installation of a jumper in the wrong panel. The jumper was removed and																										
affected systems restored.																										
Causes of the event were cognitive personnel error and incomplete verbal																										
communications. Following normal practice, the test director verbally																										
instructed the electrician to install the jumper. The test director specified																										
the correct terminal points to the electrician but failed to specify the																										
panel. Furthermore, the test director failed to recognize that the jumper was to be placed in a panel different from the panel used in the preceding twenty																										
nine steps of the test procedure.																										
The test director involved in the event was counselled. This event will be																										
reviewed with test directors on the Plant Staff Technical Section staff along																										
with guidance on proper verbal communications techniques.

At 0338 on 11-5-87, an unticipated Engineered Safeguards Feature actuation occurred on Unit One which was in Refueling. Testing and operating personnel were performing Surveillance Test SE-159-200, "18 Month Logic System Functional Test of the Primary and Secondary Containment isolation System", when the actuation occurred. Per the procedure, the utility licensed operator placed the Reactor Water Sample Valve Isolation Logic Switch in the TEST position. This resulted in a Zone III isolation (EIIS:VA) and actuations of the "B" trains of Standby Gas Treatment System (SGTS) (EIIS: BH), Control Room Emergency Ouside Air Supply System (CREOASS) (EIIS:VI), and Reactor Building Recirculation fans (EIIS:VA). Even though this response was per design for the operator's action, it was unexpected during the test since the preceding step in the test procedure installed a jumper to prevent such response. Upon re-check of completed steps, the system test engineer discovered that the jumper had been installed on the correct terminals but in the wrong panel. The jumper was removed and affected systems restored. Review of schematic drawings conclude that the panel and terminals specified in the procedure were correct, and also that the incorrect placement of the jumper did not cause any damage. Testing was subsequently successfully completed.

CAUSE OF EVENT

Causes of the event were cognitive personnel error and incomplete verbal communications. Prior to the event, the test crew assigned to the Lower Relay Room performed twenty nine steps, including the step immediately preceding the incorrect jumper placement, in panel 1C611. These steps included the installation and removal of other jumpers. Following normal practice, the test director verbally instructed the electrician to install the jumper. The test director specified the correct terminal points to the electrician but failed to specify the panel. Furthermore, the test director failed to recognize that the jumper was to be placed in panel 1C623 as stated in the procedural step instead of 1C611 where the previous jumpers were installed.

ANALYSIS

This event is reportable per 10CFR50.53(a)(2)(iv) in that the unit experienced an unanticipated Engineered Safeguards Feature actuation with the start of SGTS, CREOASS, and the Reactor Building Recirculation fans.

There were no implications to the safety of the public in this event in that SGIS, CREOASS, and the Reactor Building Recircualtion fans performed their intended function. Evaluation of safety implications under alternative conditions is not necessary since, because of prerequisites specified in the test procedure and normal scheduling philosophies, the test would not have been performed under any other set of initial conditions.

CORRECTIVE ACTIONS

The test director involved in the event was counselled. This event will be reviewed with test directors on the Plant Staff Technical Section staff along with guidance on proper verbal communications techniques.
