PSHA, how they are used to develop additional sources, or how they are used to develop a new database.

- **Seismic Wave Transmission Characteristics of the Site:** In the PSHA procedure described in RG 1.208, the controlling earthquakes are determined for generic rock conditions.

- **Ground Motion Response Spectra:** In this section, the staff reviews the applicant's procedure to determine the GMRS.

In addition, the geologic characteristics should be consistent with appropriate sections from: RG 1.60, "Design Response Spectra for Seismic Design of Nuclear Power Plants"; RG 1.132, RG 1.206; and RG 1.208.

2.5.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 2.5.2 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 2.5.2 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESP SSAR and the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 COL FSAR, the ESP SSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.

The applicant incorporated by reference Section 2.5.2 of the ESP SSAR, Revision 9. The staff's technical evaluation of Section 2.5.2 of the ESP SSAR is in NUREG-1835 and its supplement.

The staff reviewed Section 2.5.2 of the North Anna 3 COL FSAR and checked the referenced ESP SSAR. The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to this section.

During the course of staff's review of the application, the applicant changed its selection of reactor technology. Previously in RAI 2.5.2-1 dated December 21, 2010 (ADAMS Accession No. ML110270358), the staff had a concern about the elevation of the GMRS. In the response to RAI 2.5.2-1 dated March 22, 2011 (ADAMS Accession No. ML110880254), the applicant states this question is no longer applicable because of the FSAR revisions following the selection of a new reactor design. Therefore, RAI 2.5.2-1 is resolved and closed.

The staff's technical evaluation of this application is limited to the resolution of DCD COL Item 2.0-27-A, discussion of ESP VAR 2.0-4, and new and significant information regarding the August 23, 2011, Mineral earthquake, additional subsurface investigations, and the availability of the CEUS-SSC, as addressed below:

COL Items:

- NAPS COL 2.0-27-A

In accordance with COL Action Item 2.0-27-A, and to resolve COL item 2.5-3, the applicant updated the site subsurface material properties with results from COL field investigations. The applicant performed several additional borings to sample the subsurface and did additional field geophysical measurements. The staff reviewed the new information and found it important for the site response analysis. The staff used this information to perform updated confirmatory site response analysis described in Section 2.5.2.4.2 of this SER.

ESP Variance:

- NAPS ESP VAR 2.0.4

The applicant requested VAR 2.0-4 in order to use the spectral acceleration values at elevation 68.3 m (224 ft), rather than the ESP GMRS elevation of 76.2 m (250 ft). The applicant also updated its PSHA to incorporate the recent CEUS-SSC. The staff considered this variance request and determined that because the GMRS elevation was redefined based on the applicant's COL subsurface investigations, the use of the base of the RB/FB foundation for GMRS elevation in place of that determined as part of the ESP is acceptable. The staff also finds use of the CEUS-SSC acceptable as it represents the most up to date model of seismic sources in the Central and Eastern U.S.

Probabilistic Seismic Hazard Analysis Updates

On August 23, 2011, the **M**5.8 Mineral earthquake occurred approximately 23 km (14 mi) from the North Anna 3 site. The occurrence of a moderate magnitude earthquake within the site vicinity indicates that a previously unrecognized seismic source may exist that poses a hazard at the plant. This new and significant information led the staff to reopen the PSHA previously evaluated as part of the ESP. In RAI 2.5.2-4, dated November 1, 2011 (ADAMS Accession No. ML11305A261), the staff asked the applicant to assess the adequacy of the EPRI SOG (EPRI, 1986, 1989) seismic source model in light of the Mineral, Virginia earthquake. In RAI 2.5.2-8 dated July 8, 2015 (ADAMS Accession No. ML15233A433), the staff also asked the applicant to address any exceedances of the postulated GMRS by observed ground motions at the existing North Anna 1 in terms of the adequacy of the seismic design parameters in FSAR Section 3.7.1 to account for the recordings. The RAI also asked the applicant to specify the operability criteria for the as-found conditions of safety-related SSCs, until the SSC is restored to meet the original design basis and design criteria, to ensure that such demonstrations would consider the Mineral, Virginia earthquake recordings. In the response to RAI 2.5.2-4 dated February 13, 2012 (ADAMS Accession No. ML12048A096), the applicant responded that the record of the **M**5.8 Mineral earthquake is considered in development of the North Anna 3 SSE by including a comparison with the CSDRS. The applicant demonstrated that the Unit 1 containment mat earthquake recorded motion in all three directions are enveloped by the North Anna 3 CSDRS at all frequencies. Further, the applicant clarified the FSAR description of the seismic design parameters in FSAR Section 3.7.1 by noting that these site-specific recorded motions for North Anna are enveloped by the CSDRS, which is the licensing basis for all Category I structures. Regarding operability, the applicant included a criteria in Section 3.7.1 of the FSAR that the SSE design ground motion will be used in operability assessments to demonstrate plant safety for the as-found conditions of safety-related SSCs. Since the SSE design ground motion includes both the CSDRS and the site-specific FIRS, and the CSDRS envelopes these recordings and is the licensing basis for all Category I structures and would be used in determining operability or other demonstrations of plant safety, the staff considers RAI 2.5.2-8 resolved and closed**.** The staff verified that the appropriate change is incorporated in the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5.2.01 from the staff’s advanced SER for North Anna 3 is resolved and closed.

Following the Fukushima accident in Japan in March 2011, and subsequent NRC NTTF recommendations, on March 12, 2012, the NRC issued a letter, “Request for Information Pursuant to 10 CFR 50.54(f) Regarding Recommendations 2.1, 2.3, and 9.3 of the Near-Term Task Force Review of Insights from the Fukushima Dai-ichi Accident” (ADAMS Accession No. ML12053A340), requesting the operating nuclear power plants to re-assess seismic hazards at their sites using the most recent seismic source models. Consistent with existing guidance in RG 1.208, pertaining to the need to consider the latest information in the evaluation of seismic hazard, the staff issued an RAI to all COL and ESP applicants. In RAI 1.5-1 dated June 25, 2012 (ADAMS Accession No. ML12177A435), issued to North Anna 3 to reassess the seismic hazard at their sites using the new seismic source models. In the response to RAI 1.5-1 dated July 30, 2012 (ADAMS Accession No. ML12214A593), the applicant stated that based on FSAR changes made in responding to RAI 2.5.2-4, RAI 1.5-1 no longer applied at the North Anna 3 site.

The staff reviewed the applicant’s response to RAI 1.5-1, and agrees that the applicant’s response to RAI 2.5.2-4, in which the applicant stated that CEUS-SSC model would be used for PSHA, adequately addressed issues in RAI 1.5-1. Therefore, the staff considers RAI 1.5-1 resolved and closed.

In the February 13, 2012, response, the applicant also stated that it would update its COLA to use the CEUS-SSC to perform a new hard rock PSHA and develop a new site-specific GMRS for the North Anna 3 site. The applicant stated that this new PSHA would incorporate earthquake data from January 2009 through December 2011, which is subsequent to the period covered by the CEUS-SSC earthquake catalog. The applicant then updated its selection of GMM from the EPRI (2004, 2006) model to the most recent EPRI (2013) model and presented the results in the updated version of the North Anna 3 COL FSAR. The staff verified that the appropriate updates are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5.2.02 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff reviewed the applicant's response and associated FSAR updates. The CEUS-SSC, as published in NUREG-2115, is a seismic source model that represents the state of the practice concerning the conduct of PSHA in CEUS. Additionally, the applicant followed applicable guidance in updating the seismicity catalog, selecting seismic sources, and determining controlling earthquakes. Therefore, based on the updated PSHA source model, the updated site response analysis, and the staff's confirmatory analysis, discussed below, the staff considers RAI 2.5.2-4 resolved and closed.

In the response to RAI 2.5.2-4 dated February 13, 2012 (ADAMS Accession No. ML12048A096), the applicant stated that it would update the CEUS-SSC to account for seismicity occurring after the period covered by the CEUS-SSC. In its response to RAI 2.5.2-4, the applicant updated the CEUS-SSC to account for seismicity occurring after the period covered by the CEUS-SSC catalog. The applicant updated seismicity maps and evaluated the impact of updated seismicity on seismicity rates and b-values in the CEUS-SSC. The applicant did not provide detailed maps of where seismicity rates changed due to the catalog updates. In RAI 2.5.2-7 dated April 8, 2014 (ADAMS Accession No. ML14098A297), the staff asked the applicant to demonstrate quantitatively how the applicant updated the CEUS-SSC to incorporate recent seismicity. Specifically, the staff asked the applicant to demonstrate the updated recurrence rates, b-values, and comparisons of the hazard using the CEUS-SSC catalog, as published, and the updated catalog.

In the response to RAI 2.5.2-7 dated May 9, 2014 (ADAMS Accession No. ML14140A087), and supplemented on May 29, 2014 (ADAMS Accession No. ML14150A439), the applicant provided detailed information about how the updated seismicity catalog influenced rates and b-values in the CEUS-SSC and provided the requested comparison of hazard. The applicant provided plots (example shown on Figure 2.5.2-7 of this SER) of updated rates and b-values for the four distributed seismicity zones that the North Anna 3 site lays within (ECC-AM, MESE-N, MESE-W, and STUDY-R). Further In its response to RAI 2.5.2-7, the applicant provided a Table-1 and a Figure-13, comparing the updated and the baseline seismic hazard at a variety of input spectral acceleration levels. The applicant demonstrated that the updated seismic catalog increases hazard at the North Anna 3 site up to 9 percent for annual frequencies of exceedance lower then 10^{-4}.

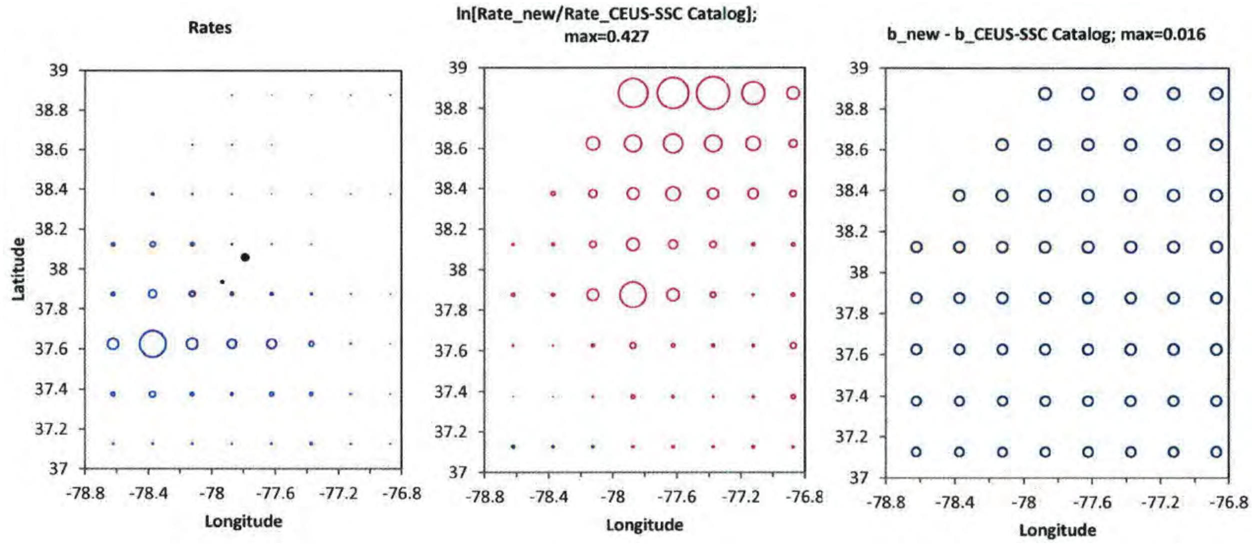

Figure 2.5.2-7. **Map** ***of Changes in Seismicity Rates and B-Values for*** **CEUS-SSC** ***Source Zone*** **ECC-AM, Case A** ***(*****Figure** ***from Applicant Response to*** **RAI** ***2.5.2-7.)***

The staff reviewed information provided by the applicant in response to RAIs about the CEUS-SSC catalog updates and the Mineral earthquake. The staff conducted a site audit on May 8, 2014, as documented in ADAMS Accession No. ML14203A179, during which the staff and the applicant discussed the details of their approach to the catalog updates and site response.

The staff also conducted an independent confirmatory analysis of the PSHA. The staff calculated the hazard at the North Anna 3 site using the published CEUS-SSC for distances up to 500 km (310 mi) for distributed seismicity sources and 1,000 km (620 mi) for RLME sources. In its confirmatory analysis, staff used the EPRI (2013) GMM. Figure 2.5.2-8 of this SER compares the PSHA results from the staff's independent confirmatory analysis with those of the applicant for PGA and frequencies of 25, 10, 2.5, and 1 Hz. The staff's and the applicant's calculations are in acceptable agreement. The staff used its independent PSHA results to develop site specific UHRS at the 10^{-4} and 10^{-5} exceedance frequencies. SER Figure 2.5.2-9 compares 10^{-4} and 10^{-5} UHRS developed by the staff with those developed by the applicant. Because the UHRS results developed by the staff are in acceptable agreement with those developed by the applicant and the applicant has incorporated seismicity after the publication of the CEUS-SSC, including the Mineral earthquake, the staff finds the applicant's PSHA acceptable.

Based on the applicant's response, the results of staff's site audit and its independent confirmatory analysis, staff considers RAI 2.5.2-7 resolved and closed.

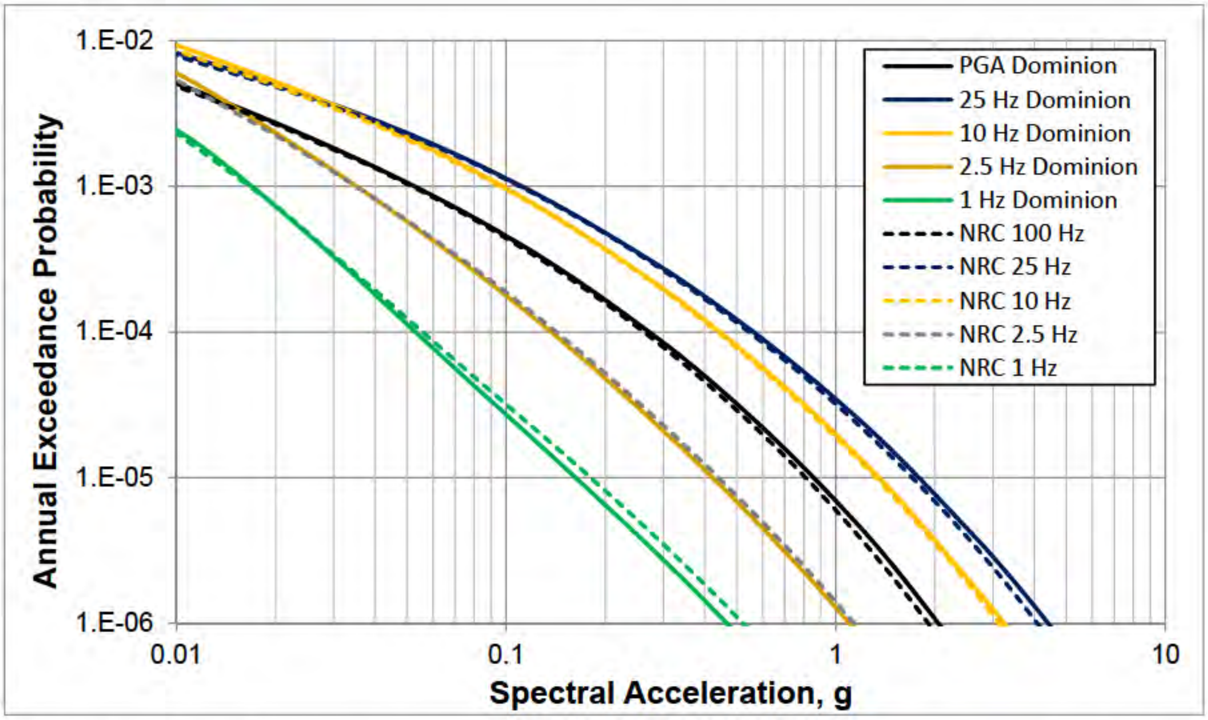

Figure 2.5.2-8. Comparison of the Applicant's Base Rock Hazard Curves with the Results of the Staff's Confirmatory Analysis

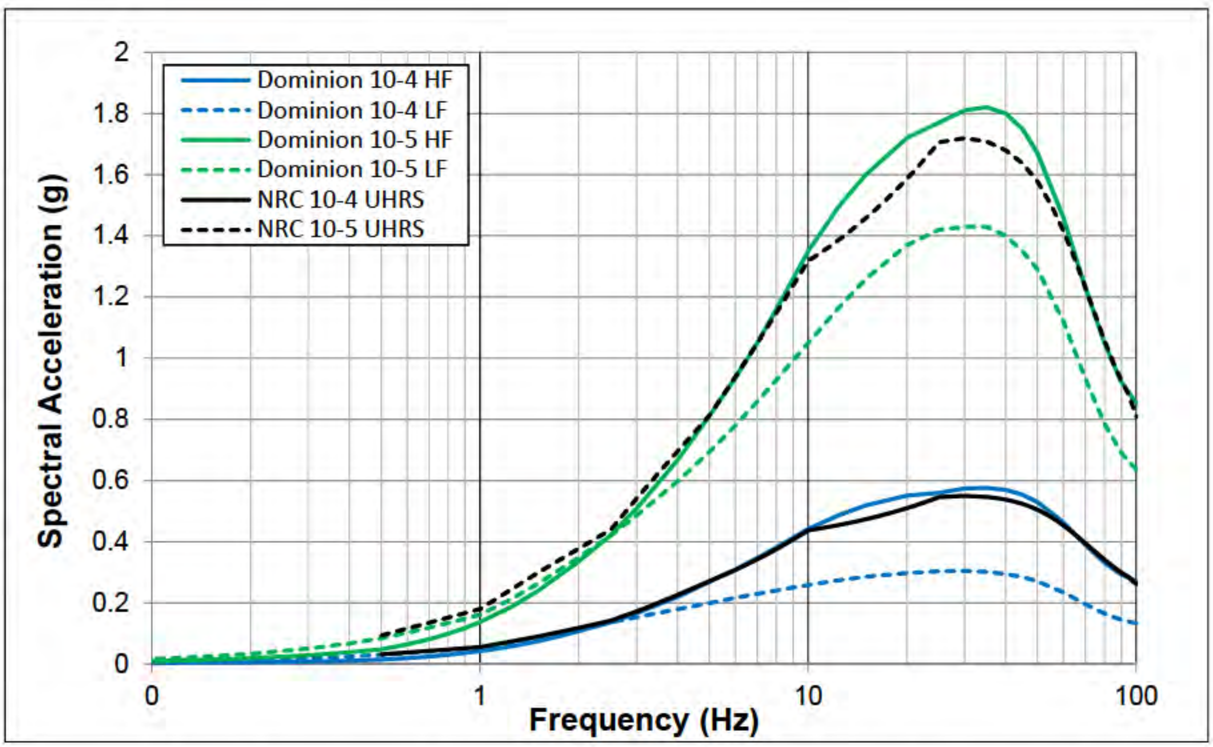

Figure 2.5.2-9. Comparison of the Applicant's UHRS at the 10-4 and 10-5 Annual Frequencies of Exceedance with the Results of Staff's Confirmatory Analysis

Ground Motion Response Spectra Updates

The applicant conducted additional site investigations subsequent to the issuance of the ESP. These investigations included additional geologic borings and subsurface geophysical measurements. As a result, the applicant developed new shear wave velocities for each of the rock units at the site. In addition, these additional borings revealed a more complex subsurface structure than was presented in the ESP SSAR. Therefore, in RAI 2.5.2-2a, dated December 21, 2010 (ADAMS Accession No. ML110340012), the staff asked the applicant to justify the use of one-dimensional site response methodology when significant topographic relief characterizes the subsurface layer interfaces. In RAI 2.5.2-2b, dated December 21, 2010 (ADAMS Accession No. ML110340012) the staff also asked, how the applicant ensured that the site response analysis captured this variability.

In the response to RAI 2.5.2-2a dated December 18, 2013 (ADAMS Accession No. ML14013A113), the applicant's response was revised. In the response to RAI 2.5.2-2b dated December 18, 2013 (ADAMS Accession No. ML14013A113), the applicant stated that even though there appears to be significant subsurface variability across the site and within the footprint of the plant, the distinction between different layers are, in fact, based on incremental differences in weathering. Because the criteria used to define the different layers within the rock are somewhat arbitrary, the layers are a result of the natural variability in the level of weathering across the site. The applicant stated that the vertical extent of this variability is small relative to the footprint of the plant, and concluded that a one-dimensional site response was appropriate. The applicant further stated that because this variability is the result of defining layers, not an actual stratification of the geology, that randomization of layer thicknesses, shear-wave velocity, and damping and shear modulus degradation curves accounts for this variability in site response. To further account for subsurface variability across the site, the applicant used data from three boreholes located within the footprint of the plant to generate shear-wave velocity profiles, and enveloped design response spectra from the RB/FB soil column and the CB soil column to determine the GMRS.

The staff reviewed the information provided by the applicant in response to RAI 2.5.2-2, and found that while the definition of different rock types (e.g., Zone III vs. Zone IV) was somewhat arbitrary, seismic shear-wave velocities varied greatly throughout the vertical soil profile of the site. As these shear-wave velocities correlate with different zones, the complex topography of the weathering profile across the site indicates that one-dimensional site response analysis may not be appropriate. In RAI 2.5.2-3a dated August 25, 2011 (ADAMS Accession No. ML11241A058), the staff asked the applicant to justify the one-dimensional site response analysis using only vertically propagating shear waves given the complex topography of the subsurface layers. In RAI 2.5.2-3b dated August 25, 2011 (ADAMS Accession No. ML11241A058), the staff requested that the applicant provide detailed site response input parameters. In RAI 2.5.2-3c dated August 25, 2011 (ADAMS Accession No. ML11241A058), the staff requested that the applicant explain how the shear-wave velocity profiles used in site response analysis were developed.

In the response to RAI 2.5.2-3a dated August 25, 2011 (ADAMS Accession No. ML11241A058), the applicant's response, supplemented on December 18, 2013 and February 23, 2015, stated that the use of one-dimensional site response analysis is appropriate because the soil and rocks at the site are all derived from the same parent rock. The applicant stated that the boundaries between rock types are gradational and so do not represent lateral impedance boundaries that may result in refraction, reflection, or trapping of shear waves traveling in horizontal directions. The applicant also stated that the uncertainties used in performing the site response such as varying the layer thicknesses, velocities, and shear modulus degradation and damping curves accounts for the variability in layer thickness across the site.

In order to ensure that appropriate uncertainties are included in their site response analysis, the applicant stated that they used geophysical data from three boreholes in their site response analysis. Data from boreholes B-901, B-907, and B-909 were used to develop a BE, log-mean, velocity profile for the RB/FB, and composite profiles, Profiles 1 and 2, were combined with the BE profile to develop the standard deviation profile for the RB/FB. The CB profile was developed using information from the closest borehole B-909. The applicant performed an independent site response analysis for each profile and enveloped the resulting response spectra to determine the GMRS for the site.

In addition, the applicant performed a sensitivity study in which the applicant calculated site response for all three boreholes individually. The applicant weighted these individual response spectra according to the borehole's proximity to the RB/FB centerline and enveloped. The applicant stated that the approach taken above to determine the GMRS is conservative relative to the results of the sensitivity study at all frequencies except for a small number of frequencies around 60 Hz.

The staff reviewed information provided by the applicant in response to RAI 2.5.2-3, but it was unclear to staff why the envelope of two site response calculations was used rather than the envelope of the three site response calculations undertaken by the applicant as part of its FIRS analysis. Therefore, in RAI 2.5.2-6 dated April 8, 2014 (ADAMS Accession No. ML14098A297), the staff requested that the applicant clarify why the GMRS was calculated as the envelope of the RB/FB and CB spectra and not the envelope of the profiles used for FIRS.

In a May 9, 2014 response (ADAMS Accession No. ML14140A087), the applicant clarified that information from all three boreholes (B-901, B-907, and B-909) was used to develop the soil profile for the RB/FB, and information from B-909 was used to develop the soil profile for the CB. The applicant stated that it used the envelope of the response spectra to represent the GMRS at the site because the envelope appropriately considered the uncertainties across the footprint of the site.

In the response to RAI 2.5.2-6 dated February 27, 2015 (ADAMS Accession No. ML15124A005), the applicant determined that the information provided sufficiently characterizes the subsurface geologic structure. The randomization procedures undertaken by the applicant appropriately account for the variability in layer thickness. Additionally, because the site materials are all derived from the same parent material, the use of multiple profiles ensures that horizontal variability in subsurface structure is accounted for.

The staff performed a confirmatory analysis of site response using values reported by the applicant for geophysical parameters. The staff independently developed BE velocity profiles, randomized the velocity profile and shear modulus degradation and damping curves and calculated site-specific amplification functions at the GMRS elevation. Figure 2.5.2-10 shows a comparison of amplification functions developed by the staff with those developed by the applicant. The differences in site amplification functions calculated by the staff and the applicant are not significant considering that staff used Approach 3 and the applicant used Approach 2, as described in NUREG/CR-6728, for the site response calculations. The staff subsequently combined its PSHA results at the 10^{-4} and 10^{-5} exceedance frequencies with its amplification functions and calculated a site-specific GMRS. Figure 2.5.2-11 shows a comparison of the site-specific GMRS developed by the staff with that developed by the applicant. The applicant's calculations are similar to that of the staff up to the frequency of about 25 Hz, and envelope staff's calculations at higher frequencies.

Based on the applicant's response to RAIs related to the site response calculations and staff's independent confirmatory analysis that is consistent with the applicant's results, the staff considers RAI 2.5.2-2, RAI 2.5.2-3, and RAI 2.5.2-6 resolved and closed.

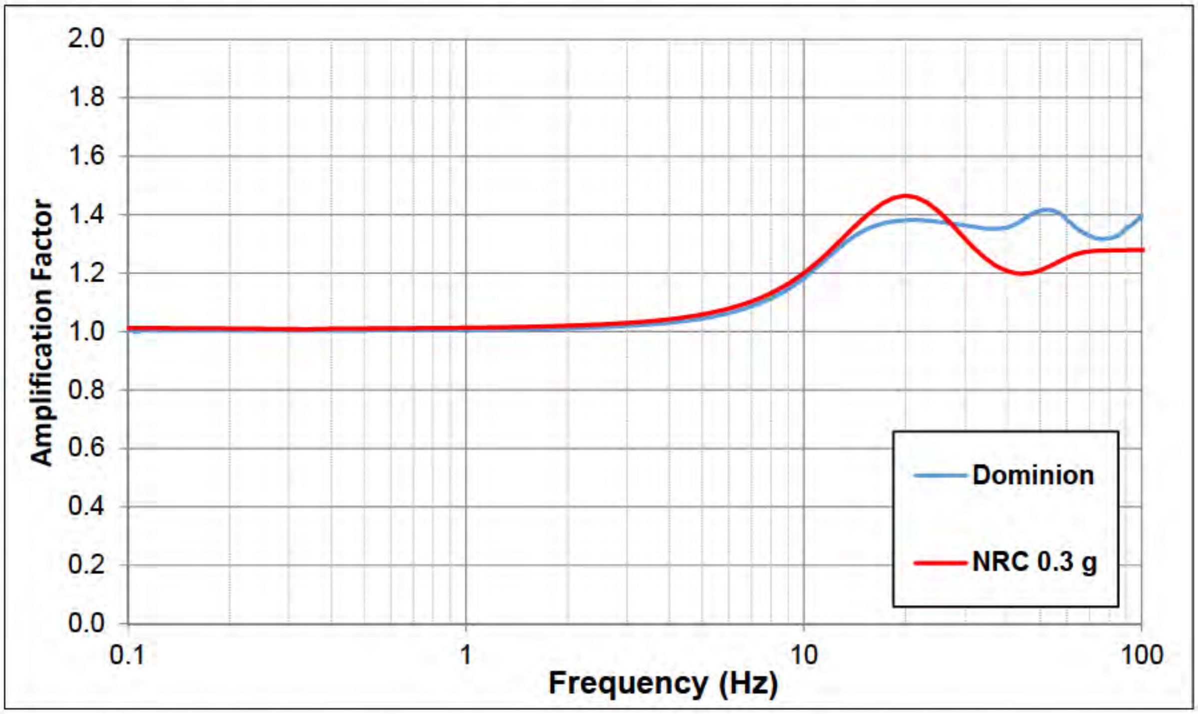

Figure 2.5.2-10. Comparison of the Applicant's Site Amplification Function with the Results of Staff's Confirmatory Analysis

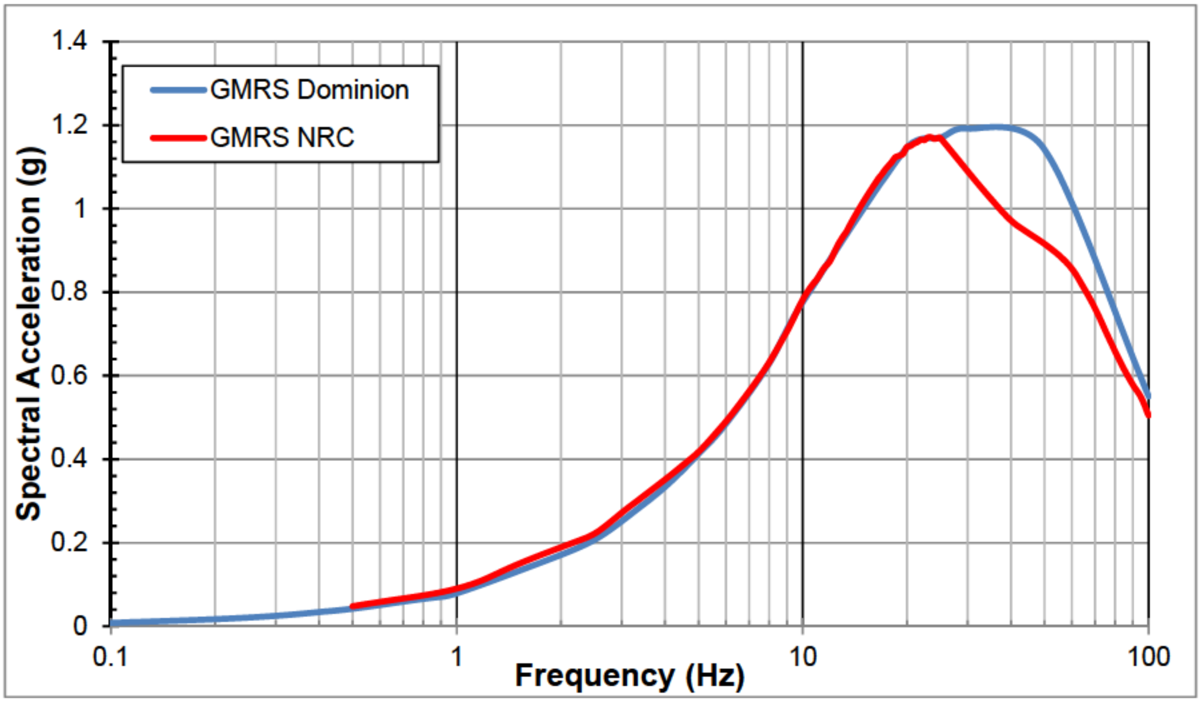

Figure 2.5.2-11. Comparison of the Applicant's GMRS with the Results of Staff's Confirmatory Analysis at Elevation 68.3 m (224 ft).

2.5.2.5 Post COL Activities

There are no post COL activities associated with this section.

2.5.2.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff's review confirmed that the applicant has addressed the relevant information and there is no outstanding information expected to be addressed in the COL FSAR related to this section.

The staff concludes that the information pertaining to North Anna 3 COL FSAR Section 2.5.2 is within the scope of the ESP and adequately incorporates by reference Section 2.5.2 of the ESP SSAR and is thus acceptable. Additionally, the staff concludes that the applicant has adequately addressed new and significant information pertaining to the Mineral, Virginia earthquake, the CEUS-SSC model, and additional subsurface geologic information from the COL subsurface investigations. Finally, the staff compared the additional COL information in the application to the relevant NRC regulations and acceptance criteria defined in NUREG-0800. The staff concluded that the applicant is in compliance with the relevant requirements of 10 CFR Parts 52 and 100. COL Action Item 2.0-27-A has been adequately addressed by the applicant and can be considered resolved. Therefore, the staff concluded that the site is suitable with respect to the vibratory ground motion criteria for new nuclear power plants.

2.5.3 Surface Faulting

2.5.3.1 Introduction

Section 2.5.3 of this SER provides information on surface faulting related to the North Anna site. Section 2.5.3.2 of this SER provides a summary of relevant geologic and seismic information contained in FSAR Section 2.5.3 of the North Anna COLA. SER Section 2.5.3.3 provides a summary of the regulations and guidance used by the applicant to perform the investigation. SER Section 2.5.3.4 reviews the staff's evaluation of FSAR Section 2.5.3, including any RAIs, open items, and confirmatory analyses performed by the staff. SER Section 2.5.3.5 discusses post COL activities. Finally, SER Section 2.5.3.6 provides an overall summary of the applicant's conclusions, as well as the staff's conclusions, restates any bases covered in the application and confirms that regulations were met or fulfilled by the applicant.

2.5.3.2 Summary of Application

Section 2.5.3 of the North Anna 3 COL FSAR, incorporates by reference Section 2.5.3 of the North Anna ESP SSAR, Revision 9. In addition, in FSAR Section 2.5.3, the applicant provided supplemental information on additional borehole data from North Anna 3 borings. The applicant stated that information contained in COL FSAR Section 2.5.3 is consistent with RG 1.208 and is intended to satisfy 10 CFR 100.23.

COL Item:

- NAPS COL 2.0-28-A

This COL FSAR section also addresses DCD COL Item 2.0-28-A of Revision 5 to the ESBWR DCD. NAPS COL 2.0-28-A addresses the permanent ground deformation from tectonic or nontectonic faulting. The ESBWR design requires the applicant to demonstrate that there is no potential for permanent ground deformation at the site area.

Early Site Permit Variance:

- NAPS ESP VAR 2.0.4

The staff's review of the ESP VAR 2.0-4 associated with North Anna 3 COL FSAR Section 2.5.3 is addressed below in the Technical Evaluation.

Geological Evidence, or Absence of Evidence, for Surface Deformation

The COL FSAR Section 2.5.3.2.1 described recent geologic mapping at the 1:24,000 scale by Hughes and Hibbard (2014) in the Ferncliff, VA 7.5' quadrangle (southwest of North Anna site) that shows the Chopawamsic fault as un-folded, in contrast to previous mapping, and the Ellisville pluton (440 Ma) intruding and cross-cutting the Chopawamsic fault. The Ellisville pluton thus postdates the Chopawamsic fault. This mapping simplifies the geometry of the Chopawamsic fault and moves the surface trace of the fault further northwest than mapped previously.

The COL FSAR Section 2.5.3.2.2 describes the main shock and deep aftershock epicenters of the Mineral earthquake as located near the LBF. The COL applicant pointed out that the Mineral earthquake aftershock-delineated rupture plane projects to the surface several miles west of the LBF.

Ages of Most Recent Deformations

The COL FSAR Section 2.5.3.4 states that the subsurface structure defined by aftershocks of the Mineral earthquake is located outside the 5-mi (8 km) radius site area. The COL applicant concluded based on its field reconnaissance in the epicentral region on April 19 to 21, 2012, that there is no evidence of surface rupture, surface fault features, or geomorphic expression of surface rupture or co-seismic surface tectonic deformation from the Mineral earthquake. The COL applicant further concluded that the rupture plane of the Mineral earthquake does not appear to coincide with a previously mapped fault.

2.5.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed within the FSER related to the ESBWR DCD and its supplements and in ESP FSER (NUREG-1835).

The applicable regulatory requirements for reviewing the applicant's discussion of surface tectonic and non-tectonic deformation are:

- 10 CFR 52.79(a)(1)(iii), relates to identifying geologic site characteristics with appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area and with sufficient margin for the limited accuracy, quantity and period of time in which the historical data have been accumulated.

- 10 CFR 100.23, provides the nature of the investigations required to obtain the geologic and seismic data necessary to determine site suitability and identify geologic and seismic factors required to be taken into account in the siting and design of nuclear power plants.

The related acceptance criteria are summarized from SRP Section 2.5.3:

- **Geologic, Seismic, and Geophysical Investigations**: In meeting the requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi),or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), and guidance in RGs 1.208, and 4.7, this area of review is considered acceptable if discussions of Quaternary tectonics, structural geology, stratigraphy, geochronologic methods used for age dating, paleoseismology, and geologic history of the site vicinity, site area, and site location are complete, compare reasonably with studies conducted by others in the same area, and are supported by detailed investigations performed by the applicant.

- **Geologic Evidence for Surface Deformation**: In meeting the requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), and guidance in RGs 1.208, and 4.7, this area of review is considered acceptable if the applicant provides sufficient surface and subsurface information for the site vicinity, area, and location to confirm and characterize presence or absence of surface deformation (e.g., faulting, growth faulting, subsidence or collapse related to dissolution of limestone, salt or gypsum deposits, or salt diapirism and paleoliquefaction) features. The applicant should also take into account the potential for blind faults.

- **Timing of Deformation**: In meeting the requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), 10 CFR 100.23(c), and 10 CFR 100.23(d)(2), this area of review is considered acceptable if recognized surface deformation features (e.g., tectonic faults and non-tectonic features including growth faults) and features associated with a blind fault, are investigated in sufficient detail to constrain the age of the most recent surface deformation event, and, if applicable, the ages of preceding deformation events.

- **Correlation of Earthquakes with Tectonic Features**: In meeting the requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi or 10 CFR 52.79(a)(1)(iii)), and 10 CFR 100.23(c), and 10 CFR 100.23(d)(2), this area of review is considered acceptable if the applicant evaluates all reported historical earthquakes within the site vicinity with respect to accuracy of hypocenter location and source of origin, and with respect to correlation to tectonic features.

- **Relationship of Geologic Features in the Site Vicinity to Regional Geologic Features**: In meeting the requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), this area of review is considered acceptable if the applicant evaluates the relationships between faults or other deformation features in the site vicinity and the regional framework. The application should provide an acceptable evaluation of the relationships between the regional (tectonic and non-tectonic) framework and deformation features in the site vicinity, including growths faults and growth fault systems. The applicant should show how this information is used in the evaluation of potential for future surface deformation at the site.

- **Potential for Surface Deformation at the Site:** To meet requirements of GDC 2 in Appendix A of 10 CFR Part 50, 10 CFR 52.17(a)(1)(vi) or 10 CFR 52.79(a)(1)(iii), and 10 CFR 100.23(c) and 10 CFR 100.23(d)(2), this area of review is considered acceptable if the applicant assessed the potential future tectonic and nontectonic surface deformation at the site. The applicant should provide sufficient geological, seismological, and geophysical information to clearly establish whether there is a potential for future surface deformation at the site. If the potential for future surface deformation exists at the site, the application must provide information that demonstrates the potential effects of surface deformation are within the design basis of the proposed facility. NRC regulations do not restrict building in an area with surface faulting potential, but if that potential exists, the regulations require that surface deformation must be taken into account in the design and operation of the proposed nuclear power plant. It is questionable whether it might be feasible to design for surface deformation with any degree of confidence that safety-related SSCs would maintain their safety functions if surface displacements occur in the future. Consequently, it is NRC policy (e.g., RG 1.208) to recommend that any site located on a surface or near-surface feature with a potential for future displacement be re-located to an alternate site.

Geologic characteristics should also be consistent with the related guidance from appropriate sections of RG 1.132, Revision 2, RG 1.198, “Procedures and Criteria for Assessing Seismic Soil Liquefaction at Nuclear Power Plant Sites,” RG 1.206, and 1.208.

2.5.3.4 Technical Evaluation

The staff reviewed Section 2.5.3 of the North Anna 3 COL FSAR and checked the referenced DCD, Revision 10 and the North Anna 3 ESP SSAR, Revision 9, to ensure that the combination of the DCD, the North Anna 3 ESP SSAR and the COLA represents the complete scope of information related to this review topic. The staff's review confirms that the information in the COL FSAR and North Anna 3 ESP SSAR addresses the required information for determining the potential for tectonic and non-tectonic surface deformation. The results of the staff's evaluation of the North Anna 3 ESP SSAR are documented in NUREG-1835.

The staff's technical evaluation of COL FSAR Section 2.5.3 is limited to reviewing (1) the resolution of DCD COL Item 2.0-26-A, and DCD COL Item 2.0-28-A, and ESP Action 2.5-1; (2) adherence to Permit Condition Section 3(E)(6); (3) resolution of ESP Variance 2.0-4 and; (4) applicant's responses to RAIs as addressed below.

The staff reviewed the information in the COL FSAR for conformance with DCD COL Item 2.0-26-A. Additional information on the site geologic characteristics is derived from additional subsurface investigations completed for the proposed North Anna 3 site. The staff concludes that the applicant included sufficient information from subsurface investigations to supplement SSAR Section 2.5.3 and to resolve DCD COL Item 2.0-26-A.

The staff reviewed COL Action Items in the North Anna 3 ESP. ESP Action Item 2.5-1 pertains to SER Section 2.5.1: A COL or CP applicant should perform additional borings to identify any weathered or fractured rock beneath the new foundations. Exact unit locations are not known at the ESP stage. The applicant made 93 borings for COL that were used to determine the geology characteristics and geotechnical properties of the subsurface material at the North Anna 3 site to resolve ESP Action Item 2.5-1. SER 2.5.4 provides staff's detailed evaluation of the additional borings. The staff concludes that the applicant included sufficient information from the additional boring program to support the COL and to resolve ESP Action Item 2.5-1.

The staff reviewed the North Anna 3 ESP Permit Conditions. Permit Condition, Section 3(E)(6) pertains to SER Section 2.5.1: If the ESP holder performs an excavation for a safety-related structure, the ESP holder shall perform geologic mapping of such excavation, evaluate any unforeseen geologic features that are encountered, and notify the NRC no later than 30 days before any such excavation is open for NRC examination and evaluation. An applicant for a CP or COL referencing this ESP shall perform geologic mapping of any excavation for a safety-related structure, evaluate any unforeseen geologic features that are encountered, and notify the NRC no later than 30 days before any such excavation is open for NRC examination and evaluation. The staff proposes that this permit condition be updated to a license condition for future excavations of safety-related structures. Section 2.5.1.4 of this report addresses this license condition.

The staff reviewed the COL FSAR variances to the ESP SSAR (NAPS ESP VAR 2.0-4) for Section 2.5.3 and DCD COL Item 2.0-28-A, and submitted an RAI. The staff's evaluation of information presented by the COL applicant in COL FSAR Section 2.5.3 and of the COL applicant's responses to the RAIs are presented below.

The COL FSAR Section 2.5.3 includes new geophysical and geotechnical information from the North Anna 3 site supplemental subsurface investigation. FSAR Section 2.5.3.2.5 states that borehole data, from the supplemental subsurface investigation described in Section 2.5.4.3, were reviewed for evidence of Quaternary fault movement and no such evidence was exhibited by the borehole data. The staff asked the COL applicant in RAI 02.05.01-6c dated April 22, 2014 (ADAMS Accession No. ML14112A156), to explain how evidence or lack of evidence for Quaternary faulting was determined in borehole data targeted for geotechnical information.

In a response to RAI 02.05.01-6c dated June 23, 2014 (ADAMS Accession No. ML14177A441), the COL applicant stated that it reviewed the borehole logs for evidence of highly weathered/sheared zones that contained fault gouge, which may have represented a major shear zone or an indication of Quaternary faulting. The applicant stated that wording in FSAR Section 2.5.3.2.5 will be revised in a future revision of the COLA to more clearly indicate that there is no evidence of major shear zones in the borehole data. The COL applicant maintains that a shear zone in W-1 is entirely within felsic gneiss and does not juxtapose different lithologic units across a fault contact. The implication being that a large amount of displacement has not occurred and the feature cannot be a major shear zone. The staff examined W-1 and W-5 at the May 8, 2014, site audit, the summary of which is available in the staff audit report (ADAMS Accession No. ML14203A179), and observed that in both borings there is a shear zone characterized by rock fragments, indication of brittle deformation, mixed with yellow-brown clay and chlorite. However, staff observed that the shear zone is confined to a single, relatively thin layer within each core. The COL applicant stated that the shear zone in W-1 and W-5 is not associated with fault 'a'. In work completed for North Anna site, Dames and Moore (1973) trenched fault 'a' and determined the fault dipped 45 to 50 degrees NW. Borings W-1 and W-5, located NW of fault 'a' would intersect fault 'a' at elevations much lower than where the micro shear-zone is located. The COL applicant looked for the micro-shear zone in adjacent borings and found no indication of this feature.

The staff reviewed several Dames and Moore reports from the 1970's regarding fault 'a' (VEPCO, 1974; 1973) in addition to the findings in the ESP SER regarding fault 'a' (NUREG-1835). The shear zone observed in W-1 and W-5 has similar features to fault 'a' but at a much less significant scale. Because the micro-shear zone in W-1 and W-5 is located northwest of fault 'a' and likely also dips northwest, it is structurally higher than fault 'a' (Figure 2.5.3-1 of this report). The staff notes that significant tectonic structures such as fault 'a' typically have a zone of deformation and deformation fabric is not necessarily limited to a single fault plane so the micro-shear zone could be associated with fault 'a'. Regardless of a structural association or not, the deformation associated with fault 'a' was determined to be geologically old, greater than 1 million years old. The staff considers the shear zone in W-1 and W-5 likely to be the same age as fault 'a' and not a potential future surface deformation hazard to the site.

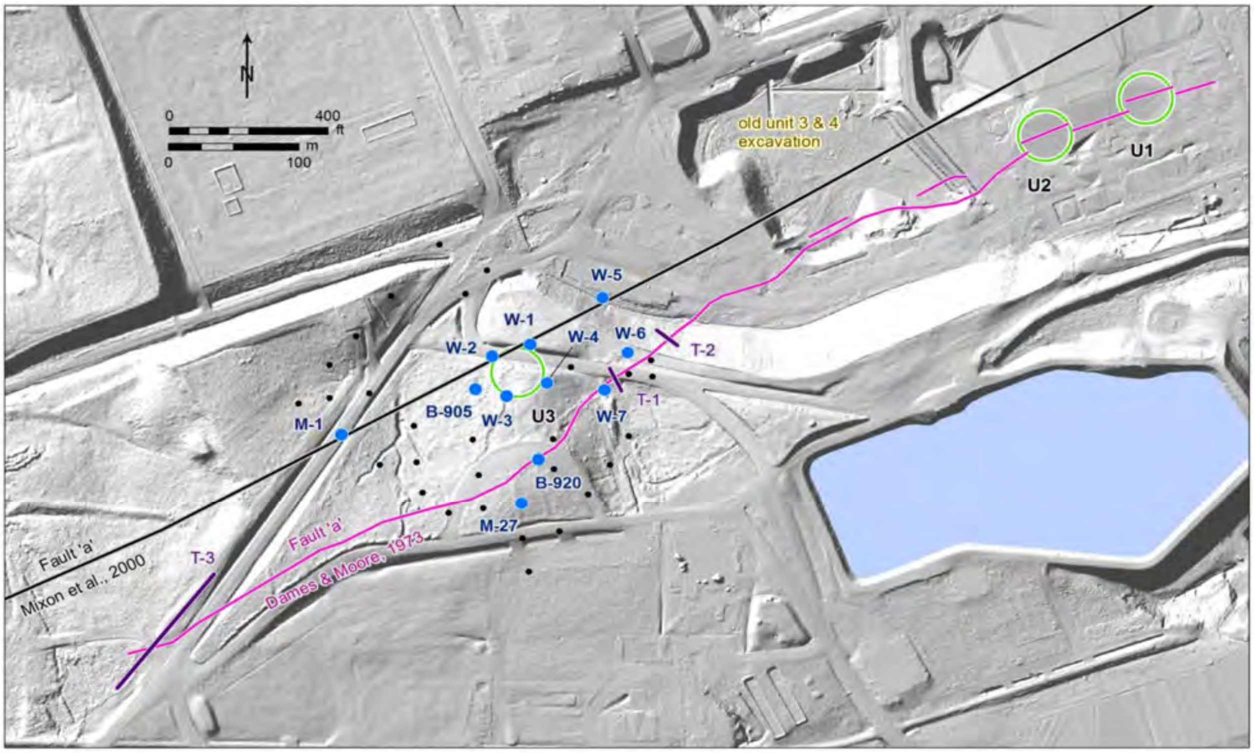

Figure 2.5.3-1. LiDAR-derived hillshade map showing locations of key North Anna 3 borings and surface mapped (Mixon et al, 2,000) and trench mapped (Dames and Moore, 1973) representations of fault 'a' (from Response to RAI 2.5.1-6d, Figure 1)

The staff reviewed DCD COL Item 2.0-28-A, which states the ESBWR design requires the applicant to demonstrate that there is no potential for permanent ground deformation at the site area. The staff concludes that the additional information from additional borings in the site area in conjunction with response to RAI 02.05.01-6c, that provides clarification regarding the possibility of finding major shear zones in the borings as opposed to determining specifically Quaternary fault movement, that there is sufficient subsurface information to resolve DCD COL Item 2.0-28-A. Accordingly and in compliance with 10 CFR 100.23 and 10 CFR 52.79, the staff considers RAI 02.05.01-6c resolved and closed.

The COL applicant proposed a future COL revision for FSAR Section 2.5.3.2.5 to more clearly indicate that there is no evidence of major shear zones in the borehole data and to remove the statement about evidence of Quaternary fault movement in borehole data. The applicant also proposed further revisions in FSAR Section 2.5.3.8 to supplement conclusions regarding tectonic and non-tectonic deformation at the site. The staff considers this to be acceptable and verified that the appropriate revisions are incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5.3-1 from the staff's advanced SER for North Anna 3 is resolved and closed.

2.5.3.5 Post Combined License Activities

There are no post COL activities related to COL FSAR Section 2.5.3. However, in Section 2.5.1.4 the staff identified a geologic mapping License Condition related to COL FSAR Section 2.5.1.2 as the responsibility of the COL licensee. Section 2.5.1.4 of this report addresses this license condition.

2.5.3.6 Conclusion

The staff reviewed the application and checked the referenced ESP SSAR. The staff's review confirmed that the applicant has addressed the relevant information and there is no outstanding information expected to be addressed in the COL FSAR related to this subsection.

The staff concludes that the information pertaining to North Anna 3 COL FSAR Section 2.5.3 is within the scope of the ESP and adequately incorporates by reference Section 2.5.3 of the ESP SSAR and investigated the potential for surface deformation in the site area. For the new information provided in COL FSAR Section 2.5.3, the staff concludes that the applicant adequately followed RGs 1.208, 1.206 and 4.7 and performed appropriate field and aerial reconnaissance of the site vicinity and conducted appropriate subsurface investigations at the site, as set forth above. In addition, the staff compared the additional COL information in the application to the relevant NRC regulations and acceptance criteria defined in NUREG-0800, and concludes that the material provided by the COL applicant meets the requirements of 10 CFR 100.23 and 10 CFR 52.79 (a)(iii). COL Action Item 2.0-28-A has been adequately addressed by the applicant and can be considered closed. Therefore, the staff concluded that the North Anna 3 site is suitable with respect to the tectonic and non-tectonic surface deformation criteria for new nuclear power plants.

2.5.4 Stability of Subsurface Materials and Foundations

This section of the SER addresses the North Anna 3 COL FSAR, Revision 8, site-specific information on the stability of subsurface materials and foundations for the North Anna 3 site identified in the ESBWR DCD, Revision 10.

Section 2.5.4.2 of this SER provides a summary of relevant geologic and seismic information in FSAR Section 2.5.4 of the North Anna 3 COLA. SER Section 2.5.4.3 provides a summary of the regulations and guidance used by the applicant to perform the investigation. SER Section 2.5.4.4 provides a review of the staff's evaluation of FSAR Section 2.5.4, including any RAIs, open items, and confirmatory analyses performed by the staff. SER Section 2.5.4.5 discusses post COL activities. Finally, SER Section 2.5.4.6 provides an overall summary of the applicant's conclusions, as well as the staff's conclusions, restates any bases covered in the application and confirms that regulations are met or fulfilled by the applicant.

2.5.4.1 Introduction

Section 2.5.4 of this FSAR discusses the stability of subsurface materials and foundations that relate to the North Anna 3 site. The properties and stability of the soil and rock underlying the site are important to the safe design and siting of the plant. The information in Section 2.5.4 of this FSAR addresses (1) geologic features in the site vicinity; (2) static and dynamic engineering properties of soil and rock strata underlying the site; (3) the relationship of the foundations for safety-related facilities and the engineering properties of underlying materials; (4) results of geophysical surveys, including in-hole and down-hole explorations; (5) safety-related excavation and backfill plans and engineered earthwork analyses and criteria; (6) groundwater conditions and piezometric pressure in all critical strata as they affect the loading and stability of foundation materials; (7) responses of site soils or rocks to dynamic loading; (8) liquefaction potential and consequences of liquefaction of all subsurface soils, including the settlement of foundations; (9) earthquake design bases; (10) results of investigations and analyses conducted to determine foundation material stability, deformation, and settlement under static conditions; (11) criteria, references, and design methods used in static and seismic analyses of foundation materials; (12) techniques and specifications to improve subsurface conditions, which are to be used at the site to provide suitable foundation conditions, and any additional information deemed necessary in accordance with 10 CFR Part 52.

Based on the information collected during ESP and COL site investigations, the applicant evaluated the stability of the site subsurface materials and foundations as well as the stability of slopes at the proposed North Anna 3 site.

2.5.4.2 Summary of Application

Section 2.5.4 of the North Anna 3 COL FSAR, incorporates by reference Section 2.5.4 of the ESP SSAR, Revision 9. In addition, in FSAR Section 2.5.4, the applicant provided the following supplements, including additional borehole data from North Anna 3 borings.

COL Items:

- NAPS COL 2.0-29-A

NAPS COL 2.0-29-A provides supplemental information and additional borehole data from the North Anna 3 borings to address the provisions listed in ESBWR DCD Table 2.0-1, regarding stability of subsurface materials and foundation requirements. The applicant provided additional information to address NAPS COL 2.0-29-A (ESBWR DCD COL Item 2.0-29-A), which requires that a COL applicant referencing the ESBWR design to provide site-specific information in accordance with SRP 2.5.4 and address: (1) localized liquefaction potential under other than seismic Category I structures, and (2) settlement and differential settlements.

- NAPS ESP COL 2.5-2

The applicant provided additional information to address ESP COL Action Item 2.5-2, which states that plot plans and profiles of all seismic Category I facilities need to be submitted for comparison with the subsurface profile and material properties.

- NAPS ESP COL 2.5-3

The applicant provided additional information to address ESP COL Action Item 2.5-3, which states that detailed excavation and backfill plans will be provided as part of the COLA.

- NAPS ESP COL 2.5-4

The applicant provided additional information to address ESP COL Action Item 2.5-4, which states that the COLA will include an evaluation of groundwater conditions as they affect foundation stability and/or detailed dewatering plans.

- NAPS ESP COL 2.5-5

The applicant provided additional information to address ESP COL Action Item 2.5-5, which states that additional site response analyses should be included at the COL stage once specific locations are selected for the nuclear power plant structures.

- NAPS ESP COL 2.5-6

The applicant provided additional information to address ESP COL Action Item 2.5-6, which states that an analysis of the stability of all planned safety-related facilities, including bearing capacity, rebound, settlement, and differential settlements under deadloads of fills and plant facilities, as well as lateral loading, will be addressed in the COLA.

- NAPS ESP COL 2.5-7

The applicant provided additional information to address ESP COL Action Item 2.5-7, which states that design-related criteria that pertain to structural design, such as wall rotation, sliding, and overturning will be addressed in the COLA.

- NAPS ESP COL 2.5-8

The applicant provided additional information to address ESP COL Action Item 2.5-8, which states that the COL applicant will provide specific plans for each proposed ground improvement technique the applicant plans to use so that the staff will be able to determine whether the chosen technique will ensure that Zone II saprolitic soils will be able to support safety-related foundations.

- NAPS ESP COL 2.5-9

The applicant provided additional information to address ESP COL Action Item 2.5-9, which states that the COL applicant is responsible for ensuring that the average shear wave velocity of the material underlying the foundation for the reactor containment equals or exceeds that of the chosen design.

- ESP Permit Condition 3.E(5)

The applicant provided additional information to address ESP Permit Condition 3.E(5), which states that the COL applicant should replace weathered or fractured rock at the foundation level with lean concrete before initiation of foundation construction.

- ESP Permit Conditions 3.E(6)

The applicant provided additional information to address ESP Permit Condition 3.E(6), which states that the COL applicant should include information on geologic mapping of future excavations for safety-related structures and should evaluate any unforeseen geologic features encountered at the site area. This permit condition has been carried forward as a license condition for future excavations of safety-related structures (Section 2.5.1.4).

- ESP Permit Condition 3.E(7)

The applicant provided additional information to address ESP Permit Condition 3.E(7), which states that the COL applicant should improve Zone II saprolitic soils to reduce any liquefaction potential if safety-related structures are to be founded on them. This permit condition is addressed in FSAR Section 2.5.4.8.

Overall Summary:

The applicant conducted additional field and laboratory tests to determine the static and dynamic properties of subsurface materials and confirmed that the associated parameters meet the design requirements defined in the ESBWR DCD, such as the minimum shear wave velocity and angle of internal friction of soil. The applicant also performed a site subsurface material liquefaction potential analysis; a static and dynamic bearing capacity analysis; and a settlement analysis to demonstrate that the subsurface materials meet the minimum static and dynamic bearing capacity, no liquefaction, and maximum total and differential settlement requirements. In the analyses, the applicant assumed properties of backfill material based on design. The liquefaction potential analysis results indicated that there might be localized liquefaction at certain depths at the site, but those potential liquefiable zones were too small and limited to have any impact on the safety of structures.

The applicant performed additional site investigations to further constrain the properties of the subsurface materials, which included redefining the elevation range at which the rock units were encountered at the site during the COL investigations. These investigations were generally of smaller ranges than those determined in the ESP investigations. The applicant also provided contour maps of the subsurface rock units as a supplement to the subsurface profiles presented as part of the ESP. The COL field investigations, a supplement to the ESP investigations, included additional exploratory borings, observation wells, CPTs, packer tests, geophysical loggings, and electrical resistivity tests. The applicant also completed additional laboratory testing, such as chemical and resonant column torsional shear (RCTS) tests, which further constrained the material properties that were determined from similar tests completed as part of the ESP. The applicant then used the results of the field investigations and the laboratory testing to further constrain the engineering properties of the subsurface materials, as determined during the ESP investigation.

The applicant also used the selected reactor design to better describe the foundation interfaces and developed more detailed subsurface profiles.

The applicant provided more detailed description of an excavation and backfill program compared to what was provided as part of the ESP. The applicant included the excavation plans and total depths to which excavation and backfilling would be required for the ESBWR design proposed for the North Anna 3 site. The applicant also included additional information regarding the groundwater conditions at the site, supplementing the earlier ESP information with design and site-specific interactions between the foundations and the groundwater level, such as construction dewatering plans and the effects of groundwater on foundation stability.

The applicant reassessed the response of soil and rock to dynamic loading at the site presented in the ESP as part of the COLA, with the consideration of the placement of concrete basemat on the native rock or backfill as part of its development of the shear wave velocity profile for the site, and the variation of shear modulus and damping with cyclic shear strain.

Regarding liquefaction potential, the applicant concluded in the ESP that the Zone IIA saprolitic soils were prone to liquefaction and would therefore be replaced with structural backfill. In the COLA, the applicant determined that the factor of safety (FS) against liquefaction of 1.1, which was determined during the ESP application, is still applicable.

The applicant revised the static stability evaluation for the site to incorporate the design-specific dimensions of structures in the COLA, as opposed to the assumed values used in the ESP application. The applicant also included the bearing capacity, settlement, and earth pressures in the structural fill or other load-bearing layers in the COLA, whereas the ESP had assumed that North Anna 3 would be constructed on Zone IIA saprolitic soils. Due to the change in load-bearing materials and the selection of a reactor design, the applicant reassessed the settlement, bearing capacity, and earth pressures to ensure that they were within the design parameters stated in the ESBWR DCD.

The applicant also restated the design criteria, including factors of safety against liquefaction and slope stability failure, as specified in the ESP, and provided additional factors of safety-related to bearing capacity and lateral earth pressure. Finally, the applicant revised the description of techniques to be used to improve subsurface material conditions, which in the ESP involved the use of vibro-stone columns to reinforce the Zone IIA saprolitic soils, while in the COL the applicant committed to removing the potentially liquefiable Zone IIA saprolitic soils and replacing the excavated material with structural backfills, both concrete and granular material fills.

2.5.4.2.1 Description of Site Geologic Features

FSAR Section 2.5.4.1 refers the description of regional and site geologic features to FSAR Sections 2.5.1.1 and 2.5.1.2. Since additional North Anna 3 borings were conducted, the applicant described the integrated site geologic features in the aforementioned sections based on information from the ESP and COL site investigation data. Section 2.5.1.4 of this SER contains the technical evaluation of this information.

2.5.4.2.2 Properties of Subsurface Materials

FSAR Section 2.5.4.2 describes the material and engineering properties of the COL site subsurface materials. This section gives an overview of the subsurface profile materials, field investigation results, and the results of laboratory tests on the subsurface samples from the North Anna 3 site investigations.

Description of Subsurface Materials

The applicant divided the subsurface materials into four zones, consistent with the site investigation findings of the ESP. FSAR Section 2.5.4.2.2 describes each zone as summarized below. The applicant also developed profiles to illustrate the subsurface across the North Anna 3 power block area. Figure 2.5.4-1 of this SER illustrated one subsurface profile, the line A-A in FSAR Figure 2.5.4-207, crossing the power block area of the North Anna 3 site. The applicant stated that the design grade elevation for North Anna 3 is at an Elevation of 88.3 m (290 ft).

Zone IV Bedrock. The applicant described the bedrock underlying the power block area as gneiss. The applicant identified the top of Zone IV rock as ranging in elevation from of 52.1 m (171 ft) to 84.7 m (278 ft), while the Zone III-IV transitional rock ranged in elevation from 56.9 m (187 ft) to 89.0 m (292 ft).

Zone III Weathered Rock. Above Zone IV, the applicant identified Zone III as weathered rock. The top of Zone III ranged in elevation from about 62.7 m (206 ft) to 85.8 m (292 ft).

Zone IIA and Zone IIB Saprolites. The applicant identified the weathered rock lying above the Zone III rock as saprolite, a highly weathered rock, divided into two zones - Zones IIA and IIB. The applicant further identified the Zone IIA saprolite as the upper layer, composed of 80 percent coarse, silty sands and 20 percent finer grained, clayey sands and silts. In contrast, the applicant described the Zone IIB saprolite as dense, silty sands with 10 to 50 percent core stone. The elevation at the top of Zone IIA ranged from 70.7 m (232 ft) to 102.1 m (335 ft) and IIB ranged from 65.5 m (215 ft) to 92.0 m (302 ft).

Zone I and Fill. The applicant stated that it will excavate all Zone I soils and existing fills, and will therefore not further consider these materials for the North Anna 3 site.

Subsurface Profiles

SER Figure 2.5.4-1 (FSAR Figure 2.5.4-207) illustrates the typical subsurface profile across the North Anna 3 power block area. The applicant also illustrated the excavation in the cross section figures to show the foundations of plant structures.

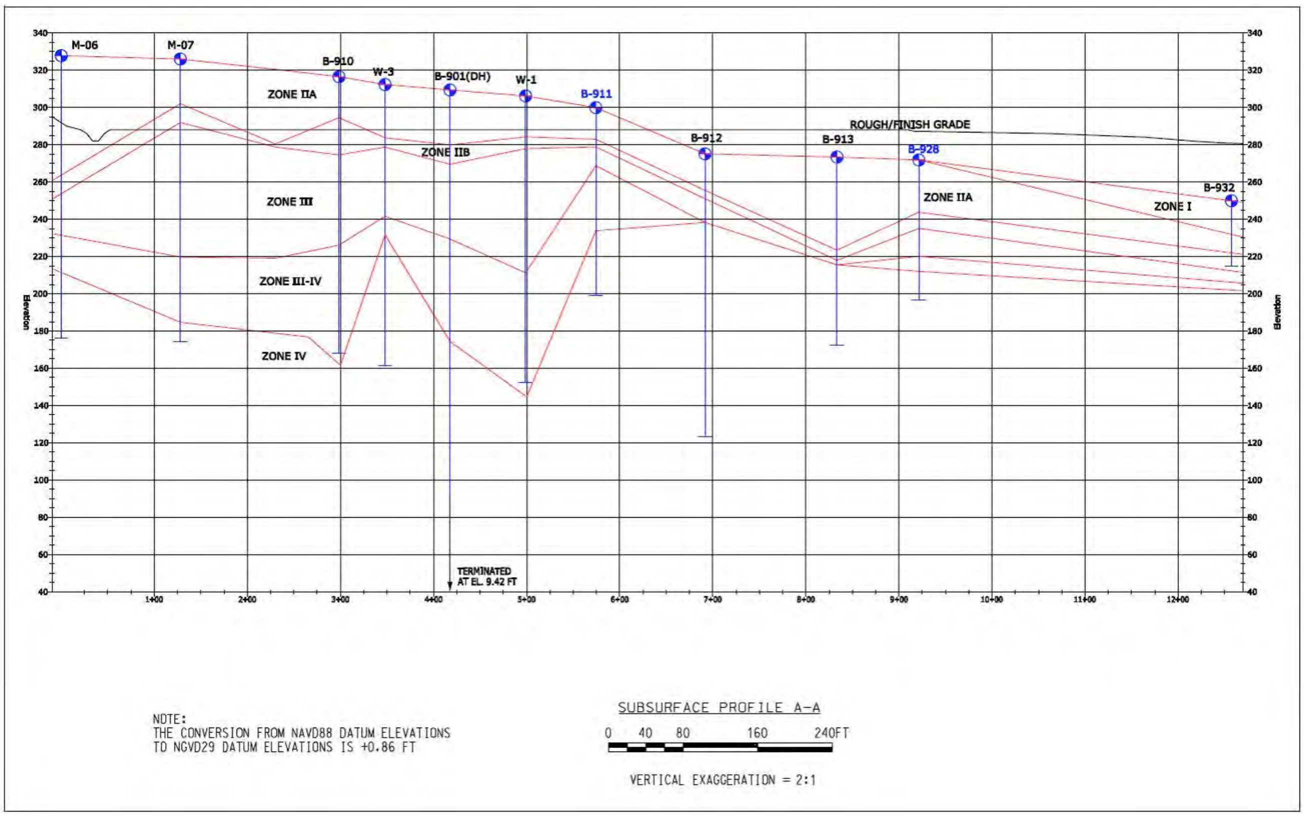

Figure 2.5.4-1. Typical Subsurface Profile across Unit 3 Power Block Area (FSAR Figure 2.5.4-207)

Field Investigations

As previously stated, the applicant performed a number of additional borings and tests in support of the COLA. The applicant stated that these investigations conformed to the guidance in

RG 1.132, and Subpart 2.20 of American Society of Mechanical Engineers (ASME) NQA-1 (ASME, 2012). FSAR Section 2.5.4.2.3 describes the additional work completed to characterize the geological, seismological, and geotechnical engineering properties of the North Anna 3 site, which included 93 borings, seven observation wells, four packer tests, 23 CPTs (including four down-hole seismic cone tests), six test pits, five sets of borehole geophysical logging, five sets of shear wave suspension logging, two sets of electrical resistivity tests, and a survey of the exploration points for all the investigations as part of the subsurface investigation program. The following paragraphs summarize the tests performed.

Borings and Samples/Cores. The applicant drilled 93 borings for the COL site investigation to depths between 6.7 to 91.4 m (22 to 300 ft) around the power block area. The applicant collected soil and rock samples in accordance with relevant American Society of Testing and Materials (ASTM) International standards, including, but not limited to, ASTM D 1586 (ASTM, 2011), D 1587 (ASTM, 2012), and D 2113 (ASTM, 2014). The applicant collected the soil samples using the standard penetration test (SPT) sampler at 0.76 m (2.5 ft) intervals to about 4.6 m (15 ft) in depth and at 1.5 m (5 ft) intervals below 4.6 m (15 ft). The applicant made nine sets of energy measurements on the automatic SPT hammers used by the drill rigs. The applicant obtained undisturbed samples by removing disturbed portions at both ends of the sample tube and trimming the ends square. The applicant also performed pocket penetrometer tests on the trimmed lower end of the samples. The applicant recovered rock core samples by first removing the cores from the split inner barrel before describing the core in detail and recording the information, such as joints and fractures, on the boring log. The applicant also computed the percentage of recovery and the RQD. Finally, the applicant labeled and transported all samples to the sample storage area.

Observation Wells. The applicant installed seven observation wells adjacent to sample borings, three in the soil/weathered rock zone and four in rock. The applicant developed each well by pumping until the pH and conductivity stabilized and the pumped water was reasonably free of suspended sediment. Using the slug test method, the applicant performed permeability tests in each of the three wells screened in soil/weathered rock and in one of the wells screened in rock. The applicant also used the packer method to conduct permeability tests in the borings adjacent to the four wells screened in rock.

Cone Penetrometer Tests. The applicant conducted 23 CPTs measuring tip resistance, sleeve friction, and porewater pressure. The applicant also performed down hole seismic and pore pressure dissipation tests in four CPTs.

Test Pits. The applicant excavated six test pits with depths ranging from 0.6 to 1.3 m (2 to 4.5 ft) at the North Anna 3 site to collect soil samples for laboratory tests. It used the test results to determine the soil properties and backfill suitability.

Laboratory Testing

FSAR Section 2.5.4.2.4 describes the results of numerous laboratory tests of soil and rock samples that the applicant performed for the North Anna 3 site investigation. The applicant performed the laboratory tests to verify the large number of test results from previous investigations, including tests performed for existing units and ESP site investigations. The applicant focused on three areas when conducting the tests and followed the guidance of RG 1.138, "Laboratory Investigations of Soils and Rocks for Engineering Analysis and Design of Nuclear Power Plants." The applicant verified that the properties of the soil and rock beneath the North Anna 3 power block area are similar to those beneath Units 1 and 2. The applicant performed chemical tests on the Zone IIA saprolites to determine corrosiveness toward buried steel and aggressiveness toward buried concrete. Finally, the applicant conducted RCTS tests on selected saprolite samples to determine the properties of shear modulus and damping ratio variation with cyclic strain. FSAR Table 2.5.4-205 summarizes the type and number of tests, and FSAR Appendix 2.5.4AA includes details and results of the laboratory tests with Appendix 2.5.4AAS1 presenting the RCTS test results.

Engineering Properties

FSAR Section 2.5.4.2.5 describes the engineering properties of selected materials in subsurface Zones IIA, IIB, Ill, III-IV, and IV based on the outcomes of the North Anna 3 field exploration and laboratory testing programs. Table 2.5.4-1 of this SER summarizes the main engineering properties of the site soil and rock layers based on FSAR Table 2.5.4-208 and related descriptions. The following sections describe the various test programs or field observations employed to derive the material properties.

Rock and Concrete Properties.

The applicant determined that the rock strength and stiffness values from the field and laboratory testing of the North Anna 3 rock are generally higher than the values obtained during the ESP site investigation. This finding suggested to the applicant that less fractured or weathered rock may underlie the North Anna 3 site, or better rock coring equipment and techniques produced better quality cores. The RQD values based on the results for each core in the boring logs are summarized in SER Table 2.5.4-1.

The applicant determined rock unconfined compressive strengths, unit weights, and elastic modulus values based on the rock strength test results. The applicant derived the shear modulus values using the elastic modulus and Poisson's ratio values. The applicant also determined that the high and low strain shear modulus values are essentially the same for high strength rock (Zones IV and III-IV). Finally, the applicant determined the shear and compression wave velocities profiles based on suspension P-S (compression and shear wave) velocity logging and CPT down-hole seismic tests performed during the COL site investigation program.

The applicant described the concrete fill that will replace Zone II soils and Zone III weathered rock beneath the RB/FB, CB, and FWSC seismic Category I structures. The applicant stated that the concrete fill would have a minimum strength of 17.2 MPa (2,500 psi), a unit weight of 232 kg/m^3 (145 pcf), and a Poisson's ratio of 0.15. Finally, because the V_s of the in-situ rock is about 1,524 m/s (5,000 fps), the applicant concluded that the concrete fill should have a V_s equal or greater to that of the in-situ rock. The applicant noted that concrete with the given strength of 17.2 MPa (2,500 psi) will have a BE V_s of 2,134 m/s (7,000 fps).

Soil Properties.

The applicant presented the engineering properties of North Anna 3 site soils in FSAR Table 2.5.4-208 (SER Table 2.5.4-1) and described the methods used to determine the properties in FSAR Section 2.5.4.2.5.b. The applicant combined laboratory test and field test (SPT and CPT) to determine the undrained shear strength of soil. The V_s values were determined based on down hole seismic tests and suspension P-S velocity measurements. The applicant calculated the low strain, defined as a strain level of 10^{-4} percent, and the shear modulus of the soil using the relationship between V_s and soil density. The applicant derived the low-strain elastic modulus using the relationship between the elastic modulus, shear modulus, and Poisson's ratio. The applicant determined the high-strain, defined as the strain level in the range of 0.25 to 0.5 percent, elastic modulus values by applying the relationship with the SPT N-value in Davie and

Lewis (1988). The applicant plans to use crushed rock as structural fill that will conform to the gradation of Size No. 21A in the Virginia Department of Transportation (VDOT) Road and Bridge Specifications (VDOT, 2002).

RCTS Testing.

The applicant performed three RCTS tests, two on Zone IIA saprolite and one on Zone IIB saprolite, to determine soil degradation properties under seismic loading conditions. The applicant then used the test results to generate curves of normalized shear modulus (G/G_{max}) and material damping ratio (D) versus shear strain. The applicant compared these results with generic curves in FSAR Section 2.5.4.7, which is summarized in Section 2.5.4.2.7 of this SER.

Table 2.5.4-1 Properties of NAPS 3 Site Subsurface Materials (FSAR Table 2.5.4-208)

STRATUM	Structural Fill	Concrete Fill	ZONE IIA	ZONE IIB	ZONE III	ZONE III-IV	ZONE IV
General description	Gravelly materials	-	Saprolite (< 10 percent core stone)	Saprolite (10 – 50 percent of core stone)	Weathered rock (> 50 percent core stone)	Moderately to slightly weathered rock	Parent rock – slightly weathered to fresh rock
Unified Soil Classification System symbol	GW	-	SM, SC	SM	-	-	-

Electrical Resistivity and Chemical Properties.

The applicant assessed corrosion potential by using field electrical resistivity and laboratory chemical tests on the Zone IIA and IIB saprolites. The test results indicated a low corrosion potential. Therefore, the applicant concluded that special sulfate resisting cement would not be necessary.

2.5.4.2.3 Foundation Interfaces

FSAR Section 2.5.4.3 describes the locations of site exploration points for the North Anna 3 subsurface investigation, including borings, observation wells, CPTs, electrical resistivity tests, and test pits made in the power block area. While FSAR Figure 2.5.4-217 illustrates these locations, FSAR Figure 2.5.4-206 shows the excavation plan for the safety-related structures and other major facilities. The applicant included the outline of these structures, plant dimensions, and the subsurface material contours under the plant structures on 10 subsurface profiles (see FSAR Figures 2.5.4-207 through 2.5.4-216). Finally, the applicant presented cross sections of the structure foundations with the proposed excavation and backfilling limits superimposed (see FSAR Figures 2.5.4-225 through 2.5.4-234).

2.5.4.2.4 Geophysical Surveys

FSAR Section 2.5.4.4 describes the geophysical testing conducted for North Anna 3, including field electrical resistivity testing, geophysical down hole testing, and seismic CPTs. The following subsections summarize these survey programs and investigations.

Field Electrical Resistivity Testing

FSAR Section 2.5.4.4.1 describes the field electrical resistivity tests performed along two crossing lines in the North Anna 3 site area. The applicant used four electrodes equidistant from a central point and inserted approximately 0.3 m (1 ft) into the ground to measure the voltage recorded at two inner electrodes after sending a current through two outer electrodes. The applicant used these results, included in FSAR Appendix 2.5.4AA, to evaluate corrosion potential in FSAR Section 2.5.4.2.5.

Geophysical Down-Hole Testing

For the North Anna 3 site geophysical investigation, the applicant performed geophysical down-hole tests in three borings (B-901, B-907 and B-909) within the footprint of Seismic Category 1 structures with depths of 91.4 m (300.0 ft), 61.1 m (200.5 ft), and 61.5 m (201.9 ft). FSAR Section 2.5.4.4.2 describes these tests, which included natural gamma, 3-arm caliper, resistivity, spontaneous potential, borehole acoustic televiewer, boring deviation, and suspension P-S velocity logging.

Natural Gamma and 3-Arm Caliper.

The applicant used a Model 3ACS 3-leg caliper probe to continuously measure natural gamma emissions from the borehole wall at 0.015 m (0.05 ft) intervals. The applicant described this probe as capable of measuring boring diameter and volume; locating hard and soft formations; identifying fissures; caving, pinching and casing damage; identifying bed boundaries; correlating strata between borings; and providing natural gamma measurements. The applicant conducted these tests by dropping the probe to the bottom of the borehole and collecting data during the return to the surface at a rate of 3.0 m (10 ft) per minute.

Resistivity, Spontaneous Potential, and Natural Gamma.

The applicant used a Model ELXG electric log probe to measure single point resistance, short and long normal resistivity, spontaneous potential and natural gamma at 0.015 m (0.05 ft) intervals. The applicant used the data to identify bed boundaries, correlate strata between borings, identify strata geometry (shale indication), and provide natural gamma measurements. Similar to the 3-arm caliper test, the applicant started this test at the bottom of the borehole and collected data while surfacing at a rate of 3.0 m (10 ft) per minute.

Acoustic Televiewer and Borehole Deviation Measurement.

The applicant used a High Resolution Acoustic Televiewer probe to measure boring inclination and deviation based on acoustic images and boring deviation data collected at 0.24 cm (0.096 in.) intervals. The images generated by processing acoustic pulses reflection data transmitted by an ultrasonic beam sensor to the borehole wall show the borehole wall at different depths. The applicant used this data to determine the need to correct soil and geophysical log depths to true vertical depths; provide acoustic imaging of the borehole to identify fractures, dikes, and weathered zones; and determine the dip and azimuth of these features. Again, the applicant conducted the survey by first dropping the instruments to the bottom of the borehole and then resurfacing at a rate of 0.91 m (3 ft) per minute.

Suspension P-S Velocity Logging.

The applicant also performed suspension P-S velocity logging tests to directly determine the average in-situ horizontal V_s and V_p of a 1.0 m high (3.3 ft) segment of the soil and rock column surrounding the borehole. This method involves dropping a source and two receivers to a specific depth in the borehole where the source creates a pressure wave and the receivers record the resulting seismic waves from the borehole wall.

Seismic Tests with Cone Penetrometer

FSAR Section 2.5.4.4.3 describes the CPTs conducted by the applicant for North Anna 3 site investigation. The applicant performed seismic CPTs to measure shear wave velocity at 1.5 m (5 ft) intervals in four CPTs and provided test results in Appendix 2.5.4AA.

Results of Shear and Compression Wave Velocity Tests

FSAR Section 2.5.4.4.4 presents the results of V_s and V_p tests for soil and rock at the North Anna 3 site. For soil, the applicant determined the V_s from suspension P-S velocity logging and seismic CPTs in saprolite. The applicant concluded that for Zone IIA saprolite, the average V_s increases with depth from 152.4 to 365.7 m/s (500 to 1,200 fps) with a median value of 259 m/s (850 fps), comparable to the median value of 289 m/s (950 fps) in the ESP SSAR. The low strain Poisson's ratio for Zone IIA saprolite is 0.35. For Zone IIB saprolite, the applicant noted that the average V_s ranges from 365.7 to 762 m/s (1,200 to 2,500 fps) with a median value of 487 m/s (1,600 fps), the same as the ESP SSAR, and with a low strain Poisson's ratio of 0.37.

For rock, the applicant illustrated the V_s measurements from suspension P-S velocity logging. The applicant noted that the V_s determined at the North Anna 3 site as part of the COL investigations are slightly higher than those determined in the ESP SSAR. The BE V_s was 914 m/s (3,000 fps) for Zone III weathered rock, 1,829 m/s (6,000 fps) for Zone III-IV partially weathered rock, and 2,743 m/s (9,000 fps) for Zone IV fresh rock.

2.5.4.2.5 Excavation and Backfill

FSAR Section 2.5.4.5, “Excavation and Backfill,” describes the extent of seismic Category I structure related excavations, fills and slopes; methods to be used for excavation and stability control; and sources of backfill including quantities, compaction specifications, and quality control.

Extent of Excavations, Fills, and Slopes

FSAR Section 2.5.4.5.1 describes the extent of excavations, fills, and slopes at the North Anna 3 site. In this section, the applicant included numerous figures to illustrate this information, including FSAR Figure 2.5.4-206 showing the extent of excavations, fills, and slopes for North Anna 3 and FSAR Figures 2.5.4-225 through 2.5.4-234 showing cross sections of the excavations. The applicant indicated that it will excavate up to 12.2 m (40 ft) to reach the design plant grade of elevation 88.2 m (290 ft), but some lower areas may need to be backfilled. The applicant estimated the total cut at about 478,140 cubic meters (625,380 cubic yards), while the amount of backfilling with compacted structural fill about 184,830 cubic meters (241,750 cubic yards) and concrete fill about 83,810 cubic meters (109,620 cubic yards). The applicant described the excavation plan as having 3-horizontal to 1-vertical (3H:1V) slopes extending up from the plant grade around the southern and eastern perimeters of the area. To the northeast of the TB, going towards the existing Units 1 and 2, ground surface elevation reduces at an approximately 5 percent slope down to elevation 85.3 m (280 ft) at the SW Building. As existing grade falls off from the power block area northeast towards Units 1 and 2, the applicant stated that it may need an additional 9.14 m (30 ft) of backfill to bring the ground level currently at elevation 76.2 m (250 ft) in the area of the originally planned Units 3 and 4 to achieve the designed finish grade.

Excavation Methods and Stability

FSAR Section 2.5.4.5.2 describes the methods of excavation and plans to maintain stability along the excavation surfaces. The applicant included plans for the excavation of both soil and rock zones at the North Anna 3 site. The following subsections summarize these excavation methods.

<u>Excavation in Soil</u>.

The applicant stated that it will use conventional equipment for excavation in soil Zones IIA and IIB and in any existing fills. For excavation of less than 6.1 m (20 ft) in height, the applicant stated that it will follow U.S. Office of Safety and Health Administration (OSHA) regulations. The applicant further described plans to use a temporary vertical wall system to stabilize the power block excavation, and the slopes around the perimeter of the power block area will be no steeper than 3H:1V, with a bench at approximately 7.5 m (25 ft) height. Due to the erosive potential of the saprolitic soils, the applicant concluded that it will need to seal and protect even temporary slopes cut into the saprolite.

<u>Excavation in Rock</u>.

Based on lessons learned from the construction of Units 1 and 2, the applicant stated that it will use techniques to reduce vibrations during rock excavation, including a temporary vertical wall system to support the excavation where necessary during North Anna 3 excavation. Because North Anna 3 is about 457.2 m (1,500 ft) from the center of the Unit 2 containment building, not

91.44 m (300 ft) as originally planned, the applicant concluded that the initially planned excavation methods would be effective for the new North Anna 3. These methods include controlled blasting techniques, preservation of the rock integrity outside of the excavations, and reinforcing the rock to ensure adequate support and safety. The applicant also stated that it would geologically map the excavations for safety-related structures and notify the NRC no later than 30 days before any safety-related excavations are open to allow for staff examination or evaluation. Finally, the applicant stated that it will not monitor the excavation in rock because there is no measurable rebound or heave of the sound rock subgrade.

Structural Fill Sources, Compaction and Quality Control

FSAR Section 2.5.4.5.3 describes the sources of backfill, compaction requirements, and quality controls for the North Anna 3 site. The applicant illustrated the anticipated extent of structural fills on the foundation cross-section plots (see FSAR Figures 2.5.4-225 through 2.5.4-234). The applicant described plans to replace moderately to severely weathered Zone III rock exposed at the bottom of the excavations for the seismic Category I RB/FB, CB, and FWSC foundation mats with concrete fill. The FSAR states that saprolitic soil material found onsite will not be used as structural fill to support or backfill seismic Category I and II structures. Because backfill material is not naturally available at the site, the applicant described plans to set up a crushing and blending plant onsite to produce crushed aggregate to the required specifications for use as structural fill. The applicant described the fill as well-graded, angular or sub-angular sand and gravel-sized particles conforming to the gradation of Size No. 21A in the “Virginia Department of Transportation Road and Bridge Specifications (VDOT, 2002)”, and it will confirm the soundness through sulfate soundness and Los Angeles abrasion tests. The applicant stated that it plans to place the structural fill in lifts of no more than 30.48 cm (12 in.) loose thickness and compacted to at least 95 percent of the maximum dry density from the modified Proctor Test (ASTM D1557) and within 3 percent of its optimum moisture content. The applicant assumed that a N_{60} value of 50 blows per foot and an internal friction angle of 40 degrees were reasonable and conservative. The applicant stated that it plans to perform confirmatory gradation tests, modified Proctor compaction tests, and CU triaxial compression tests to ensure that the structural fill meets the selected criteria.

The applicant also referred to TSs that addresses fill placement and compaction control procedures. The applicant stated that it plans to perform at least one field density test per lift of fill and at least one test for every 191 cubic meters (250 cubic yards) of fill placed. Finally, the planned test fill program will determine the optimum size roller, number of passes, lift thickness, and other data to achieve the specified compaction.

Control of Groundwater during Excavation

Although FSAR Section 2.5.4.5.4 briefly describes the applicant’s plans for controlling groundwater during the excavations, FSAR Section 2.5.4.6.2 provides more details. The applicant described plans to slope back the tops of excavations to prevent runoff down the excavated slopes during heavy rainfall and to construct lined dewatering sumps and ditches due to the erosive nature of the saprolitic soil.

2.5.4.2.6 Groundwater Conditions

In FSAR Section 2.5.4.6, the applicant briefly described the groundwater conditions at the North Anna 3 site. This section includes groundwater measurements and elevations, construction dewatering and seepage, and the effect of groundwater conditions on foundation stability. FSAR Section 2.4.12 describes the groundwater conditions at the North Anna 3 site in greater detail.

Groundwater Measurements and Elevations

FSAR Section 2.5.4.6.1 describes the groundwater measurements and elevations at the North Anna 3 site. The applicant stated that groundwater is present in unconfined conditions in both the surficial sediments and underlying bedrock. In addition to the nine wells installed as part of the ESP subsurface investigation, the applicant installed seven observation wells during the COL site investigation. The applicant stated that the groundwater level in the observation wells ranged from an elevation of 72.5 m (238 ft) to an elevation 95.7 m (314 ft) between December 2002 and August 2007. The applicant concluded that the depth of surface ground water in the North Anna 3 power block area ranges from about 5.5 m (18 ft) to 7.6 m (25 ft) below the present surface.

The applicant performed slug tests and obtained hydraulic conductivity values for saprolite and bedrock in the range of 0.076 m (0.25 ft) to 3.02 m (9.9 ft) per day with a geometric mean value of 0.53 m (1.74 ft) per day. For rock, the values ranged from 0.15 m (0.5 ft) to 1.92 m (6.3 ft) per day with a geometric mean value of 0.62 m (2.05 ft) per day. The applicant also stated that ground water movement at the site is generally to the north and east, towards Lake Anna.

The applicant stated that the maximum allowable groundwater level for operation of the power block area of North Anna 3 is at an elevation of 87.8 m (288 ft), or 0.6 m (2 ft) below the design plant grade at an elevation of 88.4 m (290 ft). The groundwater level in the power block area of North Anna 3 is presented in FSAR Section 2.4.12.4 and ranges from about an elevation of 82.6 m (271 ft) at the north end of the TB to about an elevation of 86.1 m (282.5 ft) at the south end of the RB/FB.

Construction Dewatering and Seepage

FSAR Section 2.5.4.6.2 describes dewatering plans during construction and the method used to reduce seepage in both the soil and rock zones at the site. The applicant stated that the relatively low permeability of the saprolite and underlying rock allows the use of gravity-type systems to accomplish the necessary dewatering for all major excavations. Specifically, the applicant concluded that sump-pumping ditches will be adequate to dewater the soil. For rock, the applicant stated that it plans to use sump-pumping to collect water from relief drains installed in the major rock excavation walls to prevent the buildup of hydrostatic pressure. Although the applicant noted a head of approximately 12.2 m (40 ft) between the excavation grade and Lake Anna during the final excavation stages for abandoned Units 3 and 4, the applicant did not encounter any dewatering difficulties. The applicant attributed this to the tight nature of the joints in the rock below an elevation of about 73.2 m (240 ft). The applicant anticipated negligible seepage effects from the lake since the excavation for North Anna 3 is at least 305 m (1,000 ft) from Lake Anna.

Effects of Groundwater Conditions on Foundation Stability

FSAR Section 2.5.4.6.3 refers to FSAR Section 2.5.4.10 for a description of the maximum groundwater level below plant grade. The applicant concluded that there are no buoyancy issues at the North Anna 3 site; therefore a permanent dewatering system is not necessary.

2.5.4.2.7 Response of Soil and Rock to Dynamic Loading

In FSAR Section 2.5.4.7, the applicant described the seismic ground motion amplification/attenuation estimated from the V_s profiles of the subsurface materials, the variation of shear modulus and damping with strain, and the site-specific acceleration-time histories. The applicant stated that it will found the seismic Category I structures on Zone III-IV rock, Zone IV rock, or on concrete placed on the bedrock.

Shear Wave Velocity Profile

FSAR Section 2.5.4.7.1 describes the development of the V_s profiles for the soil and bedrock at the North Anna 3 site. To develop the profiles, the applicant compiled various measurements to determine the V_s in the soil and rock at the North Anna 3 site, as described in FSAR Section 2.5.4.4. The applicant developed the BE V_s profiles beneath the seismic Category I RB/FB, CB, and Firewater Service Complex (FWSC) based on shear wave velocity data collected from borings B-901, B-907, and B-909. The bottom of foundation elevation for these structures is Elevation 68.3 m (224 ft), Elevation 73.5 m (241 ft) and Elevation 86.0 m (282 ft), respectively. SER Figure 2.5.4-2 shows the BE V_s profiles for the RB/FB and CB, and SER Figure 2.5.4-3 presents the BE V_s profiles for the FWSC.

In addition to the V_s profiles considered for the seismic Category I structures, the applicant also developed a V_s profile beyond the excavation for the power block. The applicant developed this profile based on the V_s measured in C-916, the N-values measured in B-947, the average V_s values derived from site-wide V_s measurements in saprolite, and data collected from borings B-901, B-907 and B-909. SER Figure 2.5.4-4 shows the V_s profile which the applicant used to determine the PGAs in the free-field for use in liquefaction potential and slope stability analyses.

For the structural fill to be used as backfill around the seismic Category I structures, the applicant developed a V_s profile based on the relationships between the N-value (adjusted for overburden pressure) and V_s developed by Seed, et al. (1983) and Imai and Tonoucchi (1982). The applicant averaged this profile in 1.5 m (5 ft) intervals vertically to produce the average V_s profile shown in SER Figure 2.5.4-5. The upper and lower bound values shown in this figure are 1.414 and 0.707 times the mean value of shear wave velocity, respectively. The applicant used this profile as input in the seismic response analyses.

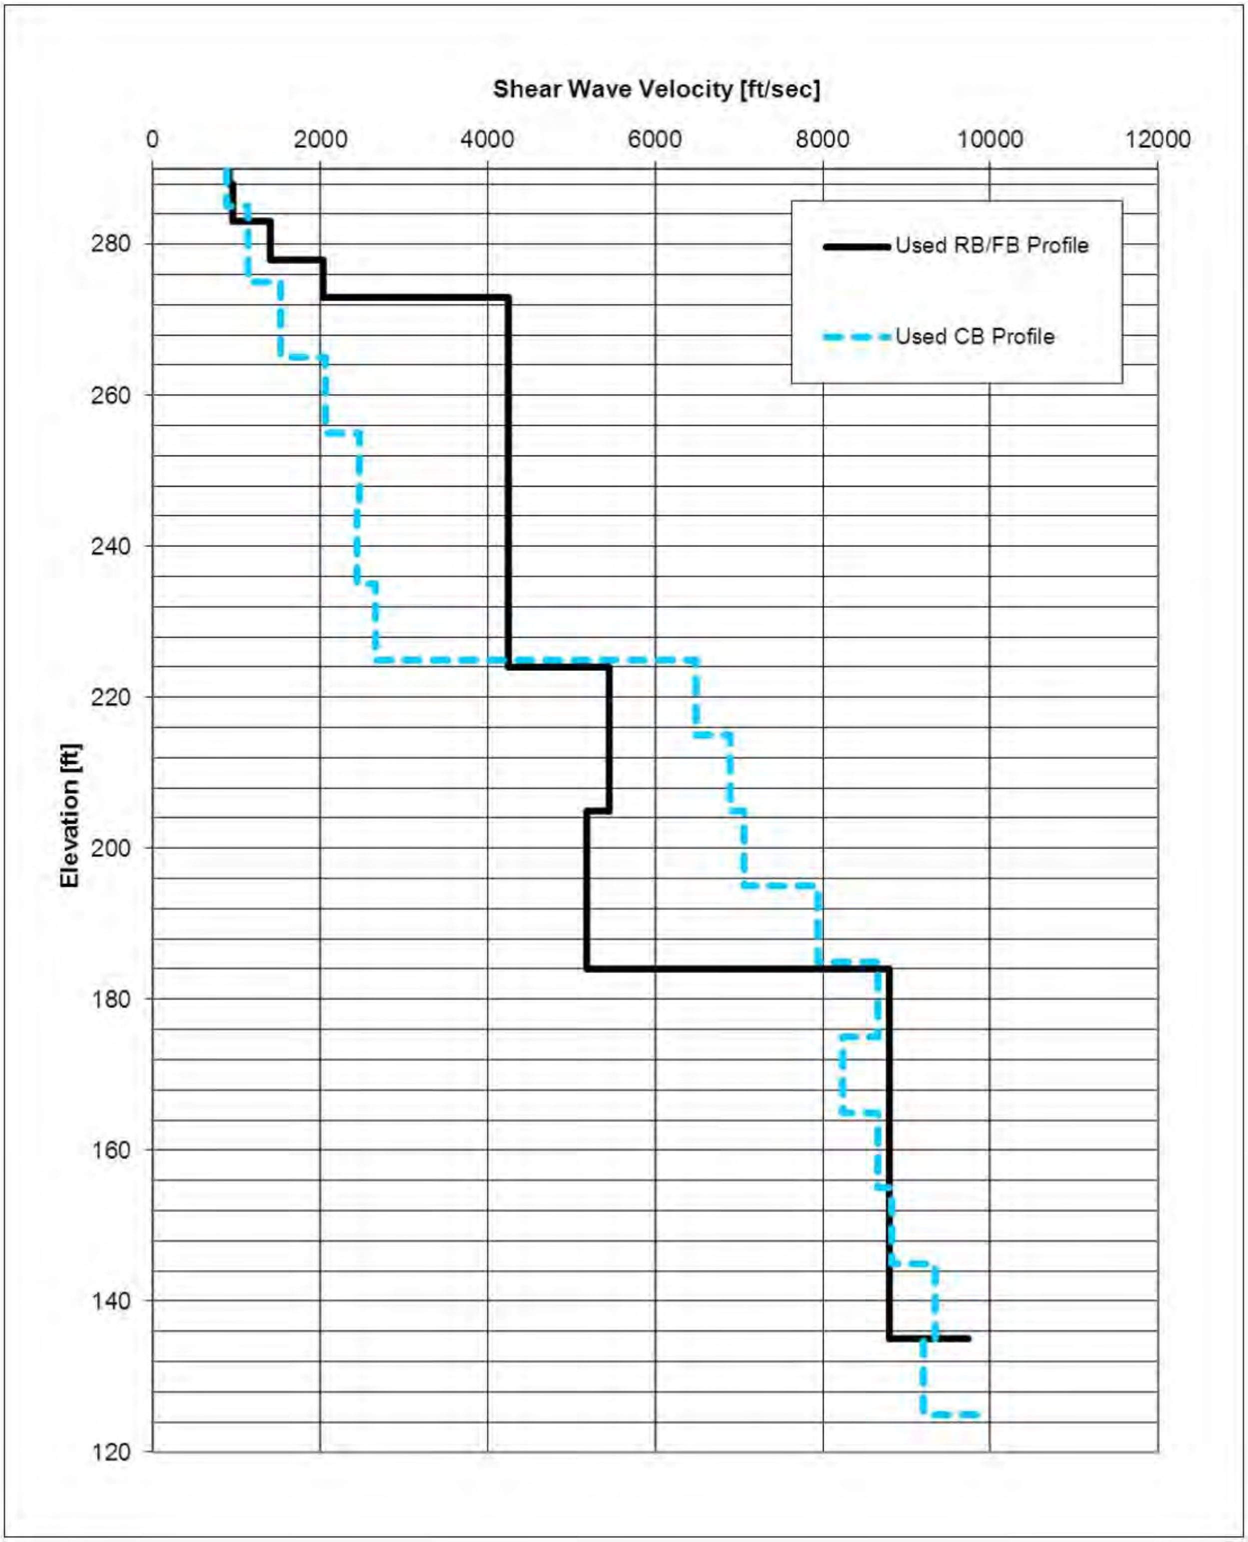

Figure 2.5.4-2. Best Estimate Shear Wave Velocity Profiles for RB/FB and CB (FSAR Figure 2.5.4-242)

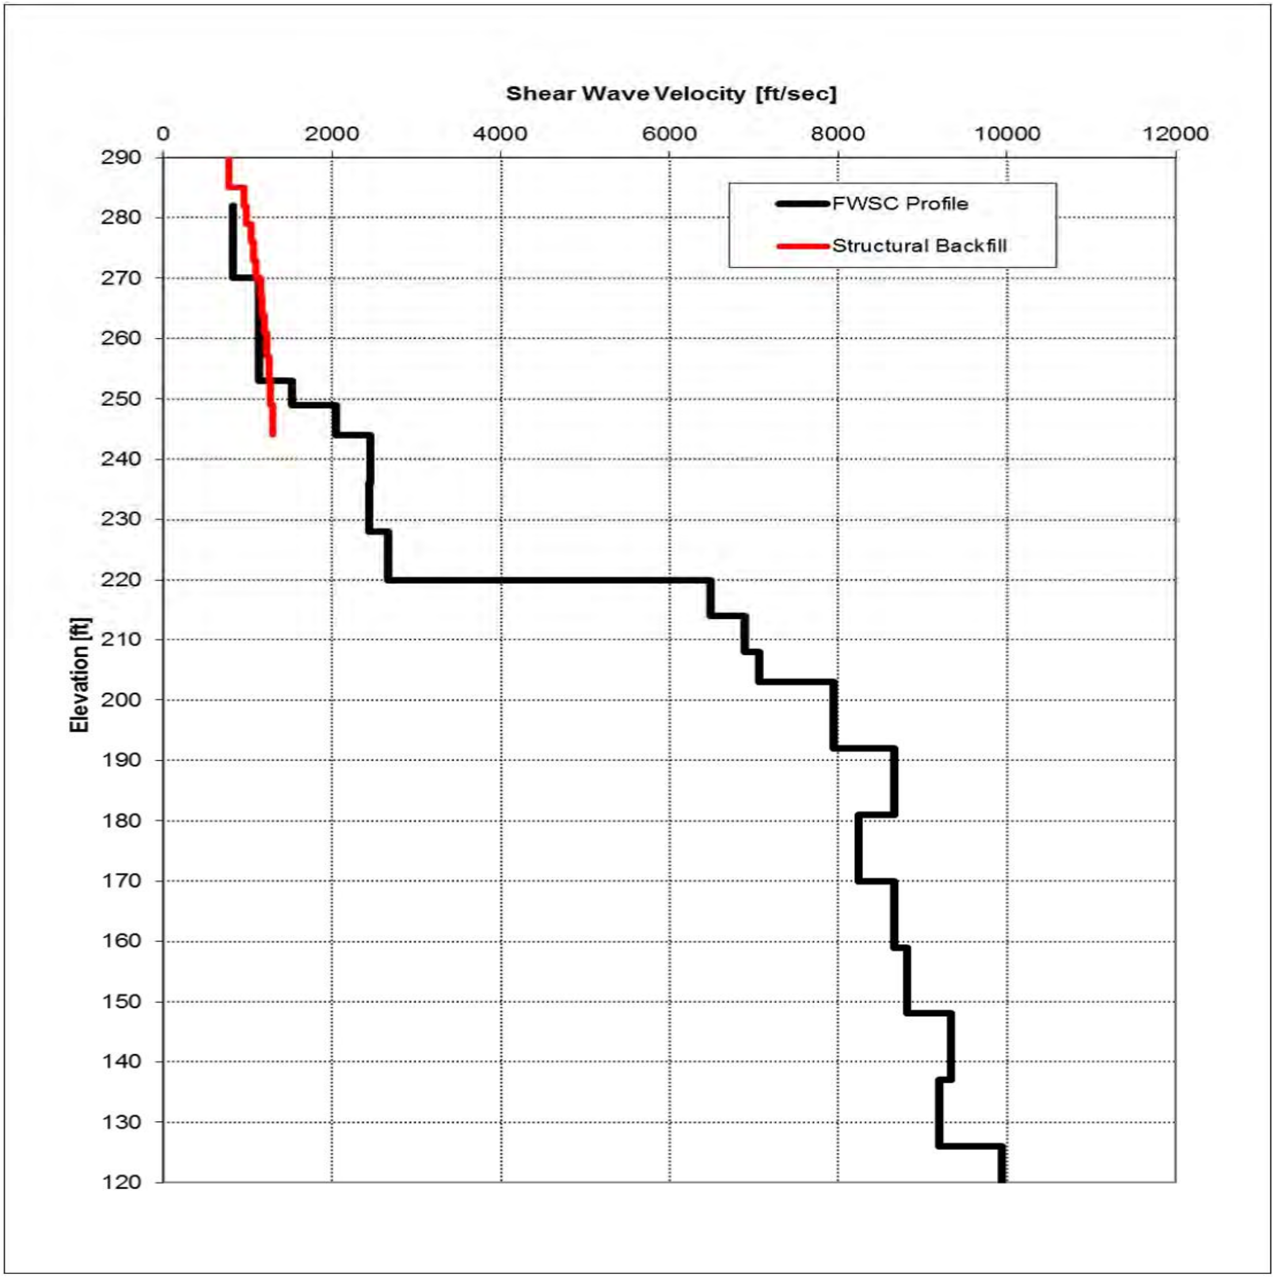

Figure 2.5.4-3. Best Estimate Shear Wave Velocity Profiles for FWSC (FSAR Figure 2.5.4-243)

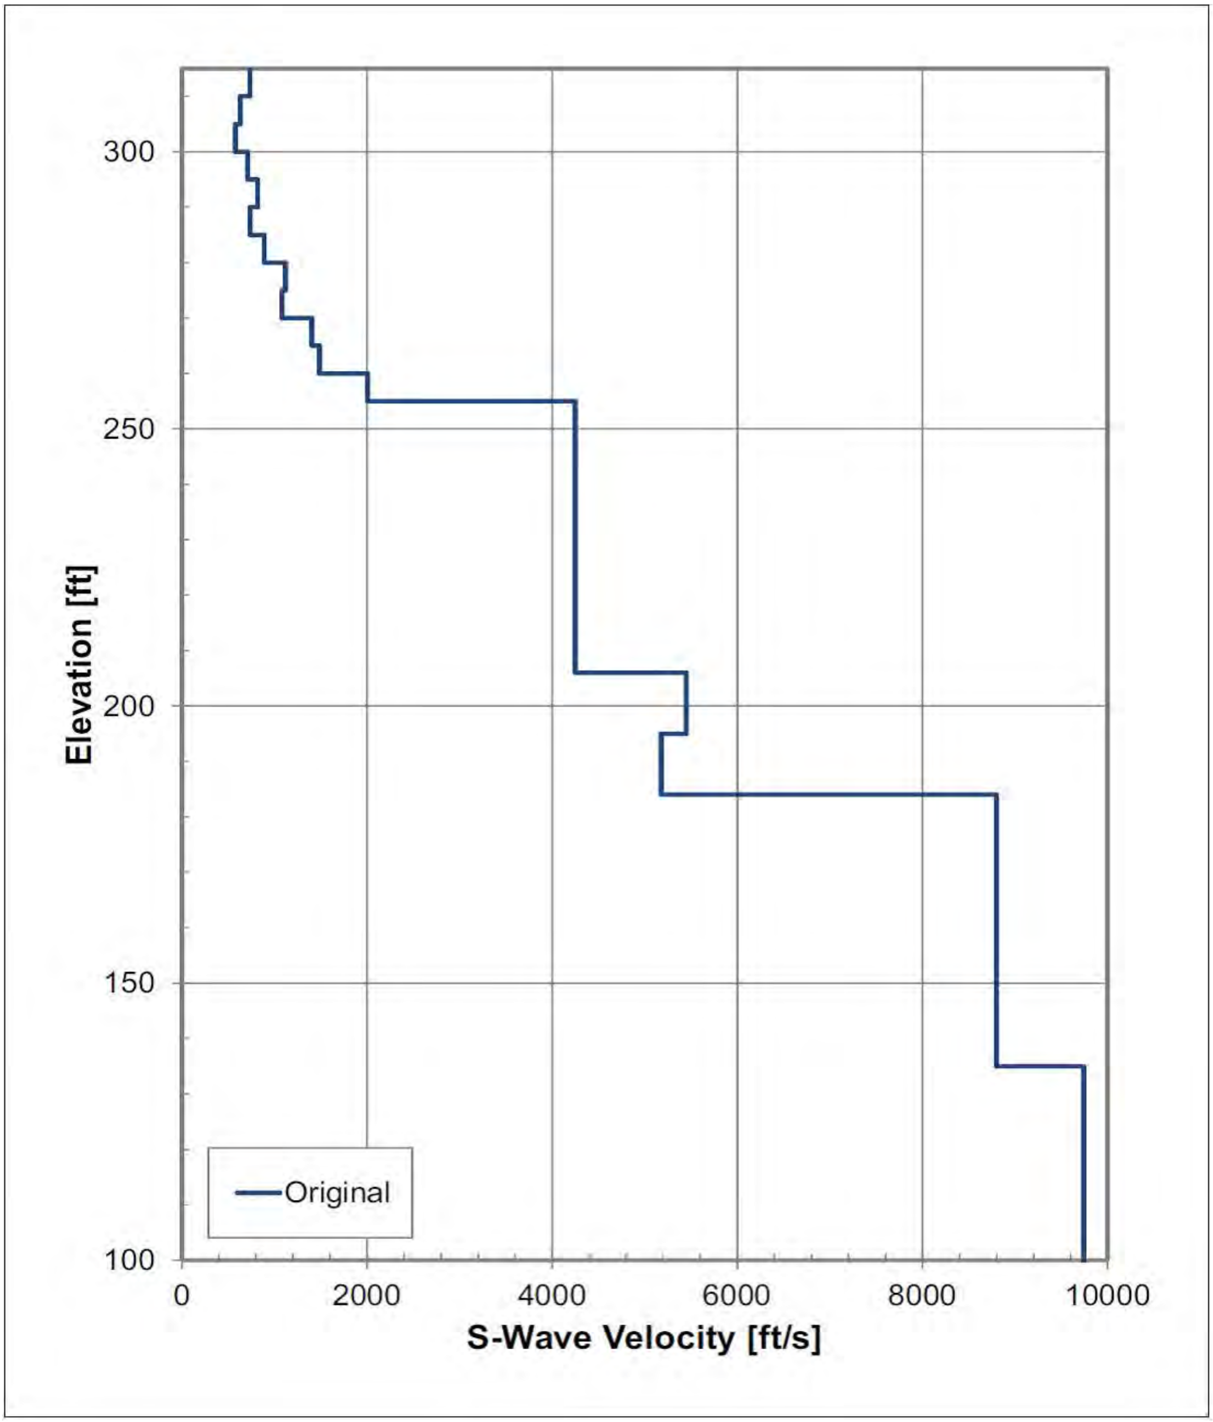

Figure 2.5.4-4. Best Estimate Shear Wave Velocity Profiles for Free-Field Slope (FSAR Figure 2.5.4-244)

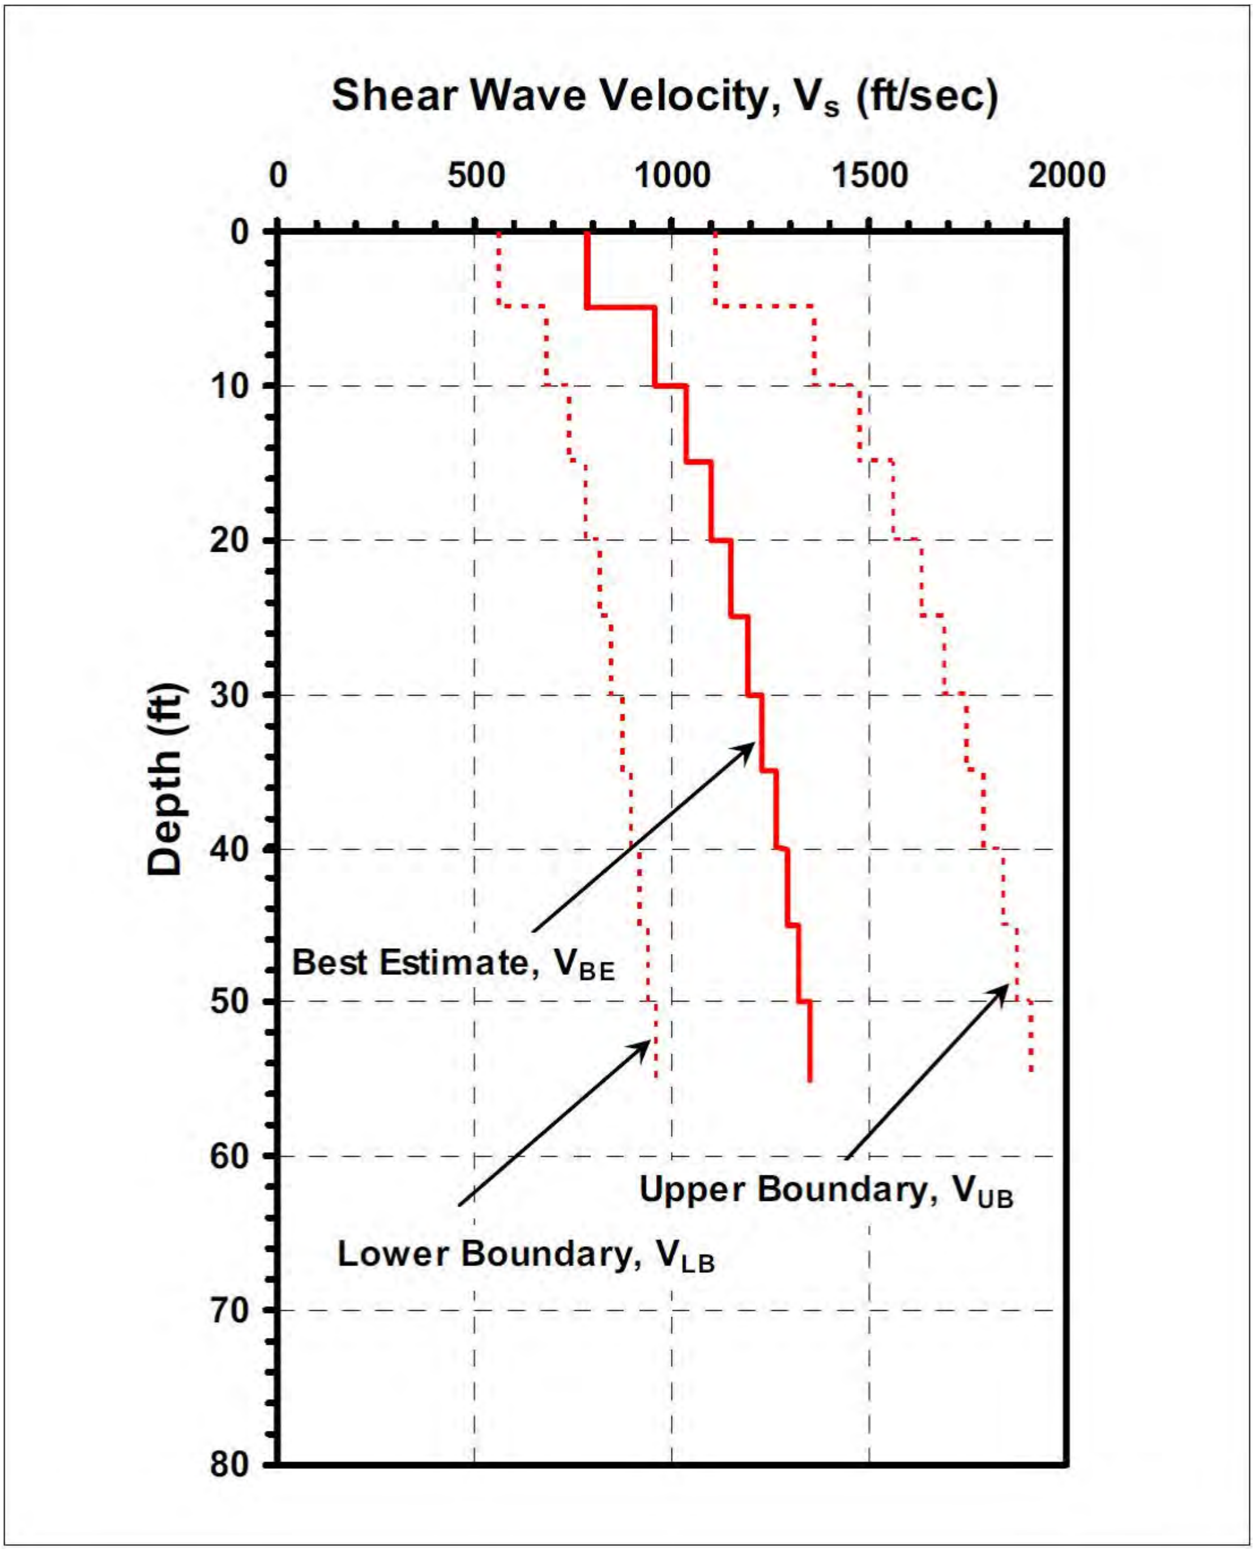

Figure 2.5.4-5. Best Estimate Shear Wave Velocity Profile for Structural Fill in 5-Foot Intervals (FSAR Figure 2.5.4-246)

Variation of Shear Modulus and Damping with Strain

FSAR Section 2.5.4.7.2 describes the effect of varying shear strain on both the shear modulus and damping. The soil degradation properties, specifically the variations of soil shear modulus and damping ratio with shear strain levels, are important inputs in site seismic response analysis. The applicant divided the section into two subsections to discuss the variations specific to the shear modulus and damping ratio.

Shear Modulus.

The applicant used the same shear modulus reduction curve as in the ESP SSAR for the Zone IIA saprolite, which was the mean of a 1970 Seed and Idriss (1970) average curve for sand and two curves from a 1993 EPRI report.

In combining these studies, the applicant took into account of several factors, including reference strain and effective vertical stress. Unlike the ESP site investigations in which the Zone IIB contained more gravel than Zone IIA, the applicant found no appreciable gravel in either Zone IIA or IIB during the COL investigations. Therefore, the applicant applied the same shear modulus reduction curve to both Zone IIA and IIB soils as shown on SER Figure 2.5.4-6.

The applicant compared the RCTS test results with a shear modulus reduction curve that represents the Zone IIA and IIB soils and it showed that the test data points are very close to that curve, which confirmed that the recommended shear modulus curve can reasonably represent the soil condition in the field. The applicant selected Curve 2 and Curve 3 from ESP SSAR Figure 2.5-63 as the shear modulus reduction curve for the structural backfill, and for the Zone III weathered rock, respectively. Finally, the applicant stated that the shear modulus of the Zone IV and Zone III-IV weathered rock was non-strain dependent.

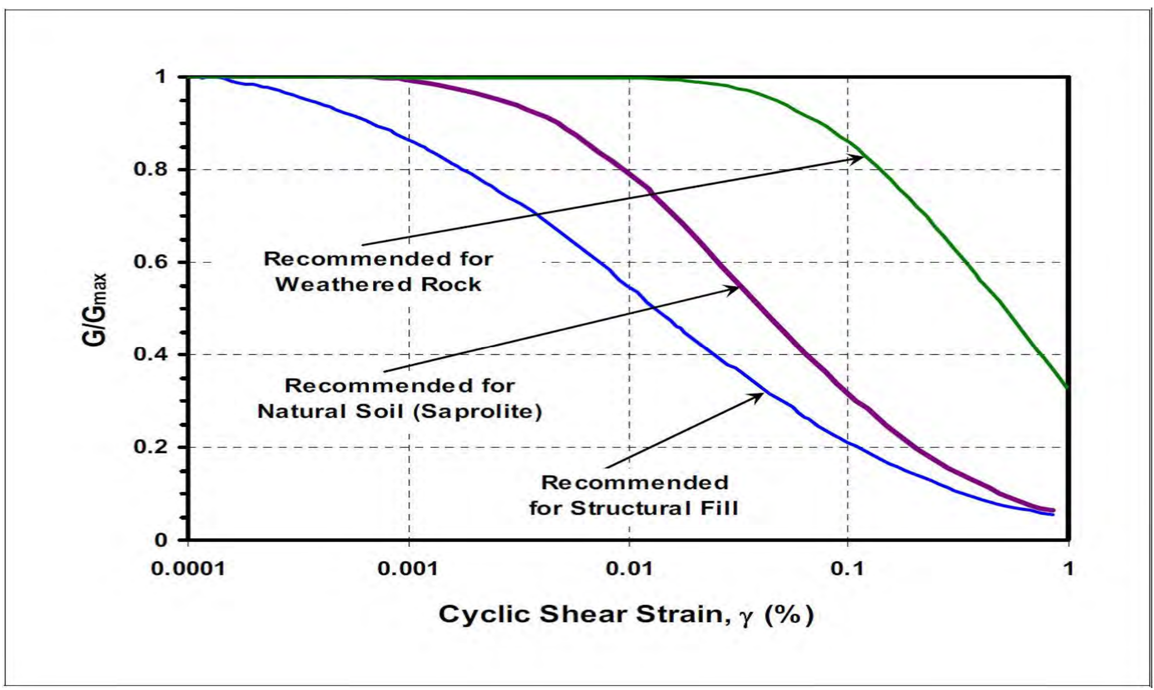

Figure 2.5.4-6. Shear Modulus Reduction Design Curves (FSAR Figure 2.5.4-247)

Damping Ratio.

SER Figure 2.5.4-7 illustrates the EPRI curves for depths of 0 to 6.09 m (0 to 20 ft) and 6.09 to 15.24 m (20 to 50 ft) selected for Zone IIA and IIB saprolite and structural backfill, and Curve 3 from ESP SSAR Figure 2.5-64 used for Zone III weathered rock. The applicant compared the results of the RCTS tests with the curve selected for granular soils and concluded that the results show reasonable agreement. The applicant also concluded that the damping ratio of the Zone III-IV and Zone IV rock does not vary with cyclic shear strain; however, the applicant selected a damping ratio of 1 percent with a ±0.5 percent variation.

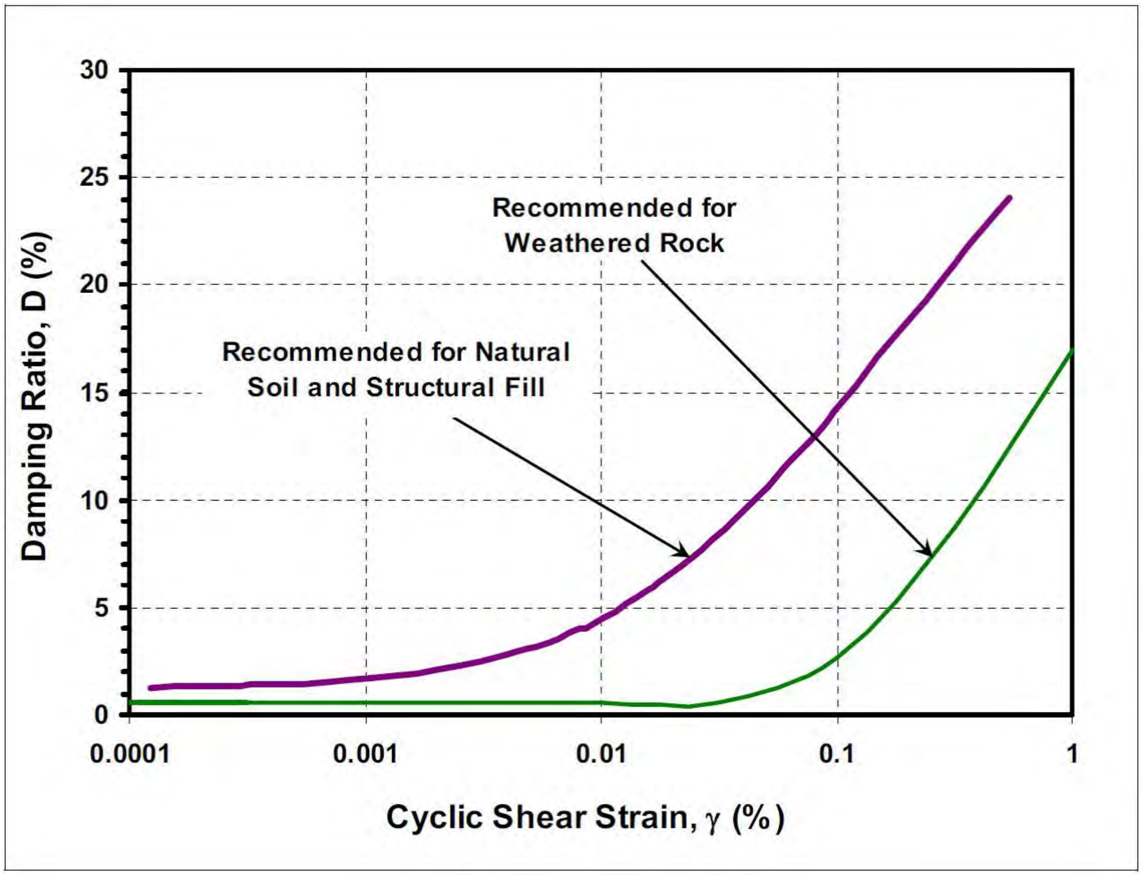

Figure 2.5.4-7. Damping Ratio versus Cyclic Shear Strain (FSAR Figure 2.5.4-249)

Site-Specific Acceleration-Time Histories

FSAR Section 2.5.4.7.3 states that the P-SHAKE program does not need acceleration-time histories as an input.

Rock and Soil Column Amplification/Attenuation Analysis

FSAR Section 2.5.4.7.4 describes the soil and rock amplification/attenuation analyses performed for the North Anna 3 site. The applicant referred to FSAR Section 3.7.1 for the acceleration response spectra as derived from the P-SHAKE analyses for seismic Category I structures. The applicant used the P-SHAKE program to obtain PGAs in the free-field for use in slope stability and liquefaction analysis with the V_s profile described in FSAR Section 2.5.4.7.1.d. The results show that the PGA occurs at about 12.8 m (42 ft) depth and the values of the PGA are about 0.56g for the HF earthquake and about 0.31g for the LF earthquake.

2.5.4.2.8 Liquefaction Potential

FSAR Section 2.5.4.8 describes the liquefaction potential evaluation of the soil at the North Anna 3 site, including the analyses performed and the conclusions reached. The applicant concluded that due to the density and high percentage of core stone in Zone III weathered rock, it is not prone to liquefaction. The applicant further concluded that the structural fill was not liquefiable because of its angularity and degree of compaction under the given seismic loading condition. The applicant identified slopes whose failure due to liquefaction could impact adjacent safety-related structures, and performed the liquefaction potential analysis for those slopes.

Liquefaction Analyses Performed for North Anna 3

FSAR Section 2.5.4.8.2 describes the liquefaction analyses performed for North Anna 3 site. The applicant first determined the magnitude and acceleration values for North Anna 3 liquefaction analyses, then performed seismic margin assessments, and analyzed samples and CPT results to estimate the liquefaction potential. The applicant followed the guidelines in RG 1.198, regarding the acceptable FS against liquefaction.

Based on rock and soil column analyses described in the previous section, the applicant obtained the peak accelerations at the natural ground surface of 0.31g and 0.56g for the LF (M= 7.4) and HF (M = 6.0) earthquake, respectively. The applicant used these values as the PGAs for the liquefaction analyses.

Because Zone IIA saprolitic soil in the power block area where the seismic Category I structures are located will be excavated, there is no need to analyze the liquefaction potential of these soils prior to excavation. Therefore, the applicant performed liquefaction analysis focused on slopes whose failure could impact safety-related structures.

The applicant used six SPT borings, two CPT borings and two V_s measurements taken from two borings to assess the liquefaction potential of the slope soils. The analysis followed the method proposed by Youd, et al. (2001) based on the evolution of the Seed and Idriss “Simplified Procedure” (1983). The analysis of the SPT results gave FS values against liquefaction greater than 1.1 for the approximately 80 Zone IIA saprolite samples, except for eight samples. The liquefaction analysis using CPT data yielded FS against liquefaction greater than 1.1 for all data points. For analysis using V_s measurements, only eight data points gave FS of less than 1.1 against liquefaction.

The applicant used the method outlined in Tokimatsu and Seed (1997) to estimate dynamic settlement of the Zone IIA saprolite due to earthquake shaking obtaining less than 12.7 cm (5 in) of the maximum dynamic settlement.

Applicant's Conclusions about Liquefaction

The applicant stated that the aforementioned liquefaction analyses showed that a very small percentage of the Zone IIA saprolitic soils have a potential for liquefaction based on the LF and HF North Anna 3 site seismic characteristics. The liquefaction analysis did not consider the beneficial effects of age, structure, fabric, and mineralogy; the applicant therefore concluded that the probability of any liquefaction occurring in the North Anna 3 site area is very low. Furthermore, the applicant concluded that any liquefaction of the Zone IIA saprolite will not impact the stability of any North Anna 3 seismic Category I structures because the safety-related structures will not be founded on Zone IIA material, which will be removed entirely during excavation at the site.

2.5.4.2.9 Earthquake Site Characteristics

FSAR Section 2.5.4.9 refers to FSAR Sections 2.5.2 and 3.7.1 for a discussion of the GMRS and FIRS for the North Anna 3 site, respectively.

2.5.4.2.10 Static Stability

FSAR Section 2.5.4.10 states that the applicant will found the North Anna 3 RB/FB structures on Zone III-IV or Zone IV bedrock. The applicant will remove and replace Zone III weathered rock or fractured rock encountered at the foundation subgrade level with concrete fill for all seismic Category I structures. For seismic Category II structures, depending on the elevation and location, there can be more than one material beneath the foundation of larger structures because of variable stratigraphy. FSAR Table 2.5.4-209 summarizes the dimensions, foundation elevation, embedment depth and design static and dynamic loads of structures including seismic Category I and II structures and the RW.

Bearing Capacity

FSAR Section 2.5.4.10.1 describes the estimation of allowable static and dynamic bearing capacity values for bedrock and soil.

<u>Allowable Bearing Capacity of Rock and Concrete Fill</u>.

FSAR Table 2.5.4-210 gives the allowable static bearing capacity values for each bedrock zone. The applicant determined the dynamic allowable bearing capacity as 957 kPa (20 ksf), that is less than 20 percent of the ultimate rock crushing strength of 6,896 kPa (144 ksf), using various building codes for moderately weathered to freshly foliated rock (D'Appolonia et al., 1975). Because the RB/FB will not be directly founded on Zone III weathered rock, the applicant stated that if excavation during construction for this foundation reveals any weathered or fractured zones at foundation level, it will be over-excavated and replaced with concrete fill. The applicant stated that the Zone III-IV and Zone IV bedrock have a design unconfined compressive strength of 62 MPa (1,296 ksf) and 117 MPa (2,448 ksf) with allowable static values of the bearing capacity of 3,830 kPa (80 ksf) and 7,660 kPa (160 ksf), respectively. The applicant selected 20 percent of the ultimate crushing strength, 12,400 kPa (259 ksf) for Zone III-IV and 23,460 kPa (490 ksf) for Zone IV, as dynamic bearing capacity. Finally, the applicant determined that the allowable bearing capacity for 17.2 MPa (2,500 psi) concrete fill is 9,528 kPa (199 ksf) for both static and dynamic loading.

Allowable Bearing Capacity for Structures.

FSAR Table 2.5.4-211 provides the estimated and selected allowable static and dynamic bearing capacity values for the seismic Category I and II structures at the North Anna 3 site. The applicant noted that there is concrete fill beneath each structure underlain by Zone III-IV bedrock. For the static case, the applicant noted that the bearing capacity of the Zone III-IV bedrock is less than that of concrete, but for the dynamic case, the bearing capacity of the concrete is less than half of that of the Zone III-IV materials. The applicant assumed the lesser bearing capacity in each case, selecting the bearing capacity of the Zone III weathered rock for both the static and dynamic cases. The applicant also limited the allowable bearing capacity to 191 kPa (4 ksf) for the Zone IIA saprolite due to settlement considerations, but noted that the actual allowable bearing capacity may be less, especially based on settlement considerations for larger foundations.

Buoyancy Effects.

The applicant predicted that the maximum groundwater level in the power block area of North Anna 3 would increase from about elevation 82.6 m (271 ft) at the north end of the TB to about elevation 86.1 m (282.5 ft) at the south end of the RB/FB and concluded that it is possible for a hydrostatic uplift force to act on the structures founded below grade. However, the applicant also concluded that the below-ground structures have sufficient applied foundation loads such that there are no net uplift forces at the maximum ground water level. The applicant indicated that uplift forces can be significant in the design of buried piping, particularly empty pipes. The applicant used a FS of 3 in its analysis of the weight and strength of the backfill above the pipe to ensure satisfactory resistance to uplift forces.

Settlement Analysis

FSAR Section 2.5.4.10.2 describes the pseudo-elastic method of analysis used for settlement estimates, an approach suitable for both granular soils and bedrock. The applicant calculated the settlement of discrete layers using a stress-strain model of analysis that determined settlement to a depth where the increase in vertical stress due to the applied load was equal to or less than 10 percent of the applied foundation pressure. SER Table 2.5.4-2 summarizes the estimated settlements for major structures. Based on the analysis, the applicant expected that the estimated average settlement for seismic Category I structures is about 2.54 mm (0.1 in) or less.

Table 2.5.4-2 Estimated Settlements Structures (FSAR Table 2.5.4-212)

STRUCTURE	APPLIED LOAD kPa (ksf)	CALCULATED SETTLEMENT Mm (in.)			
		CENTER	EDGE	AVERAGE[1]	CORNER
Reactor/Fuel Building	669 (14.6)	3.0 (0.12)	1.9 (0.075)	2.5 (0.10)	1.3 (0.05)
Control Building	292 (6.1)	0.6 (0.022)	0.4 (0.014)	0.5 (0.02)	0.3 (0.010)
Fire Water Service Complex	165 (3.45)	0.3 (0.011)	0.2 (0.008)	0.3 (0.010)	0.13 (0.005)
Turbine Building	287 (6)	56.6 (2.23)	29.0 (1.14)	42.9 (1.69)	14.7 (0.58)
Radwaste Building	287 (6)	19 (0.75)	10 (0.38)	14.5 (0.57)	6.9 (0.27)
Service Building	192 (4)	17.3 (0.68)	8.9 (0.35)	13.2 (0.52)	6.9 (0.27)
Ancillary Diesel Building	192 (4)	3.3 (0.13)	1.7 (0.065)	(0.10)	0.9 (0.034)

Notes: (1) Average is average of center and edge settlements.

Earth Pressures

FSAR Section 2.5.4.10.3 describes the estimates made for static and seismic lateral earth pressures for plant below-ground walls. The applicant considered both active and at-rest cases in the calculations. As part of the earth pressure calculations, the applicant used Rankine values as earth pressure coefficients. The applicant assumed that backfill was level with a friction angle between the soil and the wall of zero, hydrostatic pressures were 0.6 m (2 ft) below grade, and the surcharge pressure was 23.9 kPa (500 psf).

The applicant used Mononobe-Okabe method (Mononobe, 1929 and Okabe, 1926) to estimate the active lateral earth pressure. The applicant used peak LF acceleration of 0.31g as the seismic force that develops seismic active earth pressure, because it considered that using the peak HF acceleration was overly conservative given the low magnitude (energy) of this earthquake. The applicant used the method described in ASCE 4-98, "Seismic Analysis of Safety-Related Nuclear Structures," Section 3.5.3.2 (ASCE, 1998) to estimate the dynamic component of seismic at-rest lateral earth pressure for the below-grade walls of the power block structures and provided an elastic solution demonstrated in a nomograph. The applicant developed the nomograph for a dimensionless normalized in-situ lateral stress at 1.0g horizontal earthquake acceleration for a normalized depth at a given Poisson's ratio. The applicant calculated the site-specific at-rest pressure from the nomograph at various depth intervals using the site-specific acceleration and Poisson's ratio.

The applicant illustrated lateral earth pressure diagrams for the active and at-rest cases in FSAR Figures 2.5.4-253 and 2.5.4-254, respectively, and indicated that the lateral pressures in the figures are BEs with an FS of 1. The applicant concluded that the FS against a gravity wall or structure foundation sliding, as well as for a wall overturning, is normally 1.1 when seismic pressures are included.

2.5.4.2.11 Design Criteria

FSAR Section 2.5.4.11 summarizes the geotechnical design criteria discussed in other sections of the FSAR. FSAR Section 2.5.4.8 specifies that the acceptable FS against liquefaction of site soils should be equal or greater than 1.1. FSAR Section 2.5.4.10 presents bearing capacity and settlement criteria. For static bearing capacity and to prevent the failure of a buried pipe due to uplift forces, the applicant indicated that a minimum FS of 3 is required. For soils, the applicant reduced this FS to 2.25 under dynamic or transient loading conditions. FSAR Section 2.5.4.10 also provides lateral earth pressure values versus depth with FS=1.0 and notes that FS=1.1 is normally used for sliding and overturning due to these lateral loads when the seismic component is included. FSAR Section 2.5.5.2 concludes that the minimum acceptable long-term static FS against slope stability failure is 1.5. Finally, FSAR Section 2.5.5.3 indicates that 1.1 is the minimum acceptable long-term seismic FS against slope stability failure.

2.5.4.2.12 Techniques to Improve Subsurface Conditions

FSAR Section 2.5.4.12 describes plans to remove Zone IIA and IIB saprolite beneath or within the zone of influence of seismic Category I or II structures and replace the saprolite with structural fill. Furthermore, the applicant described plans to remove zones of weathered or fractured rock immediately beneath the RB/FB, CB, and FWSC foundations and replace the rock with concrete fill. Finally, for non-seismic Category I and II structures, the applicant indicated that improvement of the Zone IIA saprolite will follow the methods described in ESP SSAR Section 2.5.4.12.

2.5.4.3 Regulatory Basis

The applicable regulatory requirements for reviewing the applicant's discussion of stability of subsurface materials and foundations are:

- 10 CFR 50.55a, requires that SSCs be designed, fabricated, erected, constructed, tested, and inspected in accordance with the requirements of applicable codes and standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 1, "Quality Standards and Records," requires that SSCs important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. It also requires that appropriate records of the design, fabrication, erection, and testing of SSCs important to safety be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit.

- 10 CFR Part 50, Appendix A, GDC 2, relates to consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants," establishes quality assurance requirements for the design, construction, and operation of those SSCs of nuclear power plants that prevent or mitigate the consequences of postulated accidents that could cause undue risk to the health and safety of the public.

- 10 CFR Part 50, Appendix S, "Earthquake Engineering Criteria for Nuclear Power Plants," applies to the design of nuclear power plant SSCs important to safety to withstand the effects of earthquakes.

- 10 CFR 100.23, provides the nature of the investigations required to obtain the geologic and seismic data necessary to determine site suitability and identify geologic and seismic factors required to be taken into account in the siting and design of nuclear power plants.

The related acceptance criteria are summarized from SRP Section 2.5.4:

- **Geologic Features**: In meeting the requirements of 10 CFR Parts 50 and 100, the section defining geologic features is acceptable if the discussions, maps, and profiles of the site stratigraphy, lithology, structural geology, geologic history, and engineering geology are complete and are supported by site investigations that are sufficiently detailed to obtain an unambiguous representation of the geology.

- **Properties of Subsurface Materials**: In meeting the requirements of 10 CFR Parts 50 and 100, the description of properties of underlying materials is considered acceptable if state-of-the-art methods are used to determine the static and dynamic engineering properties of all foundation soils and rocks in the site area to sufficient depth that impact behavior during construction and over the life of the facility, including during postulated seismic events.

- **Foundation Interfaces**: In meeting the requirements of 10 CFR Parts 50 and 100, the discussion of the relationship of foundations and underlying materials is acceptable if it includes: (1) a plot plan or plans showing the locations of all site explorations, such as borings, trenches, seismic lines, piezometers, geologic profiles, and excavations with the locations of the safety-related facilities superimposed thereon; (2) profiles illustrating the detailed relationship of the foundations of all seismic Category I and other safety-related facilities to the subsurface materials; (3) logs of core borings and test pits; and (4) logs and maps of exploratory trenches in the application for a COL.

- **Geophysical Surveys**: In meeting the requirements of 10 CFR 100.23, the presentation of the dynamic characteristics of soil or rock is acceptable if geophysical investigations have been performed at the site and the results obtained therefrom are presented in detail.

- **Excavation and Backfill**: In meeting the requirements of 10 CFR Part 50, the presentation of the data concerning excavation, backfill, and earthwork analyses is acceptable if: (1) the sources and quantities of backfill and borrow are identified and are shown to have been adequately investigated by borings, pits, and laboratory property and strength testing (dynamic and static); long-term solubility properties and dissolution behavior during the life of the facility have been determined; and this data is included, interpreted, and summarized; (2) the extent (horizontally and vertically) of all seismic Category I excavations, fills, and slopes are clearly shown on plot plans and profiles; (3) compaction specifications and embankment and foundation designs are justified by field and laboratory tests and analyses to ensure stability and reliable performance over the life of the plant; (4) the impact of compaction methods are incorporated into the structural design of the plant facilities; (5) quality control methods are discussed and the quality assurance program described and referenced; (6) control of groundwater during excavation to preclude degradation of foundation materials and properties is described and referenced. If backfill is to be placed under safety-related structures, proper ITAAC should be specified in the applicant's technical submittal to ensure that the static and dynamic properties of in-place backfill material will be the same as, or better than the design parameters. In case cementitious construction material is to be placed under safety -related structures, proper ITAAC should be specified in the applicant technical submittal to ensure that the cementitious backfill placed underneath any seismic Category I structures to a thickness greater than 5 ft, meets the design, construction and testing of applicable American Concrete Institute (ACI) standards. In addition, the long-term behavior of the backfill subjected to any aggressive groundwater characteristics is evaluated; (7) For sites where deeply embedded structures are involved, deep excavation techniques will likely utilize wall retaining systems rather than a sloped excavation of the soil. Also, a description of the planned excavation technique(s) and design of the wall retention system with sufficient details is provided and it should be able to demonstrate that the excavation technique used will not significantly affect the surrounding soil properties that are relied upon in the analysis and design of the foundation and plant structures.

- **Groundwater Conditions**: In meeting the requirements of 10 CFR Parts 50 and 100, the analysis of groundwater conditions is acceptable if the following are included in this subsection or cross-referenced to the appropriate subsections in SRP Section 2.4 of the applicant's technical submittal: (1) discussion of critical cases of groundwater conditions relative to the foundation settlement and stability of the safety-related facilities of the nuclear power plant; (2) plans for dewatering during construction and the impact of the dewatering on temporary and permanent structures. This includes consideration of the potential for substantial head and volume of water due to the deep excavation for the plant structures; (3) analysis and interpretation of seepage and potential piping conditions during construction; (4) records of field and laboratory permeability tests as well as dewatering-induced settlements; (5) history of groundwater fluctuations as determined by periodic monitoring of an adequate number of local wells and piezometers. Flood conditions should also be considered; (6) Evaluation of chemical properties of the groundwater that may impact long-term behavior of the rock/soil/fill materials as well as structural elements (concrete and steel materials).

- **Response of Soil and Rock to Dynamic Loading**: In meeting the requirements of 10 CFR Parts 50 and 100, descriptions of the response of soil and rock to dynamic loading are acceptable if: (1) an investigation has been conducted and discussed to determine the effects of prior earthquakes on the soils and rocks in the vicinity of the site. Evidence of liquefaction and sand cone formation should be included; (2) field seismic surveys (surface refraction and reflection and in-hole and cross-hole seismic explorations) have been accomplished and the data presented and interpreted to develop bounding P and S wave velocity profiles; (3) dynamic tests have been performed in the laboratory on undisturbed samples of the foundation soil and rock sufficient to develop strain-dependent modulus-reduction and hysteretic damping properties of the soils and the results included. If generic soil degradation properties are used in the related preliminary analyses (e.g., site seismic response and SSI analyses), then reconciliation of the generic properties and laboratory testing results should be performed. The section should be cross-referenced with Section 2.5.2.5.

- **Liquefaction Potential**: In meeting the requirements of 10 CFR Parts 50 and 100, if the foundation materials at the site adjacent to and under seismic Category I structures and facilities are saturated soils and the water table is above bedrock, then an analysis of the liquefaction potential at the site is required.

- **Static and Dynamic Stability**: In meeting the requirements of 10 CFR Parts 50 and 100, the discussions of static and dynamic analyses are acceptable if the stability of all safety-related facilities has been analyzed from a static and dynamic stability standpoint including bearing capacity, rebound, settlement, and differential settlements under deadloads of fills and plant facilities, dynamic loads including “live” and seismic loads with consideration of loading sequences and combinations, and lateral loading conditions.

- **Design Criteria**: In meeting the requirements of 10 CFR Part 50, the discussion of criteria and design methods is acceptable if the criteria used for the design, the design methods employed, and the factors of safety obtained in the design analyses are described and a list of references presented.

- **Techniques to Improve Subsurface Conditions**: In meeting the requirements of 10 CFR Part 50, the discussion of techniques to improve subsurface conditions is acceptable if plans, summaries of specifications, and methods of quality control are described for all techniques to be used to improve foundation conditions (such as grouting, vibroflotation, bridging mats, dental work, rock bolting, or anchors).

In addition, the geotechnical engineering characteristics should be consistent with appropriate sections from: RG 1.27, RG 1.28, “Quality Assurance Program Requirements (Design and Construction)”; RG 1.132, RG 1.138, RG 1.198, and RG 1.206.

2.5.4.4 Technical Evaluation

This section provides the staff’s evaluation of the geophysical and geotechnical investigations including field and laboratory tests carried out by the applicant to determine the static and dynamic engineering properties of the materials that underlie the North Anna 3 site. The staff reviewed the resolution to the COL specific items related to the properties and stability of the soil and rock underlying the site that could affect the safe design and siting of the plant, specifically the Permit Conditions identified in NUREG-1835. In addition, the staff observed some of the applicant’s onsite borings and field explorations to determine whether the applicant had followed the guidance in RG 1.132.

The staff evaluated the information provided to resolve DCD COL Item 2.0-29-A and ESP Permit Conditions 3.E(4) to 3.E(7). DCD COL Item 2.0-29-A requires the COL applicant to complete additional borings at the COL site to address the provisions listed in ESBWR DCD, Table 2.0-1 regarding stability of subsurface material and foundation requirements, which is resolved in Section 2.5.4.4.3 of this SER. Permit Condition 3.E(4) requires that an applicant for a CP or COL referencing this ESP shall excavate weathered or fractured rock at the foundation level and replace it with lean concrete before the commencement of foundation construction for safety-related structures. This was addressed in North Anna 3 FSAR Section 2.5.1 and evaluated in Section 2.5.1.4 of this SER. More detailed discussion regarding the resolution of this permit condition was presented in Sections 2.5.4.5.2 and 2.5.4.5.3 of the North Anna 3 FSAR, and additional staff evaluation was presented in Section 2.5.4.4.5 of this SER. Permit Condition 3.E(5) requires the applicant not to use an engineered fill with high compressibility and low maximum density, such as saprolite, this is resolved in Section 2.5.4.4.5 of this SER. Permit Condition 3.E(6) requires the applicant to include information on geologic mapping of future excavations for safety-related structures and to evaluate any unforeseen geologic features encountered at the site area, which is resolved in Section 2.5.4.4.5, in conjunction with Sections 2.5.1 and 2.5.3 of this SER. Permit Condition 3.E(7) requires the applicant to improve Zone II saprolitic soils to reduce any liquefaction potential if safety-related structures are to be founded on them, which is resolved in Section 2.5.4.4.8 of this SER.

2.5.4.4.1 Description of Site Geologic Features

FSAR Section 2.5.4.1 references FSAR Sections 2.5.1.1 and 2.5.1.2. The staff's evaluations of, and conclusions for these sections are presented in Section 2.5.1.4 of this SER.

2.5.4.4.2 Properties of Subsurface Materials

FSAR Section 2.5.4.2 describes the subsurface materials and the field investigations and laboratory tests used to determine the static and dynamic engineering properties of these materials at the North Anna 3 site. The staff reviewed the applicant's description of the four zones of subsurface materials and the methods used to determine the engineering properties of those materials and to develop the subsurface profile as shown on SER Figure 2.5.4-1. The staff also reviewed the applicant's use of the latest field and laboratory methods, including boring sample analysis, observation wells, SPT, P-S suspension logger, and CPTs, to determine the properties of the subsurface materials.

To clarify how the properties of Zone IIA soil were determined, the staff issued RAI 02.05.04-1 (ADAMS Accession Number No. ML081690661) dated June 17, 2008, requesting that the applicant justify the use of an effective cohesion value (c') of 6.0 kPa (125 psf) for Zone IIA soil, given that the SPT and C-U test results imply very little effective cohesion (interpreted as c' = 0). In the applicant's response to RAI 02.05.04.-1 (ADAMS Accession No. ML082050558) dated July 14, 2008, the applicant stated that it derived the effective cohesion value from various data sources. The applicant assumed some effective cohesion due to the mineralogy, texture, and fabric of the Zone IIA saprolite. To determine the effective cohesion value, the applicant performed consolidated-undrained triaxial tests on samples of the Zone IIA saprolite and used the results—combined with the mineralogy, texture, and fabric observations—to select the effective cohesion value of 6.0 kPa (125 psf) for the Zone IIA saprolite.

The staff reviewed the applicant's response, and concluded that although it is not a conservative approach to use a small effective cohesion value, it was reasonable as detailed below. Based on the results of the staff's independent confirmatory analysis, the staff noted that the small effective cohesion value does not produce notable changes in foundation stability analyses with relatively large internal friction angles of soil. The results of the staff's confirmatory analyses also noted that with a decrease of c' value from 6.4 to 5.5 kPa (135 to 115 psf), the FS for slope stability only decreases from 1.29 to 1.26. Section 2.5.5.4.2 of this SER provides additional information regarding the staff's confirmatory analysis. Based on the results of the confirmatory analysis, which suggest that the applicant's approach of determining the effective cohesion value is reasonable, the staff concludes that the applicant provided adequate information to resolve RAI 02.05.04-1.

During the review of FSAR Section 2.5.4.2.5, the staff noted that the applicant stated that it will place concrete fill with an average thickness of 3.0 m (10 ft) and a maximum thickness of 15.2 m (50 ft) below the base of the RB/FB, CB and FWSC foundations. Because thermal cracking can be an issue for a large concrete mass, the staff issued RAI 02.05.04-22 dated February 09, 2011 (ADAMS Accession No. ML110400770). The staff asked the applicant to describe how it will place the concrete fill in the field to reduce thermal cracking distress and how it will ensure the long-term strength and stability of the concrete fill.

In the applicant's response to RAI 02.05.04-22 dated April 04, 2011 (ADAMS Accession No. ML110950474), the applicant stated that in order to minimize thermal cracking distress for large concrete masses, the general objective is to limit volume changes and the temperature differential across the concrete as much as practical by properly controlling and/or limiting the heat generated by hydration of the mass of concrete. The applicant committed to follow ACI 349, Code Requirements for Nuclear Safety-Related Structures, which provides provisions and guidelines regarding concrete material properties, quality, mixing and placing requirements, durability requirements to ensure long-term strength and stability of the concrete, and requirement to reduce thermal cracking distress. The applicant also stated that it will follow additional standards referenced in ACI 349, such as ASTM standards and publications of ACI Committees 201 and 207, in the detailed concrete fill design. The applicant also committed to revise FSAR Section 2.5.4.2.5 to include a statement referencing ACI 349 with regard to concrete fill durability, design, construction, and quality assurance.

The staff reviewed this RAI response and relevant chapters of ACI 349 and ACI 207, and finds that the applicant identified appropriate industrial standards that it will follow to address the thermal cracking distress issue in mass concrete fill. The staff noted that the applicant committed to develop construction specifications in accordance with the applicable standards to provide controls on the construction process, including placement techniques, material properties (including mix design and concrete properties during placement such as slump, air content, and mix temperature), and proposed a revision to FSAR Section 2.5.4.2.5 to reflect those focus areas of staff concern. The staff later confirmed that the latest version of the FSAR incorporated the proposed changes. Accordingly, the staff concludes that the applicant adequately addressed the long-term strength and stability of the concrete fill and provided necessary specification in its application. Therefore, the staff considers RAI 02.05.04-22 resolved and closed.

Based on the acceptable determination of the subsurface properties and the resolution of related RAIs, the staff concludes that the field investigations and laboratory testing performed by the applicant to determine the subsurface material properties were performed in accordance with RGs 1.132 and 1.138 and are sufficient to meet the relevant criteria of 10 CFR Parts 50 and 100.

2.5.4.4.3 Foundation Interfaces

FSAR Section 2.5.4.3 describes and illustrates the location of site exploration points for the North Anna 3 subsurface investigation including borings, observation wells, CPTs, electrical resistivity tests, and test pits made in the power block area; the excavation plan for the safety-related and other major facilities including the plan outline of these structures, plan dimensions, and the bottom of foundation elevations for the major structures; the location of ten subsurface profiles; and cross sections of the structure foundations and the proposed excavation and backfilling limits.

The staff reviewed the additional borings performed by the applicant to confirm engineering properties and the stability of soil and rock underlying future plant SSCs. As part of this review, the staff also examined the site exploration points for the North Anna 3 subsurface investigations, including SER Figure 2.5.4-8 (FSAR Figure 2.5.4-217), which shows the locations of additional boreholes, observation wells, CPTs, electrical resistivity tests, and test pits. The staff considered this information along with the exploration points outside of the power block area and concluded that the additional boreholes are sufficient to resolve DCD COL Item 2.0-29-A, which requires the COL applicant to complete additional borings at the COL site to address the provisions listed in ESBWR DCD Table 2.0-1, regarding stability of subsurface material and foundation requirements.

In addition, the staff reviewed the boring logs submitted in Appendix 2.5.4AA for completeness, in accordance with 10 CFR Parts 50 and 100. These regulations also require the applicant to submit plot plans and profiles of all seismic Category I facilities for comparison with the subsurface profiles and material properties at the North Anna 3 site. The staff reviewed the subsurface profiles and cross sections and plot plans and concludes that the relevant information provided by the applicant is acceptable and satisfies the previously mentioned requirements.

Finally, the staff reviewed the future excavation and backfill plans for the North Anna 3 site as illustrated in SER Figure 2.5.4-9 (FSAR Figure 2.5.4-225). The staff concludes that the information presented in these figures, together with the description in FSAR Section 2.5.4.3, meets the minimum acceptability requirements of 10 CFR Parts 50 and 100.

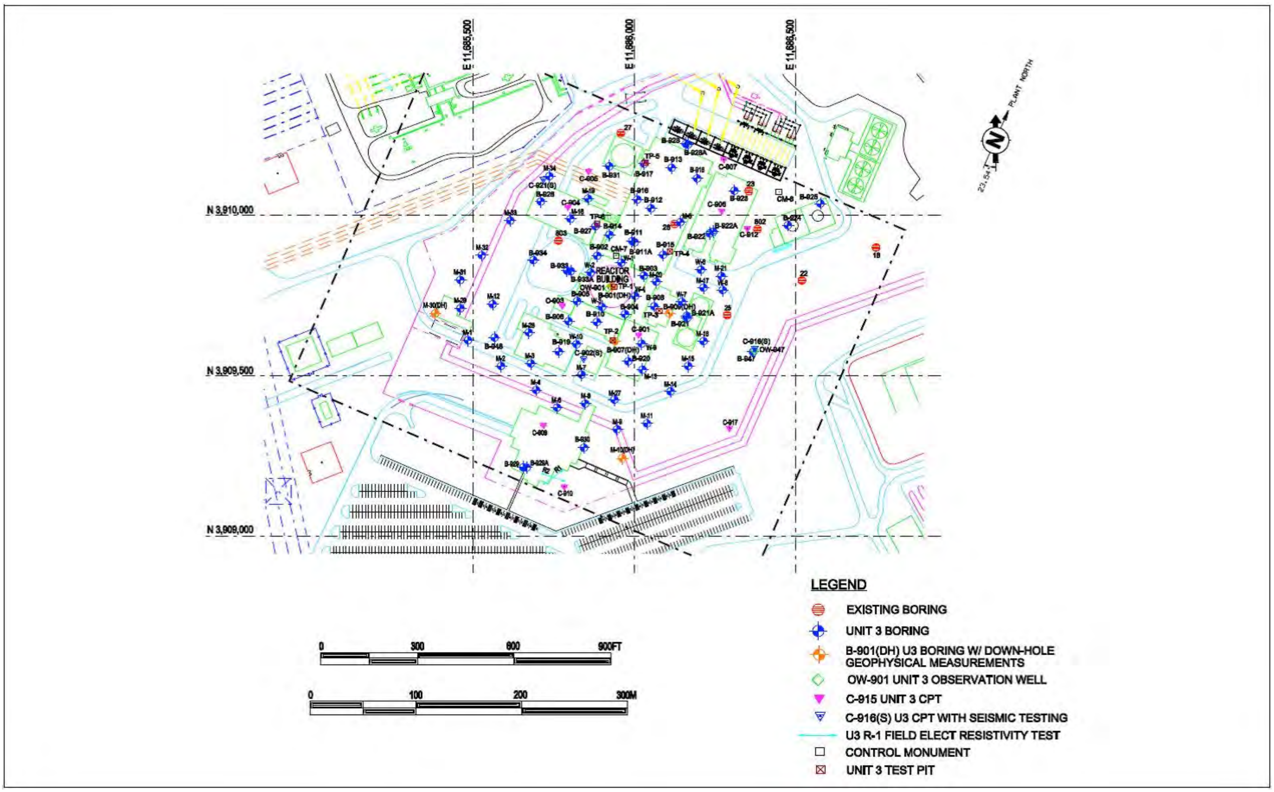

Figure 2.5.4-8. Unit 3 Boring Locations (FSAR Figure 2.5.4-217)

Resolution of ESP COL Action Items 2.5-1 to 2.5-3

ESP COL Action Item 2.5-1 was resolved in Section 2.5.1.4 of this SER. ESP COL Action Item 2.5-2 requires the applicant referencing the North Anna ESP to submit plot plans and profiles for all seismic Category I structures for comparison with the subsurface profile and material properties. FSAR Section 2.5.4.3 describes the locations of site exploration borings and provides the excavation plan for the seismic Category I structures, plan dimensions, and bottom of foundation elevations for those structures.

The applicant included several figures that show the subsurface profiles with the cross sections of foundation structures superimposed for comparison. SER Figure 2.5.4-8 shows the locations of the exploration points at the North Anna 3 site. Because the applicant included the plot plans and profiles that compare the foundations of seismic Category I structures to the subsurface profiles at the North Anna 3 site, the staff concludes that the applicant provided sufficient information to satisfy the requirements of ESP COL Action Item 2.5-2. Accordingly, the staff considers ESP COL Action Item 2.5-2 resolved.

ESP COL Action Item 2.5-3 requires the applicant referencing the North Anna ESP to provide detailed excavation and backfill plans for the North Anna 3 site. In FSAR Section 2.5.4.3, the applicant provided the plot plans and comparison figures of the excavation, subsurface profiles, and seismic Category I foundations. SER Figure 2.5.4-9 presents a representative plot plan and excavation and backfill plan. In FSAR Section 2.5.4.5.3, the applicant described details such as the source, type and material properties of backfill, the extent of excavations, and the compaction specifications that the backfill will be designed to meet. The applicant also described the quality control measures that it will employ to ensure that the backfill meets the design values. The staff concludes that the applicant provided adequate information to describe the excavation and backfill plans for the North Anna 3 site as required by ESP COL Action Item 2.5-3. Accordingly, the staff considers ESP COL Action Item 2.5-3 resolved.

Based on the information and findings above, the staff concludes that the discussion of the foundation interfaces, including the subsurface investigations at the North Anna 3 site, is acceptable and meets the relevant requirements of 10 CFR Parts 50 and 100.

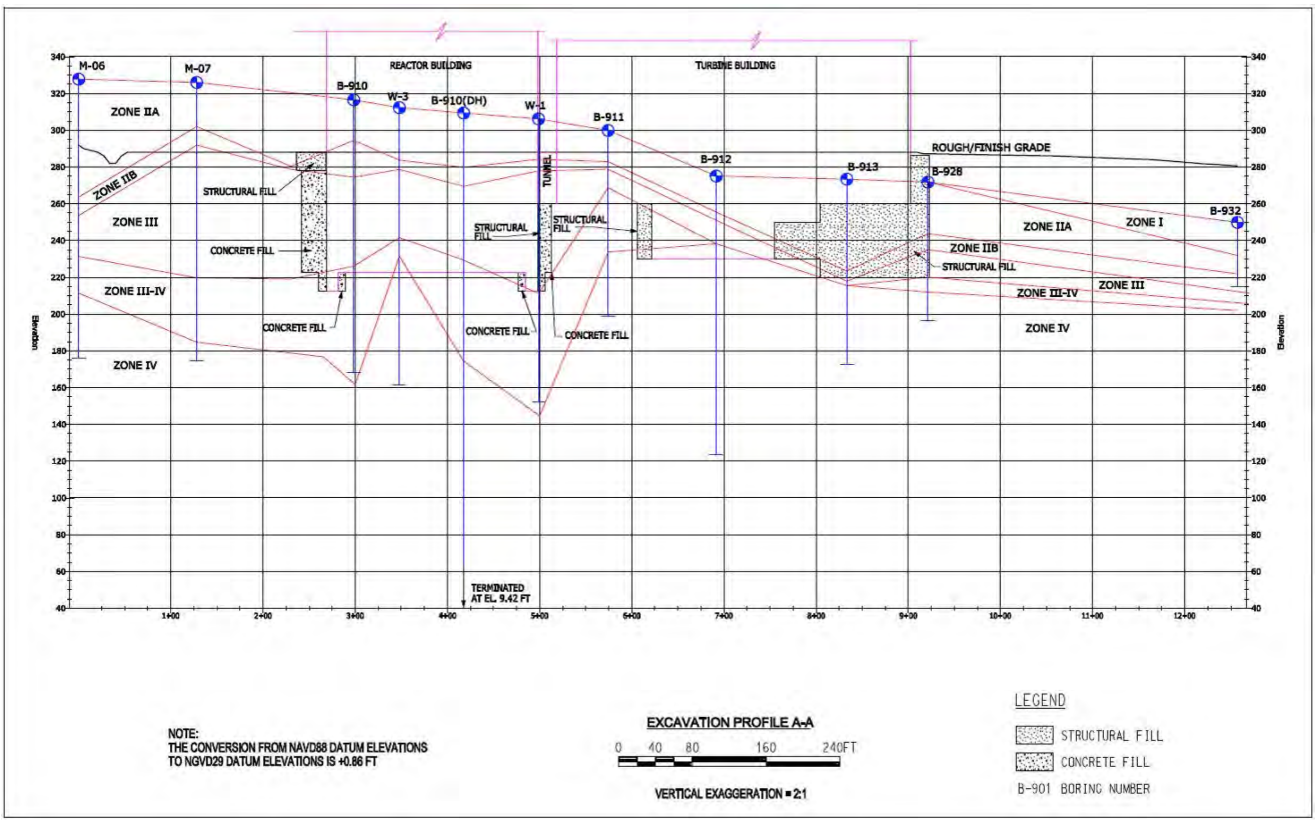

Figure 2.5.4-9. Excavation and Backfill Plan for Cross Section A-A'
(FSAR Figure 2.5.4-225)

2.5.4.4.4 Geophysical Surveys

FSAR Section 2.5.4.4 describes the geophysical investigations undertaken by the applicant to determine soil and rock dynamic properties. The applicant used field electrical resistivity testing, geophysical downhole testing, and seismic CPTs during both ESP and COL site investigations, as well as laboratory measurements of soil and rock properties to determine the shear wave velocities.

The staff reviewed the applicant's use of the latest geophysical and geotechnical testing methods and equipment in accordance with RGs 1.132 and 1.138, as well as the results that detail the dynamic properties of the soil and rock underlying the site, in accordance with 10 CFR 100.23. The staff concludes that the applicant used acceptable methods commonly used in current engineering practices to determine shear wave velocity for each of the soil and rock zones at the North Anna 3 site. The staff further concludes that the applicant adequately described the results of laboratory analyses to confirm the validity of the dynamic properties obtained from field explorations and tests.

The staff concludes that the results of the geophysical surveys completed as part of the COLA and presented in the FSAR are in accordance with 10 CFR 100.23, and therefore are acceptable. However, the staff noted a discrepancy between the previous ESP site investigations and those completed in support of the COLA. The staff issued RAI 02.05.04-2 dated June 17, 2008 (ADAMS Accession No. ML081690661), requesting the applicant explain the difference in the North Anna 3 site median V_s values presented in the ESP SSAR versus the 36 to 50 percent higher median V_s in the COL FSAR.

The applicant's response to RAI 02.05.04.-2 dated July 14, 2008 (ADAMS Accession No. ML082050558), stated that the reasons for the difference in median V_s values between the ESP SSAR and COL FSAR are two-fold. First, the applicant stated that it took the V_s values in the ESP SSAR across a widely spaced area that does not reflect the conditions of the North Anna 3 specific location. Also, the applicant pointed out that it took the V_s measurements in rock presented in the COL FSAR from closely spaced boreholes at the specific location of North Anna 3 seismic Category I structures. Second, the applicant stated that there was a difference in the equipment used to measure the V_s values during ESP and COL site investigations. The applicant used suspension P-S velocity logging equipment to measure and determine the median V_s during the COL site investigation, which is a more sophisticated and advanced method than the crosshole and downhole testing methods used during the ESP site investigations and reported in the ESP SSAR.

The staff reviewed the RAI response and agrees that the P-S suspension logging equipment will yield a better constrained measurement of median V_s. The staff also considered the refined locations of boreholes used to measure V_s values and agrees that a broader distribution of boreholes, coupled with a less sophisticated testing method, would explain the variance in median V_s values between the ESP SSAR and COL FSAR. Accordingly, the staff considers RAI 02.05.04-2 resolved and closed.

Based on the review of FSAR Section 2.5.4.4, the acceptability of the results of geophysical surveys performed in support of the COLA and the applicant's response to RAI 02.05.04-2, the staff concludes that the applicant adequately determined the dynamic properties of soil and rock through the geophysical surveys of the North Anna 3 site to satisfy the relevant requirements of 10 CFR 100.23.

2.5.4.4.5 Excavation and Backfill

FSAR Section 2.5.4.5 describes the extent of seismic Category I structure foundation excavations, fills, and slopes, the excavation methods and stability, and the backfill sources including quantity, compaction, and quality control. The applicant also addressed Permit Condition 3.E(6), as identified in the North Anna ESP. This permit condition requires the applicant to include information on geologic mapping of future excavations for safety-related structures and to evaluate any unforeseen geologic features encountered at the site area.

The staff reviewed the extent of seismic Category I structure foundation excavations, fills, and slopes, as illustrated in FSAR Figure 2.5.4-206, which shows the planned excavations relative to power block foundations. The staff compared the excavation plans with the requirements of 10 CFR 100.23 and concludes that the description of the extent of the excavations, fills, and slopes is acceptable. The staff also concludes that this information, with additional information provided in FSAR Sections 2.5.1 and 2.5.3, satisfies Permit Condition 3.E(6). The staff then reviewed the excavation methods and stability for the North Anna 3 site, which included a review of the soil excavation methods as well as the blasting techniques to be used for rock excavations, against the requirements of 10 CFR 100.23 and guidance contained in RG 1.132. The staff concludes that the methods of excavation and stability are acceptable because the applicant described plans to follow OSHA regulations when excavating into soil and will use conventional and widely accepted industry equipment to accomplish the excavation. Furthermore, the staff concludes that the applicant's plans to monitor blasting, including the use of controlled blasting techniques as part of the excavation into rock, are acceptable as it will reduce vibrations and ensure the integrity of the rock mass at the site during the excavation.

The staff also reviewed the descriptions of backfill the applicant proposed to be used in place of the removed weathered rock at the site. The staff determined that the applicant did not provide adequate information regarding the concrete fill under the seismic Category I foundation building mats. The staff issued RAI 02.05.04-3 dated June 17, 2008 (ADAMS Accession No. ML081690661), requesting the applicant to provide additional material and engineering properties of the concrete fill that will replace weathered rock exposed at the bottom of the excavation for seismic Category I building foundation mats. The applicant's initial response to RAI 02.05.04.-3 dated July 14, 2008 (ADAMS Accession No. ML082050558), stated that the properties of the concrete fill were yet to be determined. However, the applicant stated that it will design the concrete mix to have a V_s within the same range as the Zone III-IV rock at the North Anna 3 site. The applicant revised the FSAR to include a statement that the V_s of the concrete fill will be within the range of Zone III-IV rock.

In order for the staff to fully evaluate and determine the acceptability of the engineering properties of the concrete fill, the staff issued RAI 02.05.04-12 dated March 26, 2009 (ADAMS Accession No. ML090840271), and RAI 02.05.04-19 dated March 26, 2009 (ADAMS Accession No. ML090840271), in which the staff asked the applicant to provide the engineering properties of concrete fill, and, if the properties are assumed, to clarify how to ensure that the in-place concrete fill will have the same engineering properties as that used in stability analyses. The staff issued RAI 02.05.04-13 dated March 26, 2009 (ADAMS Accession No. ML090840271), in which the staff further asked the applicant to: (1) provide a detailed description of how the applicant planned to ensure that the static and dynamic properties of the backfill will meet or exceed both the requirements of the ESBWR DCD and the parameter values used in the analyses as described in the application, such as site seismic response analysis, bearing capacity and settlement estimates and SSI analysis; and (2) explain how the applicant plans to confirm that the design criteria of the ESBWR DCD and the parameter values related to backfill will be met during and after construction.

In North Anna 3 Revision 8 of FSAR Section 2.5.4.2.5a, the applicant described the detailed properties of the concrete fill: the minimum strength of 17.2 MPa (2,500 psi), the unit weight of 2,322 kg/m^3 (145 pcf), and a Poisson's ratio of 0.15. FSAR Section 2.5.4.10.1 states that the bearing capacity of the concrete fill is designed as 9,528 kPa (199 ksf) under both static and dynamic loading conditions. The applicant also provided ITAAC in Table 2.4.1-1, "ITAAC for Fill

Concrete Under and Around the Sides of Seismic Category I Structures," in COLA Part 10, "Tier 1/ITAAC," Section 2.4, "Site-Specific ITAAC," of its COLA.

Because structural soil will be backfilled surrounding the seismic Category I structures and the specific backfill soil properties were used in structural stability analyses, the applicant proposed an additional ITAAC for structural fill to ensure the in-place backfill will have the same, or better, engineering properties as designed. Table 2.4.1-2, "ITAAC for Structural Fill Surrounding Seismic Category I Structures," in COLA Part 10, "Tier 1/ITAAC," Section 2.4, "Site-Specific ITAAC" of its COLA presents the proposed ITAAC for structural fill. The staff verified that the appropriate change is incorporated in the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5.4-1 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff reviewed the additional information regarding concrete fill including the minimum strength and bearing capacity, and the ITAACs for concrete fill and structural fill to be used for seismic Category I structure foundations. The specified ITAACs describe the inspection and testing required to ensure the properties of concrete fill and structural fill placed in the field meet the design requirements. Based on the staff's review of the latest FSAR Section 2.5.4.5 and the ITAACs for concrete fill and structural fill presented in the COLA, the staff concludes that the additional information related to excavation and backfill meets the relevant requirements of 10 CFR 100.23 and is acceptable. Accordingly, RAI 02.05.04-12, 02.05.04-13, and 02.05.04-19 are resolved and closed.

During the review of the SSI analysis results for FWSC, the staff noted that the analysis results indicated that although the shear stress capacity of the monolithic concrete fill material is sufficient to withstand the seismic demands for concrete fill under the FWSC foundation, the shear resistance of the construction joints, if needed as part of the detailed design, may not be sufficient to resist the sliding demands under the seismic loading. Because the FWSC is a seismic Category I structure and the stability of the concrete fill beneath it will directly affect the stability of the FWSC, in RAI 02.05.04-26 dated January 12, 2016 (ADAMS Accession No. ML16012A520), the staff requested the applicant to specify which code/standard(s)/procedure(s) will be followed in the construction of the in-place monolithic concrete fill. The staff also requested that the applicant explain under what conditions the construction joints may exceed the shear resistance requirement, and specify necessary ITAAC if shear reinforcements are to be used to ensure the bonding condition of the concrete fill construction joints in consideration of long-term effects in order to meet the required shear resistance capacity.

In its February 02, 2016, response to RAI 02.05.04-26 (ADAMS Accession No. ML16042A247), the applicant confirmed that the maximum seismic shear demand in the horizontal planes of the concrete fill is only about 12 percent of the nominal shear strength (0.39 MPa (56.3 psi) versus 3.26 MPa (473 psi)) even if conservatively neglecting the friction resistance of the mass concrete and using the lowest measured ratio of cohesion to compressive strength based on ACI 207.1R. The applicant then stated that the friction resistance alone is insufficient to achieve a minimum FS of 1.1 against sliding for the FWSC along the unbounded horizontal construction joints. To prevent this undesirable situation from happening in the field, the applicant stated that bonded construction joints will be used by following ACI 207.1R and other standards to ensure the monolithic integration of the concrete fill block under the FWSC.

The applicant proposed a revision to FSAR Section 2.5.4.2.5 to provide further details regarding the concrete fill below the FWSC, and clarify that the provisions of ACI 207.1R and the associated requirements in Part III, Section 1, of the North Anna 3 Quality Assurance Program Description (FSAR Appendix 17AA) will be applied to the concrete fill placed around and below the FWSC, as well as the RB/FB, and CB. The applicant also clarified that no shear reinforcements to the concrete fill will be used. The staff verified that the appropriate clarification is incorporated into the FSAR, Revision 9, and, therefore, Confirmatory Item 2.5.4-2 from the staff's advanced SER for North Anna 3 is resolved and closed.

The staff reviewed the RAI response and related industrial standards, such as ACI 207.1R and USACE EM 1110-2-2200, and concludes the following:

- The shear strength of the monolithic concrete fill under the FWSC foundation is sufficient to withstand the seismic demands with adequate margin; the maximum seismic shear demand of 0.39 MPa (56.3 psi) versus allowable shear strength of 0.54 MPa (7 8.8 psi) that used a proper FS.

- ACI 207.1R states that for bonded joints, the coefficient of internal friction can be taken as 1.0 and the cohesion resistance may approach that of the parent concrete. Therefore, the staff determined that the design concrete fill shear strength can be reached in the field if the ACI 207.1R standard is followed to ensure the construction of the monolithic concrete fill.

- The applicant committed to perform necessary testing during the concrete fill construction to ensure and verify that the as-built concrete compressive strength is equal to or greater than the required design strength. The ITAAC 1 on Table 2.4.1-1 of the North Anna 3 COLA, Part 10 will enforce this planned action to ensure that in-place concrete fill will meet all design requirements.

Based on the staff's review and verification of the proposed revision of the North Anna 3 COLA being incorporated in the FSAR, Revision 9, the staff considers the RAI 02.05.04-26 resolved and Confirmatory Item 2.5.4-3 from the staff's advanced SER for North Anna 3 closed.

Resolution of Permit Conditions 3.E(4) and 3.E(5)

Permit Condition 3.E(4) requires that an applicant for a CP or COL referencing this ESP shall excavate weathered or fractured rock at the foundation level and replace it with lean concrete before the commencement of foundation construction for safety-related structures.
Permit Condition 3.E(5) requires that the permit holder and an applicant for a CP or COL referencing this ESP shall not use an engineered fill with high compressibility and low maximum density, such as saprolite.

The applicant is planning to remove weathered or fractured rock at the foundation level and place concrete fill underneath all seismic Category I structures. The applicant will also place well-graded, highly compacted, angular to sub-angular gravel-sized particles of crushed rock as structural fill surrounding foundations, the concrete and structural materials will have adequate engineering properties to support structures and are non-liquefiable under the given site-specific seismic loading condition. In addition, the applicant proposed ITAACs (Tables 2.4.1-1 and 2.4.1-2 in Section 2.4 of North Anna COLA Part 10) specifically for the concrete and structural fills to ensure its in-place properties. In conjunction with staff's evaluation in Section 2.5.1 of this SER, the staff considers the requirements of Permit Conditions 3.E(4), and 3.E(5) are met.

Because the applicant adequately addressed North Anna 3 site excavation and backfill considerations for seismic Category I structure foundations, the staff concludes that the applicant provided sufficient information to satisfy the relevant requirements of 10 CFR 100.23 and guidance contained in RG 1.132.

2.5.4.4.6 Groundwater Conditions

In FSAR Section 2.5.4.6, the applicant described groundwater measurements and elevations and construction dewatering plans. This section also references FSAR Section 2.4.12 for a more detailed description of the groundwater conditions at the North Anna 3 site. The staff reviewed the groundwater information provided in FSAR Section 2.5.4.6, including conditions before, during, and after excavation and the associated dewatering plan, as well as measures to minimize drawdown effects on the surrounding environment. The staff concludes that this information is acceptable and meets the requirements of 10 CFR Part 100 because it includes sufficient detail on the groundwater conditions at the site such as measurements and elevations, as well as dewatering plans for the excavation and construction, for staff to evaluate the stability of foundations and structures to be built at the site.

Resolution of ESP COL Action Item 2.5-4

ESP COL Action Item 2.5-4 requires the applicant referencing the North Anna ESP to evaluate the groundwater conditions as they affect foundation stability and to provide detailed dewatering plans. In FSAR Section 2.5.4.6.3, the applicant evaluated the effects of groundwater conditions on foundation stability. The applicant concluded that the maximum design allowable groundwater level was at least 0.6 m (2 ft) below the final plant grade, while the maximum predicted groundwater level in the power block area of North Anna 3 is at least 2.3 m (7.5 ft) below design plant grade, and there were no buoyancy issues with deep buried structures. The applicant also stated that no permanent dewatering system will be required. The staff considered this information and agrees with the applicant that due to the groundwater level below the final grade of the site, there will be no buoyancy issues at the site and a permanent dewatering program will not be necessary. Therefore, the staff concludes that the applicant provided sufficient information to address the requirements of ESP COL Action Item 2.5-4. Accordingly, the staff considers ESP COL Action Item 2.5-4 resolved.

The staff also considered the groundwater condition related requirements specified in RG 1.132 and 10 CFR 100.23. Based on the level of detail provided to describe the groundwater conditions at the site, including groundwater elevations, dewatering plans, and the proximity of groundwater to the final plant grade and foundations—as well as the resolution of ESP COL Action Item 2.5-4—the staff concludes that the applicant's assessment of groundwater conditions is acceptable and meets the relevant requirements of 10 CFR Parts 50 and 100.

2.5.4.4.7 Response of Soil and Rock to Dynamic Loading

FSAR Section 2.5.4.7 describes the applicant's V_s design profiles to determine the response of the soil and rock underlying the North Anna 3 site to seismic loading. The applicant also described shear modulus and damping variations with shear strain, and amplification/attenuation analyses performed for rock and soil.

The staff reviewed the applicant's modeling of the variation of soil shear modulus and damping with cyclic shear strain. The staff compared RCTS test results and the generic soil degradation curves used in ESP analyses, which yielded good agreement with the EPRI curves. The staff also reviewed the curves selected for each of the soil and rock zones to determine whether the applicant used the appropriate criteria, such as grain size, cohesiveness, confining pressure, and V_s. The staff concludes that the applicant selected shear modulus and damping degradation curves based on appropriate criteria and are suitable for Zone IIA, IIB, and III soil and rock. The staff further concludes that the damping ratio of 1 percent with a variation of about ± 0.5 percent for the Zone III-IV and Zone IV rock is acceptable because this is a conservative value for this type of rock.

Resolution of ESP COL Action Items 2.5-5 and 2.5-9

ESP COL Action Item 2.5-5 requires the applicant referencing the North Anna ESP to provide soil column amplification/attenuation analyses for the specific selected locations for the nuclear power plant structures. FSAR Section 2.5.4.7.4 describes the rock and soil column amplification/attenuation analyses conducted for North Anna 3 using the P-SHAKE computer program. The applicant illustrated the maximum acceleration versus depth and noted that the peak acceleration was 0.31g and 0.56g for the LF and HF earthquake, respectively. The PGAs occurred about 12.8 m (42 ft) below natural ground surface. The staff concludes that the applicant provided sufficiently detailed descriptions of the amplification/ attenuation analyses for use in the staff's evaluation of the applicant's site seismic response, as discussed in Section 2.5.2.4 of this SER, which also meet the requirements of ESP COL Action Item 2.5-5. Therefore, the staff considers ESP COL Action Item 2.5-5 resolved.

ESP COL Action Item 2.5-9 requires the applicant referencing the North Anna ESP to ensure that the average V_s of the material underlying the foundation for the reactor containment equals or exceeds that of the chosen design. FSAR Section 2.5.4.7.1 describes the V_s determinations that the applicant made for soil, rock, and backfill at the North Anna 3 site. The applicant compared the soil and bedrock profiles to the DCD site parameter values in FSAR Table 2.0-201 and concluded that the V_s values at North Anna 3 were greater than the minimum V_s design values. The ESBWR DCD requires a COL applicant to use the lower bound shear wave velocity value after taking into account uncertainties of soil properties under site-specific seismic loading conditions to determine the equivalent uniform shear wave velocity. Because the applicant initially combined rock layers with soil layers when determining the average soil shear wave velocity within certain depth, in RAI 02.05.04-14 dated March 26, 2009 (ADAMS Accession No. ML090840271**)**, the staff requested the applicant to properly determine the design required soil shear wave velocity.

The applicant's response to RAI 02.05.04-14 dated June 17, 2009 (ADAMS Accession No. ML091700117), revised its calculation by not mixing rock and soil layers and following the design requirement when determining average shear wave velocity. The staff reviewed the information provided in the latest revision of FSAR Section 2.5.4.7 regarding the average V_s of subsurface materials and confirmed that the revised subsurface material properties followed the ESBWR design guide and are presented in the latest revision of the FSAR. The staff therefore concludes that the applicant adequately determined shear wave velocity of subsurface materials and addressed the issue of the RAI 02.05.04-14, as well as the ESP COL Action Item 2.5-9. Accordingly, the staff considers ESP COL Action Item 2.5-9 is resolved and RAI 02.05.04-14 is resolved closed.

Because the applicant adequately addressed the response of the soil and rock to dynamic loading at the North Anna 3 site and resolved ESP COL Action Items 2.5-5 and 2.5-9, the staff concludes that the applicant provided sufficient information to satisfy the relevant requirements of 10 CFR Parts 50 and 100.

2.5.4.4.8 Liquefaction Potential

The staff reviewed FSAR Section 2.5.4.8 and evaluated the applicant's liquefaction analyses for the North Anna 3 site to ensure conformance with the criteria described in RG 1.198. The staff focused its review on the applicant's conclusion that only the Zone IIA saprolite is susceptible to liquefaction, and the applicant's liquefaction analyses for Zone IIA saprolites outside of the power block area for soils that it will not excavate, as well as the parameters used in these analyses.

The staff reviewed the applicant's liquefaction potential assessment for the North Anna 3 site based on SPT data, CPT data, and shear wave velocity data analyses. For each analysis, the applicant used the method proposed by Youd et al. (2001). The staff determined that the applicant used the latest empirical method for the liquefaction analyses in accordance with RG 1.198, and therefore concludes that the North Anna 3 liquefaction potential analysis is acceptable.

The staff reviewed the liquefaction analyses that the applicant performed for the engineered backfill designed to be granular material and possibly saturated due to the design maximum groundwater level being above the bottom of the backfill layer. In RAI 02.05.04-7a dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff asked why the applicant did not perform a liquefaction analysis for the backfill soil in accordance with the recommendations of RGs 1.206 and 1.198. The applicant's response to RAI 02.05.04-7a dated July 14, 2008 (ADAMS Accession No. ML082050558), stated that the analyses for backfill soil at the North Anna 3 site showed that the soil was non-liquefiable. The applicant further stated that the non-liquefiable nature of the soil was attributable to the fill beneath the FWSC being both dense and gravelly. The applicant cited the results of liquefaction potential analyses based on SPT, CPT and V_s data as further evidence of the non-liquefiable nature of the structural fill. The staff considers the additional information and the staff's previous review of the liquefaction potential for the ESP application to be sufficient to conclude that the applicant provided adequate information to demonstrate that the backfill soil is non-liquefiable. Accordingly, the staff considers RAI 02.05.04-7a resolved and closed.

The staff reviewed the liquefaction-induced dynamic settlement determined by the applicant using the method outlined in Tokimatsu and Seed (1997) to obtain the maximum dynamic settlement of about 41 mm (1.6 in) for the Zone IIA saprolite caused by earthquake shaking. In RAI 02.05.04-10 dated June 19, 2008 (ADAMS Accession No. ML081710161), the staff asked the applicant to explain why this value is significantly smaller than the value determined in the ESP SSAR (127 mm [5 in]). In the applicant's response to RAI 02.05.04-10 dated August 4, 2008 (ADAMS Accession No. ML082200626), the applicant stated that the maximum settlements estimated in the FSAR differed significantly from the ESP SSAR for two reasons: first, the CPT test data, which formed the basis for the FSAR settlements, was collected at some distance apart from the locations where the applicant collected the CPT test data for the ESP SSAR; second, due to the distance separating the locations, the underlying saprolitic soils do not have identical properties, which also contributed to the difference. The applicant also stated that the PGAs used in the FSAR analysis were about 40 percent lower than those used in the ESP SSAR analysis. The applicant noted that the relationship between cyclic stress ratio and dynamic settlement was non-linear, so smaller peak accelerations will give equal or lower dynamic settlement values.

The staff also reviewed this information and considered that although the applicant performed the CPT tests at different locations where soil properties may be different during ESP and COL site investigations, the soil property variation was not significant. The staff compared the strength parameters for the saprolite soil in the FSAR to those in the ESP SSAR and noted that the values presented in the ESP SSAR were higher. The applicant also indicated that "the value of cyclic stress ratio used as input to the dynamic settlement analysis is directly proportional to the peak ground acceleration." However, the staff determined that even though the PGAs used in the FSAR analysis were more than 40 percent lower than those used in the ESP SSAR, the applicant did not explain why the ESP SSAR estimated dynamic settlement was almost 3 times that presented in the FSAR. Therefore, in RAI 02.05.04-18 dated March 26, 2008 (ADAMS Accession No. ML090840271), a supplement to RAI 02.05.04-10, the staff asked the applicant to explain why the estimated dynamic settlement in the ESP SSAR was almost 3 times of that estimated in the FSAR while there is only a 40 percent difference for PGAs used in these two calculations.

In the applicant's response to RAI 02.05.04-18 dated June 17, 2009 (ADAMS Accession No. ML091700117), and in a later version of the FSAR, the applicant explained that for the estimated maximum dynamic settlement of the Zone IIA saprolite due to earthquake induced seismic loading, a significantly smaller value was obtained for the COLA than that calculated in the ESP SSAR is because in the ESP SSAR the dynamic settlement was estimated based on soil encountered in one of the CPTs performed for the ESP investigation, while the new estimate was based on overall site investigation data. Nonetheless, since the applicant chose to use the maximum dynamic settlement of 12.7 cm (5 in) in the FSAR (the same as that presented in the ESP SSAR), which is a conservative approach, the staff concludes that it is acceptable. Accordingly, RAI 02.05.04-18 is resolved and closed.

Resolution of Permit Condition 3.E(7)

This Permit Condition 3.E(7) requires the applicant to improve Zone II saprolitic soils and reduce any liquefaction potential if it will remain under any safety-related structures. Because FSAR Section 2.5.4.8 states that all safety-related structures would be founded on rock or concrete fill placed on rock, and the applicant planned to remove Zone II saprolite and replace it with engineering fills for all safety-related and/or seismic Category I structure foundations at the North Anna 3 site, the staff concludes that the requirements of Permit Condition 3.E(7) are met.

In summary, the staff reviewed FSAR Section 2.5.4.8 and the applicant's response to RAI 02.05.04-7a, regarding the non-liquefiable nature of the backfill, and finds that the applicant's conclusion of liquefaction potential at the site is acceptable because there will be no liquefiable material underneath or surrounding the seismic Category I structures and the methods used in liquefaction potential analyses for soil outside the power block are commonly used methods in engineering practices. The staff further concludes that the removal of potentially liquefiable soil from all seismic Category I structure foundations at the site is sufficient to satisfy Permit Condition 3.E(7).

Therefore, the staff concluded that the assessment of the liquefaction potential at the planned North Anna 3 site is adequate and satisfies the requirements of 10 CFR Part 50, Appendix A; 10 CFR Part 50, Appendix S; GDC 2, and 10 CFR 100.23.

2.5.4.4.9 Earthquake Design Basis

FSAR Section 2.5.2.6 presents the applicant's derivation of the SSE and Operating Basis Earthquake (OBE). Section 2.5.2.4 of this SER summarizes the staff's evaluation and conclusions.

2.5.4.4.10 Static Stability

The staff reviewed FSAR Section 2.5.4.10. The review focused on the applicant's determination of the bearing capacities for each of the soil and rock zones as well as the applicant's settlement and lateral earth pressure analysis. The applicant also presented bearing capacities and earth pressures for each of the zones and described how it obtained those results.

Bearing Capacity

The staff reviewed the initial bearing capacity calculations and identified several concerns. One area of concern was the difference in dynamic bearing capacity for the RB and FB, which was initially stated as 10,200 kPa (214 ksf) in FSAR Table 2.5-215 and 12,401 kPa (259 ksf) in FSAR Table 2.0-201. In RAI 02.05.04-6 dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff asked the applicant to clarify the values of allowable dynamic bearing capacity for the RB/FB. The applicant's response to RAI 02.05.04-6 dated July 14, 2008 (ADAMS Accession No. ML082050558), stated that the computed dynamic bearing capacity value for concrete was 10,200 kPa (214 ksf) and for Zone III-IV bedrock was 12,401 kPa (259 ksf). The applicant also stated that since the value for the concrete was lower, it will revise FSAR Table 2.0-201 to reflect the concrete dynamic bearing capacity. The applicant also estimated the allowable dynamic bearing capacity as the least value of the allowable bearing capacity of the underlying strata, regardless of thickness. In the case of the RB/FB, this least value stratum is the concrete fill. The staff reviewed the applicant's response regarding how the allowable bearing capacity was determined and concludes that it is acceptable. However, the staff had additional concerns for how the applicant determined the properties of the concrete fill to be used in the analyses, because there is no three dimensional information available about the concrete fill to be placed in the field, nor has the applicant finalized the design of the concrete fill. Therefore, in follow-up RAI 02.05.04-15 dated March 26, 2009 (ADAMS Accession No. ML090840271), the staff asked the applicant to clarify how it determined the properties of the concrete fill, such as engineering properties and thickness underneath the foundation in all directions, and used the results in the allowable bearing capacity calculation without knowing the actual concrete fill design and placement at foundation.

The applicant stated that local failure would not occur in the concrete mat foundation of the FWSC; however, the local failure not occurring in the concrete mat does not exclude the possibility of local failure in the backfill layers beneath the concrete mat. Therefore, in RAI 02.05.04-16 dated March 26, 2009 (ADAMS Accession No. ML090840271), the staff asked the applicant to address the possibility of local failure within the backfill layer beneath the concrete mat in the foundation stability analysis.

As another foundation bearing capacity related issue, in RAI 02.05.04-19 dated March 26, 2009 (ADAMS Accession No. ML090840271), the staff asked the applicant to provide details on what load combinations it used in the dynamic bearing capacity estimate and why it used one and one-third of static bearing capacity as dynamic bearing capacity for this site without actual analysis.

To address the issues identified above, the applicant's response to RAI 02.05.04-15 dated August 20, 2009 (ADAMS Accession No. ML092360773) and in the revised FSAR, the applicant specified that the concrete fill will have a minimum strength of 17,240 kPa (2,500 psi, or 360 ksf), with a unit weight of 2.32 g/cm^3 (145 pcf) and Poisson's ratio of 0.15. The applicant also stated that for the specified concrete fill, it will use 10,244 kPa (214 ksf) (the final design value is specified as 9,528 kPA (199 ksf) as the allowable bearing capacity for both static and dynamic loading conditions, in accordance with the guidelines of ACI 349-01 (2001). Therefore, this issue and RAIs are resolved and closed.

To further address the issues identified by RAI 02.05.04-16, in a response dated June 17, 2009 (ADAMS Accession No. ML091700117), the applicant stated that the large, thick, heavily-reinforced concrete mat used to support the FWSC provides the most stable kind of soil-supported foundation. This type of mat foundation has two distinct advantages: (1) the confinement of the foundation provided to a loaded granular (cohesionless) soil will increase the soil's bearing capacity; and (2) the structural integrity and resulting stiffness of the mat itself. Normally the local failure cannot occur beneath a mat foundation as long as the foundation itself does not fail structurally.

In the applicant's response to RAI 02.05.04-19 dated June 17, 2009 (ADAMS Accession No. ML091700117), the applicant stated that it will build the RB/FB and the CB on bedrock or on concrete fill above bedrock, and thus the increase in bearing capacity for dynamic loads for soils is no longer applicable. Other structures, such as RW and TB, will be supported on either structural fill or on weathered rock and sound rock or on a combination of structural fill and weathered and sound rock. The allowable bearing capacity for those buildings was conservatively determined based on the lowest allowable bearing capacity of any stratum underlying those structures (the Zone III weathered rock). Because the applicant did not use the allowable bearing pressure for soil and the increase in allowable bearing pressure as noted in the International Building Code (IBC) for any of the structures, no IBC-related load combinations are considered.

The staff reviewed the additional information and concludes that there is adequate margin by using 9,528 kPa (199 ksf) as allowable bearing capacity for the 17,240 kPa (360 ksf, or 2,500 psi) concrete fill, and all other rock layers underlying the foundation have higher bearing capacity. The staff, therefore, concludes that this is a conservative approach and acceptable. The staff also concludes that the probability of localized foundation failure at this site is negligible because no safety-related structure will be founded on a soil layer; therefore, there is no mechanism for large local settlements below the FWSC mat or other seismic Category I structures. Finally, the staff agrees with the applicant that because the revised allowable bearing capacity values did not use the IBC code to increase the bearing capacity by one-third, no IBC-related load combination needs to be considered when determine the dynamic bearing capacity.

Based on the review of the bearing capacity calculations provided in the revised FSAR referencing the ESBWR DCD, the staff noted that the applicant calculated the allowable static bearing capacity values for each bedrock zone and concrete fill following the industrial standards. The applicant used values less than 20 percent of the ultimate crushing strength of the rock as allowable static bearing capacity and allowable dynamic bearing capacity, which results in a conservative estimate of the bearing capacity for rock layers. The applicant also used a much smaller than designed concrete fill strength value as bearing capacity for concrete fill. By comparing the estimated bearing capacity values with standard design requirements, the staff finds that the minimum FS is greater than 3.3 for static loading condition; and greater than 7.9 for dynamic loading condition for all structures. The staff further concludes that the applicant conservatively selected bearing capacity values, and these parameters are enveloped by the standard design; therefore, the subsurface materials underneath the safety-related structures at the site are capable of meeting the design bearing capability requirements. The staff also verified that the latest version of the FSAR presents all revised calculation results, accordingly, Open Items previously identified by the staff are closed and the associated RAIs are resolved and closed.

Because the coefficient of friction is one of the engineering properties used for foundation stability evaluation, in RAI 02.05.04-17 dated March 26, 2009 (ADAMS Accession No. ML090840271), the staff asked the applicant to justify the site-specific coefficient of friction used to calculate the site-specific FS against sliding between the basemat and underlying material.

In the applicant's response to RAI 02.05.04-17 dated June 17, 2009 (ADAMS Accession No. ML091700117), the applicant provided the coefficient of friction used for this site. Because all seismic Category I structures will be founded on subgrade materials including Zone IV bedrock, Zone III-IV bedrock or concrete fill; and some buildings will be on compacted structural fill, different values of the coefficient of sliding for a poured concrete foundation on the site subgrade materials were specified with range from 0.55 to 0.7. The staff considers that the applicant specified coefficient of friction values based on typical material properties, and the friction angles corresponding to those coefficients, from 23 to 33 degrees, are normal values for the materials involved. The staff confirmed that the applicant specified coefficients of friction used in foundation stability analyses in Table 2.5.4-208 of the latest revised FSAR; accordingly this RAI is resolved and is closed.

Settlement Analysis

During the review of the settlement analyses performed by the applicant, the staff identified three areas requiring additional information. In FSAR Section 2.5.4.10.2, the applicant estimated settlement using a formula that included the layer elastic modulus E. In RAI 02.05.04-7c dated June 17, 2008 (ADAMS Accession No. ML081690661) and RAI 02.05.04-23, dated February 09, 2011 (ADAMS Accession No. ML110400770), the staff asked the applicant to clarify the types of E values used in the settlement calculations whether they were corresponding to small or large strains. In the July 14, 2008, and March 7, 2011, responses (ADAMS Accession Nos. ML082050558 and ML110680412), the applicant clarified that it used the high-strain elastic modulus in the settlement calculations for the North Anna 3 Seismic Category 1 structure foundations. Because the applicant used an elastic modulus in settlement calculation that would not result in underestimating the settlement at the site, the staff concludes that this approach yielded an adequate settlement estimate. Accordingly, the staff considers RAI 02.05.04-7c and RAI 02.05.04-23 resolved and closed.

Also in FSAR Section 2.5.4.10.2, the applicant initially estimated the differential settlement for the FWSC excluding the weight of the basemat. In RAI 02.05.04-7d dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff sought justification as to why the weight of the basemat was not included in the settlement calculation. In a July 14, 2008 response (ADAMS Accession No. ML082050558) to this RAI, the applicant stated that it excluded the weight of the basemat from the settlement analysis following the guidance in Note 15 of Table 2.0-1 of the ESBWR DCD, which states that the design of the foundation mat accommodates immediate and long-term differential settlements after installation of the basemat. Although DCD Table 2.0-1 excludes the weight of the basemat in the differential settlement calculations, the applicant provided estimated settlements that include the basemat to take all possible loads into consideration. The staff reviewed this response, including the information presented in ESBWR DCD Table 2.0-1 and the latest revision of FSAR Table 2.5.4-212, and concludes that although the DCD does not include the basemat in the settlement calculations, the applicant included the basemat in the settlement calculations and showed that the estimated site-specific settlement of FWSC meets the design requirement; therefore, the applicant provided sufficient information to resolve RAI 02.05.04-7d and the staff considers it closed.

In RAI 02.05.04-7e dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff asked the applicant to explain why it did not consider the seismic settlement of the FWSC foundation in the settlement analysis. The applicant's response referred to its July 14, 2008 response to RAI 02.05.04-7a (ADAMS Accession No. ML082050558), which described the structural fill as well-graded, highly compacted, angular to sub-angular gravel-sized particles of crushed rock. The applicant stated that the structural fill would be compacted to a high degree of density using a heavy vibratory steel-drummed roller. Although the applicant anticipated some small settlement of the fill under the FWSC due to tank loading, the high relative density of the fill would prevent any significant densification or settlement during a seismic event. Moreover, in the latest revision of the FSAR, the applicant stated that it will replace structural fill with concrete fill under the FWSC, and therefore seismic settlement is no longer an issue. Accordingly, the staff concludes that the applicant adequately addressed RAI 02.05.04-7e and considers the RAI resolved and closed.

Resolution of NAPS COL 2.0-29-A

NAPS COL 2.0-29-A (ESBWR DCD COL Item 2.0-29-A) requires that a COL applicant referring to the ESBWR design to provide site-specific information in accordance with SRP 2.5.4 and address: (1) localized liquefaction potential under other than seismic Category I structures, and (2) settlement and differential settlements. In FSAR Section 2.5.4.8 and Section 2.5.4.10.2, the staff concludes that the applicant provided sufficient information to address liquefaction potential under all structures, both seismic Category I structures and non-seismic Category I structures, and estimated the settlement of those structures using adequate methods to satisfy the requirements specified in NAPS COL 2.0-29-A. Therefore, the staff considers NAPS COL 2.0-29-A (ESBWR DCD COL Item 2.0-29-A) resolved.

Earth Pressures

The staff reviewed FSAR Sections 2.5.4.10.3 and 3.7.2.4.1, and related calculations, and finds that the methods used to estimate dynamic (seismic) and static lateral earth pressure on below-grade walls of the power block structures is consistent with the methodology used in ESBWR DCD. The staff also noted that in the static lateral earth pressure calculation, the applicant considered earth pressures induced by hydrostatic pressure and lateral loads on below-grade walls due to embedment and surcharge loading. In the calculations, the key site characteristics that the applicant used, such as unit weight of structural fill, at-rest pressure coefficient, and groundwater level, are the same as or enveloped by the parameters used for the ESBWR design, which ensures that the design plant static lateral earth pressure loading envelopes the North Anna 3 static lateral earth pressure loading. In the dynamic lateral earth pressure calculation, the applicant considered the active lateral earth pressure generated by earthquake-induced horizontal ground accelerations. For at-rest lateral earth pressure under seismic loading, the applicant used the Wood's soil pressure distributions model as described in ASCE 4-98. Because the lateral earth pressure induced by vertical ground accelerations is very small, the applicant did not consider this component in accordance with common engineering practices. The applicant used a peak acceleration of 0.31g, corresponding to higher magnitude but LF dominated earthquake, to develop the seismic active earth pressure diagram.

Based on the above findings, the staff concludes that the applicant considered all possible loadings, including the site SSE loading that can contribute to lateral earth pressure on plant below-ground walls in this analysis, which follows the guidance of industrial standards and RGs. The staff further concludes that the use of the peak acceleration of 0.31g for LF earthquake when developing the seismic active earth pressure is adequate because it considered higher magnitude of the corresponding earthquake that has higher energy and greater potential for moving the subsurface materials and causing damage. Finally, the staff concludes that the applicant used methods endorsed by industrial standards and commonly used in engineering practices to adequately determine the static and dynamic lateral earth pressure on below-ground walls of the power block structures.

The comparison of estimated site-specific and ESBWR design total (static and dynamic) lateral earth pressure confirms that the design lateral earth pressure diagram envelopes the site-specific estimate; therefore, the staff concludes that the site-specific lateral earth pressure will not affect the stability of foundations and structures.

Resolution of ESP COL Action Item 2.5-6

ESP COL Action Item 2.5-6 requires the applicant referencing the North Anna ESP to analyze the stability of all planned safety-related facilities, including bearing capacity, rebound, settlement, and differential settlements under deadloads of fills and plant facilities, as well as lateral loading in the COLA. FSAR Section 2.5.4.10 describes the static stability of the North Anna 3 site, including the bearing capacity, rebound, settlement, and differential settlement. The applicant also discussed lateral earth pressures at the North Anna 3 site. The staff reviewed this information and concludes that there were sufficient details to satisfy the requirements of ESP COL Action Item 2.5-6. Therefore, the staff considers ESP COL Action Item 2.5-6 resolved.

The staff reviewed FSAR Section 2.5.4.10 and applicant's responses to related RAIs, and concludes that the bearing capacity, settlement and earth pressure analyses and results for the North Anna 3 site are acceptable for satisfying the ESBWR design requirements and meeting the relevant requirements of 10 CFR Parts 50 and 100. The staff also concludes that the stability analyses were adequate to resolve ESP COL Action Item 2.5-6 and NAPS COL 2.0-29-A.

2.5.4.4.11 Design Criteria

In FSAR Section 2.5.4.11, the applicant provided general geotechnical criteria such as an acceptable FS against liquefaction, allowable bearing capacities, acceptable total and differential settlements, and an FS against slope stability failure, sliding, and overturning.

Resolution of ESP COL Action Item 2.5-7

ESP COL Action Item 2.5-7 requires the applicant referencing the North Anna ESP to include the design-related criteria that pertain to structural design in the COLA, such as wall rotation, sliding, and overturning. FSAR Section 2.5.4.11 describes the design criteria that apply to North Anna 3. These criteria include a minimum FS against sliding and overturning of 1.1, as well as an FS against liquefaction, bearing capacity failure and slope stability failure, among others. The staff reviewed this information and concludes that the applicant provided the applicable FS against sliding and overturning, as well as other design criteria, sufficient to satisfy the requirements of ESP COL Action Item 2.5-7. Therefore, the staff considers ESP COL Action Item 2.5-7 resolved.

The staff reviewed the FS used by the applicant and compared these values with those of RG 1.198, the related SRP sections and industry codes and standards, and concludes that those factors of safety are acceptable. The staff reviewed this information, including the resolution of ESP COL Action Item 2.5-7, and concludes that the applicant provided adequate design criteria for the North Anna 3 site, such as estimated settlement and earth pressure values, the factors of safety against liquefaction, bearing capacity failure, slope stability failure, sliding, and overturning to meet the relevant requirements of 10 CFR Parts 50 and 100.

2.5.4.4.12 Techniques to Improve Subsurface Conditions

FSAR Section 2.5.4.12 describes the removal of any Zone IIA saprolite beneath or within the zone of influence of seismic Category I or II structures and the replacement of the saprolite with structural fill for North Anna 3 site. The staff reviewed the plans to improve the Zone IIA saprolite in accordance with the methods described in the ESP SSAR.

Resolution of ESP COL Action Item 2.5-8

ESP COL Action Item 2.5-8 requires the applicant referencing the North Anna ESP to provide specific plans for each proposed ground improvement technique used, for the staff to determine whether the chosen technique will ensure that Zone II saprolitic soils will be able to support a safety-related foundation. In FSAR Section 2.5.4.12, the applicant described the techniques it will use to improve the subsurface conditions at the North Anna 3 site. The applicant described plans to remove the Zone IIA saprolitic soil, the only potentially liquefiable material identified at the site, and replace the excavated material with concrete fill and/or structural fill. The applicant stated that it will also remove zones of fractured or weathered rock from the areas immediately beneath the RB/FB, and FWSC basemat and replace it with concrete. The staff concludes that the applicant described the techniques it will use to improve the site, including the removal of the potentially liquefiable material from the foundation areas of the North Anna 3 structures, which meets the requirements of ESP COL Action Item 2.5-8. Accordingly, the staff considers ESP COL Action Item 2.5-8 resolved.

The staff further concludes that the methods described for subsurface improvements in FSAR Sections 2.5.4.12 and 2.5.4.5 are sufficiently detailed regarding the removal of the potentially liquefiable material and replacement with suitable structural fills at the North Anna 3 site to be acceptable and to satisfy the relevant requirements of 10 CFR Parts 50 and 100.

2.5.4.5 Post Combined License Activities

To ensure the quality of the backfills, either underneath or surrounding the seismic Category I structures, the applicant provided ITAACs in Table 2.4.1-1, “ITAAC for Fill Concrete Under and Around the Sides of Seismic Category I Structures,” Table 2.4.2-1, “ITAAC for Structural Fill Surrounding Seismic Category I Structures,” and Section 2.4, “Site Specific ITAAC,” in NAPS COLA Part 10; “Tier 1/ITAAC/Proposed License Conditions.”

The staff identified a License Condition relating to geologic mapping of both tectonic and non-tectonic surface deformation features at the site. The geologic license condition replaces ESP Permit Condition 3(E)(6) and is described in detail in Section 2.5.1.5 of this SER.

2.5.4.6 Conclusion

The staff reviewed the North Anna 3 COLA and cross checked the referenced ESP SSAR, ESBWR DCD and staff’s ESP SER. The staff’s review confirmed that the applicant addressed the relevant COL items, ESP COL Action items and ESP Permit Conditions, specifically, NAPS COL 2.0-29-A, NAPS ESP COL 2.5-2 through NAPS ESP COL 2.5-9 and ESP Permit Conditions 3.E(4) to 3.E(7). There are no outstanding issues that need to be addressed in the COL FSAR related to this section.

Based on its review, the staff concludes that the applicant conducted sufficient site investigations and performed adequate field and laboratory tests and associated analyses to provide sufficient information describing soil and rock conditions underlying the COL site of North Anna 3; provided sufficient information to characterize the subsurface materials at the site; and presented and substantiated information to assess the stability of subsurface materials and foundations. The staff reviewed the engineering properties of subsurface materials at the proposed site and backfill materials to be used during construction, the assessment of bearing capacity, liquefaction potential, settlement, and lateral earth pressure, as well as the development of a shear wave velocity profile through the site, and concludes that the applicant adequately addressed the related COL items and ESP permit conditions.

Accordingly, the staff concludes that the applicant provided sufficient information to meet the relevant requirements of ESBWR standard design and 10 CFR Part 50, Appendix A (GDC 2); Appendix S of 10 CFR Part 50; and 10 CFR 100.23, and therefore Section 2.5.4 of the North Anna 3 FSAR is acceptable.

2.5.5 Stability of Slopes

2.5.5.1 Introduction

Section 2.5.5 of this SER addresses slope stability information related to the North Anna 3 site. Section 2.5.5.2 of this SER provides a summary of relevant geologic and seismic information contained in FSAR Section 2.5.5 of the North Anna 3 COLA. SER Section 2.5.5.3 provides a summary of the regulations and guidance used by the applicant to perform the investigation. SER Section 2.5.5.4 provides a review of the staff's evaluation of FSAR Section 2.5.5, including any RAIs, open items, and confirmatory analyses. SER Section 2.5.5.5 discusses any post COL activities. Finally, SER Section 2.5.5.6 provides an overall summary of the applicant's and staff's conclusions, restates any bases covered in the application, and confirms that the application has met the requirements or fulfilled the regulations.

2.5.5.2 Summary of Application

In FSAR Section 2.5.5, the applicant provided the following:

COL Items:

- NAPS COL 2.0-30-A

NAPS COL 2.0-30-A addresses the provision in COL Item 2.0-30-A listed in the ESBWR DCD Table 2.0-1, regarding stability of slopes requirements.

- NAPS ESP COL 2.5-10

ESP COL Action Item 2.5-10 requires the COL applicant to perform a more detailed dynamic analysis of the stability of the existing slope and any new slopes using the SSE ground motion for the North Anna site.

- NAPS ESP COL 2.5-11

ESP COL Action Item 2.5-11 requires the COL applicant to provide plot plans and cross-sectional profiles of all safety-related slopes and to specify the measures that would be taken to ensure the safety of the slopes and the adjacent structures.

ESP Variance:

- NAPS ESP VAR 2.5-1

The slope stability analyses for the North Anna 3 site is presented in this FSAR section, which combine reviews of reports for the existing units and the originally planned Units 3 and 4, geotechnical literature, the ESP subsurface investigation, and the North Anna 3 subsurface investigation, and gave results that were different from those presented in ESP SSAR Section 2.5.5. To that end, the applicant also requested a variance from the information in the ESP SSAR relating to the stability of slopes, which was identified as NAPS ESP VAR 2.5-1 in the COLA. In this request, the applicant asked that the information presented in North Anna 3 FSAR Section 2.5.5 be used in place of the information presented in ESP SSAR Section 2.5.5 for the stability of slopes. The applicant stated that this request was based on the differences in slopes near North Anna 3 from the anticipated slopes in the ESP SSAR. Due to these differences, the applicant stated that for the seismic slope stability analysis, the PGA applied at North Anna 3 is also different from the ESP, although the method of analysis remains the same. The main differences are smaller PGA used in the seismic slope stability analysis than that used in ESP SSAR Section 2.5.5 and differences in the changed slope characteristics. Because the same method was used in the analyses, but with a shallower slope and a smaller applied seismic acceleration, the analyses yielded a higher computed FS against failure under both long-term static and short-term seismic conditions.

North Anna 3 FSAR Figure 2.5.5-201 presents the grading plan for North Anna 3. The applicant noted that the design plant grade for the power block area is at an elevation of 88.4 m (290 ft) sloping down to an elevation of 87.7 to 86.6 m (288 to 284 ft) around the perimeter. From the south and southwest of the TB toward the existing Units 1 and 2, the applicant noted that the slope reduces at 5 percent down to elevation 85.3 m (280 ft) at the SW Building. To attain the North Anna 3 elevations, the applicant noted that up to 9.1 m (30 ft) of fill is needed to bring the ground surface up to plant grade, where ground level is presently at around elevation 76.2 m (250 ft).

The applicant stated that there are no slopes that contribute to the support of any seismic Category I or II structures and only instability of the cut slopes at the northern and western edges of the plant could affect North Anna 3. The applicant described the southwesterly-oriented existing slopes to the west of Units 1 and 2 that were originally excavated during construction of the existing units. Additional details of the existing slopes are provided in Section 2.5.5.1.1 of the FSAR. The new slopes in the site area are cut slopes north of the power block that merge into the existing slopes to the west. The applicant noted that these new slopes reach a maximum height of 11.9 m (39 ft).

The applicant also discussed the impact of slope instability as part of ESP VAR 2.5-1, noting that the instability of the slopes surrounding the storm water management pond, as well as the temporary slopes in the site area, do not affect the safety of the plant or any of its structures. The applicant also noted that the nearest point of the existing slopes is more than 30.5 m (100 ft) from the new diesel tanks and even farther from the closest point on the SW cooling tower. The applicant also considered instability of the new 3-horizontal to 1-vertical (3h:1v) slope, but concluded it does not impact the foundation stability because the facilities are founded on concrete fill on top of bedrock.

To address NAPS ESP COL 2.5-11, the applicant discussed the stability of the existing and new slopes at the North Anna 3 site in the following subsections.

2.5.5.2.1 Slope Characteristics

North Anna 3 FSAR Section 2.5.5.1 describes the characteristics of the existing and new slopes, their subsurface conditions, and impacts of the slope instability on the seismic Category I structures at the North Anna 3 site. The applicant performed slope stability analyses for existing slopes and new slopes under static and dynamic (seismic) loadings to demonstrate that the minimum factors of safety meet the requirements defined in the DCD. Figure 2.5.5-1 in this SER illustrates that no slopes will contribute to the support of any of the Unit 3 seismic Category I structures or any of the other major power block structures.

Existing Slope Characteristics

Figure 2.5.5-1 of this report also shows the location and direction of the existing slopes, including Slope ES, a 2.4h:1v slope with a maximum height of 13.7 m (45 ft) to the southeast of the service water reservoir (SWR) for Units 1 and 2.

New Slope Characteristics

FSAR Section 2.5.5.1.2 describes the location of the new 11.9 m (39 ft) Slope SS, a 3h:1v slope to the east of the FWSC shown in plan view in SER Figure 2.5.5-1. The applicant noted that boring B-947 was drilled relatively close to the final location of the top of the slope during the North Anna 3 subsurface investigation. The stability analysis performed for Slope DD conservatively neglected a 4.6 m (15 ft) wide berm in the slope.

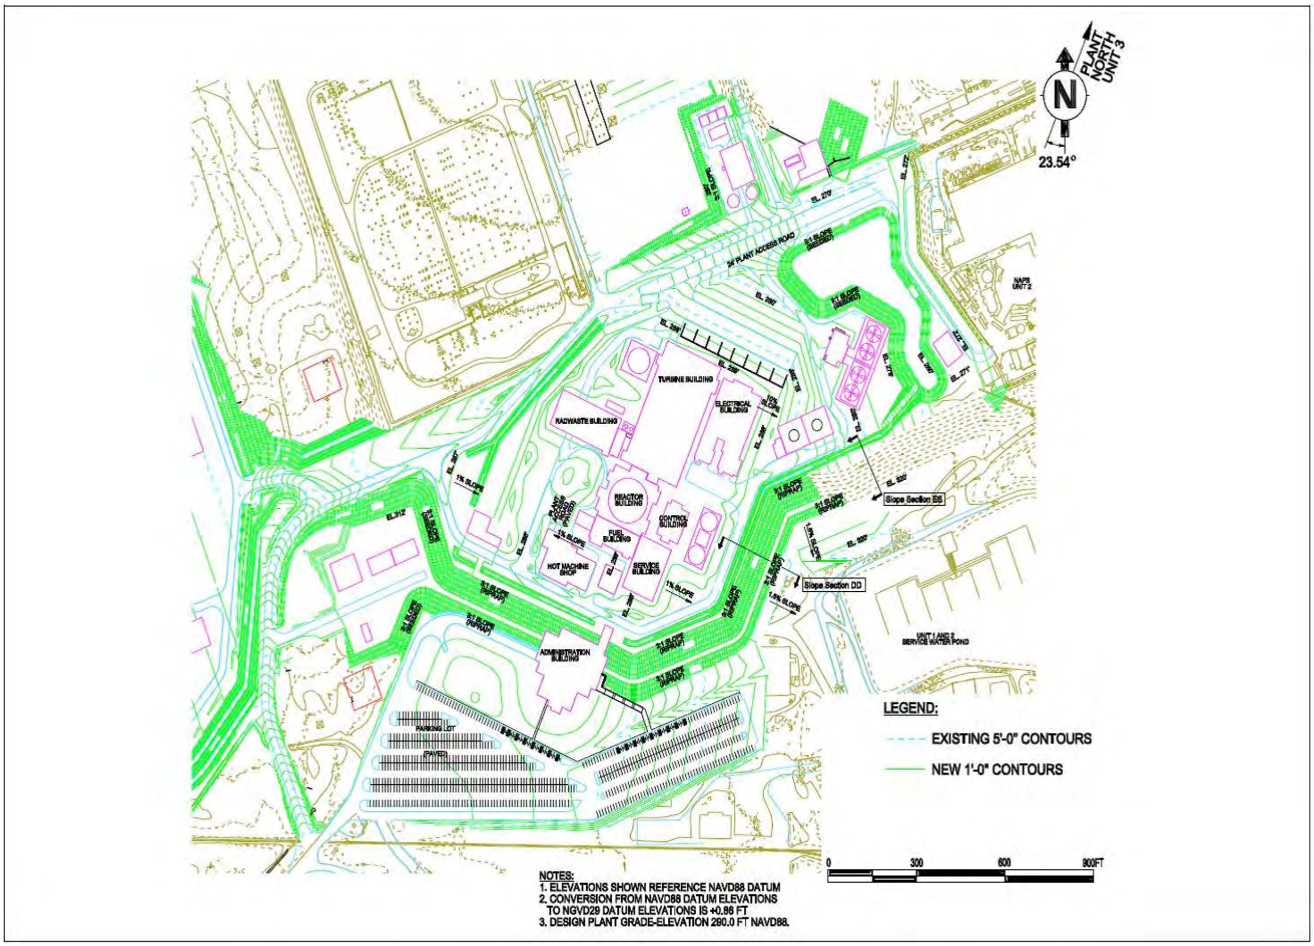

Figure 2.5.5-1. Location of Elevated Slopes (FSAR Figure 2.5.5-201)

Slope Subsurface Conditions

FSAR Section 2.5.5.1.3 describes the slope subsurface conditions at the North Anna 3 site and refers to Section 2.5.4.2.2 for details of the site soils and bedrock. Based on the site investigation data, the applicant determined that the soils in the slope consisted mostly of Zone IIA saprolites and were classified as silty sands. The applicant summarized the engineering properties of the site soils and bedrock, as well as the liquefaction characteristics of all of the Zone IIA saprolites estimated in FSAR Section 2.5.4.8.

New Slope Subsurface Conditions. The applicant also discussed the subsurface conditions of the new slopes in the site area. For the purposes of the stability analyses, the applicant noted that in B-929 Zone IIA saprolite is present down to about 14.2 m (46 ft) below the existing ground level with the remaining 5.4 m (18 ft) being Zone IIB saprolite.

Existing Slope Subsurface Conditions. The applicant summarized boring B-947 which provides information on the subsurface materials on the top of the existing slope and CPT C-916 which is adjacent to B-947. The applicant confirmed that the existing slope materials have the properties of the Zone IIA saprolite down to about 10.7 to 15.2 m (35 to 50 ft) below the existing ground level and the bottom 3.0 m (10 ft) of saprolite above weathered rock has the Zone IIB saprolite properties.

Slope Phreatic Surface

The applicant illustrated the phreatic, or groundwater, surfaces for existing and new slopes in FSAR Figures 2.5.5-202 and 2.5.5-203. The applicant developed these surfaces using water table levels measured in observation well OW-947 and derived in FSAR Section 2.4.12. Based on this information, the applicant concluded that the depth of the phreatic surface precluded any potential for liquefaction of the near-surface soils in the slopes.

2.5.5.2.2 Design Criteria and Analyses

FSAR Section 2.5.5.2 presents the design criteria for the new and existing slopes, as well as an analysis of the static and dynamic (seismic) stability analysis. The applicant presented the required FS, the stability of the existing slope, and analyses for both the existing and new slopes.

Required Factor of Safety

The applicant stated that the design criteria for the slopes are defined in the ESBWR DCD with minimum FS for static and dynamic loading of 1.5 and 1.1, respectively.

Stability of Existing Slope

The applicant stated that the existing slope (2.4h:1v) was thoroughly inspected during the ESP site investigation and shows no signs of distress.

Analysis of Existing Slope

The applicant used the computer program SLOPE/W, a commercial software product that computes the FS of earth and rock slopes, to analyze the static and dynamic stability of the existing slope ES. The properties of soil and rock are provided in FSAR Table 2.5.4-208.

<u>Long-Term Static Analysis</u>. The applicant used the Bishop method, which is available in the SLOPE/W program. The method divides the slope into slices and is based on the moment equilibrium assumption to compute long-term static stability. The applicant noted that the resulting FS of the static analysis for the existing slope was 2.29, which was above the minimum FS of 1.5 for long-term static stability.

Seismic Slope Stability Analysis. For the seismic slope stability analysis, the applicant used a pseudo-static approach that assumed the horizontal and vertical seismic forces act on the slope in a static manner as a constant force. The applicant used an average peak horizontal acceleration of 0.26g and a vertical acceleration of 0.130g in the slope for a LF earthquake, resulting in an FS of 1.30, more than the minimum 1.1 required. For the HF earthquake, the equivalent peak horizontal acceleration used was 0.42g with a vertical acceleration of 0.21g yielding an FS of about 1.04, less than the minimum 1.1. Because an actual seismic event would last only seconds, with the peak motions occurring for a small portion of the total duration, the applicant considered the pseudo-static approach to be conservative.

The applicant also used a pseudo-static approach recommended by Kramer (1996), which uses half of the peak acceleration value rather than a set peak value based on magnitude. The applicant concluded that the resulting FS against slope failure was above the required minimum of 1.1 at 1.61 and 1.41 for the LF and HF earthquake inputs, respectively.

As an alternative to applying the peak acceleration values for the pseudo-static analysis, the applicant applied the acceleration values recommended by Seed (1979) and used horizontal accelerations of 0.10g and 0.15g for HF and LF earthquake inputs with a vertical acceleration of zero. From these inputs, the applicant computed an FS of 1.76 and 1.57 for HF and LF earthquakes, respectively, which the applicant concluded were greater than the required minimum of 1.1.

The results of the applicant's analyses showed that the only case that gave a FS lower than the required minimum was the pseudo-static analysis using the HF peak acceleration. However, the applicant considered that to be an overly conservative approach and concluded that the existing 2.4h:1v slope to the southeast of the SWR will remain stable under long-term static and design seismic conditions.

Analysis of the New Slope

FSAR Section 2.5.5.2.4 analyzes the static and dynamic stability of the new 11.9 m (39 ft) high 3h:1v slope (Slope D-D) to the east of the FWSC, using the same methods as the existing slope analysis.

Long-Term Static Analysis

FSAR Figure 2.5.5-211 presents the input into the SLOPE/W program used in the analysis and the results. For long-term static stability, the applicant concluded that the calculated FS of 2.27 was well above the minimum FS of 1.5 required for safety.

Seismic Slope Stability Analysis

The applicant utilized three different methods to determine the FS for the stability of the new slope under seismic conditions. Using a pseudo-static analysis for the new 11.9 m (39 ft) high slope that incorporated an average PGA of 0.25g with a vertical acceleration of about 0.125g, the applicant determined the FS for the LF earthquake of 1.24. The applicant used an average peak horizontal acceleration of about 0.41g with a vertical acceleration of about 0.205g for the HF earthquake resulting in a FS of 1.00, less than the required minimum of 1.1. The applicant also used Seed's (1979) reduced peak acceleration and determined the FS for LF and HF earthquakes of 1.64 and 1.43, respectively. Finally, the applicant utilized the reduced peak acceleration of Kramer (1996) and determined an FS of 1.59 for the LF earthquake and 1.34 for the HF earthquake. Based on the stability analysis results and the considerations used for the existing slope, the applicant concluded that the new 3h:1v slope to the east of the FWSC will remain stable under long-term static and design seismic conditions.

2.5.5.2.3 Boring Logs

FSAR Section 2.5.5.3 summarizes the boring logs, CPT logs, observation wells, and laboratory test results for two borings, two CPTs, and one groundwater observation well in the area of the existing and new slopes. The applicant stated that borehole B-18 was drilled close to the toe of the existing 2.4h:1v slope to the north of the SWR. The applicant also described the location of boring B-947, CPT C-915 and C-916, and OW-947 as being near the top of the proposed new 3h:1v slope southeast of the FWSC. The applicant performed grain size tests for the saprolites in boring B-947.

2.5.5.2.4 Compacted Fill

FSAR Section 2.5.5.4 states that the existing 2.4h:1v slope and the new 3h:1v slope are cut slopes and do not contain fill materials in any significant quantity.

2.5.5.2.5 Applicant Conclusion

North Anna 3 FSAR Section 2.5.5.5 describes the applicant's conclusions regarding stability of the slopes at the North Anna 3 site. The applicant concluded that the existing slopes and embankments and the new slopes, such as storm water management Pond No. 1 or the temporary slopes and excavations, do not affect the stability of plant structures at North Anna 3, and therefore do not require slope stability analysis. However, the applicant noted that the only existing slope whose failure could adversely affect the safety of North Anna 3 is the 2.4h:1v slope that descends from the north of the SWR down to the southeast of the excavation made for abandoned Units 3 and 4. The applicant indicated the only analysis that gave a FS lower than the required minimum was the pseudo-static analysis, which was overly conservative. The applicant concluded that the 2.4h:1v slope would remain stable under long-term static and design seismic conditions. Based on the results of the stability analyses for the new 3h:1v slope, the applicant also concluded that the slope would remain stable under both long-term static and design seismic conditions.

2.5.5.3 Regulatory Basis

The applicable regulatory requirements for reviewing the applicant's discussion of stability of the slopes are:

- 10 CFR 50.55a, requires that SSCs shall be designed, fabricated, erected, constructed, tested, and inspected in accordance with the requirements of applicable codes and standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 1, requires that SSCs important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. It also requires that appropriate records of the design, fabrication, erection, and testing of SSCs important to safety be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit.

- 10 CFR Part 50, Appendix A, GDC 2, relates to the consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated.

- 10 CFR Part 50, Appendix A, GDC 44, "Cooling Water," requires that a system be provided with the safety function of transferring the combined heat load from SSCs important to safety to an UHS under normal operating and accidental conditions.

- 10 CFR Part 50, Appendix B, establishes quality assurance requirements for the design, construction, and operation of those SSCs of nuclear power plants that prevent or mitigate the consequences of postulated accidents that could cause undue risk to the health and safety of the public.

- 10 CFR Part 50, Appendix S, applies to the design of nuclear power plant SSCs important to safety to withstand the effects of earthquakes.

- 10 CFR Part 100, provides the criteria which guide the evaluation of the suitability of proposed sites for nuclear power and testing reactors.

- 10 CFR 100.23, provides the nature of the investigations required to obtain the geologic and seismic data necessary to determine site suitability and identify geologic and seismic factors required to be taken into account in the siting and design of nuclear power plants.

The related acceptance criteria are summarized from SRP Section 2.5.5:

- Slope Characteristics: In meeting the requirements of 10 CFR Parts 50 and 100, the discussion of slope characteristics is acceptable if the subsection includes: (1) cross sections and profiles of the slope in sufficient quantity and detail to represent the slope and foundation conditions; (2) a summary and description of static and dynamic properties of the soil and rock comprised by seismic Category I embankment dams and their foundations, natural and cut slopes, and all soil or rock slopes whose stability would directly or indirectly affect safety-related and Category I facilities; and (3) a summary and description of ground water, seepage, and high and low ground water conditions.

- Design Criteria and Analyses: In meeting the requirements of 10 CFR Parts 50 and 100, the discussion of design criteria and analyses is acceptable if the criteria for the stability and design of all seismic Category I slopes are described and valid static and dynamic analyses have been presented to demonstrate that there is an adequate margin of safety.

- Boring Logs: In meeting the requirements of 10 CFR Parts 50 and 100, the applicant should describe the borings and soil testing carried out for slope stability studies and dam and dike analyses.

- Compacted Fill: In meeting the requirements of 10 CFR Part 50, the applicant should describe the excavation, backfill, and borrow material planned for any dams, dikes, and embankment slopes.

In addition, the geologic characteristics should be consistent with appropriate sections from: RG 1.27, RG 1.28, RG 1.132, RG 1.138, RG 1.198, and 1.206.

2.5.5.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 2.5.5 of the ESBWR DCD Revision 10. The staff reviewed Section 2.5.5 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to ensure that the combination of the information in the ESBWR DCD and the information in the COL FSAR represents the complete scope of information relating to this review topic[1].

The staff reviewed the resolution to the COL specific items related to the stability of all earth and rock slopes—natural and manmade—whose failure under any conditions to which they could be exposed during the life of the plant, could adversely affect the safety of the plant. To that end, the staff reviewed the applicant's descriptions of the slope characteristics, design criteria, slope stability analyses, and conclusions drawn by the applicant.

Resolution of NAPS ESP VAR 2.5-1

The staff reviewed the applicant's variance request to use the information in FSAR Section 2.5.5 in place of the information in ESP SSAR Section 2.5.5, as it relates to the stability of slopes. Because of the shallower slopes and a smaller applied seismic acceleration for the North Anna 3 site, as described in the FSAR based on updated information, which results in an increased FS against slope failure, the staff concludes that the use of North Anna 3 FSAR Section 2.5.5 in place of North Anna 3 ESP SSAR Section 2.5.5 is acceptable.

2.5.5.4.1 Slope Characteristics

FSAR Section 2.5.5.1 describes the characteristics of the existing and new slopes, their subsurface conditions, and impacts of slope instability on the seismic Category I structures at the North Anna 3 site. The staff reviewed this information as well as the characterizations of the phreatic surfaces for new and existing slopes. As discussed below, the staff found that the information provided by the applicant meets the minimum requirements for slope characterization in 10 CFR Part 100. The staff further determined that the subsurface investigations adhered to the criteria of RG 1.132.

Resolution of ESP COL Action Item 2.5-11

ESP COL Action Item 2.5-11 requires the applicant referencing the North Anna ESP to provide plot plans and cross sections/profiles of the safety-related slopes and to specify what measures are needed at the site to ensure the safety of the safety-related structures adjacent to the slopes. In FSAR Section 2.5.5.1.2, the applicant described the location of the new 3h:1v slope to the southeast of the FWSC. FSAR Figure 2.5.5-201 illustrates the plan view, while FSAR Figures 2.5.5-202 and 2.5.5-203 show cross-section of those slopes. The staff considered this information, including the plot plans and cross section through the new slope. The staff also considered the physical characteristics of the slope and concludes that the failure of the slope would not affect the safety-related structures at the site. The staff also concludes that the applicant provided adequate plot plans and cross sections of the new slope to satisfy the criteria of ESP COL Action Item 2.5-11. Accordingly, the staff considers ESP COL Action Item 2.5-11 resolved.

The staff also considered the results and interpretations of the borings, CPTs, and observation wells conducted at the site. During the review of FSAR Section 2.5.5.1.3, the staff noted that the applicant identified two different lithologies in the same CPT and borehole analyses. In RAI 02.05.05-1 dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff asked the applicant to clarify the lithology of CPT C-916, located adjacent to boring B-947, which was alternatively identified as silty clays, clays, and silty sand saprolite. In the response to RAI 02.05.05-1 dated July 14, 2008 (ADAMS Accession No. ML082050558) the applicant stated that although the CPTs provided valuable information about the soil, the test had not obtained samples from the soil. The applicant stated that the interpretation of soil type from the friction ratio was empirical and based on historical interpretations, but the interpretation is not considered exact. Accordingly, although the friction ratio measured during the CPT indicated that the soil was mainly silty clays and clays, the visual observation and grain size testing concluded that the soil was mainly silty sand. The applicant also clarified that the silty sand profile of the soil was the profile used in the slope stability analysis.

The staff reviewed this information, including the applicant's suggestion that the visual inspection of the soil type is more reliable than the empirical interpretation of CPT results. The staff concurs with the applicant's assessment of the visual inspection and laboratory test as a more reliable determination of soil type, and therefore finds the use of the silty sand profile for slope stability analyses to be acceptable. Accordingly, the staff considers RAI 02.05.05-1 resolved and closed.

Based on the slope characterization provided and the response to the RAI, the staff concludes that the applicant's characterization of the slopes at the North Anna 3 site area is acceptable for meeting the relevant requirements of 10 CFR Parts 50 and 100.

2.5.5.4.2 Design Criteria and Analyses

FSAR Section 2.5.5.2 describes the design criteria and analyses performed for the North Anna 3 site. The applicant used SLOPE/W commercial software and three different approaches to slope stability in the analyses: a conservative pseudo-static approach, Seed's approach (1979), and the approach recommended by Kramer (1996). The results of these approaches are summarized in Section 2.5.5.2.2 of this SER. In reviewing FSAR Section 2.5.5.2, the staff focused on the design criteria for adequacy of the applicant's slope stability analyses, both static and dynamic (seismic) stability for existing and new slopes adjacent to the North Anna 3 site. The applicant used the design criteria, as defined in the ESBWR DCD, with a minimum slope stability FS of 1.5 for static (non-seismic) and 1.1 for dynamic (seismic) loading conditions. The staff identified two areas that required additional information.

The applicant stated that for the Long-Term Static Analysis, Bishop's method was the only method used. The staff compared this statement to the criteria in RG 1.206, which state that classic and contemporary methods of analysis should be used to determine slope stability. In RAI 02.05.05-2 dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff asked the applicant to explain why the only method used for the Long-Term Static Analysis was Bishop's method, which only considers moment magnitude and, depending on the slope geometry, may not yield conservative results. The applicant's July 14, 2008, response stated that although there are various methods of computing slope stability commonly in use, the methods differ mainly in the type and degree of underlying assumptions. In the response to RAI 02.05.05-2 dated July 14, 2008 (ADAMS Accession No. ML082050558), the applicant also stated that a more accurate model will give a higher FS, and lower factors of safety are not indicative of a conservative approach but of a less accurate approach. The applicant concluded that all methods use the same slope geometry and soil parameters. Thus, the applicant chose the Bishop method (Bishop, 1955) for the long-term static analysis because this method is recognized for its high degree of accuracy. Finally, the applicant noted that the use of the Bishop method was previously reviewed and approved in the North Anna ESP.

The staff considered the applicant's statement regarding the Bishop method. However, the reality is that all slope stability analysis methods have their own advantages and limitations, and the Bishop method may or may not give the most conservative results for a specific slope. Accordingly, the staff conducted an independent confirmatory analysis for a selected slope using the information provided in the FSAR. The results from the confirmatory analysis show that there is little variation among the factors of safety for the slope stability—about 7 percent among all six methods used—but higher than the applicant's estimate (about 1 percent); and all FS values are greater than the minimum requirement under the given seismic loads (i.e., the slope will not fail under the given conditions); therefore, the applicant's conclusion regarding the stability of the slopes is acceptable. Accordingly, the staff considers RAI 02.05.05-2 resolved and closed.

The staff also reviewed the assumptions used for the seismic stability analysis of slopes in the North Anna 3 area. Some of the assumptions the applicant stated include (1) no liquefaction was considered in the analysis, (2) the use of average peak acceleration as opposed to peak accelerations at the surface, and (3) the consideration of reduced accelerations. These assumptions are contrary to the guidance in RG 1.206, which states that the applicant should demonstrate the reliable performance of slopes during all conditions during the life of the plant. In RAI 02.05.05-3 dated June 17, 2008 (ADAMS Accession No. ML081690661), the staff asked the applicant to describe the impact of the possible maximum dynamic settlement of the slope soil on slope stability, and to describe how the assumptions used in the pseudo-static method of analysis were verified.

In the response to RAI 02.05.05-3 dated July 14, 2008 (ADAMS Accession No. ML082050558), the applicant stated that the possible maximum dynamic settlement of 41 mm (1.6 in.) calculated for this site, corresponding to a reduction in slope height of between 0.38 and 0.31 percent, would not impact the slope stability. The applicant also stated that the reason for slope failure during a seismic event normally is not a slip failure, but instead because, during a seismic event, the slope loses strength due to liquefaction. Although the applicant noted that liquefaction would weaken the slope, a large portion of the slope is not prone to liquefaction because 8.5 m (28 ft) of the slope is above the groundwater table with maximum slope height of 13.7 m (45 ft). In addition, the applicant concluded that, based on the LF and HF seismic characteristics, the chance of any liquefaction occurring in the Zone IIA saprolitic soils is very low. Due to the low chance of liquefaction, the applicant concluded that the strength loss of the slope from liquefaction was remote. Therefore, the slopes will remain stable during the design basis earthquake at the North Anna 3 site.

The staff also conducted reliability analyses by assigning probability distributions (uncertainties) to each input parameter and examined how the uncertainties affect the reliability of the calculated FS. During the reliability analysis, the staff used different values of coefficients-of-variation, the ratio of standard-deviation to mean-value, and assumptions of normal distribution of variables.

The results of the reliability analysis were three-fold. First, the staff noted that due to uncertainties and variations in soil properties, no single FS can represent the actual site conditions, therefore, when determining FS using deterministic methods, soil parameters should be conservatively estimated to take the uncertainties and variations into consideration. Second, the staff observed that the smaller the variation, the higher degree of confidence in the slope stability calculation. The confirmatory analysis results showed that a reduction of the coefficient of variation from 1.0 to 0.5 for seismic loading input will increase the probability of FS greater than 1.0, or the confidence level from about 42 to 70 percent, although the mean values of FS remain the same at 1.128 as shown in SER Figure 2.5.5-2. Finally, since the seismic loading used in stability analyses is based on the results of the probabilistic analysis of the site specific maximum ground acceleration, the staff concludes that seismic loading has high uncertainty that has been considered when conducting site specific seismic hazard evaluation.

Based on the staff's independent confirmatory analysis, and the applicant's response to RAI 02.05.05-3, particularly the use of the pseudo-static methods to determine the seismic slope stability at the North Anna 3 site, the staff concurs with the applicant that the use of the pseudo-static method was appropriate for the North Anna 3 site. The staff also concurs with the applicant's assessment of the liquefaction potential and slope stability at the North Anna 3 site. Finally, since the applicant's conclusions considered both the groundwater interaction and the weakening of the slope during the design seismic event, the staff considers RAI 02.05.05-3 resolved and closed.

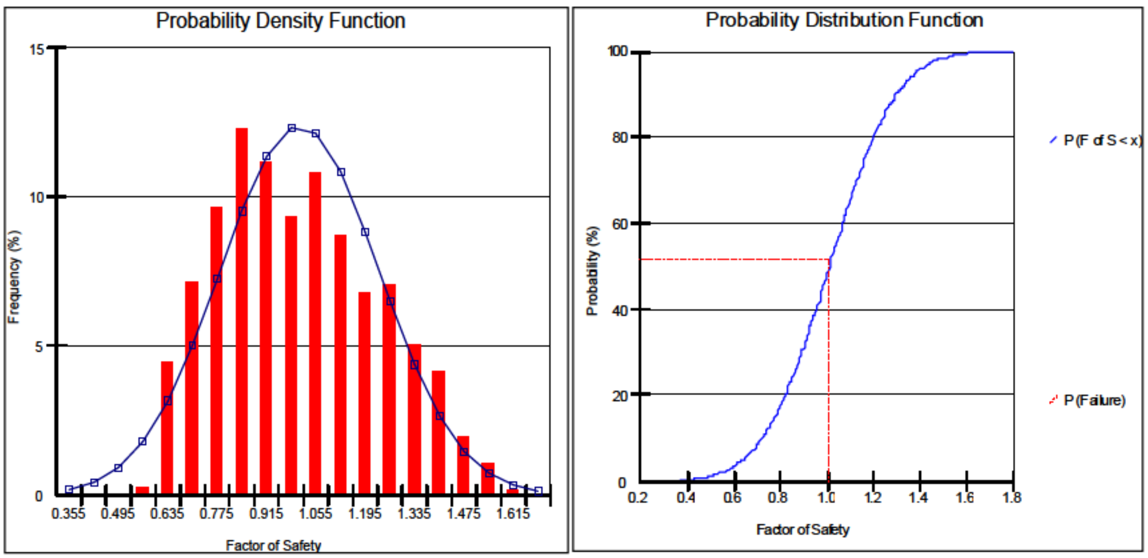

Figure 2.5.5-2. Probability Density and Distribution Functions of FS. Probabilistic Seismic Loading of a_h=0.25g and a_v = 0.125g with COV = 1.0

Resolution of NAPS COL 2.0-30-A and ESP COL Action Item 2.5-10

NAPS COL 2.0-30-A (ESBWR COL 2.0-30-A) requires the COL applicant to provide site-specific information in accordance with SRP 2.5.5 to evaluate stability of slopes at the site.

ESP COL Action Item 2.5-10 requires the applicant referencing the North Anna ESP to conduct a more detailed dynamic analysis for existing and new slopes at the site using the SSE ground motion.

North Anna 3 FSAR Section 2.5.5.2 describes the design criteria and analyses of slope stability performed for the North Anna 3 site. In addition to static slope stability analyses, the applicant presented the seismic slope analysis for the existing 2.4h:1v slope, which used SLOPE/W as part of a pseudo-static approach. From these results, the applicant determined that the existing slope at the site would remain stable under long-term static and design seismic conditions. In North Anna 3 FSAR Section 2.5.5.2.4.b, the applicant described the seismic slope analysis for the new 3h:1v slope, again using the SLOPE/W program as part of the analysis. Based on the analysis results, the applicant concluded that the new slope would also remain stable under long-term static and design seismic conditions. Because the applicant conducted static and dynamic stability analyses for both the new and existing slopes, and the results demonstrated that the slopes meet stability requirements under the design static and seismic loading conditions, the staff concludes that the applicant provided sufficient information to satisfy the requirements of NAPS COL 2.0-30-A and ESP COL Action Item 2.5-10. Accordingly, the staff considers NAPS COL 2.0-30-A and ESP COL Action Item 2.5-10 resolved.

Based on the information provided in the FSAR and the applicant's response to the RAIs listed above, the staff concludes that the applicant's assessments of the design criteria and analyses of the slopes at the North Anna 3 site area are acceptable and meet the criteria of 10 CFR Parts 50 and 100.

2.5.5.4.3 Boring Logs

The applicant provided boring logs, CPT logs, observation wells, and laboratory test results for two borings, two CPTs, and one groundwater observation wells in the existing and new slopes at the North Anna 3 site area, as well as laboratory test results related to the slope materials. The staff reviewed this information to confirm that that the applicant provided sufficient data and used appropriate material and engineering properties of slope materials in slope stability analysis, and concludes that the information provided satisfies the relevant requirements of 10 CFR Parts 50 and 100.

2.5.5.4.4 Compacted Fill

FSAR Section 2.5.5.4 states that the existing 2.4h:1v slope is a cut slope and does not contain fill materials in any significant quantity, while the top of the new 3h:1v slope will contain re-compacted backfill derived from the saprolite on the site. The staff reviewed the applicant's intent to apply the properties of the saprolite to the compacted fill and concluded that this is an acceptable approach because the compacted fill will have better engineering properties than the in-situ saprolite.

2.5.5.4.5 Conclusion

In FSAR Section 2.5.5.5, the applicant summarized the major conclusions of the slope stability analyses. The applicant concluded that the slopes will remain stable under long-term static and dynamic conditions.

The staff noted that this section states that "[e]xisting slopes and embankments that are not impacted by North Anna 3 (such as the SWR embankments) do not require analysis for North Anna 3 and are not addressed here." However, although the SWR embankments were built for Units 1 and 2 and the construction of North Anna 3 will not impact those embankments, the reevaluation of the site seismic hazard for Unit 1 and 2 based on the lessons learned from the Fukushima event determined that the updated site-specific GMRS will exceed the original design basis. Because any breach of the SWR embankment might have an impact on the North Anna 3 site. In RAI 02.05.05-4 dated April 8, 2014 (ADAMS Accession No. ML14098A297), the staff asked for an evaluation of the impact of possible failure of the SWR embankment on the stability of slopes at the North Anna 3 site.

In the response to RAI 02.05.05-4 dated May 9, 2014 (ADAMS Accession No. ML14140A087), the applicant stated that there will be no impact from a possible failure of the SWR embankment on the stability of slopes at the North Anna 3 site because: 1) at the western end of the SWR and the western portion of the northern end of the SWR, a failure of the inside slope would not result in a release of water; 2) an embankment breach of the east portion of the SWR may result in a release of water but it would flow down gradient to the east and away from North Anna 3. The staff reviewed the RAI response and conducted a site audit (ADAMS Accession No. ML14203A179) to confirm the geographic characteristics of the North Anna 3 site, the SWR and Units 1 and 2. The staff also noted that the design plant grade elevation of North Anna 3 is 88.3 m (290 ft) while for Units 1 and 2, this elevation is 82.6 m (271 ft), or about 6.3 m (19 ft) below the North Anna 3; therefore water will flow to Units 1 and 2 site if the SWR embankment fails. Based on the above, the staff concludes that there will be no impact from a possible failure of the SWR embankment on the stability of slopes at the North Anna 3 site, and accordingly, the staff considers RAI 02.05.05-4 resolved and closed.

The staff considered applicant’s conclusions and additional information regarding the stability of SWR embankment, along with the criteria and requirements of 10 CFR Parts 50 and 100. The staff concluded that the information provided in FSAR Section 2.5.5 is sufficient and acceptable for meeting relevant requirements of the ESBWR DCD and 10 CFR Parts 50 and 100.

2.5.5.5 Post Combined License Activities

There are no post COL activities related to this section.

2.5.5.6 Conclusion

The staff reviewed the application with related RAI responses, and checked the referenced ESBWR DCD and North Anna ESP SSAR. The staff’s review confirmed that the applicant addressed the relevant information and there is no outstanding information expected to be addressed in the COL FSAR related to this section.

As set forth above, the applicant presented and substantiated information to establish the stability of all earth and rock slopes - natural or manmade - at the plant site. The staff reviewed the investigations of the slope stability studies and dam and dike analyses, and performed an independent confirmatory analysis. For the reasons given above, the staff concluded the design analyses contain margins of safety that adequately demonstrate both natural and manmade slopes will remain stable under both static and dynamic (seismic) loading conditions and the safety-related earthwork will function reliably at the site to justify the soil and rock characteristics used in the design. The staff further concluded that the design analyses contain adequate margins of safety for the construction and operation of the nuclear power plant. These analyses and results meet the requirements of 10 CFR Part 50, Appendix A (GDC 1, 2, and 44); Appendices B and S of 10 CFR Part 50; and 10 CFR 100.23, and address NAPS COL Item 2.0-30-A. In conclusion, the applicant provided sufficient information for resolving NAPS COL Item 2.0-30-A, NAPS ESP VAR 2.5-1, ESP COL Action Item 2.5-10, and ESP COL Action Item 2.5-11 and for satisfying 10 CFR Parts 50 and 100. Therefore, the staff concludes that the North Anna 3 site is suitable with respect to the criteria governing the stability of slopes.

2.5.6 Embankments and Dams

2.5.6.1 Introduction

Lake Anna is used for normal plant cooling of the existing unit. The North Anna Dam is designed and constructed to meet the requirements for a seismic Category I structure in support of the existing units.

2.5.6.2 Summary of Application

Section 2.5.6, of the North Anna 3 COL FSAR incorporates by reference Section 2.5.6 of ESP SSAR, Revision 9. In addition, in FSAR Section 2.5.6, the applicant added that no embankments and dams were analyzed because Lake Anna is only used as a source of makeup water for North Anna 3. The applicant stated that the North Anna Dam is designed and constructed to meet requirements for a seismic Category I structure in support of the existing Units 1 and 2.

2.5.6.3 Regulatory Basis

FSAR Section 2.5.6 states that the applicant did not reanalyze the North Anna Dam because Lake Anna would be used only as a source of makeup water for North Anna 3. As such, the applicant did not list any regulatory guidance or cite any regulations applicable to this section. Section 2.5.6 of RG 1.70 describes the necessary information and analysis related to the investigation, engineering design, proposed construction, and performance of all embankments used for plant flood protection or for impounding cooling water. Sections 2.4.4 and 2.5.5 in RS-002, "Processing Applications for Early Site Permits," provide similar information and guidance.

2.5.6.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 2.5.6 of the ESBWR DCD, Revision 10. The staff reviewed Section 2.5.6 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to ensure that the combination of the information in the ESBWR DCD and the information in the COL FSAR represents the complete scope of information relating to this review topic[1].

Sections 2.4.4 and 2.5.5 of this SER provide the staff's evaluation of potential dam failures and slope stability, respectively.

2.5.6.5 Post Combined License Activities

There are no post COL activities related to this section.

2.5.6.6 Conclusion

Section 2.4.4 and 2.5.5 of this SER present the staff's conclusions regarding dam failures and slope stability, respectively.

3 DESIGN OF STRUCTURES, COMPONENTS, EQUIPMENT AND SYSTEMS

3 DESIGN OF STRUCTURES, COMPONENTS, EQUIPMENT AND SYSTEMS

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the NRC staff evaluation of the North Anna 3 design of structures, components, equipment and systems.

3.1 Conformance with NRC General Design Criteria

Section 3.1, "Conformance with NRC General Design Criteria [GDC]," of the North Anna 3 Combined License (COL) Final Safety Analysis Report (FSAR) Revision 8, incorporates by reference, with no departures or supplements Section 3.1, "Conformance with NRC General Design Criteria," of Revision 10 of the Design Control Document (DCD) for the Economic Simplified Boiling Water Reactor (ESBWR), referenced in Appendix E to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." As documented in NUREG–1966, "Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-Water Reactor (ESBWR) Standard Design" Agencywide Documents Access and Management System (ADAMS) Accession No. ML14100A304), the staff reviewed and approved Section 3.1 of the certified ESBWR DCD. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review.[1] The staff's review confirmed that the applicant has addressed the required information, and there is no outstanding information related to this section that remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Section VI.B.1 of Appendix E to 10 CFR Part 52, all nuclear safety issues relating to the "Conformance with NRC General Design Criteria," that were incorporated by reference have been resolved.

3.2 Classification of Structures, Systems and Components

3.2.1 Introduction

Nuclear power plant structures, systems, and components (SSCs) important to safety should be designed to withstand the effects of earthquakes without losing the capability to perform their safety functions. SSCs important to safety are defined in 10 CFR Part 50, "Domestic Licensing of Production and Utilization Facilities," Appendix A, "General Design Criteria for Nuclear Power Plants," as those SSCs that "provide reasonable assurance that the facility can be operated without undue risk to the health and safety of the public." These SSCs include safety-related SSCs whose functions ensure: (1) the integrity of the reactor coolant pressure boundary (RCPB); (2) the capability to shut down the reactor and maintain it in a safe shutdown condition; and (3) the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures. These SSCs are designed to sustain and remain functional for a design basis safe shutdown earthquake (SSE). The SSE is based on an evaluation of the maximum earthquake potential for the site and is an earthquake that produces the maximum vibratory ground motion for which SSCs are designed to remain functional. The regulatory

[1] See "*Finality of Referenced NRC Approvals*," in SER Section 1.2.2 for a discussion on the staff's review related to verification of the scope of information to be included within a COL application that references a design certification.

treatment of nonsafety systems (RTNSS) process is applied to define seismic requirements for SSCs that are nonsafety-related but perform risk significant functions.

Nuclear power plant SSCs important to safety are designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed. SSCs important to safety are those that provide reasonable assurance that the facility can be operated without undue risk to the health and safety of the public. Risk-significant nonsafety-related fluid systems that are important to safety are evaluated under the RTNSS process.

3.2.2 Summary of Application

Section 3.2, "Classification of Structures, Systems and Components," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 3.2, "Classification of Structures, Systems and Components," of the ESBWR DCD, Revision 10. Section 3.2 of the ESBWR DCD includes Sections 3.2.1, "Seismic Classification," and 3.2.2, "Quality Group Classification."

The system seismic and quality group classifications, discussed in the ESBWR DCD, address the requirement to design nuclear power plant SSCs important to safety to withstand the effects of earthquakes without a loss of capability to perform their safety functions – that means designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

This requirement is applicable to both pressure-retaining and non-pressure-retaining SSCs that are part of the RCPB, and to other systems important to safety, when reliance is placed on these systems to (1) prevent or mitigate the consequences of accidents and malfunctions originating within the RCPB, (2) permit a shutdown of the reactor and maintain it in a safe shutdown condition, and (3) retain radioactive material.

Regulatory Guide (RG) 1.29, Revision 4, "Seismic Design Classification," describes an acceptable method of identifying and classifying those plant features that should be designed to withstand the effects of SSEs. RG 1.26, Revision 4, "Quality Group Classification and Standards for Water, Steam, and Radioactive-Waste-Containing Components of Nuclear Power Plants," provides the regulatory guidance for designing safety-related SSCs to quality standards commensurate with the importance of the safety functions to be performed. Risk-significant nonsafety-related SSCs that are important to safety are evaluated under the RTNSS process described in FSAR Chapter 19 and reviewed by the staff in the DCD Final Safety Evaluation Report (FSER) Chapter 22, "Regulatory Treatment of Nonsafety Systems," of NUREG–1966.

In addition, North Anna 3 COL FSAR, Section 1.9 includes the following information related to the applicable seismic classification and quality group classification:

- In FSAR Table 1.9-201, "Conformance with Standard Review Plan" (SRP), the applicant added a line stating that the North Anna 3 application conforms to Revision 2 of the SRP for Section 3.2.1. In this table, the applicant added another line stating that the North Anna 3 application conforms to Revision 2 of the SRP for Section 3.2.2.

- In FSAR Table 1.9-202, "Conformance with Regulatory Guides," the applicant added a line stating that the North Anna 3 application conforms to RG 1.26 and 1.29. The applicant further notes that this conformance is evaluated in FSAR Appendix 17AA, "Quality Assurance Program Description" (QAPD), Part IV.

- In FSAR Table 1.9-203, “Conformance with the FSAR Content Guidance in RG 1.206,” the applicant stated that the North Anna 3 application conforms to RG 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” Regulatory Position C.III.1, Subsection C.I.3.2.1, “Seismic Classification.” The applicant also stated that there are no additional safety-related or RTNSS SSCs subject to seismic classification beyond those addressed in the DCD. In addition the applicant stated that there are no SSCs outside the referenced certified design that are required to be designed for an Operating Basis Earthquake (OBE). In this table, the applicant also stated that the North Anna 3 application conforms to RG 1.206, Position C.III.1, Subsection C.I.3.2.2, “System Quality Group Classification.”

In addition, in the North Anna 3 FSAR, Revision 8, Section 3.2, the applicant provided the following supplemental information:

Site-Specific Information Replacing Conceptual Design Information (CDI)

- STD CDI RTNSS Systems

The applicant stated in FSAR Section 3.2 that there are no site-specific safety-related or nonsafety-related RTNSS systems beyond the scope of the DCD.

- STD CDI Classification Summary-Hydrogen Water Chemistry System (HWCS)

The applicant stated that the site-specific plant design includes the HWCS. The staff reviewed the North Anna 3 HWCS in Section 9.3.9 of this SER.

- NAPS CDI Classification Summary-Zinc Injection System

The applicant stated that the site-specific plant design includes the Zinc Injection System. The staff reviewed the North Anna 3 Zinc Injection System in Section 9.3.11 of this SER.

- NAPS CDI Cold Machine Shop

The applicant stated that the North Anna 3 site-specific plant design does not include the cold machine shop.

3.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, FSER related to the certified ESBWR DCD.

In addition, the relevant requirements of Commission regulations for the seismic classification and quality group classification, and the associated acceptance criteria are in Section 3.2.1 and Section 3.2.2 of NUREG–0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants, (LWR Edition),” (SRP).

The applicable regulatory requirements for seismic classification of SSCs are as follows:

10 CFR Part 50, Appendix A, General Design Criterion (GDC) 2, “Design bases for protection against natural phenomena,” which requires (in part) that SSCs important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes.

The related acceptance criteria are as follows:

- RG 1.29 establishes an acceptable regulatory basis for meeting GDC 2 relative to seismic classification and classifies SSCs that are to be designed to withstand earthquakes.

- RG 1.206 states that the applicant should identify those SSCs important to safety that are outside the scope of the referenced certified design and that are designed to withstand the effects of earthquakes without loss of capabilities to perform their safety functions. The applicant should designate plant features that are outside the scope of the referenced certified design and that are designed to remain functional in the event of an SSE or a surface deformation as seismic Category I. The applicant should identify portions of SSCs outside the scope of the referenced certified design that are not required to continue to function, but whose failure could reduce the functioning of any seismic Category I plant feature to an unacceptable safety level or could result in an incapacitating injury to control room occupants. The design and construction of these SSCs should ensure that the SSE would not cause such failures. The applicant should also list or otherwise clearly identify all SSCs or portions thereof that are outside the scope of the referenced certified design and are intended to be designed for an OBE.

The applicable regulatory requirements for the quality group classification of SSCs are as follows:

- 10 CFR Part 50, Appendix A, GDC 1, “Quality standard and records,” which requires (in part) that SSCs important to safety shall be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be supplemented or modified as necessary to assure a quality product consistent with the required safety function.

The related acceptance criteria are as follows:

- RG 1.26 establishes an acceptable regulatory basis for meeting GDC 1 relative to quality group classification. RG 1.26 also classifies fluid systems and their supports that are important to safety, which are to be designed to quality standards commensurate with their safety function.

- RG 1.206 states that the applicant should identify those fluid systems or portions thereof that are important to safety and outside of the certified design scope, as well as the applicable industry codes and standards for each pressure-retaining component.

3.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.2 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 3.2 of the North Anna 3 COL FSAR, Revision 8, and checked the ESBWR DCD, Revision 10, to ensure that the combination of the DCD and the information in the COL represent the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR, Revision 8, as follows:

Site-Specific Information Replacing Conceptual Design Information

- STD CDI — RTNSS Systems
- STD CDI — Classification Summary – Hydrogen Water Chemistry
- NAPS CDI — Classification Summary – Zinc Injection System
- NAPS CDI — Classification Summary – Cold Machine Shop

Seismic Classification

The staff determined that the supplements, including site-specific information related to the hydrogen water chemistry, zinc injection systems, cold machine shop, and RTNSS systems do not affect the seismic classifications.

The staff reviewed the COL application information to determine whether the application contains sufficient information on the seismic classification of site-specific SSCs that are outside of the DCD scope. The staff issued several requests for additional information (RAIs) to determine whether the scope of SSCs considered to be site specific is essentially complete, and whether sufficient information concerning the seismic classification of those SSCs is included in the application. The staff reviewed the following technical topics:

Seismic Classification of Site-Specific RTNSS SSCs

GDC 2 identifies, in part, that SSCs important to safety shall be designed to withstand the effects of earthquakes. FSAR Section 3.2.1 identifies no departures or supplements relative to the seismic classification of SSCs, and the standardization matrix identifies no site-specific information that applies to Section 3.2. However, certain potential RTNSS-important SSCs, such as the plant service water system (PSWS) and makeup water system, are identified as site-specific and makeup sources for the ultimate heat sink. Also, initially it was not clear whether there were nonsafety-related SSCs outside of the DCD scope that may be important to safety. Therefore, in RAI 03.02.01-6 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the applicant clarify whether there are any site-specific, nonsafety-related SSCs outside of the DCD scope that are important to safety and, if so, to identify the appropriate seismic classification of those SSCs. For example, certain site-specific defense-in-depth RTNSS SSCs, such as the PSWS and the intake structure, may be considered nonsafety-related but may be important to safety and should be categorized as designed to withstand the effects of earthquakes. This seismic concern for RTNSS SSCs was also identified during the concurrent ESBWR DC review at that time. The applicant decided to resolve this issue in the DCD rather than in the COL for all plant SSCs, including those that are site specific. Therefore, in response to RAI 03.02.01-6 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant stated that there are no nonsafety-related SSCs important to safety (RTNSS SSCs) that are outside of the DCD scope. This response also clarified that the seismic classification of RTNSS SSCs is within the DCD scope, and Appendix 19A of the DCD had undergone substantial changes in DCD, Revision 5. The staff concurred that the seismic classification of site-specific RTNSS SSCs can be evaluated in the DCD which is reflected in the ESBWR DCD, Revision 10. Accordingly, the staff considers all issues associated with RAI 03.02.01-6 resolved and closed.

Seismic Classification of Other Site-Specific SSCs

Section 1 of the DCD identifies only limited site-specific SSCs that are outside the scope of the DCD, and for which the COL applicant is expected to provide site-specific information. COL application Table 1.9-203 indicates that there are no safety-related or RTNSS SSCs that are not included in the DCD. It is not clear, however, whether there are any other nonsafety-related SSCs that are considered important to safety but are not included in the DCD that will be addressed in the COL application.

Therefore, in RAI 03.02.01-5 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant clarify whether there are any site-specific SSCs outside of the DCD scope that are not included in DCD Table 3.2-1 and are to be seismically classified in the COL. For example, site-specific structures such as the stack and miscellaneous items such as the reactor vessel insulation, which may or may not be site specific, are not included in the tables. If so, the RAI requested the applicant to identify the appropriate seismic classification of those SSCs or clarify when those SSCs will be classified. In response to RAI 03.02.01-5 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant stated that there are no nonsafety-related SSCs important to safety (RTNSS SSCs) outside of the DCD scope, and there are no site-specific SSCs not in the DCD that are to be seismically classified. In regard to the stack (changed to three stacks in DCD, Revision 5) and reactor vessel insulation, the applicant clarified that these SSCs are not site specific. Because no site-specific SSCs will be classified in the COL, the staff considers all issues associated with RAI 03.02.01-5 resolved and closed.

Quality Assurance for Seismic Category II SSCs

In an RAI 03.02.01-4 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant clarify the extent to which pertinent Quality Assurance (QA) requirements of Appendix B, "Quality Assurance Criteria for Nuclear Power Plans and Fuel Reprocessing Plants," to 10 CFR Part 50 in Regulatory Position C.4 of RG 1.29 apply to the activities affecting safety-related functions of those portions of SSCs covered under Regulatory Positions 2 and 3 of RG 1.29, including any site-specific SSCs. This concern was also cited in an RAI for the ESBWR DC review at the time. In response to RAI 03.02.01-4 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant stated that this issue will be resolved in the ESBWR DCD, and GE-Hitachi (GEH) has included this information in DCD Section 3.2 and in DCD Appendix 19A for all SSCs, which is reflected in the ESBWR DCD, Revision 10. The staff concurred that this information has been reviewed in connection with the certified design, and applies to the COL applicants including North Anna 3 that reference that ESBWR design. Accordingly, the staff considers all issues associated with RAI 03.02.01-4 resolved and closed.

Consistency with Regulatory Guidance

FSAR Table 1.9-201 points out that the seismic classification conforms to SRP Section 3.2.1, Revision 2, and that SRP Section 3.2.1 references RG 1.29 (currently Revision 4) for seismic classification. SRP Section 3.2.1 identifies that the applicant should provide a list of SSCs that are necessary for continued safe operation that must remain functional without undue risk to the health and safety of the public and within applicable stress, strain, and deformation limits during and following an OBE, if the applicant has set the OBE ground motion to the value of one-third of the SSE ground motion. The list of SSCs may be addressed either in this section or in the operational programs for pre-earthquake planning in COL FSAR Section 3.7.4. Other than the four CDIs noted above, North Anna 3 Section 3.2 of FSAR, Revision 8, does not identify any departures or supplements relative to the seismic classification in the DCD and the conformance to RG 1.29, Revision 3 in the ESBWR DCD, Revision 10.

In RAI 03.02.01-3 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant clarify the extent to which site-specific seismic classifications of SSCs are consistent with RG 1.29, Revision 4. In response to RAI 03.02.01-3 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant clarified that the FSAR is incorrect. The classification of site-specific SSCs is consistent with the DCD that references RG 1.29, Revision 3, and COL FSAR Table 1.9-202 will be revised accordingly. In addition, the staff has indicated to the applicant that there are no site-specific SSCs requiring classification in the COL application or changes to the methodology. Therefore, the staff finds that use of RG 1.29, Revision 3 is acceptable. The staff verified that the COL FSAR Revision 8, Table 1.9-202 is revised accordingly. Therefore, the staff considers all issues associated with RAI 03.02.01-3 resolved and closed.

List of SSCs Necessary for Continued Safe Operation During and Following an OBE

In RAI 03.02.01-7 dated August 20, 2009 (ADAMS Accession No. ML092360286), the staff indicated to the applicant that, in order to be consistent with the requirements and guidance of 10 CFR Part 50, Appendix S, IV(a)(2)(l) and (3), RG 1.166, “Pre-Earthquake Planning and Immediate Nuclear Power Plant Operator Post Earthquake Actions,” and SRP Section 3.2.1 Revision 2, a list of SSCs necessary for continued operation when subjected to an OBE should be available for review if the applicant has set the OBE ground motion equal to one-third of the SSE ground motion. Since the COL applicant has not deviated from the DCD, which sets the OBE ground motion equal to one-third of the SSE ground motion, staff requested that the COL applicant provide the list of SSCs necessary for continued safe operation that must remain functional without undue risk to the health and safety of the public and within applicable stress, strain, and deformation, during and following an OBE. In response to RAI 03.02.01-7 dated December 9, 2009 (ADAMS Accession No. ML093490251), the COL applicant stated that as noted in 10 CFR Part 50, Appendix S, Section IV(a)(2)(i)(A), if the OBE ground motion is set to one-third or less of the SSE, then the requirements associated with the OBE ground motion in 10 CFR Part 50, Appendix S, Section IV (a)(2)(i)(B)(I) can be satisfied without the COL applicant performing explicit response or design analyses. Since the ESBWR has set the OBE at one-third of the SSE (as discussed in ESBWR FSAR Tier 2, Section 3.7), no further explicit response is required in accordance with 10 CFR Part 50, Appendix S, Section IV(a)(2)(i)(A).

Those SSCs that are designed to withstand an SSE are classified as seismic Category I and are given in ESBWR DCD, Tier 2, Table 3.2.-1, "Classification Summary." This classification is in accordance with SRP Section 3.2.1. Based on the COL applicant's statement that the list is addressed through ESBWR FSAR Tier 2, Table 3.2.2-1 and the staff finding that the table is acceptable, the staff considers RAI 03.02.01-7 resolved and closed.

Important to Safety SSCs

In the North Anna 3 FSAR, Section 3.2 the applicant states:

> There are no site-specific safety[-]related or non-safety[-]related RTNSS systems beyond the scope of the DCD.

The ESBWR DCD, Section 1, Revision 10, provides for COL Item 17.4-1-A identifying site-specific SSCs outside the scope of the DCD but within the scope of the reliability assurance program. In the North Anna 3 FSAR COL Item 17.4-1-A, the applicant states:

> There are no site[-]specific SSCs within the scope of the Reliability Assurance Program (RAP). The quality elements for all SSCs within the scope of the Design Reliability Assurance Program (D-RAP) are in accordance with the Quality Assurance Program Description (QAPD).

The staff finds that the applicant's response conforms to the guidance in RG 1.206 and the requirements in 10 CFR Part 50, Appendix A, GDC 1, and is therefore acceptable.

List of RTNSS SSCs

DCD, Revision 5, Section 3.2.1 refers to Table 19A-1 for a list of RTNSS SSCs. However, Table 19A-1 in Revision 5 of the DCD has been deleted. It was not clear at that time whether this list included site-specific SSCs. Therefore, in RAI 03.02.01-2 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant identify the appropriate reference for the list of site-specific RTNSS SSCs. In response to RAI 03.02.10-2 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant noted the correct reference for risk-significant RTNSS SSCs is in Table 3 of NEDO-33411. The staff further verified that the list of RTNSS SSCs can be reviewed in the ESBWR DCD, Revision 10, Appendix 19A. Table 19A-3 in addition identifies the structures housing the RTNSS functions identified in DCD Table 19A-2. Accordingly, the staff considers all issues associated with RAI 03.02.01-2 resolved and closed.

RTNSS SSCs Classified as Non-Seismic

DCD, Revision 4, Table 3.2-1 identified various nonsafety-related potential RTNSS SSCs as either Seismic II or non-seismic (NS). DCD Section 19A.8.3 classifies RTNSS Criterion B-SSCs, as a minimum, seismic Category II, and are qualified to the Institute of Electrical and Electronics Engineers (IEEE)-344-1987, "IEEE Recommended Practice for Seismic Qualification of Class 1E Equipment for Nuclear Power Generating Stations." These SSCs must be available following a seismic event. Therefore, in RAI 03.02.01-1 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant clarify the basis for the Seismic II or NS classification or identify an appropriate departure. In response to RAI 03.02.01-1 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant stated that there are no site specific, RTNSS-important SSCs beyond those identified in the DCD. The staff verified that the ESBWR DCD, Revision 10, Appendix 19A Table 19A-3 identifies the structures housing the RTNSS functions. Accordingly, the staff considers all issues associated with RAI 03.02.01-1 resolved and closed.

Summary

Based on the above evaluation of the applicant's information related to seismic classification, the staff finds that the requirements of GDC 2 are met and the information is consistent with the guidance in RGs 1.29 and 1.206 for all SSCs important to safety.

Quality Group Classification

The staff's review of North Anna 3 COL FSAR, Revision 8, finds that the applicant has incorporated by reference Section 3.2.2 of the ESBWR DCD, Revision 10. The review confirms that the information in the application and the information incorporated by reference address the required information relating to the quality group classification of SSCs.

The staff determined that the site-specific information replacing conceptual design information related to the hydrogen water chemistry and zinc injection systems does not affect the quality group classifications.

The ESBWR DCD, Section 1.10 states that the COL applicant is required to provide site-specific information as COL items.

The staff reviewed the following technical topics:

Consistency with Regulatory Guidance

FSAR Table 1.9-201 shows that the quality group classification conforms to SRP Section 3.2.2, Revision 2 and that SRP Section 3.2.2 references RG 1.26 (currently Revision 4) for quality group classification. Section 3.2 of the North Anna 3 FSAR, Revision 1, did not identify any departures or supplements relative to the quality group classification identified in the DCD and compliance with RG 1.26, Revision 3 in the DCD. But FSAR Table 1.9-202 references conformance to Revision 4, dated March 2007. QA Program AR-NA-30 references Revision 4 to RG 1.26 with the DCD exception, but incorrectly references February 1976 rather than March 2007. Therefore, in RAI 03.02.02-1 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant clarify whether classifications of site-specific SSCs are consistent with RG 1.26, Revision 4.

In response to RAI 03.02.02-1 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant clarified that the FSAR is incorrect. The classification of site-specific SSCs is consistent with the DCD that references RG 1.26, Revision 3. COL FSAR Table 1.9-202 and Appendix 17BB will be revised accordingly. COL applicants should supplement generic DCD information on conformance to RGs to address those that were issued since the time the standard design was approved. There are no site-specific SSCs classified in the COL application, so the effective RGs are appropriately referenced in the DCD. Therefore, the staff finds that use of RG 1.26, Revision 3 is acceptable. The staff verified that the COL FSAR Revision 8, Table 1.9-202 and Appendix 17BB, is revised accordingly. Therefore, the staff considers all issues associated with RAI 03.02.02-1 resolved and therefore Open Item 03.02.02-1 is closed.

Codes and Standards

The staff requirements memorandum (SRM) dated July 21, 1993, concerning SECY-93-087, “Policy, Technical, and Licensing Issues Pertaining to Evolutionary and Advanced Light-Water (ALWR) Designs,” stated that the staff will review passive plant design applications using the newest codes and standards endorsed by the NRC, and unapproved revisions to the codes will be reviewed on a case-by-case basis. Editions of various codes and standards referenced in DCD, Revision 4, Section 3.2.6 are not current, and newer codes and standards are not referenced in COL applicant FSAR Sections 3.2 or 1.9. Therefore, in RAI 03.02.02-2 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the COL applicant clarify the specific code editions the applicant has referenced that are currently endorsed by the NRC. The applicant was also asked to clarify whether current editions of codes and standards will be applied to the detailed design and procurement of ESBWR SSCs, so that these editions may be reviewed on a case-by-case basis. If the applicant decides to resolve this issue in the DCD rather than in the COL for all plant SSCs, including those that are site specific, the staff had asked the applicant to advise the NRC.

In response to RAI 03.02.02-2 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant stated that DCD Table 1.9-22 identifies industrial codes and standards and adjustments that have been made to these codes and standards. The applicant also indicated that questions regarding versions of codes and standards should be addressed to GEH. COL applicants should supplement generic DCD information on compliance with RGs to address those that have been issued since the time the standard design was approved.

The staff recognizes that there are no site-specific SSCs that are not classified in the DCD. However, regulatory guidance for site-specific SSCs should be identified in the COL application so that the correct RG revision is applied to site-specific SSCs, including those added in the future. North Anna 3 FSAR, Revision 8, Table 1.9-204 supplements the ESBWR DCD, Revision 10, Table 1.9-22 to address industrial codes and standards applicable to portions of the design that are beyond the scope of the DCD. The staff found the response acceptable because the COL applicant adequately addressed staff’s concern regarding use of codes and standards. Therefore, the staff considers all issues associated with RAI 03.02.02-2 resolved and therefore Open Item 03.02.02-2 is closed.

Special Treatment for Risk-Significant SSCs

GDC 1 identifies (in part) that SSCs important to safety shall be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be supplemented or modified as necessary to assure a quality product in keeping with the required safety function. Supplemental quality standards and the QA Program applicable to passive SSCs used in nonsafety-related RTNSS systems that may be important to safety were not clearly defined in the initial North Anna 3 COL application for site-specific SSCs.

Therefore, in RAI 03.02.02-3 dated August 6, 2008 (ADAMS Accession No. ML082190780), the staff requested that the applicant clarify what supplemental quality standards are applied to nonsafety-related, site-specific SSCs that are important to safety to ensure that all SSCs important to safety are designed, fabricated, erected, and tested to quality standards commensurate with the safety function to be performed. This concern was also identified in an RAI for the review of the ESBWR DC at the time. In response to RAI 03.02.02-3 dated September 17, 2008 (ADAMS Accession No. ML082661075), the COL applicant stated that this issue will be resolved in the DCD. The applicant clarified that GEH has included this information in DCD Section 3.2 and Appendix 19A and that these are applicable to site-specific SSCs. The staff verified that the issue was resolved in the ESBWR DCD, Revision 10. Accordingly, the staff considers all issues associated with RAI 03.02.02-3 resolved and closed.

Summary

Based on the above evaluation of the applicant's information related to quality group classification, the staff finds that the requirements of GDC 1 are met and the information is consistent with the guidance in RG 1.26 and RG 1.206.

3.2.5 Post Combined License Activities

There are no post COL activities related to this section.

3.2.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

In addition, the staff compared the additional COL information in the application to the relevant NRC regulations, the guidance in SRP Sections 3.2.1 and 3.2.2, and the applicable RGs. The staff's review concludes that the applicant has adequately addressed the seismic and quality group classifications. The staff notes that these classifications meet the requirements of GDC 1 and GDC 2 and the guidance of RG 1.26, RG 1.29, and RG 1.206. Therefore the staff also finds that North Anna 3 COL FSAR, Revision 8, Sections 3.2.1 and 3.2.2 are acceptable because they meet NRC regulatory requirements and acceptance criteria in SRP Sections 3.2.1 and 3.2.2.

3.3 <u>Wind and Tornado Loadings</u>

3.3.1 Introduction

Seismic Category I for the ESBWR structures are designed for tornado and extreme wind phenomena. Seismic Category II structures are designed for extreme and tornado wind. Safety-related systems and components are protected within wind-resistant structures and the remainder of plant structures and components not designed for extreme wind loads are arranged or designed such that their failures do not adversely affect the ability of any seismic Category I SSC to perform their safety-related function.

3.3.2 Summary of Application

Section 3.3, “Wind and Tornado Loadings,” of the North Anna 3 COL FSAR, Revision 8, incorporates by reference, with a supplement, Section 3.3, “Wind and Tornado Loadings,” of Revision 10 of the ESBWR DCD.

In addition, in North Anna 3 FSAR, Section 3.3 the applicant provided the following:

<u>*Supplemental Information*</u>

- NAPS SUP 3.3-1 Extreme Hurricane Winds

In FSAR Section 3.3.2.4, the applicant provided the following supplemental information.

> Section 2.3 defines the site-specific extreme hurricane wind speed in accordance with RG 1.221, “Design-Basis Hurricane and Hurricane Missiles for Nuclear Power Plants.” The site-specific extreme hurricane wind speed is less than the maximum tornado wind speed listed in Table 2.0-201.

3.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the FSER related to the ESBWR DCD. In addition, the relevant requirements of the Commission regulations for SSCs protection from natural phenomena and the associated acceptance criteria are in SRP Section 3.3.1, “Wind Loading,” and SRP Section 3.3.2, “Tornado Loadings.”

The applicable regulatory requirements and associated guidance for wind and tornado loadings are as follows:

- 10 CFR Part 50, Appendix A, GDC 2 requires that SSCs important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornados, hurricanes, tsunami, floods, and seiches without loss of capability to perform their safety functions as it relates to natural phenomena. The design bases for these SSCs shall reflect appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena.

3.3.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.3 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 3.3 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to ensure that the combination of the DCD and the information in the COL represent the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to the wind and tornado loadings for North Anna 3.

In 2011 the NRC issued new guidance for hurricanes in RG 1.221. This guidance demonstrated that hurricane missiles could be more severe than tornado missiles. In addition, the ESBWR DC rule includes an exclusion from finality for loads on applicable SSCs from hurricane-generated missiles, but only to the extent that such loads are not bounded by other loads analyzed in the ESBWR DCD.

The staff reviewed the relevant information in the COL FSAR as follows:

Supplemental Information

- NAPS SUP 3.3-1 Extreme Hurricane Winds

The staff reviewed NAPS SUP 3.3-1 for extreme hurricane winds in accordance with RG 1.221, Revision 1, which was guidance that was issued following the staff approval of the ESBWR DCD, Revision 10. The applicant for North Anna 3 incorporated this new guidance and therefore included this supplemental COL information to address this RG revision. As stated by the applicant the North Anna 3 site-specific hurricane wind speeds are bounded by the results of the DCD for wind loadings on safety-related structures, and therefore the staff finds that the site-specific generated hurricane wind speed and loading is acceptable for the safety-related structures as defined by the ESBWR DCD.

3.3.5 Post Combined License Activities

There are no post COL activities related to this section.

3.3.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information relating to the wind and tornado loadings, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference are resolved.

In addition, the staff compared the additional North Anna 3 supplemental information in the application including NAPS SUP 3.3-1 and NAPS SUP 3.5-3 from FSAR Section 3.5 to the relevant NRC regulations and regulatory guides. The staff's review concludes that the applicant has provided sufficient information in its supplemental information on wind, extreme hurricane winds, and tornado loadings on safety-related structures. The staff finds that the supplemental information on hurricane wind speed meets the latest guidance of RG 1.221 and the requirements of GDC 2 for SSCs important to safety that are able to withstand the effects of natural phenomena without loss of capability to perform their safety function.

3.4 Water Level (Flood) Design

Section 3.4, "Water Level (Flood) Design," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference, with no departures or supplements, Section 3.4, "Water Level (Flood) Design," of the certified ESBWR DCD, Revision 10 referenced in 10 CFR Part 52, Appendix E. As documented in NUREG–1966, the staff reviewed and approved Section 3.4 of the certified ESBWR DCD. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review.[1] The staff's review confirmed that the applicant has addressed the required information, and there is no outstanding information related to this section that remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Section VI.B.1 of Appendix E to 10 CFR Part 52, all nuclear safety issues relating to the "Water Level (Flood) Design," that were incorporated by reference have been resolved.

3.5 <u>Missile Protection</u>

3.5.1 Introduction

SSCs important to safety are analyzed for and designed to be protected from a wide spectrum of internally generated missiles such as missiles from rotating equipment, high energy fluid systems, and gravitational missiles; externally generated missiles from tornado winds and extreme winds; and missiles from proximate site sources and aircraft hazards.

Methods of protection must be provided for all SSCs that are necessary to perform functions required to attain and maintain safe shutdown or to otherwise mitigate the consequences of an accident. These methods may consist of (1) locating the system or component in a missile-proof structure, (2) separating redundant systems or components in the missile's path or range, (3) providing local shields and barriers for systems and components, or (4) designing the equipment to withstand the impact of the most damaging missile.

The specific reactor site location determines the potential for missile hazards from nearby industrial sources and the hazards from aircraft operating in the region.

3.5.2 Summary of Application

Section 3.5, "Missile Protection," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 3.5, "Missile Protection," of the ESBWR DCD, Revision 10.

In addition, in FSAR Section 3.5, the applicant provided the following:

<u>Supplemental Information</u>

- STD SUP 3.5-1 Site Proximity Missiles

The applicant provided the following supplemental information. The applicant referred to Section 2.2 for information regarding the site-specific missile sources.

- STD SUP 3.5-2 Aircraft Hazards

The applicant provided the following supplemental information. The applicant referred to Section 2.2 for information regarding the site-specific aircraft hazard analyses and site-specific critical areas.

- NAPS SUP 3.5-3 Missiles Generated by Natural Phenomena

The applicant provided the following supplemental information. The applicant referred to FSAR Section 2.3 for information regarding the site-specific extreme hurricane winds in accordance with RG 1.221.

The applicant stated the following:

> The site-specific extreme hurricane wind speed is less than the maximum tornado wind speed listed in Table 2.0-201. Table 3.5-201 lists the NA3 site hurricane missile spectrum and velocities in accordance with the guidance in RG 1.221.

3.5.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG-1966, the FSER related to the ESBWR DCD.

In addition, the relevant requirements of the Commission regulations for turbine missiles and the associated acceptance criteria are described in SRP Section 3.5.1.3, and the aircraft hazards and the associated acceptance criteria are described in SRP Section 3.5.1.6.

The applicable regulatory requirements for protection against site proximity missiles and aircraft hazards are as follows:

- GDC 4 of Appendix A to 10 CFR Part 50, "Environmental and Dynamic Effects Design Bases."

3.5.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.5 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 3.5 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to missile protection.

The staff reviewed the information in the COL FSAR as follows:

Supplemental Information

- STD SUP 3.5-1 Site Proximity Missiles

The staff reviewed STD SUP 3.5-1, which states that the site-specific missile sources are addressed in Section 2.2 of the North Anna 3 FSAR.

The staff's technical evaluation of this portion of the application is limited to reviewing the supplemental information pertaining to STD SUP 3.5-1.

The staff reviewed the conformance of Section 3.5 of the North Anna 3 COL FSAR to the guidance in RG 1.206, Regulatory Position C.III.1, Section C.I.3.5.1.3, “Turbine Missiles.” The staff finds that the FSAR appropriately incorporates by reference Section 3.5.1.1.1.2 of the ESBWR DCD, Tier 2, Revision 10.

In addition the staff noted the potential for turbine missile hazard from the proposed North Anna 3 site in proximity of two existing nuclear units. Therefore, the staff requested in RAI 03.05.01.05-1 dated August 11, 2008 (ADAMS Accession No. ML082250417) that the applicant provide an assessment of the potential for the turbine missile generation for existing Units 1 and 2 to affect the safe operation of the proposed Unit 3. The applicant’s response to RAI 03.05.01.05-1 dated September 26, 2008 (ADAMS Accession No. ML082750076), that the planes-of-rotation of the turbine generators in Units 1 and 2 are oriented approximately 90 degrees relative to Unit 3 and are located approximately 1,640 feet from that unit. On the basis of the information the applicant provided the potential for impact from turbine missiles generated as a result of that particular orientation is not considered a possible threat that could affect the safe operation of the proposed North Anna 3. The staff concludes that the applicant has established that the operation of North Anna 3 on the proposed site location is acceptable in terms of the site proximity missile hazard in accordance with the guidance in SRP Section 3.5.1.3 and therefore, RAI 3.5.1.5-1 is resolved and closed.

- STD SUP 3.5-2 Aircraft Hazards

The staff reviewed STD SUP 3.5-2 which states that the site-specific aircraft analysis and site-specific critical areas are addressed in Section 2.2 of the North Anna 3 FSAR.

The staff’s technical evaluation of this portion of the application is limited to reviewing the supplemental information pertaining to STD SUP 3.5-2.

The applicant performed the aircraft hazards evaluation in the North Anna 3 Early Site Permit (ESP) Site Safety Analysis Report (SSAR) because the ESP site lies within 5 miles of the edge of a military route and within 2 miles of the edge of a Federal airway. The applicant in its ESP SSAR addressed and evaluated potential aircraft hazards following the approach and methodology outlined in SRP Section 3.5.1.6, “Aircraft Hazards.” The applicant simulated an aircraft crash into the effective plant areas of the safety-related structures on the site. The applicant further evaluated the probability of aircraft accidents resulting in radiological consequences greater than the 10 CFR Part 100, “Reactor Site Criteria,” exposure guidelines based on the following updated analysis for the COL application:

- A third airport within 10 miles of Unit 3 opened in 2007 following the ESP evaluation. It is a private landing strip approximately 7.6 miles north-northwest of the site. The airport is not licensed for commercial use and has only three small aircraft based on the field. The expected volume of traffic is very light and would not exceed the limiting operations threshold as determined in the ESP SSAR. Therefore, no additional evaluation of potential design basis aircraft event was performed.

- One civil airway (V223) and four military training routes (IR714, IR720, IR760/ VR1754, and VR1755) pass near the North Anna 3 site. The U.S. Federal Aviation Administration (FAA) at Richmond International Airport characterized civil airway V223 as “not heavily used” and estimated the traffic to be no more than 200 aircrafts per day. The U.S. Department of the Navy identified a total of 306 flight operations in the year 2007/2008 for three of the four routes, compared with the ESP SSAR assumption of 6,000 flights per year. As a result, the number of military training flights assumed in the ESP SSAR remains bounding. To estimate the probability calculations, the applicant for the ESBWR design considered the ESBWR reactor building (RB) and fuel building (FB) and the control and radwaste buildings (RWB). The applicant estimated the total effective plant area at 0.038 square miles for civil airways and 0.041 square miles for the military routes and revised the probability calculations.

Utilizing the above revised data as part of the North Anna 3 COL application, the applicant determined that the total probabilities from civilian or military routes is an order of magnitude of 10-7 events per year. The staff obtained updated FAA flight data and determined that the applicant had used conservatively higher values for flight operations to determine the total aircraft hazard probability. On the basis of FAA flight data and the review of the applicant's calculations of the probability of aircraft hazards, the staff considered the applicant's approach reasonable and its conclusion acceptable.

- NAPS SUP 3.5-3 Missiles Generated by Natural Phenomena

The staff evaluated hurricane-generated missiles on safety-related structures in this safety evaluation report (SER) for NAPS SUP 3.3-1, Section 3.3.4 as well as in the SER Chapter 19, Appendix 19A.

3.5.5 Post Combined License Activities

There are no post COL activities related to this section.

3.5.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

In addition, the staff compared the COL supplemental information in the application to the relevant NRC regulations, the guidance in SRP Section 3.5, and other NRC RGs. The staff concluded that the supplemental information presented in the COL FSAR is acceptable and meets the requirements of GDC 4 of Appendix A to 10 CFR Part 50. The staff based this conclusion on the following:

- STD SUP 3.5-1, "Site Proximity Missiles," is acceptable because the applicant has identified potential accidents related to the generation of site proximity missiles (except aircraft) in the site vicinity that could affect a nuclear power plant or plants of the specified type that might be constructed on the proposed site. The applicant has appropriately determined those potential accidents that should be considered as design-basis events and has demonstrated that the plant is adequately protected and can be operated with an acceptable degree of safety with regard to the design-basis accidents. The staff reviewed the information in the SSAR and FSAR. For the reasons given above, the staff concluded that the applicant has established that the construction and operation of Unit 3 of the specified type on the proposed site location is acceptable and meets the requirements of 10 CFR 52.79(a)(1)(iv) and 10 CFR 52.79(a)(1)(vi) for compliance with respect to determining the acceptability of the site.

- STD SUP 3.5-2, "Aircraft Hazards," is acceptable because the applicant has identified potential accidents related to the aircraft hazards in the site vicinity that could affect a nuclear power plant or plants of the specified type that might be constructed on the proposed site. The applicant has appropriately determined those potential accidents that should be considered as design-basis events and has demonstrated that the plant is adequately protected and can be operated with an acceptable degree of safety with regard to the design-basis accidents. The staff reviewed the information in the SSAR and FSAR. For the reasons given above, the staff concluded that the applicant has established that the construction and operation of Unit 3 of the specified type on the proposed site location is acceptable and meets the requirements of 10 CFR 52.79(a)(1)(iv) and 10 CFR 52.79(a)(1)(vi) for compliance with respect to determining the acceptability of the site.

3.6 Protection Against Dynamic Effects Associated with the Postulated Rupture of Piping

Section 3.6, "Protection against Dynamic Effects Associated with the Postulated Rupture of Piping," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference, with no departures or supplements, Section 3.6, "Protection against Dynamic Effects Associated with the Postulated Rupture of Piping," of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. As documented in NUREG–1966, the staff reviewed and approved Section 3.6 of the certified ESBWR DCD. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review.[1] The staff's review confirmed that the applicant has addressed the required information, and there is no outstanding information related to this section that remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Section VI.B.1 of Appendix E to 10 CFR Part 52, all nuclear safety issues relating to the "Protection against Dynamic Effects Associated with the Postulated Rupture of Piping," that were incorporated by reference have been resolved.

3.7 Seismic Design

Safety-related SSCs are designed to withstand SSE loads and other dynamic loads, including those due to reactor building vibration (RBV) caused by suppression pool dynamics. This section addresses seismic aspects of the design and analysis in accordance with RG 1.206.

3.7.1 Seismic Design Parameters

Seismic Category I SSCs are designed to withstand the effects of an SSE event and to maintain the specified design functions. Seismic Category II and NS structures are designed or physically arranged so that the SSE could not cause unacceptable structural interactions with or the failure of seismic Category I SSCs. The ESBWR standard plant SSE design ground motion is addressed in Section 3.7 of ESBWR DCD, Tier 2, Revision 10. The horizontal and vertical SSE design ground response spectra (for 5 percent damping), also termed certified seismic design response spectra (CSDRS) for the ESBWR design were developed based on enveloping

RG 1.60, Revision 1, "Design Response Spectra for Seismic Design of Nuclear Power Plants," response spectra anchored to 0.3 g peak ground acceleration (PGA) and the high-frequency hard rock spectra anchored to 0.5 g PGA. The CSDRS for the RB/FB and the control building (CB) are shown in ESBWR DCD, Tier 2, Revision 10, Chapter 2.0, Figures 2.0-1 and 2.0-2 for horizontal and vertical directions, respectively. The CSDRS for the firewater service complex (FWSC) is 1.35 times the values shown in DCD Tier 2, Figures 2.0-1 and 2.0-2. The CSDRS have been defined as free-field outcrop spectra at the foundation level (bottom of the base slab) for the seismic design of the Category I structures included in the DC document. The applicant has provided the seismic design parameters for the North Anna 3 site in the North Anna 3 COL FSAR, Revision 9, Section 3.7.1, as documented below.

3.7.1.1 Introduction

The North Anna 3 FSAR, Revision 9, Section 3.7.1 addresses the site-specific design earthquake ground motion used for the seismic analysis and design of the seismic Category I structures. This design earthquake ground motion is based on the seismic and geologic characteristics at the North Anna 3 site and is established in terms of a set of idealized and smooth curves called the design response spectra. At the North Anna 3 site, the site-specific seismic design parameters include the design ground motion in terms of the foundation input response spectra (FIRS), design ground motion time histories, percentage of critical damping values, and the characteristics of the supporting media for seismic Category I structures.

3.7.1.2 Summary of Application

In the North Anna 3 COL FSAR Section 3.7.1, Revision 9, the applicant incorporated by reference Section 3.7.1 of ESBWR DCD, Revision 10.

In addition, in FSAR Section 3.7.1, the applicant provides the following:

Exemption

- Exemption 3 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The North Anna 3 site-specific seismic conditions described in FSAR Chapter 2 and Section 3.7.1 indicate that certain seismic design characteristics are not bounded by the DCD seismic design parameters. Therefore, Unit 3 defines the SSE to include both the CSDRS and the site-specific FIRS for each seismically qualified structure.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

This departure is described in North Anna 3 COL FSAR Part 7, Departures Report. The site-specific horizontal and vertical seismic response spectra as shown in North Anna 3 COL FSAR Figures 2.0-201 through 2.0-204 exhibit exceedances at certain frequencies, when compared to the ESBWR CSDRS. As a result of these exceedances, the applicant performed site-specific soil-structure interaction (SSI) analyses of the RB/FB, CB, and FWSC structures and revised the SSE definition to include both the ESBWR CSDRS and the site-specific FIRS for each seismically qualified structure for use in performing seismic design, analysis, and qualification of SSCs. In addition, FSAR Figure 3.7.1-285 provides the SSI input spectra defining site-specific ground motion for the FWSC at the bottom of the concrete fill (Elevation 220 ft) as discussed in FSAR Section 3.7.1.1.4.2.3.

Because the SSE is defined in DCD Tier 1, Table 5.1-1, this change to the site-specific definition requires the applicant to take a departure from the DCD Tier 1 information. Therefore, a request for exemption from DCD Tier 1 information is also provided in Exemption 3 described in North Anna 3 COL FSAR Part 7. The staff evaluated North Anna 3 Exemption 3 in Section 3.7.1.4 of this SER.

In addition, DCD Section 3.7 defines, as Tier 2* information, the ESBWR OBE as one-third of the SSE ground motion. Because the site-specific SSE is being defined through this departure as consisting of both the CSDRS and FIRS for each structure, two spectra are used to define the North Anna 3 OBE design ground motion as: one-third of the CSDRS and one-third of the site-specific SSE manifestation at grade presented in FSAR Figure 3.7.1-267. The detailed criteria for plant shutdown are evaluated in this SER in Section 3.7.1.4.

Supplemental Information

- NAPS SUP 3.7-7 — Design Ground Motion

As discussed under the departure, NAPS DEP 3.7-1, the site-specific FIRS at North Anna 3 site exceed the CSDRS. For this reason, the applicant supplemented FSAR Section 3.7.1.1 to provide site-specific seismic design parameters (such as SSI input strain-compatible soil profiles, SSI input response spectra, SSI input acceleration time histories) for the site-specific SSI analyses of the RB/FB, CB, and FWSC.

- NAPS SUP 3.7-1 — Site-specific Design Ground Motion Response Spectra

In FSAR Section 3.7.1.1.4, the applicant provided the following:

1. The development of the strain compatible dynamic properties (e.g., compression wave velocities, damping ratios) of the subsurface material profiles used in the site-specific SSI analyses of the RB/FB, CB, and FWSC in FSAR Section 3.7.1.1.4.1.

2. The development of a set of site-specific input response spectra for SSI analyses of the RB/FB, CB, and FWSC in FSAR Section 3.7.1.1.4.2. For each of the buildings, the applicant described how the site-specific SSI input response spectra are obtained from the corresponding FIRS and performance-based surface response spectra (PBSRS) by using the guidance in DC/COL-ISG-017. This supplement also described how the site-specific SSI input response spectra are augmented to obtain the final SSI input response spectra to meet the minimum ground motion requirements of 10 CFR Part 50, Appendix S.

- NAPS SUP 3.7-2 Site-specific Design Ground Motion Time History

In FSAR Section 3.7.1.1.5, the applicant provided information on two sets of three statistically independent acceleration time histories of motions (i.e., two horizontal and one vertical component) developed for the full column and partial column SSI analyses of the RB/FB and CB. For FWSC, one set of acceleration time histories were developed at two elevations, at the bottom of the basemat and at the bottom of the concrete fill. The SSI input acceleration time histories match the final SSI input response spectra developed in FSAR Section 3.7.1.1.4. The applicant used the guidance of SRP Section 3.7.1 in developing these time histories.

- NAPS SUP 3.7-3 Supporting Media for Seismic Category I Structures

This supplement provided information on the supporting media of seismic Category I structures in FSAR Section 3.7.1.3. The seismic Category I structures for North Anna 3 have concrete mat foundations on rock or concrete fill on rock.

3.7.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the seismic design and the associated acceptance criteria are in SRP Section 3.7.1. The specific requirements include the following:

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the seismic design basis to reflect the appropriate consideration of the most severe earthquakes historically reported for the site and surrounding area with a sufficient margin for the limited accuracy, quantity, and period of time in which historical data have been accumulated; and SSCs important to safety be designed to withstand the effects of earthquakes without a loss of capability to perform their intended safety functions.

- 10 CFR Part 50, Appendix S, "Earthquake Engineering Criteria for Nuclear Power Plants," as it relates to the SSE ground motion in the free-field at the foundation level of the structures to be an appropriate response spectrum with a PGA of at least 0.1 g; and if the OBE is chosen to be less than or equal to one-third of the SSE ground motion, it will not be necessary to conduct explicit response or design analyses in accordance with Section IV.(2)(i)(A) of 10 CFR Part 50, Appendix S.

In addition, the acceptance criteria and regulatory guidance associated with the review of FSAR Section 3.7.1 include the following:

- SRP Section 3.7.1 for reviewing seismic design parameters to ensure that they are appropriate and contain a sufficient margin so that seismic analyses (reviewed under other SRP sections) accurately and/or conservatively represent the behavior of SSCs during postulated seismic events.

- RG 1.60, to determine the acceptability of design response spectra for input into the seismic analysis of nuclear power plants.

- RG 1.61, Revision 1, “Damping Values for Seismic Design of Nuclear Power Plants,” to determine the acceptability of damping values used in the dynamic seismic analyses of seismic Category I SSCs.

- RG 1.208, "A Performance-Based Approach to Define the Site-Specific Earthquake Ground Motion," to review acceptability of the input FIRS.
- DC/COL–Interim Staff Guidance (DC/COL-ISG)-01, "Interim Staff Guidance on Seismic Issues of High Frequency Ground Motion."
- DC/COL-ISG-017, "Interim Staff Guidance on Ensuring Hazard-Consistent Seismic Input for Site Response and Soil Structure Interaction Analyses."
- NUREG/CR-6728, "Technical Basis for Revision of Regulatory Guidance on Design Ground Motions: Hazard- and Risk-Consistent Ground Motion Spectra Guidelines," to determine the acceptability of the site-specific FIRS used in the site-specific seismic analysis.

3.7.1.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.7.1 of the ESBWR DCD. The staff reviewed Section 3.7.1 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information relating to this section.

The staff reviewed the following information in the COL Part 7, "Departures Report" and the North Anna 3 COL FSAR, Revision 9:

Exemption

- Exemption 3 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The North Anna 3 horizontal and vertical FIRS for the RB/FB, CB, and FWSC structures are not bounded by the CSDRS at all frequencies. Therefore, the applicant made a Tier 1 Departure from the DCD to accommodate the site-specific seismological and geological conditions for North Anna 3. The applicant's definition of the SSE for North Anna 3 has therefore been revised to include both the DCD CSDRS and the site-specific FIRS for each seismically qualified structure. Site-specific SSI analyses have been performed for the North Anna 3 seismic Category I structures, and the staff evaluation of the results has confirmed the standard design to be adequate with the DCD modifications as outlined in Section 3.7 and 3.8 of the COL FSAR Revision 9. The site-specific definition of SSE will be applied in the inspections, tests, analyses, and acceptance criteria (ITAAC) for ensuring seismic capability of the plant.

The applicant provided the following in its description of this Tier 1 change to the DCD:

> The Unit 3 horizontal and vertical foundation input response spectra for the RB/FB, CB, and FWSC structures are not bounded by the CSDRS at all frequencies. The definition of the SSE for Unit 3 has therefore been revised to include both: 1) the CSDRS, as described in DCD Tier 1, Table 5.1-1, Footnote (4), and DCD Tier 1, Figures 5.1-1 and 5.1-2; and 2) the site-specific FIRS and the SSI input response spectra for the FWSC at the average elevation of the bottom of the concrete fill (Elevation 220 ft NAVD88, 220.86 ft NGVD29), representative of the Unit 3 site seismological and geological conditions. DCD Tier 1, Section 5.1, provides for site-specific soil structure interaction [SSI] analyses to be performed to confirm the seismic adequacy of the certified design using approved methods and acceptance criteria. Site-specific soil structure interaction (SSI) analyses have been performed for Unit 3 seismic Category I structures and evaluation of the results has confirmed the standard design to be adequate. The site-specific definition of SSE will be applied in the ITAAC for ensuring seismic capability of the plant.

In the North Anna 3 COL application, Revision 7, Part 7, "Departures Report," June 2016, the applicant requested an exemption from the provisions of 10 CFR Part 52, Appendix E, Section III.B, "Design Certification Rule for the ESBWR Design, Scope and Contents," which requires an applicant referencing a certified design to incorporate by reference Tier 1 information.

Specifically, in North Anna Part 7, Exemption 3, the applicant proposed to depart from the ESBWR DCD, Tier 1, SSE definition from Table 5.1-1, Footnote (4) of the DCD. This exemption represents the Tier 1 changes that relate to Departure NAPS DEP 3.7-1 for Tier 2 and Tier 2* information regarding site-specific CSDRS partial exceedances. Part 10 of the North Anna 3 COL application reflects these changes to the DCD Tier 1 information regarding the site-specific SSE. This change of the SSE definition is reflected in the revisions to site-specific ITAAC. The site-specific definition of SSE will be applied in the ITAAC for ensuring seismic capability of the plant as designed, as constructed, and for any future potential plant modifications.

<u>Regulations</u>

- 10 CFR Part 52, Appendix E, Section VIII.A.4 states that exemptions from Tier 1 information are governed by the requirements of 10 CFR 52.63(b) and 10 CFR 52.98(f). 10 CFR Part 52, Appendix E, Section VIII.A.4 also states that the Commission will deny such a request if it finds that the design change will result in a significant reduction in the level of safety otherwise provided by the design.

- 10 CFR 52.63(b)(1) allows an applicant to request NRC approval for an exemption from one or more elements of the certification information. The Commission may only grant such a request if it determines that the request complies with the requirements for specific exemptions in 10 CFR 52.7 and 10 CFR 50.12, and if the special circumstances that 10 CFR 52.7 requires to be present outweigh the potential decrease in safety due to reduced standardization. Therefore, any exemption from the Tier 1 information certified by 10 CFR Part 52, Appendix E must meet the requirements of 10 CFR 50.12, 10 CFR 52.7, and 10 CFR 52.63(b)(1).

Evaluation of Exemption

As stated in 10 CFR Part 52, Appendix E, Section VIII.A.4, an exemption from Tier 1 information is governed by the requirements of 10 CFR 52.63(b)(1) and 52.98(f). Additionally, the Commission will deny an exemption request if it finds that the requested change to Tier 1 information will result in a significant decrease in safety. Pursuant to 10 CFR 52.63(b)(1), the Commission may, upon application by an applicant or licensee referencing a certified design, grant exemptions from one or more elements of the certification information, as long as the criteria given in 10 CFR 50.12 and required by 10 CFR 52.7 outweigh any potential decrease in safety due to reduced standardization.

Applicable criteria for when the Commission may grant the requested specific exemption are provided in 10 CFR 50.12(a)(1) and (a)(2). 10 CFR 50.12(a)(1) provides that the requested exemption must be authorized by law, not present an undue risk to the public health and safety, and be consistent with the common defense and security. The provisions of 10 CFR 50.12(a)(2) list six special circumstances for which an exemption may be granted. It is necessary for one of these special circumstances to be present in order for NRC to consider granting an exemption request. The applicant stated that the requested exemption meets the special circumstances of 10 CFR 50.12(a)(2)(ii). That subsection defines special circumstances as when "[a]pplication of the regulation in the particular circumstances would not serve the underlying purpose of the rule or is not necessary to achieve the underlying purpose of the rule." The staff's analysis of each of these findings is presented below. Although the applicant requested an exemption from 10 CFR Part 52, Appendix E, Section III.B, the NRC is treating the requested exemption as one from ESBWR DCD Tier 1, Table 5.1-1, Footnote (4) to define the North Anna 3 SSE.

Authorized by Law

This exemption would allow the applicant to implement approved changes to Tier 1 information. This is a permanent exemption limited in scope to particular Tier 1 information, and subsequent changes to this Tier 1 information or any other Tier 1 information would be subject to full compliance by the applicant as specified in 10 CFR Part 52, Appendix E, Section VIII.A.4. As stated above, 10 CFR 52.63(b)(1) allows the NRC to grant exemptions from one or more elements of the certification information, namely, Tier 1. The staff determined that granting of the applicant's proposed exemption will not result in a violation of the Atomic Energy Act of 1954, as amended, or NRC regulations. Therefore, as required by 10 CFR 50.12(a)(1), the exemption is authorized by law.

No Undue Risk to Public Health and Safety

The purpose of Exemption 3 to ESBWR DCD Tier 1, Table 5.1-1, Footnote (4), for the North Anna 3 COL is to define the site-specific SSE, due to the exceedances of the ESBWR standard plant SSE at certain seismic frequencies. The site-specific SSE is then employed for the purpose of performing site-specific seismic inspections, tests, and analyses. The seismic design and qualification of SSCs are done in accordance with the methods of the standard design in conjunction with the site-specific results of the FIRS and which is then compared to the standard design. The applicant indicated that the exemption changes will augment the North Anna 3 site-specific ESBWR standard design attributes to ensure that the North Anna 3 site-specific seismic conditions are adequate and meet regulatory requirements. The North Anna 3 seismic design and analyses are verified through the appropriate ITAAC. The proposed exemption which defines the site-specific SSE ensures that the as-built plant will be seismically designed, analyzed, and qualified for meeting both the standard design and the site-specific conditions. The plant-specific Tier 1 DCD will continue to reflect the approved licensing basis for the applicant and will maintain a level of detail consistent with that which is currently provided elsewhere in Tier 1 of the plant-specific DCD. The affected design description in the plant-specific Tier 1 DCD will continue to provide the detail necessary to support the performance of the associated ITAAC. The staff has evaluated the related departure NAPS DEP 3.7-1 in applicable sections of this SER, and concluded that this departure has been addressed adequately in the North Anna 3 site-specific seismic design evaluation of the ESBWR standard design. Therefore, the staff finds Exemption 3 presents no undue risk to public health and safety as required by 10 CFR 50.12(a)(1).

Consistent with Common Defense and Security

The proposed exemption would allow the applicant to implement modifications to the Tier 1 information requested in the applicant's submittal. This is a permanent exemption limited in scope to particular Tier 1 information. Subsequent changes to this Tier 1 information or any other Tier 1 information would be subject to full compliance by the applicant as specified in 10 CFR Part 52, Appendix E, Section VIII.A.4. This change is not related to security issues. Therefore, as required by 10 CFR 50.12(a)(1), the staff finds that the exemption is consistent with the common defense and security.

Special Circumstances

Special circumstances, in accordance with 10 CFR 50.12(a)(2)(ii), are present whenever application of the regulation in the particular circumstances would not serve the underlying purposes of the rule or is not necessary to achieve the underlying purpose of the rule. The underlying purpose of the North Anna 3 COL Exemption 3 to the ESBWR DCD Tier 1, Table 5.1-1, Footnote (4) is to define the North Anna 3 SSE which will ensure that the safety-related structures that must withstand the effects of earthquakes are designed to the relevant requirements of GDC 2 and comply with Appendix S to 10 CFR Part 50 concerning natural phenomena. Standardized plants such as the ESBWR are designed to envelop the most severe earthquakes that affected a great number of sites where a nuclear plant may be located, with sufficient margin considering the limits of accuracy, quantity, and period of time during which historical data have been accumulated. In the case of North Anna 3, the site-specific horizontal and vertical foundation input response spectra for the RB/FB, CB, and FWSC structures are not bounded by the CSDRS at all frequencies. Therefore the applicant proposed a change to the Tier 1 definition of the SSE to include both the CSDRS and the site-specific FIRS which ensures that the North Anna 3 seismic structures are appropriately qualified and applied to the site-specific ITAAC. In addition, site-specific seismic analysis and design as described in FSAR Revision 9, Sections 3.7 and 3.8, show that the ESBWR standard design with necessary changes is adequate for the North Anna 3 site-specific seismological and geological conditions. Accordingly, special circumstances are present because the certified design information in ESBWR DCD, Tier 1, Table 5.1-1, Footnote (4), is not necessary to achieve the underlying purpose of the rule in view of the site-specific seismological and geological conditions. Therefore, the staff finds that special circumstances exist, as required by 10 CFR 50.12(a)(2)(ii) for the granting of an exemption from the DCD, Tier 1 information.

Special Circumstances Outweigh Reduced Standardization

This exemption would allow the applicant to change certain ESBWR DCD, Tier 1 information proposed in the North Anna 3 COL application in view of site-specific seismological and geological conditions. The key design functions of seismically qualified structures will nonetheless be maintained, based on the nature of the proposed changes to the generic ESBWR DCD Tier 1, Table 5.1-1, Footnote (4) to define the North Anna 3 SSE, and the understanding that this change ensures that the as-built plant will be seismically designed, analyzed, and qualified for meeting both the standard design and the site-specific seismic conditions. However, this exemption request and the associated changes to North Anna 3 COL Tier 1 information demonstrate that there is a minimal change from the standard information provided in the ESBWR DCD. This change augments the ESBWR DCD for the North Anna 3 site-specific seismic conditions to ensure that the adequacy of the North Anna 3 seismic design and analyses are verified through the appropriate ITAAC. Consequently, the decrease in safety due to reduced standardization would also be minimal. For this reason, the staff determined that even if other ESBWR licensees and applicants do not request a similar exemption, the special circumstances outweigh the potential decrease in safety due to reduced standardization of the ESBWR design, as required by 10 CFR 52.63(b)(1).

No Significant Reduction in Safety

The proposed exemption would not modify the function of the North Anna 3 seismically qualified structures and SSCs. This change will ensure that the adequacy of the Unit 3 seismic design and analyses are verified through appropriate ITAAC. Therefore, the staff finds that granting the exemption would not result in a significant decrease in the level of safety otherwise provided by the design, as required by 10 CFR Part 52, Appendix E, Section VIII.A.4.

Conclusion

For the reasons set forth above, the staff has concluded that pursuant to 10 CFR Part 52, Appendix E, Section VIII.A.4, the exemption: (1) is authorized by law; (2) presents no undue risk to the public health and safety; (3) is consistent with the common defense and security; (4) has special circumstances that outweigh the potential decrease in safety due to reduced standardization; and (5) does not significantly reduce the level of safety at the licensee's facility. Therefore, the staff finds that the applicant's request to depart from the information in ESBWR DCD Tier 1, Table 5.1-1, Footnote (4) is acceptable, and the applicant's request for an exemption from these Tier 1 requirements is granted.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

Seismic Design Parameters

The staff reviewed the information presented in NAPS DEP 3.7-1 submitted in North Anna 3 COL FSAR Section 3.7 and in Part 7 of the COL application. This departure described that the site-specific FIRS exceeded the CSDRS at certain frequencies and as such, revised the SSE definition to include the site-specific FIRS in addition to the CSDRS for seismic analyses of seismic Category I and Category II SSCs. Since this departure involves changes to ESBWR

DCD Tier 1, Table 5.1-1, the applicant also requested an exemption (Exemption 3 in Part 7) from the DCD Tier 1 information. This departure also includes redefinition of the OBE for the plant shutdown.

The applicant has developed the site-specific seismic design parameters (FIRS, input acceleration time histories, etc.) using the guidance in SRP Section 3.7.1. Comparisons of site-specific FIRS with the CSDRS are presented in FSAR Figures 2.0-201 through 2.0-204 for RB/FB, CB, and FWSC. These Figures indicate that site-specific FIRS exceed the CSDRS for all these structures. As such, the applicant has performed site-specific SSI analyses consistent with the guidance in SRP Section 3.7.2 to determine the site-specific seismic demand for evaluation of the acceptability of the ESBWR standard plant design at the North Anna 3 site. The applicant also indicated that North Anna 3 seismic design, analyses, and qualification of the SSCs use both the CSDRS and the site-specific FIRS as the SSE. Details of the applicant's development of site-specific FIRS and ground motion time histories are described in the supplementary information to COL FSAR Sections 3.7.1.1.4 and 3.7.1.1.5 (NAPS SUP 3.7-1 & 3.7-2).

Two spectra are used to define the North Anna 3 OBE design ground motion as: (1) one-third of the CSDRS presented in the FSAR Figures 2.0-201 and 2.0-202 and (2) one-third of the 5 percent damped site-dependent SSE spectra manifested at grade as presented in the FSAR Figure 3.7.1-267. Exceedance of the response spectra (1) & (2) is evaluated independently (not through the envelope of these two). Staff's evaluation of the plant shutdown criteria due to OBE exceedance is discussed in Section 3.7.4 of this SER. The staff finds the use of both the CSDRS and the site-specific SSE as the basis of defining the OBE to be acceptable since: (1) safety-related SSCs are designed and qualified to meet both the CSDRS and site-specific FIRS consistent with the PBSRS, (2) the OBE is defined as one-third of the SSE, as such meets the requirement of 10 CFR Part 50, Appendix S, and (3) PBSRS and corresponding FIRS were developed using the guidance in SRP Section 3.7.1 and RG 1.208.

FSAR Section 3.7.2.4 discusses the site-specific SSI analyses of the ESBWR standard plant structures. FSAR Section 3.8 discusses design evaluation of the ESBWR standard plant structures for the site-specific seismic demand. The staff's evaluation of the site-specific FIRS and ground motion time histories is provided below under "Site-Specific Design Ground Motion Response Spectra" and "Site-Specific Design Ground Motion Time History." Staff's evaluation of the plant shutdown criteria is provided in Section 3.7.4.4 of this SER. The staff's evaluation of the site-specific RB/FB, CB, and FWSC SSI analyses and the applicant's assessment of the ESBWR standard plant design adequacy at North Anna 3 site is provided in Sections 3.7.2.4 and 3.8 of this SER.

Since the applicant incorporates both the CSDRS and the site-specific FIRS as the SSE for North Anna 3 seismic design, analyses, and qualification of Category I SSCs, the staff concludes that the seismic design parameters used in site-specific seismic analyses and evaluation of the ESBWR standard design to address FIRS exceedance of the CSDRS at the North Anna 3 site are acceptable.

Single Envelope Ground Motion

DCD Section 3.7.1.1.3 provides information regarding the single envelope ground response spectra which is referred to as the CSDRS. The CSDRS is used for the design of the ESBWR standard plant structures. NAPS DEP 3.7-1 noted that the site parameter comparison indicates exceedance of the CSDRS by the North Anna 3 FIRS and thus a site-specific SSI analysis is performed as presented in COL FSAR Section 3.7.2. The applicant also clarified that SSCs are seismically designed, analyzed, and qualified to both CSDRS and FIRS as described in FSAR Sections 3.7.1, 3.7.2, 3.7.3, and 3.10. The staff finds this clarification in FSAR Section 3.7.1.1.3 to be acceptable. For staff's evaluation of acceptability of the site-specific SSI analysis, refer to this SER in Section 3.7.2.4.

Percentage of Critical Damping Values

NAPS DEP 3.7-1 in COL FSAR Section 3.7.1.2 clarifies that OBE structural damping values consistent with RG 1.61, Revision 1 are used for site-specific SSI analyses unless SSE damping in DCD Table 3.7-1 is justified by stress demand. FSAR Section 3A.13.2 further describes the damping values used in the site-specific SSI analyses. FSAR Section 3A.15 and Tables 3A.15-201 through 3A.15-206 provide details of the use of SSE damping values in specific analyses cases. The staff evaluated the acceptability of the damping values used in the site-specific SSI analyses during its review of the site-specific design basis models as discussed in this SER in Section 3.7.2.4 under the heading "*SSI Analysis Structural Models*." The staff found the applicant's method of assigning the damping values for site-specific SSI analyses acceptable per the guidance in RG 1.61, Revision 1. In addition, the maximum soil damping ratio as specified in the FSAR Tables 3.7.1-201 through 3.7.1-206 is below 15 percent in all cases and is therefore acceptable per the guidance in SRP Acceptance Criterion 3.7.2.II.4.

Supplemental Information

- NAPS SUP 3.7-7 Design Ground Motion

Design Ground Motion

ESBWR CSDRS are discussed in DCD Section 3.7.1.1 and are shown in DCD Figures 2.0-1 and 2.0-2. This supplement to COL FSAR Section 3.7.1.1 describes that the site-specific SSI analysis is carried out using the site-specific seismic design parameters. The site-specific design parameters are developed as described in COL FSAR Sections 3.7.1.1.4 and 3.7.1.1.5. These design parameters include the SSI strain compatible soil profiles, SSI input response spectra, and SSI input acceleration time histories for the Category I structures. The development of the site-dependent SSE manifestation at-grade is discussed in FSAR Section 3.7.1.1.6, which is used to define OBE. The staff's evaluation of the supplementary information is provided below under review of NAPS SUPs 3.7-1 and 3.7-2 in this SER.

- NAPS SUP 3.7-1 Site-specific Design Ground Motion Response Spectra

Site-Specific Design Ground Motion Response Spectra

The applicant in FSAR Section 3.7.1.1.4.2 stated that, for all seismic Category I structures FIRS are presented in FSAR Section 2.5.2.6. The applicant used the results of site response analyses as input to the development of the ground motion response spectra (GMRS), FIRS, and PBSRS. FIRS were developed for both full column outcrop motions and partial column outcrop motions for the RB/FB and CB. The final SSI input response spectra for the RB/FB are shown in the FSAR Figures 3.7.1-218 through 3.7.1-220, and for the CB are shown in the FSAR Figures 3.7.1-229 through 3.7.1-231. For the FWSC, two sets of site-specific SSI input response spectra were developed: one with the control motion defined at the bottom of the FWSC foundation mat (Elevation 282 ft), and the other with the control motion defined at the elevation corresponding to the bottom of concrete fill (Elevation 220 ft) supporting the FWSC foundation mat. The final FWSC SSI input response spectra at the Elevation 282 ft are shown in the FSAR Figures 3.7.1-232 through 3.7.1-234, and those at the Elevation 220 ft are shown in the FSAR Figures 3.7.1-283 through 3.7.1-285.

The applicant used the performance-based methodology as described in the FSAR Sections 2.5.2.5 and 2.5.2.6 in developing the GMRS, FIRS, and PBSRS following the guidance in RG 1.208. The applicant first developed the GMRS, FIRS, and PBSRS for the horizontal component of the motions. In accordance with the guidance in NUREG/CR-6728, Appendix J the applicant used the frequency dependent vertical-to-horizontal (V/H) response spectral ratios appropriate for the North Anna 3 site to obtain the corresponding vertical GMRS, FIRS, and PBSRS from the horizontal spectra.

For the RB/FB and CB, the applicant developed site-specific SSI input response spectra from the corresponding FIRS and PBSRS using the method described in Section 5.2.1 of DC/COL-ISG-017, to ensure hazard-consistent seismic inputs for the deterministic site-specific SSI analyses. For the FWSC, the applicant used the envelope of the results of the two SSI analyses – one with the SSI input response spectra applied at the bottom of the FWSC foundation mat (Elevation 282 ft) and the other input response spectra applied at the bottom of the concrete fill (Elevation 220 ft) – to ensure adequate consideration of the hazard-consistent SSI input for the deterministic SSI analyses.

Development of the SSI input response spectra consists of establishing the three strain compatible deterministic soil profiles for the SSI analyses, adjusting the FIRS to ensure that these three soil profiles will result in PBSRS being bounded by the envelope of the FIRS propagating to the ground surface, and verifying that the seismic input meets the minimum requirement of 10 CFR Part 50, Appendix S. The staff found the applicant's process of developing the SSI input response spectra for the seismic Category I structures acceptable, because the method and procedure used are consistent with the guidance in DC/COL-ISG-017 and SRP Section 3.7.1.II.4.A. For the FWSC, the staff found the use of one set of input control motion defined at the bottom of the FWSC foundation mat and one set at the bottom of the concrete fill to be acceptable as discussed in this SER below under *"SSI Input Response Spectra for the FWSC*".

Details of the staff's evaluation of the development of the SSI strain compatible soil profiles, SSI input response spectra from the FIRS, and the applicant's method of satisfying the minimum design ground motion requirements of 10 CFR Part 50, Appendix S are discussed as follows in this SER.

SSI Strain Compatible Soil Properties

In accordance with DC/COL-ISG-017, the applicant developed from the in-situ soil profiles three deterministic strain compatible soil profiles for the SSI analyses as follows: Best Estimate (BE), Lower Bound (LB), and Upper Bound (UB). These soil profiles were used by the applicant to adjust the FIRS to ensure that the PBSRS is bounded by the envelope of the FIRS propagating to the ground surface, as well as to account for potential effects of the variation of the soil parameters on the site-specific SSI analyses. FSAR Section 3.7.1.1.4.1 describes the methodology used by the applicant to develop these profiles. The methodology follows the guidance in RG 1.208, SRP Acceptance Criterion 3.7.2.II.4, and DC/COL-ISG-17. The methodology is based on the statistics of the strain-iterated soil properties obtained from the probabilistic site response analyses using the randomized full soil column profiles as described in FSAR Sections 2.5.2.5 and 3.7.1.1.4.1. In addition in response to staff RAI 03.07.01-8 dated February 23, 2015 (ADAMS Accession No. ML15056A047), the applicant addressed the following:

- From the probabilistic full column site response analyses of the soil columns described in FSAR 2.5.2.5, a set of 60 strain-compatible soil properties is obtained for each of the 4 input rock cases of 10^{-4} and 10^{-5} annual-frequency-of-exceedance level of low frequency (LF) and high frequency (HF) seismic events. The mean and standard deviation for each of the 4 sets of shear wave velocity (Vs) and damping ratios are calculated. These values are used to establish the mean and standard deviation of the strain compatible soil properties that are consistent with the FIRS motions.

- The UB and LB values of the soil parameters (Vs and damping ratios) are calculated as ± one log-standard deviation from the log-mean values. Maximum strain compatible damping ratios were below 15 percent in all cases and are thus consistent with SRP Acceptance Criterion 3.7.2.II.4.

- The UB and LB Vs profiles were adjusted where necessary to satisfy the minimum variation criteria of SRP Section 3.7.2. According to this criteria, LB Vs profiles should be less than or equal to $(V_S) / (\sqrt{1.5})$ and the UB Vs profile should be greater than or equal to $(V_S) \times (\sqrt{1.5})$ where V_S is the BE strain compatible Vs corresponding to the FIRS level of motion. This approach is consistent with the guidance in SRP Acceptance Criterion 3.7.2.II.4 for a site with well investigated subsurface material properties.

- The compression wave velocity profiles were based on the corresponding Vs profiles and the site-specific Poisson's ratios identified in FSAR Table 2.5.4-208. In the layers below water table, a minimum Primary wave (P-wave) was first set to a velocity of 4800 ft/sec. The Poisson's ratio is adjusted to obtain the minimum P-wave velocity. The maximum value of Poisson's ratio used is 0.48. In the layers of bedrock below the groundwater table, the compression wave velocities exceeded 4800 ft/sec in all cases and no adjustment was necessary.

FSAR Tables 3.7.1-201, 3.7.1-203, and 3.7.1-205 present the values of strain compatible in-situ subsurface material properties used for fully embedded (FE) site-specific SSI analyses for the RB/FB, CB, and FWSC, respectively. The top 7 layers (17 ft) of the RB/FB profile corresponding to saprolite are removed in the partially embedded (PE) SSI analysis of the RB/FB. The top 10 layers (25 ft) of the CB profile representing the saprolite are removed in the PE SSI analysis of the CB. In these tables, a combination of the lower Vs and P-wave velocity along with the higher damping values constitute the LB profile. Similarly, the higher shear and P-wave velocities along with the lower damping values constitute the UB profile.

FSAR Tables 3.7.1-202, 3.7.1-204, and 3.7.1-206 present the UB, BE, and LB Vs, P-wave velocity, and the damping values for the structural fill and concrete fill materials for the RB/FB, CB, and FWSC, respectively. The concrete fill is considered as linear elastic material for the purpose of SSI analyses. These strain compatible (i.e., compatible with the FIRS) fill material properties were also calculated following the same methodology discussed above for the in-situ soil profile. The strain-compatible structural fill and concrete fill materials are used for the near-field finite elements as part of the structural models.

The staff finds the above approach for developing the strain compatible soil properties for the in-situ material, structural backfill material, and the concrete fill material acceptable because these were developed using the guidance in SRP Acceptance Criterion 3.7.2.II.4 and DC/COL-ISG-17.

SSI Input Response Spectra for the RB/FB and CB

- *Nuclear Energy Institute (NEI) Check[2] per DC/COL-ISG-017*

As discussed in FSAR Sections 3.7.1.1.4.2.1 and 3.7.1.1.4.2.2, the site-specific SSI input response spectra are calculated for SSI analyses of the RB/FB and CB structure as FE structure and as PE (i.e., only considering embedment in the rock) structure. FSAR Section 2.5.2.6 described the development of full column and partial column FIRS and the corresponding PBSRS. The corresponding full column FIRS and partial column FIRS for RB/FB are shown in FSAR Figures 2.5.2-307 and 2.5.2-309 and for the CB in FSAR Figures 2.5.2-308 and 2.5.2-310. The corresponding full column PBSRS are shown in FSAR Figure 2.5.2-311. The partial column PBSRS are included in FSAR Figures 3.7.1-216 and 3.7.1-217 for the RB/FB and in FSAR Figures 3.7.1-227 and 3.7.1-228 for the CB.

The applicant used the method described in Section 5.2.1 of DC/COL-ISG-017 to adjust the FIRS to yield SSI input response spectra for the RB/FB and the CB. FSAR Figures 3.7.1-212 and 3.7.1-213 present the envelope of the ground surface response spectra obtained from the horizontal and vertical full column FIRS propagated to the ground surface through the LB, BE, and UB profiles for the RB/FB. Also presented in FSAR Figures 3.7.1-212 and 3.7.1-213 are the corresponding PBSRS and FIRS. As shown from the Figures 3.7.1-212 and 3.7.1-213, the envelope of the LB, BE, and UB ground surface response spectra does not bound the PBSRS at all frequencies. For this reason, the applicant used an adjustment factor to modify the FIRS to develop the SSI input response spectra. The frequency dependent adjustment factor is either unity where the PBSRS is bounded or the ratio of the PBSRS to the envelope of LB, BE, and UB surface response spectra. This conservative bounding adjustment factor is then applied to the corresponding FIRS to obtain the SSI input response spectra.

The applicant also used the same method described in Section 5.2.1 of DC/COL-ISG-017 for developing the input spectra for the PE case for the RB/FB and for the FE and PE cases for the CB. For the RB/FB, the FSAR Figures 3.7.1-212 and 3.7.1-213 include the SSI input response spectra for the full column case and Figures 3.7.1-216 and 3.7.1-217 for the partial column case. For the CB, Figures 3.7.1-223 and 3.7.1-224 show the SSI input response spectra for the FE case and Figures 3.7.1-227 and 3.7.1-228 show those for the PE cases.

---

[2] The NEI New Reactor Seismic Issues Resolution Program undertook several studies producing industry white papers. The guidelines developed in ISG-01, the NEI white paper, and the development of the criteria associated with this ISG result from the coordination of the industry initiative, NRC studies, and other stakeholder inputs through interactions in public meetings. In particular, the meeting of September 25–26, 2008, was instrumental in establishing a framework of common understanding (see meeting summary, ADAMS Accession No. ML082950476).

The applicant performed the above NEI check based on the random vibration theory (RVT) method, which did not use the synthetic acceleration time histories. To confirm whether the envelope of the response spectra of the spectrally matched design acceleration time histories also envelopes the PBSRS at the ground surface, the applicant, as discussed in the FSAR Sections 3.7.1.1.5.1.1 and 3.7.1.1.5.1.2, performed additional comparisons of the envelope of the response spectra of the spectrally matched design acceleration time histories to the PBSRS for RB/FB and CB, respectively. These comparisons in FSAR Figures 3.7.1-295 through 3.7.1-306 show that, except at a few locations, the enveloped response spectra at the surface exceeds the PBSRS. In a few instances as discussed below, the raw envelopes of response spectra of the acceleration time histories at the ground surface for the LB, BE, and UB soil cases were below the PBSRS for some frequencies.

For the instances in the horizontal direction, the dips were generally small and occurred in very narrow frequency ranges. These dips correlate to the dips shown on the spectrally matched response spectra, which are still consistent with the SRP Section 3.7.1 guidance. However, since the structural demands were calculated using the design time histories (not directly using the FIRS) in the SSI analysis, the staff requested during Audit 1 (ADAMS Accession No. ML16064A271) that the applicant assess the effect of these dips on the structural response. The applicant performed a sensitivity study as referenced in the North Anna 3 FSAR, Section 3.7.1.1.5.1.1, using the time history for the CB partial column in the horizontal (H1) direction, and the staff also confirmed the results during the North Anna 3 Audit 1. This time history was modified slightly so that its response spectrum was above the final SSI input response spectra around the affected frequency. The in-structure response spectra (ISRS) calculated using this modified time history did not show significant changes over the ISRS calculated using the original time history and those changes did not affect the enveloped and broadened ISRS used in the design. Therefore based on this sensitivity study, the staff concluded that the small dips which occurred in a very narrow frequency range in the raw envelope do not affect the broadened ISRS in the horizontal direction and thus, found the NEI check in the horizontal direction acceptable.

For the instance of RB/FB FE condition in the vertical direction (FSAR Figure 3.7.1-297), where the enveloped response spectrum falls below the PBSRS between 16.6 Hz and 20.4 Hz, the applicant explained during Audit 1 and also in the FSAR Section 3.7.1.1.5.1.1 that the RB/FB structural response transfer functions relative to the outcrop SSI input motion show this dip is outside of the structural frequencies of the RB/FB in the vertical direction so its effect on structural response is negligible. The staff found this justification acceptable because, as also reflected in the FSAR, the vertical input motion to the structure and the load transfer from the building primarily occur at the mat foundation and the surrounding rock interface and consequently the effects of vertical ground motion near the ground surface are insignificant for structural responses in the vertical direction.

The applicant also indicated in the FSAR Section 3.7.1.1.5.1.1 that this dip reflects a difference in the method to calculate the vertical PBSRS (by applying the frequency-dependent V/H ratio) and the method to calculate the acceleration response (through P-wave propagation). In order to understand the effect of this difference, the staff reviewed the pertinent information in DC/COL-ISG-17, FSAR Section 3.7.1.1.5.1.1, and NUREG/CR-6728. The staff confirmed this information during the North Anna 3 Audit 1. The same frequency-dependent V/H ratio was used to obtain the vertical FIRS and PBSRS from the horizontal FIRS and PBSRS, respectively, regardless the difference in the elevations of FIRS (at foundation level) and PBSRS (at ground surface). In addition, the application of V/H ratios is independent of the vertical soil profiles (LB, BE, and UB) that are used to propagate the vertical FIRS up to the ground surface. Therefore, for comparison purposes in the vertical direction, the two methods may not be consistent. The staff also concluded that while the observed difference between the vertical PBSRS and the enveloped response spectra at the ground surface is possible, the effects of these dips on the structural response are considered insignificant since: (1) FSAR Figures 3.7.1-295 through 3.7.1-306 show that, except at a few instances, the enveloped response spectra at surface exceed the PBSRS (for some cases by large margins) and (2) the seismic load transfer in the vertical direction primarily occurs at the foundation-rock interface and not at the free ground surface. For this reason, the staff found the NEI check for the SSI input spectra for the RB/FB and CB to be acceptable.

- *Meeting the Minimum Requirement of 10 CFR Part 50, Appendix S*

10 CFR Part 50, Appendix S, requires that the horizontal component of the SSE ground motion in the free-field at the foundation levels of structures must be an appropriate response spectrum with a PGA of at least 0.1 g. In FSAR Section 3.7.1.1.4.2.1, the applicant described how the final SSI input response spectra were developed from the performance-based input response spectra to meet the minimum requirement of 10 CFR Part 50, Appendix S. The applicant stated that for the full soil column analyses, the final SSI input response spectra are determined by enveloping the full column SSI input response spectra and the minimum required response spectra defined in RG 1.60 anchored at 0.1 g. Similarly, for the partial soil column analyses the final SSI input response spectra are determined by enveloping the partial column SSI input response spectra and the minimum required response spectra defined in RG 1.60 anchored at 0.1 g. The development of final horizontal and vertical SSI input response spectra for RB/FB is shown in FSAR Figures 3.7.1-218 and 3.7.1-219 and for the CB in Figures 3.7.1-229 and 3.7.1-230.

The staff reviewed the results, and notes that the initially adjusted FIRS as discussed above under "*NEI Check*" were further enhanced to ensure that the final input spectra envelop the RG 1.60 spectrum anchored at 0.1 g. For this reason, the staff concluded that the final SSI input response spectra meet the 10 CFR Part 50, Appendix S minimum horizontal ground motion requirement at the foundation level.

The staff found the applicant's final SSI input response spectra for the RB/FB and the CB SSI analyses acceptable because: (a) the method and the procedure used are consistent with the guidance in DC/COL-ISG-017 and SRP Section 3.7, (b) the envelope of the surface response spectra based on the three deterministic soil columns bounds the corresponding PBSRS for the two embedment configurations (i.e., FE and PE) with a few minor exceptions that were determined to be insignificant to structural responses, and (c) the final SSI input spectra meet 10 CFR Part 50, Appendix S minimum 0.1 g horizontal ground motion requirement.

SSI Input Response Spectra for the FWSC

In the initial submittal of FSAR Section 3.7.2, the site-specific SSI analyses considered the FWSC as a surface founded structure at Elevation 282 ft. The control motion used in the SSI analysis was applied at the bottom of the basemat and not at the bottom of the concrete fill at Elevation 220 ft. The applicant did not need to use the methodology in Section 5.2.1 of DC/COL-ISG-017 for ensuring that the SSI input spectra specified at Elevation 282 ft would envelop the PBSRS because FWSC is considered as surface-founded.

The staff, however, noted that the concrete fill below the FWSC basemat was represented as an integral part of the structural model used in the SSI analyses. Staff notes that, from the point of view of the SSI analysis, the combined FWSC-concrete fill is similar to an embedded structure and as such, the control motion for SSI analysis could also be defined at the bottom of the concrete fill. In addition, the control motion specified at the foundation level (Elevation 282 ft) may include the effect of potential de-amplification of the high frequency content of the earthquake motion through the in-situ soil material. For this reason, the staff in RAI 03.07.01-11**,** requested the applicant to provide the technical justification for defining the control motion used in the SSI analysis at the bottom of the basemat and not at the bottom of the concrete fill.

In the response to RAI 03.07.01-11 (ADAMS Accession No. ML15056A047), the applicant supplemented the FSAR Section 3.7.1.1.4.2.3 to include a new control motion at the bottom of concrete fill (Elevation 220 ft). The applicant used two sets of site-specific SSI input response spectra defined at the bottom of the FWSC basemat (Elevation 282 ft) and at the bottom of the concrete fill (Elevation 220 ft). The FIRS corresponding to the control motion applied at the bottom of the FWSC basemat (Elevation 282 ft) represent the PBSRS for the FWSC soil column as shown in FSAR Figure 2.5.2-312. The final SSI input response spectra at Elevation 282 for FWSC are the envelope of the FIRS for FWSC and the RG 1.60 spectra anchored at 0.1 g to meet the minimum requirement of 10 CFR Part 50, Appendix S. Similarly, the final SSI input response spectra at Elevation 220 ft are the envelope of the design response spectra (DRS) at Elevation 220 ft for FWSC and the RG 1.60 spectra anchored at 0.1 g to meet the minimum requirement of 10 CFR Part 50, Appendix S. The applicant calculated the DRS at Elevation 220 ft. using the same method as described in FSAR Section 2.5.2.5 and 2.5.2.6. The final SSI input response spectra at Elevation 282 ft. and at Elevation 220 ft. are respectively presented in FSAR Figures 3.7.1-232 through 3.7.1-234 and in Figures 3.7.1-283 through 3.7.1-285.

The staff reviewed the information provided in the FSAR and found the applicant's final SSI input response spectra for the FWSC SSI analyses acceptable because: (a) the applicant in addition to using the guidance in DC/COL-ISG-017 to apply SSI input response spectra at the foundation level of the FWSC, used another set of site-specific SSI input response spectra applied at the bottom of the concrete fill; (b) the results of the two sets of SSI analyses are enveloped to develop the site-specific seismic demand of the FWSC and as such, the analyses bound any potential effect of de-amplification resulting from a single input analysis with the control motion applied only at the foundation level; and (c) the final input spectra meet the 10 CFR Part 50, Appendix S minimum 0.1 g horizontal ground motion requirement.

Consideration of Backfill Material in RB/FB and CB SSI Analyses

FSAR Section 3.7.1.1.4 indicates that the in-situ saprolite is replaced by structural fill and Zone III rock is replaced by concrete fill. As discussed earlier in this SER the applicant has also developed the engineering properties of the granular fill and concrete fill. However, the applicant did not consider the backfill material (granular structural fill and concrete fill) in developing the FIRS and PBSRS. The staff therefore requested the applicant in RAI 03.07.01-7 to provide a technical basis for computing the FIRS and PBSRS which only considers the in-situ soil/rock columns and not the backfill material that would exist surrounding the seismic Category I structures.

In the response to RAI 03.07.01-7 (ADAMS Accession No. ML15056A047), the applicant stated that the backfill material that is placed below and around the seismic Category I structures is limited in extent. In order to capture the effects of the limited extent of the backfill material on the response of the RB/FB and CB, the dynamic models for the seismic response analyses use near-field elements as part of the SSI structural model representing the dynamic properties of concrete and structural fill materials. LB, BE, and UB dynamic properties of the structural fill materials compatible to strain generated by the design ground motion are developed from the results of the site response analyses as discussed in the FSAR Section 3.7.1.1.4.1. The dynamic properties used for the concrete fill are linear and independent of the strain. The site-specific seismic demand is obtained from the envelope of responses from the SSI analyses of two different embedment configurations: partial column and full column subgrade profiles representing dynamic properties of the far-field in-situ subgrade materials. The applicant used the minimum value of lateral extent of backfill for the RB/FB SSI model as one-half of the distance between the RB/FB and the adjacent Turbine Building (TB) and for the CB SSI model as one-half of the distance between the CB and the adjacent Service Building (SB). The partial and full embedment configurations bound the effect of subgrade stiffness variations related to the lateral extent of the backfill (partial columns also account for the effects of soil separation) and groundwater table variations. The partial column models provide a lower bound stiffness representation whereas the full column models represent the upper bound subgrade stiffness.

The staff reviewed the response and found the response acceptable for the RB/FB and the CB because (a) the effect of the subgrade stiffness variations on the seismic demand due to consideration of limited lateral extent of the backfill material in the SSI model is bounded by the two embedment configurations used in the SSI analyses; and (b) use of the minimum value of the lateral extent of the backfill material in the full column model which conservatively maximizes the subgrade lateral stiffness and minimizes the subgrade damping values.

Consideration of Backfill Material in FWSC SSI Analyses

The applicant in the response to RAI 03.07.01-7 (ADAMS Accession No. ML15056A047) indicated that in the structural part of the SSI model, the concrete fill placed below the FWSC foundation basemat (down to the top of the Zone III/IV rock) was modeled as solid finite elements. While the in-situ soil surrounding the concrete fill was modeled in the SSI analyses of the FWSC, the model did not include the near field structural backfill material surrounding the concrete fill. The applicant justified the backfill material not being explicitly modeled on the basis that the differences between the dynamic properties of the structural backfill and the in-situ soil are small and are not expected to significantly affect the response. This is also because the FWSC is founded on concrete fill which is supported by the in-situ rock material.

The staff reviewed the comparison of the dynamic properties of the structural fill and in-situ material for the FWSC provided in the response to RAI 03.07.01-7. However based on the information provided, the staff could not determine conclusively the potential effect on the SSI response of not including the backfill material as part of FWSC structural model. The applicant subsequently performed additional SSI analyses considering soil separation from the concrete fill, which effectively represent the cases of the lower bound of the structural fill effect. The depths of the soil separation were estimated from static and dynamic lateral soil pressures and are in the range of 4.75 m to 8.83 m, which are close to the range of the partial embedment for RB/FB and CB. The depths of the soil separation are also close to 6 m as per the American Society of Civil Engineers (ASCE) 4-98, “Seismic Analysis of Safety-Related Nuclear Structures and Commentary,” soil separation guidance. These analyses found some exceedances in structural demands and ISRS, and these exceedances are appropriately considered in the applicant’s design evaluation of the ESBWR standard design for the North Anna 3 site. More detailed evaluation of exceedance consideration is provided in this SER in Section 3.7.2. The staff also performed a confirmatory analysis of the FWSC SSI model and confirmed the applicant's conclusions. A summary of this confirmatory analysis is provided in this SER in Section 3.7.2. As discussed in that Section of this SER, the staff found the applicant's analyses and conclusions acceptable because the effect of the structural fill is adequately considered.

Supplemental Information

- NAPS SUP 3.7-2 Site-specific Design Ground Motion Time History

Site-Specific Design Ground Motion Time History

In the North Anna 3 FSAR, Section 3.7.1.1.5, the applicant describes that for each set of horizontal and vertical final SSI input response spectra presented in FSAR Section 3.7.1.1.4.2, a set of three spectrally matched acceleration time histories (two horizontal and one vertical component) were generated. The seed time histories used are those of the 1984 M6.2 Morgan Hill earthquake recorded at the station Gilroy–Gavilan College chosen from the CEUS database of acceleration time histories in NUREG/CR–6728. FSAR Section 3.7.1.1.5.1.1 describes the selection process of the seed time histories and the methodology to develop the spectrally matched time histories.

One set for each elevation of three statistically independent acceleration time histories of motions (i.e., two horizontal and one vertical component) are developed for each of the full column and partial column final SSI input response spectra for the RB/FB and the CB, respectively. For the FWSC, one set of three statistically independent acceleration time histories of motions (i.e., two horizontal and one vertical component) are developed for the final SSI input response spectra applied at each of the foundation level of the FWSC and at the bottom of the concrete fill below the FWSC.

The applicant used SRP Acceptance Criterion 3.7.1.II.1.B, Option 1, Approach 2 in developing the time histories. FSAR Figures 3.7.1-235 through 3.7.1-240 provide comparison between the response spectra of the spectrally matched time histories with the target response spectra and the lower and upper target spectra band (90 percent and 130 percent of the target response spectra). The staff reviewed these comparisons. The comparison indicates that while the response spectra for the time histories are within 90 percent to 130 percent of the target spectra for the frequency range between 0.2 and 100 Hz, under-predictions were observed approximately below a frequency of 0.2 Hz. As such in RAI 03.07.01-12, the staff requested the applicant to provide numerical results of the spectral matching checks specified in SRP Section 3.7.1 acceptance Criteria II.1.B.ii (Option 1, Approach 2) and provide a technical justification for the under predictions below 0.2 Hz. The staff also requested the applicant to provide power spectral density (PSD) functions of the time histories to verify that there are no significant gaps in the frequency content of the acceleration time histories.

The staff reviewed the applicant's response to RAI 03.07.01-12 (ADAMS Accession No. ML15056A047) and verified the following aspects of the spectrally matched time histories as discussed below:

- The cross-correlation coefficients between the three components are less than 0.16, as listed in FSAR Tables 3.7.1-210, 3.7.1-212, 3.7.1-214, and 3.7.1-218 which indicates statistical independence.

- The strong motion durations as defined in SRP Acceptance Criterion 3.7.1.II.1.B as listed in FSAR Table 3.7.1-211, 3.7.1-213, 3.7.1-215, and 3.7.1-219 are longer than the minimum value of 6 seconds.

- The time step of the time histories is 0.005 s, which corresponds to an acceptable Nyquist frequency of 100 Hz. The duration of the time histories is 30 s, which is greater than the 20 s criterion.

- The 5-percent damped response spectra of the time histories were compared with the target spectra in FSAR Figures 3.7.1-235 through 3.7.1-240 for RB/FB, 3.7.1-247 through 3.7.1-252 for the CB, 3.7.1-259 through 3.7.1-261 for FWSC at Elevation 282 ft, and 3.7.1-286 through 3.7.1-288 for FWSC at Elevation 220 ft. The comparison indicates that the response spectra for the time histories are within 90 percent to 130 percent of the target spectra for the frequency range between 0.2 and 100 Hz.

Based on the above review the staff finds that the cross-correlation coefficients, time step, and the duration of the strong motion portion of the time histories meet the guidance in the SRP Section 3.7.1 and thus are acceptable.

Concerning the under-prediction below 0.2 Hz, the applicant identified the sloshing of the water in the Gravity Driven Cooling System Pool and the Isolation Condenser/Passive Containment Cooling Expansion Pools located in the RB/FB are the only responses characterized by frequencies lower than the 0.2 Hz. No other SSCs fall in the frequency range below 0.2 Hz. The applicant also indicated that below the frequency of 0.2 Hz, CSDRS bounds the target spectrum and as such any potential under prediction of the response from site-specific analyses will be bounded by the ESBWR standard plant design. The applicant also indicated that seismic-induced hydrodynamic pressures on the pools associated with convective (sloshing) and impulsive (rigid) modes will be taken to be the larger of the standard design pressures or the North Anna 3 site-specific pressures.

The staff reviewed the Figures 1 through 6 provided in the response to RAI 03.07.01-12 and determined that significant margin exists between the CSDRS and the site-specific target spectrum for RB/FB in the frequency range below 0.2 Hz. Therefore, the staff concludes that the use of time histories which are matched to the site-specific target spectrum in the frequency range between 0.2 Hz to 100 Hz and are under-predicted below the target spectrum at frequencies less than 0.2 Hz is acceptable because (a) at the North Anna 3 site the target response spectra (i.e., final SSI input spectra) is bounded by the CSDRS by a significant margin in the low frequency range and as such (b) seismic-induced hydrodynamic load demands for the Gravity Driven Cooling System Pool and the Isolation Condenser/Passive Containment Cooling Expansion Pools will be bounded by the ESBWR standard plant design envelopes.

The applicant in the FSAR Section 3.7.1.1.5.1.1 described that the characteristics values, i.e., PGV/PGA and PGA*PGD/PGV^2 ratios for the matched time histories, do not fall within the bin values reported in NUREG/CR-6728. The PGA, PGV, and PGD refer to the peak ground acceleration, peak ground velocity, and peak ground displacement, respectively. Since the target spectra used in the spectral matching procedure is a composite of both the high frequency and low frequency earthquakes, the applicant concludes that this difference is acceptable because the time histories are spectrally matched to the final SSI input response spectra, which represent a combination of hazards from both large, distant earthquakes and smaller, closer earthquakes.

The staff further reviewed FSAR Tables 3.7.1-211, 3.7.1-213, 3.7.1-215, 3.7.1-219, and 3.7.1-220, which provided the characteristic values of the matched time histories and the corresponding bin values of the selected seed time histories reported in NUREG/CR-6728. The comparison of the PGV/PGA values of the seed earthquake and the design time histories shows that the design time histories have higher energy content (a greater maximum velocity) and are therefore conservative. The staff further determined that the design input time histories have higher energy content than the FIRS and 0.1 g RG 1.60 spectra. On this basis, the staff found the peak ground motion parameter values associated with the design time histories acceptable.

In response to RAI 03.07.01-12, the applicant performed additional verifications to demonstrate that there are no significant gaps in power for the spectrally matched time histories. To do this, PSDs were calculated for the frequency range of 0.3 to 50 Hz. The PSD plots for the suite of 18 time histories are shown in FSAR Figures 3.7.1-268 through 3.7.1-282 and 3.7.1-292 through 3.7.1-294. The applicant concludes that the PSD functions do not show any significant dip in the frequency content of the input time histories. However, this conclusion was drawn without performing comparison of the estimated PSD functions with some properly developed target PSD. To gain additional confidence on the power adequacy of the time histories, the staff conducted a confirmatory analysis of the 18 time histories by comparing their estimated PSD functions with the target PSDs developed to be compatible with the final SSI input response spectra. Some estimated PSD functions were found to have dips below the 70 percent target PSDs; however, those dips were determined to not significantly affect structural response because they occur outside of the fundamental frequencies of the SSI models. Based on the results of the staff confirmatory analysis, the staff concluded that the spectrally matched time histories are acceptable.

As described in the FSAR Section 3.7.2.4.1.2, based on the method described in DC/COL-ISG-017, the applicant developed in-column motions at the foundation levels of the RB/FB and the CB, and at the bottom of the concrete fill under the FWSC foundation. The in-column motions were developed from the time histories that were spectrally matched to the final SSI input response spectra defined as free-field outcrop response spectra at the foundation levels for the RB/FB and the CB and at the bottom of the concrete fill under the FWSC foundation. In addition, the deterministic SSI strain compatible subsurface profiles (BE, LB, and UB) as discussed before in this SER were used in developing the in-column motions. These in-column motions were used as inputs into the North Anna 3 site-specific SSI analyses described in FSAR Section 3.7.2. This approach is acceptable to the staff because it is consistent with the method described in DC/COL-ISG-17.

Site-Dependent SSE Manifestation At-Grade and OBE Response Spectra

The applicant in the FSAR Section 3.7.1.1.6 established site-dependent SSE manifestation at grade as the envelope of the following two spectra:

1. PBSRS calculated at grade (Elevation 290 ft) from full soil column analyses for RB/FB and CB and,

2. The minimum required response spectra defined as the RG 1.60 broadband horizontal and vertical response spectra at 5 percent damping anchored to 0.1 g.

The site-dependent OBE at grade is defined as one-third of the site-dependent SSE manifestation at grade. The site-dependent SSE manifestation and OBE spectra at grade are shown in the FSAR Figure 3.7.1-267. The staff found the site-dependent SSE manifestation and OBE established at the grade level to be acceptable since (a) they were derived from the PBSRS which is developed following the guidance in RG 1.208 and (b) they meet the requirement of 10 CFR Part 50, Appendix S.

Supplemental Information

- NAPS SUP 3.7-3 Supporting Media for seismic Category I Structures

Supporting Media for Seismic Category I Structures

The applicant stated that the seismic Category I structures for North Anna 3 have concrete mat foundations founded on rock or concrete fill placed on top of rock. FSAR Section 2.5.4.2 describes the static and dynamic engineering properties of the subsurface material at the North Anna 3 site. The dynamic properties used in the SSI analyses are discussed in FSAR Section 3.7.1.1.4.1. The minimum Vs of the supporting foundation material is greater than 1000 ft/sec. The staff determined that this information together with the ESBWR standard plant structural data in the ESBWR DCD, Revision 10, is sufficient per SRP Acceptance Criterion 3.7.1.II.3. The applicant has considered the potential variability of the properties of the subsurface material in the SSI analyses. The staff's review of this information is discussed above in this SER under "*SSI Strain Compatible Soil Properties.*" The staff's evaluation of the site-specific seismic analysis of the seismic Category I structures using the site characteristics described in FSAR Section 3.7.1.1.4.1 is discussed in Section 3.7.2 of this SER.

3.7.1.5 Post Combined License Activities

There are no post COL activities related to this section.

3.7.1.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to the seismic design parameters that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.7.1, other NRC RGs, DC/COL-ISG-017 and DC/COL ISG-1. The staff finds that the applicant has addressed seismic design parameters in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.7.1.3 of this SER.

3.7.2 Seismic System Analysis

3.7.2.1 Introduction

This section addresses the seismic analysis methods and acceptance criteria used for the ESBWR seismic Category I structures. Seismic Category I structures are designed to withstand the effects of the SSE event and to maintain the specified design functions. This section applies to building structures that constitute primary structural systems. The reactor pressure vessel (RPV) is not a primary structural component, but it is considered as part of the RB/FB model for the purpose of dynamic analysis because of its dynamic interaction with the supporting structure. Non-seismic Category I structures (seismic Category II and NS) are designed or physically arranged (or both) to prevent the SSE from causing unacceptable structural interactions with or the failure of seismic Category I SSCs. The ESBWR method for a standard plant seismic analysis of the Category I structures is in Section 3.7.2 of ESBWR DCD, Tier 2, Revision 10.

3.7.2.2 Summary of Application

Section 3.7.2 and Appendices 3A and 3C of the North Anna 3 COL FSAR, Revision 9, incorporate by reference Section 3.7.2 and Appendices 3A and 3C of ESBWR DCD, Revision 10. In addition, in FSAR Section 3.7.2 and Appendices 3A and 3C, the applicant provides the following departure and supplemental information:

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

In North Anna 3 FSAR, Section 3.7.2.2, the applicant described that the natural frequencies of the ESBWR standard plant structures and SSI analyses to develop the seismic demand for the seismic design of the ESBWR standard plant are presented in DCD Appendix 3A, Sections 3A.1 through 3A.9. The site-specific SSI analyses used to develop the site-specific seismic demand for the RB/FB, CB, and FWSC are presented in FSAR Sections 3.7.2.4 and 3A.10 through 3A.19. In FSAR Sections 3C.7.4, 3C.7.6, and 3C.7.7, the applicant describes, respectively, the computer codes SASSI2010, ACS SASSI, and SHAKE2000 used for the North Anna 3 site-specific SSI analysis. The staff reviewed the SSI analyses and the computer programs used in the site-specific analyses as part of its review of FSAR Section 3.7.2.4. The site-specific SSI analysis considers the North Anna 3 site conditions and follows an approach that is consistent with those used for the standard design. The structural models used for the site-specific SSI analyses have the same configuration, stiffness, and the inertia properties as the standard design basis structural models presented in DCD Appendix 3A.

As discussed earlier in this SER, the site-specific horizontal and vertical seismic response spectra as shown in North Anna 3 COL FSAR, Figures 2.0-201 through 2.0-204 exceed the ESBWR CSDRS at certain frequencies. As a result, the applicant has performed site-specific SSI analyses of the RB/FB, CB, and FWSC structures using input ground motion defined by the site-specific FIRS and strain compatible soil properties to establish the site-specific seismic demand. The resulting site-specific seismic demand (e.g., accelerations, enveloping structural loads, and ISRS) is used to demonstrate the applicability of the seismic design of the ESBWR standard design for the North Anna 3 site conditions. This departure is also applicable to the

FSAR Section 3.7.2.8 wherein the applicant addressed site-specific seismic considerations for all NS Category I structures that are within the scope of the standard design.

Supplemental Information

- NAPS SUP 3.7-5 Interaction of Non-Category I Structures with Seismic Category I Structures

The applicant stated that the locations of structures around the North Anna 3 power block area are depicted in the plant layout provided in FSAR Figure 2.1-201 and DCD Figure 1.1-1. In FSAR Section 3.7.2.8, the applicant addresses the requirements for site-specific SSI and seismic structure-soil-structure interaction (SSSI) analyses of non-seismic Category I structures both within and outside the scope of the DCD and including the TB, SB, ancillary diesel building (ADB), and RWB.

- NAPS SUP 3.7-8 Interaction of Non-Category I Structures with Seismic Category I Structures – Radwaste Building

In FSAR Section 3.7.2.8.2, the applicant describes that the RWB exterior walls have a static wall pressure capacity of at least 3 psi. For the RWB, a pressure capacity of 3 psi for the external walls is required to ensure that the safe separation distance of the RWB from the liquid hydrogen storage tanks is maintained.

3.7.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the seismic system analysis and the associated acceptance criteria are in SRP Section 3.7.2. The specific requirements include the following:

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the seismic design basis to reflect appropriate consideration of the most severe earthquakes historically reported for the site and surrounding area with a sufficient margin for the limited accuracy, quantity, and period of time in which historical data have been accumulated. In addition, SSCs important to safety should be designed to withstand the effects of earthquakes without losing the capability to perform their intended safety functions.

- 10 CFR Part 50, Appendix S, as it relates to the horizontal component of the SSE ground motion in the free-field at the foundation level of the structures to be an appropriate response spectrum with a peak ground acceleration of at least 0.1 g; and if the OBE is chosen to be less than or equal to one-third of the SSE ground motion, it is not necessary to conduct explicit response or design analyses in accordance with Section IV.(2)(i)(A) of 10 CFR Part 50, Appendix S, and the requirement of taking into account SSI effects.

In addition, the acceptance criteria and regulatory guidance associated with the review of FSAR Section 3.7.2 include the following:

- SRP Section 3.7.2 guidance to review methods for site-specific seismic analysis and modeling of structures to ensure that they accurately and/or conservatively represent the behavior of SSCs during postulated seismic events.

- DC/COL-ISG-1 and DC/COL-ISG-017 in reviewing the seismic input and the SSI dynamic model acceptability for the North Anna 3 site.

- RG 1.61 to determine the acceptability of the damping values used in the structural model.

- RG 1.122, “Development of Floor Design Response Spectra for Seismic Design of Floor Supported Equipment and Components,” to determine acceptability of development of floor design response spectra for seismic design.

3.7.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.7.2 and Appendices 3A and 3C of the ESBWR DCD. The staff reviewed Section 3.7.2 and Appendices 3A and 3C of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff’s review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the COL FSAR as follows:

<u>Departure</u>

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 related to SSI analyses included under FSAR Section 3.7.2, Appendix 3A and 3C of the North Anna 3 COL FSAR as follows:

<u>Natural Frequencies and responses</u>

The applicant presented information on natural frequencies and SSI responses of seismic Category I buildings under the CSDRS and generic site conditions in DCD Sections 3A.1 through 3A.9, which are incorporated by reference in North Anna 3 COL FSAR. The SSI responses for site-specific conditions are provided in North Anna 3 COL FSAR Sections 3.7.2.4 and 3A.10 through 3A.19. The results of staff’s evaluation of the site-specific SSI analyses are discussed below in this SER.

<u>Soil-Structure Interaction (SSI)</u>

The methodology and the results of the SSI analyses for the ESBWR standard plant seismic Category I buildings are presented in the DCD Section 3.7.2, Appendix 3A and Appendix 3C for a range of soil conditions selected for the ESBWR standard plant design. The CSDRS have been applied as the input ground motion at the building foundation level for the seismic design of the Category I structures included in the DC document. The site-specific horizontal and vertical seismic response spectra as presented in North Anna 3 COL FSAR Figures 2.0-201 through 2.0-204 exhibit exceedances at certain frequencies, when compared to the ESBWR CSDRS. As a result of these exceedances, the applicant in accordance with the requirement of DCD Tier 1, Section 5.1 performed site-specific SSI analyses of the RB/FB, CB, and FWSC structures to establish the site-specific seismic demands. FSAR Section 3.7.2.4 and Sections 3A.10 through 3A.19 present the site-specific SSI analyses of the seismic Category I RB/FB, CB, and FWSC. The staff's evaluation of the site-specific SSI analyses is discussed below:

The staff used the guidance of SRP Section 3.7.2, DC/COL-ISG-1, and DC/COL-ISG-017 in reviewing the site-specific seismic analyses. The applicant used the standard design methodology presented in the DCD to perform the North Anna 3 site-specific SSI/SSSI analyses using the computer programs SASSI2010 and ACS SASSI. The coupled soil-structure models for the SSI analyses are based on the structural models developed from the standard design structural model coupled with site-specific strain compatible dynamic subsurface properties. Specifically, the staff reviewed the methods used in the site-specific seismic analysis to account for SSI and SSSI effects including the verification and validation (V&V) of the computer programs used in the site-specific analysis.

For the RB/FB and the CB, site-specific SSI analyses were performed for two different embedment configurations representing: (1) the RB/FB and CB as being PE up to the Zone III rock nominal top elevation, and (2) the RB/FB and CB being FE up to the finished grade elevation accounting for the site-specific SSI effects of the soil above the Zone III rock. In addition, for each embedment configuration, the applicant used BE, LB, and UB soil column profiles resulting in a total of six subgrade profiles to account for the effects of the potential variability in subgrade properties and the potential soil separation from the foundation walls during an SSE event at the North Anna 3 site. The base case site-specific SSI analyses used RB/FB and CB models with uncracked reinforced concrete properties for the concrete members and 100 percent in-fill concrete stiffness contribution considered for the concrete filled steel internal structures. The envelope of responses obtained from these six analyses represent the base case North Anna 3 site-specific seismic demand. The applicant used the DCD structural models for the RB/FB and CB analysis. The applicant has also performed site-specific sensitivity evaluations of the effects of structural stiffness variations and SSSI on the North Anna 3 site-specific demands. These analyses are documented in FSAR Sections 3.7.2.4, and 3A.10 through 3A.19, and in GEH Reports WG3-U71-ERD-S-0001 Revision 4, "Reactor/Fuel Building Complex Seismic Analysis Report" (ADAMS Accession Nos. ML16097A203 and ML16097A204); and WG3-U73-ERD-S-0001 Revision 2, "Control Building Seismic Analysis Report" (ADAMS Accession Nos. ML15357A305, ML15357A312, and ML15357A313). The applicant has used the envelope of the base case analyses and the results of the sensitivity analyses for site-specific structural analysis and design evaluation of the ESBWR standard plant structures at North Anna 3 site.

For the SSI analysis of the FWSC, the applicant used two analyses configurations representing: (1) the FWSC as a surface founded structure with the input control motions applied at the bottom of the FWSC foundation (Elevation 282 ft), and (2) the FWSC together with the concrete fill below the FWSC foundation basemat as an embedded structure with the input control motions applied at the bottom of the concrete fill (Elevation 220-ft). The base case site-specific SSI analyses used FWSC model with uncracked reinforced concrete properties for the concrete members. The applicant used the DCD structural model for this analysis. The applicant has also performed site-specific sensitivity evaluations of the effects of structural stiffness variations and soil separation. The SSSI effect on the FWSC was included in the North Anna site-specific seismic demand. The staff's evaluation of the two SSI inputs for the FWSC is presented earlier in this SER in Section 3.7.1.4 under heading, *"SSI Input Response Spectra for the FWSC."* FWSC SSI analysis method and results are documented in FSAR Sections 3.7.2.4, and 3A.10 through 3A.19 and in GEH Reports WG3-U63-ERD-S-0001, Revision 4, "Firewater Service Complex Seismic Analysis Report" (ADAMS Accession No. ML16148A131).

The staff conducted two on-site seismic audits at the applicant's contractor GEH office in Wilmington, North Carolina. In the first audit during the week of September 28, 2015 (hereinafter referred to as North Anna 3 Audit 1), the staff reviewed the North Anna 3 seismic demand evaluation including the supporting calculations (ADAMS Accession No. ML16064A271). In the second audit held during the week of March 21, 2016 (hereinafter referred to as North Anna 3 Audit 2), the staff reviewed the applicant's evaluation of the structural design for North Anna 3 site-specific seismic demand (ADAMS Accession No. ML16193A047). During North Anna 3 Audit 1, the staff also reviewed calculations pertaining to the V&V of the computer program used in the site-specific SSI and SSSI analyses. The staff's evaluation of the computer program V&V documents are described later in this SER Section 3.7.2.4 under the heading of *"Verification and Validation of SASSI 2010 and ACS SASSI and Bench marking of the MSM."*

Based on its review, the staff confirmed that the applicant addressed the site-specific effects of the SSSI between the ESBWR seismic Category I structures on the site-specific seismic demand obtained from the SSI analysis. The staff reviewed the site-specific SSSI sensitivity evaluations between the RB/FB and CB as well as between the FWSC and CB. The site-specific SSSI evaluations are performed on combined models of the two buildings considering the presence of the structural and concrete fill materials in the interspace between the buildings. Site-specific evaluations of the effects of SSSI between the RB/FB and CB and between the FWSC and CB are documented respectively in GEH Reports WG3-U73-ERD-S-0005, Revision 3, "Control Building and Reactor/Fuel Building Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A271) and WG3-U73-ERD-S-0002, Revision 6, "Control Building and Firewater Service Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A270).

The various SSI and SSSI case analyses performed by the applicant are summarized in the FSAR Tables 3A.15-201 through 3A.15-206. In these tables, DM and MSM refer to the "Direct Method" and "Modified Subtraction Method" of the SASSI2010/ACS SASSI program, respectively (See the discussion below in this SER Section 3.7.2.4 under "*SSI Analysis Method.*"). The staff finds the applicant's consideration of the SSI and SSSI analyses cases acceptable because as shown in these FSAR Tables cited above, in establishing the site-specific seismic demand, the applicant has considered analysis cases to account for the effects of the potential variabilities in the properties of the soil and rock at the site, soil separation, potential stiffness variation of the structures, and SSSI in accordance with SRP Section 3.7.2.II.4.

Strain Compatible Dynamic Subsurface Material Properties

The site-specific SSI analyses considered the three site-specific subsurface material profiles (BE, LB, and UB) for the in-situ materials, structural fill and concrete fill, which are documented in FSAR Tables 3.7.1-201 through 3.7.1-206. The staff finds these profiles acceptable because they are determined to be consistent with design ground motion based on the staff-approved

2013 Ground Motion Model (GMM) and also properly account for the effects of the potential variability in the properties of the soils and rocks at the North Anna 3 site. The development of three deterministic site-specific soil profiles are consistent with the SRP Acceptance Criterion 3.7.2.II.4. The staff further reviewed selected portions of the North Anna 3 calculations and reports pertaining to the development of strain compatible dynamic subsurface material properties during North Anna 3 Audit 1 and confirmed that the approach used by the applicant is consistent with the staff guidance. The staff's detailed review of the above information is in Section 3.7.1.4 of this SER.

The staff also performed a confirmatory analysis to assess the adequacy of the method that the applicant used for calculating the log-standard deviations from the simulated low frequency profiles and the high frequency profiles. These simulated profiles were results of the applicant's probabilistic site response analysis. The log-standard deviations are used to determine the LB and UB soil profiles. The staff confirmatory analysis showed that the results were very similar to those the applicant provided. The staff also determined that the reason for this good agreement in the results from the two different methods is that the low frequency soil profiles and the high frequency profiles are very similar. As such, the staff found that the method used by the applicant to determine the standard deviation for use in calculating the LB and UB soil profiles is acceptable.

The staff finds the strain compatible dynamic subsurface material properties acceptable based on the conclusion in Section 3.7.1.4 of this SER and the conclusion of the staff confirmatory evaluation described above.

Ground Motion Time Histories

As discussed earlier in this SER in Section 3.7.1, for the RB/FB and CB, two sets of three statistically independent acceleration time histories (i.e., two horizontal and one vertical component) are developed for the full column and partial column final SSI input response spectra. For the FWSC, two sets of three statistically independent acceleration time histories (i.e., two horizontal and one vertical component) are developed for the final SSI input response spectra applied at the foundation level of the FWSC (Elevation 282 ft) and at the bottom of the concrete fill below the FWSC (Elevation 220 ft). The staff finds that these ground motion time histories are acceptable for the site-specific SSI analyses performed by the applicant since they were developed in accordance with the guidance in SRP Section 3.7.1 and were confirmed through a staff confirmatory analysis regarding their power adequacy for the frequencies of interest to the structural responses. The staff's detailed review of the above information is in Section 3.7.1.4 of this SER.

SSI Analysis Method

The applicant performed site-specific SSI analyses following the methodology in ESBWR DCD, Tier 2, Section 3A.5.2, which is based on the frequency domain complex response approach using the SASSI 2000 program. Structural responses were computed in terms of maximum absolute accelerations, relative displacements, maximum forces and moments, and ISRS at the key locations in the structures identified in ESBWR DCD, Tier 2, Appendix 3A, as well as seismic lateral soil pressures acting on below-grade exterior walls (seismic soil pressures are reviewed in Section 3.8.4.4 of this SER). The use of the frequency domain complex response approach for site-specific SSI analysis is acceptable to the staff because it is the same methodology applied in the ESBWR DCD and is consistent with SRP Acceptance Criterion 3.7.2.II.4.

The staff, however, noted that the applicant used the SASSI 2010 and ACS SASSI programs in the North Anna 3 site-specific SSI analysis instead of the SASSI 2000 program that was used for the ESBWR DCD. The applicant performed V&V analyses to ensure the acceptability of the SASSI 2010 and ACS SASSI programs for use in the site-specific SSI analyses for the North Anna 3 site. The staff's review of the applicant's V&V of the SASSI programs is described below under the heading, *"Verification and Validation of SASSI 2010 and ACS SASSI and Benchmarking of the MSM."* As concluded there, the use of the SASSI 2010 and the ACS SASSI programs is acceptable for the North Anna 3 site-specific application.

To perform the SSI analysis of embedded structures such as the RB/FB and the CB, the SASSI programs may use the DM ("Direct Method," also known as the "Flexible Volume Method"), the MSM (Modified Subtraction Method), or the SM ("Subtraction Method"). The DM is the numerically accurate but also the most computationally intensive method. The SM, if not implemented properly, could potentially result in erroneous and non-conservative SSI responses when compared to the DM.

FSAR Section 3A.14 indicates that the site-specific SSI analyses were performed using either the DM or the MSM, but not the SM. Current staff guidance regarding the use of the DM versus the MSM is provided in SRP Section 3.7.2, Revision 4 and Acceptance Criterion 3.7.2.II.4. Although the guidance states that the DM should be used to the extent practical, the MSM is also identified as an alternative for very large computer models where it is not feasible to use the DM. The guidance recommends the use of reduced-size computer models (e.g., half/quarter models) to perform direct comparisons between the MSM and the DM solutions and to draw conclusions that can be extrapolated to the full-size models.

For this reason, the staff in RAI 03.07.02-26, requested the applicant to demonstrate the adequacy of the MSM for the North Anna 3 application. In response to RAI 03.07.02-26 (ADAMS Accession No. ML15222A240), the applicant performed additional benchmark studies to include both LB and UB North Anna 3 soil profiles. The result of the bench marking analyses is contained in GEH Report SER-DMN-011, Revision 1, "Benchmarking of SASSI2010 MSM Results from NA3 Site-Specific Analysis" (ADAMS Accession No. ML15222A283). During North Anna 3 Audit 1, the staff reviewed the Benchmarking and other relevant technical reports and confirmed that the analyses results obtained from the MSM are essentially identical to those obtained from the DM analysis for the frequency range of interest to the North Anna 3 site conditions. Based on the review of the results of the Benchmark studies performed by the applicant, the staff concluded that the use of the MSM is acceptable for site-specific SSI analyses at the North Anna 3 site.

SSI Analysis Structural Models

Site-Specific Design Basis RB/FB SSI model

FSAR Section 3A.16 describes the SSI models used for the site-specific SSI analyses. Details of the site-specific design basis SSI model of the RB/FB are described in the GEH Report WG3-U71-ERD-S-0001, Revision 4, "Reactor/Fuel Building Complex Seismic Analysis Report" (ADAMS Accession Nos. ML16097A203 and ML16097A204). The site-specific RB/FB SSI model is shown in FSAR Figures 3A.16.3-201 through 3A.16.3-209. It is based on the three-dimensional lumped-mass stick model that was used for the standard design seismic response analysis in the DCD, which considers shear, bending, torsion, and axial deformations of the building. Single-degree-of-freedom (SDOF) oscillators connected to the stick models are used to represent the significant out-of-plane modes of flexible slabs and walls in the building. The RB/FB lumped-mass stick model is shown in the DCD Figure 3A.7-4. The stick models and the SDOF oscillators used in the site-specific base case SSI models are therefore acceptable because they are the same as those used in the ESBWR DCD for the same purpose and they are consistent with SRP Acceptance Criterion 3.7.2.II.3.C.iii.

The coupled soil-structure SASSI 2010 models used for the site-specific SSI analysis of the RB/FB are shown in the FSAR Figures 3A.16.3-201 through 3A.16.3-204 for the PE model and in Figures 3A.16.3-205 through 3A.16.3-209 for the FE model. The site-specific SSI model of the RB/FB differs from the standard design model in that: (a) the meshing of the below grade portion of the model is modified to match the layering and stiffness properties of the North Anna 3 subgrade, (b) near-field subgrade elements are included in the structural model to represent the structural fill and concrete fill materials surrounding the RB/FB, (c) the lower OBE damping value is used to conservatively reflect the dissipation of energy in the structures, and (d) the rigid massless outriggers are installed at each floor elevation to facilitate calculation of ISRS and displacements at floor edges. A minimum value of 3.13 m is used for the lateral extent of the near-field concrete and structural fill elements for the RB/FB model. Because of the limited lateral extent of the fill material, the staff found the applicant's method of modeling the concrete and structural fill as the near-field structural elements acceptable. Detailed staff evaluation of the item (b) above concerning lateral extent of the near-field elements used in the SSI model is provided in Section 3.7.1.4 of this SER.

The site-specific base case model for the structural portion of the RB/FB consists of the DCD RB/FB stick model based on the uncracked concrete properties, which represents the upper bound stiffness properties of the structural elements. Along with these upper bound stiffness properties, the applicant also assigned lower OBE damping values for the structural members. The use of the OBE damping values reflects lower dissipation of energy in the structures resulting in conservative seismic response determination. Sensitivity analysis to consider concrete cracking was also performed by the applicant and is evaluated later in this section. Therefore, per guidance in SRP Sections 3.7.1 and 3.7.2, and in RG 1.61, the use of uncracked section properties and OBE damping is conservative and thus acceptable for RB/FB base case model.

The exterior walls below grade and the foundation basemat are modeled using plate elements similar to the SASSI model used for the standard design RB/FB SSI analysis except that the vertical and horizontal spacing of the elements were adjusted to closely match the site-specific subsurface profile layers and to address model passing frequencies. Brick elements were used to model the near-field structural fills and the excavated soil volume for the FE and PE structures. To ensure that the dynamic response of the site-specific SSI model is adequate for the frequency range of interest, the applicant adjusted the mesh size of the below-grade portion of the model to ensure that both the horizontal and vertical mesh dimensions do not exceed 20 percent of the length of the shear wave passing through the soil material at the highest frequency of interest. In addition, the aspect ratio of the plate and brick finite elements used in the mesh should not exceed 1:4, which is validated by the applicant in V&V of SASSI 2010 program documented in GEH Report SER-DMN-020, Revision 1, "Validation Summary Report for SASSI 2010 and Appendix with Validation Problems for RAI 03.07.02-10/RAI 03.07.02-26

Response" (ADAMS Accession No. ML15222A280). Per DC/COL-ISG-1, the passing frequency of the SSI models should be at least 50 Hz.

As stated in the FSAR Section 3A.16.3.1 and GEH Report WG3-U71-ERD-S-0001, Revision 4, the maximum aspect ratio of the finite element mesh in the RB/FB embedded models is 1:3.5. The staff finds that this ratio to be acceptable since it does not exceed the aspect ratio limit (1:4) validated in the SASSI 2010 V&V analysis. The staff's evaluation of the SASSI 2010 V&V for North Anna 3 is provided in this SER under the heading *"Verification and Validation of SASSI 2010 and ACS SASSI and Benchmarking of the MSM."* The staff reviewed the finite element meshes of the RB/FB excavated volumes depicted in FSAR Figures 3A.16.3-203 and 3A.16.3-207 and the corresponding passing and cut-off frequencies shown in FSAR Table 3A.15-201. The passing frequencies are calculated based on both the maximum horizontal and vertical dimensions of the excavated volume elements and the near-field elements. The staff concluded that the mesh sizes meet the 50 Hz criteria identified above except for the SSI analysis cases corresponding to the LB full column subsurface profile. For these LB full column cases, the staff found that the passing frequency of the SSI models is 33 Hz and thus deviates from the guidance in DC/COL-ISG-1.

The staff's assessment, however, concluded that the deviation from the guidance identified above is not a concern for the following reasons:

1. The site-specific seismic responses computed for the UB subsurface profile are more susceptible to the higher frequency content of input motions above 33 Hz. These are accurately captured in the analyses because they are based on SSI models that have the required 50 Hz passing frequency.

2. The reduced passing frequency for the SSI analyses with LB full column subsurface profile reflects an insufficient mesh/layer refinement in the soil layers and near-field structural backfill elements of the model only—the mesh/layer dimensions in the rock portions below the soil layers are adequate.

3. The review of site-specific seismic responses in the structures computed from the SSI analyses of the LB full column cases indicates that these cases only bound results for the ISRS envelopes at frequencies below 9 Hz, which is 24 Hz lower than the passing and cutoff frequency 33 Hz, as stated in FSAR Section 3A.15.

4. The reduced passing frequency for the LB full column SSI analyses does not affect the seismic lateral soil pressures computed for these cases because the soil pressures are mainly the result of the low frequency responses (i.e., below 33 Hz).

According to the SRP Acceptance Criterion 3.7.2.II.4, for deep soil sites, the subsurface profile model depth generally should be at least twice the base dimension below the foundation level, which should be verified by parametric studies. For the RB/FB, the staff noted that the model depth below the foundation level is approximately two times the footprint dimension of the RB/FB. Since the computed seismic response may be sensitive to the location of the half-space interface selected, further justification was needed for the model depth selected. As discussed in FSAR Section 3A.16.3.1 and further documented in Appendix H of the GEH Report WG3-U71-ERD-S-0001, Revision 4, the applicant performed sensitivity studies to demonstrate that the lower boundary of the RB/FB site/rock model does not affect the results of SSI analysis. The staff reviewed the results of the sensitivity analysis and confirmed that the selected total depths of the site models used for the site-specific SSI analyses are appropriate and achieve sufficient accuracy of the site-specific SSI analysis results.

The applicant performed site-specific foundation uplift evaluation of RB/FB to show that the ground contact ratio is equal to or greater than 80 percent so that the linear SASSI SSI analyses are acceptable. The 80 percent criterion is provided in SRP Section 3.7.2. The analyses included four combinations of the possible directions of the input motion to consider the non-symmetric effect of the RB/FB model in the east-west (EW) direction. The minimum base contact ratio was determined to be associated with the case of the UB full column subgrade profile. During North Anna 3 Audit 1, the staff reviewed the methods for calculation of basemat uplift, and noted that the stress contours of the basemat showed that uplift occurred only along the exterior walls for RB/FB, which did not appear to be realistic for reinforced concrete structures with a thick basemat and interior walls. A further review of this issue revealed that the RB/FB SSI model does not have interior walls connected to the basemat shell model. This modeling simplification is considered to be adequate for determining the SSI responses (e.g., structural response, ISRS, etc.) because there are rigid beams connecting the super structure (lumped mass stick model (LMSM)) to the exterior walls (shell elements) at all basement floor levels above the top of the basemat. However, because the basemat was modeled as shell elements without the interior walls, which would have increased the out-of-plane stiffness of the basemat, the shell model representation of the basemat is much more flexible than the real basemat construction. Therefore, the staff requested the applicant to perform uplift evaluation to consider the effect of the interior walls.

As discussed in FSAR Section 3A.17.12.5, the applicant performed additional uplift analyses of RB/FB by assuming a rigid foundation as a bounding case. The analyses were based on a closed-form solution from the theory of elasticity using the results of the vertical base reaction and overturning moments obtained from the SSI analyses. The UB partial column and UB full column profiles were identified as critical cases based on results shown in Table 3A.17.12.5-201. The results show that a rigid foundation assumption leads to a minimum base contact ratio of 97.2 percent which is larger than those estimated based on flexible foundation models. The staff finds that the method for the additional uplift evaluation is acceptable and the linear SASSI SSI analyses are acceptable because the potential uplift of the RB/FB was found to be within the 80 percent ground contact ratio limit as recommended in SRP Section 3.7.2, Revision 4.

For the RB/FB, the applicant has performed site-specific sensitivity evaluations of the effects of structural stiffness variation. In addition, potential soil separation from the RB/FB structure is considered through the SSI analysis of partial soil column cases which do not include the softer in-situ saprolite and structural fill material above the Zone III rock. The evaluation considers the effect of concrete cracking on the response of the reinforced concrete members and the out-of-plane vibrations of the flexible slabs and walls. The staff's evaluation of the sensitivity studies including the models used in the analyses are discussed later in this SER Section 3.7.2.4 under the headings of "*Effect of Structural Stiffness Variations on Site-Specific Results"* and *"Soil Separation Analysis."*

Based on the above evaluation, the staff finds that the site-specific design basis SSI model of RB/FB described in FSAR Section 3A.16.3.1 meets the SRP Acceptance Criteria 3.7.2.II.3 and 3.7.2.II.4 and is therefore acceptable.

Site-specific Design Basis CB SSI model

The site-specific design basis CB SSI model is shown in FSAR Figures 3A.16.3-210 through 3A.16.3-213 for the PE model and in FSAR Figures 3A.16.3-214 through 3A.16.3-217 for the FE model. The connection between CB stick model and foundation is shown in the FSAR Figure 3A.16.3-218. Details of the site-specific design basis SSI model of the CB are described in the FSAR Section 3A.16.3.2 and in GEH Report WG3-U73-ERD-S-0001, Revision 2, "Control Building Seismic Analysis Report" (ADAMS Accession Nos. ML15357A305, ML15357A312, and ML15357A313). The CB lumped-mass stick model used in the site-specific CB SSI model is the same model used for the standard design seismic response analysis in the ESBWR DCD, which considers shear, bending, torsion, and axial deformations of the CB. This model is shown in the ESBWR DCD, Figure 3A.7-6 and designated in the ESBWR DCD Table 3A.6-1 as the "base" model. SDOF oscillators connected to the stick models are used to represent the out-of-plane seismic response of flexible slabs in the buildings. The lumped-mass stick model and the SDOF oscillators used in the site-specific CB SSI models are therefore acceptable because they are the same as those used in the ESBWR DCD for the same purpose and they are consistent with SRP Acceptance Criterion 3.7.2.II.3.C.

The site-specific SSI model of the CB differs from the standard design model in that: (a) the meshing of the below grade portion of the model is modified to match the layering and stiffness properties of the North Anna 3 subgrade, (b) near-field subgrade elements are included in the structural model to represent the fill materials (structure and concrete fills) surrounding and below the CB, (c) the lower OBE damping value is assigned to the uncracked concrete members for the purpose of generating site-specific design basis ISRS, and (d) the rigid massless outriggers are installed at each floor elevation to facilitate calculation of ISRS and displacements at floor edges. The staff's evaluation of the above differences between the DCD and the site-specific CB model is discussed below:

The staff reviewed the coupled soil-structure SSI base model of the CB and agreed with the applicant that the adjustment of the meshing of the below-grade portion of the model would be necessary to match the site-specific subsurface profile layers and to address model passing frequencies. A minimum value of 3.13 m is used for the lateral extent in representing the near-field subgrade elements (concrete and structural fill elements) for the CB model. Because of the limited extent of the fill material, as discussed in Section 3.7.1.4 of this SER, the staff found the applicant's method of modeling the concrete and structural fill as the near-field structural elements acceptable. The applicant assigned OBE damping values for the CB model for developing the site-specific ISRS and assigned the SSE damping value for determining the site-specific seismic demand for the CB. The staff finds the method of assigning the OBE and SSE damping values to the CB model to be acceptable since the method is in accordance with the guidance in SRP Sections 3.7.1 and 3.7.2 and in RG 1.61.

SASSI2010 CB model included approximately 4.91 m of fill concrete below the CB foundation bottom as part of the structural model. The input control motion for the CB, however, was established at the bottom of CB foundation instead of the bottom of the fill concrete. To address the potential impact of defining the SSI input control motion at the CB foundation bottom, the applicant in response to RAI 03.07.02-11 (ADAMS Accession No. ML15056A047) presented a comparison of Design Response Spectra for the CB full column and partial column profile at two different elevations (CB foundation bottom and the bottom of fill concrete). The staff reviewed the comparison provided in the response to RAI 03.07.02-11 and concluded that the results do not show any shift in the frequency content of the input or reductions of the high frequency amplitudes during upward propagation of the seismic waves. Therefore, the staff found application of the CB SSI input control motion at the CB foundation bottom acceptable.

The exterior walls below-grade and the foundation basemat are modeled using plate elements similar to the SASSI model used for the standard design CB SSI analysis except that the vertical and horizontal spacing of the elements were adjusted to closely match the site-specific subsurface profile layers and to address model passing frequencies. Solid brick elements were used to model the excavated soil volume for the FE and PE structures. To ensure that the dynamic response of the site-specific SSI model is adequate for the frequency range of interest, the applicant adjusted the mesh size of the below-grade portion of the model to ensure that both the horizontal and vertical mesh dimensions do not exceed 20 percent of the length of the shear wave passing through the soil material at the desired frequency of interest. In addition, the aspect ratio of the plate and brick finite elements used in the mesh should not exceed 1:4 for both the plate and brick elements as validated by the applicant in their V&V of SASSI2010 program documented in the GEH Report SER-DMN-020, Revision 1 In accordance with DC/COL-ISG-1, the passing frequency of the SSI models should be at least 50 Hz.

As stated in the FSAR Section 3A.16.3.2 and GEH Report WG3-U73-ERD-S-0001, Revision 2, “Control Building Seismic Analysis Report” (ADAMS Accession Nos. ML15357A305, ML15357A312, and ML15357A313) the maximum aspect ratio of the finite element mesh in the CB embedded models is 1:1.9. The staff finds this ratio to be acceptable since it did not exceed the aspect ratio limit (1:4) validated in the SASSI2010 V&V analysis.

The staff reviewed the finite element meshes of the CB excavated volumes depicted in FSAR Figures 3A.16.3-212 and 3A.16.3-216 and the corresponding passing and cut-off frequencies shown in FSAR Table 3A.15-202. The passing frequencies are calculated based on both the maximum horizontal and vertical dimensions of the excavated volume mesh and the near-field meshes. The staff concluded that the mesh sizes meet the 50 Hz criteria identified above except for the SSI analysis cases corresponding to the LB full column subsurface profile. For these LB cases, the staff found that the passing frequency of the SSI models is approximately 34 Hz and thus deviates from the guidance in DC/COL-ISG-1.

The staff’s assessment, however, concluded that the deviation from the guidance identified above is not a concern and does not affect the results for the following reasons:

1. The site-specific seismic responses computed for the UB subsurface profile are more susceptible to the higher frequency content of input motions above 34 Hz. These are accurately captured in the analyses because they are based on SSI models that have the required 50 Hz passing frequency.

2. The reduced passing frequency for the SSI analyses with LB full column subsurface profile reflects an insufficient mesh/layer refinement in the soil layers and near-field structural backfill elements of the model only; the mesh/layer dimensions in the rock portions are adequate.

3. The review of site-specific enveloping ISRS responses in the structures computed from the SSI analyses of the LB and BE full column cases indicates that above 18 Hz, these cases are bounded by the other case analyses that have the required 50 Hz passing frequency, as stated in FSAR Section 3A.15. This is because SSI effects at the North

Anna 3 site are dominated by the interaction between the structures and the rock in which they are embedded.

4. The reduced passing frequency for the LB SSI analyses does not affect the seismic lateral soil pressures computed for these cases because the soil pressures are mainly the result of the low frequency responses (i.e., below 34 Hz).

The site-specific base model for the structural portion of the CB consists of the ESBWR DCD CB stick model based on the uncracked concrete properties which represents the upper bound stiffness properties of the concrete structural elements. Along with these upper bound stiffness properties, the applicant also assigned lower OBE structural damping values for the development of the ISRS. The use of the OBE damping values reflects lower dissipation of energy in the structures and ensures that the ISRS peaks envelope the condition when the corresponding stresses in the structure are lower. For development of the site-specific seismic structural load demands, foundation uplift, and stability evaluations, the applicant used the CB base model (with uncracked concrete properties) with the SSE structural damping values. In accordance with the guidance in the RG 1.61 and SRP Section 3.7.2, the staff found the applicant's use of OBE structural damping values for developing ISRS and use of the SSE damping values for developing the structural seismic demand for the CB acceptable. The staff also found the use of SSE damping values for evaluating the potential of foundation uplift and seismic stability acceptable because these cases represent the limiting stress conditions associated with large seismic demand and the resulting foundation reactions are consistent with the structural load demand.

According to the SRP Acceptance Criterion 3.7.2.II.4, the model depth generally should be at least twice the base dimension below the foundation level which should be verified by parametric studies. For the CB, the staff found that the model depth below the foundation level of the CB is more than 88 m, which exceeds two times the maximum footprint dimension (about 30.3 m) of the CB. Based on staff's review earlier of the sensitivity studies performed by the applicant for the RB/FB as documented in Appendix H of the GEH Report WG3-U71-ERD-S-0001, Revision 4, the staff agreed with the applicant's conclusion that the selected total depths of the CB site models used for the site-specific SSI analyses does not affect the results.

The applicant performed site-specific foundation uplift evaluation of CB to show that the ground contact ratio is greater than 80 percent so that the linear SASSI SSI analyses are acceptable. The 80 percent criterion is specified in SRP Section 3.7.2. During North Anna 3 Audit 1, the staff reviewed the methods for calculation of basemat uplift, and as discussed in Section heading, "*Site-Specific Design Basis RB/FB SSI model,*" of this SER, the staff identified a similar issue regarding the appropriateness of the CB foundation model for the uplift calculation.

Therefore, the applicant performed alternative uplift calculations for the CB foundation in Appendix H of the GEH Report WG3-U73-ERD-S-0001, Revision 2. The applicant performed two sets of analyses of the CB PE model by: (1) adding rigid beams in the middle of the CB basemat to account for the effect of the in-plane stiffness of the interior wall on the CB foundation overall stiffness, and (2) assuming a rigid foundation. Appendix H of WG3-U73-ERD-S-0001, Revision 2, also indicates that adding rigid beams to the SSI model had no effect on the critical time that the maximum uplift occurred in the analysis and had very small effect on the estimate of eccentricity, but significantly affected the base stress distribution. The alternative foundation uplift calculations indicated that models with higher overall stiffness for the foundation predicted a reduction in the minimum base contact area, which is less than 80 percent. In particular, the analysis of the more realistic model that accounted for the effect of interior wall showed that the minimum contact ratio was 73 percent for a very short duration of 0.02 seconds. Since the calculation predicted a minimum contact ratio less than the guidance of SRP Section 3.7.2, the applicant provided further justification of the acceptability of the linear CB SSI analysis in the FSAR Section 3A.17.13.5. The applicant stated that the alternative uplift calculations were based on very conservative assumptions which considered the groundwater buoyancy pressure applied uniformly at the bottom of the CB foundation. The actual permeability of the concrete fill supporting the CB foundation is very small and insufficient to generate the assumed uniform buoyancy pressure. In addition, the uplift calculation based on PE configuration neglected the effect of subgrade located above the Zone III rock. Under a more realistic FE condition, additional analysis showed that the CB rigid foundation remained in full contact. In addition, the analysis based on the conservative assumptions showed that the larger uplifts (greater than 20 percent) of the CB basemat are infrequent with very short duration to have an effect on the seismic response of the CB structure.

The staff reviewed the results of alternative analyses performed by the applicant and found the applicant's justification for accepting CB SSI analyses results based on linear elastic SSI model acceptable because: (1) the assumed full permeability of the concrete to result in the full upward ground water buoyancy pressure at the interface between the CB basemat and underlying concrete fill would be unlikely, (2) the applicant's analysis of more realistic, FE conditions indicated that the CB rigid foundation remained in full contact for the entire duration of the ground motion, and (3) the larger uplift (greater than 20 percent) of the CB basemat based on conservative assumptions were infrequent within a very short duration to have any effect on the seismic response.

For the CB, the applicant has performed site-specific sensitivity evaluations of the effects of structural stiffness variation and the site-specific effects of SSSI. The evaluation considers the effect of concrete cracking on the response of the reinforced concrete members and the out-of-plane vibrations of the flexible slabs. The staff's evaluation of the sensitivity studies including the models used in the analyses are discussed in this SER under the headings of "*Effect of Structural Stiffness Variations on Site-Specific Results,*" *"SSSI Analysis,"* and *"Soil Separation Analysis."*

Based on the above evaluations, the staff finds that the site-specific design basis SSI model of CB described in FSAR Section 3A.16.3.2 meet the SRP Acceptance Criteria 3.7.2.II.3 and 3.7.2.II.4 and is therefore acceptable.

Site-specific Design Basis FWSC SSI model:

The coupled soil-structure SASSI2010 models used for site-specific SSI analysis of the FWSC are shown in the FSAR Figures 3A.16.3-219 through 3A.16.3-221. Details of the site-specific design basis SSI model of the FWSC are described in the FSAR Section 3A.16.3.3 and in the GEH Report WG3-U63-ERD-S-0001, Revision 4, "Firewater Service Complex Seismic Analysis Report" (ADAMS Accession No. ML16148A131). The FWSC SSI model is a half model with symmetric and antisymmetric boundary conditions based on the lumped-mass stick model shown in DCD Figure 3A.7-7 which considers shear, bending, torsion, and axial deformations of the structural members and is designated in the DCD Table 3A.6-1 as the "base" model. SDOF oscillators connected to the stick models are used to represent the out-of- plane seismic response of flexible slabs. The stick models and the SDOF oscillators used in the site-specific

SSI models are therefore acceptable because they are the same as those used in the ESBWR DCD for the same purpose and they are consistent with SRP Acceptance Criterion 3.7.2.II.3.C.iii.

The site-specific SSI model of the FWSC differs from the standard design model in that: (a) the model is modified to add the meshing of the below-grade portion that matches the layering and stiffness properties of the North Anna 3 subgrade, (b) a block of near-field solid elements embedded in the in-situ soil and rock is used to model the concrete fill placed below the FWSC basemat, (c) the lower OBE damping value is assigned to the uncracked concrete members for the purpose of generating site-specific design basis ISRS, and (d) rigid outriggers are installed at each floor elevation to facilitate calculation of ISRS and displacements at floor edges. The staff's evaluation of the above differences between the DCD and the site-specific FWSC model is discussed below:

As discussed in Section 3.7.1.4 under "*SSI Input Response Spectra for the FWSC*" of this SER, the staff found the representation of the concrete fill below the FWSC basemat as an integral part of the structural model acceptable because the applicant used two sets of site-specific SSI input with control motions defined at the bottom of the FWSC foundation (Elevation 282 ft) and at the bottom of the concrete fill (Elevation 220 ft). The applicant assigned OBE damping values for the FWSC model for developing the site-specific ISRS. The SSE damping values were assigned for determining other site-specific seismic demand for the FWSC. The staff finds the method of assigning the OBE and SSE damping values to the FWSC model to be acceptable since it is in accordance with the guidance in SRP Sections 3.7.1 and 3.7.2 and in RG 1.61.

The foundation basemat is modeled using plate elements similar to the SASSI model used for the standard design SSI analysis. Solid brick elements were used to model the excavated soil volume as well as the concrete fill for the embedded portion. To ensure that the dynamic response of the site-specific SSI model is adequate for the frequency range of interest, the applicant adjusted the mesh size of the below-grade portion of the model to ensure that both the horizontal and vertical mesh dimensions do not exceed 20 percent of the length of the shear wave passing through the soil material at the highest frequency of interest. In addition, the aspect ratio of the plate and brick finite elements used in the mesh should not exceed 1:4 for both the plate and brick elements as validated by the applicant in their V&V of SASSI2010 program documented in the GEH Report SER-DMN-020, Revision 1, "Validation Summary Report for SASSI 2010" (ADAMS Accession No. ML15222A280). Per DC/COL-ISG-1, the passing frequency of the SSI models should be at least 50 Hz.

As stated in the FSAR Section 3A.16.3.3 and GEH Report WG3-U63-ERD-S-0001, Revision 4, the maximum aspect ratio of the plate elements for the basemat mesh in the FWSC SSI model is 1:1.4 and the maximum aspect ratio of the 3-D solid brick elements is 1:2.9. The staff finds that these ratios are acceptable since they do not exceed the aspect ratio limit (1:4) validated in the SASSI2010 V&V analysis.

The staff reviewed the finite element mesh of the FWSC excavated soil volume depicted in FSAR Figure 3A.16.3-220 and the corresponding passing and cut-off frequencies shown in FSAR Table 3A.15-203. The passing frequencies are calculated based on both the maximum horizontal and vertical dimensions of the excavated volume. The staff concluded that the mesh sizes meet the 50 Hz criteria identified above except for the SSI analysis cases corresponding to the LB subsurface profiles as shown in FSAR Table 3A.15-203. For these LB cases, the staff found that the passing and cut-off frequency of the SSI models is 36 Hz and thus deviates from the guidance in DC/COL-ISG-1.

The staff's assessment of this deviation from the guidance, however, concluded that this deviation identified above is not a concern and does not affect the results for the following reasons:

1. The site-specific seismic responses computed for the UB subsurface profile are more susceptible to the higher frequency content of input motions above 36 Hz. These are accurately captured in the analyses because they are based on SSI models that have the required 50 Hz passing frequency.

2. The reduced passing frequency for the SSI analyses with LB subsurface profile reflects an insufficient mesh/layer refinement in the soil layers of the model only; the mesh/layer dimensions in the rock portions are adequate.

3. The review of site-specific seismic responses in the structures computed from the SSI analyses of the LB cases indicates that these cases only bound the ISRS envelopes for certain frequency ranges below 25 Hz, which is 11 Hz lower than the passing and cutoff frequency of 36 Hz, as stated in FSAR Section 3A.15. This is related to the fact that SSI effects at the North Anna 3 site are dominated by the interaction between the structures and the rock in which they are embedded.

The site-specific base model for the structural portion of the FWSC consists of the DCD FWSC stick model based on the uncracked concrete properties, which represents the upper bound stiffness properties of the concrete structural elements. Along with these upper bound stiffness properties, the applicant also assigned lower OBE structural damping values for the development of the ISRS. The use of the OBE damping values reflects lower dissipation of energy in the structures and ensures that the ISRS peaks envelope the condition when the corresponding stresses in the structure are lower. For development of the site-specific seismic structural load demands, foundation uplift, and stability evaluations, the applicant used the FWSC base model (with uncracked concrete properties) with the SSE structural damping values. In accordance with the guidance in the SRP Sections 3.7.1 and 3.7.2 and in RG 1.61, the staff found the applicant's use of OBE structural damping values for developing ISRS and use of the SSE damping values for developing the structural seismic demand for the FWSC acceptable. The staff also found the use of SSE damping values for evaluating the potential of foundation uplift and seismic stability acceptable because these cases represent the limiting stress conditions associated with large seismic demand and the resulting foundation reactions are consistent with the structural load demand.

According to the SRP Acceptance Criterion 3.7.2.II.4 for deep soil sites, the subsurface profile model depth generally should be at least twice the base dimension below the foundation level, which should be verified by parametric studies. For the FWSC, the staff found that the model depth below the foundation level of the FWSC (about 123 m) is greater than two times the maximum footprint dimension (about 52 m) of the FWSC basemat. Based on staff's review earlier of the sensitivity studies performed by the applicant for the RB/FB as documented in Appendix H of the GEH Report WG3-U71-ERD-S-0001, Revision 4, the staff agreed with the applicant's conclusion that the selected total depth of the FWSC site models used for the site-specific SSI analyses does not affect the results.

Unlike the RB/FB and the CB, the structural fill around the concrete block below the FWSC basemat was considered as part of the in-situ soil and not included as the near-field element in the FWSC SSI model. The staff found this representation to be acceptable because: (a) the properties of the in-situ soil and structural fill around the FWSC are similar as shown in the FSAR Figure 3A.12.2-203, (b) any potential effect of this representation has been captured by the FWSC-CB SSSI analysis since the structural fill is included in the combined FWSC-CB SSSI model, and (c) the FWSC site-specific design basis seismic demand is developed based on the envelope of the results obtained from site-specific SSI analyses of FWSC stand-alone model and SSSI analyses of FWSC-CB combined model.

As discussed in FSAR Section 3A.17.14.4, the applicant performed site-specific foundation uplift evaluation of FWSC to show that the ground contact ratio is equal to or greater than 80 percent so that the linear SASSI SSI analyses are acceptable. The 80 percent ground contact ratio criterion is recommended in SRP Section 3.7.2. During North Anna 3 Audit 1, the staff reviewed supporting calculations related to the FWSC uplift evaluation and confirmed that the SSI model used for the FWSC uplift evaluation is acceptable because the basemat is modeled in a manner that represents the actual structure.

For the FWSC, the applicant has performed site-specific sensitivity evaluations which consider the effect of concrete cracking, soil separation along the upper portion of the concrete block below the FWSC foundation, and SSSI on the response of the FWSC and the out-of-plane vibrations of the flexible slabs. The staff's evaluation of the sensitivity studies including the models used in the analyses are discussed in this SER later under the headings of "*Effect of Structural Stiffness Variations on Site-Specific Results," "SSSI Analysis,"* and *"Soil Separation Analysis."*

Based on the above evaluations, the staff finds that the site-specific design basis SSI model of FWSC described in FSAR Section 3A.16.3.3 meet the SRP Acceptance Criteria 3.7.2.II.3 and 3.7.2.II.4 and is therefore acceptable.

SSI Analyses Cases

The SSI analyses cases for the North Anna 3 site, performed by the applicant, are summarized in FSAR, Revision 9, Tables 3A.15-201 through 3A.15-206 for the RB/FB, CB, and the FWSC. In addition, the FSAR Tables include the North Anna 3 site-specific sensitivity analyses cases which evaluate the effect of structural stiffness variation, soil separation, and SSSI on the site-specific seismic demand. These analysis cases account for the potential variability in the site-specific soil/rock properties by considering three (LB, UB, and BE) subsurface material properties. For the RB/FB and the CB, the site-specific effect of subgrade stiffness variation related to embedment, ground water, and the layering effect of in-situ soils were accounted for by considering two embedment configurations: (1) full soil column subgrade profile and (2) partial soil column subgrade profile as discussed earlier in this SER. For the FWSC, two sets of SSI analyses were performed; one with the control motion applied at the bottom of the basemat and the other with the control motion applied at the bottom of concrete fill below the FWSC foundation, were performed. Finally sensitivity studies were performed to account for, in the SSI analysis results, the effects of the potential stiffness variation in the structural members, soil separation, and SSSI. For the FWSC, the FWSC-CB SSSI together with FWSC SSI analysis cases form the basis for the site-specific seismic demand.

The staff concludes that the SSI and SSSI cases summarized in FSAR Tables 3A.15-201 through 3A.15-206 provide sufficient information for the staff to determine the acceptability of the site-specific seismic demand at the North Anna 3 site for the Category I structures.

SSI Analysis Results – Transfer Functions

GEH Reports WG3-U71-ERD-S-0001, Revision 4, "Reactor/Fuel Building Complex Seismic Analysis," WG3-U73-ERD-S-0001, Revision 2, "Control Building Seismic Analysis," and WG3-U63-ERD-S-0001, Revision 4, "Firewater Service Complex Seismic Analysis," document the transfer functions computed for the site-specific SSI analyses. These reports present results for the following key locations as identified in DCD Appendix 3A:

- RB/FB: top of basemat, refueling floor, reinforced concrete containment vessel (RCCV) top slab, top of vent wall, top of reactor shield wall (RSW), top of RPV.
- CB: top of basemat and top of roof slab.
- FWSC: FWS wall top, FWS base, Fire Pump Enclosure (FPE) top, FPE base.

The staff reviewed the transfer function plots and found them to be generally smooth, with a sufficient density of calculated frequency points in the frequency range of interest. Although some isolated sharp spikes were noted in a few of the plots because of the interpolation scheme used by the SASSI 2010 program, these spikes had no observable impact on the ISRS or other seismic responses as described in FSAR Section 3A.14.2. During North Anna 3 Audit 1, the staff further reviewed supporting calculations for assessing the effect of the spurious peaks in some of the SASSI transfer functions on structural responses as discussed below:

To address the issue, as described in FSAR Section 3A.14.2, the applicant performed additional SASSI analyses with frequencies added near the numerical anomalies for the following cases:

- For RB/FB: UC100 model for LB, BE, UB partial columns; UC100 model LB, BE, UB full columns; CR00 and CR50 models for LB full column
- For CB: UC_OBE full columns
- For FWSC: UC_OBE full columns with input at Elevation 220 ft
- For CB-FWSC: UB full column

The staff confirmed the additional frequencies in the SASSI analyses did not result in any significant effect on the seismic responses during North Anna 3 Audit 1. Therefore, the staff concludes that the interpolated transfer functions are acceptable and the site-specific SSI analyses performed by the applicant with the SASSI 2010 program were implemented in a manner consistent with the frequency domain complex response method described in ESBWR DCD, Tier 2, Appendix 3A.

SSI Analysis Results – Maximum Structural Loads

FSAR Section 3A.17 describes the North Anna 3 site-specific SSI analysis results for the various SSI analyses cases presented in the FSAR Tables 3A.15-201 through 3A.15-206 for the RB/FB, CB, and the FWSC. This FSAR section also describes the results of the site-specific sensitivity studies to address the effects of structural stiffness variation, SSSI, and soil separation from the foundation walls or concrete fill. The applicant compared the results of the site-specific SSI and SSSI analysis of the RB/FB, CB, and FWSC with the standard seismic design envelopes presented in DCD Section 3A.9. The applicant followed the DCD method to develop the site-specific seismic demands for the RB/FB, CB, and FWSC. The applicant provided these comparisons of site-specific enveloping seismic demand for North Anna 3 Category I structures with the DCD envelope in the FSAR Section 3A.18.1.

RB/FB Site-Specific Seismic Load Demand

FSAR Tables 3A.18.1.1-201a through 3A.18.1.1-201f present the envelope of the maximum site-specific seismic forces and moments in the various stick models of the RB/FB complex obtained from the site-specific SSI analysis cases as tabulated in FSAR Table 3A.15-201 and compare these to the corresponding values in the ESBWR DCD. The adequacy of these analysis cases is evaluated above in this SER under the heading of "*SSI Analyses Cases.*" FSAR Tables 3A.18.1.1-203 and 3A.18.1.1-204 present the site-specific enveloping out-of-plane seismic load demands on the RB/FB flexible slabs and walls obtained from the site-specific SSI analyses and the staff compared these to the corresponding values in the ESBWR DCD. FSAR Section 3A.18.1.1 also includes the envelope of the maximum accelerations in the different stick models of the RB/FB complex and the staff compared these to the corresponding design values used in the standard design. The staff reviewed these results and the supporting calculations during North Anna 3 Audit 1 and concluded that the method used in establishing the site-specific seismic demand is consistent with the DCD methodology and is in accordance with the SRP Section 3.7.2 guidance. The SASSI computer programs used to develop the site-specific seismic demand were verified and validated. The staff also determined that site-specific seismic load demands in some instances for the RB/FB exceeded the corresponding loads used for the standard design of the RB/FB structures. The applicant has performed a site-specific evaluation of RB/FB structures using the site-specific seismic demands presented in FSAR Section 3A.18.1.1 that bound the effects of full/partial soil columns and structural stiffness variations to address the exceedances in seismic loads. The staff's assessment of the effect of structural stiffness variations on the site-specific seismic demand is discussed later in this SER Section 3.7.2.4 under the heading of **"***Effect of Structural Stiffness Variations on Site-Specific Results."* The staff's assessment of the site-specific evaluation of the standard design of the RB/FB is documented in this SER in Section 3.8.4.

CB Site-Specific Seismic Load Demand

The applicant followed the method used to develop the standard design enveloping maximum structural loads in developing the structural loads representative of the site-specific seismic demands on the CB. FSAR Table 3A.18.1.2-201 presents the maximum site-specific seismic forces and moments in the stick model of the CB obtained from the site-specific SSI analyses with the upper bound stiffness properties and SSE damping and compare these enveloping loads to the corresponding values in the ESBWR DCD. FSAR Table 3A.18.1.2-203 presents the site-specific out-of-plane seismic load demands on the CB flexible slabs and compare these to the corresponding values in the ESBWR DCD. The staff reviewed and confirmed these results and the supporting calculations during the North Anna 3 Audit 1 and concluded that the method used in establishing the site-specific seismic demand is consistent with the ESBWR DCD methodology and the SRP Section 3.7.2 guidance. The staff also determined that the site-specific seismic load demands for the CB exceeded the corresponding loads used for the standard design of the CB structures. As stated in the FSAR Section 3A.18.1.2, the applicant has performed a site-specific evaluation of the CB structures using the site-specific seismic demands presented in FSAR 3A.18.1.2 that bound the effects of full/partial soil columns and structural stiffness variations. The staff's assessment of the effect of structural stiffness variations on the site-specific seismic demand is discussed later in this SER Section 3.7.2.4 under the heading of **"***Effect of Structural Stiffness Variations on Site-Specific Results."* The staff's assessment of site-specific evaluation of the standard design of the CB is documented in this SER in Section 3.8.4.

FWSC Site-Specific Seismic Load Demand

The applicant followed the method used to develop the standard design enveloping maximum structural loads in developing the structural loads representative of the site-specific seismic demands on the FWSC. The site-specific North Anna 3 enveloping seismic demand on the FWSC are developed as an envelope of the results for maximum member forces and moments from the SSI and SSSI analyses of the FWSC standalone and the FWSC-CB combined SSSI models with uncracked stiffness properties and SSE damping using deep control motion applied at the bottom of the concrete fill at Elevation 220 ft. The analysis with deep control motion yields maximum responses that envelope the results with input motion applied at the surface.

FSAR Table 3A.18.1.3-201 presents the North Anna 3 enveloping seismic demand (member forces and moments) for the FWSC. This FSAR Table also presents the comparison of site-specific seismic demand with standard design enveloping maximum member forces for the FWSC. Table 3A.18.1.3-202 presents the maximum site-specific accelerations at different FWSC lumped mass locations and compare them to the corresponding design values used in the standard design. FSAR Tables 3A.18.1.3-203 and 3A.18.1.3-204 present, respectively, a comparison of the site-specific maximum accelerations of FWSC SDOF oscillators and site-specific out-of-plane load on FWS roof with those of the ESBWR standard plant design. Table 3A.18.1.3-205 presents the site-specific lateral loads on the FWSC shear keys as well as a comparison of these loads with the corresponding standard design values. The staff reviewed and confirmed these results and the supporting calculations during North Anna 3 Audit 1 and concluded that the method used in establishing the site-specific seismic demand is consistent with the DCD methodology and is in accordance with the SRP Section 3.7.2 guidance. The staff also determined that the site-specific seismic load demands in some instances for the FWSC exceeded corresponding loads used for the standard design of the FWSC structures. The applicant has performed a site-specific evaluation of the FWSC structures using the site-specific seismic demands presented in FSAR 3A.18.1.3 that bound the effects of structural stiffness variations, the effect of soil separation, and the SSSI effect of the CB on FWSC. The staff's assessment of site-specific evaluation of the standard design of the FWSC is documented in this SER in Section 3.8.4.

SSI Analysis Results – Site-Specific Design ISRS

The site-specific SSI analyses cases are summarized in FSAR Table 3A.15-201 for the RB/FB, Table 3A.15-202 for the CB, and 3A.15-203 for the FWSC. To account for the variability in the subsurface material properties, BE, LB, and UB profiles were considered. Each analysis case consists of input motions in three orthogonal directions. The site-specific acceleration response spectra (ARS) are developed for responses at the edges of the building by taking into account coupling effects between the three directional input motions. The ARS for nodal responses due to the three input motions are combined using the SRSS method. Floor ISRS are obtained for particular floor elevations as the envelope of ARS at the four outrigger locations. FSAR Figures 3A.17.12.3-201 through 3A.17.12.3-204 present the site-specific ISRS for RB/FB, FSAR Figures 3A.17.13.3-201 through 3A.17.13.3-203 present the site-specific ISRS for CB, and FSAR Figures 3A.17.14.3-201 through 3A.17.14.3-203 present the site-specific ISRS for FWSC at the key locations of the buildings. The ISRS presented in the referenced figures of FASR 3A.17 above are obtained from the site-specific design basis SSI analyses of models with upper bound stiffness properties. Also presented there are comparisons of the site-specific ISRS with the corresponding standard design ISRS. The individual ISRS obtained from the SSI analyses cases are then enveloped. The final site-specific ISRS is calculated by (+)15 percent and (-)15 percent broadening the enveloped ISRS. Details of the development of the ISRS are provided in GEH Reports WG3-U71-ERD-S-0001, Revision 4 for the RB/FB, GEH Report WG3-U73-ERD-S-0001, Revision 2 for the CB, and GEH Report WG3-U63-ERD-S-0001, Revision 4 for the FWSC. The applicant presented the enveloping site-specific design ISRS in the FSAR Figures 3A.18.2-201 through 3A.18.2-203 for RB/FB, CB, and the FWSC.

For the RB/FB and CB, the site-specific design ISRS represent the ISRS results from site-specific SSI analyses of RB/FB and CB model with upper bound stiffness properties and OBE damping (analysis cases 1 to 6 in Table 3A.15-201 for RB/FB and Table 3A.15-202 for CB). These site-specific ISRS are peak broadened and valley filled, and enhanced to bound effects of structural stiffness variations and SSSI as described in FSAR Section 3A.18.2.

Site-specific ISRS for the FWSC represent the envelope of ISRS results from: (1) the site-specific SSI analyses of the FWSC standalone model with uncracked stiffness properties and OBE damping (analysis cases 1 to 6 in FSAR Table 3A.15-203) and (2) site-specific SSSI analysis of the FWSC-CB combined model with uncracked stiffness properties and OBE damping (cases FC1 to FC6 in FSAR Table 3A.15-206). The staff noted that these site-specific design ISRS for the FWSC already include the site-specific SSSI effects of the CB on FWSC response. The FWSC ISRS are also enhanced to bound effects of structural stiffness variations and soil separation as described in FSAR 3A.18.2.

The staff reviewed and confirmed the method of development of the site-specific ISRS and the site-specific ISRS results as presented in the FSAR Sections 3A.17 and 3A.18 and supporting calculations presented during North Anna 3 Audit 1. Based on staff's review of the comparisons provided in the FSAR, the staff concludes that the site-specific ISRS exceed the corresponding standard design ISRS at some frequencies. The applicant stated that the exceedances are addressed in the site-specific evaluation of the standard design. The staff found the method of developing the site-specific ISRS to be acceptable because the method is in accordance with the guidance in the SRP Section 3.7.2 and the RG 1.122.

The applicant has performed sensitivity studies to evaluate the effect of structural stiffness variations, SSSI, and soil separation on the site-specific design envelope ISRS. The site-specific design ISRS for the RB/FB, CB, and FWSC in general envelope the results of the various sensitivity analyses with few exceedances. The staff reviewed the methodology used to address exceedances in the site-specific design ISRS due to the sensitivity studies including the acceptance criteria in FSAR sections 3A.17 and 3A.18, and found them acceptable. The staff's evaluation of the effect of sensitivity studies are discussed below in this SER.

Effect of Structural Stiffness Variations on Site-Specific Results

RB/FB Structural Stiffness Variation Sensitivity Studies

The applicant in the response to RAI 03.07.02-14 (ADAMS Accession No. ML15222A240), stated that site-specific sensitivity evaluations of the effects of structural stiffness variation on the SSI response of the RB/FB have been performed. They are described in the FSAR Section 3A.17.9.1 and in the Appendix B of the GEH Report WG3-U71-ERD-S-0001, Revision 4, "Reactor/Fuel Building Complex Seismic Analysis Report" (ADAMS Accession Nos. ML16097A203 and ML16097A204). As discussed earlier, the site-specific SSI analysis used a RB/FB model with uncracked reinforced concrete properties for the concrete members and 100 percent stiffness contribution of the concrete inside the steel plates for steel internal structures (referred in this report as UC100 model). The analysis was performed for three subsurface profiles and two embedment configurations (analysis cases 1 through 6 in FSAR Table 3A.15-201). The analyses used OBE damping values. The envelope of responses obtained from these six analyses cases constitutes the North Anna 3 site-specific base case seismic demand used for site-specific design and design evaluation of the RB/FB at North Anna 3 site. To evaluate the effect of potential concrete cracking, the applicant performed site-specific sensitivity SSI analyses of models with reduced stiffness properties and SSE damping (analysis cases S1 through S12 in FSAR Table 3A.15-201) and compared the results with those of the North Anna 3 site-specific demand.

The applicant performed the sensitivity analyses of the following two reduced stiffness models:

- CR00: fully cracked reinforced concrete structures with 50 percent reduced shear and bending stiffness along with no (0 percent) contribution of in-fill concrete to the stiffness of the concrete-filled steel structures (VW and D/F); and

- CR50: fully cracked reinforced concrete structures with 50 percent reduced shear and bending stiffness along with 50 percent contribution of in-fill concrete to the stiffness of the concrete-filled steel structures (VW and D/F).

The analyses of CR00 and CR50 models were performed for LB, BE, and UB soil profiles for the two embedment configurations (PE and FE). The CR00 and CR50 models used SSE damping values to be consistent with the cracked concrete assumption. The applicant has used the guidance in ASCE 43-05 to establish the stiffness reduction factors for cracked concrete members, which are in accordance with the SRP Section 3.7.2 guidance.

The staff reviewed Appendix 3A of the FSAR for the modeling approach for the cracked and uncracked cases and the models used by the applicant in the sensitivity analyses for the stiffness variations and found them acceptable because: (a) the method is consistent with the approach used for the standard design, (b) the method is consistent with the guidance in SRP Section 3.7.2, (c) the sensitivity analyses accounted for concrete cracking with the combined effects of the potential variation of the subsurface soil profiles along with the two embedment configurations, and (d) the use of SSE damping for the cracked models is consistent with the high stress conditions that the RB/FB structure would be subjected to during a fully cracked concrete condition.

SDOF oscillators connected to the stick models are used to represent the out-of-plane seismic response of flexible slabs and walls in the buildings. The staff confirmed that SDOF oscillators used in the UC100 model described in the FSAR Section 3A.16 are identical to those of the standard design models. Therefore, the staff finds these models used to capture the out-of-plane vibration mode up to 50 Hz for models with uncracked concrete are acceptable.

Since cracking of the concrete reduces the out-of-plane bending stiffness of the walls and slabs, the frequencies of out-of-plane vibration would be lowered due to cracking. Therefore, the staff requested the applicant in RAI 03.07.02-14(f) to confirm that the frequency ranges of the oscillators selected for the UC100 model are still adequate to capture the out-of-plane seismic response of the walls and slabs for the North Anna 3 site conditions. In the response to RAI 03.07.02-14(f) (ADAMS Accession No. ML15222A240), the applicant, besides applying the 50 percent reduction to the stiffness of all existing SDOF oscillators in the UC100 model, added additional oscillators to the CR00 and CR50 models to capture the modes of out-of-plane vibration of the cracked slabs and walls up to a frequency of 50 Hz. The FSAR Figure 3A.16.2-201 shows the configuration of the CR00 and CR50 stick models with the additional SDOF oscillators shown in red. The development of these additional SDOF oscillators under fully cracked conditions is described in the GEH Report SER-DMN-014, Revision 1, “Additional Oscillators for Fully Cracked Model for RAI 3.7.2-14(f)” (ADAMS Accession No. ML15170A188).

The staff reviewed the information provided in the FSAR Section 3A.17.9 and the GEH Report SER-DMN-014 and found the site-specific representation of the out-of-plane flexibilities of walls and slabs under a cracked condition acceptable because: (a) the applicant added additional oscillators to represent all modes of vibration up to 50 Hz under fully cracked condition, and (b) the additional SDOF oscillators were developed using the same method and eigenvalue analysis that were used for standard design.

In FSAR 3A.17.9.1, Revision 9, the applicant concluded that the site-specific design basis SSI analyses of the UC100 Model with uncracked concrete stiffness and OBE damping provide site-specific seismic demand (loads and ISRS) that envelope concrete cracking effects with few exceptions (e.g., see FSAR Table 3A.17.9.1-201 and Figure 3A.17.9.1-201). The applicant also indicated that the enveloping base case site-specific seismic load demands and site-specific design ISRS are adjusted to bound effects of structural stiffness variations as described in FSAR Section 3A.18.1 and 3A.18.2, respectively. The staff found the applicant’s approach to address any exceedances in the site-specific seismic demand (structural load) due to sensitivity studies for the concrete cracking acceptable because the site-specific seismic demand is enhanced where necessary to address the observed exceedances.

For the site-specific design ISRS, the applicant, however, stated that the North Anna 3 site-specific design and qualification of equipment and components will use enhanced ISRS that envelope all significant (>10 percent) peak exceedance of the site-specific design ISRS observed in the results of the sensitivity analysis cases for concrete cracking at frequencies below 50 Hz. The staff requested the applicant to provide a technical justification for establishing a significance level of 10 percent exceedance in developing the enhanced site-specific design ISRS for equipment and component in the pre-audit public meeting dated September 10, 2015 (ADAMS Accession No. ML15267A062).

The applicant in FSAR Section 3A.17.9 provided justification of using the 10 percent criteria. The applicant stated that sensitivity analysis for concrete cracking is very conservative since the analysis used 50 percent reduction in flexural and shear stiffness for all concrete elements throughout the entire structure. If the SSE were to occur, cracking will be limited in the vicinity of the highly stressed elements only and many concrete elements will not crack. Therefore the use of a significance level of 10 percent for enhancing the ISRS is justified. Staff found this basis acceptable because the use of the 50 percent reduction in flexural and shear stiffness for all concrete elements is very conservative since the cracking will be limited only to highly stressed elements. Therefore, the staff found the applicant's approach to address any exceedances (>10 percent) in the site-specific ISRS due to sensitivity studies for the concrete cracking acceptable because the site-specific ISRS is modified where necessary to address the observed exceedances greater than 10 percent.

The staff reviewed the results of the North Anna 3 site-specific evaluation presented in the responses to RAIs 03.07.02-14 and 03.07.02-17 as well as the supporting documents during North Anna 3 Audit 1 and North Anna 3 Audit 2 (ADAMS Accession No. ML16193A047) to verify that the effect of the stiffness variation studies on the North Anna 3 site-specific demand for the RB/FB has been considered. The North Anna 3 site-specific seismic demands including the effects of base case, concrete cracking, and soil separation are described in FSAR Section 3A.18. FSAR Section 3A.18.1.1 presented the site-specific seismic load demand for the RB/FB structures that are based on the envelope of the base case analyses results further adjusted to bound the effect of stiffness variation. Also presented there are the comparison of the site-specific demand with the standard design. Specifically, the staff verified during North Anna 3 Audit 2 that the applicant used the enveloping site-specific seismic demand in evaluating the ESBWR standard plant structures for acceptability at the North Anna 3 site. Staff's evaluation of the ESBWR standard plant structures for the site-specific demand is described in this SER in Section 3.8.

CB Structural Stiffness Variation Sensitivity Studies

The applicant in response to RAI 03.07.02-14 (ADAMS Accession No. ML15222A240) stated that site-specific sensitivity evaluations of the effects of structural stiffness variation on the SSI response of the CB have been performed. They are described in the FSAR Section 3A.17.9.2 and in the Appendix B of the GEH Report WG3-U73-ERD-S-0001, Revision 2, "Control Building Seismic Analysis Report." The site-specific SSI analysis used a CB model with uncracked reinforced concrete properties for the concrete members using the OBE damping values (referred here as the UC_{OBE} model) for determining the North Anna 3 site-specific ISRS demand and SSE damping values (referred here as the UC_{SSE} model) for determining the North Anna 3 site-specific structural load demand. These analyses cases are shown in the FSAR Table 3A.15-202 as analysis cases 1 to 12. The analysis was performed for three subsurface profiles and two embedment configurations. The envelope of responses obtained from these analyses cases constitutes the North Anna 3 site-specific base case seismic demand used for site-specific design and design evaluation of the CB at the North Anna 3 site. To evaluate the effect of potential concrete cracking, the applicant performed site-specific sensitivity SSI analyses of models with reduced stiffness properties and SSE damping (referred here as CR_{SSE} model). These sensitivity analysis cases are shown in the FSAR Table 3A.15-202 as analysis cases S1 through S6. The effect of the concrete cracking on the CB site-specific structural load demand is evaluated by comparing the enveloping seismic load demand obtained from the analysis of the UC_{SSE} models with those obtained from the analysis of the CR_{SSE} models. The effect of concrete cracking on the CB site-specific ISRS is evaluated by comparing the 5 percent damped ISRS results obtained from the analysis of the UC_{OBE} models with those obtained from the analysis of the CR_{SSE} models.

The analyses of CR_{SSE} models were performed for LB, BE, and UB soil profiles for the two embedment configurations (PE and FE). The applicant has used the guidance in ASCE 43-05 to establish the stiffness reduction factors for cracked concrete members which is in accordance with the SRP Section 3.7.2 guidance.

The staff reviewed the modeling approach for the cracked and uncracked cases and the models used by the applicant in the sensitivity analyses for the stiffness variations and found them acceptable because: (a) the method is consistent with the approach used for the standard design (b) the method is consistent with the guidance in SRP Section 3.7.2, (c) the sensitivity analyses accounted for concrete cracking with the combined effects of the potential variation of the subsurface soil profiles along with the two embedment configurations, and (d) the use of SSE damping for the cracked models is consistent with the high stress conditions that the CB structure would be subjected to during a fully cracked concrete condition.

SDOF oscillators connected to the stick models are used to represent the out-of- plane seismic response of flexible slabs and walls in the buildings. In accordance with the ESBWR DCD, use of the SDOF oscillators in the UC_{OBE} and UC_{SSE} models described in the FSAR Section 3A.16 is acceptable to capture the out-of-plane vibration mode up to 50 Hz. Since cracking of the concrete reduces the out-of-plane bending stiffness of the walls and slabs, the frequencies of out-of-plane vibration would be lowered due to cracking. Therefore, the staff requested in RAI 03.07.02-14(f) that the applicant confirm that the frequency ranges of the existing oscillators are still adequate to capture the out-of-plane seismic response of the walls and slabs for the North Anna 3 site conditions. In the response to RAI 03.07.02-14(f) (ADAMS Accession No. ML15222A240), the applicant, besides applying the 50 percent reduction to the stiffness of all existing SDOF oscillators in the UC_{OBE} and UC_{SSE} models, added additional oscillators to the CR_{SSE} models to capture the modes of out-of-plane vibration of the cracked slabs up to a frequency of 50 Hz. FSAR Figure 3A.16.2-202 shows the configuration of the CR_{SSE} stick models for the CB with the additional SDOF slab oscillators shown in red. The development of these additional SDOF oscillators under fully cracked conditions is described in the GEH Report SER-DMN-014, Revision 1. No SDOF oscillators are added to the CR_{SSE} models to represent the out-of-plane vibrations of cracked wall since the fully cracked wall frequencies are above the 50 Hz range.

The staff reviewed the information provided in the FSAR Section 3A.17.9 and the GEH Report SER-DMN-014 and found the site-specific representation of the out-of-plane flexibilities of the slabs under a cracked condition for the CB acceptable because: (a) the applicant added additional oscillators to represent all modes of slab vibration up to 50 Hz under fully cracked condition, and (b) the additional SDOF oscillators were developed using the same method and eigenvalue analysis that were used for the standard design.

In FSAR 3A.17.9.2, Revision 9 the applicant concluded that the site-specific design basis SSI analyses of the CB Model with uncracked concrete stiffness and SSE damping provide site-specific seismic load demand that envelope concrete cracking effects with few exceptions of local out-of-plane loads on some CB slabs (e.g., see FSAR Table 3A.17.9.2-201). The applicant indicated that the enveloping site-specific seismic load demands and site-specific design ISRS are adjusted to bound effects of structural stiffness variations. The applicant also stated that North Anna 3 site-specific design and qualification of equipment and components will use enhanced ISRS that envelope all significant (>10 percent) peak exceedance of site-specific design ISRS observed in the results of the sensitivity analysis cases at frequencies below 50 Hz. As discussed earlier in this SER, the staff found the use of 10 percent criteria for enhancing the design ISRS to be acceptable. The staff found the applicant's approach described in FSAR 3A.18.1.2 and 3A.18.2 to address any exceedances in the site-specific seismic demand due to sensitivity studies for the concrete cracking acceptable because the site-specific seismic demand is modified where necessary to address the observed exceedances.

The staff further reviewed the results of the North Anna 3 site-specific evaluation presented in the responses to RAI 03.07.02-14 as well as the supporting documents during North Anna 3 Audit 1 and North Anna 3 Audit 2 to verify that the effect of the stiffness variation studies on the North Anna 3 site-specific demand for the CB has been considered. The site-specific demand based on the upper bound stiffness and OBE and SSE damping values provide site-specific seismic demands on the CB that in general envelope the effect of structural stiffness variations with some exceedances. Only the local out-of-plane loads on some of the CB slabs exceed the loads obtained from the analyses of the CB model with full stiffness and SSE damping as shown on FSAR Table 3A.17.9.2-201. There are small sharp peak exceedances observed in some of the SDOF oscillator ISRS. The staff reviewed the methodology of addressing ISRS exceedances as discussed above and found them acceptable.

The North Anna 3 site-specific seismic demands including the effects of base case, SSSI, concrete cracking, and soil separation are described in FSAR Section 3A.18. FSAR Section 3A.18.1.2 presented the site-specific seismic load demand for the CB structures that are based on the envelope of the base case analyses results further adjusted to bound the effect of stiffness variation. Also presented, is a comparison of the site-specific demand with that of the standard design. Specifically, the staff verified during North Anna 3 Audit 2 that the applicant used the enveloping site-specific seismic demand in evaluating the ESBWR standard plant CB structures for acceptability at the North Anna 3 site. The staff's evaluation of the ESBWR standard plant CB structures for the site-specific demand is described in this SER in Section 3.8.4.

FWSC Structural Stiffness Variation Sensitivity Studies

The applicant in the response to RAI 03.07.02-14 (ADAMS Accession No. ML15222A240) stated that site-specific sensitivity evaluations of the effects of structural stiffness variation on the SSI response of the FWSC have been performed. They are described in the FSAR Section 3A.17.9.3 and in the Appendix B of the GEH Report WG3-U63-ERD-S-0001, Revision 4, "Firewater Service Complex Seismic Analysis Report" (ADAMS Accession No. ML16148A131). The site-specific SSI analysis used a FWSC model with uncracked reinforced concrete properties for the concrete members using the OBE damping values (referred here as UC_{OBE} model) for determining the North Anna 3 site-specific ISRS demand and SSE damping values (referred here as UC_{SSE} model) for determining the North Anna 3 site-specific structural load demand. These analyses cases are shown in the FSAR Table 3A.15-203 as analysis cases 1 to 9. The analysis was performed for three subsurface profiles with the two input control motions, one applied at the bottom of the FWSC basemat at Elevation 282 ft and the other applied at the bottom of the concrete fill located at Elevation 220 ft. The UC_{SSE} model was analyzed only for the deep control motion applied at the bottom of the concrete fill because the use of UC_{SSE} with Elevation 220 ft motion was based on comparison of results of the UC_{OBE} models with motion applied at the two different elevations.

The envelope of responses obtained from appropriate combinations of these analyses cases constitutes the North Anna 3 base case for the site-specific seismic demand of the FWSC. The ISRS envelopes are based on six UC_{OBE} cases and load demand envelopes are based on three UC_{SSE} cases.

To evaluate the effect of potential concrete cracking, the applicant performed site-specific sensitivity SSI analyses of models with reduced stiffness properties and SSE damping (referred to here as CR_{SSE} model). These analysis cases are shown in the FSAR Table 3A.15-203 as analysis cases S1 through S6. The effect of the concrete cracking on the FWSC site-specific structural load demand is evaluated by comparing the enveloping seismic load demand obtained from the analysis of the UC_{SSE} models with those obtained from the analysis of the CR_{SSE} models. The effect of concrete cracking on the FWSC site-specific ISRS is evaluated by comparing the 5 percent damped broadened and valley filled ISRS results obtained from the SSI analysis of the UC_{OBE} models with those obtained from the analysis of the CR_{SSE} models.

The analyses of CR_{SSE} models were performed for BE, LB, and UB soil profiles for both the surface control motion applied at the FWSC basemat and the deep control motion applied at the bottom of the concrete fill. The applicant has used the guidance in ASCE 43-05 to establish the stiffness reduction factors for cracked concrete members, which is in accordance with the SRP Section 3.7.2 guidance.

The staff reviewed the modeling approach for the cracked and uncracked cases and the models used by the applicant in the sensitivity analyses for the stiffness variations and found them acceptable because: (a) the method is consistent with the approach used for the standard design, (b) the method is consistent with the guidance in SRP Section 3.7.2, (c) the sensitivity analyses accounted for concrete cracking with the combined effects of the potential variation of the subsurface soil profiles along with the two input control motions, and (d) the use of SSE damping for the cracked models is consistent with the high stress conditions that the FWSC structure would be subjected to during a fully cracked concrete condition.

According to the DCD, SDOF oscillators connected to the stick models are used to represent the out-of-plane seismic response of flexible slabs and walls in the buildings. Therefore, the use of SDOF oscillators in the UC_{OBE} and UC_{SSE} models are acceptable to capture the out-of-plane vibration mode up to 50 Hz for models with uncracked concrete. The staff reviewed the issue of SDOF oscillators for cracked-concrete models for the FWSC and confirmed that, as in the case of RB/FB and CB, the applicant decreased the stiffness properties of existing oscillator and added additional oscillators to the CR_{SSE} model to capture the modes of out-of-plane vibration of the cracked slabs up to a frequency of 50 Hz. FSAR Figure 3A.16.2-203 shows the configuration of the CR_{SSE} stick models for the FWSC with the additional SDOF slab oscillators shown in red. The development of these additional SDOF oscillators under fully cracked conditions is described in the GEH Report SER-DMN-014, Revision 1, "Additional Oscillators for Fully Cracked Model for RAI 3.7.2-14(f)." No SDOF oscillators are added to the CR_{SSE} models to represent the out-of-plane vibrations of cracked wall because the fully cracked wall frequencies are above the 50 Hz range.

The staff reviewed the information provided in the FSAR Section 3A.17.9 and the GEH Report SER-DMN-014 and found the site-specific representation of the out-of-plane flexibilities of the slabs under a cracked condition for the FWSC acceptable because: (a) the applicant added additional oscillators to represent all modes of slab vibration up to 50 Hz under fully cracked condition, and (b) the additional SDOF oscillators were developed using the same method and eigenvalue analysis that were used for the standard design.

The staff reviewed the results of the North Anna 3 site-specific evaluation presented in the response to RAI 03.07.02-14 and the supporting documents during North Anna 3 Audit 1 to verify that North Anna 3 site-specific demand with upper bound stiffness and OBE/SSE damping values provide site-specific seismic demands on the FWSC that envelop the effect of structural stiffness variations. FSAR Sections 3A.18.1.3 and 3A.18.2 respectively present the approach used for enhancing the site-specific base case seismic load demand and the ISRS to account for the effect of SSSI, concrete cracking, and soil separation. Specifically, the staff verified during North Anna 3 Audit 2 that the applicant used the enhanced site-specific seismic demand in evaluating the ESBWR standard plant FWSC structures for acceptability at the North Anna 3 site. Staff's evaluation of the ESBWR standard plant FSWC structures for the site-specific demand is described in this SER in Section 3.8.4.

SSSI Analysis

To ensure that the site-specific seismic design basis envelopes the site-specific effects of SSSI, the staff requested in RAI 03.07.02-16 (ADAMS Accession No. ML14156A460), that the applicant provide in the FSAR an evaluation of the site-specific effect of SSSI on the North Anna 3 site-specific seismic demand. In the response to RAI 03.07.02-16 (ADAMS Accession No. ML15222A240), the applicant performed SSSI sensitivity analyses as described in the FSAR Section 3A.17.11. Evaluations are performed using the combined models of: (a) CB-RB/FB for evaluations of SSSI effects of the heavy RB/FB on the response of CB, (b) CB-FWSC for evaluations of SSSI effects of FWSC on the response of CB, and (c) FWSC-CB for evaluations of SSSI effects of CB on the response of FWSC. FSAR Table 3A.15-204 lists the cases used in the analyses for the SSSI effect of the RB/FB on the CB. FSAR Table 3A.15-205 and Table 3A.15-206 list the cases used in analyses for the SSSI effects of the FWSC on the CB and CB on the FWSC, respectively. These analyses cases and the results are documented in detail in the GEH Reports WG3-U73-ERD-S-0005, Revision 3, "Control Building and Reactor/Fuel Building Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A271) and WG3-U73-ERD-S-0002, Revision 6, "Control Building and Firewater Service Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A270).

The staff notes that the RB/FB is considerably more massive than the CB, so the potential SSSI effect of the RB/FB on the CB is more significant than the effect of the CB on the RB/FB. On this basis, the applicant did not evaluate the SSSI effect of the CB on the RB/FB. The staff reviewed the ESBWR DCD and determined that the basis provided by the applicant for neglecting the SSSI effect of the CB on the RB/FB is consistent with the seismic analysis methodology described in the ESBWR DCD, Tier 2, Section 3A.8.11 and is therefore acceptable.

SSSI Combined Models of the CB and RB/FB

The applicant performed the SSSI analyses of the combined model designated as "CB-RB/FB" to evaluate the interaction effect of RB/FB on CB as described in the FSAR Section 3A.17.11. The combined model is shown in the FSAR Figure 3A.17.11-201. The combined model provides an explicit representation of the North Anna 3 site conditions between the two buildings and includes the effects of dynamic interaction between the RB/FB and CB. The details of the analyses and the results for the CB-RB/FB are documented in the GEH Report WG3-U73-ERD-S-0005, Revision 3, "Control Building and Reactor/Fuel Building Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A271). The SSSI analyses used the SASSI 2010 program with the MSM where only selected nodes of the excavated volume elements are specified as interaction nodes. GEH Report SER-DMN-011, Revision 1 provides the benchmarking evaluation of the accuracy of the MSM solutions for the North Anna 3 site-specific application. Staff's evaluation of benchmarking of the MSM of the SASSI 2010 computer program is provided earlier in this section under the heading "*SSI Analysis Method*."

The combined models consist of the lumped mass beam models of the CB and RB/FB described in the ESBWR DCD Section 3A.5.1 coupled with the finite element soil model of the subgrade with the site-specific strain compatible dynamic properties. The combined model also includes the Access Tunnel that is isolated from the RB/FB and CB and the near-field solid elements representing the structural and concrete fill materials placed below the Access Tunnel and surrounding the CB. The Access Tunnel is modelled using the shell elements. For comparison purposes, the subgrade dynamic properties and input motions used for the CB-RB/FB SSSI analysis are identical to those used for the SSI analysis of the CB standalone model. The passing frequencies used for the CB-RB/FB combined models shown in the FSAR Tables 3A.15-204 meet the 50 Hz criteria specified in DC/COL-ISG-1 guidance.

Based on staff's review of the information provided in the FSAR, the technical reports, and the supporting calculations during North Anna 3 Audit 1, the staff finds the SSSI model representation of the CB and the RB/FB acceptable because: (a) the SSSI models explicitly capture the effects of dynamic coupling between the RB/FB and CB at the Unit 3 site, (b) the SSSI models use the same lumped mass beam models as the ones used in the EBSWR DCD, (c) the site-specific subgrade properties and the input motions used in the SSSI CB-RB/FB models are identical to the corresponding subgrade properties and input motion used for the stand alone SSI model of the CB, which the staff reviewed and accepted as discussed earlier in this SER, (d) the selection of interaction nodes for the MSM is based on the conclusions of the North Anna 3 benchmarking GEH Report SER-DMN-011, Revision 1, and (e) the maximum aspect ratio of the finite elements was within the aspect ratio limit of the SASSI2010 computer program which the staff found acceptable as discussed later in this SER.

SSSI Effect of RB/FB on CB (CB-RB/FB)

As discussed in the FSAR Section 3A.17.11, analyses of the CB-RB/FB SSSI models were performed for the UB and LB partial columns, and UB full column subgrade profiles representing strain-compatible dynamic soil/rock properties at the CB location, and corresponding in-layer input motions applied at the bottom of the CB foundation.

The site-specific SSSI effects of the RB/FB on the CB site-specific design basis were evaluated by comparing the results of site-specific analysis of CB-RB/FB SSSI model cases listed in the FSAR Table 3A.15-204 with the corresponding CB site-specific seismic design basis structural loads and ISRS that were developed as envelope of the results of design basis SSI analysis of the CB standalone models. Comparisons are also made with the corresponding design basis loads used for the standard design. These comparisons are shown in GEH Report WG3-U73-ERD-S-0005, Rev 3, "Control Building and Reactor/Fuel Building Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A271).

The staff reviewed the structural responses computed from the site-specific SSSI analyses in terms of the maximum forces and moments, lateral soil pressure on the below-grade exterior walls, and the 5-percent damped ISRS at the key locations in the CB identified in ESBWR DCD, Tier 2, Appendix 3A. These results are documented in the GEH Report WG3-U73-ERD-S-0005, Revision 3. Based on staff's review of the GEH report and audit of the supporting calculations during North Anna 3 Audit 1, the staff noted that the site-specific seismic structural load demand for the CB does not always envelope the SSSI effects of the RB/FB on the CB. However, the applicant in the FSAR Section 3A.17.11 stated and the staff verified that the site-specific SSSI induced shear demand (including the shear induced by torsion) is enveloped by the site-specific enveloping design basis loads specified in FSAR Section 3A.17.13.2. The staff also concluded that the exceedance of the lateral pressure on the CB west wall facing the RB/FB has no effect on the CB below-grade wall design based on the supporting configuration of the CB west wall and the location of the lateral pressure exceedance as discussed in the FSAR Section 3A.17.11. With regard to any exceedance in the ISRS, the applicant stated in FSAR Section 3A.17.11 that any exceedance in the ISRS up to 50 Hz due to SSSI effect will be incorporated in the site-specific design ISRS envelope. Since the CB site-specific ISRS are enhanced as described in FSAR Section 3A.18.2 for any exceedance due to SSSI effect, the staff found the applicant's approach acceptable.

SSSI Combined Models of the FWSC and CB

The applicant performed the SSSI analyses of the combined model designated as "CB-FWSC" to evaluate the interaction effect of FWSC on CB and the combined model designated as "FWSC-CB" to evaluate the interaction effect of CB on the FWSC as described in the FSAR Section 3A.17.11. The combined models are shown in the FSAR Figures 3A.17.11-202 and 3A.17.11-203. The details of the analysis and the results are documented in the GEH Report WG3-U73-ERD-S-0002, Revision 6, "Control Building and Firewater Service Complex Seismic Structure-Soil-Structure Interaction Analysis Report" (ADAMS Accession No. ML16076A270).

The SSSI analyses used the SASSI 2010 program with the MSM where only selected nodes of the excavated volume elements are specified as interaction nodes. GEH Report SER-DMN-011, Revision 1, provides the benchmarking evaluation of the accuracy of the MSM solutions for the North Anna 3 site-specific application. The staff's evaluation of benchmarking of the MSM of the SASSI2010 computer program is provided below under the heading *"Verification and Validation of SASSI 2010 and ACS SASSI and Benchmarking of the MSM"* in this SER.

The combined models consist of the lumped mass beam models of the CB and FWSC described in the ESBWR DCD Section 3A.5.1 coupled with the finite element soil model of the subgrade with the site-specific strain compatible dynamic properties. The combined model includes the structural and concrete fill materials placed around the CB exterior walls and concrete fill placed below the CB and FWSC basemat. Structural and concrete fill materials surrounding the exterior of the CB and between the two structures are represented in the combined model as the near-field solid elements. For comparison purposes, the subgrade dynamic properties and input motions used for the CB-FWSC SSSI analysis are identical to those used for the SSI analysis of the CB standalone model. Similarly, the subgrade dynamic properties and input motions used for the FWSC-CB SSSI analysis are identical to those used for the SSI analysis of the FWSC standalone model. The passing frequencies used for the CB-FWSC and FWSC-CB combined models are shown in FSAR Tables 3A.15-205 and 3A.15-206.

Based on staff's review of the information provided in the FSAR and the technical reports and supporting calculations during North Anna 3 Audit 1, the staff finds the SSSI model representation of the CB and the FWSC acceptable because: (a) the SSSI models use the same lumped mass beam models as the one used in the EBSWR DCD, (b) the site-specific subgrade properties and the input motions used in the two SSSI models (CB-FWSC and FWSC-CB) are identical to the corresponding subgrade properties and input motion used for the stand alone SSI model of the CB and FWSC, which the staff reviewed and accepted as discussed earlier in this SER, (c) the selection of interaction nodes for the MSM is based on the conclusions of the North Anna 3 GEH Report SER-DMN-011, Revision 1, and (d) the maximum aspect ratio of the finite elements was within the aspect ratio limit of the SASSI2010 computer program which the staff found acceptable as discussed below under the heading *"Verification and Validation of SASSI 2010 and ACS SASSI and Benchmarking of the MSM"* in this SER.

SSSI Effect of FWSC on CB (CB-FWSC)

As discussed in the FSAR Section 3A.17.11, analysis of the CB-FWSC SSSI model was performed for the UB and LB full column profiles and corresponding in-layer input motions applied at the bottom of the CB foundation. The site-specific SSSI effects of the FWSC on the CB site-specific design basis were evaluated by comparing the results of site-specific analysis of CB-FWSC SSSI model cases listed in the FSAR Table 3A.15-205 with the corresponding CB site-specific seismic design basis structural loads and ISRS that were developed as envelope of the results of design basis SSI analysis of the CB standalone models. Comparisons are also made with the corresponding design basis loads used for the standard design.

The staff reviewed the structural responses computed from the site-specific SSSI analyses in terms of the maximum forces and moments and the 5-percent damped ISRS at the key locations in the CB identified in ESBWR DCD, Tier 2, Appendix 3A. These results are documented in the GEH Report WG3-U73-ERD-S-0002, Revision 6 (ADAMS Accession No. ML16076A270). Based on review of this report, the staff concluded that the site-specific North Anna 3 design basis seismic structural load demand for the CB envelope the SSSI effects of the FWSC on the CB response with the exception of the torsional demands on the CB. To address this exceedance the applicant performed calculations to demonstrate that the additional torsion-induced shear in the CB walls are enveloped by the enveloping shear load demands obtained from the site-specific design basis SSI analysis of the CB standalone model. During North Anna 3 Audit 1, the staff reviewed the supporting information and confirmed that the additional torsion-induced shear in the CB walls are enveloped by the enveloping shear load demands obtained from the site-specific SSI analysis of the CB standalone model.

GEH Report WG3-U73-ERD-S-0002, Revision 6 indicates that North Anna 3 site-specific design ISRS based on stand-alone SSI analyses in general envelope the results of the site-specific SSSI analyses of the CB-FWSC combined model. The staff noted that there was one exceedance in the ISRS at the top of the CB basemat in vertical direction near 50 Hz. The applicant in response revised FSAR Section 3A.17.11 to indicate that the CB site-specific ISRS are enhanced as described in FSAR Section 3A.18.2, if any of the sensitivity SSSI analyses of the CB-RB/FB and the CB-FWSC combined models yield 5 percent damped ISRS that exceed the corresponding CB site-specific design ISRS based on stand-alone SSI analyses up to 50 Hz. Since the CB site-specific ISRS are enhanced as described in FSAR Section 3A.18.2 for any exceedance due to SSSI effect, the staff found the applicant's approach to include the effect of SSSI in the site-specific design envelop acceptable.

SSSI Effect of CB on FWSC (FWSC-CB)

FSAR Section 3A.17.11 and the GEH Report WG3-U73-ERD-S-0002, Revision 6 describe the site-specific evaluation of the SSSI effects of the CB on the FWSC seismic response. The evaluation is based on the comparison of the results of site-specific analysis of the FWSC-CB SSSI model cases (analysis cases FC1 through FC9) listed in the FSAR Table 3A.15-206 with the corresponding FWSC site-specific seismic design basis structural loads and ISRS that were developed as an envelope of the results of SSI analysis of the FWSC standalone model for all profiles. The SSSI effects of the CB on the FWSC site-specific design basis loads (structural load demand) are evaluated by comparing the results of the site-specific analysis of FWSC-CB SSSI model with uncracked concrete and SSE damping values (cases FC7 through FC9) with the corresponding seismic demand obtained from the results of the standalone FWSC SSI analyses with the control motion applied at Elevation 220 ft. The effects of SSSI on the site-specific design ISRS (obtained from the standalone SSI analysis of the FWSC) are evaluated based on the ISRS results obtained from the SSSI analysis of the FWSC-CB model with uncracked concrete and OBE damping values (cases FC1 through FC6) with the control motion applied both at Elevation 282 ft and 220 ft.

The staff reviewed the comparisons provided in the GEH Report WG3-U73-ERD-S-0002, Revision 6 of SSSI envelopes (cases FC7 through FC9) with the site-specific SSI enveloping maximum horizontal and vertical load demands obtained from the FWSC standalone site-specific SSI analyses with uncracked properties and SSE damping values with deep input motion at Elevation 220 ft. Also presented in the report are comparisons of the site-specific seismic demand with those used in the standard design. These comparisons show that the SSSI effect of the CB amplifies some of the site-specific FWSC seismic demands obtained from the standalone SSI analysis and in some instances resulted in exceedance of the loads used in the standard design. The structural design evaluation of the FWSC under site-specific seismic loads exceeding those of the standard design is discussed in SER Section 3.8.4.

The staff reviewed FSAR Figures 3A.17.11-207 through 3A.17.11-209 which provide a comparison of the 5 percent damped ISRS obtained from the site-specific SSSI analysis of the FWSC-CB combined model with the corresponding 5 percent damped North Anna 3 site-specific SSI enveloping ISRS and the standard design ISRS. These Figures show that the SSSI effects of the CB result in significant exceedances in some of the North Anna 3 FWSC site-specific SSI enveloping ISRS.

Based on the above review of the site-specific SSSI effects of the CB on the FWSC response, the staff concluded that the seismic responses obtained from the standalone site-specific design basis SSI analysis of the FWSC do not envelope potential SSSI-induced amplification of the FWSC responses. The applicant in the FSAR Section 3A.17.11 indicated that the results obtained from the analysis of FWSC-CB SSSI model will be used to develop the FWSC site-specific design basis that will envelop the amplifications of the FWSC response due to the SSSI effect of the CB on FWSC. Since the applicant incorporated the results from the FWSC-CB SSSI analysis into the seismic design basis, the staff found this approach acceptable.

Soil Separation Analysis

Soil Separation Consideration for RB/FB and CB

In the FSAR Section 3A.12.2, the applicant stated that consideration of the partial and full embedment configuration in the RB/FB and CB SSI analyses bounds the effects of subgrade stiffness variation related to any potential soil separation. The staff concludes that the SSI analysis with a partial embedment configuration for the RB/FB and the CB bounds the effect of any soil separation because the partial embedment configuration (without the backfill) essentially represents a condition with complete soil separation.

Soil Separation Consideration for FWSC

To evaluate the effect of soil separation between concrete fill below the FWSC foundation and the surrounding soil, the applicant has performed additional evaluation and SSI/SSSI analyses for the FWSC. These analyses are described in Section 3A.17.14.5 of the FSAR and in the GEH Report WG3-U63-ERD-S-0001, Revision 4. The applicant estimated the separation depth from the results of SSI/SSSI analyses of FWSC and FWSC-CB models using the deep input motion at Elevation 220 ft that provides bounding seismic load demands on the FWSC structures. The resultant separation depths vary from case to case in a range of 3.90 m to 8.83 m. The applicant then performed sensitivity analyses to consider the effect of soil separation using the uncracked full column FWSC SSI model (see Table 3A.15-203) and the uncracked FWSC-CB SSSI model. These analyses considered the LB, BE, and UB soil profiles and were performed with concrete fill nodes disconnected from surrounding soils at elevations above the estimated soil separation depths. The applicant used the seismic demand obtained from the soil separation sensitivity analyses to evaluate the acceptability of the site-specific seismic demand established without the consideration of soil separation.

The staff reviewed and confirmed the analytical assumptions and the results obtained from the soil separation sensitivity analyses during North Anna 3 Audit 1 and North Anna 3 Audit 2. The staff found the estimated soil separation depths acceptable because the results generally agree with the ASCE 4-98 provision for soil separation, which is 6 m. The soil separation analyses showed that the maximum increase in structural demands was about 7 percent and the maximum increase in ISRS was about 30 percent, as indicated in FSAR Section 3A.17.14.5.

The applicant also evaluated the sliding stability of the FWSC foundation using the results of the sensitivity analyses of the FWSC standalone and FWSC-CB models, representing fully separated soil conditions and FSAR Table 3A.17.14.5-202 presents a summary of the stability analyses of the FWSC foundation against sliding at the basemat-concrete fill interface. Table 3A.17.14.5-202 also compares the results for lateral load demands on the FWSC shear keys obtained from the calculations accounting for the effect of soil separation with the results obtained from the design basis analyses of the fully bonded models (without soil separation). The comparison shows that the separation between the concrete fill and surrounding soil can amplify the lateral load demand on the FWSC shear keys up to 47 percent. The staff evaluation of the design of the FWSC shear keys against site-specific load demand is presented in SER Section 3.8.5.4.A.3.

These exceedances were not initially considered for the site-specific seismic demand established for the FWSC. The applicant subsequently revised FSAR Section 3A.17.14.5 to indicate that the site-specific evaluations of FWSC structures, basemat, and shear keys use the input seismic loads presented in FSAR Section 3A.18.1.3 which incorporate enhancements to bound all exceedances due to potential separation between the concrete fill and surrounding soil. For ISRS, the FWSC site-specific design ISRS are enhanced if any of the sensitivity analysis cases for soil separation yield 5 percent damped ARS that exceed the corresponding broadened ISRS by more than 10 percent at frequencies up to 50 Hz. The FSAR states that the use of the 10 percent criterion is reasonable considering the conservatism introduced by assuming fully separated condition on all four sides of the concrete fill at all times, which is unlikely during an actual SSE. The staff finds this basis to be acceptable because of the conservatism in the analyses.

The staff's evaluation of the capacity of the concrete fill below the FWSC is discussed in Section 2.5.4 of this SER.

Verification and Validation of SASSI 2010 and ACS SASSI and Benchmarking of the MSM

In response to RAI 03.07.02-10 and RAI 03.07.02-13 (ADAMS Accession No. ML15222A240) the applicant indicated that the V&V of SASSI2010 program modules used in the North Anna 3 SSI analysis are performed in accordance with the Shimizu Quality Assurance Program. FSAR Section 3C.7.4 describes SASSI2010 and its V&V. In addition, the applicant also submitted to the staff the Shimizu Engineering Report SER-DMN-011, Revision 0, "Benchmarking of SASSI 2010 MSM Results from North Anna 3 Site-Specific SSI Analysis" (designed herein as the North Anna 3 MSM Benchmark Report). The applicant has used the MSM of the SASSI programs because of the computational limitations with the size of the computer models using direct method (DM) for the North Anna 3 SSI and SSSI analyses of models embedded in softer in-situ soil.

The staff reviewed the North Anna 3 V&V and the MSM Benchmark reports. The North Anna 3 V&V Report includes 14 test problems; all were solved using the direct method of SASSI. The North Anna 3 MSM Benchmark report indicated that MSM is used for the North Anna 3 SSI and SSSI analyses of FE models. The staff review focused on problems that are applicable to the North Anna 3 site-specific SSI analyses.

In summary, three main issues were identified with regard to SASSI2010 V&V: (1) models are not fine enough to validate the SASSI 2010 solutions up to 50 Hz and the report did not include a test problem to validate the SASSI kinematic SSI solutions for frequencies up to 50 Hz on a layered soil profile such as North Anna 3 site, (2) the results using the models with symmetry/anti-symmetry conditions are different from the full model, and (3) the validation of element aspect ratio is insufficient.

With regard to MSM Benchmarking, the staff identified one issue. To demonstrate the adequacy of MSM for the North Anna 3 application, the FWSC model was analyzed with FE and the UB soil profile only. Since the LB and BE soil profiles lead to lower fundamental frequencies for the excavated soil volume than the UB soil profile with the same interaction nodes, they represent a higher potential that MSM could produce spurious results at lower frequencies. Therefore, the staff requested that the applicant justify why the MSM provides adequate solutions compared with DM for the LB soil profile.

Therefore in a follow-up RAI 3.7.2-26 (ADAMS Accession No. ML15222A240), the staff requested additional information to address the above issues for the SASSI2010 V&V and MSM Benchmark. In response to this RAI, the applicant provided as reference a non-proprietary report to support the ESBWR DCD, Shimizu Engineering Report, SER-DMN-020, Revision 1, "*Validation Summary Report for SASSI 2010 and Appendix with Validation Problems for RAI 03.07.02-10 / RAI 03.07.02-26 Response.*" (ADAMS Accession No. ML15222A280). The staff reviewed this summary report prior to the North Anna 3 Audit 1. The staff also reviewed and confirmed the evaluation in the detailed proprietary V&V report, S/VTR-SAS, Revision 1, "Validation Test Report for SASSI 2010 Version 1" during the North Anna 3 Audit 1.

The North Anna 3 V&V test problems were revised to use a refined model and a higher Vs to be consistent with the North Anna 3 site condition, resulting in a passing frequency up to 70 Hz. FSAR Section 3C.7.4.2 was revised to indicate the passing frequency of the validation report to be 70 Hz. Additional soil layers are added to reach a depth of 325 ft in order to achieve a better comparison with "Day's solution."[3] The response also indicates that both translational and rocking responses are in good agreement with "Day's solution." Since the model passing frequency is higher than 50 Hz, the staff concludes that this RAI is closed and the issue is resolved.

To justify the applicability of SASSI2010 for the SSI analyses to the North Anna 3 layered profiles, the North Anna 3 RAI response references the DTE Energy Company Fermi 3 Reference RCOL in its response to RAI 03.07.02-11, dated July 9, 2013, (ADAMS Accession No. ML13192A302) which also utilizes SASSI2010. Because both sites are similarly layered sites and the contrast in stiffness between the soft soil and the underlying rock is more pronounced at the Fermi 3 site than at the North Anna 3 site, the staff found the response acceptable.

For the issue of correct application of symmetry/anti-symmetry conditions, the RAI response indicates that the observed differences in the responses of the full model and the half model were due to the different coordinate system: the full model using the orthogonal coordinate system and the half model using a cylindrical coordinate system. The revised results using a consistent coordinate system show the difference is negligible. As such, the staff found the response acceptable.

For the issue of validation of the maximum element aspect ratio, the North Anna 3 V&V report is revised to include comparison of maximum absolute acceleration and 5 percent damped ARS for additional locations pertaining to the 3D solid brick elements and thin shell elements that have the largest aspect ratios, in addition to the locations at the top of the CB LMSM and on the top of the CB basemat. The RAI response indicates that the difference of the maximum acceleration is less than 2 percent and the 5 percent-damped ARS shows good agreement at all nodal locations. The staff concludes that this issue is resolved.

The RAI response indicates that the MSM benchmark study of the FWSC model has been expanded to include an additional case for the LB soil profile besides the original UB soil profile. Section 4 of the MSM benchmark report summarizes the results of the SASSI2010 benchmarking analysis of the FWSC model with the revised 2013 GMPE-based subgrade properties. The benchmark analysis of the FWSC model was performed up to a passing frequency of 36 Hz, while the case of UB soil profile was analyzed up to 70 Hz. The passing frequency of 36 Hz, although lower than 50 Hz, is consistent with the cases of the North Anna 3

---

[3] *Day, S. M. 1977, "Finite Element Analysis of Seismic Scattering Problem," Doctoral dissertation, University of California, San Diego.*

FWSC LB soil profile, which do not dominate the enveloping response beyond 25 Hz. The comparison of DM and MSM indicates that the differences in the transfer functions, ISRS, and other seismic responses are very small, indicating that MSM is accurate as compared to DM to the FWSC model. As such, the staff finds the use of SASSI2010 MSM acceptable.

ACS SASSI was used to perform sensitivity analyses for Unit 3 site-specific SSI analysis for seismic Category I structures. Both the SASSI2010 and ACS SASSI use the same frequency-domain complex-response methodology. FSAR Section 3C.7.6 describes ACS SASSI and its V&V. The V&V of ACS SASSI is also documented in Appendix I to WG3-U71-ERD-S-0001, Revision 4, “Reactor/Fuel Building Complex Seismic Analysis Report” (ADAMS Accession No. ML16097A203, ML16097A204). During the North Anna 3 Audit 1, Dominion discussed ACS SASSI Product Acceptance Test and other relevant documentation. The verification was performed utilizing the RB/FB model with upper bound structural stiffness properties and OBE damping values for the UB full column profile. Comparisons of transfer functions, ISRS, and other seismic responses with SASSI 2010 indicate that the differences are generally small. The ACS SASSI MOTION module algorithm produces slightly higher ISRS results at higher frequencies than the SASSI2010. Overall, the level of differences do not affect the conclusions made from the structural stiffness variation study. The applicant documented the comparison of SASSI2010 and ACS SASSI results in FSAR Section 3A.10.1. Based on the above evaluation, the staff concludes that the use of ACS SASSI for North Anna 3 stiffness variation sensitivity analyses is acceptable.

FWSC SSI Confirmatory Analysis

The staff performed a confirmatory SSI analysis of the FWSC using the model provided by the applicant. The purpose of the staff’s confirmatory analysis was to assess some of the calculations reported by the applicant. The confirmatory analysis consisted of a base case and a case for soil separation between the concrete fill and surrounding soils. The base-case represents the uncracked concrete properties, OBE damping, the UB soil profile, and full embedment. The in-column control motion at the bottom of the concrete fill (at Elevation 220 ft) was used as the input ground motion. The analysis was performed separately for each of the three directional components of the input ground motion and the results were combined in a manner consistent with what was used by the applicant for comparison purposes. The staff used ACS SASSI (V. 3.0.0) whereas the applicant used SASSI 2010. Both programs were verified and validated by the applicant for use in North Anna 3 SSI analysis as discussed under the heading *“Verification and Validation of SASSI 2010 and ACS SASSI and Benchmarking of the MSM”* above. The staff compared the results of the staff’s base-case analysis with the corresponding results reported by the applicant in the FWSC SSI analysis report (GEH Report WG3-U63-ERD-S-0001, Revision 4 (ADAMS Accession No. ML16148A131) and found the results were in good agreement.

In order to assess the impact of soil separation on the seismic responses of the FWSC superstructure and concrete fill, the staff performed an analysis of a case that considers soil separation by removing from the base-case model the spring elements connecting the concrete fill elements and the excavated soil volume elements for an assumed separation depth. In the staff’s confirmatory analysis, the soil separation depth was assumed to be 6 m below grade on all four sidewalls of the concrete fill based on the ASCE 4-98 guideline, which is different from the values used by the applicant and serves for the purpose of confirmatory analysis using reasonably simplified assumptions. The applicant used varying depths of separation based on soil pressure estimates (8.83 m for the North-South (N.S.) walls and 3.90 m for the East-West

(E.W.) walls for the UB subgrade profile). Also, the model provided to the staff was based on the OBE damping values whereas the model actually used by the applicant in soil separation analysis was based on the SSE damping values. Considering these modeling differences, the staff found there was an acceptable agreement between the analyses of the soil-separation case by the applicant and the staff.

Supplemental Information / Departure

- NAPS SUP 3.7-5 — Interaction of Non-Category I Structures with seismic Category I Structures
- NAPS SUP 3.7-8 — Interaction of Non-Category I Structures with seismic Category I Structures – RWB Wall Capacity Pressure
- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

Interaction of Non-Seismic Category I Structures with Seismic Category I Structures

The staff reviewed NAPS SUP 3.7-5 and NAPS DEP 3.7-1 as they relate to North Anna 3 COL FSAR Section 3.7.2.8 on seismic interactions of non-seismic Category I structures with seismic Category I structures as follows:

As supplemental information to ESBWR DCD 3.7.2.8, the applicant refers to the FSAR Figure 2.1-201 and ESBWR DCD Figure 1.1-1 for the locations of site structures. FSAR Section 3.7.2.8 indicates that site-specific non-seismic Category I structures (outside the scope of the ESBWR DCD) are separated from seismic Category I structures by at least a distance equal to their height above grade. Therefore, the collapse of any site-specific non-seismic Category I structure will not cause the non-seismic Category I structure to strike a seismic Category I structure. The locations of structures are depicted in FSAR Figure 2.1-201. The staff concludes that this is consistent with SRP Acceptance Criterion 3.7.2.II.8.A and is therefore acceptable.

FSAR Section 3.7.2.8 states that two sets of site-specific seismic response analyses are performed using the North Anna 3 site-specific design ground motion and subgrade dynamic properties to demonstrate the adequacy of the ESBWR standard plant:

- Site-specific SSI analyses of the standalone TB, RW, SB, and ADB structures following methodology consistent with the site-specific seismic SSI analyses of the seismic Category I structures presented in the FSAR Section 3.7.2.4.

- Site-specific seismic SSSI analyses to evaluate any adverse effects of seismic interaction between the TB, RW, SB, and ADB structures and adjacent seismic Category I structures.

Results of these site-specific seismic SSI and seismic SSSI analyses will be discussed as part of the ITAAC completion package for the TB, RW, SB, and ADB structures to demonstrate that acceptance criteria in FSAR Tier 1, ITAAC Tables 2.4.15-1, 2.4.16-1, 2.4.17-1, and 2.4.18-1, respectively, are met.

The design and analysis of the non-seismic Category I structures (TB, SB, and ADB) and the RW-IIa identified in ESBWR DCD, Tier 2, Section 3.7.2.8 will be completed as part of the detailed design phase for the ESBWR standard plant design, per DCD Tier 2, Section 3.7.2.8.1 for the TB, Section 3.7.2.8.2 for the RWB, Section 3.7.2.8.3 for the SB, and Section 3.7.2.8.4 for the ADB; and DCD Tier 1, ITAAC Tables 2.16.8-1 for the TB, 2.16.9-1 for the RW, 2.16.10-1 for the SB, and 2.16.11-1 for the ADB.

The staff found the applicant's approach to address the site-specific effects on the seismic analysis and design of non-seismic Category I buildings acceptable because: (a) the site-specific SSI analysis and seismic evaluation of these structures are performed following the same method as the one used for the seismic Category I buildings described in the FSAR Section 3.7.2.4 which the staff found acceptable and (b) the site-specific effects of SSSI with adjacent seismic Category I structures are evaluated following an approach consistent with the approach used for the seismic Category I structures which the staff found acceptable.

Interaction of Non-Seismic Category I Structures with Seismic Category I Structures – RWB Wall Capacity Pressure

The staff reviewed NAPS SUP 3.7-8 related to the dynamic pressure capacity of the RWB exterior walls in meeting the requirements of safe separation distance from the liquid hydrogen storage tanks as follows:

In FSAR Section 2.2.3.1.3, the applicant provided the licensing basis to ensure that the nearest key structures meet the safe separation distance to the liquid hydrogen tank. To meet the requirement for safe separation distance, the nearest key structures should have a static wall pressure capacity of 3 psi. In order to assess that the static wall pressure capacity for the applicable structures are met, the staff in RAI 02.02.03-10 (ADAMS Accession No. ML14283A550), requested the applicant to provide in the FSAR an analysis demonstrating that the ESBWR standard plant static wall pressure capacity is at least 3.0 psi for the applicable structures.

In response to RAI 02.02.03-10 (ADAMS Accession No. ML15051A288), the applicant stated that the key structures nearest to the liquid hydrogen tank are the FB (seismic Category I) and the RWB. The applicant performed calculation for the FB based on the design input (e.g., wall size, span, etc.) determined from the ESBWR DCD, Figure 3G.3-5 to demonstrate that the static wall pressure capacity is at least 3 psi. The staff reviewed the calculation included in the response to the RAI and agreed with the applicant's determination that the static wall pressure capacity for the FB is at least 3.0 psi. The staff also confirmed that the design input (e.g., area of tension reinforcement, dimensions of the wall, span, specified yield strength of reinforcement and concrete, etc.) used for establishing the wall pressure capacity for the FB is consistent with the design information provided in the ESBWR DCD.

For the RW, the applicant stated that the detailed design of the RWB has not been finalized. The applicant stated that the final design of the RWB will be verified through ITAAC. In the FSAR 3.7.2.8.2, the applicant stated that the RWB exterior walls will have a static wall pressure capacity of at least 3 psi. ACI 349-01, "Code Requirement for Nuclear Safety Related Concrete Structures," will be used in the final design. The staff reviewed the pertinent portion of the

FSAR and the proposed site-specific ITAAC (FSAR Tier 1 ITAAC Tables 2.4.16-1) for the RWB. The staff confirmed that the applicant has added under the design commitment a specific requirement that the RW will have an exterior wall static pressure capacity of at least 3.0 psi. On the above basis the staff found the resolution of this issue acceptable.

3.7.2.5 Post Combined License Activities

Site-specific ITAAC and corresponding acceptance criteria for non-seismic Category I structures within the scope of the ESBWR DCD are described in the COLA Part 10 Tables 2.4.2-1, 2.4.15-1, 2.4.16-1, 2.4.17-1, and 2.4.18-1. The review of these site-specific ITAAC is in Section 3.7.2.4 of this SER.

3.7.2.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to the seismic system analysis that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.7.2, other NRC RGs, and the Interim Staff Guidance. The staff finds that the applicant has addressed the seismic system analysis in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.7.2.3 of this SER.

3.7.3 <u>Seismic Subsystem Analysis</u>

3.7.3.1 Introduction

This North Anna 3 FSAR section addresses the seismic analysis methods and acceptance criteria used for the ESBWR seismic Category I and non-seismic Category I subsystems (equipment and piping) that are qualified to satisfy the performance requirements according to their seismic Category I or seismic Category II designations. Input motions in the form of ISRS and displacements for the analysis and qualification are usually obtained from the primary system dynamic analysis described in the FSAR Section 3.7.2. Non-seismic Category I systems are designed or physically arranged (or both) to prevent the SSE from causing unacceptable structural interactions with or the failure of seismic Category I systems. The ESBWR method for a standard plant seismic analysis of the seismic Category I and non-seismic Category I subsystems is in Section 3.7.2 of ESBWR DCD, Tier 2, Revision 10.

3.7.3.2 Summary of Application

Section 3.7.3 of the North Anna 3 COL FSAR, Revision 9, incorporates by reference Section 3.7.3 of ESBWR DCD, Revision 10. In addition, in FSAR Section 3.7.3.13, Revision 9, the applicant provides the following:

Departure

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

This departure is described in North Anna 3 COL FSAR Part 7, Departures Report. The site-specific horizontal and vertical seismic response spectra as shown in North Anna 3 COL FSAR Figures 2.0-201 through 2.0-204 exhibit exceedances at certain frequencies, when compared to the ESBWR CSDRS. Therefore, the applicant In FSAR Section 3.7.3.13 indicated that the seismic input for the analysis of the seismic Category I buried piping and tunnels will consist of both the single envelope design response spectra defined in DCD Table 3.7-2, using applicable scale factors, as well as the site-specific FIRS.

3.7.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the seismic subsystem analysis, and the associated acceptance criteria, are in SRP Section 3.7.3. The specific requirements include the following:

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the seismic design basis to reflect appropriate consideration of the most severe earthquakes historically reported for the site and surrounding area with a sufficient margin for the limited accuracy, quantity, and period of time in which historical data have been accumulated. In addition, SSCs important to safety should be designed to withstand the effects of earthquakes without losing the capability to perform their intended safety functions.

- 10 CFR Part 50, Appendix S, as it relates to the horizontal component of the SSE ground motion in the free-field at the foundation level of the structures to be an appropriate response spectrum with a peak ground acceleration of at least 0.1g; and if the OBE is chosen to be less than or equal to one-third of the SSE ground motion, it is not necessary to conduct explicit response or design analyses in accordance with Section IV.(2)(i)(A) of 10 CFR Part 50, Appendix S, and the requirement of taking into account SSI effects.

In addition to the acceptance criteria and regulatory guidance associated with the review of FSAR Section 3.7.3, the basis includes the following:

- SRP Section 3.7.1, 3.7.2, and 3.7.3 guidance as applied to seismic Category I subsystems and components for site-specific seismic analysis.

- DC/COL-ISG-1 and DC/COL-ISG-017, in reviewing the seismic input and the SSI dynamic model acceptability for the North Anna 3 site.

- RG 1.61 to determine the acceptability of the damping values used in the structural model.

3.7.3.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.7.3 of the ESBWR DCD. The staff reviewed Section 3.7.3 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the NA3 FSAR as follows:

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

Seismic Category I Buried Piping, Conduits and Tunnel

FSAR Section 3.7.3.13 describes analysis procedure for seismic Category I buried piping, conduits, and tunnels, as well as buried Safety Class RW-IIa radwaste piping installed in trenches or tunnels. This FSAR section indicates that "Seismic input motions for the portions located below ground are based on the single envelope design response spectra as defined in DCD Table 3.7-2, using applicable scale factors, and site-specific SSE FIRS." Since site-specific seismic input were not established in the FSAR Section 3.7.1, Revision 6 for the buried SSCs, the applicant was requested in RAI 03.07.03-1 (ADAMS Accession No. ML14156A456), to describe in the FSAR how the seismic input motions for the applicable buried structures would be developed. The applicant was also requested to provide site-specific ITAAC to address the verification of implementation of the commitment that a site-specific analysis following the method as specified in the FSAR for seismic Category I structures has been conducted demonstrating that the as-built seismic Category I buried piping, conduits, and tunnels conform to their design.

In response to RAI 03.07.03-1 (ADAMS Accession No. ML14204A459), the applicant revised the FSAR Section 3.7.3.13 to describe the development of the seismic input motions for the applicable buried structures. FSAR Section 3.7.3.13, Revision 9 states that the site-specific FIRS will be used to define the design input ground motion at the bottom elevations of seismic Category I buried piping, conduits, and tunnels following the same methodology as used for the development of full column FIRS for the design of seismic Category I buildings as described in FSAR Sections 2.5.2 and 3.7.1. These FIRS will consider, as applicable, the variations of subgrade conditions and the strain-compatible dynamic properties of in-situ subgrade or backfill materials under and above these structures and components. The FIRS will be amplified as necessary to include the effects of the adjacent heavy foundations on the free field motion and to address the effects of SSSI on the seismic response of these buried piping, conduits, and tunnels. The applicant also added site-specific ITAAC in FSAR Tier I Sections 2.4.20 through 2.4.22 to verify that site-specific analyses, following the method as specified in the FSAR for seismic Category I structures, have been conducted and to demonstrate that the as-built applicable buried structures conform to their design. The staff found the applicant's approach to develop the site-specific input used for analysis and design of seismic Category I and safety class RW-IIa buried piping conduits, and tunnels acceptable because: (a) the site-specific seismic input is developed following the same method as the one used for the seismic Category I structures, (b) the site-specific SSE FIRS are amplified to address the effect of adjacent heavy foundations on the seismic input to the buried piping, conduits, and tunnels, (c) the input for the seismic analysis of the buried piping and tunnels consist of both the single envelope design response spectra defined in DCD Table 3.7-2, using applicable scale factors, as well as the site-specific FIRS, and (d) FSAR Tier 1, ITTAC Tables 2.4.20-1, 2.4.21-1, and 2.4.22-1 have been added to verify that a site-specific analyses, following the method as specified in FSAR Section 3.7.1 have been conducted for these as-built buried structures.

3.7.3.5 Post Combined License Activities

The applicant identifies the following site-specific ITAAC for as-built verification of Category I buried structures:

- FSAR Part 10 Table 2.4.20-1, "ITAAC for Seismic Category I Buried Piping, Conduits and Tunnels."

- FSAR Part 10 Table 2.4.21-1, "ITAAC for Access Tunnel"

- FSAR Part 10 Table 2.4.22-1, "ITAAC for Radwaste Tunnel"

3.7.3.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to the seismic subsystem analysis that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.7.3, other NRC RGs, and the Interim Staff Guidance. The staff finds that the applicant has addressed seismic subsystem analysis in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.7.3.3 of this SER.

3.7.4 Seismic Instrumentation

3.7.4.1 Introduction

The seismic instrumentation program provides time history data on the seismic response of the free-field containment structure and other seismic Category I structures. The seismic instrumentation program is annunciated in the control room when triggered by a seismic event. Installation of instrumentation that is capable of adequately measuring the effects of an earthquake at the plant site is also addressed. The criteria for the seismic instrumentation include the following:

- Comparison with RG 1.12, "Nuclear Power Plant Instrumentation for Earthquakes"
- Location and description of the instrumentation
- Control room operator notification

- Comparison of measured and predicted responses
- Tests and inspections

3.7.4.2 Summary of Application

Section 3.7.4 of the NAPS 3 COL FSAR, Revision 9, incorporates by reference Section 3.7.4 of the ESBWR DCD, Revision 10. In addition, in Section 3.7.4, the applicant provided the following:

Supplemental Information

- NAPS DEP 3.7-1

NAPS DEP 3.7-1 describes the SSE ground motion for both the ESBWR standard plant and the site-specific SSE representative of the site-specific seismological and geological conditions.

- NAPS SUP 3.7-6

In NAPS SUP 3.7-6, the applicant committed to implementing the seismic monitoring program prior to receiving fuel on site. In addition, the applicant provided details about how the location of the free-field seismic sensor will be selected, and appropriate transfer functions will be determined, to ensure that ground motions recorded at the sensor location are consistent with the geologic conditions under the facility.

Overall Summary

The applicant specified that the SSE for the proposed facility is defined by two separate spectra: the CSDRS for ESBWR SSCs and the site-specific FIRS representative of the site-specific geologic and seismological conditions. Based on the development of two SSE spectra, the applicant used two spectra to define the plant shutdown OBE. For the purposes of exceedance checks used to determine if plant shutdown is required, the applicant defined the OBE as (1) one-third of the CSDRS that define the free-field ground motion at the bottom of the RB/FB and CB foundations and (2) one-third of the site-specific SSE at-grade as described in FSAR Section 3.7.1.1.6. The applicant specified that recorded ground motions must exceed both OBE spectra for the plant to shut down.

As described in Section 2.5.4 of the FSAR, the site subsurface is characterized by significant topographic relief in weathering and subsurface geology. Therefore, the applicant provided a description of how it will select the location of the free-field seismic instrument at the site. In addition, the applicant stated that it applied the appropriate spectral ratios to recorded ground motions to account for potential differences between subsurface geologic conditions at the location of the free-field instrument and the power block area.

3.7.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the seismic instrumentation, and the associated acceptance criteria, are in SRP Section 3.7.4. The specific requirements include the following:

- 10 CFR Part 50, Appendix S, requires instrumentation to be provided so that the seismic response of safety-related nuclear plant features can be evaluated promptly after an earthquake.

- 10 CFR Part 50.55a, “Codes and standards.”

In addition, the acceptance criteria and regulatory guidance associated with the review of FSAR Section 3.7.4 is documented below:

- RG 1.12, Revision 2

- EPRI Report NP-6695, “Guidelines for Nuclear Plant Response to an Earthquake”

- EPRI Report NP-5930, “A Criterion for Determining Exceedance of the Operating Basis Earthquake”

- EPRI Technical Report TR-100082, “Standardization of the Cumulative Absolute Velocity,” as permitted by RG 1.166

- RG 1.166

- RG 1.167, “Restart of a Nuclear Power Plant Shut Down by a Seismic Event”

3.7.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.7.4 of the ESBWR DCD, Revision 10. The staff reviewed Section 3.7.4 of the NAPS 3 COL FSAR, Revision 9 and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and the information incorporated by reference address the required information relating to this section.

The staff reviewed the following supplemental information in the COL FSAR:

Supplemental Information

- NAPS DEP 3.7-1

The site-dependent SSE at grade is defined by enveloping the following two spectra:

1. PBSRS calculated at grade (Elevation 290 ft) from full soil column analyses for RB/FB and CB and,

2. The minimum required response spectra defined as the RG 1.60 broadband horizontal and vertical response spectra at 5 percent damping anchored to 0.1g at PGA to satisfy the requirements of SRP Section 3.7.1.

The applicant defined the site-dependent OBE at grade as one-third of the site-dependent SSE at grade. The site-dependent OBE response spectra at grade are one reference against which the applicant will perform OBE exceedance checks for the purpose of plant shutdown, as described in Section 3.7.1 of the FSAR. FSAR Section 3.7.4.4 includes the criteria used to determine whether a plant shutdown is required following a seismic event.

FSAR Section 2.5.2.6 presents the horizontal and vertical PBSRS at grade. The horizontal and vertical 5 percent damped site-dependent SSE spectra at grade are presented in FSAR Figures 3.7.1-265 and 3.7.1-266, respectively.

The applicant calculated the horizontal and vertical free-field site-dependent OBE at grade as one-third of the site-dependent SSE at grade and presented in FSAR Figure 3.7.1-267.

The 5 percent damped pseudo velocity response spectra for site-dependent OBE at grade is determined by dividing the ARS values at each frequency point (f) by $2\pi f$. The digital values for the site-dependent SSE and OBE at grade are presented in FSAR Tables 3.7.1-216 and 3.7.1-217, respectively.

The plant is shut down if the walkdown inspections discover damage to equipment that would affect the safe operation of the plant, or the recorded motion in the free-field in any of the three directions (two horizontal and one vertical) exceeds both the certified design and site-specific response spectrum limits and the cumulative absolute velocity limit as follows:
Certified design response spectrum limit is exceeded if:

- at frequencies between 2 and 10 Hz, the recorded response spectral accelerations of 5 percent damping exceed one-third of the corresponding CSDRS values or 0.2g, whichever is greater; or

- at frequencies between 1 and 2 Hz, the recorded response spectral velocities of 5 percent damping exceed one-third of the corresponding CSDRS values or 6 in/sec (152.4 mm/sec), whichever is greater.

Site-specific response spectrum limit is exceeded if:

- at frequencies between 2 and 10 Hz, the recorded response spectral accelerations of 5 percent damping exceed the corresponding site dependent OBE at grade presented in FSAR Table 3.7.1-216 or 0.2g, whichever is greater; or

- at frequencies between 1 and 2 Hz, the recorded response spectral velocities of 5 percent damping exceed the corresponding OBE values presented in FSAR Table 3.7.1-217 or 6 in./sec (152.4 mm/sec), whichever is greater, or

- cumulative absolute velocity limit is exceeded if the cumulative absolute velocity value calculated according to the procedures in EPRI TR-100082 (“Standardization of the Cumulative Absolute Velocity”, EPRI, Palo Alto, CA, December 1991) is greater than 0.16g/sec.

In RAI 3.7.4-2, the staff noted that the applicant considers two different spectra, the site-specific SSE and the CSDRS, when determining if a recorded ground motion exceeds the OBE ground motion. The staff requested that the applicant specify how this definition of OBE exceedance meets the requirements of Appendix S to 10 CFR Part 50, and is consistent with the guidance in DC/COL-ISG-1.

In its response, the applicant stated that all safety-related SSCs are designed, analyzed, and qualified to meet both the ESBWR CSDRS and the site-specific FIRS (Figure 3.7.4-1). The applicant also clarified that an OBE exceedance is declared when a recorded ground motion exceeds both the (a) CSDRS-derived and (b) site-specific OBE, but that these exceedances need not occur at the same frequency (i.e., envelope of (a) and (b) are not considered). For example, an earthquake response spectrum that falls below the envelope of (a) and (b), but exceeds (b) at low frequency and (a) at high frequency, would be considered an OBE exceedance, requiring plant shutdown if other criteria, as discussed in FSAR Section 3.7.4.4, are also met. Finally, the applicant stated that the consideration of (a) for determining the OBE at grade is conservative, because this selection neglects the effects of ground motion amplification or site response between the elevation of the RB/FB and CB foundations and plant grade.

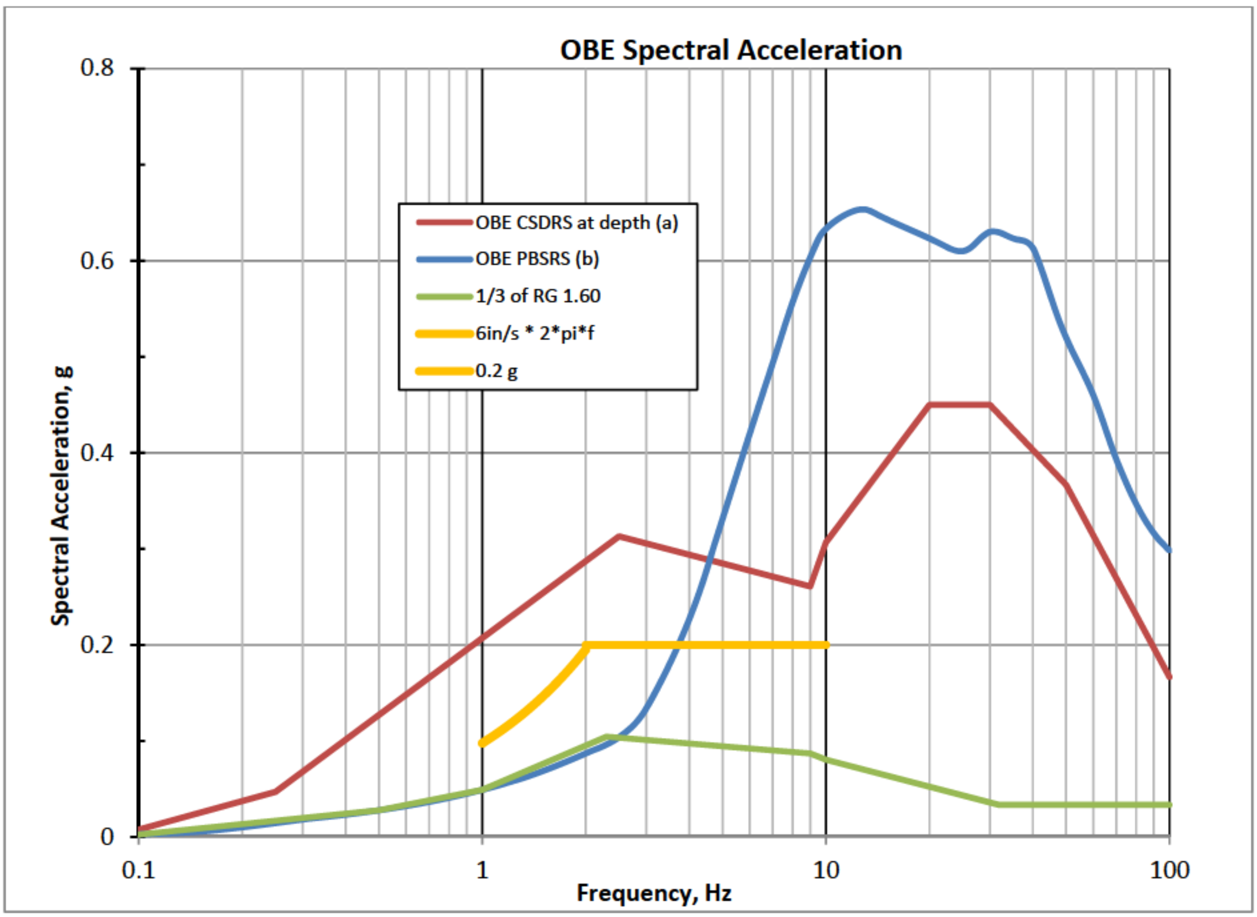

Figure 3.7.4-1. Plot comparing the CSDRS derived OBE (a) and the site-specific OBE (b) with the other requirements used to determine an OBE exceedance.

In Section 3.7.1 of Revision 9 the applicant stated that the response spectra of the 2011 **M** 5.8 Mineral, Virginia earthquake recorded at the Unit 1 containment mat, are closely representative of the Unit 3 site-specific partial column outcrop FIRS. The applicant provided comparisons confirming that the Unit 3 CSDRS envelopes the earthquake recorded motions in East-West, North-South, and vertical directions. Since the horizontal and vertical CSDRS are included in the Unit 3 SSE as the licensing basis for all seismic Category I SSCs, the August 23, 2011, **M** 5.8, Mineral, Virginia earthquake Unit 1 containment mat recordings are considered within the OBE criteria defined above for the Unit 3 SSCs.

The staff reviewed the applicant's RAI response and FSAR modifications. The applicant's response and proposed modifications adequately explain that the OBE for the site is not defined by the envelope of spectra (a) and (b), but by the individual exceedance of both. In addition, the applicant's response and proposed modifications clarify that all safety-related SSCs are designed to both spectra. Therefore, the staff agrees that the proposed OBE criteria for the North Anna site meet the criteria in Appendix S of 10 CFR Part 50 and the guidance in DC/COL-ISG-1and considers RAI 3.7.4-2 resolved and closed.

- NAPS SUP 3.7-6 Seismic Instrumentation

The seismic sensor located in the free field near the power block structures is used to determine OBE exceedance. Because of the complex subsurface stratigraphy of the site, the staff requested in RAI 3.7.4-3 (ADAMS Accession No. ML14288A724), that the applicant describe how it would select a site such that recorded ground motions in the free field adequately characterize ground motions experienced by the power block structures.

In its response to RAI 3.7.4-3 (ADAMS Accession No. ML14337A117), the applicant stated that the subsurface geologic structure of the site is considered in determination of the location of the free-field seismic instrument at the site, and the appropriate spectral ratios will be applied to the ARS and velocity response spectra of the recorded motion to account for potential differences between the subsurface geologic conditions at the location of the free-field instrument and the power block area.

The staff reviewed the applicant's RAI response and proposed FSAR changes. Based on the fact that the free-field data will be scaled using the spectral transfer function to the appropriate level at the power block area, the staff finds the response acceptable. Therefore, the staff considers RAI 3.7.4-3 resolved and closed.

The staff reviewed NAPS SUP 3.7-6 related to the seismic instrumentation included under Section 3.7.4 of the North Anna 3 COL FSAR. The staff concluded that because the seismic instrumentation and monitoring program will be installed and operational before receiving fuel at the NAPS site, and the subsurface geologic structure of the site is considered in determination of the location of the free-field seismic instrument at the site, NAPS SUP 3.7-6 is acceptable.

3.7.4.5 Post Combined License Activities

There are no post COL activities related to this section.

3.7.4.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the relevant information relating to seismic instrumentation, and no outstanding information is expected to be addressed in the COL FSAR related to this section. There are no unresolved nuclear safety issues relating to the seismic instrumentation that were incorporated by reference.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.7.4, and other NRC regulatory guides. The staff finds that the applicant addressed seismic instrumentation in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant satisfied the relevant requirements of the regulations described in Section 3.7.4.3 of this SER. In addition, the staff concludes that the relevant information presented in the COL FSAR is acceptable, because the installation and operability of the seismic monitoring program will be demonstrated before receiving fuel at the North Anna 3 site.

3.7.5 Site-Specific Information

3.7.5.1 Introduction

Section 3.7.5 of the ESBWR DCD references FSAR Chapter 2, Table 2.0-1 which defines the envelope of site-related parameters that the ESBWR standard plant is designed to accommodate. These parameters envelope most potential sites in the United States.

The ESBWR DCD, Table 2.0-2 references the guidance in the SRP, and defines the limits imposed on the acceptance criteria in Section II of the various SRPs by (1) the envelope of site-related parameters that the ESBWR plant is designed to accommodate, and (2) the assumptions, both implicit and explicit, related to site parameters that were employed in the evaluation of the ESBWR design.

3.7.5.2 Summary of Application

In the North Anna 3 COL FSAR Section 3.7.5, Revision 9, the applicant incorporated by reference Section 3.7.5 of ESBWR DCD, Revision 10.

In addition, in FSAR Section 3.7.5, the applicant provides the following:

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

3.7.5.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the FSER for the ESBWR DCD.

In addition, the relevant requirements of the Commission regulations and the associated acceptance criteria are given in the NRC SRP.

3.7.5.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.7.5 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 3.7.5 of the North Anna 3 COL FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1]

The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to this site-specific information.

In addition the staff reviewed the information in the COL FSAR as follows:

Supplemental Information

- NAPS DEP 3.7-1

The NAPS DEP 3.7.1 is a result of the North Anna site-specific FIRS exceeding the CSDRS at certain frequencies. Therefore, the applicant revised the definition for the SSE to include the site-specific FIRS for each seismically qualified structure. These changes are identified in FSAR Sections 1.3, 1.11, 2.0, 3.7, 3.8, 4.2, 9.1, 19.1, 19.2, and 19.5, and FSAR Appendices 3A, 3C, 3G, and 19A. This departure also involves redefinition of the OBE. The changes to the OBE definition are identified in FSAR Section 3.7.1.

In North Anna 3 FSAR, Section 3.7.5 the applicant replaced the Tier 2* information in the standard Table 2.0-1 that reflects the envelope of ESBWR standard plant site parameters including seismic parameters, with the North Anna 3 site-specific seismology requirements and site-specific SSI analyses for the seismic Category I structures to reflect the North Anna 3 site-specific SSE definition that is applied to the seismic analysis for North Anna 3 as described in FSAR Sections 3.7, 3.8, and 2.5.4.

The staff evaluated the NAPS DEP 3.7-1 for each applicable Section of the North Anna 3 FSAR in this staff SER under the applicable SER chapters. Each FSAR section that required this NAPS DEP 3.7-1 due to the change in the North Anna 3 site-specific SSE definition was evaluated to ensure these proposed departures from the DCD met the Commission's regulations as discussed under their respective SER sections.

3.7.5.5 Post Combined License Activities

There are no post COL activities related to this section.

3.7.5.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the relevant information relating to seismology and SSI analyses for seismic Category 1 structures as addressed in primarily in this SER in Sections 3.7 and 3.8, and no outstanding information is expected to be addressed in the COL FSAR related to this section.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, and the guidance in the SRP. The staff completed evaluations on NAPS DEP 3.7-1 as applicable in this SER in accordance with the Commission regulations, guidance in accordance with the SRP and applicable regulatory guides and industry standards. On this basis, the staff concludes that the applicant satisfied the relevant requirements of the regulations and find that the change to Tier 2* information from the ESBWR DCD in Section 3.7.5 of the North Anna 3 FSAR is acceptable.

3.8 Seismic Category I Structures

Seismic Category I structures included in the North Anna 3 design consist of the RB/FB complex, CB, and FWSC. In FSAR Revision 9, Section 3.8 and Appendix 3G, the applicant described the structural analysis and design evaluations of these seismic Category I structures for the North Anna 3 site-specific loads. This FSAR Section incorporates by reference Section 3.8 of the DCD with the departure given below.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra.

This departure relates to the North Anna 3 site-specific horizontal and vertical seismic ground response spectra. These spectra result in exceedances at certain frequencies when compared to the CSDRS as described in the DCD. For this reason, the applicant performed new seismic SSI and SSSI analyses with the site-specific ground response spectra and the site-specific subgrade properties. In some cases, the seismic structural loads were found to be higher than those used for in the standard design, and thus, a structural evaluation of the ESBWR standard plant structures for acceptability at the North Anna 3 site was performed. In a few instances where necessary, the standard design was modified to ensure seismic adequacy as described in the FSAR. The structural evaluations of the seismic Category I structures are described in DCD Appendix 3G, Sections 3G.1 through 3G.6 for the evaluations using the CSDRS seismic demands, and in North Anna 3 FSAR Chapter 3, Appendix 3G, Sections 3G.7 through 3G.10 for the evaluations using the site-specific seismic demands.

3.8.1 Concrete Containment

3.8.1.1 Introduction

Section 3.8.1 and Appendix 3G, Section 3G.7 of the North Anna 3 FSAR, Revision 9, describe the structural analysis and design of the RCCV, which is integrally connected to the RB/FB complex. The RCCV includes the reinforced concrete structure and the containment liner. Other metal components of the containment that are not backed by concrete are addressed under FSAR Section 3.8.2.

The RCCV is designed to house and support the nuclear reactor system and other internal systems and components. It is also designed to act as an essentially leak-tight barrier against the uncontrolled release of radioactivity to the environment. The RCCV is designed to withstand various operating loads; environmental loads such as wind, seismic, and tornado; and abnormal loads such as the loss of coolant accident (LOCA). The ESBWR design approach for the standard plant design of RCCV is provided in Section 3.8.1 and Appendix 3G, Section 3G.1 of ESBWR DCD, Tier 2, Revision 10.

3.8.1.2 Summary of Application

Section 3.8.1 and Appendix 3G of the North Anna 3 FSAR, Revision 9, incorporate by reference Section 3.8.1 and Appendix 3G of the ESBWR DCD, with the departure and supplement given below.

Supplemental Information

- NAPS SUP 3.8-1 — ASTM Standards C1260 and C1293 are used in testing aggregates for potential alkali-silica reactivity (ASR).

This supplement in the FSAR Section 3.8.1.6.1 relates to the potential degradation effects associated with alkali-silica reaction in reinforced concrete structures.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra.

This departure relates to the North Anna 3 site-specific horizontal and vertical seismic ground response spectra. These spectra result in exceedances at certain frequencies when compared to the DCD CSDRS. As a result, the applicant performed new site-specific seismic SSI and SSSI analyses with the site-specific ground response spectra and the site-specific subgrade properties. In some cases, the site-specific seismic structural loads were found to be higher than those used for the standard design, and thus, a structural assessment of the ESBWR standard plant structures for acceptability at the North Anna 3 site was performed. In a few instances as required for site-specific conditions, the standard design is modified to ensure seismic adequacy.

In FSAR Appendix 3G, Section 3G.7, the applicant described the site-specific structural evaluation of the RB/FB complex. Since the RCCV is integral with the RB and both the RB and FB are supported by a common basemat, the analysis of the RCCV is coupled with the RB and FB. The analytical models used for the RB/FB are described in FSAR Section 3G.7.4. In Section 3G.7.5, the applicant described the structural analysis and design. This includes the site design parameters used in the structural evaluation, design loads, load combinations, and material properties. FSAR Section 3G.7.5.4 describes the structural design evaluation which includes the RCCV wall, RCCV top slab and suppression pool slab, and RCCV foundation mat. The foundation stability evaluation is described in FSAR Section 3G.7.5.5, which includes the evaluation for seismic sliding and overturning, and soil bearing pressure.

The results in terms of RCCV member forces, from the evaluations performed for the site-specific seismic loads, are presented in FSAR Tables 3G.7-202 through 3G.7-204. The combined member forces and moments for selected load combinations that include seismic loads are presented in FSAR Tables 3G.7-205a through 3G.7-205e. The calculated stresses of the concrete and steel reinforcement and their comparison to code limits are presented in FSAR

Tables 3G.7-206a through 3G.7-206e. The calculated transverse shear and tangential shear, and their comparison to code limits are presented in FSAR Tables 3G.7-207 and 3G.7-208, respectively. The calculated RCCV liner strains and its comparison to code limits are presented in FSAR Table 3G.7-210.

For stability evaluation, the factors of safety for the RB/FB foundation stability for overturning and sliding are presented in FSAR Table 3G.7-225. The maximum calculated soil dynamic bearing pressure demand for the RB/FB is presented in FSAR Table 3G.7-231.

The results of the evaluation for the site-specific seismic loads show that, although some of the forces on the RCCV are higher than those from the DCD design, the stresses and strains of the RCCV meet the code limits. For foundation stability a factor of safety (FOS) of 1.1 for sliding and overturning is met in accordance with SRP 3.8.5. The soil dynamic bearing pressures are determined to be less than the allowable dynamic bearing pressures provided in FSAR Table 2.5.4-211.

3.8.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the concrete containment, and the associated acceptance criteria, are in SRP Section 3.8.1. The specific requirements include the following:

- 10 CFR 50.55a and 10 CFR Part 50, Appendix A, GDC 1, as they relate to concrete containment being designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the design of the concrete containment being able to withstand the most severe natural phenomena such as winds, tornadoes, hurricanes, floods, and earthquakes and the appropriate combination of all loads.

- 10 CFR Part 50, Appendix A, GDC 4 as it relates to the concrete containment being appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit.

- 10 CFR Part 50, Appendix A, GDC 16, “Containment Design,” as it relates to the capability of the concrete containment to act as a leak-tight membrane to prevent the uncontrolled release of radioactive effluents to the environment.

- 10 CFR Part 50, Appendix A, GDC 50, “Containment Design Basis,” as it relates to the concrete containment being designed with sufficient margin of safety to accommodate appropriate design loads.

- 10 CFR Part 50, Appendix B, as it relates to the QA criteria for nuclear power plants.

- 10 CFR 50.44, “Combustible gas control for nuclear power reactors,” as it relates to demonstrating the structural integrity of BWRs with Mark III type containments, all

PWRs with ice condenser containments, and all containments used in future water-cooled reactors for loads associated with combustible gas generation.

- 10 CFR 52.80(a), which requires that a COL application contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and the Commission's rules and regulations.

In addition, the acceptance criteria, regulatory guidance, and industry codes/standards associated with the review of FSAR Section 3.8.1 include the following:

- SRP Section 3.8.1 guidance to review the design, construction, and testing of the concrete containment to ensure that the containment maintains its structural integrity and can perform its intended safety function during all loading conditions.

- RG 1.7, "Control of Combustible Gas Concentrations in Containment"

- RG 1.91, "Evaluations of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plants"

- RG 1.136, "Design Limits, Loading Combinations, Materials, Construction, and Testing of Concrete Containments"

- RG 1.216, "Containment Structural Integrity Evaluation for Internal Pressure Loadings Above Design-Basis Pressure"

- RG 1.61 to determine the acceptability of the damping values used in the structural model.

- RG 1.221

- 2004 ASME Boiler and Pressure Vessel Code, Section III, Division 2, Subsection CC, "Code for Concrete Reactor Vessels and Containments"

3.8.1.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.8.1 and Appendix 3G of the ESBWR DCD. The staff reviewed Section 3.8.1 and Appendix 3G of the North Anna 3 FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic[1]. The staff's review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the North Anna 3 FSAR as discussed below.

In addition, the staff conducted an audit (ADAMS Accession No. ML16193A047) (hereinafter referred to as North Anna 3 Audit 2) during the week of March 21, 2016 at the Wilmington, North Carolina offices of the applicant's contractor GEH. The purpose of this audit was to (1) review detailed analysis reports and design calculations performed by the applicant that support the information in the FSAR, (2) confirm the basis supporting the applicant's RAI responses, and (3) review the draft FSAR revisions from RAI responses to ensure consistency with the applicant's design basis information. The staff held almost weekly public meetings with the applicant and GEH starting from the public meeting held on April 15, 2015 up through Audit 2 and some weeks after where the applicant's technical reports, draft FSAR responses and RAI responses were discussed to ensure resolution of all staff issues. An issue resolution table was developed and discussed during these numerous public meeting interactions with the applicant.

The results of the staff's technical review of the North Anna 3 FSAR is given below.

Supplement Information

- NAPS SUP 3.8-1 ASTM Standards C1260 and C1293 are used in testing aggregates for potential alkali-silica reactivity (ASR).

The staff reviewed NAPS SUP 3.8-1 related to the addition of ASTM Standards C1260 and C1293 for testing aggregates for potential ASR. The use of these ASTM standards is intended to prevent the degradation of reinforced concrete due to ASR. The potential degradation from ASR and the use of these ASTM standards to prevent ASR are described in NRC Information Notice 2011-20 (ADAMS Accession No. ML112241029). The staff finds the addition of these ASTM standards to be acceptable because they are intended to prevent potential ASR in the reinforced concrete containment.

Departure

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 related to the applicant's structural evaluation of the RCCV for the site-specific seismic loads applied to the RCCV. These evaluations are described in FSAR Section 3G.7. The staff's technical evaluation of the RCCV design considering these site-specific loads is given below. As described earlier in this report, the model and analyses of the RCCV are included in the RB/FB evaluation because the RCCV is integrally connected to the RB and these structures are on a common basemat. Therefore, the RB/FB evaluation includes the RB, FB, RCCV, and containment internal structures (CIS).

As indicated in FSAR Appendix 3G, Section 3G.7.1, DCD Appendix 3G, Section 3G.1 remains applicable for the analysis and design of the RB, RCCV, and CIS with the seismic loads based on the CSDRS. The evaluation of the RCCV for the site-specific seismic loads is provided in FSAR Section 3G.7 in order to address the exceedances from the standard design seismic loads.

Analytical Models

FSAR Section 3G.7.4.1 states that the North Anna 3 site-specific structural models are based on the standard design structural models described in DCD Sections 3G.1.4.1 for the RB and 3G.3.4 for the FB. FSAR Section 3G.7.4.2 indicates that the North Anna 3 site-specific foundation models are based on the standard design foundation models described in DCD Section 3G.1.4.2. Since the RCCV, CIS, RB, and FB are on a common basemat and the RCCV and RB are integrally connected, the structural models for these structures, including their foundations, are combined into a single integrated RB/FB global model. Therefore, the staff evaluations of the analytical models of the RCCV, CIS, RB, and FB are discussed in this SER in Section 3.8.1.4 under the heading of "*Analytical Models*," rather than evaluating the models of the CIS, RB, and FB separately in SER Sections 3.8.3.4 and 3.8.4.4.

FSAR Section 3G.7.5.2 indicates that the standard design model with the updates to address updated LOCA thermal loads also included standard design changes in the pool gate and upper pools. This updated DCD global finite element model (FEM) is used for the North Anna 3 structural evaluations that include dead load, pressure loads, temperature loads in the RB upper pools, and North Anna 3 seismic loads. FSAR Section 3G.7.5.2 also indicates that other North Anna 3 load cases are used with the original global FEM, because these cases are not affected by design changes in the pools and are the same as those considered in the standard design, DCD Section 3G.1.5.2.1.6.

In addition to the information provided in FSAR Section 3G.7, the staff reviewed the following GEH reports with regard to the analytical models used for the North Anna 3 structural evaluations for the combined RB/FB, RCCV, and CIS:

1. WG3-U71-ERD-S-0004, Revision 2, "Reactor Building Structural Design Report" (ADAMS Accession No. ML16148A081, ML16148A146 Non-public)

2. WG3-T12-ERD-S-0001, Revision 0, "Structural Design Report for Containment Internal Structures" (ADAMS Accession No. ML15342A146)

3. WG3-U97-ERD-S-0001, Revision 2, "Fuel Building Structural Design Report" (ADAMS Accession No. ML16148A128, ML16148A169 Non-public)

4. WG3-T11-DRD-S-0001, Revision 2, "RCCV Structural Design Report" (ADAMS Accession No. ML16148A049, ML16148A169 Non-public)

5. WG3-T11-DRD-S-0002, Revision 0, "Structural Design Report for Containment Liner Plate," (ADAMS Accession No. ML15357A308)

6. DE-ES-0096, Revision 0, "Liner Anchorage Evaluation" (ADAMS Accession No. ML16167A447)

The staff reviewed GEH Report WG3-U71-ERD-S-0004, Revision 2 regarding the modeling of the RB/FB global FEM. The RB/FB complex, including the fully enclosed RCCV and CIS, consists of mostly reinforced concrete slabs/walls and some steel members such as roof trusses and liners. The major structural components include the basemat, RCCV, floor slabs, external walls, shear walls, frame members, and major CIS such as the vent wall, the diaphragm floor slab, the gravity-driven cooling system (GDCS) pool, the RSW, and the RPV support brackets. The part of the FB located above Elevation 22.5 m is not included in the model, because that part is seismic Category II; however, the weights of this part of the FB are applied to the nodes at the positions of columns supporting the roof slab. This is consistent with the approach used in the standard design. Major penetrations in the RCCV are included in the model in order to consider local reduction of the wall stiffness.

The RB/FB complex is modeled and is analyzed using the NASTRAN computer code. Thick shell elements are used to model the RCCV, basemat, pools, walls, and slabs, which consider the membrane force, in-plane and transverse shear forces, and bending moment. Membrane elements are used to model liners that consider the membrane force and in-plane shear. Bar elements (i.e., beam elements) are used to model columns, girders, and roof trusses, which consider the axial force, bending moment, and transverse shear force. Rigid bar elements are used to connect the basemat and the bottom of the shear walls, as well as the shear walls and the liners. Rod elements (i.e., truss elements) are used to model penetration sleeves, which consider only the axial force.

In the North Anna 3 and standard design evaluations, the ground is modeled with spring elements. Three independent spring elements, one vertical and two horizontal, are attached to each of the basemat nodal points. The spring constants are calculated based on the generic soft site condition considered for the ESBWR standard design. The ground is assumed to be elastic and the basemat uplift is not considered in the model. The validities of using generic soft site condition for the North Anna 3 rock site and of neglecting the basemat uplift are evaluated in this SER section under the "*Structural Analysis*" heading.

Based on the review of the information provided in FSAR Section 3.8 and Appendix 3G, the GEH reports identified above, and NRC North Anna 3 Audit 2 (ADAMS Accession No. ML16193A047), the staff concluded that the analytical models used for the North Anna 3 structural evaluation of the RB/FB complex are based on the DCD analytical global FEMs. Therefore, the use of these analytical models for the site-specific structural evaluations is considered to be acceptable.

<u>Site Design Loads, Load Combinations, and Material Properties</u>

The description of the site design loads, load combinations, and material properties for the RCCV is provided in FSAR Appendix 3G, Section 3G.7.5.2. The FSAR indicates that with the exception of seismic loads, the site-specific structural evaluations utilize the loads, load combinations, and acceptance criteria that were used in the standard design. The FSAR lists the various loads and the corresponding sections in the ESBWR DCD where these are described. In addition, the staff did not identify any changes or deviations from the material properties identified in the standard design.

FSAR Appendix 3G, Section 3G.7.5.2 also indicates that North Anna 3 seismic loads are developed from the site-specific SSI analyses results described in FSAR Appendix 3A, Section 3A.18.1.1. These seismic loads consider the effects of structural stiffness variations described in FSAR Appendix 3A, Section 3A.17.9.1. The effects of SSSI and structure soil separation on the overall RB/FB complex are discussed in SER Section 3.8.4 below.

Based on the review of the information provided in FSAR Section 3.8 and Appendix 3G, the GEH reports identified above, and the North Anna 3 Audit 2, the staff concluded that for the NS loads, the North Anna 3 structural evaluation utilized the same NS loadings, the same load combinations, and the same material properties as the standard design. For the seismic loads, the staff reviewed and confirmed that the site-specific seismic bounding load results presented in FSAR Appendix 3A, Section 3A.18.1.1 for the RCCV were used for the RCCV structural evaluation. Therefore, the North Anna 3 site design loads, load combinations, and material properties are considered to be acceptable.

Structural Analysis

During its review of Revision 8 of FSAR Section 3.7.2.4.1.6.1, the staff noted that the North Anna 3 site-specific enveloping seismic loads computed from the site-specific SSI analyses of the RB/FB, CB, and FWSC exceed the corresponding standard design loads at a number of locations in the RB/FB and CB. FSAR (Revision 8) Section 3.7.2.4.1.6.1 also describes a design evaluation method that utilizes the “stress ratios” (i.e., the standard design stress demand over capacity) and “scale factors” (i.e., maximum ratios of site-specific enveloping seismic loads over standard design enveloping seismic loads). Following this method, if the products of the stress ratios and the scale factors are less than 1.0 for a given location in the structure and for the governing load combination, that location in the structure would be identified as passing the design evaluation.

The staff’s review found that the applicant’s simplified approach proposed in FSAR Revision 8, may not be appropriate because its required linear dependence of the seismic stress ratios with respect to all seismic load components may not be valid for some design situations and load combinations. Since adequate calculation of the member forces with proper consideration of the individual member force components is essential in design to ensure the structural integrity, the staff requested, in RAI 03.07.02-17, that the applicant provide the results of detailed stress checks for the seismic Category I structures without using the stress factors and scale factors, where the site-specific seismic loads exceed the corresponding ESBWR standard design.

In the response to this RAI question (ADAMS Accession No. ML16146A789), and as described in the applicant’s Seismic Closure Plan (SCP), submitted to the NRC by letter dated October 22, 2014 (ADAMS Accession No. ML14297A199), the applicant indicated that design margins will be explicitly calculated based on the site-specific seismic stress demands obtained from finite element analyses using the same methodology as used for the standard design. FSAR Revision 9 Sections 3.7, 3.8, Appendix 3A, and Appendix 3G present the updated North Anna 3 site-specific structural evaluations of the seismic Category I structures of the ESBWR standard design at the North Anna 3 site. Staff’s assessment of this evaluation is presented later in this SER Section.

The applicant in Revision 8 of the FSAR also did not consider the structural fill above the top of the Zone III rock in the SSI analysis of the RB/FB and CB models. Therefore, as part of the RAI 03.08.04-37, the staff requested the applicant to provide a justification on the adequacy of their design evaluation of the walls below grade to resist lateral soil pressure. In response to this RAI question (ADAMS Accession No. ML15364A384), the applicant performed additional SSI analysis with full embedment considering the structural fill and in-situ saprolite soil and revised appropriate sections of the FSAR to document the results. Staff’s evaluation of the SSI analysis of the FE models is presented in SER Sections 3.7.2.4. FSAR, Revision 9, Appendix 3A, Section 3A.18 presents the bounding seismic loads used in the North Anna 3 site-specific design evaluation that envelops the partial and full embedment cases. Bounding dynamic lateral soil pressures are described in FSAR Revision 9, Appendix 3G. Staff’s evaluation of the use of the bounding seismic loads in evaluating the adequacy of ESBWR standard plant structures is described later in this SER Section.

As discussed in FSAR Revision 9, Appendix 3G, Sections 3G.7.4, 3G.7.5, and 3G.9.4, the structural models for the RCCV, CIS, RB, and FB are integrated into a single RB/FB global model. Therefore, the staff evaluation of the structural analysis of the RCCV, CIS, RB, and FB is presented in this SER under the "*Structural Analysis*" heading.

The description of the structural analysis for the design evaluation of the RB/FB complex is provided in FSAR Revision 9, Sections 3.8.1, Appendix 3G, Sections 3G.7, and 3G.9, and GEH reports listed in Section 3.8.1.4 under the heading "*Analytical Models*," of this SER. The FSAR indicates that the North Anna 3 site-specific design evaluation uses the same standard design methodologies, standard design load combinations and selected elements, and the standard design loads, except that the standard design seismic loads are replaced with the North Anna 3 site-specific seismic loads. The standard design structural evaluations continue to apply and remain valid for the CSDRS seismic response. FSAR Appendix 3G also indicates that the site-specific structural evaluations supplement the standard design evaluations to address site-specific conditions including the site-specific seismic input motion exceeding the CSDRS in some frequency ranges and that the standard design of the seismic Category I structures is maintained, except where the standard design is modified by providing additional reinforcement to ensure seismic adequacy.

The staff reviewed the information provided in FSAR Appendix 3G, Sections 3G.7.5 and 3G.9.5, and GEH reports as described in SER Section 3.8.1.4B.1 above with regard to the structural analysis used for the site-specific structural evaluations of the RB/FB global model. Based on this review, the staff confirmed that the North Anna 3 site-specific structural analysis of the RB/FB global model was performed consistently with the procedure used for the standard design and utilized the NASTRAN finite element computer code, which is the same computer code used for the standard design as described in DCD Section 3.8.1.4.1.1. The global stress analysis model of the RB/FB complex is the same as the updated DCD model used for the standard design, and the site-specific seismic loads applied to the RB/FB global model for the site-specific stress analyses are determined from the design site-specific seismic loads as described in FSAR Appendix 3A, Section 3A.18. As described in FSAR Appendix 3G, Section 3G.7.5.2, the seismic loads applied to the model include all bounding seismic response loads (two horizontal, one vertical, one torsional, and two overturning moments applied at each floor elevation).

Based on staff's review above and as confirmed during the North Anna 3 Audit 2, the staff found the North Anna 3 site-specific NASTRAN analysis of the updated RB/FB model acceptable because the applicant (a) performed an explicit site-specific FEM analysis to calculate the site-specific stress demand using an approach consistent with the DCD approach, and (b) applied the site-specific bounding seismic load obtained from the site-specific seismic analysis to the NASTRAN model following the same method as used for the standard design.

The staff further evaluated the following site-specific issues in more detail related to the structural analysis of the RB/FB model: (1) the use of DCD soft-soil subgrade properties, (2) the application of bounding seismic loads to the NASTRAN design model, and (3) application of RCCV thermal loads.

Use of DCD soft-soil subgrade properties for North Anna 3 NASTRAN analysis

FSAR Appendix 3G, Sections 3G.7.5.1 and 3G.9.5.1 indicate that the North Anna 3 structural evaluation utilizes the key site design parameters identified in DCD Appendix 3G, Section 3G.1.5.1, based on soft site subgrade stiffness conditions, which are considered conservative for the Unit 3 hard rock site.

DCD Section 3.8.5.4 indicates that the worst case scenario for foundation basemat design is the soft soil because it results in the largest mat deformation. In order to confirm the appropriateness of this condition, this DCD Section provided a comparison of the basemat deformation and sectional moment between the soft soil case [Vs = 300 m/sec (984 ft/sec)] and the hard rock case [Vs = 1700 m/sec (5577 ft/sec)]. Basemat deformation for the soft soil condition was found to be much larger than that of the hard rock condition. Bending moments for the soft soil were found to be larger than the moments for the hard rock condition with few exceptions. The DCD concluded that the higher bending moments at some locations for the hard rock site have no effect on the design because they are much less than the maximum moments of the soft soil site on which rebar sizing is based.

Although North Anna 3 site-specific structural evaluations use the same generic “soft-soil” subgrade stiffness properties as those used in the standard design and the generic soft soil was justified for the standard design, the staff requested the applicant to provide a justification for using DCD generic soft-soil subgrade stiffness in evaluating the ESBWR seismic Category I structures for the North Anna 3 rock site. The rationale for this staff request is to consider the few exceptions for the hard rock conditions that are observed above in the DCD evaluation and the fact that the North Anna 3 seismic loads exceed the standard design seismic loads in some instances.

In response to this request, the applicant in FSAR Appendix 3G explains that the site-specific evaluations are based on the results of static analyses performed on NASTRAN FEMs that are identical to those used for the standard design described in DCD Appendix 3G, Section 3G.1.4, including the use of the same linear elastic spring elements and subgrade stiffness properties. Dominion also explained during the North Anna 3 Audit 2 that the design of the basemat for the soft-soil conditions is conservative because the reinforcement in a given region of the basemat is based on the maximum moments calculated in that region rather than specifying different reinforcement to closely match the moment diagram across the basemat. The design evaluation using the generic soft-soil subgrade stiffness provides design demands that envelop the effects of the stiffer site-specific rock subgrade and foundation uplift with a few exceptions that nevertheless do not affect the conclusions of the site-specific structural evaluations. For these exceptions, FSAR Appendix 3G also indicates that the results of sensitivity evaluations show that amplifications at some locations due to the higher site-specific subgrade stiffness and foundation uplift are small and that the basemat design has sufficient margin to envelop the effects of the small amplifications due to the higher site-specific subgrade stiffness or foundation uplift.

The staff reviewed the information in FSAR Appendix 3G, and confirmed this information during North Anna 3 Audit 2. The staff review concludes that the applicant’s use of the generic soft soil for North Anna 3 design evaluations is acceptable because the resultant basemat design has higher capacities than the seismic demands due to the North Anna 3 site-specific seismic input motions, North Anna 3 rock site conditions and effect of uplift.

Application of Bounding Seismic Loads to NASTRAN Design Model

In order to review how the site-specific seismic demands described in FSAR Section 3.7 and FSAR Appendix 3A, Section 3A.18 are translated into input loads for the detailed NASTRAN FEMs used in the structural design evaluation described in FSAR Section 3.8, the staff requested the applicant provide relevant information and explanation of the process involved. In response, the applicant made a presentation during a public meeting dated March 3, 2016 (ADAMS Accession No. ML16204A243), on how the site-specific bounding seismic demands obtained from seismic analyses using the LMSMs are applied to the NASTRAN FEMs for static stress analyses. The applicant explained that the methodology used to convert North Anna 3 site-specific seismic loads from LMSMs to NASTRAN FEMs is identical to the methodology used in the standard design. The applicant also explained that the loads applied to the NASTRAN models represent the same distribution of the seismic load demands as those presented in the bounding reports which were reviewed during the North Anna 3 Audit 2 and are described in the staff's Audit Summary Report (ADAMS Accession No. ML16193A047). Section 6.2.3.9.1 of the RB structural design report (WG3-U71-ERD-S-0004, Rev. 2) describes how seismic loads are developed from RB/FB LMSMs and applied to RB/FB FEMs. The same methodology is used for the CB and FWSC. The global seismic loads from LMSMs are applied to the NASTRAN FEMs at floor elevations that correspond to the LMSM nodal elevations. Dynamic soil pressure loads are applied on external below-grade walls and hydrodynamic loads are applied on walls and slabs of pools at their corresponding elevations. The applicant showed comparisons between the demands calculated from LMSM seismic analyses and the loads actually applied to the NASTRAN FEMs, which provides a check that the LMSM to NASTRAN FEM load translations are acceptable.

Based on staff's review above and as discussed during a public meeting dated March 3, 2016, and as confirmed during North Anna 3 Audit 2, the staff found the application of bounding seismic loads to the NASTRAN design model acceptable because (a) the approach of applying the bounding seismic loads is the same as the DCD approach, and (b) the applicant confirmed that the applied site-specific seismic loads to the NASTRAN model are consistent with the bounding seismic loads calculated from the LMSM seismic analyses.

Application of RCCV Thermal Loads

FSAR Sections 3.8.1 and FSAR Appendix 3G, Section 3G.7.5.2 describe that for the RCCV thermal loads, the method using 3D nonlinear analyses that was utilized in the standard design, is not used for the site-specific structural evaluation. These FSAR Sections indicate that the effects of concrete cracking due to the thermal load are considered by reducing the thermal stress using the SSDP-2D computer code described in DCD Appendix 3G, Section 3G.1.5.4. The use of SSDP-2D in the site-specific structural evaluations was possible because the design changes for the RB upper pools, described in DCD Appendix 3G, Section 3G.5.3, provided increased strength in the structures so that the thermal forces did not need to be redistributed through the 3D nonlinear program. The FSAR concludes that since the method using SSDP-2D is more conservative than the 3D nonlinear method, and because the SSDP-2D method is used for normal operating loads, it is acceptable to use the SSDP-2D method for the reduction of thermal stresses in the RCCV structural evaluation.

The staff noted that the 3D nonlinear analysis approach was utilized in the standard design in order to reduce the effects of thermal loading beyond what the SSDP computer code would provide. This occurs because the 3D nonlinear analysis method is able to redistribute member forces when cracking occurs, whereas the SSDP code does not do that. Therefore, the staff agreed that the use of the SSDP method rather than the 3D nonlinear method is conservative, and thus, acceptable for the North Anna 3 design assessment.

In summary, based on the review of the structural analysis approach used for the RCCV, CIS, RB, and FB described in FSAR Section 3.8 and Appendix 3G, the GEH reports identified above, and as confirmed in the North Anna 3 Audit 2, the staff concludes that the North Anna 3 structural analysis approach is essentially the same method as in the standard design and in the instances where they differed, as discussed above, the North Anna 3 structural analysis approach was determined to be conservative and thus, acceptable.

Structural Design

Reinforced Concrete Sections

The description of the structural design evaluation for the RCCV is provided in FSAR Appendix 3G, Section 3G.7.5.4 and GEH Report WG3-T11-DRD-S-0001, Revision 2. FSAR Appendix 3G, Section 3G.7.5.4 indicates that site-specific evaluations use the standard design models, analysis methods, loads (as described in FSAR Appendix 3G, Section 3G.7.5.2), load combinations, and acceptance criteria. However, the standard design seismic loads are replaced with the seismic loads determined from the site-specific seismic analyses described in FSAR Appendix 3A, Sections 3A.10 through 3A.19.

As described in FSAR Appendix 3G, Section 3G.7.5.4.1, the site-specific evaluations show that the RCCV standard design is adequate to resist the North Anna 3 site-specific seismic loads in combination with NS standard design loads. Furthermore, the FSAR indicates that the results of the site-specific stress checks demonstrate that the stresses of the concrete and rebar are less than the allowable stresses specified in the code and the cross sectional areas of the primary and shear reinforcement, which have been provided, meet the required values.

The staff reviewed the information in FSAR Appendix 3G, Section 3G.7.5.4 and GEH Report WG3-T11-DRD-S-0001, Revision 2. The staff found that the industry codes and standards, structural materials and their properties, loads and load combinations used in the design evaluations, and the method for checking the design of the RCCV were consistent with those used in the standard design. The staff also reviewed the results of the design evaluation for seventeen representative locations of the RCCV and found that the calculated stresses of the concrete and steel reinforcement were below allowable values. In addition, the provided reinforcement is shown to be greater than the required reinforcement for the primary and shear reinforcement. Therefore, the staff concluded that the site-specific structural design evaluation for the reinforced concrete portion of the RCCV is acceptable.

Containment Liner and Liner Anchorage

The staff reviewed FSAR Appendix 3G, Section 3G.7.5.4.1 and GEH Reports WG3-T11-DRD-S0002, Revision 0 and DE-ES-0096, Revision 0, regarding the site-specific evaluation of the containment liner plate and liner anchorage. These documents indicate that an evaluation of the structural integrity of the liner plate utilized the same methodology and acceptance criteria as that used for the standard design. The strain of the liner plate was obtained using the NASTRAN model analysis for the site-specific seismic loads combined with the NS standard design loads. The results of this evaluation, which are presented in FSAR Appendix 3G,

Table 3G.7-210, demonstrate that the maximum strains of the containment liner plate are less than the allowable limits. The staff concluded that the structural design evaluation is acceptable on the basis that it utilized the same methodology and acceptance criteria that were used in the standard design and because it demonstrated that the calculated strains are less than the code limits.

In the case of the liner anchorage, GEH Report DE-ES-0096, Revision 0, describes the evaluation of the containment liner anchorage for the North Anna 3 site-specific loadings. The evaluation approach was based on the Bechtel Topical Report BC-TOP-1, "Containment Building Liner Plate Design Report," and ACI 349-01. The effect of the fabrication/erection tolerances on the liner anchor displacement was also evaluated. Since the liner plate anchorage system was shown to satisfy the force and displacement allowable values in the ASME Code Section III, Division 2, Subsection CC, the staff concluded that the evaluation of the containment liner and liner anchorage for the North Anna 3 site-specific loadings is acceptable.

3.8.1.5 Post Combined License Activities

There are no post COL activities related to this section. ITAAC in DCD Tier 1, Revision 10, with the modification of the SSE definition will address the as-built verification of the concrete containment for the North Anna 3 seismic demand.

3.8.1.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the North Anna 3 application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to the concrete containment that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.8.1, and other NRC RGs. The staff finds that the applicant has addressed the areas related to concrete containment in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.8.1.3 of this SER.

3.8.2 Steel Components of the Reinforced Concrete Containment

3.8.2.1 Introduction

Section 3.8.2 and Appendix 3G, Section 3G.7 of the North Anna 3 FSAR, Revision 9, describe the structural analysis and design of the steel components of the RCCV that are not backed by concrete. These components include the drywell head, penetrations, personnel air locks, equipment hatches, and passive containment cooling system (PCCS) condenser. The ESBWR design approach for the standard plant design of steel components of the RCCV is provided in Section 3.8.2 and Appendix 3G, Section 3G.1 of ESBWR DCD, Tier 2, Revision 10.

3.8.2.2 Summary of Application

Section 3.8.2 and Appendix 3G of the North Anna 3 FSAR, Revision 9, incorporate by reference Section 3.8.2 and Appendix 3G of the ESBWR DCD, with the departure given below.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra.

This departure relates to the North Anna 3 site-specific horizontal and vertical seismic ground response spectra. These spectra result in exceedances at certain frequencies when compared to the DCD CSDRS. As a result, the applicant performed new site-specific seismic SSI and SSSI analyses with the site-specific ground response spectra. In some cases, the seismic structural loads were found to be higher than those obtained in the standard design, and thus, a structural evaluation of the ESBWR standard plant structures for acceptability at the North Anna 3 site was performed. In a few instances as required for site-specific conditions, the standard design is modified to ensure seismic adequacy. Including as discussed in FSAR Appendix 3G, Section 3.G.7.5.4.1 the PCCS condenser support saddle bolts and their embedment are designed to withstand the site-specific seismic loads.

In FSAR Appendix 3G, Section 3G.7, the applicant described the site-specific structural evaluation of the RB/FB complex including the evaluation of the steel components of the RCCV. The loads, load combinations, and material properties are provided in FSAR Appendix 3G, Section 3G.7.5.2, and the analysis and design evaluation are provided in FSAR Appendix 3G, Section 3G.7.5.4.1. The analysis approach and the results of the drywell head evaluation are described in FSAR Appendix 3G, Section 3G.7.5.4.1.4. The analysis approach and the results of the PCCS condenser evaluation are described in FSAR Appendix 3G, Section 3G.7.5.4.1.5.

The results of the evaluation for the drywell head show that the calculated stresses meet ASME Code limits using the standard design process. The results of the evaluation for the PCCS condenser show that although certain loads are higher than the standard design loads, the PCCS stresses remain below the allowable stress limits. The evaluation also indicated that the PCCS condenser saddle support bolt tension load due to the North Anna 3 seismic demand has increased. These bolts and their embedment will be designed to withstand the increased tension load during the final embedment design.

3.8.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the steel portions of the containment, and the associated acceptance criteria, are in SRP Section 3.8.2. The specific requirements include the following:

- 10 CFR 50.55a and 10 CFR Part 50, Appendix A, GDC 1, as they relate to designing, fabricating, erecting, testing, and inspecting steel containments to quality standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to designing steel containments to be capable of withstanding the most severe natural phenomena such as winds, tornados, floods, and earthquakes and the appropriate combination of all loads.

- 10 CFR Part 50, Appendix A, GDC 4, as it relates to the capability of steel containments to withstand the dynamic effects of equipment failures, including missiles, pipe whipping, and blowdown loads associated with LOCAs.

- 10 CFR Part 50, Appendix A, GDC 16, as it relates to the capability of the steel containment to act as a leak-tight membrane to prevent the uncontrolled release of radioactive effluents to the environment.

- 10 CFR Part 50, Appendix A, GDC 50, as it relates to designing steel containments with sufficient margin of safety to accommodate appropriate design loads.

- 10 CFR Part 50, Appendix B as it relates to the QA criteria for nuclear power plants.

- 10 CFR 50.44, as it relates to the capability of the steel containment of existing plants and new plants to resist those loads associated with combustible gas generation from a metal-water reaction of the fuel cladding.

- 10 CFR 52.80(a), which requires that a COL application contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and the Commission's rules and regulations.

In addition, the acceptance criteria, regulatory guidance, and industry codes/standards associated with the review of FSAR Section 3.8.2 include the following:

- SRP Section 3.8.2 guidance to review the design, construction, and testing of the steel components of the containment to ensure that the containment maintains its structural integrity and can perform its intended safety function during all loading conditions.

- RG 1.7

- RG 1.57, “Design Limits and Loading Combinations for Metal Primary Reactor Containment System Components”

- RG 1.216

- 2004 ASME Code, Section III, Division 1, “Nuclear Power Plant Components,” Subsection NE, Class MC

3.8.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.8.2 and Appendix 3G of the ESBWR DCD. The staff reviewed Section 3.8.2 and Appendix 3G of the North Anna 3 FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the North Anna 3 FSAR as given below.

In addition, the staff conducted a structural audit (North Anna 3 Audit 2) during the week of March 21, 2016 at the applicant's contractor GEH office in Wilmington, North Carolina. The purpose of this audit was to (1) review detailed analysis reports and design calculations performed by the applicant that support the information in the FSAR, (2) confirm the basis supporting the applicants' RAI responses, and (3) review the draft FSAR revisions from RAI responses to ensure consistency with the applicant's design basis information.

<u>Departure</u>

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 related to the applicant's structural evaluation of the steel components of the RCCV for the site-specific seismic loads applied to the RCCV. These evaluations are described in FSAR Appendix 3G, Section 3G.7. The staff's technical evaluation of the steel components of the RCCV design considering these site-specific loads is given below.

As indicated in FSAR Appendix 3G, Section 3G.7.1, DCD Appendix 3G, Section 3G.1 remains applicable for the analysis and design of the RB, RCCV, and CIS with the seismic loads based on the DCD CSDRS. The evaluation of the RCCV for the site-specific seismic loads is provided in FSAR Appendix 3G, Section 3G.7 in order to address the exceedances from the standard design seismic loads.

<u>Analytical Models</u>

The steel components of the RCCV consisting of the drywell head, penetrations, personnel air locks, equipment hatches, and PCCS condenser were not discretely modeled in the global FEM. Each of the steel component was evaluated separately. Therefore, the specific analytical models used for each of the steel components of the RCCV are addressed below under the heading, "*Structural Design*," of this SER.

<u>Site Design Loads, Load Combinations, and Material Properties</u>

The description of the site design loads, load combinations, and material properties is provided in FSAR Appendix 3G, Section 3G.7.5.2. The FSAR indicates that with the exception of seismic loads, the site-specific structural evaluations utilize the loads, load combinations, and acceptance criteria that were used in the standard design. The FSAR lists the various loads and the corresponding sections in the ESBWR DCD where these are described. In addition, the staff did not identify any changes or deviations from the material properties used in the standard design.

FSAR Appendix 3G, Section 3G.7.5.2 also indicates that North Anna 3 seismic loads are developed from the site-specific SSI analyses described in FSAR Appendix 3A, Section 3A.18.1.1. These seismic loads consider the effects of structural stiffness variations described in FSAR Appendix 3A, Section 3A.17.9.1. The effects of seismic SSSI and structure soil separation on the overall RB/FB complex are discussed in SER Section 3.8.4 below.

In addition to the information provided in FSAR Appendix 3G, Section 3G.7.5.2, the staff reviewed the GEH reports listed below related to steel components of the RCCV that are not backed by concrete.

1. WG3-T11-DRD-S-0003, Revision 0, “Structural Design Report for Containment Metal Components” (ADAMS Accession No. ML15362A008, ML15362A013 Non-public)

2. DE-ES-0089, Revision 0, “Stress Analysis Report for Drywell Head” (ADAMS Accession No. ML15362A012)

3. 002N8530, Revision 4, “North Anna 3 PCCS Condenser Seismic Analysis” (ADAMS Accession No. ML16125A366)

The information provided in FSAR Appendix 3G, Section 3G.7.5.2, regarding loads, load combinations, and material properties is acceptable because, with the exception of the seismic loads, the standard design loads, load combinations, and material properties were used. The staff also reviewed the GEH reports and found that for these components, the NS loads, load combinations, and material properties are the same as those in the standard design. The site-specific seismic loads were found to be acceptable because they correspond to the seismic loads described in FSAR Appendix 3A, Section 3A.18.

Structural Analysis

Since the steel components of the RCCV were not discretely modeled in the RB/FB global FEM, the steel components were evaluated separately. Therefore, the site-specific structural analysis used for the steel components of the RCCV is addressed below under the heading of “Structural Design.”

Structural Design

In FSAR Section 3.8.2, the applicant only made one change which is to replace the last paragraph in DCD Section 3.8.2.4.1.5 regarding the PCCS. The change made to this paragraph was to indicate that the details of the site-specific analysis of the PCCS condenser, which uses the same approach as the DCD but with North Anna 3 seismic loads, can be found in GEH Report 002N8530, Revision 4.

The staff notes that other changes to the DCD regarding the steel components of the RCCV are described in FSAR Appendix 3G, Section 3G.7, and these are also discussed below for each of the RCCV steel components.

PCCS

In response to RAI 03.07.02-21 (North Anna 3-15-037, ADAMS Accession No. ML15364A384), the applicant described the site-specific seismic evaluation of the PCCS condenser in FSAR Appendix 3G, Sections 3G.7, 3G.7.5.4.1, and 3G.7.5.4.1.5. The staff reviewed these sections regarding the evaluation of the PCCS. These sections indicate that a site-specific structural evaluation was performed for the PCCS condenser and its support, using the standard design models and methods, and the North Anna 3 site-specific seismic ISRS as input. Results of the site-specific analyses indicated that some of the site-specific loads were higher than the standard design loads. However, the PCCS condenser stresses were bounded by the standard design stresses or were shown to be below allowable stresses. For the North Anna 3 PCCS condenser support, an increase in the tension load was calculated in the support saddle bolts and this increased load will be used in the design of the bolts and the embedment.

The staff further reviewed the information in FSAR Sections 3.8.2 and FSAR Appendix 3G, Section 3G.7, GEH Report 002N8530, Revision 4, and other supporting documents during North Anna 3 Audit 2. The staff found that the analysis approach, industry codes and standards, structural materials and their properties, loads and load combinations, and the method for checking the design of the steel components were consistent with those used in the standard design. The staff verified that the response spectra used for the analysis are the North Anna 3 bounding design ISRS obtained from the site-specific bounding SSI analysis described in FSAR Appendix 3A, Section 3A.18.2. The staff also reviewed the results of the design evaluation for the steel components and the anchor bolt loads. The staff noted that with the exception of the tension load on the support saddle bolts, the calculated stresses and loads were below allowable values. Since the PCCS anchor bolts are designed during the detailed design phase, the applicant indicated that the support saddle bolts will be designed for the increased tension load due to the increased North Anna 3 seismic demand. In addition, the applicant stated that further assurance of the as-built PCCS condenser and its support to withstand the site-specific seismic load is provided through performance of ITAAC 5 of DCD Tier 1, Table 2.15.4-2.

The staff found the site-specific evaluation of the PCCS condenser and its anchorage due to increase in the North Anna 3 site-specific seismic demand acceptable because: (a) the site-specific evaluation is based on the same methodology as the standard design, but with the North Anna 3 seismic demand, (b) the PCCS saddle bolts will be designed for the increased tension load due to the North Anna 3 seismic demand, (c) the as-built PCCS condenser and its support to withstand the seismic load will be verified through ITAAC 5 of DCD Tier 1, Table 2.15.4-2, and (d) the definition of SSE for the performance of the ITAAC is changed in COLA Part 10 to include both the CSDRS and the North Anna 3 response spectra to ensure ITAAC verification for DCD CSDRS and the North Anna 3 seismic load.

RCCV Drywell Head

The staff reviewed FSAR Appendix 3G, Sections 3G.7.5.4.1 and 3G.7.5.4.1.4 regarding the evaluation of the RCCV drywell head. These sections describe the analysis and design of the drywell head using the NASTRAN finite element computer code. These sections also indicate that the stresses developed from the combination of applicable loads and the North Anna 3 site-specific seismic load were shown to be below allowable stresses except for one case under ASME Service Levels A and B, as in the standard design. In this case, it was shown to be acceptable based on the simplified elastic-plastic analysis approach in NE-3228.3 of the ASME

Boiler and Pressure Vessel Code (BPVC), Section III, using the same process as in the standard design.

The staff reviewed FSAR Appendix 3G, Table 3G.7-211 which contains the summary of the drywell head stresses and confirmed that the calculated stresses were less than the allowable stresses, and in the one exception, the simplified elastic-plastic approach in NE-3228 was utilized.

The staff also reviewed the information in two GEH reports related to the drywell head. GEH Report WG3-T11-DRD-S-0003, Revision 0 provides the site-specific evaluation for the overall drywell head. GEH Report DE-ES-0089, Revision 0 provides the site-specific evaluation of subcomponents of the drywell head consisting of the drywell head flange and flange plates, gusset plates of the flange plates, and concrete portion at the flange plates. The staff found that the structural model; loads, load combinations, and material properties; acceptance criteria; and design approach for the drywell head were consistent with those used in the standard design.

Since the North Anna 3 evaluation for the site-specific seismic loads used the same methodology as the standard design and it was demonstrated that the code limits were satisfied, the design of the drywell head is considered acceptable.

Air Lock, Hatches and Penetrations

The description, typical details, loads and load combinations, design and analysis procedures, and acceptance criteria for the air lock, hatches, and penetrations are provided in DCD Sections 3.8.2 and DCD Appendix 3G, Section 3G.1. While procedures are provided for the analysis and design of the air lock, hatches, and penetrations, the design results for these components were not provided because the DCD only provided the analysis and design results for representative/critical structural sections/components. The remaining structural sections/components would be performed as part of the detailed design stage. In the case of components such as penetrations, the loading from connecting piping were not known at the time. Similarly, in the North Anna 3 FSAR, the analysis and design results were provided for the same critical sections/components that were considered in the standard design, which did not include the air lock, hatches, and penetrations. To address the analysis and design results of these components, as well as the remaining structural members and components, the staff relies on the ITAAC for containment which are given in Table 2.15.1-2 of DCD Tier 1, Revision 10. In the case of North Anna 3, an evaluation will need to be performed considering the North Anna 3 site-specific seismic demand and this will be ensured by the ITAAC on containment which requires an ASME Code Design Report to ensure the design is acceptable.

3.8.2.5 Post Combined License Activities

There are no post COL activities related to this section. ITAAC in DCD Tier 1, Revision 10, with the modification of the SSE definition will address the as-built verification of the steel components of the RCCV for the North Anna 3 seismic demand.

3.8.2.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the North Anna 3 application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to the steel components of the concrete containment that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.8.2, and other NRC RGs. The staff finds that the applicant has addressed the areas related to steel components of the concrete containment in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.8.2.3 of this SER.

3.8.3 Concrete and Steel Internal Structures of the Concrete Containment

3.8.3.1 Introduction

Section 3.8.3 and Appendix 3G of the North Anna 3 FSAR, Revision 9, describe the structural analysis and design evaluation of the concrete and steel internal structures of the RCCV. These components include the diaphragm floor, vent wall, GDCS pool walls, RSW, RPV support brackets, and miscellaneous platforms. The ESBWR design approach for the standard plant design of the CIS is provided in Section 3.8.3 and Appendix 3G of ESBWR DCD, Tier 2, Revision 10.

3.8.3.2 Summary of Application

Section 3.8.3 and Appendix 3G of the North Anna 3 FSAR, Revision 9, incorporate by reference Section 3.8.3 and Appendix 3G of the ESBWR DCD, with the departure given below.

Departure

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra.

This departure relates to the North Anna 3 site-specific horizontal and vertical seismic ground response spectra. These spectra result in exceedances at certain frequencies when compared to the DCD CSDRS. As a result, the applicant performed new site-specific seismic SSI and SSSI analyses with the site-specific ground response spectra and the site-specific subgrade properties. In some cases, the site-specific seismic structural loads were found to be higher than those used for the standard design, and thus, a structural evaluation of the ESBWR standard plant structures for acceptability at the North Anna 3 site was performed. In a few instances as required for site-specific conditions, the standard design is modified to ensure seismic adequacy.

In FSAR Appendix 3G, Section 3G.7, the applicant described the site-specific structural evaluation of the RB/FB complex including the evaluation of the CIS. The loads, load combinations, and material properties for the CIS are provided in FSAR Appendix 3G, Section 3G.7.5.2, and the structural analysis and design evaluation of the CIS are provided in FSAR Appendix 3G, Section 3G.7.5.4.2.

FSAR Appendix 3G, Section 3G.7.5.4.2 indicates that the site-specific evaluations of the CIS are performed using the same methodology as the standard design. No design changes from the standard design were needed. Also, the CIS are within the acceptance criteria of the standard design with the exception of the diaphragm floor. However, as discussed in FSAR Appendix 3G, Section 3G.7.5.4.2.1 and FSAR Appendix 3G, Table 3G.7-212, the standard design of the diaphragm floor is acceptable. Thus, no design change is required.

3.8.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the CIS and the associated acceptance criteria are in SRP Section 3.8.3. The specific requirements include the following:

- 10 CFR 50.55a and 10 CFR Part 50, Appendix A, GDC 1, as they relate to the design, fabrication, erection, and testing of CIS in accordance with quality standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the ability of the CIS without loss of capability to perform their safety function, to withstand the effects of natural phenomena, such as earthquakes, tornadoes, hurricanes, floods, and the appropriate combination of all loads.

- 10 CFR Part 50, Appendix A, GDC 4, as it relates to the protection of CIS against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit.

- 10 CFR Part 50, Appendix A, GDC 5, “Sharing of Structures, Systems, and Components,” as it relates to safety-related structures not being shared among nuclear power units, unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions.

- 10 CFR Part 50, Appendix A, GDC 50, as it relates to the design of CIS with sufficient margin of safety to accommodate appropriate design loads.

- 10 CFR Part 50, Appendix B as it relates to the QA criteria for nuclear power plants.

- 10 CFR 52.80(a), which requires that a COL application contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and the Commission's rules and regulations.

In addition, the acceptance criteria, regulatory guidance, and industry codes/standards associated with the review of FSAR Section 3.8.3 include the following:

- SRP Section 3.8.3 guidance to review the design, construction, and testing of the CIS to ensure that the CIS maintain their structural integrity and can perform their intended safety function during all loading conditions.

- RG 1.69, “Concrete Radiation Shields for Nuclear Power Plants”

- RG 1.142, “Safety-Related Concrete Structures for Nuclear Power Plants (Other Than Reactor Vessels and Containments)”

- RG 1.160, “Monitoring the Effectiveness of Maintenance at Nuclear Power Plants”

- RG 1.199, “Anchoring Components and Structural Supports in Concrete”

- ANSI/AISC N690-1994 and Supplement 2, “Specification for the Design, Fabrication, and Erection of Steel Safety-Related Structures for Nuclear Facilities” and Supplement 2

3.8.3.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.8.3 and Appendix 3G of the ESBWR DCD. The staff reviewed Section 3.8.3 and Appendix 3G of the North Anna 3 FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff’s review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the North Anna 3 FSAR as given below.

In addition, the staff conducted a structural audit (North Anna 3 Audit 2) during the week of March 21, 2016 at the applicant’s contractor GEH office in Wilmington, North Carolina. The purpose of this audit was to (1) review detailed analysis reports and design calculations performed by the applicant that support the information in the FSAR, (2) confirm the basis supporting the applicants’ RAI responses, and (3) review the draft FSAR revisions from RAI responses to ensure consistency with the applicant’s design basis information.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 related to the applicant’s structural evaluation of the CIS for the site-specific seismic loads applied to seismic Category I structures. These evaluations are described in FSAR Appendix 3G, Section 3G.7.5.4.2. The staff’s technical evaluation of the design of CIS considering the site-specific seismic loads is given below.

As indicated in FSAR Appendix 3G, Section 3G.7.1, DCD Appendix 3G, Section 3G.1 remains applicable for the analysis and design of the RB, RCCV, and CIS with the seismic loads based on the DCD CSDRS. The evaluation of the CIS for the site-specific seismic loads is provided in

FSAR Appendix 3G, Section 3G.7 in order to address the exceedances from the standard design seismic loads.

Analytical Models

FSAR Appendix 3G, Section 3G.7.4.1 indicates that the North Anna 3 site-specific structural models are based on the standard design structural models described in DCD Appendix 3G, Sections 3G.1.4.1 for the RB and DCD Appendix 3G, Section 3G.3.4 for the FB. Since the RCCV, CIS, RB, and FB are on a common basemat and the RCCV and RB are integrally connected, the structural models for these structures are combined into a single integrated RB/FB global model.

In addition to the information provided in FSAR Appendix 3G, Section 3G.7, the staff reviewed the following GEH reports with regard to the analytical models used for the North Anna 3 structural evaluations for the CIS:

1. WG3-T12-ERD-S-0001, Revision 0

2. DE-ES-0090, Revision 0, "Local Analysis Model for GDCS Pool" (ADAMS Accession No. ML16022A115)

The RB/FB global model, which includes the CIS, is analyzed as one integrated structure utilizing the finite element computer code NASTRAN. The description and staff's technical evaluation of the RB/FB global FEM is provided in this SER Section 3.8.1.4 under the heading "*Analytical Models*."

In the case of the GDCS pools, separate local models are utilized to perform a detailed stress analysis. Both the large and small pools are analyzed using the same analysis methodology as the standard design. The staff reviewed GEH Report DE-ES-0090, Revision 0, and confirmed that the FEMs of the GDCS pools are the same as those used in the standard design. On this basis, the staff finds the analytical models to be acceptable.

Site Design Loads, Load Combinations, and Material Properties

The description of the site design loads, load combinations, and material properties for the CIS is provided in FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.7.5.4.2. The FSAR indicates that with the exception of seismic loads, the site-specific structural evaluations utilize the same loads, load combinations, and acceptance criteria as those used in the standard design. The FSAR lists the various loads and the corresponding sections in the ESBWR DCD where these are described. In addition, the staff did not identify any changes or deviations from the material properties used in the standard design.

The site-specific seismic loads for the CIS are presented in FSAR Appendix 3A, Section 3A.18.1.1. FSAR Appendix 3G, Section 3G.7.5.2 also indicates that North Anna 3 site-specific seismic loads are developed from the site-specific SSI analyses based on the site-specific GRMS and the RB/FB FIRS. The site-specific seismic structural load demand in some cases exceeds the corresponding load demand of the standard design. These site-specific seismic loads consider the effects of structural stiffness variations described in FSAR Appendix 3A, Section 3A.17.9.1. The effects of seismic SSSI and structure soil separation on the overall RB/FB complex are discussed in SER Section 3.8.4 below.

The staff reviewed FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.7.5.4.2, GEH Report WG3-T12-ERD-S-0001, Revision 0, and the other supporting information during North Anna 3 Audit 2. Based on this review, the staff concluded that the information provided in FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.7.5.4.2, regarding loads, load combinations, and material properties is acceptable because the standard design NS loads, load combinations, and material properties, along with the North Anna 3 site-specific seismic loads were used.

Structural Analysis

Since the CIS are included and analyzed as part of the RB/FB global model, the description and staff technical evaluation of the CIS structural analysis is provided under the "*Structural Analysis*" heading of this SER.

In the case of the three GDCS pools, separate local models are utilized to perform a detailed structural analysis. These pools are analyzed using the same analysis methodology as the standard design. On this basis, the staff concluded that the structural analysis approach for the GDCS pools is acceptable.

Structural Design

The description of the structural design evaluation for the CIS is provided in FSAR Appendix 3G, Section 3G.7.5.4.2 and GEH Report WG3-T12-ERD-S-0001, Revision 0. FSAR Appendix 3G, Section 3G.7.5.4.2 indicates that site-specific evaluations of the CIS are performed using the same methodology used in the standard design. FSAR Appendix 3G, Section 3G.7.5.4 indicates that the standard design seismic loads are replaced with the seismic loads determined from the site-specific seismic analyses described in FSAR Appendix 3A, Sections 3A.10 through 3A.19.

The site-specific seismic loads for the CIS are presented in FSAR Appendix 3A, Section 3A.18.1.1. As described in FSAR Appendix 3G, Section 3G.7.5.4.2, the site-specific evaluations show that, with the exception of some diaphragm floor steel members, the CIS are within the acceptance criteria of the standard design. The applicant stated that the standard design of the diaphragm floor is still acceptable based on a refined calculation for the diaphragm floor. The refined calculation uses equivalent average acceleration for the diaphragm floor instead of the maximum acceleration load applied on the total weight of the diaphragm floor slab. The method used for calculating the site-specific equivalent average acceleration for the diaphragm floor in the refined calculation is consistent with the DCD method used for the development of out-of-plane loads for other flexible slabs. Application of maximum acceleration to the total weight of the diaphragm floor slab, as was done for the DCD evaluation, results in overly conservative load demand. The refined calculation using the average acceleration yields a significantly lower demand on the slab and reduces the stress demands below the code allowable values.

The staff reviewed FSAR Appendix 3G, Section 3G.7.5.4.2, FSAR Appendix 3A, Table 3A.18.1.1-203 and other supporting documents during North Anna 3 Audit 2, and concluded that no design change for the diaphragm floor is necessary at North Anna 3 based on the following: (1) the refined method used by the applicant to calculate the equivalent average acceleration for the diaphragm floor is acceptable because the maximum acceleration level is not uniform throughout the slab and is consistent with the DCD methodology used for other flexible slabs, (2) the use of maximum acceleration applied on the total weight of the diaphragm floor slab in the DCD evaluation is overly conservative because the slab does not experience the maximum acceleration at every location, and (3) the refined calculation using the average acceleration yields a significantly lower demand on the slab and reduces the stress demands below the code allowable values.

The staff also reviewed GEH Reports WG3-T12-ERD-S-0001, Revision 0, and DE-ES-0090, Revision 0, and other supporting information confirmed by the staff during North Anna 3 Audit 2 regarding the structural evaluation of the CIS and the GDCS pools, respectively. Based on this review, the staff confirmed that the structural design evaluation for the CIS is consistent with the approach used for the standard design. For the other structural members comprising the CIS (vent wall, GDCS pool walls, RSW, and RPV support brackets), the staff also reviewed GEH Report WG3-T12-ERD-S-0001, Revision 0, and confirmed that the calculated stresses are below the allowable values, deformation limits were satisfied, and calculated anchorage loads are less than allowable values. Therefore, the site-specific structural design evaluation for the CIS is acceptable.

3.8.3.5 Post Combined License Activities

There are no post COL activities related to this section. ITAAC in DCD Tier 1, Revision 10, with the modification of the SSE definition will address the as-built verification of the CIS for the North Anna 3 seismic demand.

3.8.3.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the North Anna 3 application and checked the referenced DCD. The staff’s review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to the CIS that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.8.3, and other NRC RGs. The staff finds that the applicant has addressed the areas related to CIS in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.8.3.3 of this SER.

3.8.4 Other Seismic Category I Structures

3.8.4.1 Introduction

Section 3.8.4 and Appendix 3G of the North Anna 3 FSAR, Revision 9, describe the structural analysis and design of other seismic Category I structures. These include the RB, FB, CB, and FWSC. The ESBWR design approach for the standard plant design of these structures is provided in Section 3.8.4 and Appendix 3G of ESBWR DCD, Tier 2, Revision 10.

3.8.4.2 Summary of Application

Section 3.8.4 and Appendix 3G of the North Anna 3 FSAR, Revision 9, incorporate by reference Section 3.8.4 and Appendix 3G of the ESBWR DCD, with the departure given below.

Departure

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra.

This departure relates to the North Anna 3 site-specific horizontal and vertical seismic ground response spectra. These spectra result in exceedances at certain frequencies when compared to the DCD CSDRS. As a result, the applicant performed new site-specific seismic SSI and SSSI analyses with the site-specific ground response spectra and the site-specific subgrade properties. In some cases, the seismic structural loads were found to be higher than those used for the standard design, and thus, a structural evaluation of the ESBWR standard plant structures for acceptability at the North Anna 3 site was performed. In a few instances as required for site-specific conditions, the standard design is modified to ensure seismic adequacy.

Summary of RB and FB

In FSAR Appendix 3G, Sections 3G.7 and 3G.9, the applicant describes the site-specific structural evaluation of the RB/FB complex. Since the RB and FB are supported by a common basemat with the RCCV and CIS, and are integrated at higher elevations with each other and with the RCCV, a global integral model was analyzed for the RCCV, CIS, RB, and FB. The analytical models used for the RB and FB are described in FSAR Appendix 3G, Sections 3G.7.4 and 3G.9.4, respectively. In FSAR Appendix 3G, Sections 3G.7.5 and 3G.9.5, the applicant describes the structural analysis and design. The description includes the site design parameters used in the structural evaluation, design loads, load combinations, and material properties. FSAR Appendix 3G, Sections 3G.7.5.4 and 3G.9.5.4 describes the structural design evaluations of RB and FB including the basemat, respectively. The foundation stability evaluation is described in FSAR Appendix 3G, Sections 3G.7.5.5 and 3G.9.5.5. These FSAR sections include the evaluation for seismic sliding and overturning, and soil bearing pressure.

The results in terms of member forces for the RB, from the evaluations performed for the site-specific seismic loads, are presented in FSAR Appendix 3G, Tables 3G.7-202 through 3G.7-204. The combined member forces and moments for selected load combinations that include seismic loads are presented in FSAR Appendix 3G, Table 3G.7-220. FSAR Appendix 3G, Table 3G.7-221 shows the sectional thicknesses and rebar ratios used in the evaluation of the RB. The calculated stresses of the concrete and steel reinforcement and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.7-222. The calculated transverse shear and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.7-223.

For the FB, the results in terms of member forces, from the evaluations performed for the site-specific seismic loads, are presented in FSAR Appendix 3G, Table 3G.9-201. The combined member forces and moments for a selected load combination that includes seismic loads are presented in FSAR Appendix 3G, Table 3G.9-202. FSAR Appendix 3G, Table 3G.9-203 shows the sectional thicknesses and rebar ratios used in the evaluation of the FB. The calculated stresses of the concrete and steel reinforcement and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.9-204. The calculated transverse shear and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.9-205. FSAR Appendix 3G, Table 3G.9-206 shows the maximum stress ratios for flexure and membrane forces and identifies the element with an overstress condition that requires the application of an alternative approach to meet the ASME Code requirement.

For stability evaluation, the factors of safety for the RB/FB foundation stability for overturning and sliding are presented in FSAR Appendix 3G, Table 3G.7-225. The maximum calculated soil dynamic bearing pressure demand for the RB/FB is presented in FSAR Appendix 3G, Table 3G.7-231.

FSAR Appendix 3G, Table 3G.7-232 shows the dynamic lateral pressure loads on the RB/FB below-grade walls that were considered in the seismic structural analysis of the RB/FB global model.

<u>Summary of CB</u>

In FSAR Appendix 3G, Section 3G.8, the applicant described the site-specific structural evaluation of the CB. The analytical models used for the CB are described in FSAR Appendix 3G, Section 3G.8.4. In FSAR Appendix 3G, Section 3G.8.5, the applicant described the structural analysis and design of the CB. This section includes the site design parameters used in the structural evaluation, design loads, load combinations, and material properties. FSAR Appendix 3G, Section 3G.8.5.4 describes the structural design evaluation of the CB including the basemat. The foundation stability evaluation is described in FSAR Appendix 3G, Section 3G.8.5.5. This section includes the evaluation for seismic sliding and overturning as well as soil bearing pressure.

The NASTRAN analysis results in terms of CB member forces, from evaluations performed for the site-specific seismic loads, are presented in FSAR Appendix 3G, Tables 3G.8-202 through 3G.8-204. The combined member forces and moments for a selected load combination that includes seismic loads are presented in FSAR Appendix 3G, Table 3G.8-205. The calculated stresses of the concrete and steel reinforcement and comparison to code limits are presented in FSAR Appendix 3G, Tables 3G.8-206a and 3G.8-206b. The calculated transverse shear and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.8-207.

For stability evaluation, the factors of safety for the CB foundation stability for overturning and sliding are presented in FSAR Appendix 3G, Tables 3G.8-208, 3G.8-209a, and 3G.8-209b. The stresses and calculated transverse shear of CB external wall against wall capacity passive pressure for a selected load combination and the comparison to code limits are presented in FSAR Appendix 3G, Tables 3G.8-210a and 3G.8-210b.

The maximum calculated soil dynamic bearing pressure demand for the CB is presented in FSAR Appendix 3G, Tables 3G.8-211a and 3G.8-211b. The dynamic lateral pressure loads on CB below-grade walls are presented in FSAR Appendix 3G, Table 3G.8-212.

Summary of FWSC

In FSAR Appendix 3G, Section 3G.10, the applicant described the site-specific structural evaluation of the FWSC. The analytical models used for the FWSC are described in FSAR Appendix 3G, Section 3G.10.4. In FSAR Appendix 3G, Section 3G.10.5, the applicant described the structural analysis and design. This includes the site design parameters used in the structural evaluation, design loads, load combinations, and material properties. FSAR Appendix 3G, Section 3G.10.5.4 describes the structural design evaluation of the FWSC including the basemat. The foundation stability evaluation is described in FSAR Appendix 3G, Section 3G.10.5.5, which includes the evaluation for seismic sliding and overturning as well as soil bearing pressure.

The NASTRAN analysis results in terms of FWSC member forces, from evaluations performed for the site-specific seismic loads, are presented in FSAR Appendix 3G, Table 3G.10-202. The combined member forces and moments for a selected load combination that includes seismic loads are presented in FSAR Appendix 3G, Table 3G.10-203. FSAR Appendix 3G, Table 3G.10-204 shows the sectional thicknesses and rebar ratios of the FWSC used in the evaluation. The calculated stresses of the concrete and steel reinforcement and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.10-205. The calculated transverse shear and comparison to code limits are presented in FSAR Appendix 3G, Table 3G.10-206. For stability evaluation, the factors of safety for the FWSC foundation stability for overturning and sliding are presented in FSAR Appendix 3G, Table 3G.10-214. The maximum calculated soil dynamic bearing pressure demand for the FWSC is presented in FSAR Appendix 3G, Table 3G.10-215.

3.8.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for other seismic Category I structures, and the associated acceptance criteria, are in SRP Section 3.8.4. The specific requirements include the following:

- 10 CFR 50.55a and 10 CFR Part 50, Appendix A, GDC 1, as they relate to SSCs being designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the design of the safety-related structures being able to withstand the most severe natural phenomena such as wind, tornadoes, hurricanes, floods, and earthquakes and the appropriate combination of all loads.

- 10 CFR Part 50, Appendix A, GDC 4, as it relates to safety-related structures being appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit.

- 10 CFR Part 50, Appendix A, GDC 5, as it relates to safety-related structures not being shared among nuclear power units, unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions.

- 10 CFR Part 50, Appendix B as it relates to the QA criteria for nuclear power plants.

- 10 CFR 52.80(a), which requires that a COL application contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and the Commission's rules and regulations.

In addition, the acceptance criteria, regulatory guidance, and industry codes/standards associated with the review of FSAR Section 3.8.4 include the following:

- SRP Section 3.8.4 guidance to review the design, construction, and testing of other seismic Category I structures to ensure that these structures maintain their structural integrity and can perform its intended safety function during all loading conditions.

- RG 1.69

- RG 1.91

- RG 1.115, “Protection Against Low-Trajectory Turbine Missiles”

- RG 1.136

- RG 1.142

- RG 1.143, “Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in LWR Plants”

- RG 1.160

- RG 1.199

- RG 1.221

- 2004 ASME Boiler and Pressure Vessel Code, Section III, Division 2, Subsection CC, “Code for Concrete Reactor Vessels and Containments”

- ACI 349-01,

- ANSI/AISC N690-1994 and Supplement No. 2.

3.8.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.8.4 and Appendix 3G of the ESBWR DCD. The staff reviewed Section 3.8.4 and Appendix 3G of the North Anna 3 FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the North Anna 3 FSAR as given below.

In addition, the staff conducted a structural audit (North Anna 3 Audit 2) during the week of March 21, 2016, at the applicant's contractor GEH office in Wilmington, North Carolina. The purpose of this audit was to (1) review detailed analysis reports and design calculations performed by the applicant that support the information in the FSAR, (2) confirm the basis supporting the applicants' RAI responses, and (3) review the draft FSAR revisions from RAI responses to ensure consistency with the applicant's design basis information.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 related to the applicant's structural evaluation of other seismic Category I structures for the site-specific seismic loads. These evaluations are described in FSAR Appendix 3G, Sections 3G.7 through 3G.10 for the RB, CB, FB, and FWSC, respectively. The staff's technical evaluation of the design of other seismic Category I structures considering these revised loads is given below.

Evaluation of RB and FB

The staff reviewed FSAR Sections 3.8.4, FSAR Appendix 3A, Section 3A.18, FSAR Appendix 3G, Section 3G.7, and 3G.9, as well as the following GEH reports with regard to the North Anna 3 structural evaluations for the RB and FB:

1. WG3-U71-ERD-S-0004, Revision 2
2. WG3-U97-ERD-S-0001, Revision 2

Analytical Models (RB and FB)

The RB/FB global model, which includes the RCCV and CIS, is analyzed as one integrated structure utilizing the finite element computer code NASTRAN. Therefore, the description and staff's technical evaluation of the RB/FB global FEM is provided in this SER Section 3.8.1.4 under the heading "*Analytical Models.*"

Site Design Loads, Load Combinations, and Material Properties

The description of the site design loads, load combinations, and material properties for the RB/FB is provided in FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.9.5.2, and GEH Reports WG3-U71-ERD-S-0004, Revision 2 and WG3-U97-ERD-S-0001, Revision 2, respectively for the RB and FB. The FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.9.5.2 indicate that with the exception of seismic loads, the site-specific structural evaluations utilized the same loads and load combinations as those used in the standard design. The seismic loads in the standard design was replaced with the North Anna 3 site-specific seismic loads. The same acceptance criteria used in the ESBWR standard design were also used for the North Anna 3 site-specific design evaluation, with a few elements that required a refined evaluation following an alternative approach that is also allowed by the ASME Code. This alternative approach is evaluated in more detail later under the heading, "*Evaluation of the Alternative Approach for Concrete Element Overstress*," in this SER below. The FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.9.5.2 list the various loads and the corresponding sections in the ESBWR DCD where these loads are described.

FSAR Appendix 3G, Sections 3G.7.5.2 and 3G.9.5.2 also indicate that North Anna 3 site-specific seismic loads described in FSAR Section 3A.18.1.1 are developed from the site-specific SSI analyses results. The bounding seismic loads for the design evaluation of the RB/FB complex are provided in FSAR Appendix 3A, Section 3A.18 and FSAR Appendix 3G, Section 3G.7.5.6, the latter of which describes the site-specific dynamic lateral soil pressures imposed on the RB/FB exterior below grade walls. The site-specific bounding seismic loads are used as input in the structural evaluation of the RCCV, CIS, and RB/FB. The bounding structural responses include: bounding maximum forces and moments, maximum accelerations, maximum accelerations at slabs and roofs, and maximum dynamic lateral pressures. The supporting information for the development of bounding seismic loads was reviewed and confirmed by the staff during North Anna 3 Audit 2.

FSAR Appendix 3G, Section 3G.7.5.2 indicates that the site-specific evaluations of the RB/FB global model utilized the bounding dynamic soil pressure loads (shown in FSAR Appendix 3G, Table 3G.7-232) obtained from the SSI analyses described in FSAR Appendix 3A, Section 3A.17.12 and the lateral at-rest soil pressures that are the same as those used for the standard design shown in DCD Appendix 3G, Figure 3G.1-19. The site-specific evaluations also considered the lateral passive resistance pressures (shown in FSAR Appendix 3G, Figure 3G.7-207) obtained from the results of the sliding stability analyses in FSAR Appendix 3G, Section 3G.7.5.5. The applicant found that lateral passive resistance pressures on RB/FB walls are enveloped by the corresponding standard design loads.

The staff reviewed the information provided in FSAR Section 3.8 and Appendix 3G, the GEH reports identified above, and the North Anna 3 Audit 2. The staff's review confirmed that the bounding seismic loads envelop the effects of structural stiffness variations, structure-soil separation, and variations in the subgrade material properties. The bounding seismic design loads for the RB/FB complex in some instances exceed the seismic design loads of the standard design. These seismic loads consider the effects of structural stiffness variations (cracked vs uncracked concrete) as described in FSAR Appendix 3A, Section 3A.17.9.1. The effects of seismic SSSI of the CB on RB/FB are expected to be minimal as the RB/FB is larger and heavier than the CB. This is consistent with the ESBWR standard design which does not consider the SSSI effect of CB on the RB/FB. In addition, the interaction of RB/FB with the nearby non-seismic Category I structures, namely the TB, RWB, SB, and ADB, will be addressed through the ITAAC completion package as described in FSAR Section 3.7.2.8. The SSI analysis of RB/FB includes cases of full embedment and partial embedment (by removing the saprolite soil layer to 5.2 m below the ground surface), the latter of which represents the maximum structure soil separation on the overall RB/FB complex. Variations in subgrade material properties and structural fill and concrete fill are also considered explicitly by using three deterministic soil profiles (LB, BE, and UB). The detailed staff evaluation of seismic analysis cases to consider various loading environments is presented in SER Section 3.7.2.

In particular, in the SSI analyses of the uncracked model, OBE damping instead of SSE damping was conservatively used for developing structural responses in addition to the ISRS.

This conservatism can contribute to the few overstress conditions for RB and FB that are identified in the FSAR. However, the applicant's reconciliation of these overstress conditions does not rely entirely on this conservatism. The overstress conditions are evaluated using an alternative approach that is also allowed by the ASME Code to meet the code limits. The evaluation of this alternative approach is described under "*Structural Design (RB and FB),*" below in this SER.

In summary, the staff review confirmed that except for the seismic loads, the North Anna 3 site-specific structural evaluation utilized the same NS loadings, the same load combinations, and the same material properties as those used in the standard design. In the case of the site-specific seismic loads, the staff reviewed and confirmed during North Anna 3 Audit 2 that the site-specific seismic bounding load results presented in FSAR Appendix 3A, Section 3A.18 and FSAR Appendix 3G, Section 3G.7.5.6 were used for the RB/FB structural evaluation. The staff review concluded that the applicant's development of seismic loads for the design evaluation of the RB/FB complex considered applicable loading/site condition variations and conservatively used the OBE damping in the uncracked model for structural response calculation. In addition, the staff did not identify any changes or deviations from the material properties used in the standard design for concrete, reinforcing steel, and structural steel. Therefore, the staff concluded that the North Anna 3 site design loads, load combinations, and material properties are acceptable.

Structural Analysis (RB and FB)

Since the RB/FB global model includes the RB, FB, RCCV, and CIS and is analyzed as an integral FEM using the NASTRAN code, the description and staff technical evaluation of the RB/FB structural analysis is provided in this SER under the "*Structural Analysis*" heading.

Structural Design (RB and FB)

The applicant's structural design evaluation of the RB/FB complex utilized an alternative approach to evaluate the overstress conditions at a few locations, and included more locations in the structures than the DCD locations where the North Anna 3 site-specific structural responses are expected to be higher based on the characteristics of the North Anna 3 input motion. These aspects are evaluated below under the headings, "*Evaluation of the Alternative Approach for Concrete Element Overstress"* and "*Evaluation of the Sensitivity Study of NA3 Selected Elements,"* as generic procedures for structural design evaluation. Some of the following staff evaluation is also applicable to the CB.

Staff evaluation of the applicant's structural design evaluations of the RB and FB is provided in this SER under the headings, "*Design of the RB"* and "*Design of the FB,"* respectively.

Evaluation of the Alternative Approach for Concrete Element Overstress

FSAR Section 3.8.4.5 and FSAR Appendix 3G, Sections 3G.7.5.4 and 3G.9.5.4 indicate that the structural acceptance criteria for the site-specific structural evaluations of the RB and FB are the same as the acceptance criteria for the standard design, with an exception that the site-specific structural evaluations may use a refined evaluation (hereinafter referred to as an *alternative approach*). Most of the design evaluation was performed using the SSDP-2D computer program for the RB/FB to satisfy both ASME BPVC, Section III 2004 and ACI 349-01, which are consistent with the DCD design criteria. The FSAR also indicates that for cases where an element exceeds the ASME acceptance criteria using the SSDP-2D analysis, additional reinforcing steel is added or the element is evaluated using axial load-moment interaction curves which satisfy both ACI 349-01 and the alternative ASME acceptance criteria. The alternative approach allowed by the ASME Code involves the parabolic concrete stress-strain relationship and applicable ASME allowable stresses for a cross section subjected to membrane loads and moments due to factored loads. As compared to this alternative approach, the SSDP-2D analysis is considered more conservative because it utilizes an approach for meeting ASME Code requirements for factored loads based on the linear concrete stress-strain relationship and the concrete principal stress for comparison with the code allowable stress.

Most of the DCD selected elements and the North Anna 3 additional selected elements satisfy both ACI 349-01 and the ASME standard through the application of the SSDP-2D computer program. However, a few elements were found to exceed the ASME allowable stress in the design evaluation using the SSDP-2D program. Therefore, the approach used to design non-containment reinforced concrete members was reviewed by the applicant regarding the modification of the structural acceptance criteria identified in North Anna 3 FSAR, Section 3.8.4. More specifically, the need to revise the criteria arose because the site-specific structural evaluations indicate that one segment of the FB external wall experiences compression stress demand under combined flexure and membrane forces that exceeds the acceptance criteria of the ASME BPVC for allowable compressive stress based on the linear concrete stress-strain relationship. Similarly, among the North Anna 3 selected elements in the sensitivity study (evaluated under the heading in this SER, "*Evaluation of the Sensitivity Study of North Anna 3 Selected Elements",* below), there are three elements in the RB external wall that also exceed the ASME allowable compressive stress in concrete and allowable tensile stress for rebar. These exceedances occurred as a result of using the SSDP-2D computer program, which was used in the standard design. As indicated by the applicant, the SSDP-2D computer program is more conservative than the parabolic or nonlinear stress distribution that is also accepted by ASME BPVC, Section III, Division 2, Subsection CC.

More details on the alternate approach are discussed in the applicant's response to RAI 7536 Question 03.07.02-17 (ADAMS Accession No. ML16146A789). The staff reviewed the related information and GEH reports that support the applicant's RAI response during North Anna 3 Audit 2. The alternative approach, also allowed by the ASME Code, ensures that the more limiting acceptance criteria of the ASME Code and the ACI 349-01 Code are met. During the audit, the applicant discussed with the staff in more detail this alternative approach and the conservatism in the SSDP-2D program. Based on this review, the staff found this alternative approach for design evaluation acceptable because it is in accordance with the ASME Code and the ACI 349-01 Code.

Evaluation of the Sensitivity Study of North Anna 3 Selected Elements

FSAR Appendix 3G indicates that the adequacy of the seismic Category I structures for the North Anna 3 site-specific conditions is demonstrated by comparing the site-specific demands with the structural members section capacities for the same set of selected elements as those considered for the standard design.

In addition to the DCD selected elements, FSAR Section 3G also indicates that the applicant performed a sensitivity study to evaluate additional elements for North Anna 3. During the public meeting on November 20, 2014 on Dominion's SCP, the staff discussed with Dominion that given the North Anna 3 seismic ground motion exceeds the CSDRS at some frequencies, whether some other locations in addition to the DCD selected elements should be evaluated during the North Anna 3 design evaluation. As discussed in the March 3, 2016 public meeting and documented in FSAR Section 3G, a sensitivity study was performed for the design evaluation of additional elements in RB/FB and CB particularly at locations where North Anna 3 site-specific bounding seismic loads exceed the corresponding DCD seismic loads. There was no need for additional North Anna 3 site-specific elements for RCCV, CIS and FWSC as the DCD elements evaluated for these structures are considered sufficient. Design evaluations were performed for 96 North Anna 3 additional selected elements (62 for RB, 27 for FB, and 7 for CB). The applicant concluded that no changes to the standard design concrete member dimensions are necessary and most of the North Anna 3 selected elements were adequate by simply using the SSDP-2D approach that is also used in the DCD. However, the applicant did find three of the North Anna 3 selected elements in the RB that did not meet the ASME allowable stress using the SSDP-2D approach. The design evaluation of these elements required the use of the alternative approach, i.e., using the parabolic concrete stress-strain relationship that is also allowed by ASME, and the applicable ASME allowable stresses for a cross section subjected to membrane loads and moments due to factored loads. In addition, 12 new rebar schedules have been designed and incorporated into the structural drawings.

More details on this sensitivity study are discussed in the applicant's response to RAI 7536 Question 03.07.02-17 (ADAMS Accession No. ML16146A789). The staff reviewed the related information and GEH report that support the applicant's RAI response during North Anna 3 Audit 2. Based on this review, the staff finds the North Anna 3 sensitivity study acceptable since it evaluates additional locations in the seismic Category I structures where the North Anna 3 site-specific seismic demands are higher than the DCD demands, and provides additional confidence in the ESBWR standard design at the North Anna 3 site. The staff notes that for the design of the remaining structural members, not included in the design of the DCD selected elements and North Anna 3 additional selected elements reviewed by the staff, will be designed during the detailed design stage using the same methodology described in the DCD and FSAR.

Design of the RB

The description of the structural design evaluation for the RB is provided in FSAR Appendix 3G, Section 3G.7.5.4.3 and GEH Report WG3-U71-ERD-S-0004, Revision 2. FSAR Appendix 3G, Section 3G.7.5.4 indicates that with the exception of seismic loads, site-specific evaluations of the RB use the same standard design models, analysis methods, loads (as described in FSAR Appendix 3G, Section 3G.7.5.2), load combinations, and acceptance criteria that were used in the standard design. However, the standard design seismic loads are replaced with the seismic loads determined from the North Anna 3 site-specific seismic analyses described in FSAR Appendix 3A, Sections 3A.10 through 3A.19.

As described in FSAR Appendix 3G, Section 3G.7.5.4.3, the site-specific evaluations show that the RB standard design is adequate to resist the North Anna 3 site-specific seismic loads in combination with NS standard design loads, with the exception of a change in the arrangement of shear ties for a single wall to withstand the North Anna 3 site-specific seismic loads. The affected wall section is at the exterior wall of the RB, Elevation 22.50 m to Elevation 24.60 m, column line R7/F1. With this change in the arrangement of shear ties, the FSAR indicates that the stresses of the concrete and rebar are less than the allowable stresses specified in the codes and the areas of the primary and shear reinforcement, which have been provided, meet the required values. FSAR Appendix 3G, Section 3G.7.5.4.3 also indicates that the stresses of steel members are less than the allowable stresses specified in the code. Furthermore, as an overall conclusion, the FSAR indicates that there is no need for any change to the standard design concrete member properties (e.g., wall and slab thicknesses, beam and column sizes) to meet the standard design structural acceptance criteria.

The staff reviewed the information in FSAR Appendix 3G, Section 3G.7.5.4 and GEH Report WG3-U71-ERD-S-0004, Revision 2 regarding the structural design evaluation of the RB. The staff's review found that the analysis model and approach, the industry codes and standards, structural materials and their properties, loads and load combinations used in the design evaluations, and the method for checking the design of the RB were consistent with those used in the standard design. The staff reviewed the results of the design evaluation for 109 representative locations of the RB (including 47 DCD-selected elements and 62 North Anna 3-selected elements), which included shear walls, basemat outside containment, floor slabs, pool girders, main steam tunnel floors and walls, and IC/PCCS pool. The staff also reviewed the change in the arrangement of shear ties for one wall and the applicant's use of the alternative approach (i.e., using the parabolic concrete stress-strain relationship and applicable ASME allowable stresses for a cross section subjected to membrane loads and moments due to factored loads). The staff found that the calculated stresses of the concrete and steel reinforcement were below allowable values, the areas of the provided primary and shear reinforcement meet the required values, and the stresses of steel members are less than the allowable stresses specified in the code. Therefore, the staff concluded the site-specific structural design evaluation for the RB is acceptable.

Design of the FB

The description of the structural design evaluation for the FB is provided in FSAR Appendix 3G, Section 3G.9.5.4 and GEH Report WG3-U97-ERD-S-0001, Revision 2. FSAR Appendix 3G, Section 3G.9.5.4 indicates that with the exception of seismic loads, site-specific evaluations use the same standard design models, analysis methods, loads (as described in FSAR Appendix G, Section 3G.9.5.2), load combinations, and acceptance criteria that were used in the standard design. However, the standard design seismic loads are replaced with the seismic loads determined from the site-specific seismic analyses described in FSAR Appendix 3A, Sections 3A.10 through 3A.19.

FSAR Appendix 3G, Section 3G.9.5.4 describes the site-specific evaluations which show that the FB standard design is adequate to resist the North Anna 3 site-specific seismic loads in combination with NS standard design loads, with the following exceptions:

1. An overstress condition at the exterior wall element (Element 72004 from Elevation 4.65 m to Elevation 6.60 m), which exceeds the allowable SSDP-2D stresses by 3 percent for the axial-flexural behavior and is resolved using the alternative approach that is described in FSAR Section 3.8.4.5. This alternative approach that is also allowed in the ASME Code is evaluated above under the heading, "*Evaluation of the Alternative Approach for Concrete Element Overstress*," of this SER;

2. A change in the arrangements of reinforcements in two FB exterior wall segments (Elements 72001 and 72004, at the exterior wall, between Elevations 4.65 m and 6.60 m between columns FA and FF); and

3. A change in the arrangement of exterior wall shear ties (Element 72004) at exterior FB wall between Elevations 4.65 m and 6.60 m between columns FA and FF).

With these changes in reinforcement and the resolution of the overstress condition, the FSAR indicates that the results of the site-specific stress checks demonstrate that the stresses of the concrete and rebar are less than the allowable stresses specified in the codes and the areas of the primary and shear reinforcement, which have been provided, meet the required values. The FSAR also indicates that the stresses of steel members are less than the allowable stresses specified in the code. Furthermore, as an overall conclusion, the FSAR indicates that there is no need for any change to the standard design concrete member properties (e.g., wall and slab thicknesses, beam and column sizes) to meet the standard design structural acceptance criteria.

The staff reviewed the information in FSAR Appendix 3G, Section 3G.9.5.4 and GEH Report WG3-U97-ERD-S-0001, Revision 2. The staff found that the industry codes and standards, structural materials and their properties, loads and load combinations used in the design evaluations, and the method for checking the design of the FB were consistent with those used in the standard design. The staff also reviewed the results of the design evaluation for 53 representative locations of the FB (including 26 DCD-selected elements and 27 North Anna 3-selected elements), which included shear walls and spent fuel pool walls, floor slabs, and basemat. The staff also reviewed the three changes in the arrangement of rebar and shear ties and the applicant's use of the alternative approach (i.e., using the parabolic concrete stress-strain relationship and applicable ASME allowable stresses for a cross section subjected to membrane loads and moments due to factored loads). The staff found that the calculated stresses of the concrete and steel reinforcement were below allowable values and the provided reinforcement was greater than the required reinforcement for the primary and shear reinforcement. Therefore, the staff concluded the site-specific structural design evaluation for the FB is acceptable.

Evaluation of CB

The staff reviewed FSAR Sections 3.8.4, FSAR Appendix 3A, Section 3A.18, and FSAR Appendix 3G, Section 3G.8, as well as the following GEH report with regard to the North Anna 3 structural evaluations for the CB:

1. WG3-U73-ERD-S-0004, Revision 3, "Control Building Structural Design Report" (ADAMS Accession No. ML16148A051, ML16148A126 Non-public).

Analytical Model (CB)

The description of the analytical model for the CB is provided in FSAR Appendix 3G, Section 3G.8.4. FSAR Appendix 3G, Section 3G.8.4.1 indicates that site-specific structural model for the CB is based on the standard design structural model described in DCD Appendix 003G, Section 3G.2.4.1. FSAR Appendix 3G, Section 3G.8.4.2 also indicates that the site-specific foundation model for the CB is based on the standard design foundation model described in DCD Appendix 3G, Section 3G.2.4.2. The staff noted in FSAR Appendix 3G, Section 3G.8.5.1 that the site-specific foundation model for the CB uses spring elements based on generic soft soil conditions considered for the ESBWR DCD. GEH Report WG3-U73-ERD-S-0004, Revision 3 provides more details of the analytical model used for the site-specific structural evaluations for the CB.

The staff reviewed FSAR Appendix 3G, Sections 3G.8.4 and 3G.8.5.1, DCD Appendix 3G, Section 3G.2.4, and GEH Report WG3-U73-ERD-S-0004, Revision 3. The staff also reviewed the supporting information on the site-specific GEH analytical model during North Anna 3 Audit 2. Based on this review, the staff confirmed that the site-specific structural model and foundation model for the CB are consistent with the models used for the standard design. The staff's conclusions on the acceptability of using generic soft soil conditions for North Anna 3 site is discussed in SER Section 3.8.1.4 under the heading *"Structural Analysis."* The staff found that the results of the study for site subgrade stiffness conditions performed for RB/FB also apply to the CB because the site subgrade stiffness conditions for both CB and RB/FB are similar. Therefore, the staff concluded that the use of the CB analytical model as described in FSAR Appendix 3G, Section 3G.8.4 for the site-specific structural evaluations is acceptable.

Site Design Loads, Load Combinations, and Material Properties (CB)

The description of the site design loads, load combinations, and material properties for the CB is provided in FSAR Appendix 3G, Section 3G.8.5.2 and GEH Report WG3-U73-ERD-S-0004, Revision 3. FSAR Appendix 3G, Section 3G.8.5.2 indicates that with the exception of seismic loads, the site-specific structural evaluations of the CB utilize the same loads, load combinations, and acceptance criteria that were used in the standard design. The seismic loads in the standard design were replaced with the North Anna 3 site-specific seismic loads. FSAR Appendix 3G, Section 3G.8.5.2 lists the various loads and the corresponding sections in the ESBWR DCD where these loads are described. In addition, FSAR Appendix 3G, Section 3G.8.5.2 indicates that the site-specific structural evaluations for the CB utilize the same material properties of concrete, reinforcing steel, and structural steel as those used in the standard design. The staff did not identify any changes or deviations from the material properties used in the standard design.

The bounding site-specific seismic structural load demand for the CB is provided in FSAR Appendix 3A, Section 3A.18.1.2. This section indicates that site-specific seismic loads for the CB are developed from the site-specific SSI analyses of CB stand-alone model with full stiffness and SSE damping properties. The site-specific seismic structural load demand in some cases exceeds the corresponding load demand of the standard design. These site-specific seismic loads consider the effects of soil separation (PE and FE conditions) described in FSAR Appendix 3A, Section 3A.16.3.2 and structural stiffness variations (concrete cracking) described in FSAR Appendix 3A, Section 3A.17.9.2. However, the CB bounding site-specific seismic structural load demand does not include SSSI effects of the FWSC and RB/FB on the CB. The site-specific evaluations of effects of seismic SSSI of the FWSC and RB/FB on the seismic response of CB in FSAR Appendix 3A, Section 3A.17.11 show a few small exceedances in some of the local load demand, which have a negligible effect on the CB. Therefore, these exceedances are not included in the site-specific evaluation of the CB. In addition, the interaction of CB with the nearby non-seismic Category I structures will be addressed through the ITAAC completion package as described in FSAR Section 3.7.2.8. Variations in subgrade material properties and structural fill and concrete fill are considered explicitly by using three deterministic soil profiles (LB, BE, and UB).

FSAR Appendix 3G, Section 3G.8.5.2 indicates that the site-specific structural evaluations of the CB consider: (1) at-rest static soil pressure loads same as the ones used for the standard design shown in DCD Appendix 3G, Figure 3G.2-12, (2) site-specific lateral dynamic pressure loads (shown in FSAR Appendix 3G, Table 3G.8-212) obtained from the site-specific SSI analyses described in FSAR Appendix 3A, Section 3A.17.13.4, and (3) site-specific passive resistance pressures (shown in FSAR Appendix 3G, Table 3G.8-213) obtained from the sliding stability calculations in FSAR Appendix 3G, Section 3G.8.5.6.

The staff reviewed FSAR Appendix 3G, Section 3G.8.5.2, GEH Report WG3-U73-ERD-S-0004, Revision 3, and other supporting information as confirmed during North Anna 3 Audit 2. Based on this review, the staff determined that with the exception of seismic loads, the site-specific structural evaluations of the CB utilize the same loads, load combinations, acceptance criteria, and material properties as those used in the standard design. The staff also confirmed that the bounding site-specific seismic load demand for the CB was used as input to the CB structural evaluations. The staff further confirmed that the bounding structural loads envelop the effects of: (1) soil separation (PE and FE conditions) described in FSAR Appendix 3A, Section 3A.16.3.2, and (2) structural stiffness variations (concrete cracking) described in FSAR Appendix 3A, Section 3A.17.9.2. In addition, the staff reviewed SSSI effects of the FWSC and RB/FB on the CB, and determined that a few small exceedances in some of the local load demand have no effect on the CB structural evaluation. The staff confirmed that at-rest static soil pressure loads for the CB site-specific structural evaluation were consistent with those at-rest static soil pressure loads used in the standard design. The staff also confirmed that site-specific lateral dynamic pressure loads shown in FSAR Appendix 3G, Table 3G.8-212 and site-specific passive resistance pressures shown in FSAR Appendix 3G, Table 3G.8-213 along with at-rest static soil pressure loads were used as input to the CB structural evaluations. Therefore, the staff concluded that the North Anna 3 site design loads, load combinations, and material properties used for the CB site-specific structural evaluations are acceptable.

Structural Analysis (CB)

The description of the structural analysis performed for the CB is provided in FSAR Appendix 3G, Section 3G.8.5 and GEH Report WG3-U73-ERD-S-0004, Revision 3. The structural analysis of the CB is performed consistently with the procedure used for the standard design, and the CB model is analyzed using the same NASTRAN finite element computer program used for the standard design, as described in DCD Section 3C.2.

Section 6.2.3.6 of the CB structural design report (WG3-U73-ERD-S-0004, Rev. 3) describes how site-specific seismic loads are developed from the CB LMSM and applied to the CB FEM. The methodology used to convert North Anna 3 site-specific seismic loads from LMSM to NASTRAN FEM is identical to the methodology used in the standard design. The staff's acceptability of applying bounding site-specific seismic loads to the NASTRAN design model is discussed in this SER Section 3.8.1.4 under the heading "*Structural Analysis*." The combined member forces and moments for a selected load combination that include site-specific seismic loads are presented in FSAR Appendix 3G, Table 3G.8-205.

The staff reviewed FSAR Appendix 3G, Section 3G.8.5, GEH Report WG3-U73-ERD-S-0004, Revision 3, and other supporting information was confirmed by the staff during the North Anna 3 Audit 2. Based on this review, the staff determined that: (1) the NASTRAN FEM for the CB is the same model as one used for the standard design, (2) with the exception of seismic loads, the site-specific structural evaluations of the CB utilize the same analysis methods, loads, load combinations, and material properties as those used in the standard design, (3) site-specific seismic loads developed from the CB site-specific seismic analyses are used to replace DCD seismic loads, and (4) the site-specific seismic forces applied to the CB model for the structural evaluation are the same as the bounding site-specific seismic load demand discussed in this

SER Section 3.8.4.4 under the heading "*Site Design Loads, Load Combinations, and Material Properties (CB)*." Therefore, the staff concluded that the structural analysis performed for the CB is acceptable.

Structural Design (CB)

The description of the structural design evaluation for the CB is provided in FSAR Appendix 3G, Section 3G.8.5.4 and GEH Report WG3-U73-ERD-S-0004, Revision 3. FSAR Appendix 3G, Section 3G.8.5.4 indicates that the site-specific structural evaluation of the CB utilizes the same models, analysis methods, loads (other than seismic loads), load combinations, and acceptance criteria as those used in standard design. However, the standard design seismic loads are replaced with the seismic loads (as described in FSAR Appendix 3G, Section 3G.8.5.2) determined from the site-specific seismic analyses described in FSAR Appendix 3A, Sections 3A.10 through 3A.19. The FSAR also indicates that the site-specific structural evaluation of the CB utilizes the same methodology used for the DCD structural evaluation described in DCD Appendix 3G, Section 3G.2.5.

The site-specific evaluations in FSAR Appendix 3G, Section 3G.8.5.4 show that the standard design CB, with a design change in steel girder SG23 (NASTRAN FEM CBAR ID 21016, Elevation 4.65 m on Column-Row CB), is adequate to resist the site-specific seismic load demands in combination with the NS ESBWR standard plant loads.

The results of site-specific stress check in FSAR Appendix 3G, Section 3G.8.5.4 also indicate that: (1) the stresses of the concrete and rebar are less than the allowable stresses specified in the code, and the areas of the primary and shear reinforcement satisfy the required values, and (2) the stresses of steel members are less than the allowable stresses specified in the code with the change in steel girder SG23.

As discussed in this SER Section 3.8.4.4 under the heading "*Evaluation of the Sensitivity Study of NA3 Selected Elements,"* regarding North Anna 3 selected elements, the sensitivity study of the CB identified seven additional elements for further site-specific structural evaluation in addition to the elements selected in the DCD. The staff reviewed FSAR Appendix 3G and confirmed supporting information during North Anna 3 Audit 2. The staff determined that the additional site-specific structural evaluation results from the sensitivity study do not change the standard design member properties (e.g., wall and slab thickness, beam and column sizes) except for adding localized reinforcement as part of the detailed design.

The staff reviewed FSAR Appendix 3G, Section 3G.8, GEH Report WG3-U73-ERD-S-0004, Revision 3, and other supporting information confirmed during North Anna 3 Audit 2. Based on this review, the staff determined that with the exception of seismic loads, the CB analysis model and approach, industry codes and standards, structural materials and their properties, loads and load combinations, acceptance criteria used in the design evaluations, and the method for applying loads were consistent with those used in the standard design. The staff also confirmed that the North Anna 3 structural design evaluation of CB utilizes the same methodology as the DCD and uses the same SSDP-2D computer program, which in addition to ACI 349-01, also follows the 2004 ASME Code. According to DCD Table 3.8-15, the acceptance criteria for CB section strength are based on the strength design method per ACI 349-01. The staff found that the CB section design is conservatively taken to be more limiting of ACI 349-01 and 2004 ASME Section III, Division 2, Subsection CC requirements. For the reinforced concrete structures of the CB, the staff reviewed the calculated stresses of the concrete and steel reinforcement and comparison to code limits for a selected load combination shown in FSAR Appendix 3G, Tables 3G.8-206a and 3G.8-206b; the staff also reviewed the calculated transverse shear and comparison to code limits shown in FSAR Appendix 3G, Table 3G.8-207. Based on this review, the staff confirmed that: (1) the stresses of the concrete and rebar are less than the allowable stresses specified in the code, and (2) the areas of the primary and shear reinforcement satisfy the required values. For the steel structures of the CB, the staff reviewed the selected calculations of steel structures including design change for one structural steel girder SG23 during the North Anna 3 Audit 2. Based on this review, the staff confirmed that the stresses of the steel members are less than the allowable stresses specified in the code, with the change in steel girder SG23.

In conclusion, the staff found that the standard design CB, with the change in the steel girder SG23, is adequate to resist the site-specific seismic load demand at North Anna 3 site.

Evaluation of FWSC

The staff reviewed FSAR Section 3.8.4, FSAR Appendix 3A, Section 3A.18, FSAR Appendix 3G, Section 3G.10, as well as the following GEH report with regard to the North Anna 3 structural evaluations for the FWSC:

1. WG3-U63-ERD-S-0003, Revision 2, "Firewater Service Complex Structural Design Report" (ADAMS Accession Nos. ML16148A050, and ML16148A125 Non-public)

Analytical Model (FWSC)

The description of the analytical model for the FWSC is provided in FSAR Appendix 3G, Section 3G.10.4. FSAR Appendix 3G, Section 3G.10.4.1 indicates that the North Anna 3 site-specific structural model for the FWSC is based on the standard design structural model described in DCD Appendix 3G, Section 3G.4.4.1. FSAR Appendix 3G, Section 3G.10.4.2 indicates that the North Anna 3 site-specific foundation model for the FWSC is based on the standard design foundation model described in DCD Appendix 3G, Section 3G.4.4.2. The staff noted in FSAR Appendix 3G, Section 3G.10.5.1 that the site-specific foundation model for the FWSC is based on the generic soft soil conditions considered for the ESBWR DCD. GEH Report WG3-U63-ERD-S-0003, Revision 2 provides more details of the analytical model used in the site-specific structural evaluations of the FWSC.

The staff reviewed the information in FSAR Appendix 3G, Section 3G.10, DCD Appendix 3G, Section 3G.4, and GEH Report WG3-U63-ERD-S-0003, Revision 2. The staff also reviewed and confirmed the supporting information on analytical model during North Anna 3 Audit 2. Based on this review, the staff determined that the site-specific structural model and foundation model for the FWSC are consistent with the corresponding models for the standard design. The staff's acceptability of using the generic soft soil conditions for the North Anna 3 site is discussed in this SER 3.8.1.4 under the heading "*Structural Analysis."* The staff found that the results of the study for site subgrade stiffness conditions performed for RB/FB also apply to the FWSC because the site subgrade stiffness conditions for both FWSC and RB/FB are similar. Therefore, the staff concluded that the use of the FWSC analytical model as described in FSAR Appendix 3G, Section 3G.10.4 for the site-specific structural evaluations of the FWSC is acceptable.

Site Design Loads, Load Combinations, and Material Properties (FWSC)

The description of the site design loads, load combinations, and material properties for the FWSC is provided in FSAR Appendix 3G, Section 3G.10.5.2 and GEH Report WG3-U63-ERD-S-0003, Revision 2. FSAR Appendix 3G, Section 3G.10.5.2 indicates that, with the exception of seismic loads, the site-specific structural evaluations of the FWSC utilize the same loads, load combinations, and acceptance criteria that were used in the standard design. The seismic loads in the standard design were replaced with the North Anna 3 site-specific seismic loads. FSAR Appendix 3G, Section 3G.10.5.2 lists the various loads and the corresponding sections of the ESBWR DCD where these loads are described. In addition, FSAR Appendix 3G, Section 3G.10.5.2 indicates that the site-specific structural evaluations of the FWSC utilize the same material properties of concrete, reinforcing steel, and structural steel as those used in the standard design. The staff did not identify any changes or deviations from the material properties used in the standard design.

FSAR Appendix 3G,Section 3G.10.5.2 also indicates that the seismic loads used for the structural evaluations of the FWSC are based on the site-specific seismic demands presented in FSAR Appendix 3A, Section 3A.18.1.3. This section indicates that the site-specific seismic demands bound the effects of structural stiffness variations described in FSAR Appendix 3A, Section 3A.17.9.3, SSSI with the CB described in FSAR Appendix 3A, Section 3A.17.11, and separation between the concrete fill and surrounding soil described in FSAR Appendix 3A, Section 3A.17.14.5. In addition, the interaction of FWSC with the nearby non-seismic Category I structures will be addressed through the ITAAC completion package as described in FSAR Section 3.7.2.8.

The staff reviewed FSAR Appendix 3G, Section 3G.10.5.2, WG3-U63-ERD-S-0003, Revision 2, and confirmed the supporting information during North Anna 3 Audit 2. Based on this review, the staff determined that, with the exception of seismic loads, the site-specific structural evaluations of the FWSC utilized the same loads, load combinations, acceptance criteria, and material properties as those used in the standard design. The staff also confirmed that the bounding site-specific seismic load demands for the FWSC were used in the structural evaluations of the FWSC. The staff further confirmed that the bounding site-specific seismic demands envelop the effects of: (1) the variation of subgrade material conditions, (2) separation between the concrete fill and surrounding soil, (3) structural stiffness variations (concrete cracking), and (4) SSSI with the CB. Therefore, the staff concluded that the North Anna 3 site design loads, load combinations, and material properties used for the FWSC site-specific structural evaluations are acceptable.

Structural Analysis (FWSC)

The description of the structural analysis performed for the FWSC is provided in FSAR Appendix 3G, Section 3G.10.5 and GEH Report WG3-U63-ERD-S-0003, Revision 2. The structural analysis of the FWSC is performed consistently with the procedure used for the standard design, and the FWSC model is analyzed using the same NASTRAN finite element computer program used for the standard design, as described in DCD Section 3C.4.

Section 6.2.3.6 of the FWSC structural design report (WG3-U63-ERD-S-0003, Rev. 2) describes how site-specific seismic loads are developed from the FWSC LMSM and applied to the FWSC FEM. The methodology used to convert North Anna 3 site-specific seismic loads from LMSM to NASTRAN FEM is identical to the methodology used in the standard design.

The staff's acceptability of applying the bounding site-specific seismic loads to the NASTRAN model is discussed in this SER Section 3.8.1.4 under the heading "*Structural Analysis.*" The combined member forces and moments for a selected load combination that include site-specific seismic loads are presented in FSAR Appendix 3G, Table 3G.10-203. Section 5.6 of FWSC structural design report (WG3-U63-ERD-S-0003, Rev. 2) describes that the site-specific hydrodynamic pressures on the FWS walls and floors due to the seismic ground motions are developed following the same methodology as used in the standard design and that the site-specific lateral pressure loads applied along the FWSC shear keys are considered in the site-specific structural evaluations of the FWSC.

The staff reviewed FSAR Appendix 3G, Section 3G.10.5, GEH Report WG3-U63-ERD-S-0003, Revision 2, and confirmed the supporting information during the North Anna 3 Audit 2. Based on this review, the staff determined that: (1) the NASTRAN FEM for the FWSC is the same model as the one used for the standard design, (2) with the exception of seismic loads, the site-specific structural evaluations of the FWSC utilize the same analysis methods, loads, load combinations, and material properties as those used in the standard design, (3) site-specific seismic loads developed from the FWSC site-specific seismic analyses are used to replace the DCD seismic loads, and (4) the site-specific seismic loads applied to the FWSC model for the structural evaluations are consistent with the bounding site-specific seismic load demands discussed in this SER Section 3.8.4.4 under the heading "*Site Design Loads, Load Combinations, and Material Properties (FWSC)*." Therefore, the staff concluded that the structural analysis performed for the FWSC is acceptable.

Structural Design (FWSC)

The description of the structural design evaluation for the FWSC is provided in FSAR Appendix 3G, Section 3G.10.5.4 and GEH Report WG3-U63-ERD-S-0003, Revision 2. FSAR Appendix 3G, Section 3G.10.5.4 indicates that the site-specific structural evaluation of the FWSC utilizes the same models, analysis methods, loads (other than seismic loads), load combinations, and acceptance criteria as those used in the standard design . However, the standard design seismic loads are replaced with the seismic loads determined from the site-specific seismic analyses as described in FSAR Appendix 3A, Sections 3A.10 through 3A.19. The FSAR also indicates that the site-specific structural evaluations of the FWSC utilize the same methodology as used for the DCD structural evaluations of the FWSC described in DCD Appendix 3G, Section 3G.4.5.

The site-specific evaluations presented in FSAR Appendix 3G, Section 3G.10.5.4 show that the standard design FWSC is adequate to resist the site-specific seismic load demands in combination with the NS ESBWR standard plant loads except for a few instances in which a design change is required. Specifically, the applicant modified the standard design by changing steel reinforcement and shear ties to the following structural elements of the FWSC:

- Basemat (Element 227): primary reinforcement ratio in the E-W direction is increased from 0.604 percent to 0.705 percent.

- Shear Key (Element 72008): primary reinforcement ratio in the E-W direction is increased from 0.377 percent to 0.629 percent; shear tie reinforcement ratio is increased from 0.177 percent to 0.484 percent.

- Shear Key (Element 73017): shear tie reinforcement ratio is increased from 0.177 percent to 0.484 percent.

The staff confirmed that the details of changed reinforcement and shear ties to these elements are provided in FSAR Appendix 3G, Table 3G.10-204.

With the change of rebar in the basemat and rebar and shear ties in the shear key as discussed above, site-specific stress check calculations for the FWSC are performed to evaluate the adequacy of the FWSC at the North Anna 3 site. This design check is performed in accordance with SSDP-2D, following the same methodology as that used for the standard design. The site-specific stress checks demonstrated that the FWSC structures are adequate to resist site-specific seismic load demands in combination with NS ESBWR standard plant loads. Specifically, the stresses of the concrete and rebar are less than the allowable stresses specified in the code, and the provided area of primary and shear reinforcement, including the reinforcement changes as described above, satisfy the required values.

The staff reviewed FSAR Appendix 3G, Section 3G.10, GEH Report WG3-U63-ERD-S-0003, Revision 2, and confirmed the supporting information during North Anna 3 Audit 2. Based on this review, the staff determined that with the exception of seismic loads, the FWSC analysis model and approach, industry codes and standards, structural materials and their properties, loads and load combinations, acceptance criteria used in the design evaluations, and the method for applying loads are consistent with those used in the standard design. The staff also confirmed that the North Anna 3 structural design evaluations of the FWSC utilize the same methodology as the standard design. For the reinforced concrete structures of the FWSC, the staff reviewed the calculated stresses of the concrete and steel reinforcement and comparison to code limits for a selected load combination shown in FSAR Appendix 3G, Table 3G.10-205. The staff also reviewed the calculated transverse shear and comparison to code limits shown in FSAR Appendix 3G, Table 3G.10-206. Based on this review, the staff confirmed, with enhanced steel reinforcement and shear ties to the basemat and shear keys as described in FSAR Appendix 3G,Table 3G.10-204, that: (1) the stresses of the concrete and rebar are less than the allowable stresses specified in the code, and (2) the areas of the primary and shear reinforcement satisfy the required values.

In conclusion, the staff found that the standard design FWSC, with changes of steel reinforcement and shear ties to the basemat and shear keys, is adequate to resist the site-specific seismic load demand in combination with the NS ESBWR standard plant loads at the North Anna 3 site.

Fuel Rack and Spent Fuel in Spent Fuel Rack

The staff reviewed FSAR Section 9.1, as well as the following GEH reports with regard to the North Anna 3 structural evaluations for the fuel rack and spent fuel in the spent fuel rack:

1. 002N8467, Revision 4, “North Anna 3 Fuel Rack Seismic Analysis” (ADAMS Accession No. ML16125A364)

2. 003N0526, Revision 1, “North Anna 3 Seismic Qualification of Spent Fuel in the Spent Fuel Racks” (ADAMS Accession No. ML16153A388, ML16125A367 Non-public)

As a result of the staff's review of the prior FSAR Revision 8, the staff noted that FSAR Section 9.1 provides the structural assessment of the new and spent fuel storage racks in the buffer pool and spent fuel pool, based on the DCD seismic demands, and not the North Anna 3 site-specific seismic loadings. Therefore, the staff requested, in RAI 03.07.02-20, that the applicant provide a site-specific structural assessment of the acceptability of the new and spent fuel storage racks for the site-specific departure (NAPS DEP 3.7-1), related to any exceedances in the seismic inputs at the North Anna 3 site. In response to this RAI (ADAMS Accession No. ML15364A384), the applicant revised FSAR Sections 9.1.1 and 9.1.2 to describe the site-specific seismic evaluations of the structural design of the new fuel storage racks and the spent fuel storage racks, respectively. The revised FSAR Section 9.1.2.4 also provides evaluations of the adequacy of the spent fuel stored in the spent fuel racks to withstand the site-specific North Anna 3 SSE. Details of the site-specific assessments are described in GEH Reports 002N8467, Revision 4 and 003N0526, Revision 1.

In FSAR Revision 9, Section 9.1, the applicant stated that the site-specific assessment of the structural design of the spent and new fuel storage racks was performed using the same method as the standard design evaluations, but used the North Anna 3 seismic demand. The applicant used the guidance of Appendix D of SRP Section 3.8.4 in its assessment. Based on its site-specific evaluation for the fuel racks, the applicant concluded that: (1) the standard design of the spent fuel racks in the spent fuel pool is adequate for the site-specific seismic demand, (2) for the spent fuel racks in the buffer pool deep pit, changes in the size of the anchor bolts and the welds from the enveloping plate to the base stiffener plate are necessary to ensure seismic adequacy of these racks for North Anna 3 seismic demand, (3) for the new fuel storage racks located only in the buffer pool, changes in the size of the anchor bolts are necessary to ensure seismic adequacy of these racks for North Anna 3 site-specific seismic demand, and (4) for both the spent fuel racks in the buffer pool deep pit and the new fuel storage racks in the buffer pool, the site-specific embedment design loads for the concrete anchors are higher than the corresponding standard design embedment loads. The applicant also indicated that the increase in North Anna 3 embedment loads due to increase in site-specific seismic demand will be accommodated during the detailed design phase.

In addition to the information provided in FSAR Section 9.1, the staff reviewed the GEH Report 002N8467, Revision 4, to confirm the basis for the FSAR results. In addition the staff reviewed the response to RAI 03.07.02-20 (ADAMS Accession No. ML15364A384) and confirmed the supporting analysis used during the North Anna 3 Audit 2. GEH Report 002N8467, Revision 4 summarizes the analysis of all three fuel rack designs: spent fuel storage racks in the spent fuel pool, spent fuel storage racks in the buffer pool deep pit, and the new fuel storage racks in the buffer pool. The fuel racks were reanalyzed using the North Anna 3 site-specific ISRS. A comparison of the North Anna 3 site-specific ISRS to the standard design input response spectra used previously was presented in the report. There were some increases in the North Anna 3 ISRS at certain frequency ranges, with the more significant increases occurring primarily in the vertical direction.

The staff noted that both the transient analysis approach and the response spectra analysis approach were used for the analysis of the fuel storage racks. The transient analysis approach requires developing synthetic acceleration time histories whose spectra should envelop the input response spectra. The staff reviewed the applicant's approach for developing the synthetic time histories used in the transient analysis of the fuel racks from the site-specific input response spectra. The staff noted that for the spent fuel storage racks in the spent fuel pool and the new fuel storage racks in the buffer pool, the synthetic time histories were developed from the site-specific bounding ISRS at the corresponding locations obtained from the site-specific SSI analyses of the RB/FB. The staff also verified during North Anna 3 Audit 2 that the response spectra generated from these time histories envelop the site-specific ISRS. However, the staff noted that the site-specific buffer pool response spectra, used to develop the synthetic time histories for the evaluation of the spent fuel storage racks in the buffer pool deep pit (at a lower elevation), do not envelop the response spectra at the location of the buffer pool deep pit.

As a result of this issue as well as questions related to the review of earlier revisions of GEH Reports 002N8467 and 003N0526, the staff raised several concerns related to the spent fuel racks, new fuel racks, and spent fuel in the spent fuel racks during a public meeting on March 3, 2016 (ADAMS Accession No. ML16204A243). The staff's technical evaluation of these concerns and issues is described below.

Fuel Storage Racks - Synthetic Time Histories

The first question was to demonstrate the adequacy of the synthetic time histories used to perform the nonlinear dynamic analyses of the fuel racks. During the North Anna 3 Audit 2, the applicant provided and the staff reviewed Equipos Nucleares, S.A. (ENSA) Technical Note "ESBWR Fuel Building Pool Bottom Synthesized SSE Accelerations Time Histories," Document 5926ATN02, Revision 3 (as described in the North Anna 3 Audit 2 Summary Report, ADAMS Accession No. ML16193A047). For the spent fuel racks in the spent fuel pool, this report showed a spectral comparison between the spectra corresponding to the synthetic time histories and the required North Anna 3 floor response spectra for the spent fuel rack analysis. The staff noted that there were significant margins in the spectra comparison for the X (horizontal) direction for frequencies above the lowest rack frequency. In the Y (other horizontal direction) and Z (vertical) directions there were some small margins. The staff also noted that the stress results for the racks were substantially smaller than the allowable stress limits. Thus, the synthetic time histories were considered to be acceptable for the spent fuel rack time history analyses in terms of spectral matching to the corresponding input response spectra.

For the spent fuel racks in the buffer pool deep pit, the applicant explained that the spent fuel racks are anchored to the pool floor and thus, a response spectrum analysis is performed for evaluation of the racks. The time history analysis is only performed for evaluation of the fuel in the rack and to obtain the horizontal and vertical impact forces onto the rack due to the gaps between the fuel and the rack. For this set of time histories, the staff reviewed Empresarios "Design Report of the Spent Fuel Storage Racks in Reactor Building for North Anna 3," Document 092-175-F-M-00003, Revision 1 (as described in the North Anna 3 Audit 2 Summary Report, ADAMS Accession No. ML16193A047). Based on the spectral matching comparisons of the spectra corresponding to the synthetic time histories and the required response spectra, the substantial margin in the rack bottom plate stress, and the margins in the acceleration values for the fuel, the synthetic time histories used as input in the time history analyses were considered to be acceptable in terms of spectral matching to the corresponding input response spectra.

For the new fuel racks in the buffer pool, the fuel racks are also anchored to the pool floor and thus, a response spectrum analysis is performed for evaluation of the racks. The time history analysis is only performed for evaluation of the fuel in the rack and to obtain the horizontal and vertical impact forces onto the rack due to the gaps between the fuel and the rack. For this set of time histories, the staff reviewed Empresarios "Design Report of the New Fuel Storage Racks in the Reactor Building for North Anna 3," Document 092-322-F-M-00002, Revision 2 (as described in the North Anna 3 Audit 2 Summary Report, ADAMS Accession No. ML16193A047). Based on the spectral matching comparisons of the spectra corresponding to the synthetic time histories and the required response spectra, the substantial margin in the rack bottom plate calculated stress, and the margins in the acceleration values for the fuel, the synthetic time histories used as input in the time history analyses were considered to be acceptable in terms of spectral matching to the corresponding input response spectra.

Fuel Storage Racks - Correlation Coefficients of Seismic Synthetic Time Histories

For the new fuel racks in the buffer pool, and the spent fuel in the buffer pool deep pit the seismic time history correlation coefficients were determined to be 0.14 which are less than the 0.16 acceptance criterion provided in SRP Section 3.7.1, Revision 4, and thus, are considered to be acceptable. However, for the spent fuel racks in the spent fuel pool some of the correlation coefficients are greater than 0.16. During the North Anna 3 Audit 2, the applicant provided additional technical information to address this issue, which was included as an update in GEH Report 002N8467, Revision 4. The information provides justification based on very small coupling between horizontal and vertical response, conservative method of utilizing the peak impact dynamic loads obtained from the time history analyses and applying them to the FEM as static forces, and the substantial margins in the calculated stresses. On this basis, the staff concluded that the exceedances in correlation coefficients between pairs of synthetic time histories are acceptable.

Fuel Storage Racks - Use of Buffer Pool Response Spectra for Time History Analysis of Spent Fuel Racks in Buffer Pool Deep Pit

For the seismic time history analysis of the spent fuel racks in the buffer pool deep pit, the synthetic time histories were developed based on the response spectra of the buffer pool (at a higher elevation) rather than the elevation of the buffer pool deep pit, or the envelope of the two elevations of the two buffer pools. The applicant explained that based on the spectra comparison of the two elevations, exceedances in the spectra for the lower elevation occur only in the horizontal direction. Also, the time history analysis is only performed for evaluation of the fuel in the rack and to obtain the horizontal and vertical impact forces from the fuel onto the fuel rack due to the gaps between the fuel and the rack. The horizontal forces at the top of the rack are negligible, and the vertical spectrum used in developing the vertical time history was larger than the spectrum at the deep buffer pool elevation, and thus acceptable. Lastly, the stress analysis of the bottom plate of the rack shows substantial margin, and as discussed below, the fuel assembly qualification shows sufficient margin as well. Therefore, the staff concluded that the use of the buffer pool response spectra for evaluation of the spent fuel racks in the buffer pool deep pit is acceptable.

Spent Fuel Stored in the Spent Fuel Racks

The staff reviewed GEH Report 003N0526, Revision 0, and discussed with the applicant several questions that arose from this review. The seismic qualification methodology for the spent fuel was the same as the approach used in the ESBWR standard plant except that the results were generated using the North Anna 3 site-specific seismic input. The results of this North Anna 3 site-specific analysis provided the maximum horizontal and vertical accelerations of the fuel in the rack and compared these demand accelerations with the acceleration limits previously determined for the fuel. In the horizontal direction, the maximum accelerations in the two perpendicular directions were combined by the SRSS method to obtain the resultant horizontal peak acceleration. To demonstrate adequacy of the fuel in the rack, Table 2 in GEH Report 003N0526, Revision 0 provides comparisons between the fuel accelerations in the spent fuel pool and the buffer pool and the GE14 fuel acceleration acceptance limits. The horizontal and vertical demand acceleration values were less than the corresponding acceleration acceptance limits. However, the potential for interaction of the horizontal and vertical demand acceleration values was not considered; therefore, the staff requested the applicant to consider the interaction effects that would exist for the GE fuel. As a result, the applicant provided a figure showing the interaction curve for the GE fuel acceptance limit. The calculated demand horizontal and vertical acceleration values fell within the interaction acceptance curve demonstrating the fuel is qualified. This information was included in the GEH Report 003N0526, Revision 1 which was reviewed and information confirmed during the North Anna 3 Audit 2. Based on the above evaluation, the staff concluded that the spent fuel stored in the spent fuel racks are structurally adequate.

<u>Summary of Staff Evaluation for Fuel Racks and Spent Fuel in Spent Fuel Racks</u>

Based on the staff review of the information provided in the North Anna 3 FSAR, GEH reports, North Anna 3 Audit 2, and the above discussion, the staff found that the analysis approach, industry codes and standards, structural materials and their properties, loads and load combinations, and the method for checking the design of the steel components were consistent with those used in the standard design. The staff verified that the site-specific input response spectra used for the analysis are the North Anna 3 bounding design ISRS obtained from the site-specific bounding SSI analysis described in FSAR Appendix 3A, Section 3A.18.2. With the several design changes as described in this SER under the heading "*Fuel Rack and Spent Fuel in Spent Fuel Rack,"* above, which will be addressed in detailed design for North Anna 3 plant, the results of the reanalysis of the fuel racks show that the forces, displacements, component stresses, and maximum reactions on the bearing pads in the pool liner are either bounded by the results presented in NEDO-33373, Revision 5, "Dynamic Load-Drop and Thermal-Hydraulic Analyses for ESBWR Fuel Racks," September 2010 (GEH report for the ESBWR standard design of the racks, ADAMS Accession No. ML102990229) or are below their code allowable values. For the spent fuel stored in spent fuel racks, the applicant demonstrated that the calculated North Anna 3 site-specific demand horizontal and vertical acceleration values for the fuel fell within the interaction acceptance limits, demonstrating the fuel integrity.

3.8.4.5 Post Combined License Activities

There are no post COL activities related to this section. ITAAC in DCD Tier 1, Revision 10, with the modification of the SSE definition will address the as-built verification of the other seismic Category I structures for the North Anna 3 seismic demand.

3.8.4.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the North Anna 3 application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to other seismic Category I structures that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.8.4, and other NRC RGs. The staff finds that the applicant has addressed the areas related to other seismic Category I structures in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concludes that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.8.4.3 of this SER.

3.8.5 Foundations

3.8.5.1 Introduction

FSAR Section 3.8.5 and Appendix 3G address the structural analysis and design of foundations for the RB/FB, CB, and FWSC structures. The ESBWR design approach for the standard plant design of these structures is provided in Section 3.8.5 and Appendix 3G of ESBWR DCD, Tier 2, Revision 10.

3.8.5.2 Summary of Application

FSAR Section 3.8.5 and Appendix 3G of the North Anna 3 FSAR, Revision 9, incorporate by reference Section 3.8.5 and Appendix 3G of the ESBWR DCD, with the departure given below.

Departure

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra.

This departure relates to the North Anna 3 site-specific horizontal and vertical seismic ground response spectra. These spectra result in exceedances at certain frequencies when compared to the DCD CSDRS. As a result, the applicant performed new site-specific seismic SSI and SSSI analyses with the site-specific ground response spectra and the site-specific subgrade properties. In some cases, the seismic structural loads were found to be higher than those used for the standard design, and thus, a structural evaluation of the North Anna 3 structures was performed. As a result of the increased seismic loads, a number of additions and deletions were made to Appendix 3G related to the analysis and design of the foundations.

FSAR Appendix 3G, Section 3G.7 provides the site-specific structural evaluation of the RB foundation which is part of the RB/FB complex. FSAR Appendix 3G, Section 3G.8 provides the site-specific structural evaluation of the CB foundation. FSAR Appendix 3G, Section 3G.9 provides the site-specific structural evaluation of the FB foundation. FSAR Appendix 3G, Section 3G.10 provides the site-specific structural evaluation of the FWSC foundation. The loads, load combinations, material properties, analysis and design evaluations are provided within each of these FSAR sections.

3.8.5.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the foundations of seismic Category I structures, and the associated acceptance criteria, are in SRP Section 3.8.5. The specific requirements include the following:

- 10 CFR 50.55a and 10 CFR Part 50, Appendix A, GDC 1, as they relate to safety-related structures being designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed.

- 10 CFR Part 50, Appendix A, GDC 2, as it relates to the design of the safety-related structures that are capable of withstanding the most severe natural phenomena, such as wind, tornadoes, hurricanes, floods, and earthquakes and the appropriate combination of all loads.

- 10 CFR Part 50, Appendix A, GDC 4, as it relates to appropriately protecting safety-related structures against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit.

- 10 CFR Part 50, Appendix A, GDC 5, as it relates to not sharing safety-related structures among nuclear power units unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions..

- 10 CFR Part 50, Appendix B as it relates to the QA criteria for nuclear power plants.

- 10 CFR 52.80(a), which requires that a COL application contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and the Commission's rules and regulations.

In addition, the acceptance criteria and regulatory guidance associated with the review of FSAR Section 3.8.5 include the following:

- SRP Section 3.8.5 guidance to review the design, construction, and testing of foundations to ensure that these structures maintain their structural integrity and can perform their intended safety function during all loading conditions.

- RGs listed in SER Section 3.8.1.3 and Section 3.8.4.3 as applicable.

3.8.5.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.8.5 and Appendix 3G of the ESBWR DCD. The staff reviewed Section 3.8.5 and Appendix 3G of the North Anna 3 FSAR, Revision 9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the North Anna 3 FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information relating to this section. The staff reviewed the information in the North Anna 3 FSAR as given below.

In addition, the staff conducted a structural audit (North Anna 3 Audit 2) during the week of March 21, 2016 at the applicant's contractor GEH office in Wilmington, North Carolina. The purpose of this audit was to (1) review detailed analysis reports and design calculations performed by the applicant that support the information in the FSAR, (2) confirm the basis supporting the applicants' RAI responses, and (3) review the draft FSAR revisions from RAI responses to ensure consistency with the applicant's design basis information.

Departure

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 related to the applicant's structural evaluation of foundations for the site-specific seismic loads applied to seismic Category I structures. These evaluations are described in FSAR Appendix 3G, Sections 3G.7 through 3G.10 for the RB, CB, FB, and FWSC, respectively. The staff's technical evaluation of the design of foundations considering these site-specific loads is given below.

Foundation Evaluation of RB and FB

As described in this SER Section 3.8.1.4 for the RB/FB complex, the foundations of the RB and FB are included in the modeling, analysis, and design of the RB/FB. Therefore, the staff technical evaluation of the analytical model; site design loads, load combinations, and material properties; structural analysis; and structural design of the foundations for the RB/FB is provided in this SER Section 3.8.1.4.

The staff evaluation of other aspects of the site-specific structural evaluations for the RB/FB foundations is described in this SER Section below under the heading of "*Dynamic Bearing Pressures.*" These include site-specific evaluations performed for stability, dynamic bearing pressure beneath the foundations, and lateral subgrade pressures on embedded walls. The site-specific evaluations for these items are described in FSAR Appendix 3G, Sections 3G.7.5.5 and 3G.7.5.6 and in the GEH report identified below:

1. WG3-U71-ERD-S-0003, Revision 1, "Reactor/Fuel Building Complex Stability Analysis Report" (ADAMS Accession No. ML15362A009)

Stability Evaluation

The staff reviewed FSAR Appendix 3G, Section 3G.7.5.5 and GEH Report WG3-U71-ERD-S-0003, Revision 1, which contain the site-specific stability evaluation of the RB/FB for overturning and sliding when subjected to the site-specific seismic loading. As stated in FSAR Appendix 3G, Section 3G.7.5.5 and this GEH report, for the overturning stability evaluation, the energy approach described in DCD Tier 2, Section 3.7.2.14 was used. This approach calculated the maximum kinetic energy imparted on the RB/FB from the seismic event and the energy that is needed to overturn the structure. The energy needed to overturn the structure is equivalent to the maximum potential energy of the structure as it rotates about a pivot point before it tips over. The effect of buoyancy due to groundwater is included to reduce the weight of the structure, which reduces the potential energy. The staff also noted that the effects of embedment in providing some resistance to overturning were conservatively neglected in the calculations. The FOS was defined as the ratio of the energy needed to overturn the structure to the kinetic energy imparted on the RB/FB.

The calculations for overturning, as well as sliding stability, dynamic bearing pressure, and lateral soil pressures, were performed for the LB, BE, and UB of the partial and full column soil profiles. Each of these calculations considered pairs of N.S. and vertical and then E.W. and vertical seismic motions, which result in a total of 12 overturning cases. The results, as presented in FSAR Appendix 3G, Table 3G.7-225(a), show that the minimum FOS for all of these cases was 924 which is substantially larger than the minimum FOS of 1.1 used as the acceptance criterion. The staff noted that the minimum FOS criterion of 1.1 and the load combination used for the overturning stability evaluation are in accordance with SRP Section 3.8.5.

During the public meeting on March 3, 2016 (ADAMS Accession No. ML16204A243) prior to the North Anna 3 Audit 2, the staff questioned the applicant about the use of the North Anna 3 site-specific seismic loading corresponding to the RB/FB upper bound stiffness (uncracked) concrete properties and OBE damping values for the seismic demand in the various stability evaluations. The applicant explained that the analyses of models with the upper bound stiffness properties provide seismic demands that bound the effects of structural stiffness variations on the stability, dynamic bearing pressures beneath the structure foundation, and lateral pressure demands on the embedded walls. In addition, there is no need to check the seismic demand from SSSI analyses because as discussed in this SER Section 3.8.4.4 under the heading "*Site Design Loads, Load Combinations, and Material Properties*," the RB/FB is much more massive than the adjacent CB, and thus the seismic SSSI effects would not significantly affect the seismic SSI loads. Lastly, considering the very large FOS values calculated the use of only the SSI seismic loads are considered to be acceptable.

For sliding stability evaluation, the approach used is consistent with the methodology utilized for the standard design presented in DCD Tier 2, Section 3.8.5.5. The RB/FB sliding stability evaluations consider the critical sliding plane located at the bottom of the RB/FB basemat. The sliding evaluation is performed separately for N.S. and vertical directions and then E.W. and vertical directions, using a linear time history analysis approach. At each time step the FOS is calculated, and the minimum value obtained during the duration of the site-specific ground motion is identified as the sliding stability FOS. The sliding stability evaluation considered the frictional resistance at the bottom of the basemat, and if needed, the lateral resistance pressure on the embedded exterior wall and basemat opposite to the direction of the seismic motion. The staff notes that the calculations conservatively neglected the skin friction resistance provided by the (a) vertical surfaces of the basemat side and shear key side parallel to the direction of motion, (b) lateral resistance pressure on the shear key opposite to the direction of motion, and (c) lateral resistance from the structural fill above the Zone III rock (i.e., upper 17 ft).

The coefficient of friction value of 0.6 was used in the sliding evaluation which the staff confirmed is consistent with the value for the foundation to Zone III-IV rock interface presented in FSAR Section 2.5.4. The FOS was calculated as the ratio of the friction resistance force at the bottom of the RB/FB basemat to the time history results of the horizontal seismic driving (demand) force. The friction resistance force considered the seismic gravity load as the sum of the dead load and 25 percent of live load. In addition, the effect of buoyancy due to the ground water, in reducing the gravity load, was considered. The seismic driving force did consider the effect of the lateral soil force on the RB due to the turbine building surcharge load, which would increase the driving force. Thus the staff concludes that all applicable loads were included in the calculation of the FOS.

At a particular instance of time, if the base friction resistance beneath the basemat alone was not sufficient to develop the minimum FOS of 1.1 against sliding, the additional lateral resistance force acting on the embedded exterior wall and basemat opposite to the direction of motion was calculated. These passive lateral pressure calculations conservatively assume that the lateral resistance against sliding is provided only by the concrete fill and the Zone III rock, and neglects the lateral resistance that could be provided above the upper 17 ft of structural fill and the Zone III rock.

As in the overturning stability evaluations discussed above, the sliding stability evaluations also were performed for the LB, BE, and UB of the partial and full column soil profiles. The results, as presented in FSAR Appendix 3G, Table 3G.7-225(b), show that the minimum FOS of 1.1 is satisfied in some of the 12 cases analyzed when relying only on the friction resistance force beneath the basemat and in the other cases some passive lateral pressure resistance is needed to maintain the FOS of 1.1. As discussed below in this SER section under the heading of "*Dynamic Bearing Pressures*," these lateral passive pressures are used in the design evaluations of the RB/FB foundation walls which are enveloped by the corresponding standard design loads.

Based on the above discussion, the staff concluded that the seismic overturning and sliding stability evaluations are acceptable.

Dynamic Bearing Pressures

The staff reviewed FSAR Appendix 3G, Section 3G.7.5.5 and GEH Report WG3-U71-ERD-S-0003, Revision 1, which contain the site-specific evaluation of the RB/FB for developing the dynamic bearing pressures on the Zone III-IV rock beneath the RB/FB basemat. As stated in the above FSAR section and the GEH report, the maximum dynamic bearing pressure demands from the RB/FB basemat on the supporting Zone III-IV rock at the North Anna 3 site are evaluated using the Energy Balance/Modified Energy Balance (EB/MEB) method consistent with the methodology used in the standard design. The SASSI2010 analysis results for the spring forces at the bottom of the RB/FB basemat from the SSI analyses of RB/FB for the partial and full column LB, BE, and UB subsurface profiles were used to determine the dynamic bearing pressures. The dynamic bearing pressure evaluation considered the seismic weight of the RB/FB that consists of the building dead load and 25 percent of the design live loads. Since this method of analysis is consistent with the standard design and the criteria in SRP 3.8.5, the staff considers this approach acceptable.

As shown in FSAR Appendix 3G, Table 3G.7-231, the calculations of the maximum dynamic bearing pressure demand beneath the RB/FB foundation, results in a maximum toe bearing pressure demand of 1.37 MPa (28.6 ksf) which is lower than the maximum toe bearing pressure demand of 2.7 MPa (56.4 ksf) determined by the standard design (DCD Appendix 3G, Table 3G.1-58). In addition, the maximum calculated dynamic bearing pressure demand is also lower than the allowable dynamic bearing pressure of 12.4 MPa (259 ksf) for the Zone III-IV rock underlying the RB/FB foundation. The staff confirmed that the allowable dynamic bearing pressure of 12.4 MPa (259 ksf) for the Zone III-IV rock matches the allowable value given in FSAR Table 2.5.4-211. Therefore, the staff concluded that the calculated maximum site-specific dynamic bearing pressure is considered to be acceptable, with a large margin.

Lateral Pressures on Exterior Embedded Walls

The staff reviewed FSAR Appendix 3G, Section 3G.7.5.6 and GEH Report WG3-U71-ERD-S-0003, Revision 1, which contains the site-specific evaluation of the RB/FB for developing the lateral pressures acting on below grade exterior walls. The plots of the vertical distribution of lateral pressures acting on the various walls due to the at-rest static pressure, seismic dynamic pressure, sum of the static and dynamic pressure, as well as the passive pressure distributions are shown in FSAR Appendix 3G, Figures 3G.7-205 through 3G.7-212. These figures also show the lateral pressure distributions from the standard design to enable comparisons to be made.

The GEH report indicates that the site-specific lateral pressure demands on the embedded exterior walls were developed following the same approach that was used for the standard design. The distribution of the static pressure includes the at-rest static soil pressure and the hydrostatic pressure from the groundwater using the North Anna 3 site-specific values of the at-rest soil coefficients of lateral earth pressure and the groundwater level depth.

The dynamic pressure distributions are developed based on the SSI analysis results for horizontal forces of the contact springs located at the wall-subgrade interfaces. FSAR Appendix 3G, Figures 3G.7-205 through 3G.7-212 show the envelope of the lateral pressure results obtained from the SSI analyses of the LB, BE and UB subgrade profiles. The site-specific static and dynamic lateral pressure demands are compared with the corresponding static and dynamic lateral pressure loads used for the standard design of the RB/FB.

In addition, total lateral pressures corresponding to the sum of the site-specific static and dynamic lateral pressures are presented in FSAR Appendix 3G, Figures 3G.7-205 through 3G.7-212 and the GEH report. These plots also present the distributions of the maximum site-specific passive lateral pressures that are determined from the results of the sliding stability evaluation discussed above in order to satisfy the sliding FOS of 1.1. These two sets of site-specific lateral pressures are compared with the corresponding total lateral soil pressures calculated in the standard design and the standard design wall capacity passive resistance pressures.

The comparisons of the lateral soil pressure distributions presented in FSAR Appendix 3G, Figures 3G.7-205 through 3G.7-212 show that near the floor slab at Elevation 270.3 ft, the site-specific total lateral pressures exceed the lateral pressures used for the standard design. Therefore, for seismic loads, the North Anna 3 site-specific seismic demand pressures were used for design evaluation of the exterior embedded walls. The lateral passive pressures, needed to maintain sliding stability, were also considered in the structural evaluations. For the static lateral pressures, the higher standard design static lateral pressure loads were used in the design evaluation.

Based on the above discussion, the staff considers that the approach to calculate the lateral soil pressures is acceptable, and where the lateral pressures exceed the pressures used in the standard design, these higher demand loads are also acceptable because they are used in the site-specific design evaluations.

Foundation Evaluation of CB

The foundation for the CB is included in the modeling, analysis, and design of the CB structure. Therefore, the staff evaluation of the analytical model; site design loads, load combinations, and material properties; structural analysis; and structural design of the foundation for the CB is provided in SER Section 3.8.4.4.

The staff evaluation of other aspects of the site-specific structural evaluations for the CB foundation is described in this SER sections that follow below. These include site-specific evaluations performed for stability, dynamic bearing pressure beneath the foundation, and lateral soil pressures on embedded walls. The site-specific evaluations for these items are described in FSAR Appendix 3G, Sections 3G.8.5.5 and 3G.8.5.6 and in the GEH report identified below:

1. WG3-U73-ERD-S-0003, Revision 3, "Control Building Stability Analysis Report," (ADAMS Accession No. ML16148A129)

Stability Evaluation

The staff reviewed FSAR Appendix 3G, Section 3G.8.5.5 and GEH Report WG3-U73-ERD-S-0003, Revision 3, which contain the site-specific stability evaluation of the CB for overturning and sliding when subjected to the site-specific seismic loading. As stated in this GEH report, for the overturning stability evaluation, the energy approach described in DCD Tier 2, Section 3.7.2.14 was used. This approach calculated the maximum kinetic energy imparted on the CB from the seismic event and the energy that is needed to overturn the structure. The energy needed to overturn the structure is equivalent to the maximum potential energy of the structure as it rotates about a pivot point before it tips over. The effect of buoyancy due to groundwater is included to reduce the weight of the structure, which reduces the potential energy. The staff also noted that the effects of embedment in providing some resistance to overturning were conservatively neglected in the calculations. The FOS was defined as the ratio of the energy needed to overturn the structure to the kinetic energy imparted on the CB.

The calculations for overturning, as well as sliding stability, dynamic bearing pressure, and lateral soil pressures, were performed for the LB, BE, and UB of the partial and full column soil profiles. Each of these calculations considered pairs of N.S. and vertical and then E.W. and vertical seismic motions, which result in a total of 12 overturning cases. The results, as presented in FSAR Appendix 3G, Table 3G.8-208, show that the minimum FOS for all of these cases was 519 which is substantially larger than the minimum FOS of 1.1 used as the acceptance criterion. The staff noted that the minimum FOS criterion of 1.1 and the load combination used for the overturning stability evaluation are in accordance with SRP Section 3.8.5.

During the public meeting on March 3, 2016 (ADAMS Accession No. ML16204A243) prior to the North Anna 3 Audit 2, the staff questioned the applicant about the use of the North Anna 3 site-specific seismic loading corresponding to the CB upper bound stiffness (uncracked) concrete properties and SSE damping values for the seismic demand in the various stability evaluations. The applicant explained that the analyses of models with the upper bound stiffness properties provide seismic demands that bound the effects of concrete cracking on the seismic demands on the CB foundation and below grade exterior walls. Regarding the need to consider seismic

SSSI loads, the applicant indicated that with a few exceptions, the SSI analyses of the CB standalone model with full stiffness and SSE damping properties also provide seismic demands that bound the SSSI effects of RB/FB and FWSC on the CB foundation stability, foundation dynamic bearing pressures and below grade exterior wall lateral pressure demands. In the few exceptions, the exceedances in the lateral pressure demands on the CB wall facing the RB/FB have negligible effects on the results of the site-specific evaluations. Lastly, considering the very large FOS values calculated, the use of only the SSI seismic loads are considered to be acceptable.

For sliding stability evaluation, the approach used for the CB is consistent with the methodology utilized for the standard design presented in DCD Tier 2, Section 3.8.5.5. The CB sliding stability evaluations consider two critical sliding planes located at the bottom of the CB basemat and the bottom of the concrete fill block supporting the CB basemat. The sliding evaluation is performed separately for N.S. and vertical directions and then E.W. and vertical directions, using a linear time history analysis approach. At each time step the FOS is calculated, and the minimum value obtained during the duration of the site-specific ground motion is identified as the sliding stability FOS.

For the sliding stability evaluation located at the bottom of the CB basemat, the sliding evaluation considered the frictional resistance at the bottom of the basemat, and if needed, the lateral passive pressure resistance provided by the concrete fill and Zone III rock subgrade materials surrounding the CB embedded exterior walls and the CB basemat in the opposite direction of the seismic motion. The staff notes that the calculations conservatively neglected the skin friction resistance provided by the vertical surfaces of the CB embedded exterior walls and basemat sides parallel to the direction of seismic motion, as well as the lateral passive pressure resistance provided by the structural fill and in-situ saprolite material on the face of the embedded exterior wall in the opposite direction of the seismic motion.

For the sliding stability evaluation located at the bottom of the concrete fill supporting the CB foundation, the sliding evaluation considered the frictional resistance at the bottom of the concrete fill block, and if needed, the lateral passive pressure resistance provided by the surrounding concrete fill and Zone III rock subgrade materials. The staff notes that the calculations conservatively neglected the skin friction resistance provided by the vertical surfaces of the CB embedded exterior walls, basemat, and concrete fill block sides parallel to the direction of seismic motion. The calculations also conservatively neglected the lateral passive pressure resistance provided by the structural fill and in-situ saprolite material above the Zone III rock on the face of the embedded exterior wall in the opposite direction of the seismic motion.

The coefficient of friction value of 0.6 was used in the sliding evaluation which the staff confirmed is consistent with the value for the foundation to concrete fill and to rock interface presented in FSAR Section 2.5.4. The FOS was calculated as the ratio of the friction resistance force at the bottom of the CB basemat or bottom of the concrete fill to the time history results of the horizontal seismic driving force. The friction resistance force considered the seismic gravity load as the sum of the dead load and 25 percent of live load. In addition, the effect of buoyancy due to the ground water, in reducing the gravity load, was considered. Thus the staff concluded that all applicable loads were included in the calculation of the FOS.

At a particular instance of time, if the base friction resistance beneath the basemat and beneath the concrete fill block alone was not sufficient to develop the minimum FOS of 1.1 against sliding, the additional lateral resistance force acting on the embedded exterior wall and basemat opposite to the direction of motion was calculated.

As in the overturning stability evaluations discussed above, the sliding stability evaluations were also performed for the LB, BE, and UB of the partial and full column soil profiles. The results, as presented in FSAR Appendix 3G, Table 3G.8-209, show that the minimum FOS of 1.1 is satisfied in all 12 cases analyzed; however, to achieve this, passive lateral pressure resistance is needed to maintain the FOS of 1.1. As discussed below in this SER section, these lateral passive pressures are used in the site-specific design evaluations to confirm that the standard design envelopes the site-specific exceedances.

Based on the above discussion, the staff concluded that the seismic overturning and sliding stability evaluations are acceptable.

Dynamic Bearing Pressures

The staff reviewed FSAR Appendix 3G,Section 3G.8.5.5 and GEH Report WG3-U73-ERD-S-0003, Revision 3, which contain the site-specific evaluation of the CB for developing the dynamic bearing pressures on the concrete fill block and on the Zone III-IV rock beneath the concrete fill. As stated in the above FSAR section and the GEH report, the maximum site-specific dynamic bearing pressure demands from the CB basemat on the concrete fill and the Zone III-IV rock are evaluated using the EB/MEB method consistent with the methodology used in the standard design. The SASSI2010 analysis results for the spring forces at the bottom of the CB basemat from the SSI analyses of CB for the partial and full column LB, BE, and UB subsurface profiles were used to determine the dynamic bearing pressures. The dynamic bearing pressure evaluation considered the seismic weight of the CB that consists of the building dead load and 25 percent of the design live loads. Since this method of analysis is consistent with the standard design and the criteria in SRP Section 3.8.5, the staff considers this approach acceptable.

As shown in FSAR Appendix 3G, Table 3G.8- 211a, for the case of the maximum dynamic bearing pressure demand of the CB basemat on the concrete fill block, the maximum calculated toe bearing pressure demand of 1.46 MPa (30.5 ksf) is lower than the maximum toe bearing pressure demand of 2.19 MPa (45.7 ksf) determined by the standard design. In addition, the maximum calculated dynamic bearing pressure demand is also lower than the allowable dynamic bearing pressure of 8.0 MPa (167 ksf) for the concrete fill material based on ACI 318-05.

As shown in FSAR Appendix 3G, Table 3G.8- 211b, for the case of the maximum dynamic bearing pressure demand of the CB and the concrete fill block on the underlying Zone III-IV rock, the maximum calculated toe bearing pressure demand of 0.73 MPa (15.2 ksf) is lower than the allowable dynamic bearing pressure of 12.4 MPa (259 ksf) for the Zone III-IV rock. The staff confirmed that the allowable dynamic bearing pressure of 12.4 MPa (259 ksf) for the Zone III-IV rock matches the allowable value given in FSAR Section 2.5.4.

Therefore, the staff concluded that the calculated maximum site-specific dynamic bearing pressure demands of the CB are acceptable, with large margins against allowable values.

Lateral Pressures on Exterior Embedded Walls

The staff reviewed FSAR Appendix 3G, Section 3G.8.5.6 and GEH Report WG3-U73-ERD-S-0003, Revision 3, which contain the site-specific evaluation of the CB for developing the lateral soil pressures on below grade exterior walls. The plots of the vertical distribution of lateral pressures acting on the various walls due to the at-rest static pressure, seismic dynamic pressure, sum of the static and dynamic pressure, as well as the passive pressure distributions are shown in FSAR Appendix 3G, Figures 3G.8-203 through 3G.8-210. These figures also show the lateral pressure distributions from the standard design to enable comparisons to be made.

The GEH report indicates that the site-specific lateral pressure demands on the embedded exterior walls were developed following the same approach that was used for the standard design. The distribution of the static pressure includes the at-rest static soil pressure and the hydrostatic pressure from the groundwater using the North Anna 3 site-specific values of the at-rest soil coefficients and the groundwater level depth.

The dynamic pressure distributions are developed based on the SSI analysis results for horizontal forces of the contact springs located at the wall-subgrade interfaces. FSAR Appendix 3G, Figures 3G.8-203 through 3G.8-210 show the envelope of the lateral pressure results obtained from the SSI analyses of the LB, BE, and UB subgrade profiles. The site-specific static and dynamic lateral pressure demands are compared with the corresponding static and dynamic lateral pressure loads used for the standard design of the CB.

In addition, total lateral pressures corresponding to the sum of the site-specific static and dynamic lateral pressures are presented in FSAR Appendix 3G, Figures 3G.8-203 through 3G.8210 and the GEH report. These plots also present the distributions of the maximum site-specific passive lateral pressures that are determined from the results of the sliding stability evaluation discussed above in order to satisfy the sliding FOS of 1.1. These two sets of site-specific lateral pressures are compared with the corresponding total lateral soil pressures calculated in the standard design and the standard design wall capacity passive resistance pressures.

The comparisons of the lateral soil pressure distributions presented in FSAR Appendix 3G, Figures 3G.8-203 through 3G.8-210 show that near the floor slab at Elevation 267.9 ft and near the top of the CB basemat, the site-specific total lateral pressures exceed the total lateral pressures used for the standard design. The comparisons also indicate that the lateral passive pressures needed to ensure the stability of the CB against sliding in the EW direction exceed the pressures used in the standard design of the CB wall capacity check. Therefore, the North Anna 3 site-specific seismic demand pressures were used for the site-specific structural evaluation. The lateral passive pressures, needed to maintain sliding stability, were also considered in the structural evaluations. For the static lateral pressures, the higher standard design pressure loads were used.

Based on the above discussion, the staff considers that the approach to calculate the lateral soil pressures is acceptable, and where the lateral pressures exceed the pressures used in the standard design, these higher demand loads are also acceptable because they are used in the site-specific design evaluations.

Foundation Evaluation of FWSC

The foundation for the FWSC is included in the modeling, analysis, and design of the FWSC structure. Therefore, the staff evaluation of the analytical model; site design loads, load combinations, and material properties; structural analysis; and structural design of the foundation for the FWSC is provided in SER Section 3.8.4.4.

The staff evaluation of other aspects of the site-specific structural evaluations for the FWSC foundation is described in this SER section. These include site-specific evaluations performed for stability and dynamic bearing pressure beneath the foundation as described in FSAR Appendix 3G, Section 3G.10.5.5 and the GEH report identified below:

1. WG3-U63-ERD-S-0002, Revision 1, "Firewater Service Complex Stability Analysis Report" (ADAMS Accession No. ML15362A011)

Stability Evaluation

The staff reviewed FSAR Appendix 3G, Section 3G.10.5.5 and GEH Report WG3-U63-ERD-S-0002, Revision 1, which contain the site-specific stability evaluation of the FWSC for overturning and sliding when subjected to the North Anna 3 seismic loading. As stated in FSAR Appendix 3G, Section 3G.10.5.5 and this GEH report, for the overturning stability evaluation, the energy approach described in DCD Tier 2, Section 3.7.2.14 was used. This approach calculated the maximum kinetic energy imparted on the FWSC from the seismic event and the energy that is needed to overturn the structure. The energy needed to overturn the structure is equivalent to the maximum potential energy of the structure as it rotates about a pivot point before it tips over. The FOS was defined as the ratio of the energy needed to overturn the structure to the kinetic energy imparted on the FWSC.

The calculations for overturning stability, as well as sliding stability and dynamic bearing pressure were performed for the site-specific SSI analysis stand-alone model and separately for the site-specific SSSI analysis of the FWSC-CB combined model. For each of these two cases, the evaluation considered full (uncracked concrete) stiffness properties and SSE damping values for the LB, BE, and UB subgrade profiles using the deep input control motion applied at the bottom of the underlying concrete fill block. The overturning evaluations considered pairs of N.S. and vertical and then E.W. and vertical seismic motions, which result in a total of 12 overturning cases. The results, as presented in FSAR Appendix 3G, Table 3G.10-214(a), show that the minimum FOS against overturning for all of these cases was 902 which is substantially larger than the minimum FOS of 1.1 used as the acceptance criterion. The staff noted that the minimum FOS criterion of 1.1 and the load combination used for the overturning stability evaluation are in accordance with SRP Section 3.8.5.

During the public meeting on March 3, 2016 (ADAMS Accession No. ML16204A243) prior to the North Anna 3 Audit 2, the staff questioned the applicant about the use of the North Anna 3 site-specific seismic loading corresponding to the FWSC upper bound stiffness (uncracked) concrete properties and SSE damping values for the seismic demand in the various stability evaluations. The applicant explained that the analyses of models with the upper bound stiffness properties provide seismic demands that bound the effects of concrete cracking on the seismic demands on the FWSC foundation. Also, the staff noted the very large FOS values calculated, and thus this approach is considered to be acceptable.

For sliding stability evaluation, the approach used for the FWSC is consistent with the methodology utilized for the standard design presented in DCD Tier 2, Section 3.8.5.5. The FWSC sliding stability evaluations consider two critical sliding planes; one located at the bottom of the FWSC basemat and the other at the bottom of the concrete fill block supporting the FWSC basemat. The sliding evaluation is performed separately for N.S. and vertical directions and then E.W. and vertical directions, using a linear time history analysis approach. At each time step the FOS is calculated, and the minimum value obtained during the duration of the site-specific ground motion is identified as the sliding stability FOS.

For the sliding stability evaluation at the critical sliding plane located at the bottom of the FWSC basemat, the sliding evaluation considered the frictional resistance between the bottom of the basemat and the top of the supporting concrete fill, and the lateral resistance provided by the shear keys which are embedded in the concrete fill placed under the FWSC. The staff notes that the calculations conservatively neglected the (a) skin friction resistance provided by the sides of the basemat parallel to the direction of the seismic motion, (b) lateral passive resistance provided by the structural fill along the face of the basemat perpendicular to the direction of motion, and (c) skin friction provided by the shear key side parallel to the direction of motion.

For the sliding stability evaluation at the critical sliding plane located at the bottom of the concrete fill supporting the FWSC foundation, the sliding evaluation considered the frictional resistance at the bottom of the underlying concrete fill block, and if needed, the lateral passive pressure resistance provided by the surrounding concrete fill and Zone III rock. The staff notes that the calculations conservatively neglected the lateral resistance provided by the (a) structural fill and in-situ saprolite acting on the FWSC basemat and concrete fill block under the basemat perpendicular to the direction of motion, (b) skin friction resistance acting on the vertical surfaces of the basemat and concrete fill block sides parallel to the direction of motion, and (c) pull-out resistance of the shear keys that contribute to the base friction resistance by resisting the upward forces that would reduce the base friction.

The coefficient of friction value of 0.6 was used in the sliding evaluation which the staff confirmed is consistent with the value for the foundation to concrete fill and concrete fill to Zone III-IV rock interfaces presented in FSAR Section 2.5.4. The FOS was calculated as the ratio of the friction resistance force at the bottom of the FWSC basemat or bottom of the concrete fill to the time history results of the horizontal seismic driving force. The friction resistance force considered the seismic gravity load as the sum of the dead load and 25 percent of live load. In addition, the effect of buoyancy due to the ground water, in reducing the gravity load, was considered. Thus the staff concludes that all applicable loads were included in the calculation of the FOS.

For sliding at the bottom of the FWSC basemat, if the base friction resistance beneath the basemat alone was not sufficient to develop the minimum FOS of 1.1 against sliding, the additional lateral resistance force provided by the shear keys is calculated. Similarly, at the bottom of the concrete fill, if the base friction resistance beneath the concrete fill alone was not sufficient to develop the minimum FOS of 1.1 against sliding, the additional lateral resistance provided by Zone III rock is calculated.

As in the overturning stability evaluations discussed above, the sliding stability evaluations also were performed for a total of 12 cases (combinations of SSI/SSSI, LB/BE/UB subgrade conditions, and N.S./E.W. directions). The lateral resistance force demands on the shear keys or subgrade surrounding the concrete fill under the FWSC are computed if, at a particular instance of time, the friction resistance on a sliding plane analyzed is not sufficient to achieve a minimum FOS of 1.1 against sliding.

Sliding stability calculations showed that the separation between the concrete fill and surrounding soil can amplify the lateral force demands on the FWSC keys. The staff confirmed that the site-specific structural evaluation of the FWSC shear keys used amplified lateral pressure loads that bound the effects of soil separation. FSAR Appendix 3G, Table 3G.10-214(b) presents a summary of the sliding stability analysis at the bottom of the FWSC basemat based on the site-specific lateral force demands on the FWSC shear keys under fully bonded conditions between the concrete fill and surrounding soil. FSAR Appendix 3A, Table 3A.17.14.5-202 presents similar results but under the condition of separation between the concrete fill and surrounding soil. FSAR Appendix 3A, Table 3A.17.14.5-202 further shows that the maximum lateral resistance pressure demand on the concrete fill from the shear key is 1.26 MPa, which is below the allowable lateral bearing pressure of the concrete fill of 8.0 MPa.

FSAR Appendix 3G, Table 3G.10-214(c) presents a summary of the calculations of the FWSC sliding stability at the critical sliding plane at the bottom of the concrete fill. For the instances of time the friction resistance at the bottom of the concrete fill alone is not sufficient, the lateral passive pressure demand required to achieve a minimum FOS of 1.1 against sliding is calculated. FSAR Appendix 3G, Table 3G.10-214(c) shows that the maximum site-specific lateral passive pressure demand on the surrounding subgrade is 0.89 MPa, which is below the allowable dynamic lateral bearing pressure of 1.44 MPa of Zone III rock at the FWSC location as specified in FSAR Appendix 3G, Table 3G.10-201.

The results of the evaluations of sliding stability for the FWSC show that the minimum FOS of 1.1 is satisfied in all 12 cases analyzed, taking into account the lateral resistance force demands (1) on the shear keys at the critical sliding plane at the bottom of the FWSC basemat, and (2) on the surrounding subgrade at the critical sliding plane at the bottom of the concrete fill. The staff noted that the maximum lateral pressure demand on the concrete fill exerted by the shear keys and the maximum passive pressure demand on the subgrade surrounding the concrete fill are below their respective allowable bearing pressures.

Based on the above discussion, the staff concludes that the seismic overturning and sliding stability evaluations for the FWSC foundation are acceptable.

Dynamic Bearing Pressures

The staff reviewed FSAR Appendix 3G, Section 3G.10.5.5 and GEH Report WG3-U63-ERD-S-0002, Revision 1, which contain the site-specific evaluation of the FWSC for developing the dynamic bearing pressures on top of the concrete fill block and on the Zone III-IV beneath the concrete fill. As stated in the above FSAR section and the GEH report, the maximum site-specific dynamic bearing pressure demands from the FWSC basemat on the concrete fill and on the Zone III-IV rock are evaluated using the EB/MEB method consistent with the methodology used in the standard design. The SASSI2010 analysis results for the spring forces at the bottom of the FWSC basemat from the SSI FWSC standalone model and the SSSI analyses of the FWSC-CB combined model for the LB, BE, and UB subsurface profiles were used to determine the dynamic bearing pressures. The dynamic bearing pressure evaluation considered the seismic weight of the FWSC that consists of the building dead load and 25 percent of the design live loads. Since this method of analysis is consistent with the standard design and the acceptance criteria in SRP Section 3.8.5, the staff considers this approach acceptable.

As shown in FSAR Appendix 3G, Table 3G.10-215 for the case of the maximum dynamic bearing pressure demand of the FWSC basemat on the concrete fill block, the maximum calculated site-specific toe bearing pressure demand of 0.89 MPa (18.6 ksf) is lower than the maximum toe bearing pressure demand of 1.2 MPa (25.1 ksf) determined by the standard design. In addition, the maximum calculated dynamic bearing pressure demand is also lower than the allowable dynamic bearing pressure of 8.0 MPa (167 ksf) for the concrete fill material based on ACI 318-05.

As shown in FSAR Appendix 3G, Table 3G.10-215 for the case of the maximum dynamic bearing pressure demand of the FWSC and the concrete fill block on the underlying Zone III-IV rock, the maximum calculated toe bearing pressure demand of 1.85 MPa (38.6 ksf) is lower than the allowable dynamic bearing pressure of 12.4 MPa (259 ksf) for the Zone III-IV rock. The staff confirmed that the allowable dynamic bearing pressure of 12.4 MPa (259 ksf) for the Zone III-IV rock matches the allowable value given in FSAR Section 2.5.4.

The staff review of the adequacy of the concrete fill as foundation material, including its bearing and shear capacities, is presented in SER Section 2.5.4.

Therefore, the staff concluded that the calculated maximum site-specific dynamic bearing pressure demands of the FWSC are acceptable, with large margins against allowable values.

Lateral Pressures on Exterior Embedded Walls

Since the FWSC is a surface mounted structure there are no embedded walls, and thus, there is no lateral soil pressures that need to be evaluated.

3.8.5.5 Post Combined License Activities

There are no post COL activities related to this section.

3.8.5.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff’s review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the North Anna 3 FSAR related to this section. All nuclear safety issues relating to foundations that were incorporated by reference have been resolved.

The staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.8.5, and other NRC RGs. The staff found that the applicant has addressed the areas related to foundations in accordance with the acceptance criteria delineated in these guidance documents. On this basis, the staff concluded that the applicant has satisfied the relevant requirements of the regulations delineated in Section 3.8.5.3 of this SER.

3.9 Mechanical Systems and Components

3.9.1 Introduction

This section addresses the structural integrity and functional capability of safety-related and nonsafety-related mechanical SSCs for seismic Category I components and supports, including both those designated as ASME BPVC, Section III and those not covered by the ASME BPVC as discussed in SPR Section 3.9.1. The design includes issues such as load combinations, allowable stresses, methods of analysis, summary of results, and preoperational testing. The evaluation of this section focuses on determining whether there is adequate assurance that mechanical systems and components will perform their safety-related functions under all postulated combinations of normal operating conditions, system operating transients, postulated pipe breaks, and seismic events.

Following the issuance of the ESBWR FSER on March 9, 2011, the staff identified issues applicable to the ESBWR steam dryer structural analysis based on information obtained during the NRC review of a license amendment request for a power uprate at an operating boiling-water reactor nuclear power plant. As a result of resolving those issues, GEH revised the DCD to withdraw the licensing topical reports addressing the ESBWR steam dryer structural evaluation, and to reference new engineering reports that describe the updated ESBWR steam dryer analysis methodology. The staff reviewed the revised DCD sections, the new GEH engineering reports, and the RAI responses. NUREG–1966, Supplement 1, the Supplemental FSER related to the certified ESBWR DCD, Tier 2, Section 3.9.5 replaces in its entirety Section 3.9.5, "Reactor Pressure Vessel Internals," of the DCD FSER issued on March 9, 2011. Information related to ESBWR RPV internals other than the steam dryer (such as core support structures) was copied from the FSER and placed in the Supplemental FSER to provide the description of the staff's review of all ESBWR RPV internals in one location.

3.9.2 Summary of Application

Section 3.9, "Mechanical Systems and Components," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 3.9, "Mechanical Systems and Components," of the ESBWR DCD, Revision 10.

In addition, in North Anna 3 COL FSAR, Revision 8, the applicant provides the following:

COL Items

- CWR COL 3.9.9-1-A — Reactor Internals Vibration Analysis, Measurement and Inspection Program

To address COL Item 3.9.9-1-A, the North Anna 3 COL applicant provides the following supplemental information in FSAR Section 3.9.2.4:

> For reactor internals other than the steam dryer, the vibration assessment program, as specified in RG 1.20, "Comprehensive Vibration Assessment Program for Reactor Internals During Preoperational and Initial Startup Testing," is provided in DCD Appendix 3L and the following referenced GEH Report:

- NEDE-33259P-A, “Reactor Internals Flow Induced Vibration Program” (ADAMS Accession No. ML091660434)

The classification of the North Anna 3 reactor internals in accordance with RG 1.20 is dependent on ESBWR status, i.e., if North Anna 3 is the initial ESBWR to perform testing of the reactor internals, or if testing is performed at another reactor prior to North Anna 3 testing. There are two different scenarios:

a. A valid prototype for the Unit 3 reactor internals does not exist. Under this scenario, Unit 3 reactor internals classification is a prototype per RG 1.20.

b. A valid prototype for Unit 3 reactor internals does exist. If the prototype testing is performed outside the United States, the guidance in RG 1.20, Revision 3, Regulatory Position 1.2, would need to be satisfied in order for this reactor to be considered a “valid prototype.” Assuming that Unit 3 reactor internals are substantially similar to the valid prototype and that the valid prototype does not experience inservice problems that result in component or operational modifications, Unit 3 reactor internals will be classified as non-prototype Category I. If a change to the classification for Unit 3 reactor internals is later determined to be necessary, the classification change will be addressed at the time the change is proposed with proper evaluation/justification and documented in a revision to the FSAR.

Specific to the steam dryer, the comprehensive vibration assessment program (CVAP), as specified in RG 1.20, is provided in DCD Appendix 3L and the following referenced GEH Reports:

- NEDE-33312P, “ESBWR Steam Dryer Acoustic Load Definition” (ADAMS Accession No. ML13344B157; ML13344B163 Non-Public)

- NEDE-33313P, “ESBWR Steam Dryer Structural Evaluation” (ADAMS Accession No. ML13344B158; ML13344B164 Non-Public)

- NEDE-33408P, “ESBWR Steam Dryer- Plant Based Load Evaluation Methodology, PBLE01 Model Description” (ADAMS Accession No. ML13344B159; (ML13344B175 and ML13344B176 Non-Public)

The steam dryer is definitively classified as a prototype according to RG 1.20, Revision 3. Section 10.2 of NEDE-33313P provides four elements of a steam dryer CVAP that must be addressed. The following describes the approach for the steam dryer CVAP elements, consistent with RG 1.20 and Section 10.2 of NEDE-33313P:

a. The ESBWR steam dryer CVAP is described in DCD Section 3.9, DCD Appendix 3L, and NEDE-33313P, Section 10.0, which includes a description for preparing and submitting to the NRC a Steam Dryer Monitoring Plan (SDMP) no later than 90 days before startup.

b. The detailed design of the steam dryer will follow the methodology described in DCD Appendix 3L and the incorporated engineering reports. As described in NEDE-33313P, Section 10.2(b), an example of a steam dryer predicted analysis that concludes the steam dryer will not exceed stress limits with applicable bias and uncertainties and the minimum alternating stress ratio (MASR) of 2.0 is provided in NEDE-33408P. The final detailed design of the ESBWR steam dryer has not yet been completed. Therefore, the example of an as-designed steam dryer that has been subject to the predicted analysis process and successful startup testing described in NEDE-33408P serves as the design analysis report for the steam dryer and provides sufficient information for licensing. The post licensing commitments in ITAAC and license conditions will confirm the acceptability of the ESBWR steam dryer design.

c. The startup program and associated license conditions that include appropriate notification points during power ascension, providing data to the NRC at certain hold points and at full power, and providing to the NRC a full stress analysis report and evaluation within 90 days of reaching the full power level, are established in accordance with NEDE-33313P, Section 10.2(c).

d. Periodic steam dryer inspection during refueling outages is as described in NEDE-33313P, Section 10.2(d), and associated license conditions.

In addition, in FSAR Section 3.9.2.4, the applicant identifies a CVAP that will be developed as described in DCD Appendix 3L with no departures and that will comply with guidance specified in RG 1.20, Revision 3. These programs will be prepared as stated in this section of the North Anna 3 FSAR.

- STD COL 3.9.9-2-A — ASME Class 2 or 3 or Quality Group D Components with 60-Year Design Life

To address COL 3.9.9-2-A, the North Anna 3 COL applicant adds the following discussion in FSAR Section 3.9.3.1:

> The equipment stress reports identified in this DCD section will be completed within six months of completion of DCD ITAAC Table 3.1-1 [following plant construction]. The FSAR will be revised as necessary in a subsequent update to address the results of this analysis [on the as-built North Anna 3 power station].

- STD COL 3.9.9-3-A — Inservice Testing of Pumps and Valves

To address COL Item 3.9.9-3-A, the North Anna 3 COL applicant specifies FSAR provisions to supplement ESBWR DCD, Tier 2, Section 3.9.6, “Inservice Testing of Pumps and Valves.” For example, the North Anna 3 FSAR specifies that in addition to the provisions in ESBWR DCD, Tier 2, Section 3.9.6, milestones for implementing the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) preservice and inservice testing (IST) programs are defined in FSAR Section 13.4.

In addition to the provisions in ESBWR DCD, Tier 2, Section 3.9.6.1, “Inservice Testing of Valves,” the North Anna 3 FSAR specifies that valves are subject to preservice testing (PST). In addition to the provisions in ESBWR DCD, Tier 2, Section 3.9.6.1.4, “Valve Testing,” the North Anna 3 FSAR provides additional provisions for valve exercise tests.

The North Anna 3 FSAR also specifies additional provisions for the design and qualification process for explosively actuated valves. In addition to the power-operated valve test provisions in ESBWR DCD, Tier 2, Section 3.9.6.1.5, “Specific Valve Test Requirements,” the North Anna 3 FSAR refers to Section 3.9.6.8 for additional (non-Code) testing of power-operated valves as discussed in Regulatory Issue Summary (RIS) 2000-03, “Resolution of Generic Safety Issue 158: Performance of Safety-Related Power-Operated Valves Under Design Basis Conditions.” In addition to the check valve exercise test provisions in ESBWR DCD, Tier 2, Section 3.9.6.1.5, the North Anna 3 FSAR specifies that check valve testing includes verification that obturator movement is in the direction required for the valve to perform its safety function. The North Anna 3 FSAR also includes additional check valve test provisions for (1) acceptance criteria, (2) a disassembly examination program where test methods are impractical, (3) nonintrusive diagnostic techniques, (4) post-maintenance testing, (5) preoperational testing, and (6) data collection for testing and inspections. In addition to the provisions in ESBWR DCD, Tier 2, Section 3.9.6.5, “Valve Replacement, Repair and Maintenance,” the North Anna 3 FSAR provides additional provisions for determining new reference values.

In addition to the provisions in ESBWR DCD, Tier 2, Section 3.9.6.8, “Non-Code Testing of Power-Operated Valves,” the North Anna 3 FSAR provides additional provisions for performing periodic tests of power-operated valves that are consistent with the guidance in NRC RIS 2000-03.

- STD COL 3.9.9-4-A Snubber Inspection and Test Program

To address COL Item 3.9.9-4-A, the North Anna 3 COL applicant specifies FSAR provisions that will supplement ESBWR DCD, Tier 2, Section 3.9.3.7.1(3)e, “Snubber Preservice and Inservice Examination and Testing.” For example, the North Anna 3 FSAR provides additional provisions to supplement the provisions for preservice examination and testing, and inservice examination and testing, of snubbers in ESBWR DCD, Tier 2, Section 3.9.3.7.1(3)e. In addition, the North Anna 3 FSAR provides additional provisions for listing snubber information to supplement ESBWR DCD, Tier 2, Section 3.9.3.7.1(3)f, “Snubber Support Data.”

In addition, in FSAR Section 3.9.3.7.1(3)3, the applicant states that as part of the system specific post COL ITAAC for piping and component design a plant-specific table will include snubber information as part of a subsequent FSAR update for ASME Class 1, 2 and 3 systems.

Supplemental Information

- STD SUP 3.9-1 10 CFR 50.55a Relief Requests and Code Cases

The North Anna 3 FSAR supplements ESBWR DCD, Tier 2, Section 3.9.6.6, “10 CFR 50.55a Relief Requests and Code Cases,” by specifying that no relief from or alternative to the ASME OM Code is being requested.

- STD SUP 3.9-2 Risk-Informed Inservice Testing

The North Anna 3 FSAR supplements ESBWR DCD, Tier 2, Section 3.9.7, “Risk-Informed Inservice Testing,” by specifying that risk informed IST is not being utilized.

- STD SUP 3.9-3 Risk-Informed Inservice Inspection of Piping

The North Anna 3 FSAR supplements ESBWR DCD, Tier 2, Section 3.9.8, “Risk-Informed Inservice Inspection of Piping,” by specifying that risk informed inservice inspection is not being utilized.

North Anna 3 Departure 3.7-1 related to SSCs

In the North Anna 3 COL, Part 7, "Departures Report," Revision 6, the applicant identifies DCD departure NAPS DEP 3.7-1 for the plant specific FIRS which exceeds the CSDRS, as discussed in Section 3.7 of this SER. The staff has evaluated this departure and its related effect on the North Anna 3 SSCs.

License Conditions

Part 10, Revision 7, of the North Anna 3 COL application specifies proposed license conditions related to Mechanical Systems and Components in the following topic areas: steam dryer, explosively actuated valves, and the operational program implementation schedule.

3.9.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is addressed in NUREG–1966, the FSER related to the certified ESBWR DCD and NUREG–1966, Supplement 1.

In addition, acceptance criteria associated with the relevant requirements of the Commission regulations are given in SRP Section 3.9.2, which include the following:

- The guidance associated with the reactor internals startup testing is given in RG 1.20, (Revision 3).

- 10 CFR Part 50, Appendix A, GDC 1, which requires (in part) that components important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed.

- GDC 2, which requires (in part) that components important to safety be designed to withstand seismic events without a loss of capability to perform their safety functions.

- GDC 4, which requires that SSCs important to safety be designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operations, maintenance, testing, and postulated pipe ruptures including loss-of-coolant accidents.

- GDC 14, “Reactor Coolant Pressure Boundary,” which requires that the RCPB be designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage; rapidly propagating failures; and gross ruptures.

- GDC 15, “Reactor Coolant System Design,” which requires that the reactor coolant system and associated auxiliary, control, and protection systems be designed with sufficient margins to assure that the design conditions of the RCPB are not exceeded during any condition of normal operation, including anticipated operational occurrences.

- 10 CFR Part 50, Appendix S, as it relates to the suitability of the plant design bases for mechanical components established in consideration of site seismic characteristics.

The regulatory basis for the staff's review of the North Anna 3 FSAR is provided by 10 CFR Parts 50 and 52. Specifically, the NRC regulations in 10 CFR 52.79(a)(11) require that a COL application provide a description of the programs and their implementation necessary to ensure that the systems and components meet the requirements of the ASME BPVC and the ASME OM Code, in accordance with 10 CFR 50.55a. As discussed in the ESBWR DCD FSER, GDC 1, 2, 4, 14, 15, 37, "Testing of Emergency Core Cooling System"; 40, "Testing of Containment Heat Removal System"; 43, "Testing of Containment Atmospheric Cleanup System"; 46, "Testing of Cooling Water System"; and 54, "Systems Penetrating Containment"; in Appendix A to 10 CFR Part 50 establish the necessary design, fabrication, construction, testing, and performance requirements for SSCs that provide reasonable assurance that the facility can be operated without undue risk to the health and safety of the public. The QA criteria in 10 CFR Part 50, Appendix B provide assurance that the design, tests, and documentation related to functional design, qualification, and IST programs for pumps, valves, and dynamic restraints will comply with established standards and criteria; thereby ensuring that such equipment will be capable of performing the intended functions.

RG 1.206 provides guidance for a COL applicant in preparing and submitting the COL application in accordance with NRC regulations. For example, Section C.IV.4 in RG 1.206 discusses the requirement in 10 CFR 52.79(a) that descriptions of operational programs need to be included in the FSAR for a COL application to allow reasonable assurance for a finding of acceptability. In particular, a COL applicant should fully describe the IST and other operational programs defined in Commission Paper SECY-05-0197, "Review of Operational Programs in a Combined License Application and Generic Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria," to avoid the need for ITAAC for operational programs. The term "fully described" for an operational program should be understood to mean that the program is clearly and sufficiently described in terms of scope and level of detail to allow a reasonable assurance finding. Further, operational programs should be described at a functional level with an increasing level of detail, where implementation choices could materially and negatively affect the program's effectiveness and acceptability. In the SRM for SECY-05-0197 dated February 22, 2006, the Commission approved the SECY including the use of a license condition for operational program implementation milestones that are fully described or referenced in the FSAR.

The staff's review of the North Anna 3 COL application followed the applicable guidance in SRP Section 3.9. North Anna 3 FSAR Table 1.9-201, "Conformance with Standard Review Plan," specifies that the COL application conform to the subsections in SRP Section 3.9. The staff also compared the North Anna 3 FSAR information with the guidance in RG 1.206, as listed in North Anna 3 FSAR Table 1.9-203, "Conformance with the FSAR Content Guidance in RG 1.206."

3.9.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.9 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 3.9 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD that represent the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the required information related to the "Mechanical Systems and Components."

The staff's review of the information contained in the North Anna 3 COL FSAR is as follows:

COL Items

- CWR COL 3.9.9-1-A Reactor Internals Vibration Analysis, Measurement and Inspection Program

This COL Information Item states the following.

DCD COL Item 3.9.9-1-A in Section 3.9.9 of the ESBWR DCD states that the COL applicant will perform the following:

1. For the reactor internals, other than steam dryer, classify its reactor per the guidance in RG 1.20 and provide a milestone for submitting a description of the inspection and measurement programs to be performed (including measurement locations and analysis predictions) and the results of the vibration analysis, measurement and test program (Section 3.9.2.4).

2. For the steam dryer, which is classified as a prototype per the guidance in RG 1.20, (a) provide a milestone of no later than 90 days before startup to prepare and provide to the NRC a Steam Dryer Monitoring Plan as described in NEDE-33313P, Section 10; (b) submit or reference a steam dryer predicted analysis (for the plant-specific or a sample steam dryer) that concludes the steam dryer will not exceed stress limits with applicable bias and uncertainties and the minimum alternating stress ratio (MASR) of 2.0; (c) describe startup program (with proposed license conditions) that includes appropriate notification points during power ascension, and submittal of the completed analysis of steam dryer data within 90 days following completion of the power ascension testing and monitoring of the steam dryer; and (d) specify periodic steam dryer inspections during refueling outages (Section 3.9.2.4).

To address COL Information Item 3.9.9-1-A, the North Anna 3 COL applicant specified that the vibration assessment program for reactor internals other than the steam dryer, as discussed in RG 1.20, is provided in DCD Appendix 3L and NEDE-33259P-A. In addition, the classification of the North Anna 3 reactor internals in accordance with RG 1.20 is dependent on ESBWR plant start-up testing status, that is, if North Anna 3 is the initial ESBWR to perform testing of the reactor internals, or if testing is performed at another reactor prior to North Anna 3 testing.

Specific to the steam dryer, the CVAP, as specified in RG 1.20 is provided in ESBWR DCD Appendix 3L, NEDE-33312P, NEDE-33313P, and NEDE-33408P.

The steam dryer is classified as a prototype according to RG 1.20, Revision 3, and the applicant presents an approach that is consistent with RG 1.20 and Section 10.2 of NEDE-33313P, including four elements of a steam dryer CVAP that must be addressed.

The staff reviewed the classification of the North Anna 3 reactor internals. The North Anna 3 classification of the reactor internals has two scenarios. In the first scenario, the North Anna 3 reactor internals are classified as the ESBWR prototype for testing the reactor internals. In the second scenario, should a CVAP for an ESBWR unit other than North Anna 3 be completed and approved by the NRC as a valid prototype before the initiation of startup testing at North Anna 3, the North Anna 3 reactor internals will be classified as non-prototype Category I. As described in NUREG–1966, Supplement 1, the Supplemental FSER related to the certified ESBWR DCD, Tier 2, Section 3.9.5, the steam dryer will be classified as a prototype regardless of the presence of another ESBWR unit. The staff finds the classification approach for the North Anna 3 reactor internals to be acceptable because the classification of the reactor internals for North Anna 3 is consistent with RG 1.20, and the classification of the steam dryer as a prototype regardless of the presence of another ESBWR unit is conservative.

For reactor internals (other than the steam dryer) to be installed in North Anna 3, the staff finds the review and acceptance of the CVAP specified in the ESBWR DCD to be acceptable as described in NUREG–1966, Supplement 1, the supplemental FSER related to the certified ESBWR DCD, Tier 2, Section 3.9.5. Therefore, the staff finds the portion of COL Item 3.9.9-1-A related to the reactor internals (other than the steam dryer) for North Anna 3 to be satisfied.

For the steam dryer, a description of the staff's review and acceptance of the ESBWR steam dryer evaluation methodology is in NUREG–1966, Supplement 1, the Supplemental FSER related to the certified ESBWR DCD, Tier 2, Section 3.9.5. The North Anna 3 FSAR specifies the COL applicant's actions that are necessary to satisfy the portion of COL Item 3.9.9-1-A related to the steam dryer. For the North Anna 3 steam dryer Item (a) of COL Item 3.9.9-1-A, the CVAP to be applied is described in ESBWR DCD, Tier 2, Section 3.9 and Appendix 3L and in NEDE-33313P, Section 10.0. The CVAP includes preparing and submitting to the NRC a SDMP no later than 90 days before startup. For Item (b) of COL Item 3.9.9-1-A, the detailed design of the North Anna 3 steam dryer will follow the methodology described in DCD Appendix 3L and in the incorporated engineering reports. As described in NEDE-33313P, Section 10.2(b), an example of a steam dryer predictive analysis that concludes the steam dryer will not exceed stress limits with the applicable bias and uncertainties and the MASR of 2.0 is provided in NEDE-33408P. The example of an as designed steam dryer that was subject to the predictive analysis process and successful startup testing described in NEDE-33408P serves as the design analysis report for the steam dryer and provides sufficient information for licensing. For Item (c) of COL Item 3.9.9-1-A, the North Anna 3 startup program is based on NEDE-33313P, Section 10.2(c), which includes (1) providing appropriate notification points during power ascension; (2) providing data to the NRC at certain hold points and at full power; and (3) providing a full stress analysis report and evaluation to the NRC within 90 days of reaching the full power level. For Item (d) of COL Item 3.9.9-1-A, the periodic steam dryer inspection program for North Anna 3 during refueling outages is described in NEDE-33313P, Section 10.2(d). Part 10 of the North Anna 3 COL application provides a proposed license condition for the steam dryer startup program and the periodic inspection program.

The staff has reviewed the actions specified in the North Anna 3 FSAR for each of the individual portions of COL Item 3.9.9-1-A regarding the steam dryer. The staff determined that the North Anna 3 FSAR actions related to the steam dryer satisfy the provisions in ESBWR DCD, Tier 2 and NEDE-33312P, NEDE-33313P, and NEDE-33408P incorporated in the ESBWR DCD as accepted in NUREG–1966, Supplement 1 on ESBWR DCD, Tier 2, Section 3.9.5. These North Anna 3 actions include application of the CVAP for the steam dryer described in the ESBWR DCD, Tier 2 and NEDE-33313P, reference of the example steam dryer predictive analysis in NEDE-33408P, preparation of a North Anna 3 startup program that incorporates the SDMP in NEDE-33313P, and specification of a periodic steam dryer inspection program consistent with NEDE-33313P. The North Anna 3 steam dryer monitoring and inspection program will be verified by the license condition specified in this SER section. The staff notes that the license condition proposed in this SER, as compared to the model condition proposed in NEDE-33313P, has been reformatted to better conform with standard license condition format and has been rewritten for clarity and to remove redundancy. Some of these changes resulted in minor changes in substance, such as more clearly specifying power levels for steam dryer monitoring and methods for informing the NRC of the results of monitoring. The staff reviewed and accepted the ESBWR DCD and its referenced engineering reports on the steam dryer as part of the NRC review of the ESBWR DC application. Therefore, the staff finds that the actions specified by the North Anna 3 COL applicant satisfy the steam dryer portion of COL Item 3.9.9-1-A.

The staff notes that the ESBWR DCD identifies specific portions of the information on the structural integrity and functional capability of mechanical systems and components to be Tier 2* information. As part of this identification of Tier 2* information, the ESBWR DCD identifies Tier 2, Section 3.9.2.3 as well as the GEH Reports NEDE-33312P, NEDE-33313P, and NEDE-33408P on the ESBWR steam dryer incorporated by reference in the DCD as Tier 2* in their entirety. Therefore, the North Anna 3 steam dryer evaluation methodology will be implemented as Tier 2* information in accordance with the ESBWR DC.

Based on its review described above, the staff finds that the North Anna 3 COL applicant has satisfied the provisions in COL Information Item COL 3.9.9-1-A. The staff discusses the applicable license conditions and FSAR provisions related to reactor internals for North Anna 3 in this SER section under "Post Combined License Activities." The staff finds that the information related to reactor internals classification and testing is adequate in meeting NRC regulatory requirements and RG 1.20 guidance, and is therefore acceptable.

- STD COL 3.9.9-2-A ASME Class 2 or 3 or Quality Group D Components with 60-Year Design Life

DCD COL Item 3.9.9-2-A in Section 3.9.9 of the ESBWR DCD states the following:

> The COL Applicant will provide a milestone for completing the required equipment stress reports, per ASME BPV Code, Subsection NB, for equipment segments that are subject to loadings that could result in thermal or dynamic fatigue and for updating the FSAR, as necessary, to address the results of the analysis (Section 3.9.3.1).

North Anna 3 COL FSAR, Revision 8, Section 3.9.3.1, "Loading Combinations, Design Transients and Stress Limits," states that the required equipment stress reports will be completed within 6 months of the completion of DCD ITAAC Table 3.1-1 for the as-built piping systems and components. In addition, the North Anna 3 FSAR specifies that the FSAR will be revised as necessary in a subsequent update to address the results of this analysis. The staff observes that in order to complete the referenced ITAAC related to the pipe break analyses listed in DCD Tier 1, Table 3.1-1, the applicant will first perform equipment and piping stress analyses that support the determination of pipe break locations based on the as-built conditions. Additional ITAAC related to the completion of component and piping stress analyses in accordance with ASME BPVC requirements are in DCD Tier 1. Dominion clarified in a subsequent letter dated April 17, 2014 (ADAMS Accession No. ML14108A345), that there are currently no non-Class 1 components for North Anna 3 that are subjected to cyclic loadings of a magnitude and/or duration so severe that the 60-year design life cannot be assured. Therefore, the staff finds that no supplemental information that provides an analysis or design per the

Tier 2* provisions of ESBWR DCD, Tier 2, Section 3.9.3.1, is necessary. The staff also observes that the original basis for including these requirements in the ESBWR DCD related to the staff's concerns regarding environmentally assisted fatigue, which have been resolved through the final staff position in RG 1.207, "Guidelines for Evaluating Fatigue Analyses Incorporating the Life Reduction of Metal Components Due To the Effects of the Light-Water Reactor Environment for New Reactors," which is committed to in ESBWR DCD, Tier 2, Section 3.9.1. Therefore, the applicant has provided an acceptable milestone related to the development of the required equipment stress reports, as requested in the COL item. These milestone activities are acceptable to the staff, as they address one detail of the overall stress analysis that will be confirmed through completion of ITAAC related to ASME BPVC requirements, as well as periodic FSAR updates required by the regulations. Post licensing and inspection processes are already in place to provide final verification of these overall activities. Based on the provision of the required evaluation and FSAR updates in response to this COL item and the associated ITAAC, the staff finds the applicant's response to COL Item 3.9.9-2-A acceptable.

- STD COL 3.9.9-3-A Inservice Testing Programs

This COL item is related to the functional design, qualification, and IST Programs for pumps, valves, and dynamic restraints. COL Item 3.9.9-3-A in Section 3.9.9 of the ESBWR DCD states the following:

> The COL Applicant shall provide a full description of the IST Program and a milestone for full program implementation as identified in Section 3.9.6.1.

The staff reviewed the North Anna 3 COL application and the applicable sections in the ESBWR DCD incorporated by reference in the North Anna 3 FSAR for the functional design, qualification, and IST Programs for safety-related pumps, valves, and dynamic restraints to determine whether the North Anna 3 COL application meets the regulatory requirements to provide reasonable assurance that the applicable safety-related components at North Anna 3 will be capable of performing their safety functions. In response to several RAIs, GEH and Dominion revised the ESBWR DCD and North Anna FSAR, respectively, to provide a full description of the IST and MOV Operational Programs in support of the North Anna 3 COL application.

ESBWR DCD Section 3.9.3.5, "Valve Operability Assurance," describes the process for the functional design and qualification of valves to be used in the ESBWR. Section 3.9.3.5 in ESBWR DCD, Tier 2 specifies that valve designs not previously qualified will meet the requirements of ASME Standard QME-1-2007, "Qualification of Active Mechanical Equipment Used in Nuclear Facilities." For valve designs that were previously qualified to standards other than ASME QME-1-2007, ESBWR DCD Tier 2, Section 3.9.3.5 specifies an approach for valve qualification that follows the key principals of ASME QME-1-2007. Based on the lessons learned from valve performance experience at operating nuclear power plants, the staff found the provisions in Revision 5 to the ESBWR DCD for the functional design and qualification of safety-related valves to be acceptable.

The staff issued RAI 03.09.06-1, which requested Dominion to discuss the process, such as by component examples, for implementing the provisions specified in ESBWR DCD Tier 2, Section 3.9.3.5 for the functional design and qualification of valves and dynamic restraints. Dominion's response in a letter dated September 11, 2008, stated that GEH is responsible for the design and qualification of mechanical equipment, including valves and dynamic restraints. Dominion noted that GEH is currently developing the procurement specifications and processes that will be made available for NRC review. With respect to solenoid-operated valves, Dominion stated that GEH will supply the power supply parameters to the valve supplier, and that the supplier will be responsible for qualifying the valves to those requirements. As discussed in Section 3.9.6.3.2, “Valves,” in NUREG-1966, the staff conducted an audit of the procurement specifications for the ESBWR design. The staff described its review of the ESBWR procurement specifications in a publicly-available audit report (ADAMS Accession No. ML092390403). As a result, this RAI was closed.

In COL Item 3.9.9.3-A, the applicant provided supplemental information on the North Anna 3 IST Program which provides the overall PST of pumps, valves, and restraints. The North Anna 3 COL FSAR does not identify any additional plant-specific valves to be included in the IST Program beyond those listed in ESBWR DCD, Tier 2, Table 3.9-8. ESBWR DCD, Tier 2, Section 3.9.6.1.4, “Valve Testing,” references NUREG–1482 (Revision 1), “Guidelines for Inservice Testing at Nuclear Power Plants.” Following the issuance of the North Anna 3 COL, the guidance in NUREG–1482 (Revision 2 issued in October 2013) can be used to develop the IST Program for North Anna 3, including the specific information to be included in program documentation and tables utilized for NRC inspection.

ESBWR DCD Tier 2, Section 3.9.6 specifies that IST of the applicable ASME BPV Code, Section III, Class 1, 2, and 3 pumps and valves will be performed in accordance with the ASME OM Code required by 10 CFR 50.55a(f), including limitations and modifications set forth in 10 CFR 50.55a. ESBWR DCD Tier 2, Section 3.9.10, “References,” specifies the 2001 Edition, with the 2003 Addenda of the ASME OM Code for use in the ESBWR design. The North Anna 3 FSAR incorporates by reference these provisions in the ESBWR DCD. As Supplemental Information STD COL 3.9-1, North Anna 3 FSAR Section 3.9.6.6, “10 CFR 50.55a Relief Requests and Code Cases,” states that no relief from or alternative to the ASME OM Code is being requested beyond what is identified in the DCD. The ASME OM Code 2001 through 2003 Addenda is incorporated by reference in 10 CFR 50.55a of the NRC regulations, with certain limitations and modifications. Therefore, the staff considers the application of the ASME OM Code 2001 Edition through 2003 Addenda, as specified in the NRC regulations with applicable limitations and modifications, to be acceptable for the North Anna Unit 3 IST Program description. As specified in 10 CFR 50.55a, a COL licensee is required to incorporate in the IST Program the latest edition and addenda of the ASME OM Code approved in 10 CFR 50.55a(f), on the date 12 months before initial fuel load.

The staff reviewed the description of the ASME OM Code requirements in the North Anna 3 FSAR on the IST Program that supplements the provisions in the ESBWR DCD including the prohibition of preconditioning that undermines the purpose of the IST activities. The staff finds the North Anna 3 FSAR to be consistent with Subsection ISTC, “Inservice Testing of Valves in Light-Water Reactor Nuclear Power Plants,” of the ASME OM Code incorporated by reference in 10 CFR 50.55a, and therefore, the FSAR description of the use of ASME OM Code, Subsection ISTC, is acceptable.

North Anna 3 FSAR Section 3.9.6 describes the incorporation of lessons learned from valve experience at operating nuclear power plants into the air-operated valve (AOV) IST Program for North Anna 3. The staff issued RAI 03.09.06-3, which requested the applicant to discuss (1) the provisions in the FSAR for the periodic verification of AOV capability, (2) the application of lessons learned from valve performance to power-operated valves (POVs) other than AOVs, and (3) the basis for the statement in Section 3.9.6 of the proposed revision to the North Anna 3 FSAR that post-maintenance procedures are applied where high-risk valve performance could be affected. Dominion's response to this RAI, in a letter dated September 11, 2008, discussed the IST Program for AOVs and other POVs (with the exception of MOVs). In Revision 1 (dated December 2008) to the North Anna 3 FSAR, the applicant supplemented the ESBWR DCD with a description of the testing program for POVs to be used at North Anna 3. For example, the AOV program will include the key elements of the Joint Owners Group AOV program discussed in Regulatory Issue Summary (RIS) 2000-03, "Resolution of Generic Safety Issue 158: Performance of Safety-Related Power-Operated Valves Under Design-Basis Conditions," which also references the staff comments on the program. Among the key lessons learned in the AOV program, the North Anna 3 FSAR specifies that periodic dynamic testing of AOVs will be performed to re-verify the capability of the valve to perform its required functions, if necessary, based on valve qualification or operating experience. The North Anna 3 FSAR states that the attributes of the AOV Testing Program are applied to other POVs to the extent that they apply to and can be implemented on those valves. The North Anna 3 FSAR also clarifies that post-maintenance procedures ensure that baseline testing is re-performed as necessary, when maintenance on the valve (valve repair or replacement) has the potential to affect valve functional performance. The provisions included in the North Anna 3 FSAR to supplement the ESBWR DCD are sufficient to apply the lessons learned from valve testing to the POV Testing Program at North Anna 3. Therefore, this RAI is closed.

RAI 03.09.06-5 requested Dominion to discuss the commencement of the Preservice Testing Program. Dominion's response to this RAI in a letter dated September 11, 2008, stated that as described in RG 1.206 Section C.IV.4.3, the COL will contain a license condition that requires Dominion to submit to the NRC a schedule that supports planning for and conducting NRC inspections of Operational Programs (including preservice testing). The schedule will be submitted 12 months after the COL has been issued and will be updated every 6 months until 12 months before the scheduled fuel loading, and every month thereafter, until either the operational programs in FSAR Table 13.4-201 have been fully implemented or the plant has been placed in commercial service, whichever comes first. Dominion stated that commencement of preservice testing will be concurrent with the operational status of the equipment and its readiness to support preservice testing, with completion of the preservice testing before fuel load, as indicated in FSAR Table 13.4-201. Dominion indicated that this provision means, for example, that the installation of the valves in the piping system must be complete, along with most of the piping system itself, when the valve power and controls are in place to support valve stroking. Any post-installation construction testing and valve setup activities (such as setting torque or limit switches, lubricating the valve, packing installation or adjustment) must be complete. Dominion stated that accomplishing these activities will depend on the plant construction and turnover schedules. Because the staff found that Dominion's response clarified, in an acceptable manner, the commencement of the Preservice Testing Program, this RAI is closed.

The ESBWR DCD specifies that the ESBWR reactor design does not require the use of pumps to mitigate the consequences of design-basis accidents or to achieve or maintain a safe-shutdown condition. The post-accident long-term decay heat removal for the ESBWR is performed by nonsafety-related systems as accepted in SECY-94-084, "Policy and Technical Issues Associated with the Regulatory Treatment of Nonsafety Systems in Passive Plant Designs." The availability of systems relied on after 72 hours that is addressed under the RTNSS Program is discussed in Chapter 19.0, "Probabilistic Risk Assessment and Severe Accidents," of this SER.

The staff finds that the North Anna 3 COL FSAR as discussed above contains an acceptable description of the functional design, qualification, and IST program for North Anna 3 that provides reasonable assurance that meets the NRC regulations and the ASME OM Code requirements.

Adverse Flow Effects

Nuclear power plant operating experience has revealed the potential for adverse flow effects from vibration caused by hydrodynamic loads and acoustic resonance within reactor coolant, steam, and feedwater systems, as well as reactor internal components such as steam dryers. Therefore in RAI 03.09.02-1 dated August 19, 2008 (ADAMS Accession No. ML082320133), the staff requested that Dominion describe the planned implementation of the program to address potential adverse flow effects on safety-related valves and dynamic restraints within the IST Program in the reactor coolant, steam, and feedwater systems at North Anna Unit 3 from hydraulic loading and acoustic resonance during plant operation.

In response to RAI 03.09.02-1 dated October 2, 2008 (ADAMS Accession No. ML082810405), the applicant presented a plan to use the overall Initial Test Program (ITP), which includes preoperational and startup testing, to address potential adverse flow effects on safety-related valves and dynamic restraints. The program will confirm attributes of the component design described in the ESBWR DCD, with implementation described in FSAR Section 14.2 and Table 13.4-201. As part of ESBWR DCD Tier 2, Section 3.9.2, the COL applicant referred to ESBWR DCD Tier 2, Section 3.9.2.1, "Piping Vibration, Thermal Expansion and Dynamic Effects," which states that the overall test program is divided into the preoperational test phase and the initial startup test phase with piping vibration, thermal expansion, and dynamic effects testing performed during both phases and described in ESBWR DCD Tier 2, Chapter 14. The COL applicant also referred to ESBWR DCD Tier 2, Section 3.9.2.1.1, "Vibration and Dynamic Effects Testing," which states that the purpose of these tests is to confirm that the piping, components, restraints, and supports of specified high- and moderate-energy systems have been designed to withstand the dynamic effects of steady-state, flow induced vibration (FIV) and anticipated operational transient conditions.

The North Anna 3 COL applicant referenced ESBWR DCD Tier 2, Section 3.9.3.5, which requires valve specifications to incorporate lessons learned from nuclear power plant operations and research programs, including applicable load combinations. The COL applicant also referred to ESBWR DCD Tier 2, Sections 3.9.3.7 and 3.9.3.8, which require analyses or tests for component supports to assure their structural capability to withstand seismic and other dynamic excitations. With respect to reactor internals, ESBWR DCD Section 3.9.2.3 states that the major reactor internal components within the vessel are subjected to extensive testing, coupled with dynamic system analyses, to properly evaluate the resulting FIV phenomena during normal reactor operation and from anticipated operational transients. The preoperational and startup tests are described in DCD Section 14.2.8.1.42, "Expansion, Vibration and Dynamic Effects Preoperational Test," and in DCD Section 14.2.8.2.10, "System Vibration Test," which describe the applicable preoperational and startup tests. Based on this information, the staff found the COL applicant's description of plans to implement the provisions in the ESBWR DCD to address potential adverse flow effects for safety-related valves and dynamic restraints at North Anna 3 to reflect nuclear power plant operating experience. In particular, the COL applicant plans to address the effects of steady-state FIV and operational transients, including lessons learned from operating experience and research programs as part of equipment qualification. Further, the COL applicant plans to address potential adverse flow effects by monitoring piping vibration during the ITP for North Anna 3. The staff's review of the qualification provisions for potential adverse flow effects as part of the review of design and procurement specifications is documented in SER Section 3.9.6. The implementation of the provisions in ESBWR DCD Tier 2, Chapter 14 will be reviewed as part of future NRC inspections at North Anna 3. The staff finds the North Anna 3 COL applicant's plans acceptable because they recognize the safety significance of potential adverse flow effects with future regulatory activities to monitor the details of those plans. Therefore, RAI 03.09.02-1 is resolved and closed.

The staff issued RAI 03.09.02-2 dated August 19, 2008 (ADAMS Accession No. ML082140136), requesting North Anna 3 COL applicant to indicate when it proposed to submit to the staff an implementation schedule to review the comprehensive FIV assessment program for reactor internals, in accordance with RG 1.20, Revision 3 and SRP Sections 3.9.2 and 3.9.5. In response to RAI 03.09.02-2 dated October 2, 2008 (ADAMS Accession No. ML082810405), the COL applicant stated that the comprehensive FIV assessment program for reactor internals was submitted by GEH to the staff as part of the ESBWR DCD review; this is now reflected in the ESBWR DCD, Revision 10. The reactor internals vibration analysis, measurement and inspection program is addressed under COL Information Item 3.9.9-1-A. The response of the North Anna 3 COL applicant to this COL Information Item has been evaluated by the staff as discussed above in this SER section. Therefore, RAI 03.09.02-02 is resolved and closed.

Special Tests

As part of STD COL 3.9.9-3-A the COL applicant in FSAR Section 3.9.6.1.4 (4), provided the following additional information for development of the IST program for explosively actuated (i.e., squib) valves.

> Industry and regulatory guidance is considered in development of IST program for explosively actuated valves. In addition, the IST program for explosively actuated valves incorporates lessons learned from the design and qualification process for these valves such that surveillance activities provide reasonable assurance of the operational readiness of explosively actuated valves to perform their safety functions.

Subsection ISTC-5260, "Explosively Actuated Valves," in the ASME OM Code specifies that at least 20 percent of the charges in squib valves shall be fired and replaced at least once every 2 years. If a charge fails to fire, the ASME OM Code states that all charges with the same batch number shall be removed, discarded, and replaced with charges from a different batch. In light of the updated design and safety significance of squib valves in new reactors, the need for improved surveillance activities for squib valves is being considered by the ASME.

In RAI 03.09.06-1 for the Fermi 3 RCOL application, the staff requested Detroit Edison to describe its plans for addressing the surveillance of squib valves that will provide reasonable assurance of the operational readiness of those valves to perform their safety functions in support of the Fermi 3 COL application. In a letter dated November 9, 2010 (ADAMS Accession No. ML103140611), Detroit Edison submitted a planned revision to Fermi 3 COL FSAR Section 3.9.6 to specify that industry and regulatory guidance will be considered in the development of the IST Program for squib valves. Detroit Edison indicated that the FSAR would also state that the IST Program for squib valves will incorporate lessons learned from the design and qualification process for these valves, such that surveillance activities provide reasonable assurance of the operational readiness of squib valves to perform their safety functions. The staff found that the planned changes to the Fermi 3 COL FSAR were sufficient to describe the IST Program for squib valves for incorporating the lessons learned from the design and qualification process in developing surveillance activities that will provide reasonable assurance of the operational readiness for squib valves to perform their safety functions.

Dominion, following its COLA revision to the ESBWR on April 25, 2013, adopted the response to this RAI in a letter dated August 30, 2013 (ADAMS Accession No. ML13247A394) and provided the FSAR updated information as part of FSAR Revision 6, July 2013. The staff finds that this supplemental information for development of the squib valve IST program for North Anna 3 is acceptable.

As discussed later in this SER section, North Anna 3 incorporated the FERMI License Condition directing the implementation of a surveillance program for squib valves in the gravity-driven cooling system and the automatic depressurization system for North Anna 3 prior to fuel load to supplement the IST requirements in the ASME OM Code, consistent with the licensing of other passive design new reactors. The staff considers the application of the ASME OM Code as incorporated by reference in 10 CFR 50.55a prior to startup of North Anna 3 to be sufficient for squib valves in the standby liquid control (SLC) system for North Anna 3, without the additional provisions of License Condition 3.9 that are necessary for the gravity driven cooling system and the automatic depressurization system, based on operating experience with SLC squib valves in current boiling-water reactor nuclear power plants.

- STD COL 3.9.9-4-A Snubber Inspection and Test Program

DCD COL Item 3.9.9-4-A in Section 3.9.9 of the ESBWR DCD states the following:

> The COL Applicant shall provide a full description of the snubber preservice and inservice inspection and testing programs, and a milestone for program implementation, including development of a data table identified in Subsection 3.9.3.7.1(3)f (Subsection 3.9.3.7.1(3)e).

The staff reviewed the applicant's information related to the snubber preservice and inservice examination and testing programs included under Section 3.9.3.7.1(3)e of the North Anna 3 COL FSAR, which states the following:

> A preservice thermal movement examination is also performed; during initial system heatup and cooldown, for systems whose design operating temperature exceeds 121°C (250°F), snubber thermal movement is verified.
>
> Additionally, preservice operational readiness testing is performed on all snubbers. The operational readiness test is performed to verify the parameters of ISTD-5120. Snubbers that fail the preservice operational readiness test are evaluated to determine the cause of failure, and are retested following completion of corrective action(s).
>
> Snubbers that are installed incorrectly or otherwise fail preservice testing requirements are re-installed correctly, adjusted, modified, repaired or replaced, as required. Preservice examination and testing is re-performed on installation-corrected, adjusted, modified, repaired or replaced snubbers as required.

The preservice inspection and testing programs for snubbers will be completed in accordance with milestones described in Section 13.4.

Inservice examination and testing of all safety-related snubbers is conducted in accordance with the requirements of the ASME OM Code, Subsection ISTD. Inservice examination is initially performed not less than two months after attaining 5 percent reactor power operation and will be completed within 12 calendar months after attaining 5 percent reactor power. Subsequent examinations are performed at intervals defined by ISTD-4252 and Table ISTD-4252-1. Examination intervals, subsequent to the third interval, are adjusted based on the number of unacceptable snubbers identified in the then current interval.

An inservice visual examination is performed on all snubbers to identify physical damage, leakage, corrosion, degradation, indication of binding, misalignment or deformation and potential defects generic to a particular design. Snubbers that do not meet visual examination requirements are evaluated to determine the root cause of the unacceptability, and appropriate corrective actions (e.g., snubber is adjusted, repaired, modified, or replaced) are taken. Snubbers evaluated as unacceptable during visual examination may be accepted for continued service by successful completion of an operational readiness test.

Snubbers are tested inservice to determine operational readiness during each fuel cycle, beginning no sooner than 60 days before the scheduled start of the applicable refueling outage. Snubber operational readiness tests are conducted with the snubber in the as-found condition, to the extent practical, either in place or on a test bench, to verify the test parameters of ISTD-5210. When an in-place test or bench test cannot be performed, snubber subcomponents that control the parameters to be verified are examined and tested. Preservice examinations are performed on snubbers after reinstallation when bench testing is used (ISTD-5224), or on snubbers where individual subcomponents are reinstalled after examination (ISTD-5225).

Defined test plan groups (DTPG) are established and the snubbers of each DTPG are tested according to an established sampling plan each fuel cycle. Sample plan size and composition are determined as required for the selected sample plan, with additional sampling as may be required for that sample plan based on test failures and failure modes identified. Snubbers that do not meet test requirements are evaluated to determine root cause of the failure, and are assigned to failure mode groups (FMG) based on the evaluation, unless the failure is considered unexplained or isolated. The number of unexplained snubber failures not assigned to an FMG determines the additional testing sample. Isolated failures do not require additional testing. For unacceptable snubbers, additional testing is conducted for the DTPG or FMG until the appropriate sample plan completion criteria are satisfied.

Unacceptable snubbers are adjusted, repaired, modified, or replaced. Replacement snubbers meet the requirements of ISTD-1600. Post-maintenance examination and testing, and examination and testing of repaired snubbers, is done to ensure that test parameters that may have been affected by the repair or maintenance activity are verified acceptable.

> Service life for snubbers is established, monitored and adjusted as required by ISTD-6000 and the guidance of ASME OM Code Nonmandatory Appendix F.
>
> The inservice inspection and testing programs for snubbers will be completed in accordance with milestones described in Section 13.4.

In the North Anna 3 FSAR, Section 3.9.3.7.1(3)e, “Snubber Support Data,” it is stated that for the ASME Class 1, 2, and 3 systems listed in DCD Tier 1, Section 3.1, that contain snubbers, a plant-specific table will be prepared in conjunction with the closure of the system-specific ITAAC for piping and component design and will include specific snubber information. This information will be included in the FSAR as part of a subsequent FSAR update.

The staff finds that the provisions specified in the North Anna 3 FSAR on the snubber inspection and test program together with the ESBWR DCD provisions incorporated by reference in the North Anna 3 FSAR adequately describe the snubber inspection and test program as consistent with the 3-87 ASME OM Code provisions in accordance with Commission policy to review a description of the operational programs (including the snubber IST program) in support of the COL application review. As indicated in a license condition specified later in this SER section, the licensee will submit a schedule that supports planning and conducting NRC inspections of operational programs. During inspections of the North Anna 3 operational programs, the staff will confirm that the PST and IST Operational Programs (including the snubber program) have been established consistent with the North Anna 3 FSAR and this SER section, including completion of the applicable requirements specified in the North Anna 3 FSAR. Therefore, COL Item 3.9.9-4-A is satisfied.

Supplemental Information

The North Anna 3 COL application also provides three instances of standard supplemental information in Section 3.9. In Section 3.9.6.6, STD SUP 3.9-1 states that no relief from or alternative to the ASME OM Code is being requested. In Section 3.9.7, STD SUP 3.9-2 states that risk-informed IST is not being utilized, replacing a statement in the ESBWR DCD that risk-informed IST initiatives, if any, are included in IST Program implementation plans. Similarly, in Section 3.9.8, STD SUP 3.9-3 states that risk-informed inservice inspection is not being utilized, replacing a statement in the ESBWR DCD that initiatives for risk-informed inservice inspection of piping, if any, are included in inservice inspection implementation plans. All three of these supplemental statements confirm that the North Anna 3 applicant intends to follow the processes for ASME OM Code implementation, IST Program implementation, and inservice inspection implementation described in the ESBWR DCD, as supplemented in the North Anna 3 COL application and evaluated as described in this SER section. Therefore, the staff finds this supplemental information acceptable.

North Anna 3 Departure 3.7-1 related to SSCs

In the North Anna 3 COL, Part 7, "Departures Report," Revision 6, the applicant identifies DCD departure NAPS DEP 3.7-1 for the plant-specific FIRS which exceeds the CSDRS, as discussed in Section 3.7 of this SER.

In ESBWR DCD 3.9, “Mechanical Systems and Components,” it states that, in accordance with GDC 2 and 10 CFR Part 50, Appendix S, the RPV assembly and its safety-related internal components are designed to withstand seismic events with site-specific seismic characteristics. In response to RAI 03.09.02-3 dated August 1, 2014 (ADAMS Accession No. ML14217A472), Dominion verified that the North Anna 3, ASME Code Design and Purchase Specification of all components designed and purchased to ASME Code, Section III, Class 1, 2, and 3 and related ASME code subsections requirements; including the RPV assembly and its safety related internal components along with its core support structures, in the requirements for loads and load combinations, will include both the CSDRS and the Unit 3 site specific FIRS in establishing the SSE ground motion response spectra, as defined in FSAR Section 3.7.1 The applicant further stated that according to the Unit 3 COLA, Part 7, departure NAPS DEP 3.7-1, and FSAR Section 3.7.1, the Unit 3 SSE design ground motion in FSAR Section 3.7.1 applies to the seismic design, analysis, and qualification of North Anna 3 plant SSCs, including the ASME Code components. The applicant's response also stated that the RPV evaluation which is described in FSAR Section 3.7.2.4 is performed utilizing both CSDRS and Unit 3 site-specific FIRS. The staff reviewed FSAR, Revision 8, Section 3.7.1, "Seismic Design Parameters," NAPS DEP 3.7-1 and verified that according to this section for each structure and each equipment location within the buildings, the site-specific ISRS that exceed the standard design ISRS, are used in conjunction with the standard design ISRS for seismic design and qualification of equipment and components. In addition the staff reviewed FSAR 3.7.2.4.1.8, "Site-Specific Seismic Design and Analysis of Structures, Systems, and components," which confirms that the seismic capability of the RPV subsystem is verified through the DCD Tier 1, Table 2.1.1-3, "ITAAC For the Reactor Pressure Vessel and Internals," using SSE loads developed from the results of site-specific SSI analysis of the RB/FB model.

Based on its review above, the staff finds the applicant's response acceptable because it demonstrated that the GDC 2 and 10 CFR Part 50, Appendix S requirements have been satisfied that equipment and components including the RPV assembly and its safety-related internal components will be designed to withstand seismic events of the evaluated site-specific seismic characteristics.

Interfaces for Standard Design

ESBWR DCD, Tier 2, Section 1.8, "Interfaces with Standard Design," identifies site-specific interfaces with the standard ESBWR design. DCD Table 1.8-1, "Matrix of NSSS Interfaces," references Section 3.9 for the supporting interface areas of mechanical SSCs. The staff reviewed the North Anna 3 COL application for interface requirements with the ESBWR standard design regarding the functional design, qualification, and IST Programs for safety-related valves and dynamic restraints using the review procedures described in SRP Section 3.9.6. The staff finds that the applicant's consideration of design interface items is acceptable based on compliance with NRC regulations discussed in this SER section.

3.9.5 Post Combined License Activities

With respect to the ESBWR steam dryer, NEDE-33313P specifies Tier 2* provisions for the COL holder to complete the design and construction of the steam dryer for an ESBWR nuclear power plant. For example, Section 9.1, "Instrumentation for Monitoring Steam Dryer Response," in NEDE-33313P describes the process to meet ITAAC 12, 13, and 14 in DCD Tier 1, Table 2.1.1-3, for the installation of pressure sensors, strain gages, and accelerometers on the as-built steam dryer to monitor its performance during power ascension. Section 10.1.1, "Steam Dryer Design Analysis Report," in NEDE-33313P specifies the elements for the as-designed ESBWR steam dryer analysis report. Section 10.1.2, "Steam Dryer As-Built Analysis

Report," in NEDE-33313P specifies the process to satisfy ITAAC 16 in DCD Tier 1, Table 2.1.1-3, in verifying that the as-built steam dryer fatigue analysis provides at least a MASR of 2.0 to the allowable alternating stress intensity of 93.7 MPa (13,600 psi). Appendix A, "ITAAC for Reactor Pressure Vessel Internals," to NEDE-33313P describes the process to meet ITAAC 8.b in DCD Tier 1, Table 2.1.1-3, to provide assurance that the reactor internal structures will meet the provisions of ASME BPVC, Subsection NG-3000, except for the weld quality and fatigue factors for secondary structural non-load bearing welds. Appendix B, "ITAAC for Main Steam Line [MSL] and [Safety Relief Valve] SRV/Safety Valve [SV] Branch Piping Acoustic Resonance," to NEDE-33313P describes the process to meet ITAAC 36 in DCD Tier 1, Table 2.1.2-3, to provide assurance that the MSL and SRV/SV branch piping geometry will preclude first and second shear layer wave acoustic resonance conditions from occurring and avoids excessive pressure loads on the steam dryer at plant normal operating conditions. These post-COL activities for the ESBWR steam dryer will be performed by the COL holder for North Anna 3 as described by the Tier 2* provisions in the ESBWR DCD and its referenced engineering reports unless the COL holder obtains regulatory approval for an alternative process.

Section 3.9.2.4 of the North Anna 3 FSAR provides the following provisions for the submittal of reports regarding reactor internals after receipt of the COL:

- For reactor internals other than the steam dryer, the comprehensive vibration assessment program will be developed and implemented as described in DCD Appendix 3L with no departures. The vibration measurement and inspection programs will comply with the guidance specified in RG 1.20, Revision 3, consistent with the Unit 3 reactor internals classification. A summary of the vibration analysis program and description of the vibration measurement (including measurement locations and analysis predictions) and inspection phases of the comprehensive vibration inspection program will be submitted to the NRC 6 months prior to implementation.

- For reactor internals other than the steam dryer, the preliminary and final reports (as necessary), which together summarize the results of the vibration analysis, measurement and inspection programs will be submitted to the NRC within 60 and 180 days, respectively, following the completion of the programs.

The staff finds these provisions for the submittal of a summary of the vibration analysis program, a description of the vibration measurement and inspection phases of the comprehensive vibration inspection program, and the preliminary and final reports of the vibration analysis, measurement, and inspection programs for reactor internals other than the steam dryer to be acceptable as consistent with the provisions of the ESBWR DCD and R-COLA FSAR. For the steam dryer, these actions are addressed in the license condition specified below.

License Conditions:

FSAR Section 13.4 indicates that FSAR Table 13.4-201 lists each operational program, the regulatory source for the program, the associated implementation milestones, and the FSAR section where the operational program is fully described, as discussed in RG 1.206. RG 1.206, Regulatory Position Section C.IV.4.3 states that the COL will contain a license condition that requires the licensee to submit to the NRC a schedule that supports planning and conducting NRC inspections of operational programs including PST, IST, reactor material surveillance and containment leakage testing. The schedule must be submitted 12 months after the NRC issues the COL. The schedule will be updated every 6 months, until 12 months before scheduled fuel loading, and every month thereafter until either the operational programs in FSAR Table 13.4-201 have been fully implemented or the plant has been placed in commercial service, whichever comes first.

3.6 Operational Program Readiness

The licensee shall submit to the Director of NRO, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented. This schedule shall also address:

- The implementation of site-specific Severe Accident Management Guidelines
- The spent fuel rack coupon monitoring program implementation

The staff has determined that a license condition is required for safety significant squib valves based on its review of the North Anna 3 COL application and as evaluated by the staff in Section 3.9.4 under the heading “Special Tests,” as follows:

3.9 Explosively Actuated Valves

Before initial fuel load, the licensee shall implement a surveillance program for explosively actuated valves (squib valves) in the Gravity-Driven Cooling System and the Automatic Depressurization System at Unit 3 that includes the following provisions in addition to the requirements specified in the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code) as incorporated by reference in 10 CFR 50.55a.

a. Preservice Testing (PST)

All explosively actuated valves shall be preservice tested by verifying the operational readiness of the actuation logic and associated electrical circuits for each explosively actuated valve with its pyrotechnic charge removed from the valve. This must include confirmation that sufficient electrical parameters (voltage, current, resistance) are available at the explosively actuated valve from each circuit that is relied upon to actuate the valve. In addition, a sample of at least 20 percent of the pyrotechnic charges in all explosively actuated valves shall be tested in the valve or a qualified test fixture to confirm the capability of each sampled pyrotechnic charge to provide the necessary motive force to operate the valve to perform its intended function without damage to the valve body or connected piping. The sampling must select at least one explosively actuated valve from each redundant safety train. Corrective action shall be taken to resolve any deficiencies identified in the operational readiness of the actuation logic or associated electrical circuits, or the capability of a pyrotechnic charge. If a charge fails to fire or its capability is not confirmed, all charges with the same batch number shall be removed, discarded, and replaced with charges from a different batch number that has demonstrated successful 20 percent sampling of the charges.

b. Operational Surveillance

Explosively actuated valves shall be subject to the following surveillance activities after commencing plant operation:

(1) At least once every 2 years, each explosively actuated valve shall undergo visual external examination and remote internal examination (including evaluation and removal of fluids or contaminants that may interfere with operation of the valve) to verify the operational readiness of the valve and its actuator. This examination shall also verify the appropriate position of the internal actuating mechanism and proper operation of remote position indicators. Corrective action shall be taken to resolve any deficiencies identified during the examination with post-maintenance testing conducted that satisfies the PST requirements.

(2) At least once every 10 years, each explosively actuated valve shall be disassembled for internal examination of the valve and actuator to verify the operational readiness of the valve assembly and the integrity of individual components and to remove any foreign material, fluid, or corrosion. The examination schedule shall provide for each valve design used for explosively actuated valves at the facility to be included among the explosively actuated valves to be disassembled and examined every 2 years. Corrective action shall be taken to resolve any deficiencies identified during the examination with post-maintenance testing conducted that satisfies the PST requirements.

(3) For explosively actuated valves selected for test sampling every 2 years in accordance with the ASME OM Code, the operational readiness of the actuation logic and associated electrical circuits shall be verified for each sampled explosively actuated valve following removal of its charge. This must include confirmation that sufficient electrical parameters (voltage, current, resistance) are available for each valve actuation circuit. Corrective action shall be taken to resolve any deficiencies identified in the actuation logic or associated electrical circuits.

(4) For explosively actuated valves selected for test sampling every 2 years in accordance with the ASME OM Code, the sampling must select at least one explosively actuated valve from each redundant safety train. Each sampled pyrotechnic charge shall be tested in the valve or a qualified test fixture to confirm the capability of the charge to provide the necessary motive force to operate the valve to perform its intended function without damage to the valve body or connected piping. Corrective action shall be taken to resolve any deficiencies identified in the capability of a pyrotechnic charge in accordance with the PST requirements.

This license condition supplements the current requirements in the ASME OM Code for explosively actuated valves, and sets forth requirements for PST and operational surveillance, as well as any necessary condition. The license condition will expire either when (1) the license condition is incorporated into the Unit 3 IST program; or (2) the updated ASME OM Code requirements for squib valves in new reactors (i.e., plants receiving a construction permit, or a

COL for construction and operation, after January 1, 2000), as accepted by the NRC in 10 CFR 50.55a, are incorporated into the Unit 3 IST program. For the purpose of satisfying the license condition, the licensee retains the option of including in its IST program either the requirements stated in this condition, or including updated ASME OM Code requirements.

The staff has determined that a license condition related to the steam dryer for North Anna 3 is needed, based on its review of the North Anna 3 COL application and as evaluated by the staff in Section 3.9.4, CWR COL 3.9.9-1-A item, as follows:

3.10 Steam Dryer License Conditions

1. Dominion Virginia Power shall prepare a Steam Dryer Monitoring Plan (SDMP) and submit the SDMP to the NRC no later than 90 days before the scheduled date for initial fuel loading.

2. Dominion Virginia Power shall provide Power Ascension Test (PAT) procedures for steam dryer monitoring to the NRC resident inspectors at least 10 days before the scheduled date for initial fuel loading. The PAT procedures must include the following:

   - Level 1 and Level 2 acceptance limits, as defined in Report NEDE-33313P (Revision 5, December 2013), for on-dryer strain gage and on-dryer accelerometer measurements to be used up to 100 percent power;

   - The power levels at which the steam dryer will be monitored (subject to Conditions 3 and 4 of this license) during power ascension, and the duration of monitoring at each power level;

   - A description of activities to be accomplished during monitoring at each power level;

   - Plant parameters to be monitored;

   - A description of the actions to be taken if acceptance criteria are not satisfied; and

   - A description of the process for verification of the completion of commitments and planned actions specified in the PAT procedures.

3. Dominion Virginia Power shall complete the actions specified in Item 2 of the model license condition specified in paragraph (c) of Section 10.2, “Comprehensive Vibration Program Elements for a COL Applicant,” in NEDE-33313P (Revision 5) between 65 and 75 percent thermal power.

4. Dominion Virginia Power shall measure, record, and evaluate pressures, strains, and accelerations from the steam dryer instrumentation at power levels approximately 5 percent higher than the previous power level at which Dominion Virginia Power measured, recorded, and evaluated such parameters until 100 percent thermal power is reached. Dominion Virginia Power shall generate data trending and a projection of strain levels for each successive power level, including full power. Dominion Virginia Power shall use data trending analysis to assess whether the Level 1 or Level 2 acceptance limits would be exceeded at the next higher power level for which the PAT specifies monitoring. Dominion Virginia Power shall provide the data trending results and revised limit curves to the NRC project manager by facsimile or electronic transmission.

5. At each power level for which Conditions 3 and 4 of this license require steam dryer monitoring, Dominion Virginia Power shall measure and record pressure, strain, and acceleration responses over a range of plant conditions sufficient to confirm that loading and fatigue effects from normal variations in plant conditions at power levels up to and including 100 percent thermal power will not adversely affect the life of the dryer. Dominion Virginia Power shall include its evaluation of steam dryer performance during such variations in plant conditions, including during Power Maneuvering in the Feedwater Temperature Operating Domain testing, in the dryer structural response as part of the full stress analysis report described in Condition 9 of this license.

6. If a flow-induced resonance is identified at any power level at which Conditions 3 and 4 of this license require steam dryer monitoring, and the strains or vibrations exceed the pre-determined Level 1 or Level 2 limit curve, Dominion Virginia Power shall cease power ascension until completing the actions specified in Item 5 of the model license condition specified in paragraph (c) of Section 10.2 in NEDE-33313P (Revision 5) and the following:

    a. If a Level 1 limit curve is exceeded, Dominion Virginia Power shall reduce power to the last power level at which Dominion Virginia Power performed steam dryer monitoring pursuant to Conditions 3 and 4 of this license and at which the Level 1 limit curve was not exceeded. Dominion Virginia Power shall perform a stress analysis to develop a new Level 1 limit curve before increasing power to the next level at which Condition 4 of this license requires steam dryer monitoring.

    b. If a Level 2 limit curve is exceeded, or if data trending indicates that a Level 1 limit curve may be challenged before the next power level at which Condition 4 of this license requires steam dryer monitoring is reached, Dominion Virginia Power shall evaluate the Level 1 and Level 2 limit curves and perform a stress analysis that demonstrates that the stress acceptance limits are satisfied at the higher power level before power is increased.

7. Dominion Virginia Power shall determine end-to-end bias and uncertainties by comparing the predicted and measured strain or acceleration on the steam dryer at each power level at which Dominion Virginia Power performs steam dryer monitoring pursuant to Conditions 3 and 4 of this license and confirm the conservatism of the predicted dryer stress field. At each such power level, Dominion Virginia Power shall adjust the predicted strain and acceleration responses using the frequency-dependent end-to-end bias errors and uncertainty values. If any of the measured sensor data at that power level exceeds the adjusted predictions, Dominion Virginia Power shall either (a) modify the bias errors and uncertainty values and limit curves and ensure measured sensor responses do not exceed the adjusted predictions, or (b) quantitatively evaluate the effect on fatigue life.

8. At the initial power level at which Condition 3 of this license requires steam dryer monitoring and at approximately 85 and 95 percent power, Dominion Virginia Power shall provide the steam dryer data analysis and results to the NRC project manager by facsimile or electronic transmission; and shall not exceed the power level at which it performed the steam dryer monitoring for at least 72 hours after the NRC project manager has confirmed receipt of the transmission.

9. Dominion Virginia Power shall provide data collected from the steam dryer monitoring required by Condition 4 of this license at 100 percent power to the NRC project manager by facsimile or electronic transmission within 72 hours of completing the collection of that data, with receipt confirmation from the NRC project manager. Dominion Virginia Power shall submit a full stress analysis report and evaluation to the NRC document control desk in accordance with 10 CFR 52.4 within 90 days of first reaching 100 percent thermal power. The report must include the minimum stress ratio and the final dryer load definition using steam dryer data, and associated bias errors and uncertainties, and must demonstrate that the steam dryer will maintain its structural integrity over its design life considering variations in plant parameters, including, but not limited to, reactor pressure and core flow rate. If the structural integrity of the steam dryer for the full plant life is not demonstrated by the stress analysis, Dominion Virginia Power shall describe its compensatory actions, such as future dryer replacement, in the stress analysis report.

10. Dominion Virginia Power shall implement a periodic steam dryer inspection program as follows:

    a. During the first two refueling outages after first reaching 100 percent thermal power, Dominion Virginia Power shall perform a visual inspection of all accessible areas and susceptible locations of the steam dryer in accordance with industry guidance on steam dryer inspections in the latest NRC staff-approved version of BWRVIP-139-A, "BWR Vessel and Internals Project, Steam Dryer Inspection and Flaw Evaluation Guidelines," with any conditions or limitations specified in the NRC staff approval. The results of these baseline inspections shall be submitted to the NRC within 60 days following startup after each outage.

    b. At the end of the second refueling outage after reaching 100 percent thermal power, Dominion Virginia Power shall update the Steam Dryer Monitoring Program to include a long-term inspection plan based on plant-specific and industry operating experience, and shall submit the updated program to the NRC within 180 days following startup from the second refueling outage.

In addition to the above three license conditions, the staff notes that, as discussed earlier in this SER section, Part 10 of the North Anna 3 COL application lists a detailed license condition for the ITP that includes activities to address COL Item STD COL 14.2.3-A, "Preoperational and Startup Test Procedures." This license condition will ensure that the COL licensee implements the ITP, which includes the reactor internals initial start-up FIV testing.

ITAAC

ESBWR DCD, Tier 1 includes numerous ITAAC to verify the acceptability of the as-built mechanical systems and components at North Anna 3. A sample of the ITAAC related to the North Anna 3 steam dryer includes the following:

ESBWR DCD, Tier 1, Table 2.1.1-3, "ITAAC for the Reactor Pressure Vessel and Internals"

ITAAC Item 8b. The RPV internal structures listed in Table 2.1.1-1 (chimney and partitions, chimney head and steam separators assembly, and steam dryer assembly) meet the requirements of ASME BPVC, Subsection NG-3000, except for the weld quality and fatigue factors for secondary structural non-load bearing welds.

ITAAC Item 12. The number and locations of pressure sensors installed on the steam dryer for startup testing ensure accurate pressure predictions at critical locations.

ITAAC Item 13. The number and locations of strain gages and accelerometers installed on the steam dryer for startup testing are capable of monitoring the most highly stressed components, considering accessibility and avoiding discontinuities in the components.

ITAAC Item 14. The number and locations of accelerometers installed on the steam dryer for startup testing are capable of identifying potential rocking and of measuring the accelerations resulting from support and vessel movements.

ITAAC Item 16. The as-built steam dryer predicted peak stress is below the fatigue limitation. ESBWR DCD, Tier 1, Table 2.1.2-3, "ITAAC for the Nuclear Boiler System.

ITAAC Item 36. The main steam line and SRV/SV [safety relief valve/safety valve] branch piping geometry precludes first and second shear layer wave acoustic resonance conditions from occurring and avoids pressure loads on the steam dryer at plant normal operating conditions.

With respect to the ESBWR steam dryer, NEDE-33313P specifies Tier 2* provisions for the COL licensee to complete the design and construction of the steam dryer for an ESBWR nuclear power plant. For example, Section 9.1, "Instrumentation for Monitoring Steam Dryer Response," in NEDE-33313P describes the process to meet ITAAC Items 12, 13, and 14 in DCD Tier 1, Table 2.1.1-3, for the installation of pressure sensors; strain gages; and accelerometers on the as-built steam dryer to monitor its performance during power ascension. Section 10.1.1, "Steam Dryer Design Analysis Report," in NEDE-33313P specifies the elements for the as-designed ESBWR steam dryer analysis report. Section 10.1.2, "Steam Dryer As-Built Analysis Report," in NEDE-33313P specifies the process to satisfy ITAAC Item 16 in DCD Tier 1, Table 2.1.1-3, for verifying that the as-built steam dryer fatigue analysis provides at least a MASR of 2.0 to the allowable alternating stress intensity of 93.7 MPa (13,600 psi). Appendix A, "ITAAC for Reactor Pressure Vessel Internals," to NEDE-33313P describes the process to meet ITAAC Item 8b in DCD Tier 1, Table 2.1.1-3, so as to provide assurance that the reactor internal structures will meet the provisions of ASME BPVC, Subsection NG-3000, except for the weld quality and fatigue factors for secondary structural non-load bearing welds. Appendix B, "ITAAC for Main Steam Line and SRV/Safety Valve Branch Piping Acoustic Resonance," to NEDE-33313P describes the process to meet ITAAC 36 in DCD Tier 1, Table 2.1.2-3, to provide assurance that the main steam line and SRV/SV branch piping geometry will preclude first and second shear layer wave acoustic resonance conditions from occurring and avoids excessive pressure loads on the steam dryer at plant normal operating conditions. These post COL activities for the ESBWR steam dryer will be performed by the COL licensee for North Anna 3, as described by the Tier 2* provisions in the ESBWR DCD and its referenced engineering reports, unless the COL licensee obtains regulatory approval for an alternative process.

3.9.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the relevant information relating to the dynamic testing and analysis of SSCs, and no outstanding information is expected to be addressed in the COL FSAR related to this section.

The staff reviewed North Anna 3 FSAR, Section 3.9 and the provisions specified in ESBWR DCD, Tier 2, Section 3.9 that are incorporated by reference in the North Anna 3 FSAR for structural integrity and functional capability of mechanical systems and components for the North Anna 3 nuclear power plant. The staff review of the information provided in Section 3.9 of the ESBWR DCD, Tier 2 is provided in the FSER on the ESBWR DC applicant as modified by NUREG–1966, Supplement 1 on Section 3.9.5 of the ESBWR DCD, Tier 2. Based on its review, the staff concludes that the North Anna 3 COL applicant has provided reasonable assurance that mechanical systems and components to be installed in North Anna 3 will have the structural integrity and functional capability to perform their design functions for the safe operation of the North Anna 3 nuclear power plant.

North Anna 3 Departure 3.7-1 related to SSCs

The staff, by its above review, finds that the applicant has adequately addressed NAPS DEP 3.7-1 as it relates to *SSCs* and has provided sufficient information to meet GDC 2 and 10 CFR Part 50, Appendix S.

In addition, based on the staff's review discussed in this SER section, the staff concluded that the North Anna 3 COL application, together with incorporation by reference of the ESBWR DCD, provides an acceptable description of the Dynamic and Analysis and Testing Program to be used at North Anna 3 considering the site-specific SSE as defined in FSAR Section 3.7.1. The staff has determined that the North Anna 3 COL applicant has provided sufficient information to satisfy the requirements of 10 CFR Parts 50 and 52 for the dynamic testing and analysis of North Anna 3 SSCs.

3.10 Seismic and Dynamic Qualification of Mechanical and Electrical Equipment

3.10.1 Introduction

Seismic and dynamic qualification of seismic Category I equipment include the following types:

- Safety-related active mechanical equipment that performs a mechanical motion while accomplishing a system safety-related function. Examples include pumps, valves, and valve operators.

- Safety-related, non-active mechanical equipment whose mechanical motion is not required while accomplishing a system safety-related function, but whose structural integrity must be maintained in order to fulfill its design safety-related function.

- Safety-related instrumentation and electrical equipment and certain monitoring equipment.

Mechanical and electrical equipment (including instrumentation and controls and where applicable, their supports) classified as seismic Category I must demonstrate that they are capable of performing their intended safety-related functions under the full range of normal and accident (including seismic loadings). This equipment includes devices associated with systems that are essential to safe shutdown, containment isolation, reactor core cooling, and containment and reactor heat removal, or are otherwise essential in preventing a significant release of radioactive material into the environment or in mitigating the consequences of accidents.

3.10.2 Summary of Application

Section 3.10 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 3.10 of the ESBWR DCD, Revision 10. In addition, in FSAR Section 3.10, the applicant provided the following:

<u>COL Items</u>

- STD COL 3.10.4-1-A Dynamic Qualification Report

In FSAR Section 3.10.1.4, the applicant described its implementation schedule for completing ITAAC to be provided to the NRC no later than 1 year after issuance of the COL or the start of construction as defined in 10 CFR 50.10(a), whichever is later.

Supplemental Information

- STD SUP 3.10-1 Quality Assurance Program for Equipment Qualification

In FSAR Section 3.10.1.4, the applicant states that the North Anna 3 QA Program is in FSAR Section 17.5, including requirements for handling safety-related quality records; control of purchased material, equipment, and services; test control; and other quality related processes.

3.10.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the FSER related to the certified ESBWR DCD. In addition, the relevant requirements of the Commission regulations for the seismic and dynamic qualification of mechanical and electrical equipment, and the associated acceptance criteria are in SRP Section 3.10. Specific requirements include the following:

- GDC 1 and GDC 30, “Quality of Reactor Coolant Pressure Boundary,” as they relate to qualifying equipment to appropriate quality standards commensurate with the importance of the safety functions to be performed.
- GDC 2 and Appendix S to 10 CFR Part 50, as they relate to designing equipment to withstand the effects of natural phenomena such as earthquakes.
- GDC 4, as it relates to qualifying equipment as capable of withstanding the dynamic effects associated with external missiles and internally generated missiles, pipe whip, and jet impingement forces.
- GDC 14, as it relates to qualifying equipment associated with the reactor coolant boundary so that there is an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture.
- 10 CFR Part 50, Appendix B, as it relates to qualifying equipment using the QA criteria.

- 10 CFR Part 50, Appendix B, Criterion III, as it relates to verifying and checking the adequacy of a design by the performance of a suitable test program (among other options), which specifically requires that a test program used to verify the adequacy of a specific design feature shall include suitable qualification testing of a prototype unit under the most adverse design conditions.

- 10 CFR 52.80(a), which requires that a COL application to contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and NRC's regulations.

3.10.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.10 of the certified ESBWR DCD. The staff reviewed Section 3.10 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the ESBWR DCD and the information in the North Anna 3 COL FSAR appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR, Revision 8, as follows:

<u>*COL Items*</u>

- STD COL 3.10.4-1-A Dynamic Qualification Report

The staff reviewed the conformance of Section 3.10 of the North Anna COL FSAR to the guidance in RG 1.206, Chapter 3, Sections C.I.3.10 and C.III.1.3.10, "Seismic and Dynamic Qualification of Mechanical and Electrical Equipment." The staff's review of Section 3.10 of the North Anna COL FSAR found that the applicant has appropriately incorporated by reference Section 3.10 of the ESBWR DCD, Revision 10. In addition to meet the guidance in Section C.I.3.10.4 and C.III.3.10.4 of RG 1.206, the applicant should provide the results of tests and analyses to demonstrate adequate seismic qualification of equipment. However, RG 1.206 acknowledges that this level of detail may not be available and provides an alternative provision for an implementation plan that includes milestones and completion dates. The information included with this plan should address those details not addressed in the DCD. Those details include, for example, a listing of the equipment to be qualified, the method of qualification, and who will be performing the qualification. The expectation is that all information for these planning phases would be completed before component procurement and would be available for inspection by the staff as necessary.

Therefore the staff in RAI 3.10-1 requested that the applicant provide an implementation plan that includes the level of detail that will be completed prior to procurement and the plan for completing equipment qualification as called for in RG 1.206. This information is necessary for the staff to make a reasonable assurance safety finding for licensing (i.e., to find that the design is in accordance with the regulations). It is expected that this information would be available to be audited by the staff prior to equipment installation. In its response to RAI 3.10-1, the applicant provided its qualification plan including its ITAAC implementation schedule as well as stating in Section 3.10.1.4 of North Anna 3, FSAR Revision 8 the following:

> The Dynamic Qualification Report and documentation that describe the seismic and dynamic qualification methods will be made available for NRC staff review, inspection, and audit. Information that verifies the seismic and dynamic qualification will be made available to the NRC to facilitate reviews, inspections, and audits throughout the process. FSAR information will be revised, as necessary, as part of a subsequent FSAR update.

As described in the North Anna 3 COL FSAR, Revision 8, Section 3.10, the applicant provided requirements that meet the alternative provision for an implementation plan that includes applicable ITAAC and milestones and completion dates as required in RG 1.206. Therefore, RAI 3.10-1 is resolved and closed and the staff finds the North Anna 3 FSAR Supplemental Information Item STD SUP 3.10-1 acceptable.

Supplemental Information

- STD SUP 3.10-1 Quality Assurance Program for Equipment Qualification

The staff reviewed the additional information provided in STD SUP 3.10-1, which provides a pointer to North Anna 3 COL FSAR, Revision 8, Section 17.5 for the quality requirements related to equipment qualification (including seismic qualification). This pointer provides additional clarification and does not affect the staff's conclusions on either the ESBWR DCD information incorporated by reference or the technical information specific to the North Anna 3 COL FSAR, Revision 8, Section 3.10; therefore, it is acceptable to the staff.

3.10.5 Post Combined License Activities

The applicant identifies the following FSAR requirements related to safety-related seismic and dynamic equipment qualification:

- An implementation schedule for completing ITAAC will be provided to the NRC no later than 1 year after issuance of the combined license or at the start of construction as defined in 10 CFR 50.10(a), whichever is later. Dominion shall submit updates to the ITAAC schedules every 6 months thereafter and, within 1 year of its scheduled date for initial loading of fuel, and shall submit updates to the ITAAC schedules every 30 days until the final notification is provided to the NRC under paragraph 10 CFR 52.99(c)(1).

- The Dynamic Qualification Report and documentation that describe the seismic and dynamic qualification methods will be made available for the NRC staff review, inspection, and audit. Information that verifies the seismic and dynamic qualification will be made available to the NRC to facilitate reviews, inspections, and audits throughout the post COL construction process.

3.10.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the seismic and dynamic qualification of mechanical and electrical equipment that were incorporated by reference have been resolved.

In addition, the staff compared the additional COL information in the application to the relevant NRC regulations, the guidance in SRP Section 3.10, and other NRC RGs. The staff's review concluded that the applicant has adequately addressed COL Item STD COL 3.10.4-1-A and Supplemental Item STD SUP 3.10-1. Therefore, the staff finds that North Anna 3 COL FSAR, Revision 8, Section 3.10, is acceptable and meets the NRC regulatory requirements and acceptance criteria in SRP Section 3.10 and RG 1.206 including GDC 1, GDC 2, GDC 4, GDC 14, and GDC 30; Appendix S to 10 CFR Part 50, 10 CFR Part 50, Appendix B, Criterion III, and 10 CFR 52.80(a).

3.11 <u>Environmental Qualification of Mechanical and Electrical Equipment</u>

3.11.1 Introduction

This FSAR section describes the Environmental Qualification (EQ) Program to be used at North Anna 3 for the electrical and mechanical safety-related equipment. The objective of the EQ Program is to reduce the potential for common failures resulting from specified environmental events and to demonstrate that the equipment within the scope of the EQ Program is capable of performing its intended design function under all conditions, including environmental stresses resulting from design-basis events. During plant operation, the COL licensee implements the EQ Program, which specifies the replacement frequencies of affected safety-related equipment in harsh environments. The EQ Program also addresses nonsafety-related equipment failures under the postulated environmental conditions that could prevent the satisfactory performance of the safety function requirements of the specified safety-related equipment, and certain post-accident monitoring equipment.

The safety-related equipment must perform its safety functions under all normal environmental conditions, abnormal operational occurrences, design-basis events, post-design-basis events, and containment test conditions. This capability is demonstrated through qualification testing and analysis of similar equipment under the temperature, pressure, humidity, chemical effects, radiation, and submergence conditions in which the equipment will be expected to operate. The qualification information shall include identification of the equipment required to be environmentally qualified. Each component shall have onsite and in an auditable form, the designated functional requirements; the definition of the applicable environmental parameters; the periodic maintenance to support the qualified life; the accident that the component is required to mitigate; the required operation time; and the documentation of the qualification process employed to demonstrate the required environmental capability. This information shall be maintained and remain current.

3.11.2 Summary of Application

Section 3.11 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 3.11 of the ESBWR DCD, Revision 10. In addition, in FSAR Section 3.11 the applicant provides the following:

COL Items

- STD COL 3.11-1-A Environmental Qualification Documentation

In FSAR Section 3.11.4.4 the applicant provides additional information to address COL Item 3.11-1-A. The applicant states that the EQ Program consists of the equipment and certain post-accident monitoring devices that are in scope and that must be environmentally qualified for use in a harsh environment as identified in the ESBWR DCD, Tier 2, Section 3.11, Table 3.11.1. This EQ Master Equipment List (EQMEL) consists of equipment that is essential to emergency reactor shutdown, containment isolation, reactor core cooling, or containment and reactor heat removal or that is otherwise essential in preventing a significant release of radioactive material to the environment. The North Anna 3 FSAR also specifies that the implementation of the EQ Program, including the development of the Environmental Qualification Document (EQD), will be in accordance with the milestone schedule in FSAR Section 13.4, "Operational Program Implementation."

3.11.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is discussed in NUREG–1966.

The relevant requirements of the Commission regulations for the EQ operational program and EQD and the associated acceptance criteria are in SRP Section 3.11.

The applicable regulatory requirements for the EQD are as follows:

- 10 CFR 50.49, "Environmental qualification of electrical equipment important to safety for nuclear plants," requires an applicant for a nuclear power plant license to establish a program that qualifies electrical equipment for environmental effects.

- GDC 1 requires components important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

- GDC 2 requires components important to safety be designed to withstand the effects of natural phenomena without loss of capability to perform their safety function.

- GDC 4 requires components important to safety be designed to accommodate the effects of, and be compatible with, the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including loss of coolant accidents.

- GDC 23, "Protection system failure modes," requires protection systems to be designed to fail in a safe state, or in a state demonstrated to be acceptable on some other defined basis, if conditions such as postulated adverse environments occur (e.g., extreme heat or cold, pressure, steam, water, or radiation).

- 10 CFR Part 50, Appendix B, Criterion III, “Design Control,” requires measures to be established to ensure that applicable regulatory requirements and the associated design bases are correctly translated into specifications, drawings, procedures, and instructions. These measures should include provisions to ensure that appropriate quality standards are included in design documents and deviations from established standards are controlled. A process should also be established to determine the suitability of equipment that is essential to safety-related functions and to identify, control, and coordinate design interfaces between participating design organizations. Where a testing program is used to verify the adequacy of a specific design feature, the test shall include suitable qualification testing of a prototype unit under the most adverse design conditions.

- 10 CFR Part 50, Appendix B, Criterion XI, “Test Control,” requires a test control plan to be established to ensure that all tests needed to demonstrate a component's performance capability are identified in accordance with required procedures and acceptance limits in the applicable design documents.

- 10 CFR Part 50, Appendix B, Criterion XVII, “Quality Assurance Records,” requires sufficient records to be maintained to furnish evidence of activities affecting quality. The records must include inspections, tests, audits, work performance monitoring, and materials analyses. Records must be identifiable and retrievable.

The related acceptance criteria are as follows:

- In accordance with SECY-05-0197, as accepted in the Commission’s SRM dated February 22, 2006, equipment qualification is an Operational Program that will be reviewed in the COL application. The staff reviews this program to make a reasonable assurance finding on the program. A COL applicant should fully describe the EQ and other Operational Programs as defined in SECY-05-0197 to avoid the need for ITAAC to implement those programs. The term “fully described” for an operational program should be understood to mean that the program is clearly and sufficiently described in terms for scope and level of detail to allow a reasonable assurance finding of acceptability. Further, Operational Programs should be described at a functional level and an increasing level of detail where implementation choices could materially and negatively affect the program effectiveness and acceptability. The Commission approved the use of a license condition for operational program implementation milestones that are fully described or referenced in the FSAR as discussed in the SRM for SECY-05-0197, dated February 22, 2006.

3.11.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.11 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 3.11 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the ESBWR DCD and the information in the North Anna 3 COL FSAR, appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the North Anna 3 COL application and the applicable sections in the ESBWR DCD incorporated by reference into the North Anna 3 FSAR for the description of the EQ Program for mechanical and electrical equipment to determine whether the North Anna 3 COL application meets the regulatory requirements to provide reasonable assurance that the applicable equipment at North Anna 3 will be capable of performing their intended functions.

The staff reviewed the following information in the North Anna 3 COL FSAR as follows:

COL Items

- STD COL 3.11-1-A Environmental Qualification Documentation

The staff reviewed the additional information related to the environmental qualification documentation under Section 3.11.7 of the North Anna 3 COL FSAR, Revision 8, which states the following:

> This COL item is addressed in Section 3.11.4.4.

In ESBWR DCD, Tier 2, Section 3.11.7, COL Item 3.11-1-A states that the COL applicant will provide a full description and a milestone for implementing the EQ Program that will include completion of the plant-specific EQD per Section 3.11.4.4, "Environmental Qualification Documentation." In FSAR Section 3.11.4.4, the applicant states that a description of the EQ Program is provided in ESBWR DCD, Tier 2, Section 3.11. The applicant also states that the implementation of the EQ Program, including the development of the EQD will be in accordance with the milestone schedule in FSAR Section 13.4. The staff reviewed the applicant's resolution to ESBWR COL Item 3.11-1-A in FSAR Section 3.11.4.4. In addition to reviewing the North Anna 3 COL application, the staff reviewed the information in the ESBWR DCD. Provisions in the ESBWR DCD support the North Anna 3 COL application by fully describing the EQ Operational Program for North Anna 3.

North Anna 3 FSAR, Section 3.11 incorporates by reference ESBWR DCD, Tier 2, Section 3.11 with supplemental information. In RAI 03.11-1 the staff requested Dominion provide or reference certain information related to the EQ Program for safety-related mechanical equipment or indicate the status of and the schedule for its availability. In Dominion's RAI response dated September 11, 2008 (ADAMS Accession No. ML082730754), which noted that the ESBWR DCD, Tier 2, Section 3.11, Revision 5, COL Item 3.11-1-A, had been revised requiring a full description of the EQ program along with a milestone for program implementation by the COL applicant. The North Anna 3 FSAR, Section 3.11, Revision 8, reflects this change. For example, ESBWR DCD, Tier 2, Table 3.11-1, "Electrical and

Mechanical Equipment for Environmental Qualification," identifies the environment in which a component within the scope of the EQ Program will be located. The RAI response stated that no site-specific, safety-related equipment will be used beyond that described in the ESBWR DCD, Section 3.11.4.1, "Harsh Environment Qualification," in ESBWR DCD, Tier 2, indicates that the qualification of mechanical equipment includes materials that are sensitive to environmental effects (e.g., seals, gaskets, lubricants, and fluids for hydraulic systems). The RAI response stated that the completion of the plant-specific EQD will be accomplished as specified in FSAR Section 3.11.4.4. Furthermore, the RAI response indicated that the completion of the EQ Program for plant equipment will be confirmed by the close-out of the ITAAC, which is specified in ESBWR DCD, Tier 1, Table 3.8-2, "ITAAC for Environmental Qualification of Mechanical and Electrical Equipment." As noted in Section 3.9.4 of this SER, GEH is responsible for the design and qualification of mechanical equipment, and the GEH procurement specifications and processes were made available for NRC to review.

In RAI 03.11-3 the staff requested Dominion to clarify whether the FSAR would be updated to include additional equipment not identified in ESBWR DCD, Tier 2, Table 3.11-1. In Dominion's RAI response dated September 11, 2008, the applicant stated that there is no safety-related equipment or safe shutdown equipment outside the scope of the ESBWR design. As a result, there is no additional equipment covered by the EQ Program that is not identified in DCD Table 3.11-1. Therefore, RAI 03.11-3 is resolved and closed.

In RAI 03.11-5 the staff requested that Dominion describe consideration of FIV in the qualification of safety-related mechanical equipment, including acoustic resonance and hydraulic loading. In Dominion's RAI response dated September 11, 2008, the applicant stated that ESBWR DCD, Tier 2, Section 3.9.3.5 requires the ESBWR general valve requirement specification to include requirements related to the design and functional qualification of safety-related valves that incorporate lessons learned from nuclear power plant operations and research programs. ESBWR DCD, Tier 2, Section 3.10 addresses methods of testing and analysis employed to ensure the capability of mechanical and electrical equipment under the full range of normal and accident loadings. The RAI response indicated that testing, as described in ESBWR DCD, Tier 2, Section 3.9.2 and FSAR Section 14.2, will provide confidence in the capability of safety-related equipment to perform their safety functions. For example, ESBWR DCD, Tier 2, Section 3.9.2.1.1 discusses vibration and dynamic effects testing that will be performed during the ITP, as described in DCD Sections 14.2.8.1.42 and 14.2.8.2.10. The objective of these tests will be to confirm that the piping, components, restraints, and supports of specified high and moderate-energy systems were designed to withstand the dynamic effects of steady-state FIV and anticipated operational transient conditions. The staff considers that the actions specified in the ESBWR DCD will address potential adverse flow effects on safety-related valves and dynamic restraints including the consideration of lessons learned from nuclear power plant operating experience. Therefore, RAI 03.11-5 is resolved and closed.

In the North Anna 3 FSAR, Section 13.4, Table 13.4-201, "Operational Programs Required by NRC Regulations," lists each operational program, the regulatory source for the program, the FSAR section where the operational program is described and the associated implementation milestones. This Table specifies the implementation milestone for the EQ Program as "prior to fuel load." In RAI 03.11-6 the staff requested that Dominion further clarify the commencement of the EQ Program and its transition into an operating reactor program. Dominion's RAI response dated September 11, 2008, stated that the COL application will contain a license condition that will require the COL licensee to submit a schedule to the NRC 12 months after the issuance of the COL, which will support planning and conducting NRC inspections of operational programs including the EQ Program, with periodic updating of the schedule. This schedule will address additional program implementation details, such as commencement of the EQ Program. The transition of the EQ Program into an operating program will occur as part of the plant turnover process. The staff finds that the RAI response clarified plans for the implementation and turnover of the EQ Program during plant construction and startup. Therefore, RAI 03.11-6 is resolved and closed.

ESBWR DCD, Tier 1, Revision 10, Section 3.8, "Environmental Qualification of Mechanical and Electrical Equipment," specifies the EQ ITAAC for safety-related mechanical and electrical equipment in Table 3.8-2. The inspections, tests, and analyses for safety-related or RTNSS mechanical equipment located in a harsh environment state that type tests, or a combination of type tests and analyses will be performed. In RAI 03.11-7 that staff requested the applicant to describe the plan for the implementation of the ITAAC for safety-related mechanical equipment located in a harsh environment, as specified in ESBWR DCD, Tier 1. Dominion's response to the staff RAI 03.11-7, dated September 11, 2008, stated that ESBWR DCD, Tier 1, Section 1.1.2.2 provides the description of ITAAC implementation. Part 10 of the North Anna 3 COL application incorporates the DCD ITAAC by reference. With respect to specific ITAAC implementation, the NRC regulations in 10 CFR 52.99, "Inspection during construction," require the licensee to submit a schedule for completing the inspections, tests, or analyses in the ITAAC, no later than 1 year after COL issuance or the start of construction as defined in 10 CFR 50.10(b) with subsequent updates to the ITAAC schedule. The RAI response stated that plans and schedules for implementing the ITAAC will be provided in accordance with 10 CFR 52.99. The staff finds that these provisions for addressing the EQ ITAAC are consistent with the regulations and are acceptable. Therefore, RAI 03.11-7 is resolved and closed.

ESBWR DCD, Tier 2, Section 3.11 describes the program for the initial EQ of electrical and mechanical equipment within the EQ Program for nuclear power plants applying the ESBWR reactor design. An NRC audit at the GEH office in Wilmington, NC, in July 2009, found that the ESBWR DCD does not address the transition from the initial EQ program to the operational aspects of the EQ Program. As discussed in RG 1.206 and Commission Paper SECY-05-0197, COL applicants must fully describe their operational programs to avoid the need for ITAAC regarding those programs. Therefore, the staff requested in RAI 03.11-8 that Dominion address the operational aspects of the EQ Program in the FSAR. Dominion's RAI response dated February 4, 2010 (ADAMS Accession No. ML100470588), provided a proposed revision to the FSAR to enhance the EQ Program description and to address the operational aspects of the program. The staff found that the planned revision to the COL FSAR which is included in Revision 8 provides an acceptable description of the transition from the initial EQ Program to the operational aspects of the EQ Program. The North Anna 3 FSAR, Revision 8 describes the EQMEL that identifies the electrical and mechanical equipment that must be environmentally qualified for use in a harsh environment. The FSAR describes the control of revisions to the EQ files and the EQMEL. The FSAR specifies that the operational aspect of the EQ Program will include: (1) evaluation of EQ results for design life to establish activities to support continued EQ; (2) determination of surveillance and preventive maintenance activities based on EQ results; (3) consideration of EQ maintenance recommendations from equipment vendors; (4) evaluation of operating experience in developing surveillance and preventive maintenance activities for specific equipment; (5) development of plant procedures that specify individual equipment identification, appropriate references, installation requirements, surveillance and maintenance requirements, post-maintenance testing requirements, condition monitoring requirements, replacement part identification, and applicable design changes and modifications; (6) development of plant procedures for reviewing equipment performance and EQ operational activities, and for trending the results to incorporate lessons learned through appropriate modifications to the EQ operational program; and (7) development of plant procedures for the control and maintenance of EQ records. Therefore, since the applicant meets the intent of the EQ and other Operational Programs as defined in SECY-05-0197, RAI 03.11-8 is resolved and closed. Based on the above evaluation, the staff finds that the applicant has adequately addressed COL Item STD COL 3.11-1-A, and it is therefore acceptable.

Interfaces for Standard Design

ESBWR DCD, Tier 2, Section 1.8, "Interfaces with Standard Design," identifies site-specific interfaces with the standard ESBWR design. DCD Table 1.8-1, "Matrix of NSSS Interfaces," references Section 3.11 for the supporting interface of the design of mechanical and electrical equipment in accordance with its potential operational environmental conditions. The staff reviewed the North Anna 3 COL application for interfacing requirements with the ESBWR standard design regarding the EQ of mechanical and electrical equipment using the review procedures described in SRP Section 3.11. The staff finds the applicant's consideration of design interface items to be acceptable based on compliance with 10 CFR 50.49 as discussed above.

3.11.5 Post Combined License Activities

The following items were identified as the responsibility of the COL licensee:

License Conditions

Dominion has proposed the following license conditions to address the North Anna 3 EQ programs as follows:

> 3.6 Operational Program Readiness
>
> The licensee shall submit to the Director of NRO, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented. This schedule shall also address:
>
> - The implementation of site-specific Severe Accident Management Guidelines
> - The spent fuel rack coupon monitoring program implementation

License Condition 3.6, "Operational Program Implementation," in Part 10 of the North Anna 3 COL application includes the EQ Program in FSAR table 13.4-201. This license condition will require the EQ Program to be implemented prior to initial fuel load. The schedule for implementation of the EQ program must be available to the staff no later than 12 months after issuance of the COL. The condition will also require that the schedule be updated every 6 months until 12 months before scheduled fuel load, and every month thereafter until the operational programs listed in the North Anna 3 COL FSAR Table 13.4-201 have been fully implemented or the plant has been placed in commercial service, whichever comes first.

3.11.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the EQ of the mechanical and electrical equipment that were incorporated by reference have been resolved.

In addition, the staff compared the supplemental information in the COL application to the relevant NRC regulations, the guidance in SRP Section 3.11, and other NRC RGs. The staff's review concluded that the applicant has provided sufficient information to satisfy the NRC requirements. Therefore, the staff concludes that the North Anna 3 COL FSAR, with the incorporation by reference of the ESBWR DCD, provides an acceptable description of the EQ of electrical and mechanical equipment to be used at North Anna 3, which provides reasonable assurance that the electrical and mechanical equipment within the scope of the North Anna 3 EQ Program will be capable of performing their safety functions in accordance with NRC regulations.

3.12 Piping Design Review

3.12.1 Introduction

This FSAR section covers the design of the metallic piping system and piping support for seismic Category I, Category II, and nonsafety systems. The discussion also includes the adequacy of the structural integrity, and the functional capability of the safety-related piping system, piping components, and their associated supports. The design of the piping systems should ensure that they perform their safety-related functions under all postulated combinations of normal operating conditions, system operating transients, postulated pipe breaks, and seismic events. This includes pressure retaining piping components and their supports, buried piping, instrumentation lines, and the interaction of non-seismic Category I piping and associated supports with seismic Category I piping and associated supports. This section also covers the design transients and resulting loads and load combinations with appropriate specified design and service limits for seismic Category I piping and piping supports - including those designated as ASME Code Class 1, 2, and 3.

3.12.2 Summary of Application

Section 3.12 of the North Anna 3 COL FSAR, Revision 8, references the related sections of Chapter 3 and Chapter 5 of the ESBWR DCD, Revision 10 for the information on seismic Category I and II and NS piping analyses. In addition in FSAR Section 3.12, the applicant provides the following:

Supplemental Information

- CWR SUP 3.12-1 Piping Design Review

In FSAR Section 3.12, the applicant states the following:

> Information on seismic Category I and II, and non-seismic piping analysis and their associated supports is presented in DCD Sections 3.7, 3.9, 3D, 3K, 5.2 and 5.4.

3.12.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966.

In addition, the relevant requirements of the Commission regulations for the piping and support design, and the associated acceptance criteria, are in SRP Section 3.12.

3.12.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Chapters 3 and 5 of the ESBWR DCD. The staff reviewed Section 3.12 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the ESBWR DCD and the information in the North Anna 3 COL FSAR appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the following information in the North Anna 3 COL FSAR:

Supplemental Information

- CWR SUP 3.12-1 Piping Design Review

The staff reviewed Supplemental Information STD SUP 3.12-1. The ESBWR DCD does not have Section 3.12. Therefore, this supplemental information is being considered as an editorial change to provide a map for the piping design information. The staff finds this change acceptable.

The staff also reviewed COL application FSAR Section 3.7 to verify that the site-specific structural response spectra has been used to evaluate North Anna 3 seismic Category I and II and NS piping. This evaluation is documented in Section 3.7.2 of this SER. On the basis that site-specific response spectra was used for the piping design evaluation as evaluated under North Anna 3 departure NAPS DEP 3.7-1, in this SER, Sections 3.7 and 3.9, the staff finds that the ESBWR standard plant design as modified by NAPS DEP 3.7-1 is acceptable at the North Anna 3 site.

In addition to the piping design acceptance criteria (DAC) ITAAC in ESBWR DCD, Tier 1, the staff also reviewed COL Item NAPS COL 14.3A-1-1 which provides a schedule for completing the piping DAC ITAAC. On the basis that the applicant's proposed DAC are sufficient to provide reasonable assurance in meeting the requirements of 10 CFR 52.80(a), the staff finds this acceptable.

3.12.5 Post Combined License Activities

The following activities will be implemented following issuance of the COL:

Piping DAC

1. The ASME Code piping and support design reports are completed on a system-by-system basis for applicable systems in order to support closure of the DAC ITACC.

2. Reconciliation of the as-built piping to the design analysis requirements.

3.12.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the relevant information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. In addition, the staff compared the additional COL information in the application to the relevant NRC regulations and the guidance in SRP Section 3.12. The staff's review concludes that the applicant is in compliance with NRC regulations. The applicant has adequately addressed the COL information item involving the completion of the piping DAC ASME Design Reports. In conclusion, the applicant has provided sufficient information for satisfying 10 CFR Part 52 requirements by providing reasonable assurance that the piping system will be designed and built in accordance with the certified ESBWR design.

3.13 <u>Threaded Fasteners – ASME BPV Code Class 1, 2 and 3</u>

3.13.1 Introduction

This FSAR section covers the selection of the materials and design, and the inspecting and testing for threaded fasteners before initial service and during service and is limited to threaded fasteners in the ASME BPVC Class 1, 2 or 3 systems.

ESBWR DCD, Revision 10 does not contain Section 3.13 because the DCD application was submitted before the new SRP Section 3.13 was issued in March 2007. However, ESBWR DCD, Tier 2, Section 3.9.3.9, "Threaded Fasteners - ASME BPVC Class 1, 2 and 3," provides sufficient information for the staff to conclude that the selection of the materials and design, and inspecting and testing for threaded fasteners before initial service and during service are acceptable. Therefore, North Anna 3 FSAR, Revision 8, Section 3.13 provides supplemental information that references ESBWR DCD, Tier 2, Section 3.9.3.9.

3.13.2 Summary of Application

Section 3.13 of the North Anna 3 FSAR, Revision 8, references Section 3.9.3.9 of the ESBWR DCD, Revision 10. Section 3.9 of North Anna 3 FSAR incorporates by reference Section 3.9.3.9 of the ESBWR DCD. In addition, in FSAR Section 3.13 the applicant provides the following:

Supplemental Information

- STD SUP 3.13-1 Threaded Fasteners – ASME Code Class 1, 2, and 3

In FSAR Section 3.13, the applicant states the following:

> Criteria applied to the selection of materials, design, inspection and testing of threaded fasteners (i.e., threaded bolts, studs, etc.) are presented in DCD Section 3.9.3.9, with supporting information in DCD Sections 4.5.1, 5.2.3, and 6.1.1.

3.13.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966.

The relevant requirements of the Commission regulations for the piping and support design, and the associated acceptance criteria, are in SRP Section 3.13. Specific requirements include the following:

- 10 CFR Part 50, Appendix A, GDC 1 and 30, as they relate to the requirement that SSCs important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed.

- GDC 4, as it relates to the compatibility of components with environmental conditions.

- GDC 14, as it relates to the requirement that the RCPB be designed, fabricated, erected, and tested in a manner that provides assurance of an extremely low probability of abnormal leakage, rapidly propagating failure, or gross rupture.

- GDC 31, "Fracture Prevention of Reactor Coolant Pressure Boundary," as it relates to the requirement that the RCPB be designed with a sufficient margin to ensure that when stressed under operating, maintenance, testing, and postulated accident conditions the boundary behaves in a non-brittle manner and the probability of rapidly propagating fracture is minimized.

- 10 CFR Part 50, Appendix B, as it relates to controlling the cleaning of material and equipment to prevent damage or deterioration.

- 10 CFR Part 50, Appendix G, "Fracture Toughness Requirements," as it relates to materials testing and acceptance criteria for fracture toughness of reactor pressure boundary components.

- 10 CFR 50.55a incorporates by reference the design criteria of ASME BPVC, Section III, Class 1, 2, and 3 components. The selection of materials, design, testing, fabrication, installation and inspection of threaded fasteners and mechanical joints are acceptable if they meet the criteria of ASME BPVC, Section III Class 1, 2, and 3 components. However, 10 CFR 50.55a(b)(4) permits the use of code cases that have been adopted by the staff in RG 1.84, "Design, Fabrication, and Materials Code Case Acceptability, ASME Section III," in lieu of applicable criteria in ASME BPVC, Section III, Class 1, 2, and 3 component.

- 10 CFR 52.47(b)(1), which requires a DC application to contain the proposed ITAAC that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, a plant that incorporates the DC is built and will operate in accordance with the DC, the provisions of the Atomic Energy Act, and NRC's regulations.

- 10 CFR 52.80(a), which requires that a COL application to contain the proposed inspections, tests, and analyses, including those applicable to emergency planning, that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that, if the inspections, tests, and analyses are performed and the acceptance criteria met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act, and the NRC's regulations.

3.13.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 3.9.3.9 of the certified ESBWR DCD. The staff reviewed Section 3.13 of the North Anna 3 COL FSAR, Revision 8, which references ESBWR Section 3.9.3.9, and checked the referenced ESBWR DCD to ensure that the combination of the information in the ESBWR DCD and the information in the North Anna 3 COL FSAR, Revision 8, appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirms that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the following information in the North Anna 3 COL FSAR:

Supplemental Information

- STD SUP 3.13-1 Threaded Fasteners – ASME Code Class 1, 2, and 3

The staff reviewed STD SUP 3.13-1 related to the criteria for the selection of materials, design, inspection, and testing of threaded fasteners included under Section 3.13 of the North Anna 3 COL FSAR. STD SUP 3.13-1 which points to ESBWR DCD Tier 2, Sections 4.5.1, 5.2.3, and 6.1.1. Those sections provide additional and specific requirements concerning threaded fasteners used in reactor internals, the reactor coolant system, and other engineered safety features. The staff found that STD SUP 3.13-1 appropriately points out the DCD sections that identify the specific use of threaded fasteners in reactor internals, the reactor coolant system, and other engineered safety features. The staff reviewed the conformance of Section 3.13 of the North Anna 3 COL FSAR to the guidance of RG 1.206, Section C.III.1, Chapter 3, C.I.3.13, "Threaded Fasteners." The staff's review of Section 3.13 of the North Anna 3 COL FSAR found that the applicant has appropriately incorporated by reference Section 3.9.3.9 of ESBWR DCD, Revision 10. The staff considers the applicant's Supplemental Information Item STD SUP 3.13-1 to adequately address threaded fasteners and is therefore acceptable.

3.13.5 Post Combined License Activities

There are no post COL activities related to this section.

3.13.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the relevant information, and no outstanding information is expected to be addressed in the COL FSAR related to this section.

In addition, the staff compared the additional COL information in the application to the relevant NRC regulations, the guidance in SRP Section 3.13, and other NRC RGs. The staff's review concludes that the information in North Anna 3 COL FSAR, Section 3.13 is within the scope of the DC and adequately incorporates by reference Section 3.9.3.9 of the ESBWR DCD, which addresses SRP Section 3.13. The information is thus acceptable and meets the NRC regulations.

4.0 REACTOR

4.0 REACTOR

4.1 Introduction

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the staff evaluation of the North Anna 3 Combined License (COL) Final Safety Analysis Report (FSAR) Chapter 4 which describes the reactor mechanical components of the North Anna 3 Economic Simplified Boiling-Water-Reactor (ESBWR), which includes the reactor internals, control blades and control rod drive, core support structural materials, fuel system design (fuel rods and assemblies), nuclear design, and thermal-hydraulic design. Furthermore, it provides an evaluation of the capability of the reactor to perform its safety functions throughout its design lifetime under all normal operational modes, including transient, steady-state, and accident conditions. This chapter also includes information to support the accident analysis in Chapter 15 of this SER.

4.2 Summary of Application

Chapter 4 of the North Anna 3 COL application (COLA), FSAR, Revision 8, incorporates by reference Chapter 4 of Revision 10 of the Design Control Document (DCD) for the ESBWR, referenced in Appendix E to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." In addition, in FSAR Chapter 4, the applicant provides the following:

Tier 2 Departures Requiring Prior NRC Approval

- NAPS DEP 3.7-1 — Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

This departure increases the fuel assembly and control blade seismic loads beyond the certified design fuel assembly and control blade loads by including the site-specific seismic response as part of the safe shutdown earthquake (SSE) for North Anna 3.

COL items

- STD COL 4.3-1-A — Variances from Certified Design

The applicant shall address changes to the reference design of the fuel, control rod or core design.

- STD COL 4A-1-A — Variances from Certified Design

The applicant shall address changes to the reference design of the fuel, control rod or core design.

For all combined license (COL) items, the applicant states that there are no changes to the fuel, control rod, or core design from the referenced certified design.

4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is described in NUREG–1966, "Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-

Water Reactor." In addition, the relevant requirements of the Commission regulations for the reactor, and the associated acceptance criteria, are in Chapter 4 of NUREG–0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition)," Revision 3, March 2007.

In accordance with Section VIII, "Processes for Changes and Departures," of Appendix E to Part 52, the applicant identifies Tier 1 and Tier 2 departures. Tier 1 departures require prior NRC approval and are subject to the requirements specified in 10 CFR Part 52, Appendix E, Section VIII.A.4. Tier 2 departures affecting technical specifications require prior NRC approval and are subject to the requirements of 10 CFR Part 52, Appendix E, Section VIII.C.4. Tier 2 departures not requiring prior NRC approval are subject to the requirements of 10 CFR Part 52, Appendix E, Section VIII.B.5, which are similar to the requirements of 10 CFR 50.59, "Changes, tests, and experiments."

The staff review of North Anna 3 Departure NAPS DEP 3.7-1 and whether it is acceptable is based on compliance with 10 CFR Part 50, "Domestic Licensing of Production and Utilization Facilities," Appendix A, "General Design Criteria for Nuclear Power Plants," General Design Criteria (GDC) 2, "Design Bases for Protection Against Natural Phenomena," as it relates to the structural protection for fuel assemblies and control blades during accidents involving earthquakes. GDC 2 requires the design bases of structures, systems, and components, which include fuel assemblies and control blades, to reflect appropriate consideration of natural phenomena, which includes consideration of combined loading due to natural phenomena and limiting hydrodynamic loads.

4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Chapter 4 of the ESBWR DCD. The staff reviewed Chapter 4 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the required information relating to this chapter.

Chapter 4 of the North Anna 3 COL FSAR contains the following sections:

4.1 Summary Description
4.2 Fuel System Design
4.3 Nuclear Design
4.4 Thermal and Hydraulic Design
4.5 Reactor Materials
4.6 Functional Design of Reactivity Control System

Appendix 4A Typical Control Rod Patterns and Associated Power Distribution for ESBWR
Appendix 4B Fuel Licensing Acceptance Criteria
Appendix 4C Control Rod Licensing Acceptance Criteria
Appendix 4D Stability Evaluation

[1] See "*Finality of Referenced NRC Approvals*" in SER Section 1.2.2 for a discussion on the staff's review related to verification of the scope of information to be included in a COL application that references a design certification.

The staff reviewed the following information in the COL FSAR:

<u>Tier 2 Departures Requiring Prior NRC Approval</u>

- NAPS DEP 3.7-1 Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra

The staff reviewed NAPS DEP 3.7-1 as it relates to the site-specific seismic ground motion exceedances of the ESBWR Certified Seismic Design Response Spectra (CSDRS) and documented its safety finding in Chapter 3 of this report. In the COLA, Part 7: Departures Report, regarding NAPS DEP 3.7-1, the applicant stated a change to FSAR Chapter 4.2 was made as a result of site-specific seismic exceedances. The staff reviewed the changes to Chapter 4.2 to ensure the site-specific fuel assemblies and control blades were still in compliance with the Commission’s regulations. The staff notes that the ESBWR standard plant seismic analysis, which utilizes the CSDRS, forms the basis of the GE14E fuel assembly and ESBWR Marathon control blade mechanical designs. DCD Tier 2* Reference 4.2-4 (in ESBWR DCD Section 4.2.7) describes the structural capability of the GE14E assembly and assembly components to withstand seismic/dynamic loading. DCD Tier 2* Reference 4.2-8 describes the structural capability of the ESBWR Marathon control rod blade.

As a result of the site-specific seismic exceedances of the CSDRS, the staff was unable to determine from the information provided in the FSAR whether the fuel and control blades to be loaded in the North Anna 3 reactor would be able to withstand loads resulting from natural phenomena, as required by GDC 2. Therefore, on July 24, 2014, the staff asked the applicant in RAI 04.02-1, to provide site-specific supplemental information in Chapter 4.2 of the FSAR that demonstrates that the North Anna 3 fuel assembly and control blade mechanical loads remain bounded by the component design analyses and testing performed for the ESBWR Design Certification (Agencywide Documents Access and Management System (ADAMS) Accession No. ML14283A563). On May 19, 2016, the applicant provided a response to RAI 04.02-1 (ADAMS Accession No. ML16146A277). The staff’s review of the response and supplemental information is described below.

Fuel Assembly

As part of its response to RAI 04.02-1, the applicant provided to the staff a site-specific Technical Report WG3-002N9544, “North Anna Unit 3 Site-Specific GE14E Fuel Assembly Mechanical Design Report,” Revision 2 (ADAMS Accession No. ML16146A278), which documents the analysis performed to show that the North Anna 3 fuel assembly mechanical loads remain bounded by the fuel assembly capacity limits.

In general, the staff notes that the applicant’s methodology for evaluating the site-specific fuel assembly mechanical loads follows the methodology described in the ESBWR DCD, Chapter 4; that is, the applicant provided an evaluation of combined loads (*i.e.*, loss of coolant accident (LOCA), SSE, and safety relief valve (SRV) actuation load) on the fuel assembly to demonstrate that the site-specific loads remain bounded by the capacity limits of the GE14E fuel assembly, as described in DCD Tier 2* (ESBWR DCD, Revision 10, Reference 4.2-4, NEDC-33240P-A, “GE14E Fuel Assembly Mechanical Design Report,” Revision 1) and approved for application to the ESBWR design in 10 CFR Part 52, Appendix E. The applicant also stated in the response to RAI 04.02-1 that the inspections, tests, analyses, and acceptance criteria (ITAAC) associated with the fuel assembly (DCD Tier 1, ITAAC Item 15, Table 2.1.1-3, “ITAAC for the Reactor Pressure Vessel and Internals”) ensures that a full analysis, as described in WG3-002N9544 and NEDC-33240P-A, will be completed prior to fuel load using the as-built characteristics of the fuel assembly and reactor pressure vessel to confirm that the as-built North Anna 3 combined loads on the fuel assembly remain bounded by the fuel assembly capacity limits. Furthermore, the ITAAC Item 15 in Table 2.1.1-3 requires a fuel lift analysis in accordance with NEDC-21175-3-P-A, "BWR [Boiling Water Reactor] Fuel Assembly Evaluation of Combined Safe Shutdown (SSE) and Loss-of-Coolant Accident (LOCA) Loadings (Amendment No. 3)," to ensure fuel bundle lift-out from the fuel support piece does not exceed the acceptance limit given in WG3-002N9544. While the applicant has not performed the fuel lift analysis as part of its current evaluation presented in WG3-002N9544, the staff confirmed that the methodology described in WG3-002N9544 is in accordance with the ESBWR DCD and assures as-built fuel assembly compliance with GDC 2.

During the review of the site-specific fuel assembly analysis, the staff noted that the site-specific exceedances of the seismic response spectra parameters would result in a reduction in margin to the GE14E fuel capacity limits. Therefore, the staff considered several areas to examine more closely, which included the overall methodology for addressing the site-specific seismic exceedances at the fuel assembly level, the site-specific seismic calculation for determining the seismic accelerations of the fuel, the combination of loads for assessing fuel assembly structural adequacy, and the irradiation effects on the fuel assembly seismic response analyses. Between March 2016 and May 2016, the staff conducted a regulatory audit to confirm the information presented in the applicant's response to RAI 04.02-1 and the supplemental information provided in WG3-002N9544 in the areas listed above (ADAMS Accession No. ML16077A343). The regulatory audit included a 3-day onsite meeting (March 23 – March 25, 2016) with the applicant to review supporting calculations. The audit also included the staff's use of the applicant's Electronic Reading Room to review additional calculations and supporting information related to Chapter 4 of the FSAR. The staff issued an audit report to document the results of the audit (ADAMS Accession No. ML16188A142). A summary of the staff's audit activities related to the site-specific fuel analyses is set forth below.

During the on-site audit and during subsequent public meetings,[2] the applicant clarified the specific steps of the methodology followed to address the fuel assembly response due to the site-specific seismic exceedances. Subsequently, the applicant submitted to the NRC, by letter dated May 19, 2016, a revised RAI 04.02-1 response and associated technical reports (ADAMS Accession No. ML16146A277). The revised response included FSAR Chapter 4 markups. The staff confirmed how the applicant obtained the site-specific accelerations at the fuel and confirmed that the methodology used in WG3-002N9544 for determining combined loads follows the methodology described in the ESBWR DCD. Additionally, the staff confirmed that the method for determining the site-specific accelerations, which is described in the FSAR Section 4.2 markups (ADAMS Accession No. ML16146A277), is identical to that used to complete ITAAC Item 15 of Table 2.1.1-3 in the ESBWR DCD. The staff further confirmed that all changes to the FSAR as provided in the revised response to RAI 04.02-1 (ADAMS Accession No. ML16146A277) were incorporated in Revision 9 of Part 2 (FSAR) of the North Anna 3 COLA. Furthermore, the applicant updated Revision 9 of Part 2 of the North Anna 3 COLA to correct Section 4.2.7 regarding the Tier 2* marking of Reference 4.2-201. Therefore

[2] Summaries of these meetings are posted in ADAMS at Accession Nos. ML16050A485, ML16071A370, ML16078A401, ML16103A343, ML16078A429, ML16097A606, ML16095A194, ML16110A022, ML16110A023, ML16111B309, ML16137A064, ML16147A433, and ML16148A091. Portions of the public meetings were closed to discuss proprietary information.

the Confirmatory Item 4.2-1 from the staff advanced SER for North Anna 3 is resolved and closed.

Also during the audit, the staff examined the calculations the applicant had completed to develop the site-specific seismic loading at the fuel assembly. The staff noted that the applicant analyzed the time-history motion of the fuel assemblies for determining the maximum resultant horizontal fuel acceleration. The staff confirmed that the calculations represent the most limiting seismic motions (as reviewed in Chapter 3 of this SER) and that the applicant's method for determining the maximum seismic acceleration in the horizontal and vertical directions, which is described in the FSAR Section 4.2 markups (ADAMS Accession No. ML16146A277), is consistent with NRC Regulatory Guide 1.92, "Combining Modal Responses and Spatial Components in Seismic Response Analysis," Revision 2. The staff also confirmed that the applicant's methodology for calculating the seismic accelerations of the fuel assemblies is identical to the methodology described in the DCD. The staff further confirmed that all changes to the FSAR as provided in the revised response to RAI 04.02-1 (ADAMS Accession No. ML16146A277) were incorporated in Revision 9 of Part 2 (FSAR) of the North Anna 3 COLA. Furthermore, the applicant updated Revision 9 of Part 2 of the North Anna 3 COLA to correct Section 4.2.7 regarding the Tier 2* marking of Reference 4.2-201. Therefore the Confirmatory Item 4.2-1 from the staff advanced SER for North Anna 3 is resolved and closed.

Due to the decrease in margin to the GE14E fuel assembly capacity limits, the staff also audited the applicant's calculation for combining loads (i.e., seismic + accident loads) to confirm that accident loads (i.e., LOCA and SRV) in addition to the increased site-specific seismic loads do not cause the fuel assembly capacity limits to be exceeded. The applicant provided a calculation, as mentioned in the response to RAI 04.02-1 that considered bounding LOCA and SRV loadings in combination with the site-specific seismic loads. The staff confirmed that the calculation of combining loads is conservative for the North Anna 3 reactor and that the site-specific loads at the fuel assembly, as presented in the response to RAI 04.02-1 (ADAMS Accession No. ML16146A277), are less than the fuel assembly's capacity limits. The staff further confirmed that all changes to the FSAR as provided in the revised response to RAI 04.02-1 (ADAMS Accession No. ML16146A277) were incorporated in Revision 9 of Part 2 (FSAR) of the North Anna 3 COLA. Furthermore, the applicant updated Revision 9 of Part 2 of the North Anna 3 COLA to correct Section 4.2.7 regarding the Tier 2* marking of Reference 4.2-201. Therefore the Confirmatory Item 4.2-1 from the staff advanced SER for North Anna 3 is resolved and closed.

During the staff's review of the application, the staff determined that the applicant's primary structure model (FSAR Chapter 3) is the same as the DCD model, and both the applicant's and DCD's models use mass and stiffness as inputs for the fuel. The staff further noted that, identical to the DCD model, the applicant's primary structure model does not account for fuel assembly spacer grids and other fuel assembly components. The staff determined that due to the increased site-specific seismic loadings and decreased margin to the site-specific fuel assembly acceptance limits, the effect of spacer grid spring relaxation due to irradiation, as discussed in NRC Information Notice (IN) 2012-09, "Irradiation Effects on Fuel Assembly Spacer Grid Crush Strength," could cause an additional increase in site-specific seismic loads; however, the staff also noted that boiling water reactor fuel is channeled and that, in general, the fuel channel dominates the fuel bundle's structural response to loads. During the audit, the staff examined a condition report that documented the applicant's assessment of IN 2012-09. The staff confirmed that the applicant's site-specific primary structure model is adequate for determining fuel assembly seismic loads in light of IN 2012-09 because the stiffness of the fuel assembly channel box dominates the fuel assembly mechanical response.

To summarize the staff's review regarding the site-specific fuel assembly, the staff gathered information in the regulatory audit that confirmed the information provided in the docketed RAI response, which is incorporated into Revision 9 of Part 2 of the North Anna 3 COLA. Based on the applicant's response to RAI 04.02-1 and Technical Report WG3-002N9544, Revision 2, as confirmed by the staff's regulatory audit, the staff finds that the GE14E fuel to be loaded into the North Anna 3 reactor meets GDC 2.

Control Blade

As part of its response to RAI 04.02-1 (ADAMS Accession No. ML16146A277), the applicant provided to the staff a site-specific Technical Report 002N8005, "North Anna 3 Control Rod Seismic Analysis," Revision 2 (ADAMS Accession No. ML16146A279), which documents the analysis performed to show that the North Anna 3 control blade mechanical loads and scram insertion times are bounded by the control blade capacity limits and scram insertion time limits in the ESBWR DCD, Chapter 4.2.4.

In general, the staff noted that the applicant's methodology for evaluating the site-specific control blade mechanical loads follows the methodology described in the ESBWR DCD, Chapter 4; that is, the applicant provided an analysis of combined loads (i.e., LOCA, SSE, and SRV actuation load) on the control blades to demonstrate that the site-specific loads remain bounded by the capacity limits of the ESBWR Marathon control blade, as described in DCD Tier 2* Reference 4.2-8 (NEDE-33244P-A, "ESBWR Marathon Control Rod Mechanical Design Report," Revision 2.). The staff noted increases in the site-specific control blade loads from the analysis presented in the DCD; however, margin to the control blade capacity limits still exists. The applicant also evaluated the site-specific seismic motion on the effect of control blade insertion times. The staff noted ample margin in the site-specific calculation of fuel assembly displacement to the acceptance limits defined in the ESBWR DCD, Chapter 4 and NEDE-33244P-A for the Marathon control blade.

As part of the North Anna 3 COLA, the applicant added a site-specific ITAAC for the control blades (COLA Part 10, ITAAC Item 1, Table 2.4.19-1). In accordance with the methodology described in the DCD, the applicant stated in the response to RAI 04.02-1 (ADAMS Accession No. ML16146A277), that the site-specific ITAAC associated with the control blades ensures that a full analysis, as described in Technical Report 002N8005 and NEDE-33244P-A, will be completed prior to fuel load using the as-built characteristics of the control blades and other reactor components to confirm that the North Anna 3 combined loads on the control blade remain bounded by the control blade capacity limits and the scram insertion time limits for the Marathon control blade. The staff determined this site-specific ITAAC to be acceptable and confirmed that the methodology described assures as-built control blade compliance with GDC 2.

During the same regulatory audit, the staff reviewed the calculation that determined the site-specific fuel channel oscillation and confirmed that the results presented in Technical Report 002N8005 accurately represent the site-specific seismic analysis. The staff issued an audit report to document the audit results (ADAMS Accession No. ML16188A142).

Based on the applicant's response to RAI 04.02-1 and Technical Report 002N8005, Revision 2, as confirmed by the staff's regulatory audit, the staff finds that the Marathon control blades to be used in the North Anna 3 reactor meet GDC 2.

In conclusion, despite the seismic exceedances from the ESBWR DCD in ground motion at the North Anna 3 site, the applicant has adequately demonstrated that these exceedances do not cause the GE14E fuel assemblies nor the Marathon control blades to be used in the North Anna 3 reactor to experience accident and seismic loads in excess of the design's acceptance limits. Accordingly, the staff finds that the GE14E fuel assemblies and Marathon control blades to be used in the North Anna 3 reactor are in compliance with the Commission's regulations.

COL Information Items

- STD COL 4.3-1-A Variances from Certified Design
- STD COL 4A-1-A Variances from Certified Design

For COL Items STD COL 4.3-1-A and STD COL 4A-1-A, the applicant states that there are no changes to the fuel, control rod or core design from the referenced certified design. The staff reviewed the information in the COL FSAR and concludes that the application does not depart from the standard design in regards to fuel, control rod, or core design, and no further evaluation of these matters is necessary.

4.5 Post Combined License Activities

The applicant added a site-specific ITAAC in Part 10 of the COLA Table 2.4.19-1, Item 1, to ensure that a full analysis, as described in Technical Report 002N8005 and NEDE-33244P-A, will be completed prior to fuel load using the as-built characteristics of the control blades and other reactor components to confirm that the site-specific combined loads on the control blade remain bounded by the control blade capacity limits and the scram insertion time limits for the Marathon control blade.

4.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information remains to be addressed in the COL FSAR related to this chapter. The results of the staff's technical evaluation of the DCD information are incorporated by reference in NUREG–1966. The staff's review confirmed that the applicant has adequately addressed COL Items STD COL 4.3-1-A and STD COL 4A-1-A.

The staff's review also confirmed that the applicant has adequately addressed NAPS DEP 3.7-1 relating to the North Anna 3 fuel assemblies and control blades. The staff reviewed the applicant's analysis of the fuel assemblies and control blades relating to NAPS DEP 3.7-1 and, for the reasons set forth above, finds that analysis acceptable. The staff further confirmed that all changes to the FSAR as provided in the revised response to RAI 04.02-1 (ADAMS Accession No. ML16146A277) were incorporated in Revision 9 of Part 2 (FSAR) of the North Anna 3 COLA. Furthermore, the applicant updated Revision 9 of Part 2 of the North Anna 3 COLA to correct Section 4.2.7 regarding the Tier 2* marking of Reference 4.2-201. Therefore the Confirmatory Item 4.2-1 from the staff advanced SER for North Anna 3 is resolved and closed.

5.0 REACTOR COOLANT SYSTEM AND CONNECTED SYSTEMS

5.0 REACTOR COOLANT SYSTEM AND CONNECTED SYSTEMS

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the NRC staff evaluation of the North Anna 3 Combined License (COL) reactor coolant system (RCS) and connected systems of the Economic Simplified Boiling-Water Reactor (ESBWR) design including those systems and components that contain or transport fluids coming from or going to the reactor core. These systems form a major portion of the reactor coolant pressure boundary (RCPB). This chapter also provides information on the North Anna 3 RCS and pressure-containing appendages out to and including isolation valves. This grouping of components is characterized as the RCPB and is defined in Title 10 *Code of Federal Regulations* (10 CFR) 50.2, "Definitions."

5.1 <u>Summary Description</u>

Section 5.1, "Summary Description," of the North Anna 3 COL Final Safety Analysis Report (FSAR), Revision 8, incorporates by reference with no departures or supplements Section 5.1, "Summary Description," of Revision 10 of the Design Control Document (DCD) for the ESBWR, referenced in Appendix E to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the summary description have been resolved.

5.2 <u>Integrity of Reactor Coolant Pressure Boundary</u>

Section 5.2, "Integrity of Reactor Coolant Pressure Boundary," of the North Anna 3 FSAR discusses measures employed to provide and maintain the integrity of the RCPB.

5.2.1 Compliance with Codes and Code Cases

5.2.1.1 Compliance with 10 CFR 50.55a

5.2.1.1.1 Introduction

Section 5.2.1.1 of the North Anna 3 COL FSAR, Revision 8, addresses the American Society of Mechanical Engineers (ASME) code edition and addenda to be used at North Anna 3 in order to demonstrate compliance with the NRC regulations in 10 CFR 50.55a, "Codes and standards."

5.2.1.1.2 Summary of Application

Section 5.2.1.1 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.2.1.1 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 5.2.1.1, the applicant provides the following:

<u>Supplemental Information</u>

- STD SUP 5.2-2

In FSAR Section 5.2.1.1, the applicant provided supplemental information that preservice inspection (PSI) and In-Service Inspection (ISI) of the RCPB are conducted in accordance with the applicable edition and addenda of the ASME Boiler and Pressure Vessel Code (BPV Code)

Section XI, which is required by 10 CFR 50.55a. FSAR Section 5.2.1.1 also states the following:

> As described in DCD Section 3.9.6 for pumps and valves, and in DCD Section 3.9.3.7.1 for dynamic restraints, preservice and in-service testing of RCPB components is in accordance with the edition and addenda of the ASME OM Code required by 10 CFR 50.55a.

5.2.1.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, “Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-Water Reactor.” In addition, the relevant requirements of the Commission regulations for compliance with 10 CFR 50.55a, and the associated acceptance criteria, are in Section 5.2.1.1 of NUREG–0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants (LWR Edition),” (SRP).

In particular, NRC regulations in 10 CFR Part 50, “Domestic Licensing of Production and Utilization Facilities,” and Part 52 provide the regulatory basis for the staff’s review of the information in the North Anna 3 COL application (COLA). For example, NRC regulations in 10 CFR Part 50, Appendix A, “General Design Criteria for Nuclear Power Plants,” General Design Criterion (GDC) 1, “Quality standards and records,” require that nuclear power plant structures, systems, and components (SSCs) important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed. Furthermore, NRC regulations in 10 CFR 50.55a, as they relate to the establishment of the minimum quality standards for the design, fabrication, erection, construction, testing, and inspection of nuclear power plant components, require conformance with appropriate editions of published industry codes and standards.

Also, the staff followed the guidance in Regulatory Guide (RG) 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” June 2007, in evaluating North Anna 3 COL FSAR Section 5.2.1.1 for compliance with NRC regulations.

5.2.1.1.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.2 of the certified ESBWR DCD. The staff reviewed Section 5.2.1.1 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff’s review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

---

[1] See “*Finality of Referenced NRC Approvals*” in SER Section 1.2.2, for a discussion on the staff’s review related to verification of the scope of information to be included in a COL application that references a design certification.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

Supplemental Information

- STD SUP 5.2-2

The FSAR incorporates by reference Section 5.2.1.1 of the ESBWR DCD Tier 2, which refers to Table 3.2-1, “Classification Summary,” and Table 3.2-3, “Quality Group Designations – Codes and Industry Standards,” of the ESBWR DCD for the ASME Code applied to components in the ESBWR design with respect to Section III of the ASME BPV Code.

In Request for Additional Information (RAI) 05.02.01.01-1(Agencywide Documents Access and Management System (ADAMS) Accession No. ML082110133), dated July 28, 2008, the staff requested that the applicant address the application of other sections of the ASME BPV Code and the ASME *Code for Operation and Maintenance of Nuclear Power Plants* (OM Code) in its implementation of the ESBWR reactor design. In its response to this RAI dated September 11, 2008 (ADAMS Accession No. ML082610417), the applicant stated that the FSAR would be revised to provide references to the appropriate sections that discuss compliance with ASME BPV Code Section XI and the ASME OM Code, “Operation and Maintenance of Nuclear Power Plants.” As a result, FSAR Section 5.2.1.1 states that the PSI and ISI of the RCPB will be conducted in accordance with the applicable edition and addenda of the ASME BPV Code Section XI, required by 10 CFR 50.55a as described in FSAR Section 5.2.4. FSAR Section 5.2.1.1 also states that preservice testing (PST) and in-service testing (IST) of the RCPB components will be in accordance with the edition and addenda of the ASME OM Code required by 10 CFR 50.55a as described in DCD Section 3.9.6, for pumps and valves and DCD Section 3.9.3.7.1, for dynamic restraints. The staff verified these revisions and finds that the reference to the applicable sections of the ESBWR DCD for the application of appropriate ASME Code editions and addenda is consistent with NRC regulations and is therefore acceptable. Therefore, RAI 05.02.01.01-1 is resolved and closed.

5.2.1.1.5 Post Combined License Activities

There are no post COL activities related to this section.

5.2.1.1.6 Conclusion

The staff’s finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff’s review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to compliance with 10 CFR 50.55a that were incorporated by reference have been resolved.

In addition, the staff compared the additional COL supplemental information in the application to the relevant NRC regulations, the guidance in Section 5.2.1.1 the SRP, and other NRC RGs. The staff’s review concludes that the applicant has presented adequate information in the North Anna 3 COL FSAR to meet the requirements in 10 CFR 50.55a.

5.2.1.2 Applicable Code Cases

5.2.1.2.1 Introduction

Section 5.2.1.2, “Applicable Code Cases,” of the North Anna 3 COL FSAR, Revision 8, addresses the applicable Code Cases for the ASME BPV Code and the ASME OM Code. This section also addresses NRC RGs that indicate the acceptance of ASME Code Cases with or without conditions. In general, ASME develops a Code Case based on inquiries from the nuclear industry associated with code clarifications, modifications, or alternatives to the code. All Code Cases will remain valid and available for use until annulled by the ASME. ASME Code Cases acceptable to the staff are published in RG 1.84, Revision 35, “Design and Fabrication Code Case Acceptability, ASME Section III, Division 1”, RG 1.147,Revision 16, “In-Service Inspection Code Case Acceptability, ASME Section XI, Division 1”, and RG 1.192, “Operation and Maintenance Code Case Acceptability, ASME OM Code”, in accordance with requirements of 10 CFR 50.55a(b)(4), 10 CFR 50.55a(b)(5) and 10 CFR 50.55(b)(6), respectively.

5.2.1.2.2 Summary of Application

Section 5.2.1.2 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.2.1.2 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E, without supplemental information or departures.

5.2.1.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the applicable code cases, and the associated acceptance criteria, are in Section 5.2.1.2 of the SRP. The NRC regulations in 10 CFR Part 50 and 10 CFR Part 52 provide the regulatory basis for the staff’s review of the information in the North Anna 3 COLA. For example, 10 CFR Part 50, Appendix A, GDC 1 requires that nuclear power plant SSCs important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed. Furthermore, NRC regulations in 10 CFR 50.55a, that are related to the establishment of the minimum quality standards for the design, fabrication, erection, construction, testing, and inspection of nuclear power plant components, require conformance with appropriate editions of published industry codes and standards.

As one acceptable means of meeting the applicable NRC regulations, RG 1.84 lists the ASME BPV Code Section III Code Cases related to design, fabrication, materials, and testing that are acceptable with applicable conditions for implementation at nuclear power plants. RG 1.147 lists ASME BPV Code Section XI Code Cases that are acceptable, with the applicable conditions for use in the ISI of nuclear power plant components and their supports. RG 1.192 lists Code Cases related to the ASME OM Code for operation and maintenance of nuclear power plant components that are acceptable with applicable conditions for implementation at nuclear power plants.

The staff followed the guidance in SRP Section 5.2.1.2 and RG 1.206 to evaluate North Anna 3 FSAR Section 5.2.1.2 for compliance with NRC regulations.

5.2.1.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.2.1.2 of the certified ESBWR DCD. The staff reviewed Section 5.2.1.2 of the North Anna 3 COL FSAR and checked the referenced DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to applicable Code Cases.

The North Anna 3 FSAR incorporates by reference Section 5.2.1.2 of the ESBWR DCD Tier 2, without departures or supplemental information. In ESBWR DCD, Tier 2, Section 5.2.1.2 indicates that the various ASME Code Cases that may be applied to components in the ESBWR design are listed in ESBWR DCD, Tier 2, Table 5.2-1. ESBWR DCD, Tier 2, Section 5.2.1.2 also notes that RG 1.84 and RG 1.147 provide a list of ASME Code design and fabrication Code Cases that the NRC has generically approved.

In RAI 05.02.01.02-1, dated July 28, 2008 (ADAMS Accession No. ML082110133), the staff requested that the applicant discuss the use of any Code Cases related to the ASME BPV Code and the OM Code not listed in ESBWR DCD, Tier 2, Table 5.2-1. In the response to this RAI dated September 11, 2008 (ADAMS Accession No. ML082610417), the applicant stated that no ASME BPV Code Section III or Section XI Code Cases, other than those listed in Table 5.2-1 of the ESBWR DCD, had been identified as necessary. The applicant stated that other Code Cases approved by the NRC in RG 1.147 might be used during the development and implementation of the PSI and ISI Programs. ESBWR DCD, Tier 2, Section 3.9.3.7.1b, "Inspection, Testing, Repair, and/or Replacement of Snubbers," references RG 1.192 for the use of Code Cases (such as Code Case OMN-13) applicable to IST of dynamic restraints. ESBWR DCD, Tier 2, Section 3.9.6.6, "10 CFR 50.55a Relief Requests and Code Cases," indicates that the IST Program for the ESBWR does not use any ASME Code Cases. In addition, the applicant stated that other Code Cases approved by the NRC in RG 1.192 might be used during the development and implementation of the PST and IST Programs for North Anna 3. In the RAI response, the applicant indicated that the FSAR would be revised to reference RG 1.192 in Section 5.2.1.2. Subsequently, the ESBWR DCD was revised to include RG 1.192 in the list of RGs to be used in meeting the requirements of GDC 1 and 10 CFR 50.55a. The staff finds that the description of the planned use of ASME Code Cases in ESBWR DCD, Tier 2, Section 5.2.1.2, is consistent with the applicable NRC regulations and RGs. Therefore, RAI 05.02.01.02-1 is closed without the need to revise Section 5.2.1.2 of the North Anna 3 FSAR.

In RAI 05.02.01.02-2, dated July 28, 2008 (ADAMS Accession No. ML082110133), the staff requested that the applicant discuss its compliance with the requirements regarding the use of annulled Code Cases specified in 10 CFR 50.55a(b)(4), (5), and (6). In the response to this RAI dated September 11, 2008 (ADAMS Accession No. ML082610417), the applicant stated that the design, fabrication, and construction of safety-related components will be conducted in accordance with ASME Code requirements specified in ESBWR DCD, Tier 2, Table 3.2-1, "Classification Summary," and Table 3.2-3, "Quality Group Designations – Codes and Industry Standards." The applicant also noted that Section 5.2.1.1 of the ESBWR DCD specifies that the ESBWR meets the relevant requirements of 10 CFR 50.55a. The applicant added that these requirements include the application of any limitations and modifications to the applicable Code edition and addenda as may be specified in 10 CFR 50.55a, including any limitations regarding the use of annulled Code Cases. With respect to PSI/ISI and PST/IST of safety-related components, the applicant stated that the applicable edition and addenda of the ASME Code as identified in 10 CFR 50.55a is used, subject to the limitations and modifications specified in 10 CFR 50.55a—including those limitations specified in 10 CFR 50.55a(b)(4), (5), and (6) regarding the use of Code Cases. The staff finds that the plans described by the applicant for using ASME Code Cases at North Anna 3 meet the applicable NRC regulations. Therefore, RAI 05.02.01.02-2 is resolved and closed.

5.2.1.2.5 Post Combined License Activities

There are no post COL activities related to this section.

5.2.1.2.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

5.2.2 Overpressure Protection

This FSAR section addresses the safety and relief valves and the portion of the reactor protection system that ensures overpressure protection for the RCPB during operation at power.

Section 5.2.2, "Overpressure Protection," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.2.2, "Overpressure Protection," of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E, with no departures or supplements. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review.[1] The staff's review confirmed that no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the overpressure protection have been resolved.

5.2.3 Reactor Coolant Pressure Boundary Materials

This FSAR section addresses information related to the materials selection, fabrication, and processing of RCPB piping and components, as well as the compatibility of RCPB materials with the reactor coolant.

Section 5.2.3, "Reactor Coolant Pressure Boundary Materials," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.2.3, "Reactor Coolant Pressure Boundary Materials," of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E, with no departures or supplements. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review. The staff's review confirmed that no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the RCPB materials have been resolved.

5.2.4 Preservice and In-Service Inspection and Testing of Reactor Coolant Pressure Boundary

5.2.4.1 Introduction

Section 5.2.4 of the North Anna 3 COL FSAR discusses components that are part of the RCPB, which must be designed to permit periodic inspection and testing of important areas and features to assess their structural and leak-tight integrity. ISI Programs are based on the requirements of 10 CFR 50.55a in that Code Class 1 components, as defined in Section III of the ASME BPV Code, meet the applicable inspection requirements set forth in Section XI of the ASME Code, "Rules for In-Service Inspection of Nuclear Power Plant Components."

5.2.4.2 Summary of Application

Section 5.2.4 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.2.4 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix, Section VI.B.1. In addition, the applicant provided the following information in FSAR Section 5.2.4:

COL Items

- STD COL 5.2-1-A — Preservice and In-Service Inspection Program Description

The applicant provided additional information in FSAR Section 5.2.4 and Sections 5.2.4.3.4, 5.2.4.6, and 5.2.4.11 in order to fully describe the PSI and ISI Programs; including the applicable ASME Code Edition and Addenda, the certification of nondestructive examination (NDE) personnel as amended by 10 CFR 50.55a, system leakage tests as amended by 10 CFR 50.55a, and the PSI and ISI Program implementation milestones.

- STD COL 5.2-3-A — Preservice and In-Service Inspection NDE Accessibility Plan Description

The applicant provided additional information in FSAR Section 5.2.4 and Section 5.2.4.2 to address Class 1 austenitic or dissimilar metal welds and preservation of accessibility during construction to enable the performance of ISI examinations during the operational phase.

Supplemental Information

- STD SUP 5.2-1

The applicant provided supplemental information in FSAR Section 5.2.4.6 to describe the relevant Technical Specification (TS) sections that address system pressure tests and RCS pressure-temperature (P-T) limits.

License Condition

- Part 10, License Condition 3.6 — Operational Program Readiness

In Section 3.6 of Part 10, "Tier 1/ITAAC/Proposed License Conditions," of the COLA, the applicant proposed an operational program readiness license condition.

5.2.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the RCPB in-service inspections and testing, and the associated acceptance criteria, are in Section 5.2.4 of the SRP.

The regulatory basis for accepting the COL items (STD COL 5.2-1-A, STD COL 5.2-3-A) is in GDC 32, "Inspection of reactor coolant pressure boundary," as it relates to the periodic inspection and testing of the RCPB; and 10 CFR 50.55a, as it relates to the requirements for testing and inspecting the Code Class 1 components as specified in Section XI of the ASME BPV Code. In addition, SECY-05-0197, "Review of Operational Programs in a Combined License Application and Generic Emergency Planning Inspections, Tests, Analyses, and Acceptance Criteria," provides the Commission policy for fully describing an operational program. Moreover, the regulatory basis for accepting STD SUP 5.2-1 is 10 CFR 50.55a.

5.2.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.2.4 of the certified ESBWR DCD. The staff reviewed Section 5.2.4 of the North Anna COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

COL Items

- STD COL 5.2-1-A — Preservice and In-Service Inspection Program Description

ESBWR DCD COL Item 5.2-1-A states that the COL applicant is responsible "for providing a full description of the preservice and in-service inspection programs and augmented inspection programs by supplementing, as necessary, the information in Section 5.2.4 and to provide the milestones for their implementation." To address this COL item, the applicant provided additional information in FSAR Section 5.2.4 and Sections 5.2.4.3.4, 5.2.4.6, and 5.2.4.11 in order to provide a full description of the North Anna 3 PSI and ISI Programs.

In FSAR Section 5.2.4, the applicant stated that "the initial in-service inspection program incorporates the latest edition and addenda of the ASME BPV Code approved in 10 CFR 50.55a(b) on the date 12 months before initial fuel load." 10 CFR 50.55a(g)(4)(i) states that in-service examinations and pressure tests conducted during the initial 120-month inspection interval must comply with the requirements in the latest edition and addenda of the Code (or Code Cases) incorporated by reference in paragraph (b) of this section (10 CFR 50.55a) on the date 12 months before the date scheduled for initial loading of fuel under a COL under 10 CFR Part 52 of this chapter subject to the limitations and modifications listed in paragraph (b) of this section. The staff finds that the information provided by the applicant in FSAR Section 5.2.4 is acceptable because it is in compliance with the requirements of 10 CFR 50.55a(g)(4) and 10 CFR 50.55a(b).

In FSAR Section 5.2.4.3.4, the applicant stated that "certification of NDE personnel shall be in accordance with ASME Section XI, IWA-2300, as modified by 10 CFR 50.55a(b)(2)(xviii)." 10 CFR 50.55a(b)(2)(xviii) imposes a modification on the use of the latest edition and addenda of the Code incorporated by reference into 10 CFR 50.55a by requiring that Level I and Level II NDE personnel be recertified on a 3-year interval in lieu of the 5-year interval specified in Section XI, IWA-2314. Given that the initial ISI program will be in accordance with the latest edition and addenda of the ASME Code incorporated by reference in 10 CFR 50.55a, the information provided in the FSAR Section 5.2.4.3.4 is acceptable because it is in compliance with 10 CFR 50.55a(b).

In FSAR Section 5.2.4.6 the applicant stated that "system leakage and hydrostatic pressure tests will meet all the requirements of ASME Code Section XI, IWA-5000 and IWB-5000 for Class 1 components, including the limitation of 10 CFR 50.55a(b)(2)(xxvi)." 10 CFR 50.55a(b)(2)(xxvi) imposes a limitation on the use of the 2001 Edition through the latest edition and addenda of the ASME Code incorporated by reference in 10 CFR 50.55a by requiring that the provisions of IWA-4540(c) from the 1998 Edition of Section XI for pressure testing Class 1, 2, and 3 mechanical joints be applied. Given that the initial ISI program will be in accordance with the latest edition and addenda of the ASME Code incorporated by reference in 10 CFR 50.55a, the information provided in the FSAR Section 5.2.4.6 is acceptable because it is in compliance with 10 CFR 50.55a(b).

In FSAR Section 5.2.4.11, the applicant stated that DCD Section 5.2.4 "fully describes the Preservice and In-Service Inspection and Testing Programs for the RCPB and that the implementation milestones for the Preservice and In-Service Inspection and Testing Programs are provided in FSAR Section 13.4." Since the PSI Program uses essentially the same elements of the ISI Program and the PSI Program requirements are stated under ASME Section XI, the staff concurs with the statement that the PSI/ISI Programs are fully described. The staff reviewed Table 13.4-201 and found that the implementation milestones for the PSI/ISI operational programs are listed.

In North Anna 3 COL FSAR, Part 10, Section 3.6, the applicant has also provided a proposed license condition related to the PSI/ISI operational program which includes the programs listed in Table 13.4-201.

The staff finds implementation milestones are acceptable because they are in accordance with the requirements of ASME Section XI and 10 CFR 50.55a. The staff also finds that the proposed license condition is acceptable because it is in accordance with SECY-05-0197. As discussed in SECY-05-0197, a COL applicant should provide schedules for the implementation of operational programs in order to support the planning for and conducting of NRC inspections. Therefore, the staff will include such license condition in the North Anna 3 COL.

Based on the evaluation described above, STD COL 5.2-1-A is acceptable.

- STD COL 5.2-3-A Preservice and In-Service Inspection NDE Accessibility Plan Description

ESBWR DCD COL Item 5.2-3-A states that the COL applicant is responsible "for developing a plan and providing a full description of its use during construction, PSI, ISI, and during design activities for components that are not included in the referenced certified design, to preserve accessibility to piping systems to enable NDE of ASME Code Class 1 austenitic and dissimilar metal welds during in-service inspection." To address this COL item, the applicant provided additional information in FSAR Sections 5.2.4 and Section 5.2.4.2.

In FSAR Section 5.2.4, the applicant stated that all Class 1 austenitic or dissimilar metal welds are included in the referenced certified design. The applicant described in FSAR Section 5.2.4.2 how anomalies and construction issues are addressed using change control procedures during the construction phase of the project. Procedures require that changes to approved design documents, including field changes and modifications, are subject to the same review and approval process as the original design. Control of accessibility for inspection and testing during licensee design activities affecting Class 1 components is provided via procedures for design control and plant modifications. The applicant explained that ultrasonic techniques (UT) will be the preferred NDE method for all PSI and ISI volumetric examinations; radiographic techniques (RT) will be used as a last resort only if UT cannot achieve the necessary coverage. The same NDE method used during PSI will be used for ISI to the extent possible to assure a baseline point of reference. If a different NDE method is used for ISI than was used for PSI, equivalent coverage will be achieved as required by the Code.

During normal plant operation, ultrasonic examination is the desired NDE method for austenitic and dissimilar metal welds due to ease in obtaining examination coverage of piping that is filled with water and as low as reasonably achievable considerations. The use of RT is an acceptable replacement for UT and is allowed under ASME Section XI, Table IWB-2500, since the examination technique specified for these welds is volumetric. The information provided by the applicant meets the requirements under 10 CFR 50.55a(g)(3), which requires that plants be designed to enable the performance of in-service examinations. The use of RT as a supplemental examination technique with 100 percent coverage meets the requirements of ASME Section XI, Table IWB-2500. The information provided by the applicant provides reasonable assurance that during construction, controls will exist to maintain the accessibility to enable the performance of in-service examinations for austenitic and dissimilar metal welds. The information provided by the applicant meets the requirements of 10 CFR 50.55a(g)(3) and ASME Section XI. Based on the evaluation described above, STD COL 5.2-3-A is acceptable.

Supplemental Information

- STD SUP 5.2-1

Under Section 5.2.4.6, the applicant stated that system pressure tests and correlated TS requirements are provided in the plant TS 3.4.4, "RCS Pressure and Temperature P/T Limits," and TS 3.10.1, "In-Service Leak and Hydrostatic Testing Operation." The proposed change provides additional information with respect to system pressure testing that is located within the TS.

Since the location of additional information regarding pressure testing is at the discretion of the licensee, and, the proposed change under STD COL 5.2-1-A (discussed above) meets the ASME Code and the limitations under 10 CFR 50.55a(b)(2)(xxvi), the staff concludes that the supplemental information as it pertains to pressure testing is acceptable.

5.2.4.5 Post Combined License Activities

In FSAR Table 13.4-201, the applicant provided the implementation milestones for the PSI and ISI Programs.

The applicant proposed a license condition in Part 10 of the COLA Revision 8 as follows:

3.6 Operational Program Readiness

The licensee shall submit to the Director of NRO, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented.

5.2.4.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

In addition, the staff concludes that the information in North Anna 3 COL FSAR Section 5.2.4 meets the relevant guidelines in SRP Section 5.2.4 and RG 1.206, and is therefore acceptable. The staff further concludes that the North Anna 3 COL FSAR PSI/ISI Programs and implementation milestones are consistent with the policy established in SECY-05-0197. Conformance with these guidelines and the policy provides an acceptable basis for satisfying in part, the requirements of GDC 32 and 10 CFR 50.55a.

5.2.5 Reactor Coolant Pressure Boundary Leakage Detection

5.2.5.1 Introduction

Section 5.2.5 of the North Anna 3 COL FSAR discusses the RCPB leakage detection systems that are designed to detect and, to the extent practical, identify the source of reactor coolant leakage.

5.2.5.2 Summary of Application

Section 5.2.5 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.2.5 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 5.2.5, the applicant provides the following:

<u>*COL Item*</u>

- STD COL 5.2-2-A Leak Detection Monitoring

In the ESBWR DCD, Revision 9, STD COL Item 5.2-2-H becomes STD COL 5.2-2-A.

In FSAR Section 5.2.5, the applicant provided additional information to address STD COL 5.2-2-A. The applicant replaced Section 5.2.5.9, "Leak Detection Monitoring," of the ESBWR DCD, Tier 2 with new information stating that operators are provided with procedures for detecting, monitoring, recording, trending, and determining the sources of the RCPB leakage. In addition, FSAR Section 13.5, "Plant Procedures," provides a description of the plant procedures program and implementation milestones.

5.2.5.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG-1966. In addition, the relevant requirements of the Commission regulations for RCPB leakage detection, and the associated acceptance criteria, are in Section 5.2.5 of the SRP.

The staff's acceptance of the leakage detection design is based on meeting the requirements of the following criteria:

- GDC 2, "Design basis for protection against natural phenomena," as it relates to the capability of the design to maintain and perform its safety function following an earthquake.

- GDC 30, "Quality of reactor coolant pressure boundary," as it relates to the detection, identification, and monitoring of the source of reactor coolant leakage.

Also, the staff followed the guidance in RG 1.206 for evaluating the compliance of North Anna 3 COL FSAR Section 5.2.5 with NRC regulations.

5.2.5.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.2.5 of the certified ESBWR DCD. The staff reviewed Section 5.2.5 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

COL Item

- STD COL 5.2-2-A Leak Detection Monitoring

In the ESBWR DCD, Revision 9, STD COL Item 5.2-2-H becomes STD COL 5.2-2-A.

The staff identified that the substitution of Tier 2, Section 5.2.5.9 of the ESBWR DCD with STD COL 5.2-2-H text appears to inappropriately limit the intended scope of the procedures contained in Tier 2, Section 5.2.5.9 of the ESBWR DCD. In addition, inclusion in FSAR, Revision 0 of the STD COL 5.2-2-H text of the examples "sump pump run time, sump level, and condensate transfer rate" without inclusion of "radioactivity," also appears to inappropriately limit the scope of the procedures. In RAI 05.02.05-1 (ADAMS Accession No. ML081750645) dated June 23, 2008, the staff requested the following:

a) Revise the FSAR to clarify the scope of procedures relative to TSs. In addition to establishing the leakage rates for the limits in the TS, the operators should be able to use the procedures to identify and monitor the unidentified leakage at a level much lower than the TS limit so that the operator can monitor leakage, evaluate trends, determine the source of leakage, and evaluate potential corrective actions. This level to provide operators an early alert to initiate actions prior to the TS limit should be established as an alarm. The alarm level being established in an approved revision of the ESBWR DCD Section 5.2.5 is acceptable for the COLA.

b) Confirm the procedure scope addresses the conversion of different parameter indications to include all three detection instrumentation in TS Limiting Condition for Operation 3.3.4.1, and clarify STD COL 5.2-2-H accordingly. The procedures should include indications from 1) the drywell floor drain high conductivity water sump monitoring system, 2) drywell air coolers condensate flow monitoring system, and 3) drywell fission product monitoring system.

In the letter dated August 8, 2008, the applicant revised FSAR Section 5.2.5.9 and STD COL 5.2-2-H to clarify that the procedures will fully address the topics described in Items (a) and (b) of the RAI and will be consistent with Section 5.2.5 of the ESBWR DCD, Revision 5. The revised FSAR Section 5.2.5.9 and STD COL 5.2-2-H states as follows:

> Operators are provided with procedures for detecting, monitoring, recording, trending, and determining the sources of RCPB leakage. Examples of parameters that are monitored are sump pump run time, sump level, condensate transfer rate, and process chemistry/radioactivity.
>
> The procedures are used for converting different parameter indications for identified and unidentified leakage into common leak rate equivalents (volumetric or mass flow) and leak rate rate-of-change values, including indications from: 1) the drywell floor drain high conductivity water sump monitoring system, 2) the drywell air coolers condensate flow monitoring system, and 3) the drywell fission product monitoring system.
>
> The procedures are used to monitor leakage at levels well below Technical Specifications limits and provide guidance for evaluating potential corrective action plans to prevent the plant from exceeding a Technical Specifications limit.
>
> An unidentified leakage rate-of-change alarm provides an early alert to the operators to initiate corrective actions prior to reaching a Technical Specifications limit.

The staff reviewed the applicant's response to the above RAI. The staff found that the response addresses all the concerns identified in the RAI, and that the applicant is committed to be consistent with ESBWR DCD, Tier 2, Section 5.2.5. Tier 2, Section 5.2.5 of the DCD Revision 10, includes an alarm that annunciates if a step increase in the unidentified leak rate occurs ("reference DCD Section 5.2.5.4, Limits for Reactor Coolant Leakage Rates within the Drywell.") The standard design and procedures will enable the operators to monitor leakage at levels well below TS limits, and initiate actions to prevent the plant from exceeding a TS limit. Based on the above, the staff finds RAI 05.02.05-1 resolved, and the staff confirmed the applicant provided the appropriate information in FSAR Revision 9.

FSAR Section 13.5.2.1, “Operating and Emergency Operating Procedures,” states the following:

> Operating procedures are developed at least six months prior to fuel load to allow sufficient time for plant staff familiarization and to allow staff adequate time to review the procedures and to develop operator licensing examinations.

The staff concludes that the above information meets the relevant guidelines in SRP Section 5.2.5 and RG 1.206, Regulatory Positions C.III.1 and C.I.5.2.5, and is thus acceptable. Conformance with these guidelines and with GDC 2 and GDC 30 provides an acceptable basis for satisfying the NRC requirements.

5.2.5.5 Post Combined License Activities

The applicant proposed a license condition in Part 10 of the COLA Revision 8 as follows:

> 3.6 Operational Program Readiness

The licensee shall submit to the Director of NRO, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented.

5.2.5.6 Conclusion

The staff’s finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff’s review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

In addition, the staff compared the additional supplemental information in the COLA to the relevant NRC regulations, the guidance in Section 5.2.5 of the SRP, and other NRC RGs. The staff’s review concluded that the applicant has presented adequate information in the North Anna 3 COL FSAR to meet the requirements of GDC 2 and GDC 30, and the guidance in RG 1.206 and SRP Section 5.2.5.

5.3 Reactor Vessel

5.3.1 Reactor Vessel Materials

5.3.1.1 Introduction

Section 5.3.1, “Reactor Vessel Materials,” of the North Anna 3 COL FSAR, Revision 8, addresses the reactor vessel (RV) material specifications, including weld materials, special processes used to manufacture and fabricate components, special methods for NDE, special controls and special processes used for ferritic steels and austenitic stainless steels, fracture toughness, reactor vessel materials surveillance program (RVSP), and RV fasteners.

5.3.1.2 Summary of Application

Section 5.3.1 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.3.1 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 5.3.1, the applicant provides the following:

COL Items

- STD COL 5.3-2-A Materials and Surveillance Capsule

The applicant provided additional information in FSAR Section 5.3.1.8 in order to fully describe the North Anna 3 RVSP and its implementation.

- STD COL 16.0-1-A 5.6.4-1 Pressure-Temperature Limit Curves

This COL item is discussed in SER Section 5.3.2, “Pressure-Temperature Limits.”

- NAPS COL 5.3-2-A

In FSAR Section 5.3.1.6, the applicant states a need to delete the parenthetical statement in the first sentence of the first paragraph in ESBWR DCD, Tier 2, Section 5.3.1.6. This statement refers to DCD Section 5.3.1.8, the content of which is completely replaced with new information in FSAR Section 5.3.1.8 by the resolution of STD COL 5.3-2-A.

License Conditions

- Part 10, License Condition 3.5.7 Fuel Loading
- Part 10, License Condition 3.6 Operational Program Readiness

5.3.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for RV materials, and the associated acceptance criteria, are in Section 5.3.1 of the SRP.

In particular, the regulatory basis for the acceptance of the RVSP information (COL Items NAPS COL 5.3-2-A and STD COL 5.3-2-A) is established in:

- 10 CFR Part 50, Appendix A, GDC 32, as it relates to the RVSP
- 10 CFR 50.60, “Acceptance criteria for fracture prevention measures for light-water nuclear power reactors for normal operation,” as it relates to compliance with the requirements of 10 CFR Part 50, Appendices G and H
- 10 CFR Part 50, Appendix G, “Fracture Toughness Requirements,” as it relates to materials testing and acceptance criteria for fracture toughness
- 10 CFR Part 50, Appendix H, “Reactor Vessel Material Surveillance Program Requirements,” as it relates to the RVSP
- SECY-05-0197, as it relates to fully describing an operational program

Also, the staff followed the guidance in RG 1.206 for evaluating the compliance of North Anna 3 COL FSAR Section 5.3.1 with NRC regulations.

5.3.1.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.3.1 of the certified ESBWR DCD. The staff reviewed Section 5.3 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

<u>*COL Items*</u>

- STD COL 5.3-2-A and NAPS COL 5.3-2-A Reactor Vessel Materials Surveillance Program

ESBWR DCD COL Item 5.3.2-A states that the COL applicant will "develop a description of the RV material surveillance program and milestones per Section 5.3.1.8." To address this COL item, the applicant provided STD COL 5.3-2-A and NAPS COL 5.3-2-A in order to fully describe the North Anna 3 RVSP and its implementation.

After reviewing the information provided in North Anna 3 COL FSAR Revision 0, Section 5.3.1, including the information referenced in DCD Tier 2, Section 5.3.1, the staff found that the COL applicant had not met the minimum guidelines in RG 1.206 for a description of the RVSP and its implementation. The staff determined that more information was needed to fully describe the RVSP in accordance with SECY-05-0197 to reach a resolution for this COL item. Thus, the staff requested additional information in RAI 5.03.01-1 (ADAMS Accession No. ML082030183), dated July 21, 2008, in order to complete this review.

In RAI 05.03.01-1, the staff requested that the applicant provide additional information on the preparation of the surveillance capsule specimens, the surveillance capsule locations, and the number and type of specimens in each capsule associated with the RVSP. In the response to RAI 05.03.01-1 dated September 3, 2008 (ADAMS Accession No. ML082520378), the applicant described in detail the preparation of the capsule specimens, the number and type of specimens, and the location of the specimen capsules in the core beltline region; the applicant also agreed to update the FSAR. The staff determined that the applicant's response appropriately addressed the issue in RAI 05.03.01-1. The staff reviewed FSAR Section 5.3.1.8 and confirmed that the information described in the response to RAI 05.03.01-1 has been included in Revision 1 of the FSAR. Therefore, the staff finds that the applicant has adequately addressed this issue and RAI 05.03.01-1 is resolved and closed.

In FSAR Revision 8, Section 5.3.1.8, the applicant describes in detail the preparation of the surveillance capsule specimens; the number and type of specimens; the location of the specimen capsules in the core beltline region; and the reporting of test results. The staff finds that the information in FSAR Section 5.3.1.8 is acceptable because it is in accordance with ASTM International (ASTM) E185-82, "Standard Practice for Conducting Surveillance Tests for Light-Water Cooled Nuclear Power Reactor Vessels," and 10 CFR Part 50, Appendix H.

The implementation milestone for the RVSP is provided in FSAR Section 13.4. In Table 13.4-201, the applicant has stated that the RVSP is to be implemented prior to fuel load and required by a license condition. In addition, in North Anna 3 COL, Part 10, the applicant has provided the following proposed license conditions related to the RVSP:

> The licensee shall implement the Reactor Vessel Materials Surveillance Program prior to initial fuel load. (North Anna 3 COL, Part 10, Section 3.5.7)
>
> The licensee shall submit to the Director of NRO, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented. (North Anna 3 COL, Part 10, Section 3.6)

Based on the information described above, the staff finds the applicant's proposed license conditions are acceptable because they provide assurance that the operational program will be implemented with specific milestones consistent with policy established in SECY-05-0197. The staff finds that the COL applicant has met the minimum guidelines provided in RG 1.206 regarding the description of the RVSP and its implementation and that the applicant has provided a sufficient level of detail to "fully describe" its RVSP as an operational program. On this basis, the COL information items are acceptable.

- STD COL 16.0-1A 5.6.4-1 Pressure-Temperature Limit Curves

The staff's evaluation of STD COL 16.0-1-A 5.6.4-1 is in Section 5.3.2 of this SER.

5.3.1.5 Post Combined License Activities

In FSAR Table 13.4-201, the applicant described the implementation milestone for the RVSP.

As discussed above, the staff has identified the following license conditions:

In Section 3.5.7 of Part 10 of the COLA, Revision 8, the applicant identifies the following license conditions:

> The licensee shall implement each operational program prior to initial fuel load:
>
> - Reactor Vessel Material Surveillance Program

In Section 3.6 of Part 10 of the COLA, the applicant identifies the following license condition:

> The licensee shall submit to the Director of NRO, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented.

5.3.1.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved. In addition, the staff compared the additional information in the COLA to the relevant NRC regulations, the guidance in Section 5.3.1 of the SRP, and other NRC RGs. The staff's review concludes that the applicant has adequately addressed STD COL 5.3-2-A, in accordance with the acceptance criteria in SRP Section 5.3.1, the guidance in RG 1.206 and is consistent with the policy established in SECY-05-0197. Conformance with these guidelines and the policy provides an acceptable basis for satisfying the requirements of 10 CFR Part 50, Appendices G and H. The applicant's additional information is therefore acceptable.

5.3.2 Pressure-Temperature Limits

5.3.2.1 Introduction

This section of the North Anna 3 COL FSAR discusses P-T limits that are required as a means of protecting the RV during startup and shut down to minimize the possibility of a fast fracture. The methods outlined in Appendix G of Section XI of the ASME Code are employed in the analysis of protection against a non-ductile failure. Beltline material properties degrade with radiation exposure, and this degradation is measured in terms of the adjusted reference temperature, that includes a reference nil ductility temperature (NDT) shift, initial RT_{NDT}, and margin.

5.3.2.2 Summary of Application

Section 5.3.2 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.3.2 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 5.3.1.5, the applicant provided the following:

COL Item

- STD COL 16.0-1-A 5.6.4-1 Pressure-Temperature Limit Curves

In ESBWR DCD, Revision 9, COL Item 16.0-1-H 5.6.4-1 becomes STD COL 16.0-1-A 5.6.4-1.

In FSAR Section 5.3, the applicant provides supplemental information in Section 5.3.1.5, "Fracture Toughness Compliance with 10 CFR Part 50, Appendix G," which states:

> The pressure-temperature limit curves are developed in accordance with the Pressure and Temperature Limits Report, as discussed in the Technical Specifications Section 5.6.4. Prior to fuel load, the pressure-temperature limit curves will be updated to reflect plant-specific material properties, if required.

In addition, the applicant has provided technical report NEDC-33441P, "GE Hitachi Nuclear Energy Methodology for the Development of Economic Simplified Boiling Water Reactor (ESBWR) Reactor Pressure Vessel Pressure-Temperature Curves," Revision 6. This report is referenced in North Anna 3 TS Section 5.6.4 as providing the analytical methods used to determine the RCS pressure and temperature limits.

5.3.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the regulatory basis for the acceptance of STD COL 16.0-1-A 5.6.4-1 is in 10 CFR Part 50, Appendix G, which provides the requirements for P-T limits.

5.3.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.3.2 of the certified ESBWR DCD. The staff reviewed Section 5.3.2 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

COL Item

- STD COL 16.0-1-A 5.6.4-1 Pressure-Temperature Limit Curves

ESBWR DCD, Tier 2, Section 5.3.1.5 states that the COL applicant, in accordance with the ESBWR TS (Chapter 16, Section 5.6.4), will furnish bounding P-T curves either as part of the TS or as part of a pressure and temperature limit report (PTLR) submittal for NRC to review. To address this item, the North Anna 3 COL FSAR, Revision 1, Section 5.3.1.5, states that "the pressure-temperature limit curves are developed in accordance with the PTLR as discussed in North Anna Unit 3 TSs (Part 4 of the COLA) Section 5.6.4." In Section 5.6.4, the applicant states that the PTLR methodology is scheduled for submittal to the NRC in the second quarter of 2009. This was tracked as Open Item 5.3.2-2.

In addition, the staff identified the need for the applicant to address the submittal of plant-specific P-T limits in the FSAR. Therefore, in RAI 05.03.02-1(ADAMS Accession No. ML091480213), dated May 28, 2009, the staff requested that the FSAR be revised to provide a commitment to submit the P-T limits using plant-specific material properties before fuel loading. This RAI was tracked as Open Item 5.3.2-1.

The resolution of the Open Items is described in the sections below.

Resolution of Standard Content Open Items

To address Open Item 5.3.2-2, the applicant submitted Technical Report NEDC-33441P, "GE Hitachi Nuclear Energy Methodology for the Development of Economic Simplified Boiling Water Reactor (ESBWR) Reactor Pressure Vessel Pressure-Temperature Curves," Revision 6, in a letter dated December 6, 2013 (ADAMS Accession No. ML13346A654) (hereafter referred to as the ESBWR PTLR). This report was prepared by GE-Hitachi (GEH) and was submitted in support of the North Anna 3 COLA to address the COL Item described above. As such, the purpose of this report is to provide the bounding P-T limits and the associated methodology for the development of the PTLR using the criteria in Generic Letter (GL) 96-03, "Relocation of

Pressure Temperature Limit Curves and Low Temperature Overpressure Protection System Limits."

The first part of the staff's review was to ensure that the information provided in the proposed PTLR and the revised TS pages are in accordance with the guidance in GL 96-03. The second part of the staff's review was to verify that the proposed P-T limits have been developed appropriately using the methodology provided in ESBWR PTLR.

5.3.2.4.1 Summary of the Regulatory Requirements for the Submittal of a PTLR

The NRC established requirements in 10 CFR Part 50 to protect the integrity of the RCPB in nuclear power plants. The staff evaluates the acceptability of a facility's proposed PTLR based on the following NRC regulations and guidance: Appendix G to 10 CFR Part 50; Appendix H to 10 CFR Part 50; RG 1.99, Revision 2, "Radiation Embrittlement of Reactor Vessel Materials"; GL 92-01, Revision 1,"Reactor Vessel Structural Integrity, 10 CFR 50.54(f)"; GL 92-01; Revision 1, Supplement 1,"Reactor Vessel Structural Integrity"; SRP Section 5.3.2; and GL 96-03. Appendix G to 10 CFR Part 50 requires that facility P-T limits for the RPV be at least as conservative as those obtained by applying the linear elastic fracture mechanics methodology of Appendix G to Section XI of the ASME Code. Appendix H to 10 CFR Part 50 establishes requirements related to facility RPV material surveillance programs. RG 1.99, Revision 2 contains methodologies for determining the increase in transition temperature and the decrease in upper-shelf energy resulting from neutron radiation. GL 92-01, Revision 1 requested that licensees submit the RPV data for their plants to the staff for review. In GL 92-01, Revision 1, Supplement 1, the staff requested that licensees provide and assess data from other licensees that could affect their RPV integrity evaluations. SRP Section 5.3.2 provides an acceptable method for determining the P-T limits for ferritic materials in the beltline of the RPV based on the ASME Code, Section XI, Appendix G methodology.

The most recent version of Appendix G to Section XI of the ASME Code which has been endorsed in 10 CFR 50.55a, and therefore, by reference in 10 CFR Part 50, Appendix G, is the 2007 Edition through the 2008 Addenda of the ASME Code. The P-T limit methodology based on this edition of Appendix G to Section XI of the ASME Code (ASME Code Section XI, Appendix G methodology) incorporates the provisions of ASME Code Cases N-588, "Alternative to Reference Flaw Orientation of Appendix G for Circumferential Welds in Reactor Vessels Section XI, Division 1"; and N-640, "Alternative Reference Fracture Toughness for Development of P-T Limit Curves Section XI, Division 1." Additionally, Appendix G to 10 CFR Part 50 imposes minimum head flange temperatures when the system pressure is at or above 20 percent of the preservice hydrostatic test pressure.

GL 96-03 addresses the technical information necessary for a licensee to implement a PTLR. GL 96-03 establishes the information that must be included in (1) an acceptable PTLR methodology (with the P-T limit methodology as its subset), and (2) the PTLR itself. Technical specification task force (TSTF)-419 provides additional guidance, which includes an alternative format for documenting the implementation of a PTLR in the "Administrative Controls" section of a facility's TS.

5.3.2.4.2 Evaluation of the North Anna 3 COL Technical Specification Requirements for Implementation and Control of a PTLR

The North Anna 3 COL TS contain all of the necessary provisions required for the implementation and control of a PTLR. The North Anna 3 TS are in Part 4 of the COLA. The relevant TS requirements include the TS definition of the PTLR (TS Section 1.1); the TS limiting conditions of operation (LCO) for the reactor coolant system P-T limits (LCO 3.4.4), including LCO Action Statements, SRs, and related applicability criteria; and the necessary administrative controls governing the PTLR content and reporting requirements (TS 5.6.4). All of the TS pages related to the implementation and control of a PTLR are acceptable to the staff.

5.3.2.4.3 Evaluation of the ESBWR Generic PTLR Contents and Methodology against the Seven Criteria for PTLR Contents in Attachment 1 of GL 96-03

As discussed in Section 1.0 of the ESBWR PTLR, this report describes the methodology used to develop the P-T limits and provides specific P-T curves for the RV. Accordingly, the PLTR utilizes generic inputs for the RV beltline material chemistry, the initial nil-ductility reference temperature (RT_{NDT}) values, and the projected neutron fluence to determine the P-T limit curves. These generic inputs are intended to be bounding for the design and represent the maximum allowable limits on the input parameters. Therefore, these generic inputs will be substantiated for use in the North Anna 3 COL PTLR in order to verify that actual plant-specific RV beltline properties remain bounded by the generic inputs contained in the PTLR.

Attachment 1 of GL 96-03 contains seven technical criteria (PTLR Criteria) that the contents of PTLRs should conform to if P-T limits are to be located in a PTLR. The staff's evaluations of the contents of the ESBWR PTLR against the seven criteria in Attachment 1 of GL 96-03 are in the subsections that follow.

5.3.2.4.3.1 PTLR Criterion 1

PTLR Criterion 1 states that the PTLR contents should include the neutron fluence values that are used in the calculations of the adjusted reference temperature (ART) values for the P-T limit calculations. Accurate and reliable neutron fluence values are required in order to satisfy the provisions GDC 14,"Reactor coolant pressure boundary"; GDC 30; and GDC 31,"Fracture prevention of reactor coolant pressure boundary," of 10 CFR Part 50, Appendix A; as well as the specific fracture toughness requirements of 10 CFR Part 50, Appendix G. ESBWR PTLR Section 3.3, "Predicted Fluence," states that the fluence analysis for the ESBWR is based on the NRC-approved methodology provided in GE Licensing Topical Report NEDC-32983P-A, "General Electric Methodology for Reactor Pressure Vessel Fast Neutron Flux Evaluations." In addition, the applicant provides the peak RV neutron fluence values projected to 60 years of facility operation in Section 3.3 of the ESBWR PTLR. The staff determined that these 60-year neutron fluence values were calculated using an NRC-approved methodology that is consistent with the guidelines in RG 1.190, "Calculational and Dosimetry Methods for Determining Pressure Vessel Neutron Fluence." The inclusion of valid peak RV neutron fluence values calculated using a neutron fluence methodology that is in conformance with RG 1.190 fulfills the provisions of PTLR Criterion 1. Therefore, the staff determined that PTLR Criterion 1 is satisfied.

5.3.2.4.3.2 PTLR Criterion 2

The requirements for designing and implementing RV material surveillance programs are found in NRC regulation 10 CFR Part 50, Appendix H. The rule requires that RV material surveillance programs for operating reactors comply with the specifications of ASTM E 185. The rule requires that the program design and the surveillance capsule withdrawal schedules for the programs must meet the edition of ASTM E 185 that is current on the issue date of the ASME

Code that the RV was purchased; although the rule permits more recent versions up through the 1982 version of ASTM E 185 to be used.

To ensure conformance with these requirements, PTLR Criterion 2 states that the PTLR should either provide the RV surveillance capsule withdrawal schedule or provide references, by title and number, for the documents containing the RV surveillance capsule withdrawal schedule. The criterion also states that the PTLR should reference, by title and number, any applicable surveillance capsule reports placed on the docket by the licensee requesting approval of the PTLR for its units. This criterion assures that the ART calculations will appropriately follow the RV material surveillance program requirements of 10 CFR Part 50, Appendix H. A discussion of the RV material surveillance program is provided in Section 7.0 of the PTLR. Section 7.0 states that the material surveillance program complies with Appendix H to 10 CFR Part 50 and ASTM E 185-82. The surveillance program description states that four capsules are provided to consider the 60-year design life of the vessel. This amount exceeds the three capsules specified in ASTM E 185-82, because the predicted transition temperature shift is less than 55.6 degrees Celsius (°C) (100 degrees Fahrenheit [°F]) at the inside of the vessel. The capsule withdrawal schedule is also provided in this section, and it is stated that each surveillance capsule will be tested in accordance to 10 CFR Part 50, Appendix H. The applicant also states that the results of the material surveillance program will be used to verify the ΔRT_{NDT} values in accordance with RG 1.99, Revision 2, and the P-T limits will be adjusted, as necessary, based on these results. The staff reviewed the recommended surveillance capsule withdrawal schedule and determined that it is in accordance with the specifications of ASTM E 185-82. On this basis, the staff determined that the provisions of PTLR Criterion 2 are satisfied.

5.3.2.4.3.3 PTLR Criterion 3

PTLR Criterion 3 states that the low temperature overpressure protection system lift- setting limits for the power operated relief valves developed using NRC-approved methodologies may be included in the PTLR. This criterion is not applicable to the ESBWR design and is thus not applicable to the North Anna 3 COL.

5.3.2.4.3.4 PTLR Criterion 4

The P-T limits for operating reactors are generated using a method that accounts for the effects of neutron embrittlement on the fracture toughness of the RV beltline materials in accordance with 10 CFR Part 50, Appendix G. For P-T limits, the effects of neutron embrittlement on the fracture toughness of RV beltline materials is defined in terms of the shift in the RT_{NDT} values resulting from neutron irradiation over a given period of facility operation. The final ART value for a material resulting from neutron embrittlement over a certain period of facility operation is defined as the sum of the initial (unirradiated) reference temperature (initial RT_{NDT}), the mean value of the shift in reference temperature caused by irradiation (ΔRT_{NDT}), and a margin term. RG 1.99, Revision 2, provides the staff's recommended methodologies for calculating the ART values used for P-T limit calculations. ΔRT_{NDT} is a product of a chemistry factor (CF) and a fluence factor. The CF is dependent upon the amount of copper and nickel in the material and may be determined from tables in RG 1.99, Revision 2, or from surveillance data. The fluence factor is dependent upon the neutron fluence at the maximum postulated flaw depth. The margin term is dependent upon whether the initial RT_{NDT} is a plant-specific or a generic value and whether the CF was determined using the tables in RG 1.99, Revision 2, or surveillance data. The margin term is used to account for uncertainties in the values of the initial RT_{NDT}, the copper and nickel contents, the fluence, and the calculation procedures. Appendix G to

Section XI of the ASME Code requires that licensees determine the ART at the 1/4T and 3/4T locations (T is the vessel beltline thickness).

To ensure compliance with the requirements of 10 CFR Part 50, Appendix G, PTLR Criterion 4 states that the PTLR contents should identify the limiting materials and limiting ART values at the 1/4T and 3/4T locations in the wall of the RV. The ART values and all inputs for the ART calculations including RV beltline material chemistry values, initial RT_{NDT} values (Table 3-1), and peak RV beltline neutron fluence projections at 60 years are in Section 3 of the PTLR. In PTLR Section 3.4, the applicant describes how the procedures outlined in RG 1.99, Revision 2, were applied to determine the ΔRT_{NDT} and ART values. In this section, the applicant states that the nominal irradiation temperature in the beltline region is less than 273.9 °C (525 °F). The staff notes that for the procedures of this RG to be valid for nominal irradiation temperatures less than 273.9 °C (525°F), a correction factor shall be used to compensate for greater embrittlement. To address this issue, the applicant proposed to utilize a correction factor equal to a 0.56 °C (1 °F) increase in the ΔRT_{NDT} for each 0.56 °C (1 °F) decrease in irradiation temperature below 287.8 °C (550 °F). This method will be validated for North Anna 3 using the results of the materials surveillance capsule program. The staff determined that this approach is acceptable because it provides a conservative estimate of the additional effect of irradiation on the beltline region at lower temperatures and that the applicant will verify the applicability of the assumption upon receipt of the surveillance capsule data.

The ART calculations and margin term values for the RV beltline materials are in Section 3.5. These values are determined for a 60-year design life. Based on the ART calculations, the applicant has identified the shell forging as limiting material to be used for the derivation of the P-T limits. To evaluate the proposed P-T limits for the RV, the staff confirmed the applicant's selection of the shell forging as the limiting beltline material and performed an independent calculation of the ART values provided in the report using the RG 1.99, Revision 2, methodology. The staff noted that the applicant had not calculated the ART value at the 3/4T location, which is relevant to the heatup P-T limit calculation, because the ART value at 1/4T is assumed to be bounding for heatup and cooldown. The staff verified that the applicant's assumption is valid.

Based on the evaluation described above, the staff finds that the procedure used to calculate the ART values is consistent with the guidance of RG 1.99, Revision 2. The procedure is therefore acceptable. Also, the PTLR clearly identifies the limiting materials and limiting ART values at the 1/4T location. Therefore, the staff determined that the provisions of PTLR Criterion 4 are satisfied.

5.3.2.4.3.5 PTLR Criterion 5

Section IV.A.2 of 10 CFR Part 50, Appendix G requires that the P-T limits for operating reactors and the minimum temperatures established for the stressed regions of RVs (i.e., for the RV flange and stud assemblies) be met for all conditions. The rule also requires that the P-T limits for operating reactors must be at least as conservative as those that would be generated if the methods of analysis in ASME Code Section XI, Appendix G were used to generate the P-T limit curves. In 10 CFR Part 50, Appendix G, Table 1 summarizes the required criteria for generating the P-T limits for operating reactors.

To ensure that PTLRs are in compliance with the above requirements, PTLR Criterion 5 states that the PTLR contents should provide the P-T limit curves for heatup and cooldown operations, core critical operations, and pressure testing conditions for operating light-water reactors.

Table 4-2 of the PTLR includes P-T limit data for heatup and cooldown operations, core critical operations, and hydrostatic and pressure testing. The P-T limit curves corresponding to these data points are in Figure 4-1 of the PTLR. In Section 5.0, the applicant also provided P-T limit data and the corresponding curves for several non-beltline components—including the closure head flanges and the main steam, feedwater, standby liquid control, and core differential pressure (DP) nozzles. These data meet the provisions of PTLR Criterion 5. This criterion specifies that the PTLR include the P-T limit curves for reactor heatup, cooldown, critical operations, and pressure testing conditions.

The staff also performed independent analyses to verify the P-T limit curves for heatup and cooldown operations, core critical operations, and hydrostatic pressure and leak testing provided in the PTLR. Based on this independent verification, the staff determined that the applicant's proposed P-T limits were developed in accordance with ASME Code Section XI, Appendix G and therefore satisfy the requirements of 10 CFR Part 50, Appendix G. Hence, the applicant's proposed P-T limit curves are acceptable for RV operation.

5.3.2.4.3.6 PTLR Criterion 6

Section IV.A.2 of 10 CFR Part 50, Appendix G requires that the P-T limits for operating reactors and the minimum temperature requirements for the highly stressed regions of the RVs (i.e., for the RV flange and stud assemblies) be met for all conditions. Table 1 of 10 CFR Part 50, Appendix G identifies the required criteria for meeting the minimum temperature requirements for the highly stressed regions of the RV.

PTLR Criterion 6 states that the minimum temperature requirements of 10 CFR Part 50, Appendix G shall be incorporated into the P-T limit curves, and the PTLR shall identify minimum temperatures on the P-T limit curves such as the minimum boltup temperature and the hydrotest temperature. The staff determined that the curves were in compliance with the minimum temperature requirements of 10 CFR Part 50, Appendix G. Furthermore, the PTLR clearly identifies the minimum boltup temperature and hydrotest temperature in Section 6.0. Therefore, the staff determined that the provisions of PTLR Criterion 6 are satisfied.

5.3.2.4.3.7 PTLR Criterion 7

RG 1.99, Revision 2 provides the staff’s recommended methods for calculating the ART values for RV beltline materials. These ART values are calculated for the 1/4T and 3/4T locations in the vessel wall. ASME Code Section XI, Appendix G and 10 CFR Part 50, Appendix G require these values to be used for calculating P-T limit curves for reactors. 10 CFR Part 50, Appendix G also requires that the ART values include the applicable results of the RV material surveillance program of 10 CFR Part 50, Appendix H. ART values for ferritic RV base metal and weld materials increase as a function of accumulated neutron fluence and the quantity of alloying elements in the materials, copper and nickel in particular. The procedures of the RG specify the use of a CF as a means for quantifying the effect of the alloying elements on the ART values. Furthermore, the RG specifies that a CF be calculated and input into the calculation of the final ART value for each beltline material. The RG cites two possible methods for determining the CF values for the RV beltline base metal and weld materials: (1) Regulatory Position 1.1 in the RG allows the licensee to determine the CF values from applicable tables in the RG as a function of copper and nickel content or, (2) Regulatory Position 2.1 allows the use of applicable RV surveillance data to determine the CF values if the base metal or weld materials are represented in a licensee’s RV material surveillance program and if two or more credible surveillance data sets become available for the material in question. The RG defines the criteria for determining the credibility of the RV surveillance data sets. In accordance with the requirements of 10 CFR Part 50, Appendix G, the RG states that if the procedure of Regulatory Position 2.1 results in a higher ART value than that obtained by using the procedure of Regulatory Position 1.1, the surveillance data should be used to determine the CF and the ART. If the procedure of Regulatory Position 2.1 results in a lower value for the ART, either procedure may be used for determining the CF and the ART.

To ensure that PTLRs are in compliance with the above regulatory requirements and guidelines, PTLR Criterion 7 states that if surveillance data are used in the calculations of the ART values, the PTLR contents should include the surveillance data and calculations of the CF values for the RV base metal and weld materials, as well as an evaluation of the credibility of the surveillance data against the credibility criteria of RG 1.99, Revision 2. However, the PTLR is generic for the design and is based on bounding embrittlement correlations for which surveillance data is not yet available. Therefore, the incorporation of surveillance data and related calculations is currently not applicable to the PTLR. As previously discussed, the CF and ART values in the PTLR were determined using the procedures of Regulatory Position 1.1 in RG 1.99, Revision 2. Therefore, the staff determined that the provisions of PTLR Criterion 7 are satisfied.

5.3.2.4.4 Staff Findings on the Acceptability of the PTLR

Based on the evaluation described above, the staff has determined that the contents of the PTLR conform to the staff's technical criteria for PTLRs, as defined in Attachment 1 of GL 96-03. The staff also determined that the PTLR satisfies the requirements of 10 CFR Part 50, Appendix G. Furthermore, the staff determined that the PTLR is compatible with the TS and the PTLR-related TS provisions meet the technical criteria of GL 96-03. The staff notes that the PTLR provides generic, not plant-specific, heatup and cooldown P-T curves based on bounding material properties and projected fluence.

To address the submittal of plant-specific P-T limits (Open Item 5.3.2-1), the COL applicant provided the following statement in FSAR, Revision 9, Section 5.3.1.5:

> Prior to fuel load, the pressure-temperature limit curves will be updated to reflect plant-specific material properties, if required.

The staff finds that this approach is consistent with the guidelines of GL 96-03 and is therefore acceptable. Based on this evaluation, the staff finds that STD COL 16.0-1-A 5.6.4-1 is acceptable. As a result, the Phase 2 North Anna 3 SER with Open Items 5.3.2-1 and 5.3.2-2 are resolved.

5.3.2.5 Post Combined License Activities

The staff has noted the following FSAR requirement for North Anna 3:

- Prior to fuel load, the pressure-temperature limit curves will be updated to reflect plant-specific material properties, if required.

5.3.2.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR

52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

In addition, the staff concludes that the ESBWR PTLR (NEDC-33441P, Revision 6) is acceptable for use by the North Anna 3 COL for establishing limiting P-T limit curves and related input parameters. Pursuant to North Anna 3 TS requirement 5.6.4c, future COL holders and licensees will be required to provide updated, plant-specific PTLRs to the NRC "upon issuance for each RV neutron fluence period and for any PTLR revision or supplement thereto." Finally, per GL 96-03, any subsequent changes in the methodology used to develop the P-T must be approved by the NRC.

The staff also concludes that the information in STD COL 16.0-1-A 5.6.4-1 meets the relevant acceptance criteria of SRP Section 5.3.2 and the guidance in RG 1.206. Conformance with these guidelines provides an acceptable basis for satisfying the requirements of 10 CFR Part 50, Appendix G.

5.3.3 Reactor Vessel Integrity

5.3.3.1 Introduction

This section of the North Anna 3 COL FSAR discusses all factors related to RV integrity.

5.3.3.2 Summary of Application

Section 5.3.3 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.3.3 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 5.3.3, the applicant provided the following:

Supplemental Information

- STD SUP 5.3-1

In FSAR Section 5.3.3.6, the applicant provides supplemental information regarding operating procedures intended to ensure that the P-T limits are not exceeded during normal operating conditions or anticipated plant transients.

5.3.3.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for RV integrity, and the associated acceptance criteria, are in Section 5.3.3 the SRP and RG 1.206.

5.3.3.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.3.3 of the certified ESBWR DCD. The staff reviewed Section 5.3.3 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to the review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

Supplemental Information

- STD SUP 5.3-1

In FSAR Section 5.3.3.6, the applicant added supplemental information stating that the development of plant operating procedures is addressed in Section 13.5. These procedures require compliance with the TS, which are intended to ensure that the P-T limits identified in DCD Section 5.3.2 are not exceeded during normal operating conditions and anticipated plant transients. The staff finds that STD SUP 5.3-1 acceptable because it is in accordance with the recommendations of RG 1.206, Regulatory Position C.I.5.3.2.2, which states that the FSAR should include a commitment that plant operating procedures will ensure that the P-T limits will not be exceeded during any foreseeable upset condition.

5.3.3.5 Post Combined License Activities

There are no post COL activities related to this section.

5.3.3.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG 1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

The staff also concluded that the information in STD SUP 5.3-1 meets the guidance in RG 1.206 and is therefore acceptable. Conformance with this guidance provides an acceptable basis for satisfying the requirements in 10 CFR Part 50, Appendix G. The staff also concluded that the information in STD SUP 5.3-1 meets the guidance of RG 1.206 and is therefore acceptable. Conformance with this guidance provides an acceptable basis for satisfying the requirements of 10 CFR Part 50, Appendix G.

5.4 Reactor Coolant System Component and Subsystem Design

5.4.1 Introduction

Section 5.4, "Reactor Coolant System Component and Subsystem Design," of the North Anna 3 COL FSAR, Revision 8, including the corresponding sections in the referenced ESBWR DCD. Specifically, the staff verified that the following sections of the ESBWR DCD contain information appropriate for incorporation by reference and that any supplemental information to be provided by the COL applicant is addressed in the COLA:

5.4.1 Reactor Recirculation System
5.4.2 Steam Generators (not applicable to the ESBWR)
5.4.3 Reactor Coolant Piping
5.4.4 Main Steamline Flow Restrictors
5.4.5 Nuclear Boiler System Isolation
5.4.6 Isolation Condenser System
5.4.7 Residual Heat Removal System

5.4.8 Reactor Water Cleanup/Shutdown Cooling System
5.4.9 Main Steamlines and Feedwater Piping
5.4.10 Pressurizer (not applicable to the ESBWR)
5.4.11 Pressurizer Relief Discharge System (not applicable to the ESBWR)
5.4.12 Reactor Coolant System High Point Vents
5.4.13 Safety and Relief Valves and Depressurization Valves
5.4.14 Component Supports
5.4.15 COL Information
5.4.16 References

5.4.2 Summary of Application

Section 5.4 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 5.4 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 5.4, the applicant provides the following:

Supplemental Information

- STD SUP 5.4-1

In FSAR Section 5.4.8, the applicant states that operating procedures will provide guidance to prevent severe water hammer caused by mechanisms such as voided lines.

- STD SUP 5.4-2

In FSAR Section 5.4.12, the applicant states that the human factors analysis of control room displays and controls for the RCS vents is included as part of the overall human factors analysis of the control room displays and controls described in ESBWR DCD Chapter 18.

- STD SUP 5.4-3

In FSAR Section 5.4.12, the applicant states that operating procedures for the reactor vent system address considerations regarding when venting is and is not needed, including a variety of initial conditions that may require venting. Section 13.5 of the North Anna 3 COL FSAR addresses the development of operating procedures.

5.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966. In addition, the relevant requirements of the Commission regulations for the reactor coolant system component and subsystem design, and the associated acceptance criteria, are in Section 5.4 of the SRP.

5.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 5.4 of the certified ESBWR DCD. The staff reviewed Section 5.4 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD appropriately represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference address the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR as follows:

Supplemental Information

- STD SUP 5.4-1

In FSAR Section 5.4.8, the applicant stated that operating procedures will provide guidance to prevent severe water hammer caused by mechanisms such as voided lines.

The staff finds that supplement STD SUP 5.4-1 is acceptable because water hammer is to be addressed in the plant operating procedures.

- STD SUP 5.4-2

In FSAR Section 5.4.12, the applicant stated that the human factors analysis of the control room displays and controls for the RCS vents is included as part of the overall human factors analysis of the control room displays and controls described in DCD Chapter 18.

The staff found that this information is entirely incorporated into Chapter 18 of the North Anna 3 COL FSAR. The staff thus concludes that STD SUP 5.4-2 is acceptable.

- STD SUP 5.4-3

In FSAR Section 5.4.12, the applicant stated that operating procedures for the reactor vent system address considerations regarding when venting is needed and when it is not needed.

The staff finds that supplement STD SUP 5.4-3 is acceptable because system venting is to be addressed in the plant's operating procedures.

5.4.5 Post Combined License Activities

There are no post COL activities related to this section.

5.4.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information, and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to this section that were incorporated by reference have been resolved.

In addition, the staff compared the supplemental information in the COLA to the relevant NRC regulations and the guidance in Section 5.4 of the SRP. The staff's review finds that the applicant has adequately addressed the supplemental information in accordance with NRC regulations. The supplemental information is therefore acceptable.

6.0 ENGINEERED SAFETY FEATURES

6.0 ENGINEERED SAFETY FEATURES

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) discusses the NRC staff evaluation of the North Anna 3 Combined License (COL) engineered safety features (ESFs) of the Economic Simplified Boiling-Water Reactor (ESBWR) plant, which are designed to mitigate the consequences of postulated accidents. The ESFs consist of containment systems, core cooling systems, habitability systems, and fission product removal and control systems. The containment systems include the primary containment system, the passive containment cooling system, the containment isolation system, and the hydrogen control system. The passive core cooling system provides emergency core cooling following postulated design-basis events and is designed to operate without the use of active equipment such as pumps and alternating current power sources. Similarly, the passive containment cooling system removes heat from the containment without the use of active equipment or alternating current power sources. The control room habitability system is designed so that the main control room remains habitable following a postulated design-basis event. Natural removal processes inside containment, the containment boundary, and the containment isolation system provide control of fission products following a postulated design-basis event.

6.1 <u>Design Basis Accident Engineered Safety Feature Materials</u>

Section 6.1, "Design Basis Accident Engineered Safety Feature Materials," of the North Anna 3 COL Final Safety Analysis Report (FSAR), Revision 8, incorporates by reference with no departures or supplements, Section 6.1, "Design Basis Accident Engineered Safety Feature Materials," which includes Section 6.1.1, "Metallic Materials," and Section 6.1.2, "Organic Materials," of Revision 10 of the Design Control Document (DCD) for the ESBWR, referenced in Appendix E to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." Materials used in the ESF components have been evaluated to ensure that material interactions do not occur that can potentially impair operation of the ESFs. Materials have been selected to withstand the environmental conditions encountered during normal operation and during any postulated loss-of-coolant accident (LOCA). Their compatibility with core and containment spray solutions has been considered, and the effects of radiolytic decomposition products have been evaluated.

As documented in NUREG-1966, "Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-Water Reactor Standard Design," issued April 2014, the staff reviewed and approved Section 6.1 of the certified ESBWR DCD. Section 6.1 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 6.1 of the certified ESBWR DCD, Revision 10, with no departures or supplements. The staff reviewed the application and checked the referenced DCD to confirm that the scope of information relating to this review topic is complete.[1] The staff's review confirmed that the applicant has addressed the required information, and there is no outstanding information related to this section that remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the design basis accident (DBA) ESF materials that were incorporated by reference have been resolved.

[1] See "*Finality of Referenced NRC Approvals*" in SER Section 1.2.2, for a discussion on the staff's review related to verification of the scope of information to be included in a COL application that references a design certification.

6.2 Containment Systems

As documented in NUREG-1966, the staff reviewed and approved Section 6.2, “Containment Systems,” of the certified ESBWR DCD. Section 6.2 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 6.2, of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E with no departures or supplements. The staff reviewed the application and checked the referenced DCD to confirm that the scope of information relating to this review topic is complete.[1] The staff’s review confirmed that no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to containment systems that were incorporated by reference have been resolved.

6.3 Emergency Core Cooling System

As documented in NUREG-1966, the staff reviewed and approved Section 6.3, “Emergency Core Cooling Systems,” of the certified ESBWR DCD. Section 6.3 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 6.3 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E with no departures or supplements. The staff reviewed the application and checked the referenced DCD to confirm that the scope of information relating to this review topic is complete.[1] The staff’s review confirmed that no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the emergency core cooling system that were incorporated by reference have been resolved.

6.4 Control Room Habitability Systems

6.4.1 Introduction

The control room habitability area (CRHA) provides protection for the plant operators and ensures suitable environmental conditions for the equipment necessary to monitor and control the plant during normal operation and to maintain the plant in a safe condition during accident conditions. The control room ventilation system and control building layout and structures ensure that plant operators are adequately protected against the effects of accidental releases of toxic chemicals and radioactive material.

6.4.2 Summary of Application

Section 6.4 “Control Room Habitability Systems” of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 6.4 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 6.4, the applicant provides the following:

COL Items

- STD COL 6.4-1-A — Control Room Habitability Area (CRHA) Procedures and Training

The applicant provided additional information in STD COL 6.4-1-A. The applicant stated that the operators are provided with training and procedures for control room habitability that address the applicable aspects of NRC Generic Letter (GL) 2003-01, “Control Room Habitability,” dated June 12, 2003, and are consistent with the intent of Generic Issue (GI) 83, “Control Room Habitability,” Revision 3. FSAR Sections 13.4 and 13.5 contain the implementation milestones for training and procedures, respectively.

- NAPS COL 6.4-2-A Toxic Gas Analysis

The applicant provided additional information in NAPS COL 6.4-2-A. The applicant stated that potential toxic gas sources are evaluated to confirm that an external release of hazardous chemicals does not impact control room habitability.

Supplemental Information

- NAPS SUP 6.4-1 System Safety Evaluation

The applicant described the evaluation of the impact of a postulated design-basis accident in Units 1 or 2 on the Unit 3 control room.

6.4.3 Regulatory Basis

The applicable regulatory requirements for control room habitability are as follows:

- General Design Criterion (GDC) 4, “Environmental and Dynamic Effects Design Bases,” of Appendix A, “General Design Criteria for Nuclear Power Plants,” to 10 CFR Part 50, “Domestic Licensing of Production and Utilization Facilities,” as it relates to structures, systems, and components (SSCs) important to safety being designed to accommodate the effects of, and to be compatible with, the environmental conditions associated with postulated accidents.

- GDC 5, “Sharing of Structures, Systems and Components,” as it relates to ensuring that sharing among nuclear power units of SSCs important to safety will not significantly impair the ability to perform safety functions, including in the event of an accident in one unit and an orderly shutdown and cooldown of the remaining unit(s).

- GDC 19, “Control Room,” as it relates to maintaining the nuclear power unit in a safe condition under accident conditions and providing adequate radiation protection to permit access and occupancy of the control room under accident conditions.

- 10 CFR 50.34(f)(2)(xxviii), as it relates to evaluation of potential radiation exposure pathways for an accident source term and design provisions to preclude control room habitability problems resulting from exposure through such pathways.

- 10 CFR 52.80(a), “Contents of application; additional technical information,” which requires a COL application (COLA) to address the proposed inspections, tests, and analyses (including those applicable to emergency planning) that the licensee shall perform, and the acceptance criteria that are necessary and sufficient to provide reasonable assurance that if the inspections, tests, and analyses are performed and the acceptance criteria are met, the facility has been constructed and will operate in conformity with the COL, the provisions of the Atomic Energy Act of 1954, as amended, and NRC regulations.

The regulatory basis of the information incorporated by reference is in NUREG–1966, related to the certified ESBWR DCD. In addition, the relevant requirements of the Commission regulations for habitability systems and the associated acceptance criteria are , Section 6.4, “Control Room Habitability System,” of NUREG-0800, “Standard Review Plan for the Review of

Safety Analysis Reports for Nuclear Power Plants: LWR Edition" (SRP), contains the relevant regulatory requirements for habitability systems and the associated acceptance criteria.

The following regulatory guidance applies to control room habitability:

- Three Mile Island (TMI) Action Plan, Item III.D.3.4.
- Regulatory Guide (RG) 1.78, Revision 1, "Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release," issued December 2001.
- RG 1.52, Revision 3, "Design, Inspection, and Testing Criteria for Air Filtration and Adsorption Units of Post Accident Engineered Safety Feature Atmosphere Cleanup Systems in Light Water Cooled Nuclear Power Plants," June 2001.
- RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)," issued June 2007.
- RG 1.196, "Control Room Habitability at Light Water Nuclear Power Reactors," May 2003.

6.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 6. 4, "Control Room Habitability Systems," of the certified ESBWR DCD, Revision 10. The staff reviewed Section 6.4 of the North Anna 3 COL FSAR Revision 8, and checked the referenced ESBWR DCD to confirm that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference include all the relevant information related to control room habitability systems.

The staff reviewed the information in the North Anna 3 COL FSAR, Revision 8 as follows:

COL Items

- STD COL 6.4-1-A CRHA Procedures and Training

The staff reviewed NAPS COL 6.4-1-A, which relates to the procedures and training included under Section 6.4 of the FSAR. The applicant provided additional information as follows:

> Operators are provided with training and procedures for control room habitability that address the applicable aspects of NRC Generic Letter 2003-01 and are consistent with the intent of [generic issue] GI 83. Training and procedures are developed and implemented in accordance with [FSAR] Sections 13.2 and 13.5, respectively.

The staff determined that the applicant has provided adequate information regarding the development of operator training and procedures for control room habitability to address the applicable aspects of NRC GL 2003-01 and GI 83. Specifically, in FSAR Section 13.2 and 13.5 the applicant has described the operator training and procedures to be in place 6 months prior to scheduled fuel loading. The staff evaluation of the adequacy of these programs as well as its safety finding is documented in FSAR Sections 13.2 and 13.5 of this this Safety Evaluation Report (SER).

- NAPS COL 6.4-2-A Toxic Gas Analysis

The applicant provided additional information to address DCD COL Item 6.4-2-A, which states:

> The COL applicant will identify potential site-specific toxic or hazardous materials that may affect control room habitability in order to meet the requirements of TMI Action Plan III.D.3.4 and GDC 19.

The potential sources of hazardous chemicals include offsite industrial facilities, transportation routes, and nuclear units on the site. In FSAR Section 2.2, "Nearby Industrial, Transportation, and Military Facilities," the applicant evaluated potentially hazardous offsite chemicals and concluded that there are no significant control room habitability impacts from potential sources within 8 kilometers (km) (5 miles) of the control room. The applicant also performed a toxic gas analysis for potentially hazardous chemicals stored on site, in accordance with the guidance from RG 1.78. The applicant concluded that concentrations of toxic gas in the control room will not exceed the toxicity concentrations in RG 1.78 and National Air Quality Standards.

The applicant also analyzed the onsite hazards of a postulated instantaneous release of toxic gas followed by a vapor cloud explosion or the intake of a flammable vapor concentration into a safety-related intake. The applicant found the locations of the onsite storage facilities as well as the hazards from a tank truck delivery to be acceptable in accordance with the guidance in RG 1.78. Therefore the applicant concluded that seismic Category I safety-related toxic gas monitoring instrumentation is not required.

The applicant identified in FSAR Table 2.2-203 gases that are not toxic but could be an asphyxiant in some circumstances. Nitrogen, for example, is stored onsite as liquid nitrogen in a tank. The applicant's analysis shows that the maximum air concentration for nitrogen as well as the other listed asphyxiants listed in FSAR Table 2.2-203 that have a potential of penetrating inside the CRHA will be significantly less than the maximum concentration recommended in RG 1.78. The staff finds the applicant's analysis acceptable because the applicant's screening methodology follows the guidance of RG 1.78. Accordingly, the staff finds that the information the applicant provided in response to COL Item NAPS COL 6.4-2-A conforms to the requirements of 10 CFR 50.34(f)(2)(xxviii) and GDC 19.

In the evaluation presented in Section 2.2.3 of this SER, the staff performed calculations on seven selected chemical hazards and confirmed that the concentrations at the control room intake and inside the control room are lower than as specified in the applicable guidance, as described in detail below.

The staff conducted an audit (Agencywide Documents Access and Management System (ADAMS) Accession Number No. ML15096A147) to review the applicant's calculations supporting the chemical hazards analysis. The staff determined that the applicant's calculation results were consistent with the results of the staff's independent verification calculations for the selected analyses. In all cases, the applicant's results are well below the maximum concentrations listed in RG 1.78. While reviewing the applicant's chemical spill calculations, the staff noted that when meteorological stability class F was selected, only the nighttime temperature of 21.9 degrees Celsius (C) (71.5 degrees Fahrenheit (F)) was used. Therefore, on December, 9, 2014, the staff issued Request for Additional Information (RAI) 06.04-8, (ADAMS Accession No. ML14344A107), requesting the applicant to explain why the daytime temperature of 33.1 degrees C (91.5 degrees F) could not coexist with meteorological stability class F. The applicant's response to this RAI dated February 3, 2015 (ADAMS Accession No. ML15035A523), states that:

> high temperature conditions beyond those considered in the [The Areal Locations of Hazardous Atmospheres (ALOHA) code] ALOHA sensitivity analysis coupled with stable conditions conducive to high [atmospheric dispersion factor] X/Q (i.e., temperatures above 71.5 ^{o}F concurrent with stability class F or G) occur only approximately 1.6 percent of the total hours under consideration, regardless of wind speed and wind direction.
>
> Therefore, a broad range of conditions was simulated using a conservative approach to estimate control room concentrations, and to ensure the values presented are not exceeded more than 5 percent of the time as required by RG 1.78, Section C, 3.3.

As described, the applicant used conservative meteorological conditions in its dispersion analysis, and provided an atmospheric dilution that is exceeded only 5 percent of the time, consistent with RG 1.78. Therefore, the staff finds that the applicant's approach is consistent with RG 1.78, Section C.3.3, and therefore acceptable. Accordingly, RAI 06.04-8 is closed and resolved.

The staff reviewed the information submitted by the applicant in Section 2.2 of the COL FSAR and confirmed that there are no significant control room habitability impacts from hazardous chemicals stored on-site, off-site or transported along offsite routes within 8 km (5 miles) of the plant (see the evaluation in Section 2.2.3 of this SER). Therefore, the staff concludes that the applicant adequately performed the required chemical screening in accordance with guidance of RG 1.78. In addition, based on the independent staff calculations described above and resolution of RAI 06.04-08, the staff confirmed that the applicant correctly estimated control room concentrations of toxic gases, and that those results are acceptable.

Supplemental Information

- NAPS SUP 6.4-1 System Safety Evaluation

The applicant provided additional information that states:

> The impact of a postulated design basis accident (DBA) in Units 1 or 2 on the Unit 3 control room was evaluated. The bounding case is a release from the Unit 2 RB to the Unit 3 Control Building receptor based on a minimum distance criterion. The evaluation was performed as follows:
>
> - Atmospheric dispersion factors, χ/Qs, at the Unit 3 MCR [main control room] intakes were conservatively calculated assuming a point source, a distance of approximately 400 m (1312 ft), and a release height of 10 m (32.8 ft). Meteorological data used for cross-unit impact is consistent with that used for the χ/Q values presented in Section 2.3. A nominal "receptor to source" direction of 60 degrees was assumed (clockwise with respect to "true north"). The χ/Q values are presented in Table 2.3-207.

- The Unit 2 LOCA as described in Section 15.4.1.8 of the Units 1 and 2 UFSAR [updated final safety analysis report] was reviewed. The resultant dose at the Unit 3 MCR intake was determined by adjusting the [low population zone] LPZ dose consequences by the ratio of the χ/Q values, and the ratio of the breathing rates (BR) for the LPZ versus the control room values. Detailed modeling of the Unit 3 control room was not performed because the doses are bounded by a postulated Unit 3 LOCA. No credit was taken for the reduced control room occupancy factor, the Unit 3 control room emergency filtration units, or the “finite cloud” model allowed per RG 1.194.

Based on this conservative analysis, the resultant dose is bounded by the control room operator dose from a postulated Unit 3 DBA, and is less than the GDC 19 limits. The staff reviewed this supplemental information added to Section 6.4 of the COLA. The staff has determined that the applicant correctly identified the relative locations of the accident release points on the unit at which an accident is postulated and the release and control room receptor locations for proposed North Anna 3. Since the latter form the basis for the DBA radiological consequences analysis for the control room at the North Anna 3, the staff has determined that the applicant calculations described above are conservative. Accordingly, the staff finds that the supplemental information, NAPS SUP 6.4-1, provided by the applicant adequately addresses the impact on Unit 3 control room habitability from a DBA at a nearby unit on the North Anna site by showing it is bounded by the dose in the Unit 3 control room from a DBA at Unit 3.

In view of the foregoing, the staff concludes that detailed modeling of the Unit 3 control room in the event of a Unit 1 or 2 DBA is not necessary because the doses are bounded by a postulated Unit 3 LOCA, as documented in Chapter 15 of the North Anna 3 FSAR and reviewed by the staff in Section 15.4 of this SER. Furthermore, simultaneous accidents at multiple units on a common site are considered to be outside the design basis, unless there is a reliance on shared systems between the units. This is not the case for the ESBWR design, which is referenced in the North Anna 3 COLA.

The staff’s evaluation of the applicant’s compliance with the control room habitability dose requirements of GDC 19 in the Unit 3 control room from a postulated Unit 3 DBA is documented in Section 15.4 of this SER.

In view of the above, the staff finds that the applicant’s Supplemental Information NAPS SUP 6.4-1 is adequately addressed and therefore acceptable.

6.4.5 Post Combined License Activities

There are no post COL activities related to this section.

6.4.6 Conclusion

The staff’s finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. As described above, the staff confirmed that the applicant has addressed the additional outstanding information relating to control room habitability identified in the COL items in Section 6.4 of the DCD. In regard to the rest of Section 6.4 of the DCD, the staff confirmed that no outstanding information related to this section remains to be addressed in the North Anna 3 FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to control room habitability that were incorporated by reference have been resolved.

In addition, for the reasons set forth above, the staff concludes that the information presented in the COL FSAR is acceptable and meets the requirements of GDC 4 and 19 of Appendix A to 10 CFR Part 50, "Domestic Licensing of Production and Utilization Facilities"; 10 CFR 50.34(f)(2)(xxviii); and 10 CFR 52.80(a). This conclusion is also based on the following:

- STD COL 6.4-1-A is acceptable because the applicant has provided adequate information regarding the development and implementation of operator training and procedures for control room habitability to address the applicable aspects of GL 2003-01 and GI 83. In conclusion, the applicant has provided sufficient information for satisfying 10 CFR 50.34(a)(6) and (10) and 10 CFR 50.34(b)(6)(iv) and (v).

- NAPS COL 6.4-2-A is acceptable because the staff verified that an external release of hazardous chemicals will not impact control room habitability, in accordance with the requirements of 10 CFR 50.34(f)(2)(xxviii) and GDC 19.

- NAPS SUP 6.4-1 is acceptable because the staff finds that the impact of a postulated DBA in Units 1 or 2 on the Unit 3 control room is bounded by a postulated Unit 3 LOCA.

6.5 Atmospheric Cleanup Systems

As documented in NUREG-1966, the staff reviewed and approved Section 6.5, "Atmosphere Cleanup Systems," of the certified ESBWR DCD. Section 6.5 of the COL FSAR incorporated Section 6.5 of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E with no departures or supplements. The staff reviewed Section 6.5 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to confirm that the combination of the information in the ESBWR DCD and information in the COL FSAR represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the applicant has addressed the required information, and no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the atmospheric cleanup systems have been resolved.

6.6 Preservice and In-service Inspection and Testing of Class 2 and 3 Components and Piping

6.6.1 Introduction

In-service inspection (ISI) programs are based on the requirements of 10 CFR 50.55a, "Codes and Standards," in that for Code Class 1, 2 and 3 components, as defined in Section III of the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC), an applicant is required to meet the applicable inspection requirements set forth in ASME BPVC Section XI, "Rules for In-service Inspection of Nuclear Power Plant Components." ISI includes preservice examinations before initial plant startup, as required by IWB-2200 (for Class 1 components), IWC-2200 (for Class 2 components) and IWD-2200 (for Class 3 components) of ASME BPVC Section XI.

6.6.2 Summary of Application

Section 6.6, “Preservice and In-service Inspection and Testing of Class 2 and 3 Components and Piping,” of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 6.6 of the certified ESBWR DCD, Revision 10 referenced in 10 CFR Part 52, Appendix E. In addition, in FSAR Section 6.6, the applicant provides the following:

COL Items

- STD COL 5.2-1-A Preservice and In-service Inspection Program Description

In FSAR Section 6.6, the applicant provided additional information in STD COL 5.2-1-A to address pressure testing information for Class 2 and 3 components. The applicant states that system leakage and hydrostatic tests will meet all applicable requirements of ASME BPVC Section XI, IWA-5000, IWC-5000, and IWD-5000 for Class 2 and 3 components; including the limitations of 10 CFR 50.55a(b)(2)(xx) and 10 CFR 50.55a(b)(2)(xxvi).

- STD COL 6.6-1-A Preservice Inspection and In-service Inspection Program for Class 2 and 3 components

The applicant provided additional information in STD COL 6.6-1-A to address COL Item 6.6-1-A. The applicant states that (a) the preservice inspection (PSI)/ISI program descriptions for Class 2 and 3 components and piping is in DCD Section 6.6, (b) no relief requests for PSI/ISI programs have been identified, (c) the initial ISI program will be based on the latest edition and addenda of the ASME Code incorporated by reference in 10 CFR 50.55a(b) on the date 12 months before fuel load, and (d) the milestones for the PSI/ISI program implementation are in FSAR, Section 13.4.

The applicant also provided additional information in STD COL 6.6-1-A to address the flow acceleration corrosion (FAC) program. The applicant states that before startup, a comprehensive FAC susceptibility screening will be performed to identify any plant systems that may be susceptible to FAC degradation. Should any plant systems remain susceptible, a FAC program will be implemented with PSI baseline nondestructive examinations (NDEs) and material constituency identified for each as-fabricated piping component in the susceptible systems.

- STD COL 6.6-2-A PSI/ISI NDE Accessibility Plan Description

The applicant provided additional information in STD COL 6.6-2-A to address the accessibility and NDE of Class 1, 2, and 3 austenitic or dissimilar metal welds. The applicant stated that during the construction phase of the project, anomalies and construction issues will be addressed using the change control procedures. These procedures provide that changes to approved design documents, including field changes and modifications, be subject to the same review and approval process as the original design. Accessibility and inspectability are key components of the design process. The control of component accessibility for inspection and testing affecting Class 2 and 3 components during licensee design activities and during plant construction is provided via the procedures for design control and plant modifications. Ultrasonic techniques (UTs) will be the preferred NDE method for all PSI and ISI volumetric examinations; radiographic techniques (RTs) will be used only if UTs cannot achieve the necessary coverage. The same NDE method used during PSI will be used for ISI to the extent practical to assure a baseline point of reference. If a different NDE method is used for the ISI than was used for the PSI, equivalent coverage will be achieved as required by the ASME Code.

6.6.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the staff FSER related to the certified ESBWR DCD. In addition, the relevant requirements of Commission regulations for the PSI/ISI for Class 2 and 3 components, and the associated acceptance criteria, are stated in SRP Section 6.6.

The applicable regulatory requirement for the PSI/ISI programs for Class 2 and 3 components is as follows:

- 10 CFR 50.55a

The related acceptance criteria are as follows:

- ASME BPVC Section XI

The basis for review of the supplementary information submitted in response to COL information items on the ISI of Class 2 and 3 Components is established in 10 CFR 50.55a, as it pertains to the specification of the PSI, ISI, and testing requirements of the ASME Code for Class 2 and 3 components. Review of the description of the FAC program is based on addressing the concerns described in GL 1989-008, "Erosion/Corrosion-Induced Pipe Wall Thinning," dated May 2, 1989, as they pertain to establishing an erosion-corrosion monitoring program. SRP Section 10.3.6, "Steam and Feedwater System Materials," discusses the need for a FAC program and identifies acceptance criteria.

6.6.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 6.6 of the certified ESBWR DCD. The staff reviewed Section 6.6 of the North Anna 3 COL FSAR and checked the referenced ESBWR DCD to confirm that the combination of the information in the DCD and the information in the COL FSAR represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference include all the information related to the PSI, ISI, and testing of Class 2 and 3 components required in an application.

The staff reviewed the conformance of FSAR Section 6.6 to the guidance in RG 1.206, Section C.III.1, Chapter 6, C.I.6.6, "In-service Inspection of Class 2 and 3 Components." The staff determined that FSAR Section 6.6 incorporates by reference Section 6.6 of the ESBWR DCD. The specific version of ASME BPVC Section XI that is used as the baseline Code in the ESBWR certified design is the 2001 edition, up to and including the 2003 addenda. The staff did not identify any portions of the ESBWR ISI program for Class 1, 2, and 3 components that were excluded from the scope of the staff's review of the ESBWR design. North Anna COL FSAR Section 6.6 states that the PSI/ISI program descriptions for Class 2 and 3 components and piping are in ESBWR DCD Tier 2, Section 6.6. Therefore, the staff's conclusions remain unchanged with regard to the acceptability of the ESBWR ISI program based on the 2001 edition, up to and including the 2003 addenda of ASME BPVC Section XI with regard to the preservice and in-service inspectability of Class 2 and 3 components.

The staff's evaluation of the operational program aspects of the ASME Code Class 2 and 3 ISI program and Augmented Inspection programs is addressed with the Class 1 ISI in Section 5.2.4 of this SER. The adequacy of the ISI program for metal containment (Class MC) components is discussed in Section 3.8.2 of this SER. Accordingly, the staff's evaluation of this section focuses on the acceptability of the COLA supplemental information and responses to the ESBWR COL items as they relate to the ISI of ASME Code Class 2 and 3 components.

The staff also considered whether Section 6.6 of the FSAR conforms to the guidance in RG 1.206, Section C.III.1, Chapter 10, C.I.10.3.6, "Steam and Feedwater System Materials," as it relates to developing an FAC monitoring program to address GL 1989-008, which is discussed in ESBWR DCD Section 6.6 and documented in NUREG-1966, Section 6.6. SRP Section 10.3.6 contains the acceptance criteria used by the staff to evaluate FSAR Section 6.6 as it relates to the FAC program. The SRP indicates that conformance with Electric Power Research Institute (EPRI) NSAC 202L-R2, "Recommendations for an Effective Flow-Accelerated Corrosion Program," dated April 8, 1999, is adequate for this purpose and that the implementation of a FAC program consistent with EPRI NSAC 202L-R2 addresses staff concerns identified in GL 1989-008. The applicant has included a license condition to implement a FAC program before commercial service as outlined in Operational Programs Table 13.4-201, "Operational Programs Required by NRC Regulations," in FSAR Part 10, Section 3.6, "Operational Programs Readiness."

The staff reviewed the following information in the North Anna 3 COL FSAR:

- STD COL 5.2-1-A — Preservice and In-service Inspection Program Description

In FSAR Section 6.6, the applicant provided additional information in STD COL 5.2-1-A to address pressure testing for Class 2 and 3 components. The staff addresses this information in Section 5.2.4 of this SER including the limitations under 10 CFR 50.55a. The applicant states that system leakage and hydrostatic tests will meet all applicable requirements of ASME BPVC Section XI, IWA-5000, IWC-5000, and IWD-5000 for Class 2 and 3 components, including the limitations of 10 CFR 50.55a(b)(2)(xx) and 10 CFR 50.55a (b)(2)(xxvi).

The staff finds that Revision 1 to the North Anna 3 COL FSAR agrees with the limitations for pressure testing Class 1, 2, and 3 components in 10 CFR 50.55a and is therefore acceptable.

- STD COL 6.6-1-A — Preservice Inspection and In-service Inspection Program Information

The COL applicant provided a full description of the PSI/ISI programs and the augmented inspection programs for Class 2 and 3 components by supplementing the information in DCD Section 6.6. The COL applicant also provided milestones for program implementation in FSAR Section 13.4.

This COL item is addressed in the FSAR, in part, by replacing the last sentence and the parenthetical statement in the third paragraph of DCD Section 6.6 with the following:

> The PSI/ISI program description for Class 2 and 3 components and piping is provided in DCD Section 6.6.

A PSI/ISI program encompasses Class 1, 2, and 3 components and is evaluated in Section 5.2.4 of the staff's SER on the ESBWR DCD (NUREG–1966). Though Section 6.6

applies to Class 2 and 3 components, the augmented ISI programs that protect against postulated piping failures and the erosion/corrosion of piping include portions of the PSI/ISI programs and include Class 1 components. This topic is discussed in Section 5.2.4 of this SER. Since the staff evaluated the PSI/ISI program for Class 1, 2, and 3 components and the implementation milestones and finds them acceptable as discussed under Section 5.2.4 of this SER, the staff concludes that this portion of STD COL 6.6-1-A is acceptable for Section 6.6 of this SER. The augmented inspection program to address the applicant's FAC program is discussed below.

The staff previously documented its review of the applicant's FAC program in Section 10.3 of the Phase 2 North Anna SER (ADAMS Accession No. ML091520434) because its placement in SER Section 10.3.6 is consistent with the SRP, which provides the FAC acceptance criteria in SRP Section 10.3.6 as noted above. However, the staff has determined that the evaluation of the FAC program is more appropriately addressed in this Section of the SER because the FAC program is addressed in North Anna FSAR Section 6.6, ESBWR DCD Section 6.6, and NUREG-1966, Section 6.6.

STD COL 6.6-1-A also provides supplemental information related to the applicant's FAC program. The staff reviewed the information provided by the applicant in Section 6.6.7.1 of the North Anna 3 COL FSAR, which describes the FAC program. FSAR Section 6.6.7.1 also refers to FSAR Section 13.4 for program implementation milestones. Therefore, the staff also reviewed the information provided in FSAR Table 13.4-201, "Operational Programs Required by NRC Regulations."

On June 5, 2008, in RAI 10.03.06-1 and 10.03.06-2 (ADAMS Accession No. ML081580132) the staff requested detailed FAC program information (e.g., FAC program activities that will be conducted during the plant construction phase and the schedule for those activities) and requested that the applicant confirm (1) that the FAC program will include pre-service thickness measurements of the as-built components considered susceptible to FAC, and (2) that these measurements will use the grid locations and measurement methods most likely to be used for ISI according to industry guidelines. In its response dated July 14, 2008 (ADAMS Accession No. ML082050559), the applicant stated that the FAC program is considered an Operational Program under the ISI program listed in Table 13.4-201, "Operational Programs Required by NRC Regulations." The letter included a revised Table 13.4-201 that explicitly lists the FAC program under the ISI program in the FSAR with an implementation milestone of "prior to commercial service." The response also stated that during the construction phase, a comprehensive FAC susceptibility screening and preservice inspection of susceptible systems will be performed.

The applicant's response provided portions of a FAC program description the applicant had developed to address ESBWR DCD Revision 5, COL Item 6.6-1-A. The proposed description of the FAC program includes a statement that the North Anna 3 FAC program will be based on EPRI NSAC 202L-R2. The response also states that preservice, baseline, and NDE will be performed on as-fabricated components in susceptible systems and that these PSIs will use grid locations and measurement methods most likely to be used for ISIs.

The changes proposed in the applicant's response addressed the staff's concerns about the implementation activities and schedule by making the FAC program an explicit part of the operational programs. The proposed revision also addressed the staff concerns about PSI by adding a description of the PSI plan to the FSAR, including the affirmation that locations and measurement methods used for PSI will be those most likely to be used in subsequent inspections.

The staff reviewed the FAC program information provided in FSAR, Revision 1, Section 6.6.7.1 and Table 13.4-201 and confirmed that the proposed modifications in the applicant's July 14, 2008 RAI response were incorporated into the FSAR. The inclusion of the FAC program in Chapter 13 as an operational program addresses the concerns discussed above regarding PSI requirements. Therefore, the staff finds the information on the FAC program acceptable.

Based on the information described above, the staff finds that the FAC program is acceptable because it is consistent with the guidance provided in EPRI NSAC 202-L-R2 and addresses the concerns described in GL 1989-008 as they pertain to establishing an erosion-corrosion monitoring program. Therefore STD COL 6.6-1-A is acceptable.

- STD COL 6.6-2-A PSI/ISI NDE Accessibility Plan Description

The applicant replaced the last sentence in the second paragraph of the ESBWR DCD, Revision 5, with the following:

> During the construction phase of the project, anomalies and construction issues are addressed using change control procedures. Procedures require that changes to approved design documents, including field changes and modifications, are subject to the same review and approval process as the original design. Accessibility and inspectability are key components of the design process. Control of accessibility for inspectability and testing during licensee design activities affecting Class 2 and 3 components is provided via procedures for design control and plant modifications. Ultrasonic techniques (UT) will be the preferred NDE method for all PSI and ISI volumetric examinations; radiographic techniques (RT) will be used as a last resort only if UT cannot achieve the necessary coverage. The same NDE method used during PSI will be used for ISI to the extent possible to assure a baseline point of reference. If a different NDE method is used for ISI than was used for PSI, equivalent coverage will be achieved as required by the Code.

Accessibility of Class 1, 2, and 3 components, and the use of alternative NDE methods are discussed under Section 5.2.4 of this SER and, for the reasons stated in that section, are acceptable to the staff. Accordingly, STD COL 6.6-2-A is acceptable.

6.6.5 Post Combined Operating License Activities

In FSAR Table 13.4-201, the applicant provided the implementation milestones for the PSI/ISI programs. The staff's evaluation of the operational program aspects of the PSI and ISI programs for ASME Class 1, 2, and 3 components is described in Section 5.2.4 of this SER. As discussed in SER Section 5.2.4, the staff has identified the following license condition related to the PSI/ISI programs:

> <u>License Condition 5.2.4-1</u>
>
> The licensee shall submit to the Director of Office of New Reactors, NRC, or the Director's designee, a schedule, no later than 12 months after issuance of the COL, for implementation of the operational programs listed in FSAR Table 13.4-201. The schedule shall be updated every 6 months until 12 months

before scheduled fuel loading, and every month thereafter until the operational programs in the FSAR table have been fully implemented.

As stated in this SER, Section 5.2.4, the staff will inspect the North Anna 3 PSI and ISI programs during construction to ensure that the implementation of these operational programs will be consistent with the COL FSAR and the requirements of 10 CFR 50.55a.

6.6.6 Conclusion

The staff's findings related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirmed that the applicant has addressed the required information relating to PSI/ISI of Class 2 and 3 components and piping, and no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to "Preservice and in-service inspections and testing of Class 2 and 3 Components and Piping: that were incorporated by reference have been resolved.

In addition, the staff compared the information in the COLA to the relevant NRC regulations, the guidance in Section 6.6 of the SRP, and other NRC RGs. For the reasons set forth above, the staff concludes that the information to address COL Items 5.2.1-A, 6.6-1-A, and 6.6-2-A, as provided in Section 6.6 of the North Anna COL FSAR, meet the relevant guidelines in Sections 6.6 and 10.3.6 of the SRP and are therefore acceptable. Conformance with these guidelines provides an acceptable basis for satisfying, in part, the requirements of 10 CFR 50.55a and the guidance in GL 1989-008 in regard to PSI/ISI programs.

References

7.0 INSTRUMENTATION AND CONTROL SYSTEMS

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the NRC staff evaluation of the North Anna 3 Combined License (COL) specific detailed design and performance information for the instrumentation and control (I&C) systems for the Economic Simplified Boiling-Water Reactor (ESBWR). These systems help ensure the integrity of the reactor coolant pressure boundary, the capability to shut down the reactor and maintain it in a safe shutdown condition, and the capability to prevent or mitigate the consequences of anticipated operational occurrences and postulated accidents. They are significant for plant operation and are used throughout the plant. This chapter provides information on the systems and components that sense various reactor parameters and transmit signals to the control systems during normal operations and to the reactor trip and engineered safety features systems during abnormal and accident conditions. The I&C system for the ESBWR design is a distributed control and information system (DCIS). DCIS is designated as either safety-related DCIS (Q-DCIS) or nonsafety-related DCIS (N-DCIS). The Q-DCIS and N-DCIS functions include diverse power and sensors and diverse hardware and software architectures to significantly reduce the consequence of a potential software common cause failure in the primary I&C protection system.

The Q-DCIS includes the reactor protection system, the neutron monitoring system, the independent control platform, and the safety system logic and control for the emergency safety feature actuation system. The N-DCIS includes the diverse protection system, the balance of plant systems, the plant investment protection systems, the plant computer functions and workstations, and the severe accident mitigation system (deluge system).

Chapter 7 of the North Anna 3, COL Final Safety Analysis Report (FSAR), Revision 8, incorporates by reference, with no departures or supplements, Chapter 7, "Instrumentation and Control Systems," of Revision 10 of the Design Control Document (DCD) for the ESBWR, referenced in Appendix E to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." The NRC staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review. The staff's review confirmed that the COL application addressed the required information relating to the I&C systems, and there is no outstanding information expected to be addressed in the North Anna 3 COL FSAR related to this chapter. The NRC staff documented the results of its technical evaluation of the information incorporated by reference in the North Anna COLA in NUREG-1966, "Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-Water Reactor Standard Design," issued April 2014.

8.0 ELECTRIC POWER

8.0 ELECTRIC POWER

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides information on the functional adequacy of the offsite power systems and safety related onsite electric power systems as applicable to the Economic Simplified Boiling-Water Reactor (ESBWR) design proposed for North Anna 3 Combined License (COL). The electric power system is the source of power for station auxiliaries during normal operation and for the reactor protection system and engineered safety features during abnormal and accident conditions. The NRC staff's review of the electric power systems ensures that these systems have adequate redundancy, independence, and testability in conformance with the current criteria established by the NRC.

8.1 <u>Introduction</u>

8.1.1 Introduction

This section of the COL final safety analysis report (FSAR) describes the transmission grid and its interconnection to the nuclear unit and other grid interconnections. It describes those onsite alternating and direct current (ac and dc) loads that are added to the certified ESBWR design and the function provided by these loads.

The section also includes a regulatory requirements applicability matrix that lists design bases, criteria, regulatory guides (RGs), standards, and other documents to be implemented in the design of the electrical systems that are site specific to the North Anna 3 station. The review of this section is coordinated closely with the reviews described in Sections 8.2, 8.3.1, and 8.3.2, and 8.4 of this SER.

8.1.2 Summary of Application

Section 8.1 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 8.1 of Revision 10 of the Design Control Document (DCD) for the ESBWR, referenced in Appendix E to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants." In addition, in Part 7, "Departures Report," of the North Anna 3 COL application (COLA) and in FSAR Section 8.1, the applicant provided the following information:

<u>Exemption and Tier 1 and Tier 2 Departures</u>

- Exemption 2 — Electric Power Distribution System Functional Arrangement (Associated with NAPS DEP 8.1-1).

The applicant proposed the site-specific Tier 1 DCD departure from Figure 2.13.1-1, Sheet 1, *Electric Power Distribution System Functional Arrangement*.

In addition, the applicant has identified the following departure in FSAR Section 8.1.5.2.4 Regulatory Requirements – NRC Regulatory Guides:

- NAPS DEP 8.1-2 — Switchyard Surge Protection

The departure lists the subsections for which departures are taken from the Institute of Electrical and Electronics Engineers (IEEE) Standard (Std) C62.23, “Application Guide for Surge Protection of Electric Generating Plants” (as endorsed by RG 1.204, “Guidelines for Lightning protection of Nuclear Power Plants” issued November 2005), which is described in ESBWR DCD, Tier 2.

Supplemental Information

- NAPS SUP 8.1-1 Utility Power Grid Description

This supplemental information describes the connection of North Anna 3 to the 500/230-kilo Volt (kV) switchyard.

8.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, “Final Safety Evaluation Report Related to the Certification of the Economic Simplified Boiling-Water Reactor Standard Design,” issued April 2014, and it’s Supplement 1, issued September 2014. In addition, Section 8.1, “Electric Power—Introduction,” of NUREG 0800, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition” (SRP), includes the relevant regulatory requirements for the electric power systems (the transmission system and its connections to the nuclear power unit) and the associated acceptance criteria.

The NRC requirements governing the COLA supplemental information are in General Design Criterion (GDC) 17, “Electric power systems,” of Appendix A, “General Design Criteria for Nuclear Power Plants,” to Title 10 of the *Code of Federal Regulations* (10 CFR) Part 50, “Domestic Licensing of Production and Utilization Facilities.”

An applicant who seeks to depart from information in Tier 1 of a DCD for a certified standard design must request an exemption, as does an applicant who believes its proposed design need not comply with one or more NRC regulations. Exemptions are submitted pursuant to 10 CFR 52.7 and 52.93 and special circumstances as defined in 10 CFR 50.12(a) must be present.

8.1.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 8.1 of the certified ESBWR DCD. The staff reviewed Section 8.1 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to confirm that the combination of the information in the ESBWR DCD and the information in the COL FSAR represents the complete scope of information relating to the review topic.[1] The staff’s review confirmed that the information in the application and the information incorporated by reference includes all the information necessary for the review of this section, related to the North Anna 3 offsite power systems and safety-related onsite electric power systems.

[1] See *“Finality of Referenced NRC Approvals”* in SER Section 1.2.2 for a discussion on the staff’s review related to verification of the scope of information to be included in a COL application that references a design certification.

The staff reviewed the following information in the COLA Part 7, "Departures Report" and FSAR:

Exemption and Tier 1 and Tier 2 Departures

The applicant proposed the following site-specific Tier 1 exemption and departure in Part 7 of its license application.

- Exemption 2: Electric Power Distribution System Functional Arrangement (Associated with NAPS DEP 8.1-1).

In the on-site power supply system specified in DCD Tier 1, Figure 2.13.1-1, Sheet 1, "Electric Power Distribution System Functional Arrangement," the applicant made a departure from the DCD to accommodate, due to special constraints on the North Anna 3 site, an intermediate switchyard that does not change the functions performed by these components as part of the on-site power supply system for the ESBWR standard plant design.

The applicant provided the following in its description of this Tier 1 Exemption to the DCD:

> The addition of the intermediate switchyard to DCD Tier 1, Figure 2.13.1-1, Sheet 1, adds details regarding the site-specific design of the switchyard for Unit 3 and is consistent with this DCD figure in that it specifies the off-site normal and alternate preferred power supplies are in the switchyard area of the plant. This change more specifically identifies that some of the off-site normal preferred power supply is located in the site-specific intermediate switchyard. Adding the intermediate switchyard to the figure does not change the functions performed by the components shown on this figure and has no effect on how the functions are performed by the components.

In the North Anna 3 COLA, Revision 8, Part 7, "Departures Report," the applicant requested an exemption from the provisions of 10 CFR Part 52, Appendix E, Section III.B, "Design Certification Rule for the ESBWR Design, Scope and Contents," which requires an applicant referencing a certified design to incorporate by reference Tier 1 information. Specifically, in North Anna Part 7, Exemption 2, the applicant proposed to revise the ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1 to accommodate site space constraints by adding an intermediate switchyard to revise the location information for the main generator circuit breaker and the two motor-operated disconnects (MOD).[2]

Regulations

- 10 CFR Part 52, Appendix E, Section VIII.A.4 states that exemptions from Tier 1 information are governed by the requirements of 10 CFR 52.63(b) and 10 CFR 52.98(f). 10 CFR Part 52, Appendix E, Section VIII.A.4 also states that the Commission will deny such a request if it finds that the design change will result in a significant reduction in the level of safety otherwise provided by the design.

---

[2] *While the applicant describes the requested exemption as being from Section III.B of 10 CFR Part 52, Appendix E, the entirety of the exemption pertains to proposed departures from Tier 1 information in the generic DCD. In the remainder of this evaluation, the NRC will refer to the exemption as an exemption from Tier 1 information to match the language of Section VIII.A.4 of 10 CFR Part 52, Appendix E, which specifically governs the granting of exemptions from Tier 1 information.*

- 10 CFR Part 52.63(b)(1) allows an applicant to request NRC approval for an exemption from one or more elements of the certification information. The Commission may only grant such a request if it determines that the request complies with the requirements of 10 CFR 52.7, which, in turn, points to the requirements listed in 10 CFR 50.12 for specific exemptions, and if the special circumstances present outweigh the potential decrease in safety due to reduced standardization. Therefore, any exemption from the Tier 1 information certified by 10 CFR Part 52, Appendix E must meet the requirements of 10 CFR 50.12, 10 CFR 52.7, and 10 CFR 52.63(b)(1).

Evaluation of Exemption

As stated in 10 CFR Part 52, Appendix E, Section VIII.A.4, an exemption from Tier 1 information is governed by the requirements of 10 CFR 52.63(b)(1) and 52.98(f). Additionally, the Commission will deny an exemption request if it finds that the requested change to Tier 1 information will result in a significant decrease in safety. Pursuant to 10 CFR 52.63(b)(1), the Commission may, upon application by an applicant or licensee referencing a certified design, grant exemptions from one or more elements of the certification information, as long as the criteria given in 10 CFR 50.12 are met and the special circumstances as defined by 10 CFR 50.12 outweigh any potential decrease in safety due to reduced standardization.

Applicable criteria for when the Commission may grant the requested specific exemption are provided in 10 CFR 50.12(a)(1) and (a)(2). 10 CFR 50.12(a)(1) provides that the requested exemption must be authorized by law, not present an undue risk to the public health and safety, and be consistent with the common defense and security. The provisions of 10 CFR 50.12(a)(2) list six special circumstances for which an exemption may be granted. It is necessary for one of these special circumstances to be present in order for NRC to consider granting an exemption request. The applicant stated that the requested exemption meets the special circumstances of 10 CFR 50.12(a)(2)(ii). That subsection defines special circumstances as when "[a]pplication of the regulation in the particular circumstances would not serve the underlying purpose of the rule or is not necessary to achieve the underlying purpose of the rule." The staff's analysis of each of these findings is presented below. Although the applicant requested an exemption from 10 CFR Part 52, Appendix E, Section III.B, the NRC is treating the requested exemption as one from ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, since the applicant is seeking to depart from the information reflected on that figure.

Authorized by Law

This exemption would allow the applicant to implement approved changes to Tier 1 information. This is a permanent exemption limited in scope to particular Tier 1 information, and subsequent changes to this Tier 1 information or any other Tier 1 information would be subject to full compliance by the applicant as specified in 10 CFR Part 52, Appendix E, Section VIII.A.4. As stated above, 10 CFR 52.63(b)(1) allows the NRC to grant exemptions from one or more elements of the certification information, namely, Tier 1. The staff determined that granting of the applicant's proposed exemption will not result in a violation of the Atomic Energy Act of 1954, as amended, or NRC regulations. Therefore, as required by 10 CFR 50.12(a)(1), the exemption is authorized by law.

No Undue Risk to Public Health and Safety

The underlying purpose of ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, is to identify the standard ESBWR switchyard layout and configuration that will function in a manner the NRC has determined satisfied NRC requirements. The addition of an intermediate switchyard supports the system's intended design functions and does not affect the offsite power system compliance with GDC 17, since the intermediate switchyard is simply an additional space used to hold the plant's output breakers from the plant generator and introduces no new failure modes. The plant-specific Tier 1 DCD will continue to reflect the approved licensing basis for the applicant and will maintain a level of detail consistent with that which is currently provided elsewhere in Tier 1 of the plant-specific DCD. The affected design description in the plant-specific Tier 1 DCD will continue to provide the detail necessary to support the performance of the associated inspection, test, analysis, and acceptance criterion (ITAAC). Therefore, the staff finds the exemption presents no undue risk to public health and safety as required by 10 CFR 50.12(a)(1).

Consistent with Common Defense and Security

The proposed exemption would allow the applicant to implement modifications to the Tier 1 information requested in the applicant's submittal. This is a permanent exemption limited in scope to particular Tier 1 information. Subsequent changes to this Tier 1 information or any other Tier 1 information would be subject to full compliance by the applicant as specified in 10 CFR Part 52, Appendix E, Section VIII.A.4. This change is not related to security issues. Therefore, as required by 10 CFR 50.12(a)(1), the staff finds that the exemption is consistent with the common defense and security.

Special Circumstances

Special circumstances, in accordance with 10 CFR 50.12(a)(2)(ii), are present whenever application of the regulation in the particular circumstances would not serve the underlying purposes of the rule or is not necessary to achieve the underlying purpose of the rule. The underlying purpose of the specific ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, is to identify the standard ESBWR switchyard layout and configuration that will function in a manner the NRC has determined satisfies NRC requirements. This site-specific change modifies the standard design to accommodate physical space constraints on the North Anna 3 site for the switchyard. The intermediate switchyard configuration in the requested exemption will continue to perform its intended function and will, therefore, meet the underlying purpose of the rule. Accordingly, special circumstances are present because the certified design information in ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, is not necessary to achieve the underlying purpose of the rule in view of the space constraints on the North Anna 3 switchyard. Therefore, the staff finds that special circumstances required by 10 CFR 50.12(a)(2)(ii) for the granting of an exemption from Tier 1 exist.

Special Circumstances Outweigh Reduced Standardization

This exemption would allow the applicant to change certain ESBWR DCD, Tier 1 information proposed in the North Anna 3 COLA in view of site-specific space constraints. The key design functions of the switchyard will nonetheless be maintained, based on the nature of the proposed changes to the generic ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, and the understanding that these changes support the design function of the switchyard. However, this exemption request and the associated changes to North Anna 3 COLA Tier 1 information demonstrate that there is a minimal change from the standard information provided in the ESBWR DCD. Consequently, the decrease in safety due to reduced standardization would also be minimal. For this reason, the staff determined that even if other ESBWR licensees and applicants do not request similar departures, the special circumstances outweigh the potential decrease in safety due to reduced standardization of the ESBWR design, as required by 10 CFR 52.63(b)(1).

No Significant Reduction in Safety

The proposed exemption would not modify the function of the North Anna 3 switchyard from that described in the ESBWR DCD. Therefore, the staff finds that granting the exemption would not result in a significant decrease in the level of safety otherwise provided by the design, as required by 10 CFR Part 52, Appendix E, Section VIII.A.4.

Conclusion

For the reasons set forth above, the staff has concluded that pursuant to 10 CFR Part 52, Appendix E, Section VIII.A.4, the exemption: (1) is authorized by law; (2) presents no undue risk to the public health and safety; (3) is consistent with the common defense and security; (4) has special circumstances that outweigh the potential decrease in safety due to reduced standardization; and (5) does not significantly reduce the level of safety at the licensee's facility. Therefore, the staff finds that the applicant's request to depart from the information in ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, is acceptable, and the applicant's request for an exemption from these Tier 1 requirements is granted.

Tier 2 Departure

- NAPS DEP 8.1-2 Switchyard Surge Protection

The applicant identified specific sections of IEEE Standard. C62.23 concerning switchyard surge protection with which the switchyard design is not in conformance. Use of this standard is one of the recommendations of RG 1.204. On August 4, 2008, in a Request for Additional Information (RAI) 08.02-61, (Agencywide Documents Access and Management System (ADAMS) Accession Number No. ML11195A365), the staff requested the specific bases for the non-conformance. In its response to RAI 08.02-61 on September, 16, 2011 (ADAMS Accession No. ML11264A130), the applicant addressed each subsection of the standard for which an exception was taken.

The staff reviewed each exception and concurred with the applicant that either the subsection did not apply or that the measures taken provided equivalent protection, as described in the following table.

IEEE Standard.C62.23 Section	Title	Staff Finding
4.3.5	Shielding	This section recommends shielding of distribution lines. The proposed design has one line (342) that fits this description. Instead of shielding the line, the proposed design provides equivalent protection by using multiple metal oxide surge arrestors at the 34.5 kV switchyard interconnection.
5.3.2	Incoming Surges	This section references a paper that discusses alternate wiring practices when redesigning a chemical plant. This provision is not applicable.
5.3.2.1	Control Systems	This section recommends circuit separation based upon voltage level in order to prevent coupling between power cables and low voltage, low energy digital and analog instrument and control (I&C) circuits. The proposed design provides equivalent protection by shielding the cables as power cable voltages in the switchyard are limited to either 120 Vac or 125 Vdc.
5.3.3.1	Control Systems	This section recommends creating a separate radial ground system for control and instrumentation circuits to minimize electrical noise. The proposed design provides equivalent protection by using grounded messenger cables in parallel with cable runs and using grounded, shielded cable in control circuits.
5.3.3.2	Communications Systems	This section recommends gathering communication circuit grounds on a communication backboard and then connecting the grouping to ground with a single insulated ground wire. The proposed design provides equivalent protection by using a non-insulated ground wire that does not touch any other circuit.
5.3.3.3	Electrostatic Discharge	This section recommends using anti-static flooring material or some other equivalent to prevent static discharge between humans and equipment. The proposed design provides equivalent protection by using concrete floors with grounded racks and equipment cabinets grounded to the racks.
5.3.4.1	Communication and Power Circuit Coupling	This section recommends methods for reducing field coupling between parallel cables. The proposed design provides equivalent protection by using shielded control cable with messenger cables from switchyard components to the control house. Within the control house, shielded cable is used and fiber optics is used from the data collectors to point’s offsite.

IEEE Standard.C62.23 Section	Title	Staff Finding
5.3.4.2	Lightning-induced Voltages in Control Cables	This section recommends use of telecommunication cables with grounded sheaths and grounding of both ends of unused conductors. The proposed design provides equivalent protection by using shielded control cables with messenger cables from switchyard components and grounds both ends of the cable shields when run with the messenger cables.
5.3.5.2	Sources of Interference	This section identifies sources of noise that can radiate or be induced into switchyard cables and equipment. However, no specific recommendations are provided. The proposed design addresses this problem by the techniques discussed above by employing a combination messenger cable/shielded cable and continuously grounded open racks to minimize signals induced into the system.
5.3.5.6.2. a)	Single Point Guidelines for a Multipoint Grounding System	This subsection recommends wiring for computer equipment, communications and control systems within a control house to be connected to a multipoint ground system in only one place. The proposed design provides equivalent protection by using shielded cable run in a grounded tray with continuous grounding along the floor and ceiling and around the racks.

Therefore, the applicant has adequately addressed the provisions of IEEE Std. C62.23, and the staff finds that this issue is acceptably resolved.

Supplemental Information

- NAPS SUP 8.1-1 Utility Power Grid Description

The staff reviewed the supplemental information provided by the applicant to modify Section 8.1.2.1, “Utility Power Grid Description.” The applicant provided the following supplement to Section 8.1.2.1:

> The output of Unit 3 is delivered to a main 500/230 kV switchyard through the unit main step-up transformers, and an intermediate switchyard. The main switchyard serves four 500 kV lines and one 230 kV line. The plant is connected to the main switchyard by a 500 kV normal preferred transmission line, and a 230 kV alternate preferred transmission line that supplies power to the two reserve auxiliary transformers.

The staff finds that the applicant has adequately described the North Anna 3 connection to the utility grid. In addition, the staff has determined the switchyard is connected to the grid by at least two separate circuits. Therefore, the staff finds that the connection conforms to the requirements of GDC 17.

8.1.5 Post Combined License Activities

There are no post COLA activities related to this section.

8.1.6 Conclusion

As described in detail above, the Tier 1 departure requiring an exemption as described in North Anna 3 Part 7, Exemption 2, “Electric Power Distribution System Functional Arrangement,” is acceptable because pursuant to 10 CFR Part 52, Appendix E, Section VIII.A.4, the exemption: (1) is authorized by law; (2) presents no undue risk to the public health and safety; (3) is consistent with the common defense and security; (4) has special circumstances that outweigh the potential decrease in safety due to reduced standardization; and (5) does not significantly reduce the level of safety at the licensee’s facility. Therefore, the staff finds that the applicant’s request to depart from the information in ESBWR DCD, Tier 1, Figure 2.13.1-1, Sheet 1, is acceptable, and the applicant’s request for an exemption from these Tier 1 requirements is granted.

The staff’s finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff finds that the application includes all the information relevant to the North Anna 3 offsite power systems and safety-related onsite electric power systems, and the staff confirmed that no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, “Design Certification Rule for the Economic Simplified Boiling-Water Reactor,” Section VI.B.1, all nuclear safety issues relating to the transmission system and its connections to the nuclear power unit that were incorporated by reference are resolved.

In addition, as set forth above, the staff compared the additional COLA supplemental information in the application to the relevant NRC regulations, the guidance in SRP Section 8.1, and other NRC RGs. For the reasons set forth above, the staff concludes that the applicant has provided sufficient information to satisfy the requirements of GDC 17 for this section.

8.2 <u>Offsite Power System</u>

8.2.1 Introduction

This section of the North Anna 3 FSAR describes analyses and referenced documents that include electrical single-line diagrams, electrical schematics, logic diagrams, tables, and physical arrangement drawings for the offsite power system. Industry standards and RGs refer to the offsite power system as the “preferred power system.” The offsite power system should include two or more physically independent circuits capable of operating independently of the onsite standby power sources. The system encompasses the grid, transmission lines (overhead or underground), transmission line towers, transformers, switchyard components and control systems, switchyard battery systems, the main generator, generator circuit breakers, disconnect switches, and other switchyard equipment, such as capacitor banks and volt amperes reactive compensators. The system supplies electric power to safety-related and other equipment.

- The ESBWR passive reactor design used at North Anna 3 minimizes the potential risk contribution of a station blackout (SBO) (loss of all ac power) by not crediting ac power sources for design-basis events for 72 hours. The plant's safety-related passive systems automatically establish and maintain safe-shutdown conditions for the plant following design-basis events, including the extended loss of ac power sources. The passive systems can maintain these safe-shutdown conditions after design-basis events for 72 hours without operator action, following loss of both onsite and offsite ac power sources. As described in the ESBWR DCD, for the standard design for off-site power systems that are not safety related, GDC 5, "Sharing of Structures, Systems, and Components" and GDC 18, "Inspection and Testing of Electric Power and Protective Systems" are not applicable; however, the nonsafety-related offsite and onsite ac systems that supply ac power to the isolation power centers are testable and meet GDC 18 requirements. In addition, the ESBWR Preferred Power Supply (PPS) complies with GDC 17 requirements for two physically independent and separate offsite power circuits, each with the capacity and capability to power equipment during design basis operating modes (plant start-up, normal operation, safe shutdown, accident, and post-accident operation).

8.2.2 Summary of Application

Section 8.2 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 8.2 of the ESBWR DCD, Revision 10.

In addition, in FSAR Section 8.2, the applicant provided site-specific supplemental information to resolve COL Items 8.2.4-1-A through 8.2.4-10-A. The applicant adds the following site-specific supplemental information:

COL Items

- NAPS COL 8.2.4-1-A Transmission System Description

In FSAR Section 8.2.1.1, the applicant provided detailed information on the designs of the plant site 500 kV switchyard, the four 500 kV and one 230 kV transmission lines connecting the plant switchyard to Dominion's transmission system, and the interface of the switchyard with the transmission grid. The applicant provided Figures 8.2-201 through 8.2-203, which show a one-line diagram of the electrical system from the switchyard to the onsite electrical system, physical arrangement of the offsite power source, and a map of offsite transmission lines, respectively.

- NAPS COL 8.2.4-3-A Normal Preferred Power
- NAPS COL 8.2.4-4-A Alternate Preferred Power

The applicant provided additional information in FSAR Section 8.2.1.2, "Offsite Power System," describing details of normal preferred power and alternate preferred power including an arrangement drawing (Figure 8.2-202).

- NAPS COL 8.2.4-2-A Switchyard Description
- NAPS COL 8.2.4-6-A Switchyard DC Power
- NAPS COL 8.2.4-7-A Switchyard AC Power
- NAPS COL 8.2.4-8-A Switchyard Transformer Protection
- NAPS DEP 8.1-2 Switchyard Surge Protection

The applicant provided additional information in FSAR Section 8.2.1.2.1, “Switchyard,” that described details of the switchyard, switchyard dc and ac power, switchyard transformer protection, and switchyard surge protection and included tables on capacities of switchyard components.

- NAPS COL 8.2.4-5-A Protective Relaying

The applicant provided new information in Section 8.2.1.2.2 that specifically addresses the monitoring of the unit auxiliary transformers (UAT) and reserve auxiliary transformers (RAT) for open circuit conditions as discussed in NRC Bulletin 2012-01, “Design Vulnerability in Electric Power System,” (ADAMS Accession No. ML12074A115). Section 8.2.1.2.3 describes the existing relay schemes that protect the 500 kV transmission lines, switchyard buses, generating unit tie-line, and auxiliary transformers.

[NOTE: The applicant added information concerning the subject of Bulletin 2012-01 in Section 8.2.1.2.2 and renumbered Sections 8.2.1.2.2 and 8.2.1.2.3 as 8.2.1.2.3 and 8.2.1.2.4, respectively.]

- NAPS COL 8.2.4-9-A Stability and Reliability of the Offsite Transmission Power System

- NAPS COL 8.2.4-10-A Interface Requirements

The applicant provided additional information in FSAR Section 8.2.2.1, “Reliability and Stability Analysis,” describing details of a transmission system study performed regularly to verify grid stability, switchyard voltage, and frequency. The purpose of the study was to confirm the transmission system capability and demonstrate formal agreement between the control room and the transmission operator.

Supplemental Information

- NAPS SUP 8.2-1 Bulletin 2012-01

In FSAR Section 8.2.1.2.2, the applicant provided commitments for developing procedures and training for the operations and maintenance staff in support of the transformer open circuit monitoring system.

- NAPS SUP 8.2-2 Testing and Inspection

The applicant provided FSAR Section 8.2.1.2.4, “Testing and Inspection,” which gives details of testing and inspection of the switchyard components.

- NAPS SUP 8.2-3 Failure Mode and Effects Analysis

The applicant provided FSAR Section 8.2.2.3, “Failure Modes and Effects Analysis,” which describes details of the failure modes and effect analysis of transmission system, switchyard, and intermediate switchyard components.

8.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the final safety evaluation report (FSER) related to the ESBWR DCD and NUREG–1966, Supplement 1, FSER related to the Certification of the ESBWR Standard Design, Supplement 1. In addition, the relevant requirements of the Commission regulations for the offsite power system and the associated acceptance criteria are in SRP Section 8.2.

The NRC requirements governing the COL supplemental information are in GDC 17 of Appendix A to 10 CFR Part 50, and specifically, as follows:

- for NAPS COL 8.2.4-1-A, the requirements of GDC 17
- for NAPS COL 8.2.4-3-A and 8.2.4-4-A, the requirements of GDC 17
- For NAPS COL 8.2.4-2-A, 8.2.4-6-A, and 8.2.4-7-A, the requirements of GDC 17 and GDC 5
- for NAPS COL 8.2.4-5-A and 8.2.4-8-A, the requirements of GDC 17
- for NAPS COL 8.2.4-9-A and 8.2.4-10-A, the requirements of GDC 17
- For NAPS SUP 8.2-1, the requirements of GDC 17
- for NAPS SUP 8.2-2, the requirements of GDC 18

The guidance and specific acceptance criteria that apply to the supplemental information are as follows:

- For NAPS COL 8.2.4-9-A and 8.2.4-10-A, the guidelines of RG 1.206, "Combined License Applications for Nuclear Power Plants (LWR Edition)"; Branch Technical Position (BTP) 8-3, "Stability of Offsite Power Systems"; BTP 8-6, "Adequacy of Station Electric Distribution System Voltages"; RG 1.160, "Monitoring the Effectiveness of Maintenance at Nuclear Power Plants"
- For NAPS SUP 8.2-2, the guidelines of RG 1.118, "Periodic Testing of Electric Power and Protection Systems"
- For NAPS SUP 8.2-3, the guidelines of RG 1.206

8.2.4 Technical Evaluation

As documented in NUREG–1966 and NUREG–1966, Supplement 1, the staff reviewed and approved Section 8.2 of the ESBWR DCD. The staff reviewed Section 8.2 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to ensure that the combination of the information in the ESBWR DCD and the information in the COL FSAR represents the complete scope of information relating to this review topic.[1]

The staff's review confirmed that the information in the application and the information incorporated by reference include all the information relevant to the offsite power system.

The staff reviewed the following information in the COL FSAR:

<u>*COL Items*</u>

- NAPS COL 8.2.4-1-A Transmission System Description

The applicant provided additional information in NAPS COL 8.2.4-1-A to address COL Item 8.2.4-1-A. The applicant stated that the following replaces DCD Section 8.2.1.1:

> NAPS, that is, Units 1, 2, and 3, is connected to the Dominion transmission system by four 500 kV lines and one 230 kV line. The lines are designed and located to minimize the likelihood of simultaneous failure. The Unit 3 main generator feeds electric power through a 27 kV isolated phase bus to a bank of three single phase transformers, stepping the generator voltage up to the transmission voltage of 500 kV. Figure 8.2-201 provides a one-line diagram of the electric system from the switchyard to the onsite system. The transmission lines and towers connecting the switchyard to the transmission system are as follows:
>
> - Two 500 kV overhead lines to the Ladysmith substation (approximately 15 miles)
> - A 500 kV overhead line to the Midlothian substation (approximately 41 miles)
> - A 500 kV overhead line to the Morrisville substation (approximately 33 miles)
> - A 230 kV overhead line to the Gordonsville substation (approximately 31 miles)
>
> Two Ladysmith lines utilize a common right-of-way. Each of the other lines utilizes separate right-of-way. The 230 kV Gordonsville line crosses under the 500 kV Ladysmith and Morrisville lines near the switchyard.

The applicant stated that transmission tower separation, line installation, and clearances are consistent with the National Electric Safety Code (NESC) and Dominion transmission line standards. Adequate clearance exists between wire galloping ellipses to minimize conductor or structural damage.

The staff's review of FSAR Chapter 8, Figure 8.2-201, indicated a discrepancy with the corresponding DCD Revision 4, Figure 8.1-1. Figure 8.1-1 showed the main generator circuit breaker as part of the onsite power system, while Figure 8.2-201 showed the same breaker as being in the intermediate switchyard. Also, in Figure 8.1-1, the main transformer and UATs are connected at the high-voltage side of the main transformer; however, in Figure 8.2-201, UATs high-side voltage is 230 kV, and the main transformer's high-side voltage is 500 kV. It was not clear how the connection can be made with different voltages. On June 13, 2008, the staff issued RAI 08.02-1 (ADAMS Accession No. ML081650433), the staff asked the applicant to clarify the apparent discrepancies. In the response letter dated July 28, 2008, to RAI 08.2-1 (ADAMS Accession No. ML082170400), the applicant stated that the main generator circuit breaker is physically located in the NAPS intermediate switchyard. The applicant stated that it will revise FSAR Figure 8.2-201 to remove the main generator circuit breaker symbol from the figure and will add a note to clarify the interface between DCD Figure 8.1-1 and FSAR Figure 8.2-201. The applicant stated that at North Anna 3, the high-voltage side of the UATs and RATs will be at 230 kV and generator step-up transformers will be at 500 kV on the high side. Because of this, a 500/230 kV transformer bank will be located in the intermediate switchyard to step down 500 kV to 230 kV for use by the UATs, as depicted in FSAR Figure 8.2-201. The applicant added a note to FSAR Figure 8.2-201 to clarify that equipment on the offsite power portion of FSAR Figure 8.2-201 replaces equipment on the offsite power portion of DCD Figure 8.1-1. This Tier 1 departure was evaluated as an exemption above and was determined to be acceptable to the staff. Therefore as described in Section 8.1.6 of this SER, the staff finds that the applicant has adequately addressed the staff's question. The staff confirmed that these changes are incorporated in FSAR Revision 8, and the note to the figure was removed and the issue is resolved.

The staff finds that the information the applicant provided in response to COL Item 8.2-4-1-A conforms to the requirements of GDC 17.

- NAPS COL 8.2.4-3-A Normal Preferred Power
- NAPS COL 8.2.4-4-A Alternate Preferred Power

The applicant provided additional information in North Anna 3 COL 8.2.4-3-A and 8.2.4-4-A to address COL Items 8.2.4-3-A and 8.2.4-4-A. The applicant stated that it has replaced the first and second paragraph of DCD Section 8.2.1.2 with the following:

> The offsite power system is a non-safety-related system. Power is supplied to the plant from multiple independent and physically separate offsite power sources.
>
> The normal preferred power source is any one of the four 500 kV lines, and the alternate preferred power source is any one of the other three 500 kV lines.
>
> The normal preferred power source is supplied to the UATs through the intermediate transformer, MODs [motor operated disconnect] and isolation circuit breakers. The normal preferred power interface with offsite power system occurs at the high voltage terminals of the main generator circuit breaker MOD and UAT MODs. The MOD feeding a faulted UAT will be opened after the UAT high voltage breaker opens.

On June 13, 2008, the staff issued RAI 08.02-2 (ADAMS Accession No. ML081650433), requesting the applicant provide a discussion of the routing of control and instrumentation cables, and miscellaneous power cables associated with normal and alternate preferred circuits, between the switchyard and the power block. In the response letter dated July 28, 2008, to RAI 08.02-2 (ADAMS Accession No. ML082170400), the applicant stated that adequate separation is ensured either by routing cables associated with the normal preferred circuit in a duct bank separate from cables associated with the alternate preferred circuit, or by routing these cables in separate conduits within the same duct bank. The applicant revised FSAR Section 8.2.1.2 to add a description of the routing of control, instrumentation, and miscellaneous power cables. Because normal I&C cables and power cables associated with those I&C circuits will be in duct banks separate from those for the alternate circuits, or will be in separate conduits in the same duct bank, the staff finds that the applicant has adequately addressed the issue of cable separation. The staff confirmed that these changes are incorporated in FSAR Revision 8, and the issue is resolved.

Since underground cables are susceptible to moisture, on June 13, 2008, the staff issued RAI 08.02-4 (ADAMS Accession No. ML081650433), requesting the applicant identify the design features and/or in situ monitoring programs that it will use to monitor the degradation of the cable from the effects of moisture. In the response letter dated July 28, 2008, to RAI 08.02-4 (ADAMS Accession No. ML082170400), the applicant stated that the normal preferred power supply and alternate preferred power supply both use 230 kV underground cable. The applicant stated further that it would periodically monitor cable insulation for underground medium-voltage and high-voltage cable to detect potential cable degradation from moisture intrusion using one of the following methods or an equivalent: partial discharge testing, time domain reflectometry, dissipation factor testing, or very-low-frequency ac testing. On the basis of its review, the staff determined that the applicant did not address the testing frequency. Additionally, the staff determined that testing alone is not sufficient.

The manholes should be inspected every 6 months for water accumulation, and adequate corrective actions (increased inspection frequency) should be taken if water accumulation is found, as required by the maintenance rule 10 CFR 50.65 and as recommended by RG 1.160. Furthermore, the staff needed technical justification for using one of the testing methods indicated above to detect potential high-voltage (230 kV) cable degradation.

On October 16, 2008, the staff issued RAI 08.02-29 (ADAMS Accession No. ML082900201), requesting the applicant to address these issues. In the response letter dated December 1, 2008, to RAI 08.02-29 (ADAMS Accession No. ML083390401), the applicant stated that these 230 kV underground cables in duct banks have a metallic sheath to prevent moisture ingress into the cable insulation. The applicant indicated that it would inspect manholes associated with these duct banks every 6 months for excessive accumulation of water, and would take corrective actions (such as increased inspection frequency), as required by the maintenance rule, 10 CFR 50.65, if excessive water accumulation is found. Duct bank inspection on a 6-month frequency allows for the evaluation of performance and condition monitoring activities every refueling outage, as required by 10 CFR 50.65(a)(3). Accordingly, the applicant has adequately addressed this issue. The staff confirmed that the applicant has revised COL FSAR Section 8.2.1.2 to add manhole inspections for water accumulation in Revision 8 of the FSAR.

Since these 230 kV underground cables are part of the design that satisfies the GDC 17 requirement for having two circuits from the transmission network to the onsite power distribution system, these circuits fall under the requirements of 10 CFR 50.65(a)(1) of the maintenance rule. The staff confirmed that COL FSAR Section 17.6.4 provides the following statement:

> Condition monitoring of underground or inaccessible cables is incorporated into the maintenance rule program. The cable condition monitoring program incorporates lessons learned from industry operating experience, addresses regulatory guidance, and utilizes information from detailed design procurement documents to determine the appropriate inspections, tests and monitoring criteria for underground and inaccessible cables within the scope of the maintenance rule (10 CFR 50.65).

Given that 10 CFR 50.65, "Maintenance Rule," applies for these cables, and the applicant's Maintenance Rule Program is adequate as described in Section 17.6.4 of this SER, further response is not needed for this review. On this basis, the staff finds that the 230 kV underground cables will be included as required by the maintenance rule in a cable condition monitoring program, the cables are monitored for degradation and subsequent action can be taken, if necessary. Accordingly, the issue is resolved.

The FSAR Section 8.2.1.2.1 notes that the 500 kV transmission line rated current is 3,954 amps and the 500 kV bus is rated as 3,891 amps. On June 13, 2008, the staff issued RAI 08.02-5 (ADAMS Accession No. ML081650433), requesting the applicant to explain why the bus rating is less than the transmission line rating and clarify the actual loading of the line and bus. In the response letter dated July 28, 2008, to RAI 08.02-5 (ADAMS Accession No. ML082170400), the applicant stated that transmission line loading (normal loading and emergency loading) is well below the bus rating. Additionally, both Dominion and the Pennsylvania, New Jersey, and Maryland Interconnection (PJM) perform periodic studies to verify that bus work and transmission lines can be operated within their rating. Since transmission line loading (normal loading and emergency loading) is below the bus rating in the switchyard, the staff finds the applicant's response adequate, and this issue is resolved.

Since all North Anna units share the same switchyard, the offsite power system provided for the site should have sufficient capacity and capability to safely shut down all units. As documented in NRC generic communications (e.g., NRC Generic Letter (GL) 07-01, "Inaccessible or Underground Power Cable Failures That Disable Accident Mitigation Systems or Cause Plant Transients," dated February 7, 2007; NRC Information Notice (IN) 98-07, "Offsite Power Reliability Challenges from Industry Deregulation," dated February 27, 1998; and NRC IN 95-37, "Inadequate Offsite Power Voltages During Design-Basis Events," dated September 7, 1995), operational experience has shown the need to demonstrate that the offsite power system operation supports equipment important to safety and avoids plant transients. In addition, NRC GL 06-02, "Grid Reliability and the Impact on Plant Risk and the Operability of Offsite Power," dated February 1, 2006, states that, "For nuclear plants licensed in accordance with the GDC in Appendix A to 10 CFR Part 50, the design criteria for onsite and offsite electrical power systems are provided in GDC 17…which requires, among other things, that an offsite electric power system be provided to permit the functioning of certain structures systems and components (SSCs) important to safety in the event of anticipated operational occurrences."

On July 9, 2008, the staff issued RAI 08.02-28 (ADAMS Accession No. ML081910316), requesting that the applicant discuss the capacity and capability of the offsite system (i.e., the 500 kV lines and associated switchyard equipment) to mitigate the consequences of anticipated abnormal operational occurrences associated with unit operation. In the response letter dated August 21, 2008 (ADAMS Accession No. ML083470290), the applicant deferred its technical response to within 45 days following the General Electric Hitachi Nuclear America, LLC (GEH) response to DCD RAI 14.3-394, to ensure that the response was consistent and complete.

GEH submitted their responses to DCD RAI 14.3-394 on August 27, 2008 (ADAMS Accession No. ML082420291), and DCD RAI 14.3-394 S01 on December 9, 2008 (ADAMS Accession No. ML083470290). The applicant provided its subsequent response to RAI 08.02-28 on November 19, 2008 (ADAMS Accession No. ML083260325). The applicant stated in its response as follows: The switchyard for North Anna Power Station was evaluated under a system impact study (SIS) for interconnection of Unit 3 by PJM, the regional transmission operator (RTO). The SIS was performed to verify load flow capability, short-circuit capability, and system stability of the local transmission system in the vicinity of the North Anna 3 switchyard. The study was performed in accordance with North American Electric Reliability Corporation (NERC) criteria. The applicant stated that this level of detail meets the specific requirements of the RTO and ensures that the local transmission system, including the North Anna 3 switchyard, will be a reliable power source. The applicant also stated that the SIS recommended specific upgrades to the transmission system to ensure that PJM interconnection criteria are met with the interconnection of North Anna 3. In the SIS, PJM concludes that the transmission system is capable of accepting the interconnection of North Anna 3 and of operating with the transmission system contingencies evaluated. The evaluation covers NERC contingency classes A, B, and C, where class A assumes all facilities in service function normally, class B considers the loss of any single element of the grid, and class C considers events resulting in the loss of two or more grid elements. The applicant includes in Part 10, “ITAAC” Table 2.4.8-1 of the COLA specific analysis to confirm these offsite interfaces would remain current for North Anna 3 prior to plant operation. The staff reviewed the ITAAC, and finds that it specifies analyses adequate to verify that the as-built offsite interfaces continue to function properly under the NERC contingency classes.

Furthermore, the applicant notes that the DCD does not state the limits for voltage and frequency variation that need to be met by site-specific offsite power systems, as stated in the DCD, “the COL Applicant is responsible for the interface protocol requirements (COL 8.2.4-10-A).” The staff observes that this interface requirement does not set specific electrical characteristics for offsite power systems. The applicant indicated further that it would analyze the as-built onsite power system to determine the maximum load during all operating modes. The applicant stated that these analyses will, in part, specify maximum power, voltage, frequency, and interrupting capability necessary for the offsite power system to support safety-related load operation during all operating modes. These analyses will be re-evaluated as part of a site-specific ITAAC (see Section 14.3 of this SER) and will ensure that each as-built offsite circuit has sufficient capacity and capability. Because the applicants SIS evaluation and the required re-evaluation as part of the North Anna 3 ITAAC requirements in Part 10, Table 2.4.8-1 of the COLA are together sufficient to establish the electrical performance of the offsite power system described above, the staff finds that the applicant has addressed the issue adequately, and the issue is resolved.

For the reasons stated above, and since the offsite circuit interface with the onsite portions of the preferred power supply is adequately rated to supply the load credited during design basis operating modes (as described in DCD ITAAC Table 2.13.1-2, Item 9), the staff finds that the information the applicant provided in response to COL Items 8.2.4-3-A and 8.2.4-4-A conforms to the requirements of GDC 17 and is therefore acceptable.

- NAPS COL 8.2.4-2-A — Switchyard Description
- NAPS COL 8.2.4-6-A — Switchyard DC Power
- NAPS COL 8.2.4-7-A — Switchyard AC Power

The applicant provided additional information in North Anna 3 COL 8.2.4-2-A, 8.2.4-6-A, and 8.2.4-7-A to address COL Items 8.2.4-2-A, 8.2.4-6-A, and 8.2.4-7-A. The applicant replaced the last paragraph of DCD Section 8.2.1.2.1, in part, with the following:

> The NAPS switchyard, prior to the point of interconnection with Unit 3, is a 500/230 kV, air-insulated, breaker-and-a-half bus arrangement Unit 3 is connected to this switchyard by an overhead conductor circuit.
>
> The physical location and electrical interconnection of the switchyard is shown on Figures 8.2-201 and 8.2-202.
>
> The North Anna switchyard uses surge suppressors on the high and low sides of Transformers 1, 2, 3, 5, and 6 to protect equipment from voltage surges, including lightning events. The insulation coordination and surge protective devices are applied in compliance with IEEE 1313.2 (Reference 8.2-205) and IEEE C62.22 (Reference 8.2-206). The surge protective devices are maintained according to NEMA requirements and manufacturer's recommendations.

The FSAR Revision 1, Chapter 1, Table 1.9-201, "Conformance with Standard Review Plan," for SRP Section 8.2, indicated that GDC 5 is not applicable. DCD Revision 4, Section 8.2.2.2 stated that the ESBWR reference plant is designed as a single-unit plant, and therefore, GDC 5 is not applicable. However, the staff noted that the North Anna 3 switchyard is shared with Units 1 and 2 and, therefore, on June 13, 2008, the staff issued RAI 08.02-16 (ADAMS Accession No. ML081650433), requesting the applicant to clarify the applicability of and conformance with GDC 5. In the response letter dated July 28, 2008, to RAI 08.02-16 (ADAMS Accession No. ML082170400), the applicant stated that the North Anna switchyard is not important to safety for North Anna 3, and thus, GDC 5 is not applicable. The staff agrees that GDC 5 related to sharing SSCs important to safety is not applicable and that the switchyard as well as the grid connections are not safety-related class 1E components that provide safety-related offsite electric power systems for functioning of SSCs important to safety. In addition, since the North Anna 3 switchyard and offsite power is not safety related, RG 1.32 does not apply to either the switchyard or the off-site power distribution systems. This is the conclusion in DCD Section 8.1.5.2.4, "Regulatory Requirements," and North Anna 3 did not depart from this aspect of Section 8.1.5.2.4 of the DCD.

The staff has determined that the North Anna 3 UATs and RATs are not shared with North Anna 1 and 2. Although the Unit 3 UATs and RATs are connected to the same grid as the Unit 1 and 2 transformers, the capacity of the offsite power system is large compared to the safety-related loads (battery chargers and uninterruptible power supply (UPS)) fed by these transformers, and those loads will not affect the functioning of any offsite power systems.

The ESBWR DCD, Section 8.2.3 states that a station ground grid is provided that consists of a ground mat below grade at the switchyard that is connected to the foundation embedded loop grounding system provided for the entire power block and associated buildings. On June 13, 2008, the staff issued RAI 08.02-24 (ADAMS Accession No. ML081650433), requesting the applicant to describe the station ground grid. In the response letter dated July 28, 2008, to RAI 08.02-24 (ADAMS Accession No. ML082170400), the applicant stated that a description of the station ground grid appears in Appendix 8a to DCD Section 8. However, the staff noted that the North Anna Station ground grid consists of the switchyard ground grid, the existing Unit 1 and 2 ground grid, and the new Unit 3 ground grid. On October 16, 2008 the staff issued

RAI 08.02-37 (ADAMS Accession No. ML082900201), requesting that the applicant discuss the interface and impact of station grounding resulting from the addition of the Unit 3 ground grid to the existing station ground consisting of the switchyard and the Unit 1 and 2 grounding. In addition, the staff asked the applicant to provide a summary description of the existing grounding system at North Anna and the proposed grounding of Unit 3 to achieve a single point ground at the site.

In the response letter dated December 1, 2008, to RAI 08.02-37 (ADAMS Accession No. ML083390401), the applicant provided additional information. The applicant stated as follows: The ground grids for Unit 3, the intermediate switchyard, and the existing North Anna switchyard will be interconnected. Since each of these ground grids either will provide, or is currently designed to provide, adequate grounding for the associated structures and equipment, the interconnection of all of these ground grids will serve to improve the quality of each of the ground grids. Because each structure provides adequate grounding alone in accordance with IEEE standards as provided in ESBWR DCD, Section 8A.1.2, and the capacity is increased by tying together the ground grids into a single grid for the North Anna site, the staff finds that the applicant has adequately addressed switchyard grounding, and therefore the issue is resolved.

The SRP Section 8.2 (III.1.I) identifies the need to address provisions for surge protection and lightning protection. The staff determined that Chapter 8 of the application did not address these issues. On June 13, 2008, the staff issued RAI 08.02-25 (ADAMS Accession No. ML081650433), requesting that the applicant discuss the adequacy of the surge protection and lightning protection of the offsite power system. In the response letter dated July 28, 2008, to RAI 08.02-25 (ADAMS Accession No. ML082170400), the applicant stated as follows: The North Anna switchyard uses surge suppressors on the high and low sides of transformers 1, 2, 3, 5, and 6. The insulation coordination and surge protective devices are applied in conformance with IEEE 1313.2 (2004), “IEEE Guide for the Application of Insulation Coordination,” and IEEE C62.22 (2003), “IEEE Guide for Application of Metal Oxide Surge Arresters for Alternating Current Systems.” The surge protective devices are maintained according to National Electrical Manufacturers Association requirements and manufacturer’s recommendations. A shield wire arrangement is designed for lightning abatement in the switchyard in accordance with IEEE Standard 62.22-2003; IEEE Standard 988-2000, “Guide to Direct Lightning Shielding of Substations;” and “Insulation Coordination for Power Systems,” by Andrew R. Hileman. The staff finds that the applicant has provided the appropriate surge and lightning protection in accordance with industry approved standards and such protection is acceptable, therefore this issue is resolved.

Based on the above discussion, the staff finds that the information the applicant provided in response to COL Items 8.2.4-2-A, 8.2.4-6-A, and 8.2.4-7-A conforms to the requirements of GDC 17 and GDC 5.

- NAPS COL 8.2.4-5-A Protective Relaying
- NAPS COL 8.2.4-8-A Switchyard Transformer Protection

The applicant provided additional information in NAPS COL 8.2.4-5-A and 8.2.4-8-A to address COL Items 8.2.4-5-A and 8.2.4-8-A. The applicant added the following, in part, to Section 8.2.1.2.3, “Protective Relaying:”

The 500 kV transmission lines are protected with redundant high-speed relay schemes with re-closing and communication equipment to minimize line outages. The 500 kV switchyard buses have redundant bus differential protection using separate and independent current and control circuits. Generating unit tie-lines and auxiliary transformer underground cable circuits are protected with redundant high-speed relay schemes. Transformers 1, 2, 3, 5, and 6 are protected with sudden pressure relays and differential relays.

Dominion is responsible for engineering, constructing, operating, and maintaining its electric transmission system, and for interfacing with PJM, the Regional Transmission Organization (RTO). Dominion's responsibility includes designing, maintaining, and operating all switchyard protective relaying associated with connecting Unit 3 to the North Anna switchyard. PJM studied the interconnection of Unit 3 to the North Anna switchyard and recommended no additional design requirements above those typically used by Dominion in the design of the protective relaying scheme at the switchyard.

The 500 kV circuit breakers are equipped with dual trip coils. Each redundant protection circuit that supplies a trip signal is powered from its redundant DC power load group and connected to a separate trip coil. Equipment and cabling associated with each redundant system is physically separated from its redundant counterpart. Breakers are provided with a breaker failure scheme that isolates a breaker that fails to trip due to a malfunction.

The IEEE Standard 141, "Electrical Power Distribution for Industrial Plants," and Standard 242, "Protection and Coordination of Industrial and Commercial Power System," address the provision of sudden pressure relay and ground fault protection for transformers. On June 13, 2008, the staff issued RAI 08.02-6 (ADAMS Accession No. ML081650433), requesting that the applicant discuss the provision for such transformer protection. In addition, the staff asked the applicant to discuss the monitoring schemes it implements for detection of ground faults in the system if the transformer neutrals are high-resistance grounded.

In the response letter dated July 28, 2008, to RAI 08.02-6 (ADAMS Accession No. ML082170400), the applicant stated as follows: Transformers 1, 2, 3, 5, and 6 in the North Anna switchyard are protected by sudden pressure relays. Transformers 1 and 2 have solid grounds on their 500 kV, wye connected windings. The 34.5 kV, delta connected windings have zigzag transformers connected on the bus, which creates a ground source. This ground source is monitored by relays for ground fault detection. Differential relays applied across these transformers also provide ground fault protection. Since transformers 3, 5, and 6 have no tertiary winding, differential relays provide ground fault protection. The staff finds that the applicant had provided adequate fault protection to the switchyard transformers in accordance with industry IEEE standards and Dominion Engineering controls and practices and the proposed fault protection is therefore acceptable.

In addition the staff determined that the applicant did not identify transformers 1, 2, 3, 5, and 6 in the North Anna 3 site-specific Figure 8.2-201. Therefore, on October 16, 2008, the staff issued RAI 08.02-30 (ADAMS Accession No. ML082900201), requesting the applicant to revise or supplement Figure 8.2-201 accordingly. In the response letter dated December 1, 2008 to RAI 08.02-30 (ADAMS Accession No. ML083390401), the applicant stated that it will revise FSAR Figure 8.2-201 to identify transformers 1, 2, 3, 5, and 6. The staff finds the applicant's response acceptable, and the issue is resolved. The staff confirmed that these changes have been incorporated into the North Anna 3 FSAR Revision 8.

The DCD Revision 4, Section 8.2.4, item 8.2.4-5-A, notes that the COL applicant is responsible for switchyard protective relaying and will ensure that such relaying is coordinated, reviewed, and accepted by the applicable grid reliability organization. On June 13, 2008, the staff issued RAI 08.02-7 (ADAMS Accession No. ML081650433), requesting that the applicant discuss how it will accomplish such coordination, review, and acceptance. In the response letter dated July 28, 2008 to RAI 08.02-7 (ADAMS Accession No. ML082170400), the applicant stated as follows: Dominion is responsible for engineering, constructing, operating, and maintaining the electric transmission system and interfacing with the RTO, PJM. This responsibility includes the design, maintenance, and operation of the switchyard protective relaying associated with the interconnection of Unit 3 to the North Anna switchyard. PJM studied the interconnection of Unit 3 to the North Anna switchyard and recommended no additional design features or functions above those typically used by Dominion in the design of the protective relaying scheme at the switchyard. The staff in its review determined that the applicant has applied industry practice as well as its standard Dominion industrial maintenance program for the North Anna site switchyard therefore this issue is resolved.

For the reasons set forth above, the staff finds that the information the applicant provided in response to COL Items 8.2.4-5-A and 8.2.4-8-A conforms to the requirements of GDC 17.

- NAPS COL 8.2.4-9-A — Stability and Reliability of the Offsite Transmission Power System
- NAPS COL 8.2.4-10-A — Interface Requirements

The applicant provided additional information in NAPS COL 8.2.4-9-A and 8.2.4-10-A to address COL Items 8.2.4-9-A and 8.2.4-10-A. The applicant replaced DCD Section 8.2.2.1, "Reliability and Stability Analysis," with the following:

> A system impact study was performed to assess the effects of interconnection of the 1933 MVA ESBWR on the transmission system in the areas of load flow, import/export capability, short circuit analysis, system stability, and voltage sensitivity. (Reference 8.2-201) The study was prepared using the 2013 summer light load base case and the 2013 summer peak load case projections. The analysis was performed using Power Technology International Software PSS/E for load flow, import/export capability and stability evaluation, and ASPEN One-liner for short circuit evaluation.

The applicant stated that grid availability in the region over the past 20 years was examined and it was confirmed that the system has been highly reliable with minimal outages due to equipment failures.

On June 13, 2008 the staff issued RAI 08.02-10, (ADAMS Accession No. ML081650433), requesting the applicant to clarify whether the analysis addressed multiple facility contingencies (e.g., did the analysis included tripping of all three nuclear units). In the response letter dated July 28, 2008, to RAI 08.02-10 (ADAMS Accession No. ML082170400), the applicant stated that it performed the grid stability analysis in accordance with NERC criteria and subsequently included a case for loss of all generating units at a single station in the latest SIS for PJM

Generator Interconnection (North Anna 3) dated September 2013 that does include an evaluation for all three generating units tripping at North Anna. On October 16, 2008, the staff issued RAI 08.02-31 (ADAMS Accession No. ML082900201), requesting the applicant provide a discussion (including failure mode and effect analysis) of why it believes that an event similar to that at Palo Verde that occurred on June 14, 2004, will not cause the loss of three units at North Anna Station, or if such an event occurs, why it will not impact grid stability.

In the response letter dated December 1, 2008 to RAI 08.02-31 (ADAMS Accession No. ML083390401), the applicant stated as follows: The applicant had reviewed the description of the Palo Verde event in NRC IN 2005-15, "Three-Unit Trip and Loss of Offsite Power at Palo Verde Nuclear Generating Station," dated June 1, 2005. As a result of its review of IN 2005-15, Dominion implemented certain modifications to the protective scheme within the 230 kV portion of the North Anna switchyard. The 500 kV portion of the North Anna switchyard and its connecting substations has circuit breakers with dual trip coils and dual control circuits. The 230 kV portion of the North Anna switchyard and its connecting substation has circuit breakers with single trip coils and single control circuits. The circuit protection scheme at the 230 kV transmission level uses overlapping zones of protection and relies on communications that span the transmission lines from substation to switchyard. If a fault occurs on the 230 kV line at the first remote substation from the North Anna switchyard and the remote substation breaker fails to open, a transfer trip signal will be sent to open the North Anna breaker. This same logic is true for a fault on the 230 kV line near the North Anna switchyard. Also, if a fault occurs on the 230 kV line at North Anna that is not immediately cleared because of breaker failure to operate, trip signals will be generated to open breakers in expanding zones of protection until the fault is cleared. If necessary, the 500 kV breakers will open to isolate the 230 kV portion of the switchyard. At this level, the breakers have dual trip coils and dual control circuits. Since North Anna 1 and 2 interconnect at the 500 kV level, and since Unit 3 is proposed to interconnect at the 500 kV level, the generating units are ultimately protected by equipment that uses dual trip coils and dual control circuits, thus limiting the possibility of an event similar to the Palo Verde event. The staff finds the applicant's response includes a protective breaker and a half scheme that would appropriately isolate a transmission system fault preventing a multi-unit trip like the Palo Verde event and therefore the staff finds the North Anna protective scheme acceptable.

The FSAR Revision 1, Section 8.2.2.1, stated that the stability analysis did not consider the 34.5 kV portion of the North Anna switchyard. The staff review identified the station auxiliary loads for all three units to be substantial. Accordingly, on June 13, 2008, the staff issued RAI 08.02-11 (ADAMS Accession No. ML081650433), requesting the applicant to provide the basis, and identify the connected total station auxiliary loads (of all three units), for excluding analysis of the 34.5 kV portion of the switchyard. In the response letter dated July 28, 2008, to RAI 08.02-11 (ADAMS Accession No. ML082170400), the applicant stated as follows: The stability analysis discussed in the FSAR is an angular stability analysis that verifies stability of the transmission system when exposed to loss of selected transmission and generation assets. This study is performed at the transmission voltage level and would therefore exclude loads operating at distribution voltage levels of 34.5 kV as they have limited ability to cause angular stability difficulties at the transmission level. This is the standard method for performing angular stability by Dominion and PJM.

On October 16, 2008 the staff issued RAI 08.02-32 (ADAMS Accession No. ML082900201), requesting the applicant to quantify the 34.5 kV distribution loads (MW/MVA) in terms of the total load modeled for the 500 kV transmission system. In addition, the staff asked the applicant to explain the reason for its belief that the distribution loads have limited ability to affect the grid stability. In the response letter dated December 1, 2008 to RAI 08.02-32 (ADAMS Accession No. ML083390401), the applicant stated as follows: In the North Anna switchyard, the 34.5 kV buses are fed from either the 500 kV switchyard or the 230 kV switchyard. Each of the 34.5 kV buses serves plant auxiliary loads associated with Units 1 and 2 only. There is no generation source connected to the 34.5 kV buses. The study did not explicitly model the 34.5 kV buses in the North Anna switchyard, but it did include the plant auxiliary loads on each of these buses at the 500 kV level. The applicant stated that it will revise FSAR Section 8.2.2.1 to indicate that the 34.5 kV loads are considered at the 500 kV level. Because the total load represented by plant auxiliaries was included in the analysis of the 500 kV system, and the staff verified that FSAR Revision 8 reflects this fact, therefore, the staff finds the applicant's response acceptable. The staff confirmed that these changes are incorporated in FSAR Revision 8, and the issue is resolved.

FSAR Section 8.2.2.1 states that an examination of grid availability in the region over the past 20 years confirmed that the system has been highly reliable with minimal outages resulting from equipment failure. On June 13, 2008 the staff issued RAI 08.02-12 (ADAMS Accession No. ML081650433), requesting the applicant to provide supporting information for this statement to include the frequency, duration, and causes of outages over the past 20 years for both the transmission system accepting the unit's output and the transmission system providing the preferred power for the unit's load. In the response letter dated July 28, 2008 to RAI 08.02-12 (ADAMS Accession No. ML082170400), the applicant stated that Dominion has reviewed equipment failure history for the period from 1988 to 2008. The applicant indicated further that major types of equipment that can affect the reliability of the North Anna switchyard are transmission lines, transformers, and specific circuit breakers within the switchyard. The applicant concluded that the switchyard has experienced relatively few equipment lockouts because of equipment failure and the equipment lockouts have been limited to individual pieces of equipment. In view of this the information, the staff determined that the North Anna switchyard and local transmission system has been reliable and has not experienced a complete loss of power in the past 20 years. Accordingly, the applicant has shown that the grid as well as the switchyard has been reliable with few cases of equipment failures, therefore, this issue is resolved.

FSAR Revision 1, Section 8.2.2.1 states:

> Upon approaching or exceeding a [maximum, minimum, or degraded switchyard voltage] limit, these procedures verify availability of required and contingency equipment and materials, direct notifications to outside agencies and address unit technical specifications (TS) actions until the normal voltage schedule can be maintained."

On June 13, 2008, the staff issued RAI 08.02-13 (ADAMS Accession No. ML081650433), requesting the applicant to clarify the reference to North Anna 3 TS in this statement. In the response letter dated July 28, 2008, to RAI 08.02-13 (ADAMS Accession No. ML082170400), the applicant stated as follows: The operating procedures for controlling the normal voltage schedule for existing Units 1 and 2 reference the associated Unit 1 and 2 TS for the offsite power system. Unit 3 will implement similar operating procedures to maintain the switchyard voltage schedule and address challenges to the maximum and minimum limits. However, the Unit 3 procedures will not reference any TS for offsite power, because they are not required. Therefore, Dominion will revise the FSAR Section 8.2.2.1 discussion of the operating procedures to delete the reference to the TS. The ESBWR passive reactor design used at

North Anna 3 does not require an offsite or diesel-generated ac source of power for 72 hours after an abnormal event, and the switchyard as well as any off-site power system is not safety related. However the ESBWR DCD prescribes periodic inspection and testing of the nonsafety-related offsite and onsite ac systems that supply ac power to the isolation power centers. Therefore, by implementing procedures to maintain the switchyard voltage schedule as done for the existing Units 1 and 2, the staff finds that the applicant has adequately addressed the issue of maintaining the switchyard limits. The staff confirmed that these changes are incorporated in FSAR Revision 8, and the issue is resolved.

On June 13, 2008, the staff issued RAI 08.02-14 (ADAMS Accession No. ML081650433), requesting the applicant to provide the basis for using 2011 summer light-load and 2014 summer base-case projections rather than the summer heavy-load projections. The staff also asked the applicant to clarify whether the summer loads bound winter peak loads. In the response letter dated July 28, 2008 to RAI 08.02-14 (ADAMS Accession No. ML082170400), the applicant indicated as follows: Load flow analysis and the import/export study portion of the SIS was based on data projected for the timeframe corresponding to Dominion's requested interconnection date of April 2014. The 2014 summer base case was used because it is considered to be the peak load for the transmission system affected and envelops the peak winter load. The stability study portion of the SIS uses a lighter load to identify any problems with angular stability of the system. Dominion submitted the stability study request to the RTO in 2006. The RTO uses a 5-year horizon for its studies; therefore, the 2011 summer case was selected for the stability study. After 2011, the RTO will perform annual baseline analyses to update the Regional Transmission Expansion Plan and identify potential reliability problems. The applicant includes in Part 10, "ITAAC" Table 2.4.8-1 of the COLA specific analyses to confirm these offsite interfaces would remain current for North Anna 3 prior to plant operation. As described above, the staff accepted the applicant's response, and this issue is resolved.

On June 13, 2008 the staff issued RAI 08.02-15 (ADAMS Accession No. ML081650433), requesting the applicant to identify the maximum and minimum grid frequency. Additionally, the staff asked the applicant to discuss how the auxiliary power system studies consider the combined effect of frequency and voltage variation on the operation of safety-related loads (safety-related battery chargers and safety-related UPS) and other running motor loads. In the response letter dated July 28, 2008 to RAI 08.02-15 (ADAMS Accession No. ML082170400), the applicant stated that the potential maximum and minimum grid frequency can be 62 hertz (Hz) to 57.5 Hz with the time restrictions for PJM generators. Generators and their protective systems must be capable of operating at a frequency of 57.5 Hz for 5 seconds or longer, or 58.0 Hz for 30 seconds or longer, to coordinate with system preservation under-frequency load shedding. Additionally, generators and their protective systems must be capable of operation at over frequency up to 62 Hz for a limited duration. These limits are included to increase system reliability as well as set protections for individual generators. The applicant stated further that the auxiliary power system studies conducted by GEH consider the combined effect of frequency and voltage variations on the safety-related loads and other motor loads. The isolation power centers supply power to safety-related loads of their respective division. These loads consist of the safety-related battery chargers or rectifiers as discussed in Section 8.3.1.1.2 and 8.3.1.1.3 of the ESBWR DCD. Isolation power centers are protected against degraded voltage and frequency conditions by way of voltage and frequency relays installed in each isolation power center to provide alarms and facilitate isolation power center bus isolation and transfer functions as described in ESBWR DCD Section 8.3.1.1.2. The staff accepted the applicant's response, and this issue is resolved.

The FSAR Revision 1, Chapter 1, Table 1.9-201, “Conformance with Standard Review Plan,” for SRP Section 8.2 indicated that North Anna 3 satisfies the requirements of 10 CFR 50.65, “Maintenance Rule”. However, the staff review of North Anna 3 FSAR Chapter 8 found no discussion of 10 CFR 50.65. On June 13, 2008, the staff issued RAI 08.02-19 (ADAMS Accession No. ML081650433), requesting the applicant to clarify compliance with the requirements of 10 CFR 50.65(a)(4). In the response letter dated July 28, 2008, to RAI 08.02-19 (ADAMS Accession No. ML082170400), the applicant stated as follows: North Anna 3 complies with the requirements of 10 CFR 50.65(a)(4). In particular, the subject regulation is one aspect of the “Maintenance Rule” (10 CFR 50.65), an operational program. Item 17 in FSAR Table 13.4-201 addresses the implementation of the program, and FSAR Section 17.6 discusses its content.

However, the staff requested that the applicant address the applicability of the Maintenance Rule to switchyard equipment. Accordingly, on October 16, 2008, the staff issued RAI 08.02-36 (ADAMS Accession No. ML082900201), requesting the applicant to address the applicability of the Maintenance Rule to switchyard components, discuss actions to limit the risk associated with transmission system degradation, and discuss actions planned before performing “grid-risk-sensitive” maintenance activities for switchyard components. In the response letter dated December 1, 2008 to RAI 08.02-36 (ADAMS Accession No. ML083390401), the applicant stated as follows: Maintenance Rule Program implementation incorporates by reference Nuclear Energy Institute (NEI) Technical Report 07-02A, “Generic FSAR Template Guidance for Maintenance Rule Program Description for Plants Licensed Under 10 CFR Part 52.” The scope of SSCs covered by the Maintenance Rule Program is determined using the scoping procedure defined in the program description in NEI 07-02A. The offsite power system and its components will be evaluated for inclusion in the Maintenance Rule Program in accordance with these scoping procedures during program implementation. NEI 07-02A, Section 17.X.1.5, addresses risk assessment and risk management pursuant to 10 CFR 50.65(a)(4) and considers the issues associated with grid and offsite power system reliability as identified in NRC GL 06-02, items 5 and 6. Therefore, although detailed Maintenance Rule Program development is not anticipated in advance of the schedule defined in Table 13.4-201, performance of grid reliability evaluation as part of the maintenance risk assessment before performing grid-risk-sensitive maintenance activities (such as surveillances, post maintenance testing, and preventive and corrective maintenance) is considered a necessary part of the program in accordance with NEI 07-02A guidance. Since North Anna 3 will implement the Maintenance Rule in accordance with NRC endorsed NEI 07-02A guidance, the staff finds the applicant has provided in its COLA an acceptable plan to implement the Maintenance Rule, and the issue is resolved.

The DCD Revision 10, Section 8.2.3, states that a transmission system reliability and stability review of the site-specific configuration to which the plant is connected will be performed to determine the reliability of the offsite power system and verify that it is consistent with the analysis of Chapter 19. On June 13, 2008, the staff issued RAI 08.02-23 (ADAMS Accession No. ML081650433), requesting the applicant to clarify the manner in which the reliability of the offsite power system is verified to be consistent with the analysis of Chapter 19. In the response letter dated July 28, 2008, to RAI 08.02-23 (ADAMS Accession No. ML082170400), the applicant stated as follows: The ESBWR probabilistic risk assessment (PRA) used site-specific PRA information from the North Anna site to develop PRA parameters for loss of preferred power (LOPP) frequency. The LOPP frequency is divided into plant-centered, switchyard, grid-related, and weather-related initiating events. ESBWR LOPP frequencies are based on NUREG/CR-6890, “Reevaluation of Station Blackout Risk at Nuclear Power Plants, Analysis of Loss of Offsite Power Events: 1986–2004,” issued November 2005. The North

Anna LOPP frequencies were compared to the ESBWR frequencies to identify any outliers. The data show that grid-related losses of power are significantly more frequent than plant-centered, switchyard, or weather-related losses of power. There is a variance in the values for the LOPP frequencies, but their range is acceptable because the change in core damage frequency by using the highest frequency is less than $1x10^{-10}$ per year. Furthermore, the conclusions in DCD Tier 2, Section 19.2.3.1, "Risk from Internal Events," remain valid for the minor variances in LOPP frequencies. Therefore, the ESBWR PRA provides a reasonable representation of the parameters and conditions that are specific to the North Anna site. Additionally, the SIS has identified the transmission facility upgrades necessary to ensure that reliability is not reduced below the set standards. Finally, when the upgrades are made, the reliability of the offsite power system will be consistent with the analysis of Chapter 19, because the applicant is required to be in conformance with the change in core damage frequency as specified in Chapter 19 of the ESBWR DCD related to the switchyard risk, therefore the staff accepted the applicant's response, and this issue is resolved.

FSAR Section 8.2.2.1, "Reliability and Stability Analysis," NAPS COL 8.2.4-9-A, identified maximum and minimum switchyard voltage limits of 534 kV and 505 kV. On July 9, 2008 the staff issued RAI 08.02-27 (ADAMS Accession No. ML081910316), requesting the applicant to explain how these limits were established and confirm that these voltage limits are acceptable for auxiliary power system equipment operation, including safety-related battery chargers and safety-related UPS during different operating conditions. The staff requested that the confirmation include assumptions, acceptance criteria, and summary of results for the following: load flow analysis (bus and load terminal voltages of the station auxiliary system), short-circuit analysis, equipment sizing studies, protective relay setting and coordination, and motor starting with minimum and maximum grid voltage conditions. The staff also requested a separate set of calculations for each available connection to offsite power supply. In addition, the applicant was requested to discuss how the results of the calculations will be verified.

On August 21, 2008 (ADAMS Accession No. ML083470290), the applicant stated that Dominion would submit its response at a later date. On November 19, 2008 (ADAMS Accession No. ML083260325), the applicant indicated as follows: The North Anna 500 kV switchyard voltage limits of 540 kV and 505 kV were established for the operation of Units 1 and 2. Furthermore, the DCD does not then include limits for voltage and frequency variation that need to be met by site-specific offsite power systems. Analyses of the as-built onsite power system will be performed to determine the maximum load during design-basis operating modes. These analyses will, in part, specify credited power, voltage, frequency, and interrupting capability necessary for the offsite power system to support safety-related load operation during design-basis operating modes. These analyses will be accomplished as part of a site-specific ITAAC (see Section 14.3 of this SER) and will ensure that each as-built offsite circuit has sufficient capacity and capability.

On March 18, 2009 (ADAMS Accession No. ML090790310), the applicant stated that the effect of a North Anna 3 trip on the switchyard voltage and frequency limits is addressed as a part of the ITAAC process (see Section 14.3 of this SER). The North Anna 3 COL ITAAC require verification that the offsite portion of the preferred power system has the capability to provide voltage and frequency sufficient to meet the voltage and frequency determined as part of completing DCD ITAAC Table 2.13.1-2, Item 9. The staff finds that the applicant will adequately address the issue of North Anna 3 generator trip on the North Anna site switchyard in its analysis as part of ITAAC prior to plant operation. Therefore the issue is resolved.

For the reasons set forth above, the staff finds that the information the applicant provided in response to COL Items 8.2.4-9-A and 8.2.4-10-A, and as discussed above, conforms to the guidance of RG 1.206; BTP 8-3; BTP 8-6; RG 1.160, and therefore the design complies with the requirements of 10 CFR 50.65 and GDC 17 in this regard.

- NAPS SUP 8.2-1 Monitoring of Transformers for Open Circuit (Bulletin 2012-01)

The applicant has incorporated by reference the ESBWR design for open phase protection described in in ESBWR DCD, Revision 10, Section 8.2.1.2.2 (see Bulletin 2012-01 for discussion of open phase conditions). Operator actions and training are addressed in procedures, as described in North Anna 3 FSAR Section 13.2 and 13.5. Analysis and testing of the monitoring system are performed to determine set points and to verify proper monitoring system functionality. The applicant as well will develop training and procedures for the operations and maintenance staff to support this protection system throughout the plant lifetime. The applicant has also incorporated the following into North Anna COL FSAR Section 8.2.1.2.2 of the FSAR:

> Plant operating procedures associated with the monitoring system, including off-normal operating procedures, will be developed in accordance with Section 13.5.2.1 at least six months prior to fuel load.
>
> Maintenance and testing procedures associated with the monitoring system, including calibration and setpoint determination procedures will be developed in accordance with Section 13.5.2.2.6.1 prior to fuel load.
>
> Control Room operator and maintenance technician training associated with the operation and maintenance of the monitoring system will be developed in accordance with Section 13.2.1 for reactor operators and Section 13.2.2 for non-licensed plant staff. Training will be completed prior to fuel load.

The staff has reviewed the above Dominion FSAR training and procedures associated with the monitoring system for single phase faults, and, for the reasons set forth in Sections 13.2 and 13.5 of this SER, finds them to be acceptable for implementing the monitoring system for open phase faults described in the ESBWR DCD. Therefore the staff finds that the North Anna 3 training and procedures associated with the design for addressing the concerns presented in Bulletin 2012-01 are acceptable.

- NAPS SUP 8.2-2 Testing and Inspection

The applicant provided a new Section 8.2.1.2.4, "Testing and Inspection," as NAPS SUP 8.2-2 with the following addition:

> Transmission lines are inspected via an aerial inspection program approximately twice per year. The inspection focuses on such items as right-of-way encroachment, vegetation management, conductor and line hardware condition, and the condition of supporting structures. Routine switchyard inspection activities include, but are not necessarily limited to, the following:
>
> - Daily transformer inspections

- Periodic inspections of circuit breakers and batteries
- Quarterly infrared scans
- Semi-annual infrared scans (relay panels)
- Semi-annual inspection of substation equipment
- Annual infrared scans
- Annual corona camera scan

Routine switchyard testing activities include, but are not necessarily limited to, the following:

- Transformers – dissolved gas analysis every 5 months
- Electromechanical Relay testing (500 kV) –every 2 years
- Electromechanical Relay testing (230 kV) – every 3 years
- Microprocessor Relay testing (500 kV and 230 kV) – every 4 years
- Transformer Load Tap Changers – dissolved gas analysis every
- Battery Discharge testing – every 5 years
- Circuit Breakers – maintenance and inspection every 6 years
- [Current Transformer] CT maintenance – every 6 years
- Disconnect Switches (line zone) – maintenance and inspection every 6 years
- Ground Grid testing – every 8 years
- Disconnect Switches (bus zone) – maintenance and inspection every 10 years
- [Potential Transformer] PT testing – every 10 years
- [Capacitive Voltage Transformer] CCVT testing – every 10 years
- Arrester testing (bus zone) – every 10 years
- Wave Trap testing – every 12 years

On June 13, 2008, the staff issued RAI 08.02-8 (ADAMS Accession No. ML081650433), requesting the applicant to address the industry (Federal Energy Regulatory Commission, NERC, and IEEE) standards that will be followed for switchyard protection system, monitoring, maintenance, and testing. The staff also asked the applicant to confirm that generator circuit breakers will meet IEEE Standard C37.013, "Standard for AC High-Voltage Generator Circuit Breakers Rated on a Symmetrical Current." In the response letter dated July 28, 2008 to RAI 08.02-8 (ADAMS Accession No. ML082170400), the applicant stated as follows: Monitoring, maintenance, and testing of the switchyard protection system are performed under NERC Standard PRC-005-1, "Transmission and Generation Protection System Maintenance and Testing"; Standard PRC-008-0, "Underfrequency Load Shedding Equipment Maintenance Program"; and Standard PRC-017-0, "Special Protection System Maintenance and Testing." IEEE C37.013 was written specifically for high-current circuit breakers installed between generators and transformer terminals. The proposed Unit 3 at North Anna places the circuit breaker on the high side terminals of the generator step-up transformers. Thus, IEEE C37.013 does not directly apply to the ESBWR standard design, however IEEE C37.010 does apply to the ESBWR generator breaker configuration and is referenced in ESBWR DCD, Section 8.3.1.1 for breaker sizing and design.

The applicant stated that it will revise FSAR Section 8.2.1.2.3 to include the above NERC standards for monitoring, maintenance, and testing of the switchyard protection system. The staff finds that the applicant's commitment to these industry standards acceptable such that switchyard components (but not transformers) will be adequately tested and maintained. The staff confirmed that these changes are incorporated in FSAR Revision 8, and the issue is resolved.

On June 13, 2008, the staff issued RAI 08.02-9 (ADAMS Accession No. ML081650433), requesting the applicant to include transformer testing as part of the overall routine switchyard component testing. In the response letter dated July 28, 2008 to RAI 08.02-9 (ADAMS Accession No. ML082170400), the applicant stated as follows: North Anna switchyard transformers have dissolved gas analysis performed every 6 months. Additionally, if the transformer has a load tap changer (LTC), the dissolved gas analysis is performed on the LTC every 4 years. Infrared scans are performed quarterly on transformers. FSAR Section 8.2.1.2.3 will be revised to indicate that semiannual dissolved gas analysis on transformers and 4-year dissolved gas analysis on LTC will be conducted. The staff confirmed that these changes are incorporated in FSAR Revision 8, in FSAR Section 8.2.1.2.4 and that the testing provided provides increased reliability to these electrical systems. Accordingly, the staff finds that the applicant addressed the issue of testing the non-Class 1E electrical system adequately.

Based on the foregoing, the staff concludes that the information in NAPS SUP 8.2-2, which provides for testing and inspection of off-site electrical components and conforms with the guidance of RG 1.118 and therefore meets the requirements of GDC 18 as described in the ESBWR DCD.

- NAPS SUP 8.2-3 Failure Mode and Effects Analysis

The applicant provided Section 8.2.2.3, "Failure Modes and Effects Analysis," as NAPS SUP 8.2-3 with the following, in part, addition:

> Unit 3 is connected to the Dominion transmission system via four 500 kV and one 230 kV overhead transmission lines. Each transmission line occupies a separate right-of-way, except the two parallel Ladysmith lines, which share the same right- of-way. Failure of any one tower due to structural failure can at most disrupt and cause a loss of power distribution to itself and the adjacent line. Failure of a line conductor would cause the loss of one of the four 500 kV lines, with the other three lines remaining available as normal and alternate preferred power sources.
>
> A breaker-and-a-half scheme is incorporated in the design of the switchyard. This arrangement offers the following flexibility to control a failed condition within the switchyard.
>
> - Any faulted transmission line into the switchyard can be isolated without affecting any other transmission line.
> - Either bus can be isolated without interruption of any transmission line or other bus.
> - Relay schemes used for protection of the offsite power circuits and switchyard equipment include primary and backup protection features. All breakers are equipped with dual trip coils. Each protection circuit that supplies a trip signal is connected to a separate trip coil.

According to the applicant, the failure of any component within the intermediate switchyard may disrupt the normal preferred power supply. However, the alternate preferred power supply will remain available to supply the load.

On the basis of its review, the staff determined that Dominion, in its failure mode and effects analysis, showed that is unlikely that any individual switchyard component failure would prevent the North Anna 3 offsite power system from performing its function to provide normal or alternate power to Unit 3, and therefore the switchyard design meets the guidance of RG 1.206. Therefore, as described above, the North Anna 3 switchyard design meets the requirements of GDC 17 for providing two separate and redundant off-site sources of power, which provides additional reliability to its safety system functions.

8.2.5 Post Combined License Activities

There are no post COLA activities related to this section.

8.2.6 Conclusion

The staff reviewed the application and checked the referenced DCD. The staff finds that the application includes all the information relevant to this section, and the staff confirmed that no outstanding information related to this section remains to be addressed in the COL FSAR. The results of the staff's technical evaluation of the information incorporated by reference in the North Anna 3 COLA are documented in NUREG–1966, and NUREG–1966, Supplement 1.

In addition, the staff has compared the additional COLA and supplemental information within the application for this section to the relevant NRC regulations, guidance in SRP Section 8.2 and other NRC RGs. For the reasons set forth above, the applicant has adequately addressed COL Information Items NAPS COL 8.2.4-1-A through 8.2.4-10-A involving the design details of the plant site switchyard and its interface with the local transmission grid and NAPS SUP 8.2-1, 8.2-2 and 8.2-3 involving monitoring of transformers for open phase(s), testing and inspection of switchyard components and failure modes and effects analysis. Accordingly, the staff concludes that the application meets the requirements of GDC 17 and 18 and 10 CFR 50.65 in regard to offsite power.

8.3 Onsite Power Systems

8.3.1 AC Power System

8.3.1.1 Introduction

This section of the COL FSAR provides descriptive information, analyses, and referenced documents that include the applicant's information on electrical single-line diagrams, electrical schematics, logic diagrams, tables, and physical arrangement drawings for the onsite ac power system. The onsite ac power system includes those standby power sources, distribution systems, and auxiliary support systems that supply power to safety-related equipment or equipment important to safety, for all normal operating, anticipated operational occurrences (AOO), and accident conditions.

In the North Anna 3 ESBWR passive reactor design, the onsite ac power system consists of power supplied to the plant from two independent offsite power sources, the "Normal Preferred" power source and the "Alternate Preferred" power source. The on-site ac system consists of safety-related and nonsafety-related power systems. Two nonsafety-related ancillary diesel generators are capable of supplying power to the ancillary buses when no other sources of ac power are available. There are four independent safety-related dc divisions to provide power for the safety-related loads discussed in more detail in the next section of this SER.

The onsite power system is divided into two medium voltage power levels of 13.8 kV and 6.9 kV for operational flexibility of the plant nonsafety-related non-Class 1E systems that provide reliable ac power to the various electrical loads. These non-Class 1E nonsafety systems do not perform any safety-related functions or provide a risk-important, nonsafety-related active systems function. These redundant non safety capabilities enhance plant system reliability in normal or abnormal plant operational conditions. Plant loads for investment protection can be manually loaded on the standby power supplies. Diesel generator sets are used as the standby power source for the onsite ac power systems. Those portions of the onsite ac power systems that are not related to safety are described only in sufficient detail to permit an understanding of their interactions with the safety-related portions.

The plant's UPS system (120 V of ac vital power) comprises independent Class 1E and non-Class 1E UPS systems. Each system consists of rectifiers, inverters, ungrounded batteries, and distribution panels. The Class 1E UPS system provides reliable power for the safety-related equipment, including the plant instrumentation, control, monitoring, and other systems that perform vital functions needed to shut down the plant. In addition, the Class 1E UPS system provides power to the emergency lighting in the main control room and the remote shutdown area.

8.3.1.2 Summary of Application

Section 8.3 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 8.3 of the ESBWR DCD, Revision 10. Section 8.3 of the ESBWR DCD includes Section 8.3.1, "AC Power Systems," which addresses SRP Section 8.3.1, "AC Power Systems (Onsite)."

In addition, in FSAR Section 8A,"Miscellaneous Electrical Systems," the applicant provided the following information:

COL Items

- NAPS COL 8A.2.3-1-A Cathodic Protection System

The applicant provided additional information regarding a cathodic protection system to address NAPS COL 8A.2.3-1-A.

Supplemental Information

- NAPS SUP 8.3-1 Onsite Power Description

In FSAR Section 8.3.1.1, "Description," the applicant provided information describing an intermediate switchyard to transition offsite power from the NAPS switchyard.

8.3.1.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the FSER related to the ESBWR DCD and NUREG–1966, Supplement 1, FSER related to the Certification of the ESBWR Standard Design, Supplement 1. In addition, the relevant requirements of the Commission regulations for the offsite power system and the associated acceptance criteria are in SRP Section 8.3.1," AC Power Systems (Onsite)."

In addition, the NRC requirements governing the COL supplemental information are in GDC 17.

8.3.1.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 8.3.1 and Appendix 8A of the certified ESBWR DCD. The staff reviewed Section 8.3.1 and Appendix 8A of the North Anna 3 COL FSAR and checked the referenced DCD to ensure that the combination of the DCD and the information in the COLA represent the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and incorporated by reference includes all the information necessary for the review of ac power systems (onsite).

The staff reviewed the following information contained in the COL FSAR:

COL Item

- NAPS COL 8A.2.3-1-A Cathodic Protection System

The applicant provided additional information in NAPS COL 8A.2.3-1-A. The applicant stated that a cathodic protection system is provided, as required, and that the system is designed in accordance with the standards of the National Association of Corrosion Engineers.

The staff finds that the applicant has adequately addressed the COL item.

Supplemental Information

- NAPS SUP 8.3-1 Onsite Power Description

The applicant provided the following supplemental information to modify Section 8.3.1.1, "Description":

> An intermediate switchyard is utilized to transition off-site power from the NAPS switchyard to the Unit 3 main power transformers, and unit auxiliary transformers (UATs). This intermediate switchyard contains the main generator circuit breaker, and a supply circuit breaker, which provides power to 500/230 kV intermediate transformers used to supply power to the UATs. These intermediate transformers consist of three single phase transformers and include an installed spare transformer. Also included in the intermediate switchyard is a transmission tower which supports a 500 kV disconnect switch that is identified as the point of interconnection between the onsite power sources and offsite power sources.

The staff finds that the applicant has adequately described the North Anna 3 connection to the utility grid and the connection conforms to the requirements of GDC 17 because the North Anna 3 normal and alternate power supplies would provide sufficient capacity and capability to assure that safety system vital functions are maintained in the event of an AOO or postulated accidents.

8.3.1.5 Post Combined License Activities

There are no post COLA activities related to this chapter.

8.3.1.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff finds that the application includes all the information relevant to this section, and the staff confirmed that no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the onsite ac power system that were incorporated by reference have been resolved.

In addition, the staff has compared the additional COL item and supplemental information within the application to the relevant NRC regulations, guidance in SRP Section 8.3.1, and other NRC RGs and, for the reasons discussed above, concludes that the applicant is in compliance with the NRC regulations.

As discussed above, the staff concludes that the applicant has adequately addressed the North Anna 3 COL item involving cathodic protection systems and supplemental information involving the transmission system and its electrical connection to the plant. In conclusion, the staff finds that the applicant has provided sufficient information to satisfy the requirements of GDC 17 for this section.

8.3.2 DC Power Systems

8.3.2.1 Introduction

This section of the COL FSAR provides descriptive information, analyses, and referenced documents that include the applicant's information on electrical single-line diagrams, electrical schematics, logic diagrams, tables, and physical arrangement drawings for the onsite dc power systems. Onsite dc power systems include those power sources and their distribution systems that supply motive or control power to safety-related equipment. The non-safety-related portions are described only in sufficient detail to permit an understanding of their interactions with the safety-related portions. This section clearly identifies the safety loads and states the length of time they would be operable in the event of a loss of ac power.

The plant's dc power system is comprised of independent Class 1E and non-Class 1E dc power systems. Each system consists of ungrounded stationary batteries, dc distribution equipment, and the UPS.

The Class 1E dc and UPS system in the ESBWR passive reactor design plant is capable of providing reliable power for the safe shutdown of the plant without the support of battery chargers, during a loss of all ac power sources coincident with a design-basis accident for 72 hours. The system is designed so that no single failure will result in a condition that will prevent the safe shut down of the plant.

The non-Class 1E dc and UPS system in the ESBWR passive reactor design plant provides continuous and reliable electric power to the plant's non-Class 1E control and instrumentation loads and equipment, which are used for plant operation and investment protection and for the hydrogen igniters located inside containment. Operation of the non-Class 1E dc and UPS system is not required for nuclear safety-related systems.

8.3.2.2 Summary of Application

Section 8.3 of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 8.3 of the certified ESBWR DCD, Revision 10. Section 8.3 of the ESBWR DCD includes Section 8.3.2, "DC Power Systems," which addresses SRP Section 8.3.2, "DC Power Systems (Onsite)."

In addition, in FSAR Section 8.3.2, the applicant provided the following:

COL Items

- NAPS COL 8.3.4-1-A — Safety-Related Battery Float and Equalizing Voltage Values

In FSAR Section 8.3.2.1.1, "Safety-Related Station Batteries and Battery Chargers," the applicant provides information on safety-related battery float and equalizing voltage values. Additionally, the applicant modifies DCD Table 8.3-4 item b.

- NAPS COL 8.3.4-2-A — Underground or inaccessible power and control cable

In FSAR Section 8.3.3.2, "Cables and Raceways" the applicant provides information on accident mitigating functions that are supplied by DC power that is susceptible to protracted exposure to wetted environments.

Supplemental Information

- NAPS SUP 8.3-2 — Safety-Related Station Batteries and Battery Chargers Station Blackout

In FSAR Section 8.3.2.1.1, "Safety-Related Station Batteries and Battery Chargers Station Blackout," the applicant provided information on the training and procedures to mitigate SBO, with references to Sections 13.2 and 13.5 of the FSAR and DCD Section 15.5.5.

8.3.2.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the FSER related to the ESBWR DCD and NUREG–1966, Supplement 1, FSER related to the Certification of the ESBWR Standard Design, Supplement 1. In addition, the relevant requirements of the

Commission regulations for the DC power system and the associated acceptance criteria are in SRP Section 8.3.2," DC Power Systems (Onsite)."

In addition, the NRC requirements governing the COL supplemental information are in 10 CFR 50.63, "Loss of All Alternating Current Power." The guidance and acceptance criteria for meeting Section 50.63 are in the guidelines of RG 1.155, "Station Blackout"; and Nuclear Management and Resource Council (NUMARC) 87-00, "Guidelines and Technical Bases for NUMARC Initiatives Addressing Station Blackout at Light Water Reactors," issued November 1987, and endorsed by RG 1.155.

8.3.2.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 8.3.2 of the certified ESBWR DCD. The staff reviewed Section 8.3.2 of the North Anna 3 COL FSAR and checked the referenced DCD to ensure that the combination of the information in the ESBWR DCD and the information in the COL FSAR represents the complete scope of information relating to this review topic.[1] The staff's review confirmed that the information in the application and the information incorporated by reference includes all the information necessary for review of the DC power system.

The staff reviewed the following additional information in the COL FSAR:

COL Items

- NAPS COL 8.3.4-1-A Safety-Related Battery Float and Equalizing Voltage Values

The applicant provides additional information to address COL Item 8.3.4-1-A. The applicant replaces the fourth paragraph of DCD Section 8.3.2.1.1 with the following:

> In Divisions 1, 2, 3, and 4, the two 250 volt safety-related batteries per division are sized together so that their total rated capacity will exceed the required battery capacity per division for 72-hour station blackout conditions. The DC system minimum battery terminal voltage at the end of the discharge period is 210 VDC (1.75 volts per cell). The maximum equalizing charge voltage for safety-related batteries is specified by the battery vendor and is as allowed by the voltage rating of the connected loads (UPS inverters). The UPS inverters are designed to supply 120 VAC power with DC input less than the minimum discharge voltage (210 VDC) and greater than the maximum equalizing charge voltage. The safety-related battery float voltage and maximum equalizing charge voltage values are included in Table 8.3-4R.

Additionally, the applicant modifies DCD Table 8.3-4 item b to include float and maximum equalizing charge voltage as follows:

- float voltage at 77°F- 267.6 VDC at the battery terminals
- maximum equalizing charge voltage at 77°F-288 VDC at the battery terminals.

The staff finds that optimum long-term battery performance is obtained by maintaining a float voltage within established design values of 2.22 volts per cell to 2.24 volts per cell provided by the battery manufacturer, which corresponds to nominally 2.23 volts per cell or 267.6 Vdc at 77°F. This provides adequate over-potential, which limits the formation of lead sulfate and self discharge. Therefore, float voltage of 267.6 Vdc at 77°F is acceptable. Additionally, the maximum equalizing charge voltage of 288 Vdc at the battery terminals is acceptable because the UPS inverters (only connected load on dc bus) are designed to function properly with dc input less than the minimum discharge voltage (210 VDC) and greater than the maximum equalizing charge voltage (288 Vdc).

In view of the forging, the staff finds that the applicant adequately resolved COL Item 8.3.4-1-A and float and maximum equalizing charge voltage values were consistent with battery vendor's recommendation and in conformance with the requirements of GDC 17.

- NAPS COL 8.3.4-2-A Underground or inaccessible power and control cable

The applicant stated in FSAR Section 8.3.3.2, "Cables and Raceways" that:

> Underground or inaccessible power and control cable runs to the [Plant Service Water System] PSWS and DG Fuel Oil Transfer System that have accident mitigating functions and are susceptible to protracted exposure to wetted environments or submergence as a result of seasonal or weather event water intrusion are adequately identified and monitored for appropriate corrective actions under the Maintenance Rule (MR) program described in Section 17.6.4.

Given that 10 CFR 50.65, "Maintenance Rule," requirements will be applied to these control cables, and the applicant's Maintenance Rule Program is adequate as described in Section 17.6.4 of this SER, these underground power and control cables will be adequately monitored to ensure reliability of these accident mitigating functions and is therefore acceptable.

Supplemental Information

- NAPS SUP 8.3-2 Safety-Related Station Batteries and Battery Chargers Station Blackout

The applicant provided supplemental information in Section 8.3.2.1.1 of the FSAR for addressing training and procedures to mitigate an SBO event by adding the following at the end of FSAR Section 8.3.2.1.1:

> Training and procedures to mitigate an SBO event are implemented in accordance with Sections 13.2 and 13.5, respectively. As recommended by NUMARC 87-00 (Reference 8.3-201), SBO event mitigation procedures address SBO response (e.g., restoration of on-site standby power sources), AC power restoration (e.g., coordination with transmission system load dispatcher), and severe weather guidance (e.g., identification of site-specific actions to prepare for the onset of severe weather such as an impending tornado), as applicable. The ESBWR is a passive design and does not rely on offsite or onsite AC sources of power for at least 72 hours after an SBO event, as described in DCD Section 15.5.5, Station Blackout. In addition, there are no nearby large power sources, such as a gas turbine or black start fossil fuel plant, that can directly connect to the station to mitigate the SBO event. Restoration from an SBO

event will be contingent upon power being made available from any one of the following sources:

- Any of the standby or ancillary diesel generators.
- Restoration of any one of the four 500 kV transmission lines described in Section 8.2.
- Restoration of the 230 kV transmission line described in Section 8.2.

According to NUMARC 87-00, which is endorsed by RG 1.155, the SBO response procedures include (1) SBO response guidelines, (2) ac power restoration, and (3) severe weather guidelines. On June 19, 2008, the staff issued RAI 08.03.02-1 (ADAMS Accession No. ML081710161), in which the staff asked the applicant to confirm that training and procedures cover all three SBO response procedures. In the response letter dated August 4, 2008 to RAI 08.03.02-1 (ADAMS Accession No. ML082200626), the applicant stated that it will revise the FSAR to indicate that procedures will include these three areas. The applicant further stated that licensed and non-licensed plant personnel receive adequate training for responding to all plant events, both normal and abnormal, and such training encompasses an SBO event. The staff finds that the applicant conforms to the guidance of RG 1.155 and therefore meets the requirements of 10 CFR 50.63, contingent on maintaining these procedures and personnel training. Because the detailed training and procedures will not be fully developed until required by license condition, they will be subject to inspection after implementation. Accordingly, the subject RAI is adequately addressed. The staff confirmed that these changes are incorporated in Revision 8 of the FSAR, and the issue is resolved.

In view of the above, the staff finds that NAPS SUP 8.3-2 conforms to the guidance of RG 1.155 and therefore complies with the requirements of 10 CFR 50.63.

8.3.2.5 Post Combined License Activities

There are no post COL activities related to this section.

8.3.2.6 Conclusion

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff finds that the application includes all the information relevant to this section, and the staff confirmed that no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the onsite DC power system that were incorporated by reference have been resolved.

In addition, the staff has compared the supplemental information within the application to the relevant NRC regulations, guidance in SRP Section 8.3.2, and other NRC RGs and, for the reasons discussed above, concludes that the applicant is in compliance with the NRC regulations.

As discussed above, the applicant has adequately addressed North Anna 3 COL supplemental information pertaining to training and procedures to mitigate an SBO event. Accordingly, the staff finds that the applicant has provided sufficient information to satisfy the requirements of 10 CFR 50.63 for this section.

8.4 Station Blackout

The North Anna 3 COL FSAR does not include Section 8.4. Instead, the COL FSAR analyzes SBO in FSAR Section 15.5.5, “Station Blackout.” ESBWR DCD, Section 15.5.5 presents the SBO safety analysis. In the North Anna 3 COL FSAR, Revision 8, Section 15.5.5, “Station Blackout,” the applicant incorporated by reference Section 15.5.5, “Station Blackout,” of the ESBWR DCD, Revision 10, with no departures or supplements. The staff evaluation is set forth in Section 15.5.5 of the staff SER for findings related to information incorporated by reference in NUREG–1966.

9.0 Auxiliary Systems

9.0 AUXILIARY SYSTEMS

This chapter of the U.S. Nuclear Regulatory Commission's (NRC's) safety evaluation report (SER) provides the NRC staff evaluation of the North Anna 3 Combined License (COL) auxiliary systems for the Economic Simplified Boiling-Water Reactor Standard (ESBWR) design including fuel handling and storage, process water and cooling systems, process auxiliaries, alternate shutdown, fire protection, plant communication systems, lighting and diesel generator systems.

9.1 Fuel Storage and Handling

9.1.1 New Fuel Storage

Section 9.1.1, "New Fuel Storage," of the North Anna 3 COL Final Safety Analysis Report (FSAR), Revision 8, incorporates by reference Section 9.1.1, "New Fuel Storage," of the ESBWR Design Control Document (DCD), Revision 10, referenced in Title10 *Code of Federal Regulations* (CFR) Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants," Appendix E, "Design Certification Rule for the ESBWR Design." As documented in NUREG–1966, "Final Safety Evaluation Report related to the Certification of the Economic Simplified Boiling-Water Reactor Standard Design," the U.S. Nuclear Regulatory Commission (NRC) staff reviewed and approved Section 9.1.1 of the certified ESBWR DCD. The staff reviewed the COL application (COLA) and checked the referenced DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1]

Section 9.1.1.7 of the ESBWR DCD indicates that the applicant is to address DCD COL Item 9.1-4-A related to programs that address fuel handling operations, including criticality safety. The COL applicant removed the two references that DCD Section 9.1.1.7 made to COL 9.1-4-A and addressed them as STD COL 9.1-4-A in Section 9.1.4 of the COL FSAR. The staff's review of STD COL 9.1-4-A is discussed in Section 9.1.4 of this safety evaluation report (SER).

The seismic evaluations for new fuel storage performed in the ESBWR DCD are based on ESBWR standard plant seismic inputs. The North Anna 3 site-specific seismic demands exceed the certified seismic design response spectra (CSDRS). Therefore, the applicant introduced the departure NAPS DEP 3.7-1, "Ground Response Spectra for Seismic Structural Loads and Floor Response Spectra," and referenced it in Section 9.1.1.5 of the North Anna 3 COL FSAR, Revision 9 submitted June, 2016. The applicant performed a site-specific assessment of the new fuel storage rack structural design using the DCD methodology, as approved by the staff in NUREG–1966, the ESBWR DCD Final Safety Evaluation Report (FSER). The North Anna 3 site-specific seismic demands, evaluated in Section 3.7 of this SER, result in changes to the size of anchor bolts for new fuel storage racks in the buffer pool and higher embedment loads than in the ESBWR DCD, Revision 10. The staff evaluated NAPS DEP 3.7-1 with respect to the new fuel storage seismic structure loads in Section 3.8 of this SER.

The inclusion of NAPS DEP 3.7-1 in Section 9.1.1 was verified by the staff in the North Anna 3 FSAR, Revision 9, which incorporated the appropriate changes described in the applicant's

[1] See "*Finality of Referenced NRC Approvals*" in SER Section 1.2.2, for a discussion on the staff's review related to verification of the scope of information to be included within a COL application that references a design certification.

revised seismic request for additional information (RAI) responses on May 18, 2016 (Agencywide Documents Access and Management Systems (ADAMS) Accession No. ML16146A789). Therefore, Confirmatory Item 09.01-1 from the staff advanced SER for North Anna 3 is resolved and closed.

The staff's review confirms that the applicant has addressed the required information, and no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Section VI.B.1 of Appendix E to 10 CFR Part 52, all nuclear safety issues relating to new fuel storage that were incorporated by reference have been resolved.

9.1.2 Spent Fuel Storage

Section 9.1.2, "Spent Fuel Storage," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 9.1.2, "Spent Fuel Storage," of the certified ESBWR DCD, Revision 10, referenced in 10 CFR Part 52, Appendix E. As documented in NUREG–1966, the staff reviewed and approved Section 9.1.2 of the certified ESBWR DCD. The staff reviewed the application and checked the referenced DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD represents the complete scope of information relating to this review topic.[1]

The seismic evaluations for spent fuel storage performed in the ESBWR DCD are based on ESBWR standard plant seismic inputs. The North Anna 3 site-specific seismic demands exceed the CSDRS, so the applicant introduced the departure NAPS DEP 3.7-1, "Seismic Design," and referenced it in Section 9.1.2.4 of the North Anna 3 COL FSAR, Draft Revision 9 submitted on May 20, 2016 (ADAMS Accession No. ML16146A789). The applicant performed a site-specific assessment of the spent fuel storage rack structural design using the DCD methodology, as approved by the staff in NUREG–1966. The North Anna 3 site-specific seismic demands, evaluated in Section 3.7 of the SER, result in changes to the size of anchor bolts and the welds from the enveloping plate to the base plates for spent fuel storage racks in the buffer pool deep pit and higher embedment loads than in the ESBWR DCD, Revision 10. The staff evaluated NAPS DEP 3.7-1 with respect to the spent fuel pool (SFP) seismic structure loads in Section 3.8 of this SER.

The inclusion of NAPS DEP 3.7-1 was verified by the staff in the North Anna 3 FSAR, Revision 9, which incorporated the appropriate changes described in the applicant's revised seismic RAI responses on May 18, 2016. Therefore, Confirmatory Item 09.01-2 from the staff advanced SER for North Anna 3 is resolved and closed.

The staff's review confirms that the applicant has addressed the required information, and no outstanding information related to this section remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Section VI.B.1 of Appendix E to 10 CFR Part 52, all nuclear safety issues relating to spent fuel storage that were incorporated by reference are resolved.

9.1.3 Spent Fuel Cooling and Cleanup System

Section 9.1.3, "Spent Fuel Cooling and Cleanup System," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference, with no departures or supplements Section 9.1.3, "Spent Fuel Cooling and Cleanup System," of the certified ESBWR DCD, Revision 10 referenced in 10 CFR Part 52, Appendix E. As documented in NUREG–1966, the staff reviewed and approved Section 9.1.3 of the certified ESBWR DCD. The staff reviewed the application and checked the referenced DCD to ensure that no issue relating to this section remains for review.[1]

The staff's review confirmed that the applicant has addressed the required information, and there is no outstanding information related to this section that remains to be addressed in the COL FSAR. Pursuant to 10 CFR 52.63(a)(5) and Section VI.B.1 of Appendix E to 10 CFR Part 52, all nuclear safety issues relating to the "Spent Fuel Cooling and Cleanup System" that were incorporated by reference have been resolved.

9.1.4 Light Load Handling System (Related to Refueling)

9.1.4.1 Introduction

The light load handling system is used to handle the spent fuel assemblies underwater from the time they leave the reactor vessel until they are placed in a container for shipment from the site. Characteristics of the system are aimed at avoiding criticality accidents, radioactivity releases resulting from damage to irradiated fuel, and unacceptable personnel radiation exposure.

9.1.4.2 Summary of Application

Section 9.1.4, "Light Load Handling System (Related to Refueling)," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 9.1.4 of the certified ESBWR DCD, Revision 10. In addition, in North Anna 3 COL FSAR, Section 9.1.4, the applicant provided the following:

COL Item

- STD COL 9.1-4-A Fuel Handling Operations

The applicant provided additional information in STD COL 9.1-4-A to address DCD COL Item 9.1.4-A. The applicant described the scope of the fuel handling procedures and procedures for equipment used to move fuel. The applicant states that these procedures will be developed 6 months before fuel receipt. The applicant states that the fuel handling equipment is inspected for operating conditions before each refueling and that a quality assurance (QA) program is applied to monitoring, implementing and assuring compliance with fuel handling procedures. The QA program is described in Section 17.5 of the COL FSAR.

9.1.4.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, FSER related to the certified ESBWR DCD. In addition, the relevant requirements of the Commission regulations for the "Light Load Handling System (Related To Refueling)" and the associated acceptance criteria are in Section 9.1.4 of NUREG–0800, "Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants: LWR Edition," the Standard Review Plan (SRP).

The applicable regulatory requirements and associated guidance for fuel handling operations are as follows:

- General Design Criterion (GDC) 61, "Fuel Storage and Handling and Radioactivity Control," of Appendix A, "General Design Criteria for Nuclear Power Plants," to 10 CFR

Part 50, “Domestic Licensing of Production and Utilization Facilities,” as it relates to radioactive releases resulting from fuel damage and the avoidance of excessive personnel radiation exposure.

- GDC 62, “Prevention of Criticality in Fuel Storage and Handling,” as it relates to prevention of criticality accidents.

- Regulatory Guide (RG) 1.206, “Combined License Applications for Nuclear Power Plants (LWR Edition),” June 2007.

9.1.4.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 9.1.4 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 9.1.4 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced ESBWR DCD to ensure that the combination of the information in the COL FSAR and the information in the ESBWR DCD that represent the complete scope of information relating to this review topic.[1]

The staff’s review confirms that the information in the application and the information incorporated by reference address the required information related to the “Light Load Handling System (Related to Refueling).”

The staff’s review of the information contained in the North Anna 3 COL FSAR is as follows:

<u>*COL Items*</u>

- STD COL 9.1-4-A Fuel Handling Operations

The staff reviewed STD COL 9.1-4-A, Fuel Handling Operations, related to the fuel handling operations included under Section 9.1.4 of the North Anna 3 COL FSAR. DCD COL Item 9.1.4-A in Section 9.1.6, “COL Information,” of the ESBWR DCD, Revision 10, states that the applicant will provide a description of programs that address the following:

- Criticality safety of fuel handling operations
- Fuel handling procedures
- Maintenance manuals and procedures for equipment used to move fuel
- Equipment inspection and test plans for equipment used to move fuel
- Personnel qualifications, training, and control programs for fuel handling personnel
- [Quality Assurance] QA programs to monitor, implement, and assure compliance to fuel handling operations

In FSAR Section 9.1.4.13, “Refueling Operations,” and FSAR Section 9.1.4.19, “Inspection and Testing Requirements,” the applicant addressed DCD COL Item 9.1.4-A in STD COL 9.1-4-A. The applicant added a paragraph in FSAR Section 9.1.4.13 identifying the general subject matter of fuel handling procedures that will be developed. The program described by the applicant in FSAR Section 9.1.4.13 provides procedures for fuel handling, inspection and testing of fuel handling equipment in adequate time to support training and qualification of fuel handling personnel. These procedures will be completed 6 months prior to fuel receipt. In further response to DCD COL Item 9.1.4-A (STD COL 9.1-4-A), the applicant states that qualifications, training and the control programs for fuel handling personnel are addressed in FSAR Section 13.2, "Training." In RAI 09.01.04-1 dated June 24, 2008 (ADAMS Accession No. ML081760334), the staff asked the applicant to clarify how FSAR Section 13.2 addresses personnel qualification and training for fuel handlers. In their response to RAI 09.01.04-1 dated August 4, 2008 (ADAMS Accession No. ML082200545), the applicant stated that FSAR Section 13.2 refers to Appendix 13BB, "Training Program," which incorporates by reference Nuclear Energy Institute (NEI) 06-13A, "Template for an Industry Training Program Description." On December 5, 2008, the NRC endorsed NEI 06-13A, Revision 1, as an acceptable template for describing reactor operator (RO) and non-licensed plant staff training programs for COLAs. The staff finds that the applicant has adequately addressed training and qualification of fuel handlers. Therefore, RAI 09.01.04-1 is resolved and closed.

Also in response to DCD COL Item 9.1.4-A, the applicant revised Section 9.1.4.19 of the FSAR to identify that the QA program described in FSAR Section 17.5, "Quality Assurance Program Description-Design Certification, Early Site Permits, and New License Applicants," will monitor, implement and assure compliance with fuel handling procedures. The applicant also states that fuel handling equipment is inspected prior to each refueling. In RAI 09.01.04-2 dated June 24, 2008 (ADAMS Accession No. ML081760334), the staff asked the applicant to clarify how testing and inspection before each refueling operation ensures that safety features and interlocks perform satisfactorily and prevent excessive personnel radiation exposure and fuel damage, in keeping with the requirements of GDC 61. In their response to RAI 09.01.04-2 dated August 4, 2008 (ADAMS Accession No. ML082200545), the applicant stated that the fuel handling procedures required by FSAR Section 9.1.4.13 include checking the status of interlocks. The interlocks for the refueling machine and the fuel handling machine are specified in ESBWR DCD, Section 9.1.4.5, "Refueling Equipment." Additionally, the applicant stated that the ESBWR DCD Technical Specifications (TS) includes TS 3.9.1, "Refueling Equipment Interlocks," which prevent operation of the refueling equipment with fuel loaded over the core whenever any control rod is withdrawn, and prevent control rod withdrawal whenever fuel-loaded refueling equipment is over the core. The staff finds that the applicant's response to RAI 09.01.04-2 is satisfactory and it clarifies the applicant's response in STD COL 9.1-4-A to DCD COL Item 9.1.4-A. Therefore, RAI 09.01.04-2 is resolved and closed.

The staff evaluated COL Item STD COL 9.1-4-A using the relevant NRC regulations and acceptance criteria in SRP Section 9.1.4, along with GDC 61 and 62 and the guidance in RG 1.206. The staff finds that the applicant has satisfactorily addressed this COL Item.

9.1.4.5 Post Combined License Activities

There are no post COL activities related to this section.

9.1.4.6 Conclusions

The staff's finding related to information incorporated by reference is in NUREG–1966. The staff reviewed the application and checked the referenced DCD. The staff's review confirms that the applicant has addressed the required information relating to the "Light Load Handling System (Related to Refueling)," and no outstanding information is expected to be addressed in the COL FSAR related to this section. Pursuant to 10 CFR 52.63(a)(5) and 10 CFR Part 52, Appendix E, Section VI.B.1, all nuclear safety issues relating to the light load handling system (Related To Refueling), that were incorporated by reference are resolved.

In addition, the staff compared the additional information in the application to the relevant NRC regulations, the guidance in SRP Section 9.1.4, and other NRC regulatory guides. The staff's review concludes that the applicant's information is acceptable and meets the requirements of GDC 61 and 62 and the guidance in RG 1.206. The staff finds that the applicant has satisfactorily addressed DCD COL Item 9.1-4-A.

9.1.5 Overhead Heavy Load Handling System

9.1.5.1 Introduction

The overhead heavy load handling systems for North Anna 3 are used to lift loads whose weight is greater than the combined weight of a single spent fuel assembly and its handling device. The principal equipment is the fuel building (FB) crane and reactor building (RB) crane. The overhead heavy load handling system is designed to ensure that inadvertent operations or equipment malfunctions, separately or in combination, will not cause a release of radioactivity, a criticality accident, inability to cool fuel within the reactor vessel or SFP, or prevent safe shutdown of the reactor.

9.1.5.2 Summary of Application

Section 9.1.5, "Overhead Heavy Load Handling System," of the North Anna 3 COL FSAR, Revision 8, incorporates by reference Section 9.1.5 of the certified ESBWR DCD, Revision 10. In addition, in North Anna 3 COL FSAR, Section 9.1.5, the applicant provides the following:

COL Items

- STD COL 9.1-5-A Handling of Heavy Loads

The applicant provided additional information in STD COL 9.1-5-A to address DCD COL Item 9.1-5-A. The applicant described the scope of the heavy load handling procedures. The applicant stated that they will be developed prior to fuel load. The applicant stated that the fuel handling equipment is inspected for operating conditions before each refueling. The applicant described the criteria for inspection of special lifting devices and the inspection and testing of cranes. The applicant described the training and qualification standard for crane operators and the application of specific quality program controls for heavy load handling. The QA program is described in Section 17.5 of the COL FSAR.

9.1.5.3 Regulatory Basis

The regulatory basis of the information incorporated by reference is in NUREG–1966, the FSER related to the certified ESBWR DCD. In addition, the relevant requirements of the Commission regulations for the overhead heavy load handling system and the associated acceptance criteria are in SRP Section 9.1.5.

The regulatory basis for acceptance of the COL information items is established in:

- GDC 1, “Quality Standards and Records,” of 10 CFR Part 50, as it relates to design, fabrication, and testing of structures, systems, and components (SSCs) important to maintain quality standards.

- GDC 4, “Environmental and Dynamic Effects Design Bases” of 10 CFR Part 50, as it relates to the protection of fuel and safety-related equipment from the effects of internally generated missiles (i.e., dropped loads).

9.1.5.4 Technical Evaluation

As documented in NUREG–1966, the staff reviewed and approved Section 9.1.5 of the certified ESBWR DCD, Revision 10. The staff reviewed Section 9.1.5 of the North Anna 3 COL FSAR, Revision 8, and checked the referenced DCD to ensure that the combination of the DCD and the information in the COL represent the complete scope of information relating to this review topic.[1]

The staff’s review confirmed that the information contained in the application and incorporated by reference addresses the relevant information related to this section.

The staff reviewed the information in the North Anna 3 COL FSAR, Revision 8, as follows:

COL Items

- STD COL 9.1-5-A Handling of Heavy Loads

The staff reviewed STD COL 9.1-5-A related to the handling of heavy loads included under Section 9.1.5 of the North Anna 3 COL FSAR. DCD COL Item 9.1-5-A in Section 9.1.6, “COL Information,” of the ESBWR DCD Tier 2, Revision 10 states that the applicant will provide a description of the program governing heavy loads handling, and the schedule for implementation, that addresses the following:

- Heavy loads and heavy load handling equipment outside the scope of loads described in the referenced certified design and the associated heavy load attributes (load weight and typical load path);

- Requirements for heavy load handling safe load paths and routing plans including descriptions of automatic and manual interlocks not described in the referenced certified design and safety devices and procedures to assure safe load path compliance;

- Summary description of requirements to develop heavy load handling equipment maintenance manuals and procedures;

- Requirements for heavy load handling equipment inspection and test plans;

- Requirements for heavy load personnel qualifications, training, and control programs;

- QA program requirements to monitor, implement, and ensure compliance with the heavy load handling program; and

- Issues described in Regulatory Issue Summary (RIS) 2005-25, Supplement 1, "Clarification of NRC Guidelines for Control of Heavy Loads," related to the use of non-metallic slings with single failure proof lifting devices.

In FSAR Section 9.1.5, "Overhead Heavy Load Handling Systems," the applicant states that no heavy loads are identified that are outside the scope of the certified design.

In accordance with the ESBWR DCD COL Item 9.1-5-A, the COL applicant is to provide a description of automatic and manual interlocks not described in the reference certified design. The applicant's response in STD COL 9.1-5-A in North Anna 3, Revision 1 of the FSAR did not provide this information. In RAI 09.01.05-2 dated June 24, 2008 (ADAMS Accession No. ML081760334), the staff requested that the applicant provide this additional information. In their response to RAI 09.01.05-2 dated August 4, 2008 (ADAMS Accession No. ML082200545), the applicant stated that there are neither heavy load handling equipment nor interlocks associated with heavy load handling equipment that are outside the scope of the certified design. Therefore, RAI 09.01.05-02 is resolved and closed. Based on the information provided by the applicant in the North Anna 3 FSAR, Revision 8, Section 9.1.5.9, the staff finds that the applicant has satisfied this element of the COL information item requirement.

In FSAR Sections 9.1.5.6, "Other Overhead Load Handling Systems," 9.1.5.8, "Operational Responsibilities", and 9.1.5.9, "Safety Evaluations," the applicant addressed ESBWR DCD COL Item 9.1-5-A in STD COL 9.1-5-A.

The second item listed in COL Item STD COL 9.1-5-A pertains to requirements for heavy load handling safe load paths and routing plans. In FSAR Section 9.1.5.8, the applicant discusses the development of administrative procedures. In that section, the applicant specifies that North Anna 3 FSAR, Section 13.5, "Plant Procedures," requires the development of administrative procedures to control heavy loads prior to fuel load. The section also specifies that heavy load handling procedures address approved safe load paths and exclusion areas. The applicant states that paths are defined in procedures and equipment layout drawings, and that safe load path procedures address specific requirements. There are procedures to limit the height and the times that heavy loads are carried over the SFP, reactor vessel, or the safe shutdown equipment. In addition, when heavy loads could be carried but are not required to be carried directly over the SFP, reactor vessel, or the safe shutdown equipment, procedures will define an area over which loads shall not be carried so that if the load is dropped, it will not result in damage to spent fuel or operable safe shutdown equipment or compromise reactor vessel integrity. A requirement for supervision to be present during heavy load lifts to enforce procedural requirements is also discussed in FSAR Section 9.1.5.8. Based on the information that was provided by the applicant in FSAR Section 13.5 and Section 9.1.5.8, the staff finds that the applicant has satisfied this element of the COL information item requirement since it specifies that the heavy load handling program will include program elements for safe paths, routing plans, and administrative controls.

The third and fourth item listed above in COL Item STD COL 9.1-5-A pertains to the applicant providing a description of requirements to develop heavy load handling equipment maintenance manuals and procedures, and with the requirements for heavy load handling equipment inspection and test plans.
