In order to ensure that the DG is tested under load conditions that are as close to design basis conditions as possible, testing must be performed using a power factor ≤ 0.9 lagging. This power factor is chosen to be representative of the actual design basis inductive loading that the DG would experience.

The Frequency of 24 months is based on engineering judgement, taking into consideration plant conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths.

SURVEILLANCE — SR 3.8.1.7 (continued)

REQUIREMENTS

232

This SR is modified by a Note stating that this Surveillance shall not be performed in MODE 1, 2, 3, or 4. The first Note states that this Surveillance shall not be performed in MODE 1, 2, 3, or 4. The reason for the Note is that during operation in these MODES, performance of this SR could cause perturbations to the electrical distribution systems that could challenge continued steady state operation and, as a result, plant safety systems.

SR 3.8.1.8

232

This SR demonstrates that DG noncritical protective functions. The second Note acknowledges that credit may be taken for unplanned events that satisfy this SR.

(continued)

BASES

SURVEILLANCE SR 3.8.1.8
REQUIREMENTS

(continued)

169

This SR demonstrates that DG noncritical protective functions (e.g., overcurrent, reverse power, local stop pushbutton) are bypassed on an actual or simulated SI actuation signal, and critical protective functions (engine overspeed, low lube oil pressure, and start failure (overcrank) relay) trip the DG to avert substantial damage to the DG. The noncritical trips are bypassed during DBAs but still provide an alarm on an abnormal engine condition. This alarm provides the operator with sufficient time to react appropriately. The DG availability to mitigate the DBA is more critical than protecting the engine against minor problems that are not immediately detrimental to emergency operation of the DG.

The Frequency of 24 months is based on engineering judgment, taking into consideration plant conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths. Operating experience has shown that these components usually pass the SR when performed at the 24 month Frequency. Therefore, this Frequency is acceptable from a reliability standpoint.

232

This SR is modified by a Note stating that this Surveillance shall not be performed in MODE 1, 2, 3, or 4. The first Note states that this Surveillance shall not be performed in MODE 1, 2, 3, or 4. The reason for the Note is that performing the Surveillance would remove a required DG from service which is undesirable in these MODES.

~~REQUIREMENTS~~

(continued)

169 This SR demonstrates the DG operation during an actual or simulated loss of offsite power signal in conjunction with an actual or simulated SI actuation signal. In lieu of actual demonstration of connection and loading of loads, testing that adequately shows the capability of the DG system to perform these functions is acceptable. This testing may include any series of sequential, overlapping, or total steps so that the entire connection and loading sequence is verified.

The Frequency of 24 months is based on engineering judgement, taking into consideration plant conditions required to perform the Surveillance, and is intended to be consistent with expected fuel cycle lengths.

~~THE FOLLOWING TEXT WAS MOVED~~

~~This SR is modified by two Notes.~~ This SR is modified by three Notes.

~~THE PRECEDING TEXT WAS MOVED~~

Note 1 states that all DG starts may be preceded by an engine prelube period which is intended to minimize wear and tear on the DGs during testing. For the purpose of this testing, the DGs must be started from standby conditions, that is, with the engine lube oil continuously circulated and temperature maintained consistent with manufacturer recommendations for the DGs. Note 2 states that this Surveillance shall not be performed in MODE 1, 2, 3, or 4 since performing the Surveillance during these MODES would remove a required offsite circuit from service, cause perturbations to the electrical distribution systems, and challenge safety systems.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.2 AC Sources - MODES 5 and 6

BASES

BACKGROUND

The Background section for Bases 3.8.1, "AC Sources - MODES 1, 2, 3, and 4" is applicable to these Bases, with the following modifications.

In MODE 5 or 6 the minimum required AC sources may be reduced since less energy is retained within the reactor coolant system than during higher MODES. Also, a significant number of required testing and maintenance activities must be performed under these conditions such that equipment and systems, including the AC power sources, must be removed from service. The minimum required AC sources is based on the requirements of LCO 3.8.10, "Distribution Systems - MODES 5 and 6."

APPLICABLE SAFETY ANALYSES

The OPERABILITY of the minimum AC electrical power sources during MODES 5 and 6 ensures that:

- a. Systems needed to mitigate a fuel handling accident are available; and
- b. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available;

In general, when the plant is shut down, the Technical Specifications requirements ensure that the plant has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. Therefore, the OPERABILITY of the AC electrical power sources ensures that one train of the onsite power or offsite AC sources are OPERABLE in the event of:

(continued)

BASES

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

- a. An assumed loss of all offsite AC power;
- b. An assumed loss of all onsite standby AC power; or
- c. A worst case single failure.

This reduction in required AC sources is allowed because many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6. Worst case bounding events are deemed not credible in MODES 5 and 6 because the energy contained within the reactor pressure boundary (reactor coolant temperature and pressure) and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and result in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCOs for the systems required in MODES 5 and 6.

During MODES 1, 2, 3, and 4, various deviations from the analysis assumptions and design requirements are allowed within the Required Actions. This allowance is in recognition that certain testing and maintenance activities must be conducted provided an acceptable level of risk is not exceeded. During MODES 5 and 6, performance of a significant number of required testing and maintenance activities is also required. In MODES 5 and 6, the activities are generally planned and administratively controlled. Relaxations from MODE 1, 2, 3, and 4 LCO requirements are acceptable during shutdown modes based on:

- a. The fact that time in an outage is limited. This is a risk prudent goal as well as a utility economic consideration.
- b. Requiring appropriate compensatory measures for certain conditions. These may include administrative controls, reliance on systems that do not necessarily meet typical design requirements applied to systems credited in operating MODE analyses, or both.

(continued)

BASES

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

- c. Prudent utility consideration of the risk associated with multiple activities that could affect multiple systems.
- d. Maintaining, to the extent practical, the ability to perform required functions (even if not meeting MODE 1, 2, 3, and 4 OPERABILITY requirements) for systems assumed to function during an event.

In the event of an accident while in MODE 5 or 6 this LCO ensures the capability to support systems necessary to mitigate the postulated events during shutdown, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power.

The AC sources satisfy Criterion 3 of the NRC Policy Statement.

LCO

One qualified independent offsite power circuit supplying the associated AC electrical power distribution subsystem required to be OPERABLE by LCO 3.8.10, "Distribution Systems—MODES 5 and 6," ensures that all required loads are powered from offsite power. An OPERABLE DG, capable of supporting the distribution system required to be OPERABLE by LCO 3.8.10, ensures a diverse power source is available to provide electrical power support, assuming a loss of the independent offsite power circuit. Together, OPERABILITY of the required offsite circuit and DG ensures the availability of sufficient AC sources to operate the plant in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents).

An OPERABLE qualified offsite circuit is one that is capable of maintaining rated frequency and voltage, and accepting required loads during an accident, while connected to the 480 V safeguards bus(es). Power from either offsite power circuit 751 or 767, or by backfeeding through auxiliary transformer 11 satisfies this requirement.

(continued)

BASES

(continued)

BASES

LCO
(continued)

A DG is considered OPERABLE when:

- a. The DG is capable of starting, accelerating to rated speed and voltage, and connecting to its respective 480 V safeguards buses on detection of bus undervoltage within 10 seconds;
- b. All loads on each 480 V safeguards bus except for the safety related motor control centers, component cooling water (CCW) pump, and containment spray (CS) pump are capable of being tripped on an undervoltage signal (CCW pump must be capable of being tripped on coincident safety injection (SI) and undervoltage signal);
- c. The DG is capable of accepting required loads manually. Since most equipment which receives a SI signal are isolated in these MODES due to maintenance or low temperature overpressure protection concerns, and the DBA of concern (i.e., a fuel handling accident) would not generate a SI signal, manual loading of the DGs will most likely be required. These loads must be capable of being added to the OPERABLE DG within 10 minutes;
- d. The DG day tank is available to provide fuel oil for ≥ 1 hour at 110% design loads;
- e. The fuel oil transfer pump from the fuel oil storage tank to the associated day tank is OPERABLE including all required piping, valves, and instrumentation (long-term fuel oil supplies are addressed by LCO 3.8.3, "Diesel Fuel Oil"); and
- f. A ventilation train consisting of at least one of two fans and the associated ductwork and dampers is OPERABLE.

(continued)

BASES

(continued)

BASES

APPLICABILITY

The AC sources required to be OPERABLE in MODES 5 and 6 provide assurance that systems required to mitigate the effects of postulated events and to maintain the plant in the cold shutdown or refueling condition are available.

The AC power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.1, "AC Sources-MODES 1, 2, 3, and 4."

ACTIONS

A.1

As discussed in LCO 3.0.6, the Distribution System's ACTIONS would not be entered even if all AC sources to it are inoperable, resulting in de-energization. Therefore, the Required Actions of Condition A are modified by a Note to indicate that when Condition A is entered with no onsite or offsite AC power to any required 480 V safeguards bus, the ACTIONS for LCO 3.8.10 must also be immediately entered. This Note allows Condition A to provide requirements for the loss of the offsite power circuit, whether or not a train is de-energized. LCO 3.8.10 would provide the appropriate restrictions for the situation involving a completely de-energized train.

(212)

With ~~no~~ offsite power available to one or more required 480 V safeguards bus(es) ~~inoperable~~, assurance must be provided that there is not a complete loss of required safety features. Although two trains may be required by LCO 3.8.10, one train with offsite power available may be capable of supporting sufficient required features to allow continuation of CORE ALTERATIONS, or operations involving positive reactivity additions. By allowing the option to declare required features inoperable that are not powered from offsite power, appropriate restrictions will be implemented in accordance with the LCO ACTIONS of the affected required features. Required features remaining powered from a qualified offsite power circuit, even if that circuit is considered inoperable because it is not powering other required features, are not declared inoperable by this Required Action.

(continued)

BASES

ACTIONS
~~(continued)~~

~~A.2.1, A.2.2, and A.2.3~~

~~With the offsite power circuit not available to all required AC electrical trains, the option exists to declare all required features inoperable per Required Action and A.12.4~~

(continued)

212

~~With the offsite power circuit not available to all required AC electrical trains, the option exists to declare all required features inoperable per Required Action A. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions is made. Therefore, immediate suspension of CORE ALTERATIONS, and operations involving positive reactivity additions is an acceptable option to Required Action A. Performance of Required Actions A.1.2.1 and Performance of Required Actions A.2.2 shall not preclude completion of movement of a component to a safe position or normal cooldown of the coolant volume for the purpose of system temperature control. A.2.1, A.2.2, and A.2.3 shall not preclude completion of movement of a component to a safe position or normal cooldown of the coolant volume for the purpose of system temperature control within established procedures.~~

It is further required to immediately initiate action to restore the required offsite power AC sources and to continue this action until restoration is accomplished in order to provide the necessary AC power to the plant safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required offsite power sources should be completed as quickly as possible in order to minimize the time during which the plant safety systems may be without sufficient power.

The restoration of the required DG should be completed as quickly as possible in order to minimize the time during which the plant safety systems may be without sufficient redundant power.

L
SURVEILLANCE REQUIREMENTS

SR 3.8.2.1

This SR requires the performance of SRs from LCO 3.8.1 that are necessary for ensuring the OPERABILITY of the AC sources in MODES 5 and 6.

This SR precludes requiring the OPERABLE DG(s) from being paralleled with the offsite power network or otherwise rendered inoperable during performance of SRs, precludes de-energizing a required 480 V safeguards bus, and precludes unnecessary transfers of the offsite power source configurations. With limited AC sources available, a single event could compromise both the required circuit and the DG. Therefore, the requirement to perform SR 3.8.1.3, and SR 3.8.1.6 through 3.8.1.9 is suspended. It is the intent that these SRs must still be capable of being met, but actual performance is not required during periods when the DG is required to be OPERABLE. Refer to the corresponding Bases for LCO 3.8.1 for a discussion of each SR.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.3 Diesel Fuel Oil

BASES

BACKGROUND

*Change,
not in final
draft*

Fuel oil is provided to each emergency diesel generator (DG) by a dedicated 350 gal day tank located near the DG. Each day tank is supplied from an associated 6000 gal underground fuel oil storage tank. Each storage tank provides a minimum fuel oil capacity of 5000 gal. The two storage tanks are sufficient to operate both DGs at design ratings for 24 hours. The total minimum fuel oil capacity also ensures that both DGs can operate for a period of 40 hours while providing for a maximum post loss of coolant accident (LOCA) load demand. The maximum load demand is calculated using the assumption that both DGs are available and is less than the DG design rating. The minimum onsite fuel capacity is sufficient to operate the DGs for longer than 8 hours which is the time required to replenish the onsite supply from outside sources (Ref. 1).

Fuel oil is transferred from each storage tank to the associated day tank by a dedicated fuel oil transfer pump. Each fuel oil transfer pump is powered by a 480 V safeguards bus that is backed by the associated DG. One fuel oil transfer pump has the capability to supply both DGs operating with 110% of their design loads. Redundancy of pumps and piping precludes the failure of one pump, or the rupture of any pipe, valve or tank to result in the loss of more than one DG.

All outside tanks, pumps, and piping are located underground to protect them from potential missiles. Heat tracing is provided in the exposed suction piping to the fuel oil pumps in the event that heating is lost in the DG rooms. The heat tracing is thermostatically controlled to maintain the fuel oil in the pipe > 40°F which is above the cloud point temperature of the fuel oil (0°F).

(continued)

BASES

APPLICABLE
SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses (Refs. 2 and 3), assume Engineered Safety Feature (ESF) systems are OPERABLE. The DGs are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that fuel, Reactor Coolant System and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, "Power Distribution Limits;" Section 3.4, "Reactor Coolant System (RCS);" and Section 3.6, "Containment Systems."

Since diesel fuel oil supports the operation of the standby AC power sources, it satisfies Criterion 3 of the NRC Policy Statement.

LCO

Stored onsite diesel fuel oil is required to have sufficient supply for 40 hours of maximum post-LOCA load demand. It is also required to meet specific standards for quality. This requirement, in conjunction with an ability to obtain replacement fuel oil supplies within 8 hours, supports the availability of DGs required to shut down the reactor and to maintain it in a safe condition for an anticipated operational occurrence (AOO) or a postulated DBA with loss of offsite power. DG day tank fuel requirements, as well as transfer capability from the storage tank to the day tank, are addressed in LCO 3.8.1, "AC Sources - MODES 1, 2, 3, and 4," and LCO 3.8.2, "AC Sources - MODES 5 and 6."

APPLICABILITY

The AC sources (LCO 3.8.1 and LCO 3.8.2) are required to ensure the availability of the required power to shut down the reactor and maintain it in a safe shutdown condition after an AOO or a postulated DBA. Since stored diesel fuel oil supports LCO 3.8.1 and LCO 3.8.2, stored diesel fuel oil is required to be within limits in MODES 1, 2, 3 and 4, and when the associated DG is required to be OPERABLE in MODES 5 and 6.

(continued)

BASES

ACTIONS

A.1

30

With one or more required DGs with an onsite supply of < 5000 gal of fuel oil, the assumed 40 hour fuel oil supply for a DG is not available. This circumstance may be caused by events, such as full load operation after an inadvertent start with an initial minimum required fuel oil level, or feed and bleed operations, which may be necessitated by increasing fuel oil particulate levels or any number of other oil quality degradations. Required Action A.1 allows sufficient time for obtaining the requisite replacement volume and performing the analyses required prior to addition of fuel oil to the tank. The Completion Time of 48 1/2 hours is considered sufficient to complete restoration of the required level prior to declaring the DG inoperable. This period is acceptable based on the remaining capacity, the fact that actions will be initiated to obtain replenishment, and the low probability of an event during this brief period.

B.1

21

If one or more DGs has stored fuel oil with total particulates not within limits ~~for reasons not related to new fuel oil~~, the fuel oil must be restored within limits within 7 days. The fuel oil particulate properties of ~~viscosity, water, and sediment~~ are verified by SR 3.8.3.2. Trending of particulate levels normally allows sufficient time to correct high particulate levels prior to reaching the limit of acceptability. Poor sample practices (bottom sampling), contaminated sampling equipment, or errors in laboratory analysis can produce failures that do not follow a trend. Since the presence of particulates does not mean failure of the fuel oil to burn properly in the diesel engine, and particulate concentration is unlikely to change significantly between Surveillance Frequency intervals, and proper engine performance has been recently demonstrated (within 31 days), it is prudent to allow a brief period prior to declaring the associated DG inoperable. The 7 day Completion Time allows for further evaluation, resampling and re-analysis of the DG fuel oil.

(continued)

BASES

ACTIONS
(continued)

C.1

212

~~With a Required Action and associated Completion Time not met, or one or more DG's fuel oil properties defined in SR 3.8.3.2 not within required limits, a period of 30 days is allowed for reasons other than addressed by Conditions A or B (restoring the stored fuel oil properties. This period provides sufficient time to test the stored fuel oil to determine that the new fuel oil, when mixed with previously stored fuel oil, remains acceptable, or to restore the stored fuel oil properties. This restoration may involve feed and bleed procedures, filtering, or combinations of these procedures. Even if a DG start and load was required during this time interval and the fuel oil properties were outside limits, there is a high likelihood that the DG would still be capable of performing its intended function.~~

D.1

212

~~With a Required Action and associated Completion Time not met, or one or more DG's fuel oil not within limits for reasons other than addressed by Conditions A, B, or C (e.g., cloud point temperature reached), the associated DG may be incapable of performing its intended function and must be immediately declared inoperable.~~

SURVEILLANCE
REQUIREMENTS

SR 3.8.3.1

169

~~This SR verifies an onsite supply of ≥ 5000 gal of fuel oil is available for each required DG. This ensures that there is an adequate inventory of fuel oil in the storage tanks to support each DG's operation for 40 hours while providing maximum post-LOCA loads. The 40 hour period is sufficient time to place the plant in a safe shutdown condition and to bring in replenishment fuel from an offsite location.~~

each fuel oil storage tank contains

The Frequency of 31 days is adequate to ensure that a sufficient supply of fuel oil is available, since indications are available to ensure that operators would be aware of any large uses of fuel oil during this period.

(continued)

BASES

(continued)

BASES

SURVEILLANCE

SR 3.8.3.2

(continued)

REQUIREMENTS

This SR provides a means of determining whether new and stored fuel oil has been contaminated with substances that would have an immediate, detrimental impact on diesel engine combustion. This ensures the availability of high quality fuel oil for the DGs. Fuel oil degradation during long term storage is indicated by an increase in particulate, due mostly to oxidation. The presence of particulate does not mean the fuel oil will not burn properly in a diesel engine. The particulate can cause fouling of filters and fuel oil injection equipment, however, which could eventually cause engine failure.

A fuel oil sample is analyzed to establish that properties specified in Table 1 of ASTM D975-78 (Ref. 4) for viscosity, water, and sediment are met for the stored fuel oil.

~~SURVEILLANCE — SR 3.8.3.2 (continued)~~

REQUIREMENTS

The Frequency of this SR takes into consideration fuel oil degradation trends that indicate that particulate concentration is unlikely to change significantly between Frequency intervals. The Frequency, as specified in the Diesel Fuel Oil Testing Program, is 92 days.

AC Sources - MODES 1, 2, 3, and 4
B 3.8.1

DC Sources - MODES 1, 2, 3, and 4
B 3.8.4

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.4 DC Sources - MODES 1, 2, 3, and 4

BASES

BACKGROUND

A source of electrical power is required for most safety related and nonessential active components. Two sources of electrical power are available, alternating current (AC) and direct current (DC). Separate distribution systems are developed for these two electrical power sources which are further divided and organized based on voltage considerations and whether they are Class 1E (i.e., supply safety related or engineered safeguards functions) or nonessential. This LCO is provided to specify the minimum sources of DC power which are required to supply the DC buses and their associated distribution system during MODES 1, 2, 3, and 4.

The station DC electrical power subsystem provides the AC emergency power system with control power. It also provides both motive and control power to selected safety related equipment and preferred AC instrument bus power (via inverters). Atomic Industrial Forum (AIF) GDC 39 (Ref. 1) requires emergency power sources be provided and designed with adequate independence, redundancy, capacity, and testability to permit the functioning of the engineered safety features and protection systems.

The 125 VDC electrical power system consists of two independent and redundant safety related Class 1E DC electrical power distribution train (Train A and Train B). Each subsystem consists of one 125 VDC battery, two battery chargers supplied from the 480 V system, distribution panels and buses, and all the associated control equipment and interconnecting cabling (see Figure B 3.8.4-1). The batteries and battery chargers are addressed by this LCO.

(continued)

BASES

(continued)

BASES

BACKGROUND
(continued)

Each battery provides a separate source of DC power independent of AC power. Each of the two batteries is capable of carrying its expected shutdown loads following a plant trip and a loss of all AC power for a period of 4 hours without battery terminal voltage falling below 105 V. Major loads and approximate operating times on each battery are discussed in the UFSAR (Ref. 2).

There are four battery chargers available to the batteries. Chargers 1A and 1B are rated at 150 amps and chargers 1A1 and 1B1 are rated at 200 amps. Battery chargers 1A and 1A1 are normally aligned to battery A, and battery chargers 1B and 1B1 are normally aligned to battery B. A charging capacity of at least 150 amps is normally required to supply the necessary DC loads on each train and to provide a full battery charge to ensure the availability of the required power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated Design Basis Accident (DBA). The DC power distribution system is described in more detail in Bases for LCO 3.8.9, "Distribution System—MODES 1, 2, 3, and 4," and LCO 3.8.10, "Distribution Systems—MODES 5 and 6."

The DC electrical power distribution subsystem also provide DC electrical power to the inverters, which in turn power the AC instrument buses. The inverters are described in more detail in Bases for LCO 3.8.7, "AC Instrument Bus Sources—MODES 1, 2, 3, and 4," and LCO 3.8.8, "AC Instrument Bus Sources—MODES 5 and 6."

Train A Engineered Safety Feature (ESF) equipment is supplied from battery A, while Train B ESF equipment is supplied from battery B. Additionally, the 480 V ESF switchgear and diesel generator (DG) control panels are supplied from either battery by means of an automatic transfer circuit in the switchgear and control panels. The normal supply from Train A (Buses 14 and 18 and DG A) is from DC distribution panels A. These panels also provide the emergency DC supply for Train B. Similarly, the normal supply from Train B (Buses 16 and 17 and DG B) is from DC distribution panels B. These panels also provide the emergency dc supply for Train A.

(continued)

BASES

BACKGROUND
(continued)

Each 125 VDC battery and associated battery chargers are separately housed in a ventilated room with its associated distribution center. Each subsystem is located in an area separated physically and electrically from the other subsystem to ensure that a single failure in one subsystem does not cause a failure in a redundant subsystem. The two battery rooms are supplied with ventilation by a common AC powered air conditioning and heating unit which also provides sufficient air changes to prevent hydrogen buildup. A redundant DC powered fan is also available in the event that all AC power is lost. The failure of both the AC powered and DC powered units does not result in unacceptable room service conditions until after 5 hours of continuous battery operation during a DBA (Ref. 2).

The batteries for Train A and Train B DC electrical power distribution subsystem are sized to produce required capacity at 80% of nameplate rating, corresponding to warranted capacity at end of life cycles and the 100% design demand. Battery size is based on 125% of required capacity for aging considerations. The minimum voltage limit is 2.13 V per cell, which corresponds to a total minimum voltage output of 128 V per battery.

Each battery charger for the Train A and Train B DC electrical power distribution subsystem has ample power output capacity for the steady state operation of connected loads required during normal operation, while at the same time maintaining its battery bank fully charged. Each battery charger also has sufficient capacity to restore the battery from the design minimum charge to its fully charged state within 24 hours while supplying normal steady state loads discussed in the UFSAR, Chapter 8 (Ref. 2).

APPLICABLE
SAFETY ANALYSES

(149)

The initial conditions of a DBA and transient analyses (Refs. 3, 4, and 4-5), assume that ESF systems are OPERABLE. The DC electrical power system provides normal and emergency DC electrical power for the DGs, emergency auxiliaries, and control and switching during all MODES of operation.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

The OPERABILITY of the DC sources is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the plant. This includes maintaining at least one train of DC source OPERABLE in the event of:

- a. An assumed loss of all offsite AC power or all onsite standby AC power; and
- b. A worst case single failure.

In the event of a DBA, the OPERABILITY requirements of the DC electrical power sources ensures that one train of DC electrical power is available with:

- a. An assumed loss of all offsite power; and
- b. A worst case single failure (including the loss of one DC electrical power source).

In general, the accident analyses assume that all offsite power is lost at the time of the initiating event except where the availability of offsite power provides worst case conditions (e.g., steam line break with continued operation of the reactor coolant pumps). The availability of redundant offsite power sources (i.e., circuits 751 and 767) helps to reduce the potential to lose all offsite power. Providing redundant sources of DC power ensures that at least one DC power source is available if all onsite standby AC power is unavailable coincident with a single failure of one offsite power source during non accident conditions. In the event the plant is in the 100/0 or 0/100 mode, a redundant source of offsite power can be obtained by backfeeding through the main transformer using a flexible connection that can be tied into the plant auxiliary transformer 11. The plant can survive on the available battery power, alternate power sources, and turbine driven Auxiliary Feedwater pump during the estimated 8 hours required to provide this power transfer (Ref. 6). Therefore, the requirements of GDC 17 (Ref. 7) can be met at all times.

The DC sources satisfy Criterion 3 of the NRC Policy Statement.

(continued)

BASES (continued)

LCO

The Train A and Train B DC electrical power sources, each consisting of one battery, a charging capacity of at least 150 amps, and the corresponding control equipment and interconnecting cabling within the train are required to be OPERABLE to ensure the availability of the required power to shut down the reactor and maintain it in a safe condition after an AOO or a postulated DBA. Loss of any one train DC electrical power source does not prevent the minimum safety function from being performed.

(169) An OPERABLE DC electrical power source requires the battery and at least one battery ~~battery~~-charger with a capacity \geq 150 amps to be operating and connected to the associated DC bus. The AC powered and DC powered fan units are not required to be OPERABLE for this LCO, but some form of ventilation may be required for SR 3.8.6⁴² and SR 3.8.6.5

APPLICABILITY

The DC electrical power sources are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure safe plant operation and to ensure that:

- a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients; and
- b. Adequate core cooling is provided, and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

The DC electrical power requirements for MODES 5 and 6 are addressed in LCO 3.8.5, "DC Sources—MODES 5 and 6."

(continued)

BASES (continued)

ACTIONS

A.1

With one DC electrical power source inoperable, OPERABILITY must be restored within 2 hours. In this Condition, redundancy is lost and only one train is capable to completely respond to an event. If one of the required DC electrical power sources is inoperable, the remaining DC electrical power source has the capacity to support a safe shutdown and to mitigate an accident condition. A subsequent worst case single failure would, however, result in the complete loss of the remaining 125 VDC electrical power distribution subsystem with attendant loss of ESF functions. The 2 hour Completion Time reflects a reasonable time to assess plant status as a function of the inoperable DC electrical power subsystem and, if the DC electrical power source is not restored to OPERABLE status, to prepare to effect an orderly and safe plant shutdown.

B.1 and B.2

(129)

If the inoperable DC electrical power source cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

C.1

If both DC electrical power sources are inoperable, a loss of multiple safety functions exists; therefore, LCO 3.0.3 must be immediately entered.

(continued)

BASES (continued)

SURVEILLANCE
REQUIREMENTS

SR 3.8.4.1

234

~~This SR verifies that each battery has a battery charger with a capacity of ≥ 150 amps. Verifying battery terminal voltage while on float charge for the batteries helps to ensure the effectiveness of the charging system and the ability of the batteries to perform their intended function. This verification helps to ensure float charge is the effectiveness of the charging system condition in which the charger is supplying the continuous charge required to overcome the internal losses of a battery (or battery cell) and the ability of the batteries to perform their intended function maintain the battery (or a battery cell) in a fully charged state. The frequency of 31 days is considered acceptable voltage requirements are based on operating experience the nominal design voltage of the battery and other indications available are consistent with the initial voltages assumed in the control room that alert the operator to battery malfunctions battery sizing calculations. The 7 day Frequency is consistent with manufacturer recommendations and IEEE-450 (Ref. 8).~~

SR 3.8.4.2

This SR verifies that the capacity of each battery is adequate to supply and maintain in OPERABLE status, the required emergency loads for the design duty cycle when subjected to a battery service test. A battery service test is a special test of battery capability, as found, to satisfy the design requirements (battery duty cycle) of the DC electrical power system. The discharge rate and test length corresponds to the design duty cycle requirements specified in Reference 2.

149

The Surveillance Frequency of 24 months is consistent with the recommendations of Regulatory Guide 1.32 (Ref. 5-9) and Regulatory Guide 1.129 (Ref. 6-10), which state that the battery service test should be performed during refueling operations or at some other outage, with intervals between tests not to exceed 24 months.

This SR is modified by two Notes. Note 1 states that SR 3.8.4.3 may be performed in lieu of SR 3.8.4.2. This substitution is acceptable because SR 3.8.4.3 represents a

(continued)

BASES (continued)

more severe test of battery capacity than does SR 3.8.4.2. Note 2 states that this surveillance shall not be performed in MODE 1, 2, 3, or 4 because performing the Surveillance would perturb the electrical distribution system and challenge safety systems.

(continued)

BASES (continued)

(continued)

BASES

SURVEILLANCE
REQUIREMENTS
(continued)

SR 3.8.4.3

This Surveillance verifies that each battery capacity is $\geq 80\%$ of the manufacturer's rating when subjected to a performance discharge test. A battery performance test is a test of constant current capacity of a battery, normally done in the as found condition, after having been in service, to detect any change in the capacity as determined by specified acceptance criteria. The test is intended to determine overall battery degradation due to age and usage.

A battery should be replaced if its capacity is below 80% of the manufacturer rating. A capacity of 80% shows that the battery rate of deterioration is increasing, even if there is ample capacity to meet the load requirements.

The Frequency for this SR is 60 months when the battery is $< 85\%$ of its expected life with no degradation and 12 months if the battery shows degradation or has reached 85% of its expected life with a capacity $< 100\%$ of the manufacturer's rating. When the battery has reached 85% of its expected life with capacity $\geq 100\%$ of the manufacturer's rating, the Frequency becomes 24 months. Battery degradation is indicated when the battery capacity drops by more than 10% relative to its capacity on the previous performance test or when it is $\geq 10\%$ below the manufacturer rating. These Frequencies are considered acceptable based on the testing being performed in a conservative manner relative to the battery life and degradation. This ensures that battery capacity is adequately monitored and that the battery remains capable of performing its intended function.

This SR is modified by a Note stating that this SR shall not be performed in MODE 1, 2, 3, or 4. The reason for the Note is that during operation in these MODES, performance of this SR could cause perturbations to the electrical distribution system and challenge safety systems.

Figure B 3.8.4-1

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.5 DC Sources - MODES 5 and 6

BASES

BACKGROUND

The Background section of the Bases for LCO 3.8.5, "DC Sources - MODES 1, 2, 3, and 4" is applicable to these Bases, with the following modifications.

(169) In MODE 5 or 6, the number of required DC electrical sources may be reduced since less energy is retained within the reactor coolant system than during higher MODES. Also, a significant number ~~of~~ required testing and maintenance activities must be performed under these conditions such that equipment and systems, including the DC electrical sources, must be removed from service. The minimum required DC electrical sources is based on the requirements of LCO 3.8.10, "Distribution Systems - MODES 5 and 6."

APPLICABLE SAFETY ANALYSES

The OPERABILITY of the minimum DC electrical power sources during MODES 5 and 6 ensures that:

- a. Required features needed to mitigate a fuel handling accident are available;
- b. Required features necessary to mitigate the effects of events that can lead to core damage during shutdown are available; and
- c. Instrumentation and control capability is available for monitoring and maintaining the plant in a cold shutdown condition or refueling condition.

In general, when the plant is shut down, the Technical Specifications requirements ensure that the plant has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. Therefore, the OPERABILITY of the DC electrical power sources ensures that one train of DC sources are OPERABLE in the event of:

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

- a. An assumed loss of all offsite AC power;
- b. An assumed loss of all onsite standby AC power; or
- c. A worst case single failure.

This reduction in required AC sources is allowed because many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6. Worst case bounding events are deemed not credible in MODES 5 and 6 because the energy contained within the reactor pressure boundary (reactor coolant temperature and pressure) and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and result in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCOs for the systems required in MODES 5 and 6.

During MODES 1, 2, 3, and 4, various deviations from the analysis assumptions and design requirements are allowed within the Required Actions. This allowance is in recognition that certain testing and maintenance activities must be conducted provided an acceptable level of risk is not exceeded. During MODES 5 and 6, performance of a significant number of required testing and maintenance activities is also required. In MODES 5 and 6, the activities are generally planned and administratively controlled. Relaxations from MODE 1, 2, 3, and 4 LCO requirements are acceptable during shutdown modes based on:

- a. The fact that time in an outage is limited. This is a risk prudent goal as well as a utility economic consideration.
- b. Requiring appropriate compensatory measures for certain conditions. These may include administrative controls, reliance on systems that do not necessarily meet typical design requirements applied to systems credited in operating MODE analyses, or both.
- c. Prudent utility consideration of the risk associated with multiple activities that could affect multiple systems.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

- d. Maintaining, to the extent practical, the ability to perform required functions (even if not meeting MODE 1, 2, 3, and 4 OPERABILITY requirements) for systems assumed to function during an event.

In the event of an accident while in MODE 5 or 6, this LCO ensures the capability to support systems necessary to mitigate the postulated events during shutdown, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power.

The DC sources satisfy Criterion 3 of the NRC Policy Statement.

LCO

(149)

The DC electrical power sources are required to be OPERABLE to support the distribution subsystems required OPERABLE by LCO 3.8.10, "~~Distribution Systems - Shutdown Systems - MODES 5 and 6.~~" If only one DC electrical power distribution train is required to be OPERABLE, the minimum source consists of a battery, a charging capacity of at least 150 amps, and the corresponding control equipment and interconnecting cabling within the required train. If both DC electrical power trains are required, one DC source must contain a battery, a charging capacity of at least 150 amps, and the corresponding control equipment and interconnecting cabling within the train system. The second DC source may consist of only a battery charger with a capacity of at least 150 amps, or a battery, and the corresponding control equipment and interconnecting cabling. The two must be sufficiently independent that a loss of all offsite power sources, a loss of onsite standby power, or a worst case single failure does not affect more than one required DC electrical power train. This ensures the availability of sufficient DC electrical power sources to operate the plant in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents).

The AC powered and DC powered fan ventilation units are not required to be OPERABLE for this LCO, but some form of ventilation may be required to meet SR 3.8.6⁴³²

and SR 3.8.6.5

(149)

(continued)

BASES

APPLICABILITY The DC electrical power sources required to be OPERABLE in MODES 5 and 6 provide assurance that systems required to mitigate the affects of a DBA and to maintain the plant in the cold shutdown or refueling condition are available.

The DC electrical power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.4, "DC Sources - MODES 1, 2, 3, and 4."

ACTIONS

A.1

Although two trains may be required by LCO 3.8.10, "Distribution Systems - MODES 5 and 6," the remaining DC electrical train may be capable of supporting sufficient systems to allow continuation of CORE ALTERATIONS, and operations with a potential for positive reactivity additions. By allowing the option to declare required features inoperable associated with the required inoperable DC power source(s), appropriate restrictions will be implemented in accordance with the LCO ACTIONS of the affected required features. Required features remaining powered from a DC electrical source, even if that source is considered inoperable because it is not powering other required features, are not declared inoperable by this Required Action.

(continued)

D
BASES

ACTIONS
(continued)

A.2.1, A.2.2, A.2.3, and A.2.4

212
With one or more required DC electrical power sources inoperable, the option exists to declare all required features inoperable per Required Action A.1. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions is made. Therefore, immediate suspension of CORE ALTERATIONS, movement of irradiated fuel assemblies, and operations involving positive reactivity additions is an acceptable option to Required Action A.1. Performance of Required Actions A.2.1, A.2.2, and A.2.3 shall not preclude completion of movement of a component to a safe position or normal cooldown of the coolant volume for the purpose of system temperature control.

It is further required to immediately initiate action to restore the required DC electrical power source and to continue this action until restoration is accomplished in order to provide the necessary DC electrical power to the plant safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required DC electrical power subsystems should be completed as quickly as possible in order to minimize the time during which the plant safety systems may be without sufficient power.

SURVEILLANCE
REQUIREMENTS

SR 3.8.5.1

149
~~SR 3.8.5.1~~ This SR requires the performance of SRs from LCO 3.8.4 that are necessary for ensuring the OPERABILITY of the DC electrical power subsystem in MODES 5 and 6.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.8.5.1 (continued)

This SR precludes requiring the OPERABLE DC electrical power source from being removed from service to perform a battery service test or a performance discharge test. With limited DC sources available, a single event could compromise multiple required safety features. It is the intent that these SRs must still be capable of being met, but actual performance is not required during periods when the DC electrical power source is required to be OPERABLE. Refer to the corresponding Bases for LCO 3.8.4 for a discussion of the specified SR.

REFERENCES

None.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.6 Battery Cell Parameters

BASES

BACKGROUND

Each DC electrical power train contains a 125 VDC battery which is capable of carrying the expected shutdown loads following a plant trip and a loss of all AC power for a period of 4 hours without battery terminal voltage falling below 105 V. Major loads and approximate operating times on each battery are discussed in the UFSAR (Ref. 1). The batteries are normally in standby since the associated battery chargers provide for the required DC system loads.

The batteries for Train A and Train B DC electrical power are sized to produce required capacity at 80% of nameplate rating, corresponding to warranted capacity at end of life cycles and 100% design demand. Battery size is based on 125% of required capacity for aging considerations.

(212)

~~The minimum voltage limit is 2.13 V per cell, which corresponds to a total minimum voltage output of 128 V per battery.~~

This LCO delineates the limits on electrolyte temperature, level, float voltage, and specific gravity for the DC power source batteries to ensure that the batteries are capable of performing their safety function as required by LCO 3.8.4, "DC Sources - MODES 1, 2, 3, and 4," and LCO 3.8.5, "DC Sources - MODES 5 and 6."

(continued)

BASES

APPLICABLE
SAFETY ANALYSES

(109)

The initial conditions of Design Basis Accident (DBA) and transient analyses assume Engineered Safety Feature systems are OPERABLE (Refs. 2 and 3). The DC electrical power system provides normal and emergency DC electrical power for the diesel generators, emergency auxiliaries, and control and switching during all MODES of operation. The DC sources are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to Engineered Safety Feature systems so that fuel, Reactor Coolant System and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, "Power Distribution Limits;" Section 3.4, "Reactor Coolant System (RCS);" and Section 3.6, "Containment Systems."

Battery cell parameters satisfy Criterion 3 of the NRC Policy Statement.

LCO

(22)

This LCO requires that battery cell parameters for Train A and B batteries be within limits to ensure availability of the required DC power to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence or a postulated DBA. Battery cell parameters are defined for electrolyte level, temperature, float voltage, and specific gravity. The limits for electrolyte level, float voltage, and specific gravity are conservatively established for both designated pilot cells and connected cells (Category A and B, respectively of Table B-3.8.6-1) within plant procedures. Failure to meet these established limits may allow continued DC electrical system function even with Category A and B limits not met for a limited duration provided that the upper limit specified in the associated Surveillance Requirement for each connected cell (Category C) is not exceeded. In addition, the average electrolyte temperature of the term "connected cell" excludes any battery cells that may be $\geq 65^{\circ}\text{F}$ jumpered out.

(continued)

BASES (continued)

212 ~~The battery cell parameters are specified in Table B-3.8.6-1. This table delineates the limits on electrolyte level, float voltage, and specific gravity for three different categories. The meaning of each category is discussed below.~~

(continued)

BASES (continued)

~~LCO~~ ~~Category A~~
~~(continued)~~

~~Category A defines the normal parameter limit for each designated pilot cell in each battery. The cells selected as pilot cells are those whose temperature, level, voltage, and electrolyte specific gravity approximate the state of charge of the entire battery.~~

~~The Category A limits specified for electrolyte level are based on manufacturer recommendations and are consistent with the guidance in IEEE 450 (Ref. 3), with an additional allowance of 1/4 inch above the high water level indication mark for operating margin to account for temperature and charge effects. In addition to this allowance, footnote a to Table B 3.8.6-1 permits the electrolyte level to be above the specified maximum level during equalizing charge, provided it is not overflowing. The specified maximum level is defined as 1/4 inch above the maximum indication mark. These limits ensure that the plates suffer no physical damage, and that adequate electron transfer capability is maintained in the event of transient conditions. IEEE 450 (Ref. 3) recommends that electrolyte level readings should be made only after the battery has been at float charge for at least 72 hours.~~

~~The Category A limit specified for float voltage is ≥ 2.13 V per cell. This value is based on the recommendations of IEEE 450 (Ref. 3), which states that prolonged operation of cells < 2.13 V can reduce the life expectancy of cells.~~

~~The Category A limit specified for specific gravity for each pilot cell is ≥ 1.193 for Battery A and ≥ 1.197 for Battery B (0.015 below the manufacturer fully charged, nominal specific gravity) or a battery charging current that is stabilized at a value of < 2 amps. This value is characteristic of a charged cell with adequate capacity.~~

~~According to IEEE 450 (Ref. 3), the specific gravity readings are based on a temperature of 77°F (25°C). The specific gravity readings are corrected for actual electrolyte temperature and level. For each 3°F (1.67°C) above 77°F (25°C), 1 point (0.001) is added to the reading; 1 point is subtracted for each 3°F below 77°F. The specific gravity of the electrolyte in a cell increases with a loss of water due to electrolysis or evaporation.~~

(continued)

BASES (continued)

~~LCO~~ ~~Category A (continued)~~

~~Footnote b to Table B 3.8.6-1 requires the above mentioned correction for electrolyte level and temperature, with the exception that level correction is not required when battery charging current is < 2 amps on float charge. This current provides, in general, an indication of overall battery condition and can be used as an alternative to specific gravity.~~

Category B

~~Category B defines the normal parameter limits for each connected cell. The term "connected cell" excludes any battery cell that may be jumpered out.~~

~~The Category B limits specified for electrolyte level and float voltage are the same as those specified for Category A and have been discussed above. The Category B limit specified for specific gravity for each connected cell is ≥ 1.188 for Battery A and ≥ 1.192 for Battery B (0.020 below the manufacturer fully charged, nominal specific gravity) or a battery charging current that is stabilized at a value < 2 amps. The average of all connected cells must also be > 1.198 for Battery A and > 1.202 for Battery B (0.010 below the manufacturer fully charged, nominal specific gravity). These values are based on manufacturer's recommendations. The minimum specific gravity value required for each cell ensures that the effects of a highly charged or newly installed cell will not mask overall degradation of the battery. The temperature correction for specific gravity readings is the same as that for Category A and has been discussed above.~~

(continued)

BASES (continued)

~~LCO~~ ~~Category C~~
~~(continued)~~

~~Category C defines the limits for each connected cell. The term "connected cell" excludes any battery cell that may be jumpered out. These limits, although reduced from the Category A and B limits, provide assurance that sufficient capacity exists to perform the intended function and maintain a margin of safety. When any battery parameter is outside the Category C limit, the assurance of sufficient capacity described above no longer exists, and the battery must immediately be declared inoperable.~~

~~The Category C limits specified for electrolyte level (above the top of the plates and not overflowing) ensure that the plates suffer no physical damage and maintain adequate electron transfer capability. The Category C limit for float voltage is based on IEEE 450 (Ref. 3), which states that a cell voltage of 2.07 V or below, under float conditions and not caused by elevated temperature of the cell, indicates internal cell problems and may require cell replacement.~~

~~The Category C limit for the average of all connected cells specifies a specific gravity ≥ 1.188 for Battery A and ≥ 1.192 for Battery B (0.020 below the manufacturer recommended fully charged, nominal specific gravity). These values are based on manufacturer recommendations. In addition to that limit, it is required that the specific gravity for each connected cell must be no more than 0.020 below the average of all connected cells. This limit ensures that the effect of a highly charged or new cell does not mask overall degradation of the battery. The temperature correction for specific gravity readings is the same as that for Category A and has been discussed above.~~

~~Because of specific gravity gradients that are produced during the recharging process, delays of several days may occur while waiting for the specific gravity to stabilize. A stabilized charger current is an acceptable alternative to specific gravity measurement for determining the state of charge. This phenomenon is discussed in IEEE 450 (Ref. 3).~~

(continued)

BASES (continued)

APPLICABILITY

(212)

The battery cell parameters for Train A and Train B batteries are required solely for the support of the associated DC electrical power subsystem. Therefore, the battery cell parameter limits ~~of Table B-3.8.6-1~~ are required to be met when the DC power source is required to be OPERABLE. Since the Train A and Train B batteries support LCO 3.8.4 and LCO 3.8.5, the battery cell parameters ~~of Table B-3.8.6-1~~ are required to be met in MODES 1, 2, 3, and 4, and when the associated DC electrical power subsystems are required to be OPERABLE in MODES 5 and 6.

ACTIONS

(212)

The ACTIONS are modified by a Note to provide clarification that separate condition entry is allowed for each battery. Separate Condition entry is acceptable since the battery cell parameters ~~of Table B-3.8.6-1~~ are provided on a battery basis.

A.1

(212)

With one or more batteries with one or more battery cell parameters outside the limits for any connected cell, Asufficient capacity to supply the maximum expected load requirement is not assured and the corresponding DC electrical power train must be immediately declared inoperable and actions taken per LCO 3.8.4 or LCO 3.8.5.

(continued)

BASES (continued)

~~2. SURVEILLANCE~~ SR 3.8.6.1
~~REQUIREMENTS~~

~~This SR verifies that the electrolyte level of each connected battery cell is above the top of the plates and Anot overflowing. 3~~

212
~~With one or more batteries this is consistent with one or more battery cell parameters not within limits (IEEE-450 (Ref. e4) and ensures that the plates suffer no physical damage and maintain adequate electron transfer capability. Category A limits not met, Category B limits not met, or Category A and B limits not met) but within the Category C limits specified in Table B 3.8.6-1 the battery cells are degraded but the battery still has sufficient capacity to perform its intended function. The Frequency of 31 days is consistent with IEEE-450.—~~

~~Therefore, the affected battery is not required to be considered inoperable per LCO 3.8.4 or LCO 3.8.5 solely as a result SR: 3.8.6.2~~

~~This SR verifies that the float voltage of Category A or B limits not met and operation is permitted for a limited period before the each connected battery cell parameters must be restored within limits is > 2.07 V.~~

~~With one or more batteries with one or more battery cell parameters not within Category A or B limits, the pilot cell electrolyte level and float voltage are required to be verified to meet the Category C limits of Table B 3.8.6-1 within 1 hour. This check will provide a quick indication of the status of the remainder of the battery cells. The Completion Time of one hour provides sufficient time to inspect the electrolyte level and to confirm the float voltage of the pilot cells.—~~

(continued)

BASES (continued)

~~ACTIONS~~ ~~A.1, A.2, and A.3~~ (continued)

~~If the pilot cell's electrolyte level and float voltage are found to be within the Table B 3.8.6-1 Category C limits, all connected cells must be verified to be within Category C limits within 24 hours. Completion Time of 24 hours is allowed to complete the initial verification. This takes into consideration both the time required to perform the required verification (including specific gravity measurements) and the assurance that the battery pilot cell parameters are not severely degraded. This verification is required every 7 days until all battery cell parameters are restored to Category A and B limits. This periodic verification is more restrictive than the normal frequency of pilot cell surveillances.~~

~~Battery cell parameters must be restored to within Category A and B limits within 31 days. A Completion Time of 31 days to restore battery cell parameters to within limits is acceptable since the battery remains capable of performing its intended function in this condition.~~

B.1

~~If the Required Action and associated Completion Time of Condition A are not met, or with one or more batteries with an average electrolyte temperature of representative cells $< 65^{\circ}\text{F}$, or with one or more batteries with one or more battery cell parameters outside the Category C limits for any connected cell, sufficient capacity to supply the maximum expected load requirement is not assured and the corresponding DC electrical power train must be immediately declared inoperable and actions taken per LCO 3.8.4 or LCO 3.8.5.~~

(continued)

BASES (continued)

~~SURVEILLANCE~~ ~~SR 3.8.6.1~~
REQUIREMENTS

(212) This SR verifies that Table B-3.8.6-1 Category A battery cell parameters are consistent with IEEE 450 (Ref. 3), which recommends regular battery inspections including float voltage, specific gravity, and electrolyte level of each pilot cell. The Completion Time of one hour provides sufficient time to inspect the electrolyte level and to confirm the float voltage of the pilot cells. This limit is based on IEEE-450 (Ref. —

(continued)

BASES (continued)

~~ACTIONS~~ A4) which states that a cell voltage of 2.07 V or below, under float conditions and not caused by elevated temperature of the cell, indicates internal cell problems and may require cell replacement. 1—The frequency of 31 days is also consistent with IEEE-450.

~~2, and SR 3.8.6.3~~

This SR verifies the specific gravity of the designated pilot cell in each battery is ≥ 1.188 for Battery A and ≥ 1.192 for Battery B. 3—(continued)

(212) If the pilot cell's electrolyte level and float voltage these values are found to be within the Table B 3.8.6-1 Category C limits, all connected cells must be verified to be within Category C limits within 24 hours based on manufacturer recommendations. Completion Time of 24 hours is allowed according to complete the initial verification IEEE 450 (Ref.— This takes into consideration both the time required to perform the required verification (including 4) the specific gravity measurements) and the assurance that the battery pilot cell parameters readings are not severely degraded based on a temperature of 77°F (25°C). This verification is required every 7 days until all battery cell parameters the specific gravity readings are restored to Category A corrected for actual electrolyte temperature and B limits level. This periodic verification is more restrictive than for each 3°F (1.67°C) above 77°F (25°C), 1 point (0.001) is added to the normal frequency of pilot cell surveillance reading; 1 point is subtracted for each 3°F below 77°F.

Battery The specific gravity of the electrolyte in a cell parameters must be restored increases with a loss of water due to within Category A and B limits within 31 days electrolysis or evaporation.—

A Completion Time of 31 Because of specific gravity gradients that are produced during the recharging process, delays of several days to restore battery cell parameters to within limits is acceptable since the battery remains capable of performing its intended function in this condition may occur while waiting for the specific gravity to stabilize.

PARAMETER The power source for one 120 VAC instrument bus (Instrument Bus D) is normally supplied from offsite power via a non-Class 1E constant voltage transformer (CVT) such that only three buses are considered safety related (see

(continued)

BASES (continued)

Figure 3.8.4-1). These three 120 VAC instrument buses (A, B, and C) supply a source of power to instrumentation and controls which are used to monitor and actuate the Reactor Protection System (RPS) and Engineered Safety Features (ESF) and other components (Ref. 1). The loss of Instrument Bus D is addressed in LCO 3.3.2, "Engineered Safety Features Actuation System (ESFAS) Instrumentation," and LCO 3.3.3, "Post-Accident Monitoring Instrumentation."

Instrument Buses A and C can be supplied power either from inverters which are powered from separate and redundant DC power sources, a non-Class 1E CVT (maintenance CVT) powered from offsite power, or a Class 1E CVT (see Figure B 3.8.4-1). The inverters are the preferred source of power for Instrument Bus A and C because of the stability and reliability they achieve.

Instrument Bus B can be supplied power from either a Class 1E CVT or a non-Class 1E CVT (maintenance CVT) powered from offsite power. The Class 1E CVT, supplied by motor control center C (MCC C is supplied by 480 V safeguards Bus 14), is the preferred source of power for Instrument Bus B because of the potential to have a power interruption if offsite power were unavailable.

(continued)

BASES (continued)

BACKGROUND
(continued)

The majority of instrumentation and controls supplied by the 120 VAC instrument buses are fail safe devices such that they go to their post accident position upon loss of power. However, a notable exception to this is the actuation logic for Containment Spray (CS) System which requires 120 VAC and 125 VDC power in order to function. This prevents a spurious CS actuation from occurring if control power were lost. The actuation logic for CS is powered from all three instrument buses and from both DC electrical power distribution trains.

APPLICABLE
SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses (Refs. 2 and 3), assume Engineered Safety Feature systems are OPERABLE. The AC instrument bus power sources are designed to provide the required capacity, capability, redundancy, and reliability to ensure the availability of necessary power to the RPS and ESF instrumentation and controls so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, "Power Distribution Limits;" Section 3.4, "Reactor Coolant System (RCS);" and Section 3.6, "Containment Systems."

The OPERABILITY of the AC instrument bus power sources is consistent with the initial assumptions of the accident analyses and is based on meeting the design basis of the plant. This includes maintaining required AC instrument buses OPERABLE in the event of:

- a. An assumed loss of all offsite AC electrical power or all onsite standby AC power; and
- b. A worst case single failure.

In the event of a DBA, the OPERABILITY requirements of the AC instrument bus power sources ensures that one train of AC instrument buses are available with:

- a. An assumed loss of all offsite power; and
- b. A worst case single failure (including the loss of one AC instrument bus power source).

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES
(continued)

In general, the accident analyses assume that all offsite power is lost at the time of the initiating event except where the availability of offsite power provides worst case conditions (e.g., steam line break with continued operation of the reactor coolant pumps). The availability of redundant offsite power sources (i.e., circuits 751 and 767) helps to reduce the potential to lose all offsite power. Providing redundant sources of AC instrument bus power also ensures that at least one train of AC instrument buses is available if all onsite standby AC power is unavailable coincident with a single failure of one offsite power source during non accident conditions. In the event the plant is in the 100/0 or 0/100 mode, a redundant source of offsite power can be obtained by backfeeding through the main transformer using a flexible connection that can be tied into the plant auxiliary transformer 11. The plant can survive on the available battery power, alternate power sources, and turbine driven Auxiliary Feedwater pump during the estimated 8 hours required to provide this power transfer (Ref. 4). Therefore, the requirements of GDC 17 (Ref. 5) can be met at all times.

The AC instrument bus sources satisfy Criterion 3 of the NRC Policy Statement.

LCO

The AC instrument bus sources ensure the availability of 120 VAC electrical power for the instrumentation for systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA.

Maintaining the required AC instrument bus sources OPERABLE ensures that the redundancy incorporated into the design of the RPS and ESF instrumentation and controls is maintained. The two inverters ensure an uninterruptible supply of AC electrical power to AC Instrument Bus A and C even if the 480 V safeguards buses are de-energized. The Class 1E 480 V safeguard bus supply to Instrument Bus B provides a reliable source for the third instrument bus.

(continued)

BASES (continued)

LCO
(continued)

For an inverter to be OPERABLE, the associated instrument bus must be powered by the inverter with output voltage within tolerances with power input to the inverter from a 125 VDC power source (see LCO 3.8.4, "DC Sources - MODES 1, 2, 3, and 4").

For a Class 1E CVT to be OPERABLE, the associated instrument bus must be powered by the CVT with the output voltage within tolerances with power to the CVT from a Class 1E 480 V safeguards bus. The 480 V safeguards bus must be powered from an acceptable AC source (see LCO 3.8.1, "AC Sources - MODES 1, 2, 3, and 4").

APPLICABILITY

The AC instrument bus power sources are required to be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

- a. Acceptable fuel design limits and reactor coolant pressure boundary limits are not exceeded as a result of AOOs or abnormal transients; and
- b. Adequate core cooling is provided and containment OPERABILITY and other vital functions are maintained in the event of a postulated DBA.

AC instrument bus power requirements for MODES 5 and 6 are covered in the Bases for LCO 3.8.8, "~~Inverters - MODES~~" AC Instrument Bus Sources - MODES 5 and 6."

(169)
ACTIONS

A.1, A.2, and A.3

With an inverter inoperable, its associated AC instrument bus becomes inoperable until it is re-energized from either its Class 1E or non-Class 1E CVT.

Required Action A.1 allows the instrument bus to be powered from either its associated Class 1E CVT or from a non-Class 1E CVT. For Instrument Buses A and C, the non-Class 1E power is supplied by a non-safety related motor control center (MCC A) which is supplied by 480 V Bus 13. The Completion Time of 2 hours is consistent with LCO 3.8.9, "Distribution Systems - MODES 1, 2, 3, and 4".

(continued)

BASES (continued)

ACTIONS

A.1, A.2, and A.3 (continued)

Required Action A.2 is intended to limit the amount of time that the instrument bus can be connected to a non-Class 1E power supply. The 24 hour Completion Time is based upon engineering judgement, taking into consideration the time required to repair the Class 1E CVT or the inverter and the additional risk to which the plant is exposed because of the connection to a non-Class 1E power supply.

Required Action A.3 allows 72 hours to fix the inoperable inverter and restore it to OPERABLE status. The 72 hour Completion Time is based upon engineering judgment, taking into consideration the time required to repair an inverter and the additional risk to which the plant is exposed because of the inverter inoperability. This must be balanced against the risk of an immediate shutdown, along with the potential challenges to safety systems such a shutdown might entail. When the AC instrument bus is powered from its CVT, it is relying upon interruptible AC electrical power sources (offsite and onsite). The uninterruptible, battery backed inverter source to the AC instrument buses is the preferred source for powering instrumentation trip setpoint devices.

B.1 and B.2

With the Class 1E CVT for Instrument Bus B inoperable, the instrument bus becomes inoperable until it is re-energized from its non-Class 1E CVT. Required Action B.1 requires Instrument Bus B to be powered from its non-Class 1E CVT within 2 hours. The non-Class 1E power is supplied by a nonsafety related 480 V motor control center (MCC A) which is supplied by 480 V Bus 13.

(continued)

BASES (continued)

ACTIONS

B.1 and B.2 (continued)

Required Action B.2 is intended to limit the amount of time that Instrument Bus B can be connected to a non-Class 1E power supply. The 7 day limit is based on engineering judgement, taking into consideration the time required to repair the Class 1E CVT and the additional risk to which the plant is exposed because of the Class 1E CVT inoperability. This must be balanced against the risk of an immediate shutdown, along with the potential challenges to safety systems such a shutdown might entail. When Instrument Bus B is powered from its non-Class 1E CVT, it is relying upon interruptible offsite AC electrical power sources. The Class 1E, diesel generator backed, CVT to Instrument Bus B is the preferred power source for powering instrumentation trip setpoint devices.

C.1 and C.2

149
If the inoperable devices or components cannot be restored to OPERABLE status or other Required Actions are not completed within the required Completion Time of Condition A or B, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

D.1

If two or more required AC instrument bus power sources are inoperable, the plant is in a condition outside the accident analyses; therefore, LCO 3.0.3 must be entered immediately. This Condition must be entered when both inverters, or one or more inverters and the Class 1E CVT to Instrument Bus B are discovered to be inoperable.

(continued)

BASES (continued)

SURVEILLANCE
REQUIREMENTS

SR 3.8.7.1

This SR verifies correct static switch alignment to Instrument Bus A and C. This verifies that the inverters are functioning properly and AC Instrument Bus A and C are energized from their respective inverter. The verification ensures that the required power is available for the instrumentation of the RPS and ESF connected to the AC instrument buses. The Frequency of 7 days takes into account the redundant capability of the inverters and other indications available in the control room that alert the operator to inverter malfunctions.

SR 3.8.7.2

This SR verifies the correct Class 1E CVT alignment to Instrument Bus B. This verifies that the Class 1E CVT is functioning properly and supplying power to AC Instrument Bus B. The verification ensures that the required power is available for the instrumentation of the RPS and ESF connected to the AC instrument bus. The Frequency of 7 days takes into account the redundant instrument buses and other indications available in the control room that alert the operator to the Class 1E CVT malfunctions.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.8 AC Instrument Bus Sources—MODES 5 and 6

BASES

BACKGROUND.

The Background section of the Bases for LCO 3.8.7, "AC Instrument Bus Sources—MODES 1, 2, 3, and 4" is applicable to these Bases, with the following modifications.

In MODE 5 or 6, the number of required AC instrument buses may be reduced since less energy is retained within the reactor coolant system than during higher MODES. Also, a significant number of required testing and maintenance activities must be performed under these conditions such that equipment and systems, including the AC instrument bus sources, must be removed from service. The minimum required AC instrument bus electrical subsystem is based on the requirements of LCO 3.8.10, "Distribution Systems—MODES 5 and 6."

APPLICABLE
SAFETY ANALYSES

The OPERABILITY of the minimum AC instrument bus power sources to each required AC instrument bus during MODES 5 and 6 ensures that:

- a. Systems needed to mitigate a fuel handling accident are available;
- b. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available; and
- c. Instrumentation and control capability is available for monitoring and maintaining the plant in a cold shutdown condition or refueling condition.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

In general, when the plant is shut down, the Technical Specifications requirements ensure that the plant has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. Therefore, the OPERABILITY of the AC instrument bus power sources ensures that one train of the AC instrument buses are OPERABLE in the event of:

- a. An assumed loss of all offsite AC power;
- b. An assumed loss of all onsite standby AC power; or
- c. A worst case single failure.

This reduction in required AC sources is allowed because many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6. Worst case bounding events are deemed not credible in MODES 5 and 6 because the energy contained within the reactor pressure boundary (reactor coolant temperature and pressure) and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and result in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCOs for the systems required in MODES 5 and 6.

During MODES 1, 2, 3, and 4, various deviations from the analysis assumptions and design requirements are allowed within the Required Actions. This allowance is in recognition that certain testing and maintenance activities must be conducted provided an acceptable level of risk is not exceeded. During MODES 5 and 6, performance of a significant number of required testing and maintenance activities is also required. In MODES 5 and 6, the activities are generally planned and administratively controlled. Relaxations from MODE 1, 2, 3, and 4 LCO requirements are acceptable during shutdown modes based on:

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

- a. The fact that time in an outage is limited. This is a risk prudent goal as well as a utility economic consideration.
- b. Requiring appropriate compensatory measures for certain conditions. These may include administrative controls, reliance on systems that do not necessarily meet typical design requirements applied to systems credited in operating MODE analyses, or both.
- c. Prudent utility consideration of the risk associated with multiple activities that could affect multiple systems.
- d. Maintaining, to the extent practical, the ability to perform required functions (even if not meeting MODE 1, 2, 3, and 4 OPERABILITY requirements) for systems assumed to function during an event.

In the event of an accident while in MODE 5 or 6, this LCO ensures the capability to support systems necessary to mitigate the postulated events during shutdown, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power.

The AC instrument bus power sources satisfy Criterion 3 of the NRC Policy Statement.

LCO

Maintaining the required AC instrument bus sources OPERABLE ensures that the redundancy incorporated into the design of the RPS and ESF instrumentation and controls is maintained. The two inverters ensure an uninterruptible supply of AC electrical power to AC Instrument Bus A and C even if the 480 V safeguards buses are de-energized. The Class 1E 480 V safeguard bus supply to Instrument Bus B provides a reliable source for the third instrument bus.

For an inverter to be OPERABLE, the associated instrument bus must be powered by the inverter with output voltage within tolerances with power input to the inverter from a 125 VDC power source (see LCO 3.8.4, "DC Sources - MODES 1, 2, 3, and 4).

(continued)

BASES

LCO
(continued)

For a Class 1E CVT to be OPERABLE, the associated instrument bus must be powered by the CVT with the output voltage within tolerances with power to the CVT from a Class 1E 480 V safeguards bus. The 480 V safeguards bus must be powered from an acceptable AC source (see LCO 3.8.1, "AC Sources - MODES 1, 2, 3, and 4). Power sources ensure the availability of sufficient power to the required AC instrument buses to operate the plant in a safe manner and to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents).

APPLICABILITY

The inverters required to be OPERABLE in MODES 5 and 6 provide assurance that systems required to mitigate the effects of a DBA and to maintain the plant in the cold shutdown or refueling condition are available.

AC Instrument Bus power requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.7.

ACTIONS

A.1

Although two trains may be required by LCO 3.8.10, "Distribution Systems - MODES 5 and 6," the remaining OPERABLE AC instrument bus train may be capable of supporting sufficient required features to allow continuation of CORE ALTERATIONS and operations with a potential for positive reactivity additions. By allowing the option to declare required features inoperable with the associated AC instrument bus power source inoperable, appropriate restrictions will be implemented in accordance with the LCO ACTIONS of the affected required features. This condition must be entered when the inverters for Instrument Bus A or C are inoperable, or the Class 1E CVT for Instrument Bus B is inoperable.

(continued)

BASES

ACTIONS

(continued)

A.2.1, A.2.2, A.2.3, and A.2.4

~~With one or more required AC instrument bus power sources inoperable, and the option exists to declare all required features inoperable per Required Action A.2-5~~

(continued)

(212)

movement of

~~With one or more required AC instrument bus power sources inoperable, the option exists to declare all required features inoperable per Required Action A.1. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions is made. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions. Therefore, immediate suspension of CORE ALTERATIONS, irradiated fuel assemblies, and operations involving positive reactivity additions is made an acceptable option to Required Action A. Therefore, immediate suspension of CORE ALTERATIONS and operations involving positive reactivity additions is an acceptable option to Required Action A.1. Performance of Required Actions A.2.1, A.2.2, and A.2.3 shall not preclude completion of movement of a component to a safe position or normal cooldown of the coolant volume for the purpose of system temperature control.~~

It is further required to immediately initiate action to restore the required AC instrument bus power source and to continue this action until restoration is accomplished in order to provide the necessary power to the plant safety systems.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required AC instrument bus power source should be completed as quickly as possible in order to minimize the time the plant safety systems may be without power or powered from an alternate power source.

SURVEILLANCE REQUIREMENTS

SR 3.8.8.1

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.9 Distribution Systems - MODES 1, 2, 3, and 4

BASES

BACKGROUND

A source of electrical power is required for most safety related and nonessential action components. Two sources of electrical power are available, alternating current (AC) and direct current (DC). Separate distribution systems are developed for each of these electrical power sources which are further divided and organized based on voltage considerations and safety classification. This LCO is provided to specify the AC, DC, and AC instrument bus power electrical power distribution subsystems which are required to supply safety related and Engineered Safety Feature (ESF) Systems in MODES 1, 2, 3, and 4.

The onsite Class 1E AC, DC, and AC instrument bus electrical power distribution subsystems are each divided into two redundant and independent distribution trains. Each of these electrical power distribution subsystems, and their trains, are discussed in detail below.

(continued)

BASES (continued)

BACKGROUND
(continued)

AC Electrical Power Distribution Subsystem

The Class 1E AC electrical power distribution subsystem is organized into two redundant and independent trains (Train A and Train B). Each train consists of two 480 V safeguards buses, distribution panels, motor control centers and load centers (see Figure B 3.8.1-1). The 480 V safeguards buses for each train are capable of being supplied from two sources of offsite power as well as a dedicated onsite emergency diesel generator (DG) source. These power sources are discussed in more detail in the Bases for LCO 3.8.1, "AC Sources—MODES 1, 2, 3, and 4." The 480 V safeguards buses in turn supply motor control centers, distribution panels and load centers which supply motive power to required motor operated valves, pumps, dampers, or any other component which requires AC power to perform its safety related function. The AC electrical power distribution subsystem also supplies one of the three required AC instrument buses through a constant voltage transformer and provides a backup source for the other two instrument buses. The list of all required AC 480 V safeguards buses is provided in Table B 3.8.9-1.

BACKGROUND——DC Electrical Power Distribution Subsystem

(149)
—(continued)

The Class 1E DC electrical power distribution subsystem is organized into two redundant and independent trains (Train A and Train B). Each train consists of a Class 1E battery and two battery chargers (with a charging capacity of at least 150 amps) which supply a main 125 VDC distribution panel (see Figure B 3.8.4-1). These power sources are discussed in more detail in the Bases for LCO 3.8.4, "DC Sources—MODES 1, 2, 3, and 4." Each main distribution panel supplies secondary distribution panels which provide control power to AC powered components and control power for other devices such as solenoid operated valves and air operated valves. The DC electrical power distribution subsystem also supplies two of the four AC instrument buses through inverters. The list of all required DC distribution panels is provided in Table B 3.8.9-1.

(continued)

BASES (continued)

(continued)

BASES (continued)

BACKGROUND
(continued)

AC Instrument Bus Electrical Power Distribution Subsystem

The AC instrument bus electrical power distribution subsystem consists of four 120 VAC instrument buses. The power source for one 120 VAC instrument bus (Instrument Bus D) is supplied from offsite power via a non Class 1E constant voltage transformer (CVT) such that only three buses are considered safety related (see Figure ~~B3.8.4-1~~ ~~3.8.4-1~~). These three buses are organized into two redundant and independent trains (Train A and Train B). These trains supply a source of power to instrumentation and controls which are used to monitor and actuate ESF and other components. Train A consists of two buses with one bus (Instrument Bus A) normally powered from an inverter and the other (Instrument Bus B) normally powered from a Class 1E CVT. Train B consists of one bus (Instrument Bus C) normally powered from an inverter. The long-term alternate power supplies for Instrument Bus A and C are two Class 1E CVTs, each powered from the same train as the associated battery chargers, and their use is governed by LCO 3.8.7, "AC Instrument Bus Sources—MODES 1, 2, 3, and 4." The list of required 120 VAC instrument buses is provided in Table B 3.8.9-1. The loss of Instrument Bus D is addressed in LCO 3.3.2, "Engineered Safety Feature Actuation Actuation System (ESFAS) Instrumentation," and LCO 3.3.3, "Post-Accident Monitoring (PAM) Instrumentation."

109

107

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES

The initial conditions of Design Basis Accident (DBA) and transient analyses (Refs. 1 and 2) assume ESF systems are OPERABLE. The AC, DC, and AC instrument bus electrical power distribution subsystems are designed to provide sufficient capacity, capability, redundancy, and reliability to ensure the availability of necessary power to ESF systems so that the fuel, Reactor Coolant System, and containment design limits are not exceeded. These limits are discussed in more detail in the Bases for Section 3.2, "Power Distribution Limits;" Section 3.4, "Reactor Coolant System (RCS);" and Section 3.6, "Containment Systems."

The OPERABILITY of the AC, DC, and AC instrument bus electrical power distribution subsystems is consistent with the initial assumptions of the accident analyses and is based upon meeting the design basis of the plant. This includes maintaining power distribution subsystems OPERABLE in the event of:

- a. An assumed loss of all AC offsite power or all onsite standby AC power; and
- b. A worst case single failure.

In the event of a DBA, the OPERABILITY requirements of the AC, DC, and AC instrument bus electrical power distribution subsystems ensures that one train of each distribution subsystem is available with:

- a. An assumed loss of all offsite power; and
- b. A worst case single failure (including the loss of one train of offsite standby AC power).

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES
(continued)

In general, the accident analyses assume that all offsite power is lost at the time of the initiating event except where the availability of offsite power provides worst case conditions (e.g., steam line break with continued operation of the reactor coolant pumps). The availability of redundant offsite power sources (i.e., circuits 751 and 767) helps to reduce the potential to lose all offsite power. Providing redundant sources of offsite power also ensures that at least one AC, DC, and AC instrument bus train is available if all onsite standby AC power is unavailable coincident with a single failure of one offsite power source during non accident conditions. In the event the plant is in the 100/0 or 0/100 mode, a redundant source of offsite power can be obtained by backfeeding through the main transformer using a flexible connection that can be tied into the plant auxiliary transformer 11. The plant can survive on the available battery power, alternate power sources, and turbine driven Auxiliary Feedwater train during the estimated 8 hours required to provide this power transfer (Ref. 3). Therefore, the requirements of GDC 17 (Ref. 4) can be met at all times.

The AC, DC, and AC instrument bus electrical power distribution subsystems satisfy Criterion 3 of the NRC Policy Statement.

LCO

Train A and Train B of the AC, DC, and AC instrument bus electrical power distribution subsystems are required to be OPERABLE. The power distribution subsystems and their trains listed in Table B 3.8.9-1 ensure the availability of AC, DC, and AC instrument bus electrical power for the systems required to shut down the reactor and maintain it in a safe condition after an anticipated operational occurrence (AOO) or a postulated DBA.

(continued)

BASES (continued)

LCO
(continued)

OPERABLE AC, DC, and AC instrument bus electrical power distribution subsystems require the associated buses, load centers, motor control centers, and distribution panels to be energized to their proper voltages. Maintaining the Train A and Train B AC, DC, and AC instrument bus electrical power distribution subsystems OPERABLE ensures that the redundancy incorporated into the design of ESF is not compromised. Therefore, a single failure within any system or within the electrical power distribution subsystems will not prevent safe shutdown of the reactor.

Tie breakers between redundant safety related AC, DC, and AC instrument bus power distribution subsystems, if they exist, must be open. This prevents any electrical malfunction in any power distribution subsystem from propagating to the redundant subsystem, which could cause the failure of a redundant subsystem and a loss of essential safety function(s).

If any of the following listed tie breakers are closed, the affected redundant electrical power distribution subsystem is considered inoperable. This does not, however, preclude AC buses from being powered from the same offsite circuit.

- a. AC power 480 V safeguards bus tie breakers (Ref. 5)

213

TSC/Battery A Fused Disconnect Switch
TSC/Battery B Fused Disconnect Switch

~~The trains as specified in Table B 3.8.9-1 only identify the~~
~~major AC, DC, and AC instrument bus electrical power~~
~~distribution subsystem components.~~ A train is defined to
begin from the boundary of the power source for the
respective subsystem (as defined in the power source LCOs),
and continues up to the isolation device for the supplied
safety related or ESF component (e.g., safety injection
pump). The isolation device for the supplied safety related
or ESF component is only considered part of the train when
the device is not capable of opening to isolate the failed
component from the train (e.g., breaker unable to open an
overcurrent). Otherwise, the failure of the isolation
device to close to provide power to the component is
addressed by the respective component's LCO. The isolation
device for nonsafety related components are considered part
of the train since these devices must be available to
protect the safety related functions. Therefore, the train
boundary essentially ends at the motor control center or bus
which supplies multiple components.

The inoperability of any component within the above defined
train boundaries renders the train inoperable.

APPLICABILITY

The electrical power distribution subsystems are required to
be OPERABLE in MODES 1, 2, 3, and 4 to ensure that:

- a. Acceptable fuel design limits and reactor coolant
pressure boundary limits are not exceeded as a result
of AOOs or abnormal transients; and
- b. Adequate core cooling is provided, and containment
OPERABILITY and other vital functions are maintained
in the event of a postulated DBA.

(continued)

BASES

APPLICABILITY (continued) Electrical power distribution subsystem requirements for MODES 5 and 6 are addressed in LCO 3.8.10, "Distribution Systems - MODES 5 and 6."

ACTIONS

A.1

With one AC electrical power distribution train inoperable, the remaining AC electrical power distribution train is capable of supporting the minimum safety functions necessary to shut down the reactor and maintain it in a safe shutdown condition. The overall reliability is reduced, however, because a single failure in the remaining AC power distribution train could result in the minimum required ESF functions not being supported. Therefore, the required AC buses, load centers, motor control centers, and distribution panels which comprise a train must be restored to OPERABLE status within 8 hours.

The worst case Condition A scenario is one train without AC power (i.e., no offsite power to the train and the associated DG inoperable). In this Condition, the plant is more vulnerable to a complete loss of AC power.

The Completion Time for restoring the inoperable train before requiring a plant shutdown is limited to 8 hours because of:

- a. The potential for decreased safety if the plant operator's attention is diverted from the evaluations and actions necessary to restore power to the affected train; and
- b. The potential for an event in conjunction with a single failure of a redundant component in the OPERABLE train with AC power which results in the loss of multiple safety functions.

(continued)

BASES

ACTIONS
(continued)

B.1

212

With one ~~required~~-AC instrument bus electrical power distribution train inoperable, the remaining OPERABLE AC instrument bus train is capable of supporting the minimum safety functions necessary to shut down the plant and maintain it in the safe shutdown condition. Overall reliability is reduced, however, because a single failure in the remaining AC instrument bus train could result in the minimum ESF functions not being supported. Therefore, the ~~required~~-AC instrument bus train must be restored to OPERABLE status within 2 hours.

Condition B represents one AC instrument bus train without power which includes the potential loss of both the DC source and the associated AC sources to the instrument bus. In this situation, the plant is significantly more vulnerable to a complete loss of all noninterruptible power. Therefore, the Completion Time is limited to 2 hours due to the potential vulnerabilities. Taking exception to LCO 3.0.2 for components without adequate 120 VAC power, that would have Completion Times shorter than 2 hours if declared inoperable, is acceptable because of:

- a. The potential for decreased safety by requiring a change in plant conditions (i.e., requiring a shutdown) and not allowing stable operations to continue;
- b. The potential for decreased safety by requiring entry into numerous Applicable Conditions and Required Actions for components without adequate 120 VAC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected train; and
- c. The potential for an event in conjunction with a single failure of a redundant component in the OPERABLE AC instrument bus train.

(continued)

BASES

ACTIONS
(continued)

B.1 (continued)

The 2 hour Completion Time takes into account the importance to safety of restoring the AC instrument bus train to OPERABLE status, the redundant capability afforded by the other OPERABLE instrument bus train, and the low probability of a DBA occurring during this period.

C.1

With one DC electrical power distribution train inoperable, the remaining DC electrical power distribution train is capable of supporting the minimum safety functions necessary to shut down the reactor and maintain it in a safe shutdown condition. The overall reliability is reduced, however, because a single failure in the remaining DC electrical power distribution train could result in the minimum required ESF functions not being supported. Therefore, the required DC distribution panels must be restored to OPERABLE status within 2 hours.

Condition C represents one train without adequate DC power (e.g., the battery and required battery charger are inoperable). In this situation, the plant is significantly more vulnerable to a complete loss of all DC power. Therefore, the Completion Time is limited to 2 hours due to this potential vulnerability. Taking exception to LCO 3.0.2 for components without adequate DC power, which would have Completion Times shorter than 2 hours, is acceptable because of:

- a. The potential for decreased safety by requiring a change in plant conditions (i.e., requiring a shutdown) and not allowing stable operations to continue;
- b. The potential for decreased safety by requiring entry into numerous applicable Conditions and Required Actions for components without DC power and not providing sufficient time for the operators to perform the necessary evaluations and actions for restoring power to the affected train; and

(continued)

BASES

ACTIONS

C.1 (continued)

- c. The potential for an event in conjunction with a single failure of a redundant component in the OPERABLE train with DC power.

D.1 and D.2

If the inoperable distribution subsystem cannot be restored to OPERABLE status within the required Completion Time, the plant must be brought to a MODE in which the LCO does not apply. To achieve this status, the plant must be brought to at least MODE 3 within 6 hours and to MODE 5 within 36 hours. The allowed Completion Times are reasonable, based on operating experience, to reach the required plant conditions from full power conditions in an orderly manner and without challenging plant systems.

E.1

(212) ~~If with two or more trains are with inoperable electrical power distribution subsystems,~~ the potential for a loss of safety function is greater. If a loss of safety function exists, no additional time is justified for continued operation and LCO 3.0.3 must be entered. This Condition may be entered with the loss of two trains of the same electrical power distribution subsystem, or with loss of Train A of one electrical power distribution subsystem coincident with the loss of Train B of a second electrical power distribution subsystem such that a loss of safety function exists.

(continued)

BASES

SURVEILLANCE
REQUIREMENTS

SR 3.8.9.1

(212)

This SR verifies that the AC, DC, and AC instrument bus electrical power distribution subsystems ~~trains~~ are functioning properly, with all required power source circuit breakers closed, tie-breakers open, and the buses energized from their allowable power sources. Required voltage for the AC electrical power distribution subsystem is ≥ 420 VAC; for the DC electrical power distribution subsystem, ≥ 108.6 VDC; and for AC instrument bus electrical power distribution subsystem, between 113 VAC and 123 VAC. Required voltage for the twinco panels supplied by the 120 VAC instrument buses is between 115.6 VAC and 120.4 VAC. The verification of proper voltage availability on the buses ensures that the required power is readily available for motive as well as control functions for critical system loads connected to these buses. The Frequency of 7 days takes into account the redundant capability of the AC, DC, and AC instrument bus electrical power distribution subsystems, and other indications available in the control room that alert the operator to subsystem malfunctions.

B 3.8 ELECTRICAL POWER SYSTEMS

B 3.8.10 Distribution Systems—MODES 5 and 6

BASES

BACKGROUND

The Background section of the Bases for LCO 3.8.9, "Distribution Systems—MODES 1, 2, 3, and 4" is applicable to these Bases, with the following modifications.

(109) In MODES 5 or 6, the number of required AC, DC, and AC instrument bus electrical power distribution subsystems, or the number of required trains within these electrical power distribution subsystems may be reduced since less energy is retained within the reactor coolant system than during higher MODES. Also, a significant number of required testing and maintenance activities must be performed under these conditions such that equipment and systems, including the electrical power distribution subsystems, must be removed from service.

APPLICABLE
SAFETY ANALYSES

The OPERABILITY of the minimum AC, DC, and AC instrument bus electrical power distribution subsystems during MODES 5 and 6 ensures that:

- a. Systems needed to mitigate a fuel handling accident are available;
- b. Systems necessary to mitigate the effects of events that can lead to core damage during shutdown are available; and
- c. Instrumentation and control capability is available for monitoring and maintaining the plant in a cold shutdown condition and refueling condition.

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES
(continued)

In general, when the plant is shut down, the Technical Specifications requirements ensure that the plant has the capability to mitigate the consequences of postulated accidents. However, assuming a single failure and concurrent loss of all offsite or all onsite power is not required. Therefore, the OPERABILITY of the AC, DC, and AC instrument bus electrical power distribution subsystems ensures that one train of the onsite power or offsite AC sources are OPERABLE in the event of:

- a. An assumed loss of all offsite AC power;
- b. An assumed loss of all onsite standby AC power; or
- c. A worst case single failure.

This reduction in required AC sources is allowed because many Design Basis Accidents (DBAs) that are analyzed in MODES 1, 2, 3, and 4 have no specific analyses in MODES 5 and 6. Worst case bounding events are deemed not credible in MODES 5 and 6 because the energy contained within the reactor pressure boundary (reactor coolant temperature and pressure) and the corresponding stresses result in the probabilities of occurrence being significantly reduced or eliminated, and result in minimal consequences. These deviations from DBA analysis assumptions and design requirements during shutdown conditions are allowed by the LCOs for the systems required in MODES 5 and 6.

During MODES 1, 2, 3, and 4, various deviations from the analysis assumptions and design requirements are allowed within the Required Actions. This allowance is in recognition that certain testing and maintenance activities must be conducted provided an acceptable level of risk is not exceeded. During MODES 5 and 6, performance of a significant number of required testing and maintenance activities is also required. In MODES 5 and 6, the activities are generally planned and administratively controlled. Relaxations from MODE 1, 2, 3, and 4 LCO requirements are acceptable during shutdown modes based on:

(continued)

BASES (continued)

APPLICABLE
SAFETY ANALYSES
(continued)

- a. The fact that time in an outage is limited. This is a risk prudent goal as well as a utility economic consideration.
- b. Requiring appropriate compensatory measures for certain conditions. These may include administrative controls, reliance on systems that do not necessarily meet typical design requirements applied to systems credited in operating MODE analyses, or both.
- c. Prudent utility consideration of the risk associated with multiple activities that could affect multiple systems.
- d. Maintaining, to the extent practical, the ability to perform required functions (even if not meeting MODE 1, 2, 3, and 4 OPERABILITY requirements) for systems assumed to function during an event.

In the event of an accident while in MODE 5 or 6 this LCO ensures the capability to support systems necessary to mitigate the postulated events during shutdown, assuming either a loss of all offsite power or a loss of all onsite diesel generator (DG) power.

The AC, DC, and AC instrument bus electrical power distribution subsystems satisfy Criterion 3 of the NRC Policy Statement.

(continued)

BASES (continued)

LCO

Various combinations of AC, DC, and AC instrument bus electrical power distribution subsystems, trains within these subsystems, and equipment and components within these trains are required OPERABLE by other LCOs, depending on the specific plant condition. Implicit in those requirements is the required OPERABILITY of necessary support features. This LCO explicitly requires energization of the portions of the electrical distribution system necessary to support OPERABILITY of required systems, equipment, and components - all specifically addressed in each LCO and implicitly required via the definition of OPERABILITY.

The LCOs which apply when the Reactor Coolant System is $\leq 200^\circ\text{F}$ and which may require a source of electrical power are:

- LCO 3.1.1 SHUTDOWN MARGIN (SDM)
- LCO 3.3.1 Reactor Trip System (RTS) Instrumentation
- (167) LCO ~~3.3.53~~ 3.4 Loss of Power (LOP) Diesel Generator (DG) Start Instrumentation
- LCO ~~3.3.73~~ 3.5/6 Control Room Emergency Air Treatment System (CREATS) Actuation
- LCO 3.4.7 RCS Loops - MODE 5, Loops Filled
- LCO 3.4.8 RCS Loops - MODE 5, Loops Not Filled
- LCO 3.4.12 Low Temperature Overpressure Protection (LTOP) System
- LCO 3.7.9 Control Room Emergency Air Treatment System (CREATS)
- (167) LCO 3.9.2 Nuclear Instrumentation
- LCO ~~3.9.3~~ Residual Heat Removal (RHR) and Coolant Circulation - High Water Level
- ~~LCO-3.9.4~~ Residual Heat Removal (RHR) and Coolant Circulation - Water Level ≥ 23 Ft
- ~~LCO 3.9.5~~ Residual Heat Removal (RHR) and Coolant Circulation - Low Water Level Water Level < 23 Ft

(212) Maintaining these portions of the necessary trains of the AC, DC, and AC instrument bus electrical power the distribution subsystems energized ensures the availability of sufficient power to operate the plant in a safe manner to mitigate the consequences of postulated events during shutdown (e.g., fuel handling accidents).

(continued)

BASES (continued)

APPLICABILITY The AC, DC, and AC instrument bus electrical power distribution subsystems required to be OPERABLE in MODES 5 and 6 provide assurance that systems required to mitigate the effects of a postulated event and maintain the plant in the cold shutdown or refueling condition are available.

The AC, DC, and AC instrument bus electrical power distribution subsystems requirements for MODES 1, 2, 3, and 4 are covered in LCO 3.8.9, "Distribution Systems—MODES 1, 2, 3, and 4."

ACTIONS

A.1

Although redundant required features may require redundant trains of electrical power distribution subsystems to be OPERABLE, one OPERABLE distribution subsystem train may be capable of supporting sufficient required features to allow continuation of CORE ALTERATIONS and operations involving positive reactivity additions. By allowing the option to declare required features associated with an inoperable distribution subsystem or train inoperable, appropriate restrictions are implemented in accordance with the LCO ACTIONS of the affected required features.

A.2.1, A.2.2, A.2.3, A.2.4, and A.2.5

With one or more required electrical power distribution subsystems or trains inoperable, the option exists to declare all required features inoperable per Required Action A.1. Since this option may involve undesired administrative efforts, the allowance for sufficiently conservative actions is made. Therefore, immediate suspension of CORE ALTERATIONS, movement of irradiated fuel assemblies, and operations involving positive reactivity additions is an acceptable option to Required Action A.1. Performance of Required Actions A.2.1, A.2.2, and A.2.3 shall not preclude completion of movement of a component to a safe position of normal cooldown of the coolant volume for the purpose of system temperature control within established procedures.

(212)

(continued)

BASES (continued)

ACTIONS A.2.1, A.2.2, A.2.3, A.2.4, and A.2.5 (continued)

It is further required to immediately initiate action to restore the required AC, DC, and AC instrument bus electrical power distribution subsystems and to continue this action until restoration is accomplished in order to provide the necessary power to the plant safety systems.

In addition to performance of the above conservative Required Actions, a required residual heat removal (RHR) loop may be inoperable. In this case, Required Actions A.2.1, A.2.2, A.2.3, and A.2.4 do not adequately address the concerns relating to coolant circulation and heat removal. Pursuant to LCO 3.0.6, the RHR ACTIONS would not be entered. Therefore, Required Action A.2.5 requires declaring RHR inoperable, which results in taking the appropriate RHR actions.

The Completion Time of immediately is consistent with the required times for actions requiring prompt attention. The restoration of the required distribution subsystems should be completed as quickly as possible in order to minimize the time the plant safety systems may be without power.

(continued)

BASES (continued)

SURVEILLANCE
REQUIREMENTS

SR 3.8.10.1

(212) This Surveillance verifies that the AC, DC, and AC instrument bus electrical power distribution subsystems are functioning properly, with all the required power source circuit breakers closed, required tie-breakers open, and the required buses energized from their allowable power sources. Required voltage for the AC power distribution electrical subsystem is ≥ 420 VAC, for the DC power distribution electrical subsystem ≥ 108.6 VDC, and for AC instrument bus power distribution electrical subsystem is between 113 VAC and 123 VAC. Required voltage for the twinco panels supplied by the 120 VAC instrument buses is between 115.6 VAC and 120.4 VAC. The verification of proper voltage availability on the buses ensures that the required power is readily available for motive as well as control functions for critical system loads connected to these buses. The Frequency of 7 days takes into account the capability of the AC, DC, and AC instrument bus electrical power distribution subsystems, and other indications available in the control room that alert the operator to subsystem malfunctions.

B 3.9 REFUELING OPERATIONS

B 3.9.1 Boron Concentration

BASES

BACKGROUND

The limit on the boron concentration ensures the reactor remains subcritical during MODE 6. Refueling boron concentration is the soluble boron concentration in the filled portions of the Reactor Coolant System (RCS), the refueling canal, and the refueling cavity that are hydraulically coupled to the reactor core during refueling.

The soluble boron concentration offsets the core reactivity and is measured by chemical analysis of a representative sample of the coolant. The refueling boron concentration limit is specified in the Core Operation Limits Report (COLR). Plant refueling procedures ensure the specified boron concentration in order to maintain an overall core reactivity of $k_{eff} \leq 0.95$ during fuel handling, with control rods and fuel assemblies assumed to be in the most adverse configuration (least negative reactivity) allowed by plant refueling procedures.

Atomic Industrial Forum (AIF) GDC 27 requires that two independent reactivity control systems preferably of different design principles be provided (Ref. 1). In addition to the reactivity control achieved by the control rods, reactivity control is provided by the chemical and volume control system (CVCS) which regulates the concentration of boric acid solution neutron absorber (neutron absorber) in the RCS. The CVCS is designed to prevent, under anticipated system malfunction, uncontrolled or inadvertent reactivity changes which may stress or damage the fuel beyond allowable limits.

The reactor is brought to shutdown conditions (i.e., MODE 5) before beginning operations to open the reactor vessel for refueling. After the RCS is cooled and depressurized the vessel head is unbolted and removed. The refueling canal and the refueling cavity are then flooded with borated water from the refueling water storage tank through the open reactor vessel by gravity feeding or by use of the Residual Heat Removal (RHR) System pumps.

(continued)

BASES

BACKGROUND

The pumping action of the ~~Residual Heat Removal (RHR)~~RHR System

(continued)
(continued)

into the RCS, and the natural circulation due to thermal driving heads in the reactor vessel and refueling cavity provide mixing for the borated coolant in the refueling canal.

194

The RHR System is in operation during refueling (see LCO 3.9.3, "~~Residual Heat Removal (RHR) and Coolant Circulation - Water Level \geq 23 Ft.~~" and LCO 3.9.4, "~~Residual Heat Removal (RHR) and Coolant Circulation - Water Level \geq 23 Ft.~~" and LCO 3.9.5, "~~Residual Heat Removal (RHR) and Coolant Circulation - Water Level $<$ 23 Ft.~~") to provide forced circulation in the RCS and assist in maintaining the boron concentration in the RCS, the refueling canal, and the refueling cavity above the COLR limit.

195

APPLICABLE
SAFETY ANALYSES

During refueling operations, two types of accidents can occur within containment that affect the fuel and require control of reactivity. These two accident types are a fuel handling accident and a boron dilution event. Both accidents assume that initial core reactivity is at its highest (i.e., at the beginning of the fuel cycle or the end of refueling).

194

A fuel handling accident ~~occurs~~can occur during fuel movement in the reactor vessel, the refueling canal, or the refueling cavity and includes a dropped fuel assembly and an incorrectly transferred fuel assembly. The most limiting fuel handling accident is a dropped fuel assembly which is dropped adjacent to other fuel assemblies such that it results in the largest exposure of fuel in the dropped assembly. The negative reactivity effect of the soluble boron compensates for the increased reactivity for both types of accidents. Hence, the boron concentration ensures that $k_{\text{eff}} \leq 0.95$ (i.e., 5% $\Delta k/k$ SHUTDOWN MARGIN) during the refueling operation.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

The second type of accident is a boron dilution event which results from inadvertent addition of unborated water to the RCS, refueling cavity, and refueling canal. The assumptions used in the boron dilution event (Ref. 2) provide for a maximum dilution flow of 120 gpm through two charging pumps (i.e., 60 gpm per pump) using unborated water as supplied by the two reactor makeup water pumps (60 gpm per pump). The RCS is also assumed to be at low water levels, uniformly mixed by the RHR System, with the minimum boron concentration as specified in the COLR. The operator has prompt and definite indication of significant boron dilution from an audible count rate function provided by the source range neutron flux instrumentation (see LCO 3.9.2, "Nuclear Instrumentation"). The increased count rate is a function of the effective subcritical multiplication factor. The results of this analysis conclude that an operator has at least 48.8 minutes before SHUTDOWN MARGIN is lost and the reactor goes critical which is sufficient time for operators to mitigate this event. This time is also greater than the 30 minutes required by Reference 3 for dilution events during refueling. Isolating the boron dilution source is performed by closing valves and/or stopping the reactor makeup water pumps.

The RCS boron concentration satisfies Criterion 2 of the NRC Policy Statement.

LCO

(194)

The LCO requires that a minimum boron concentration be maintained in the ~~portions of the RCS, the refueling canal, and the refueling cavity~~ and the portions of the RCS that are hydraulically coupled with the reactor core while in MODE 6. The boron concentration limit specified in the COLR ensures that a core k_{off} of ≤ 0.95 is maintained during fuel handling operations and that a core k_{off} of < 1.0 is maintained during a boron dilution event. Violation of the LCO could lead to an inadvertent criticality during MODE 6.

(continued)

BASES (continued)

APPLICABILITY

(194)

(195)

This LCO is applicable in MODE 6 to ensure that the fuel in the reactor vessel will remain subcritical. The required boron concentration ensures a $k_{\text{off}} \leq 0.95$ during fuel handling operations. In MODES 1 and 2 with $k_{\text{off}} \geq 1.0$, LCO 3.1.4, "Rod Group Alignment Limits Limit," LCO 3.1.5, "Shutdown Bank Insertion Limits Limit," and LCO 3.1.6, "Control Bank Insertion Limits" ensure an adequate amount of negative reactivity is available to shut down the reactor. In MODES 2 with $k_{\text{off}} < 1.0$ and MODES 3, 4, and 5, LCO 3.1.1, "SHUTDOWN MARGIN (SDM)" ensures an adequate amount of negative reactivity is available to maintain the reactor subcritical.

ACTIONS

A.1, A.2, and A.3

If the boron concentration of the filled portions of the RCS, the refueling canal, and the refueling cavity hydraulically coupled to the reactor core, is less than its limit, an inadvertent criticality may occur due to a boron dilution event or incorrect fuel loading. To minimize the potential of an inadvertent criticality resulting from a fuel loading error or an operation that could cause a reduction in boron concentration, CORE ALTERATIONS and positive reactivity additions must be suspended immediately.

(194)

Suspension of CORE ALTERATIONS and positive reactivity additions shall not preclude moving a component to a safe position or normal cooldown of the coolant volume for the purpose of system temperature control (i.e., other than normal cooldown of the coolant volume for the purpose of system temperature control within established procedures) shall not preclude moving a component to a safe position.

In addition to immediately suspending CORE ALTERATIONS or positive reactivity additions, boration to restore the concentration must be initiated immediately.

There are no safety analysis assumptions of boration flow rate and concentration that must be satisfied. The only requirement is to restore the boron concentration to its required value as soon as possible. In order to raise the boron concentration as soon as possible, the operator should begin boration with the best source available for plant conditions.

(continued)

BASES (continued)

(continued)

BASES

ACTIONS

A.1, A.2, and A.3 (continued)

Once action has been initiated, it must be continued until the boron concentration is restored. The restoration time depends on the amount of boron that must be injected to reach the required concentration.

SURVEILLANCE
REQUIREMENTS

SR 3.9.1.1

(194) This SR ensures the coolant boron concentration of the refueling canal, the refueling cavity, and the portions of the RCS that are hydraulically coupled, is within the COLR limits. The boron concentration of the coolant is determined by chemical analysis. The sample should be representative of the portions of the RCS, the refueling canal, and the refueling cavity that are hydraulically coupled with the reactor core.

A Frequency of once every 72 hours is a reasonable amount of time to verify the boron concentration of representative samples. The Frequency is based on operating experience, which has shown 72 hours to be adequate.

B 3.9 REFUELING OPERATIONS

B 3.9.2 Nuclear Instrumentation

BASES

BACKGROUND

The source range neutron flux channels~~monitors~~ are used during refueling operations to monitor the core reactivity condition. The installed source range neutron flux channels~~monitors~~ (N-31 and N-32) are part of the Nuclear Instrumentation System (NIS). These detectors are located external to the reactor vessel and detect neutrons leaking from the core.

195

The installed source range neutron flux detectors are proportional counters that are filled with boron trifluoride (BF₃) gas (Ref. 1). The detectors monitor the neutron flux in counts per second and provide continuous visual indication in the control room. Audible count rate is also available in the control room from either of the source range neutron flux channels~~monitors~~ to alert operators to a possible boron dilution event. The NIS is designed in accordance with the criteria presented in Reference 2.

195

APPLICABLE

Two OPERABLE source range neutron flux channels~~monitors~~ are required

SAFETY ANALYSES

to provide redundant indication to alert operators of unexpected changes in core reactivity. An increase in the audible count rate alerts the operators that a boron dilution event is in progress. Sufficient time is available for the operator to recognize the increase in audible count rate and to terminate the event prior to a loss of SHUTDOWN MARGIN (see Bases for LCO 3.9.1, "Boron Concentration"). Isolating the boron dilution source is performed by closing valves and stopping reactor makeup water pumps.

195

195

The source range neutron flux channels~~monitors~~ satisfy Criterion 3 of the NRC Policy Statement.

(continued)

BASES (continued)

LCO

(195)

This LCO requires two source range neutron flux channels ~~monitors~~ be OPERABLE to ensure redundant monitoring capability is available to detect changes in core reactivity.

To be OPERABLE, each ~~channel~~ ^{monitor} must provide visual indication and at least one of the two ~~channels~~ ^{monitors} must provide an audible count rate function in the control room.

(194)

~~With the discharge of fuel from core positions adjacent to source range detector locations, counts decreasing to zero is the expected response. Based on this indication alone, source range detection should not be considered inoperable. Following a full core discharge, source range response is verified with the initial fuel assembly reload.~~

APPLICABILITY

(195)

In MODE 6, the source range neutron flux ~~channels~~ ^{monitor} must be OPERABLE to determine changes in core reactivity. There are no other direct means available to check core reactivity conditions in this MODE. In MODES 2, 3, 4, and 5, these same installed source range detectors and circuitry are also required to be OPERABLE by LCO 3.3.1, "Reactor Trip System (RTS) Instrumentation."

ACTIONS

A.1 and A.2

(195)

With only one source range neutron flux channel ~~monitor~~ OPERABLE, redundancy has been lost. Since these instruments are the only direct means of monitoring core reactivity conditions, CORE ALTERATIONS and positive reactivity additions must be suspended immediately. Performance of Required Actions A.1 and A.2 shall not preclude completion of movement of a component to a safe position ~~or normal cooldown of the coolant volume for the purpose of system temperature control~~.

(194)

(194)

~~For the purpose of this Condition, a source range neutron flux channel is inoperable when no visual indication is available. The loss of the audible count rate function is addressed by Condition C, other than normal cooldown of the coolant volume for the purpose of system temperature control within established procedures).~~

(continued)

BASES

B.1 and B.2

195

With no source range neutron flux monitor OPERABLE there are no direct means of detecting changes in core reactivity. Therefore, actions to restore a monitor to OPERABLE status shall be initiated immediately and continue until a source range neutron flux monitor is restored to OPERABLE status.

~~SURVEILLANCE~~ — SR 3.9.2.1
~~REQUIREMENTS~~

~~SR 3.9.2.1 is the performance of a CHANNEL CHECK. The 12 hour
Frequency is reasonable, which is a comparison considering
the low probability of the parameter indicated on one
channel to a similar parameter on another channel a change in
core reactivity during this time period.~~

195

(continued)

BASES (continued)

SURVEILLANCE REQUIREMENTS SR 3.9.2.1

193
191

This SR is the performance of a CHANNEL CHECK, which is a comparison of the parameter indicated on one monitor to a similar parameter on another monitor. It is based on the assumption that the two indication channels should be consistent with core conditions. Changes in fuel loading and core geometry can result in significant differences between source range channels monitors, but each channel monitor should be consistent with its local conditions.

194

~~The inoperability of one source range neutron flux channel prevents performance of a CHANNEL CHECK for the operable channel. However, the Required Actions for the inoperable channel requires suspension of CORE ALTERATIONS and positive reactivity addition such that the CHANNEL CHECK of the operable channel can consist of ensuring consistency with known core conditions.~~

The Frequency of 12 hours is consistent with the CHANNEL CHECK Frequency specified similarly for the same instruments in LCO 3.3.1, "Reactor Trip System (RTS) Instrumentation."

SR 3.9.2.2

197

195

~~SR 3.9.2.2~~ This SR is the performance of a CHANNEL CALIBRATION every 24 months. This SR is modified by a Note stating that neutron detectors are excluded from the CHANNEL CALIBRATION. The CHANNEL CALIBRATION for the source range neutron flux channels monitors consists of obtaining the detector plateau or preamp discriminator curves, evaluating those curves, and comparing the curves to baseline data. The 24 month Frequency is based on the need to perform this Surveillance under the conditions that apply during a plant outage. Operating experience has shown these components usually pass the Surveillance when performed at the 24 month Frequency.

B 3.9.3

B-3.9 REFUELING OPERATIONS

B 3.9.3 ~~Residual Heat Removal (RHR) and Coolant Circulation Water Level~~
~~> 23 Ft Containment Penetrations~~

In MODE 5, there are no accidents of concern which require containment.

BASES

BACKGROUND

~~The purpose of the RHR System in MODE 6 is to remove decay heat and sensible heat from the Reactor Coolant System (RCS) during CORE ALTERATIONS or movement of irradiated fuel assemblies within containment, and to provide mixing of the boric acid coolant to prevent thermal and boron stratification. (Re) release of fission product radioactivity within containment will be restricted from escaping to the environment when the LCO requirements are met. In MODES 1, 2, 3, and 4, this is accomplished by maintaining containment OPERABLE as described in LCO 3.6.1, "Containment." In MODE 6, the potential for containment pressurization as a result of an accident is not likely; therefore, requirements to isolate the containment from the outside atmosphere can be less stringent. The LCO requirements are referred to as "containment closure" rather than "containment OPERABILITY." Containment closure means that all potential escape paths are closed or capable of being closed. Since there is no potential for containment pressurization, the Appendix J leakage criteria and tests are not required.~~

~~The containment serves to contain fission product radioactivity that may be released from the reactor core following an accident, such that offsite radiation exposures are maintained within the requirements of 10 CFR 100. Additionally, the containment provides radiation shielding from the fission products that may be present in the containment atmosphere following accident conditions.~~

~~The containment equipment hatch, which is part of the containment pressure boundary, provides a means for moving large equipment and components into and out of containment. During CORE ALTERATIONS or movement of irradiated fuel assemblies within containment, the equipment hatch must be held in place. Good engineering practice dictates that the bolts required to hold the equipment hatch in place be~~

bolted →

and that the bolts

a minimum of 4 bolts be used

(continued)

10/10/10

10/10/10

BASES

221

approximately equally spaced. As an alternative, the equipment hatch can be isolated by a closure plate that restricts air flow from containment.

(continued)

BASES

BACKGROUND
(continued)

221

The containment equipment and personnel air locks, which are also part of the containment pressure boundary, provide a means for personnel access during MODES 1, 2, 3, and 4 in accordance with LCO 3.6.2, "Containment Air Locks." Each air lock has a door at both ends. The doors are normally interlocked to prevent simultaneous opening when containment OPERABILITY is required. During periods of plant shutdown when containment closure is not required, the door interlock mechanism may be disabled, allowing both doors of an air lock to remain open for extended periods when frequent containment entry is necessary. During CORE ALTERATIONS or movement of irradiated fuel assemblies within containment, containment closure is required; therefore, the door interlock mechanism may remain disabled, but one air lock door must always remain closed in the personnel and equipment hatch (unless the equipment hatch is isolated by a closure plate).

The requirements for containment penetration closure ensure that a release of fission product radioactivity within containment will be restricted from escaping to the environment. The closure restrictions are sufficient to restrict fission product radioactivity release from containment due to a fuel handling accident during refueling.

The Containment Purge and Exhaust System includes two subsystems. The Shutdown Purge System includes a 36 inch purge penetration and a 36 inch exhaust penetration. The second subsystem, a Mini-Purge System, includes a 6 inch purge penetration and a 6 inch exhaust penetration. During MODES 1, 2, 3, and 4, the shutdown purge and exhaust penetrations are isolated by a blind flange with two O-rings that provide the necessary boundary. The two air operated valves in each of the two mini-purge penetrations can be opened intermittently, but are closed automatically by the Containment Ventilation Isolation Instrumentation System. Neither of the subsystems is subject to a Specification in MODE 5.

(continued)

BASES

BACKGROUND
(continued)

221

In MODE 6, large air exchangers are used to support refueling operations. The normal 36 inch Shutdown Purge System is used for this purpose, and each air operated valve is closed by the Containment Ventilation Isolation Instrumentation in accordance with LCO 3.3.5, "Containment Ventilation Isolation Instrumentation."

The Mini-Purge System also remains operational in MODE 6, and all four valves are also closed by the Containment Ventilation Isolation Instrumentation.

The other containment penetrations that provide direct access from containment atmosphere to outside atmosphere must be isolated on at least one side. Isolation may be achieved by an OPERABLE automatic isolation valve, or by a manual isolation valve, blind flange, or equivalent. Equivalent isolation methods may include use of a material that can provide a temporary, atmospheric pressure, ventilation barrier for the other containment penetrations during fuel movements.

APPLICABLE
SAFETY ANALYSES

During CORE ALTERATIONS or movement of irradiated fuel assemblies within containment, the most severe radiological consequences result from a fuel handling accident. The fuel handling accident is a postulated event that involves damage to irradiated fuel (Ref. 1). Fuel handling accidents, analyzed using the criteria of Reference 2, include dropping a single irradiated fuel assembly and handling tool or a heavy object onto other irradiated fuel assemblies. The requirements of LCO 3.9.6, "Refueling Cavity Water Level," and the minimum decay time of 100 hours prior to CORE ALTERATIONS ensure that the release of fission product radioactivity, subsequent to a fuel handling accident, results in doses that are within the guideline values specified in 10 CFR 100. Standard Review Plan (SRP), Section 15.7.4, Rev. 1 (Ref. 2), requires containment closure even though this is not an assumption of the accident analyses. The acceptance limits for offsite radiation exposure is 96 rem (Ref. 3).

Containment penetrations satisfy Criterion 3 of the NRC Policy Statement since these are assumed in the SRP.

(continued)

221

LCO This LCO limits the consequences of a fuel handling accident in containment by limiting the potential escape paths for fission product radioactivity released within containment. The LCO requires any penetration providing direct access from the containment atmosphere to the outside atmosphere to be closed except for the OPERABLE containment purge and exhaust penetrations. For the OPERABLE containment purge and exhaust penetrations, this LCO ensures that at least one valve in each of these penetrations is isolable by the Containment Ventilation Isolation System.

APPLICABILITY The containment penetration requirements are applicable during CORE ALTERATIONS or movement of irradiated fuel assemblies within containment because this is when there is a potential for a fuel handling accident. In MODES 1, 2, 3, and 4, containment penetration requirements are addressed by LCO 3.6.1. In MODES 5 and 6, when CORE ALTERATIONS or movement of irradiated fuel assemblies within containment are not being conducted, the potential for a fuel handling accident does not exist. Therefore, under these conditions, no requirements are placed on containment penetration status.

ACTIONS A.1 and A.2

If the containment equipment hatch (or its closure plate), air lock doors, or any containment penetration that provides direct access from the containment atmosphere to the outside atmosphere is not in the required status, including the Containment Ventilation Isolation System not capable of automatic actuation when the purge and exhaust valves are open, the plant must be placed in a condition where the isolation function is not needed. This is accomplished by immediately suspending CORE ALTERATIONS and movement of irradiated fuel assemblies within containment. Performance of these actions shall not preclude completion of movement of a component to a safe position.

(continued)

SURVEILLANCE REQUIREMENTS SR 3.9.3.1

This SR demonstrates that each of the containment penetrations required to be in its closed position is in that position. The Surveillance on the open purge and exhaust valves will demonstrate that the valves are not blocked or otherwise prevented from closing (e.g., solenoid unable to vent).

221

The Surveillance is performed every 7 days during CORE ALTERATIONS or movement of irradiated fuel assemblies within containment. The Surveillance interval is selected to be commensurate with the normal duration of time to complete fuel handling operations. ~~A surveillance before the start of refueling operations will provide two or three surveillance verifications during the applicable period for this LCO.~~ As such, this Surveillance ensures that a postulated fuel handling accident that releases fission product radioactivity within the containment will not result in a release of fission product radioactivity to the environment.

SR 3.9.3.2

This SR demonstrates that each containment purge and exhaust valve actuates to its isolation position on manual initiation or on an actual or simulated high radiation signal. The 24 month frequency maintains consistency with other similar instrumentation and valve testing requirements. In LCO 3.3.5, the Containment Ventilation Isolation instrumentation requires a CHANNEL CHECK every 12 hours and a COT every 92 days to ensure the channel OPERABILITY during refueling operations. Every 24 months an ACTUATION LOGIC TEST and CHANNEL CALIBRATION is performed. These Surveillances will ensure that the valves are capable of closing after a postulated fuel handling accident to limit a release of fission product radioactivity from the containment.

B 3.9 REFUELING OPERATIONS

B 3.9.4 Residual Heat Removal (RHR) and Coolant Circulation—Water Level
 \geq 23 Ft

221

BASES

BACKGROUND: The purpose of the RHR System in MODE 6 is to remove decay heat and sensible heat from the Reactor Coolant System (RCS), and to provide mixing of the borated coolant to prevent thermal and boron stratification (Ref. 1). Heat is removed from the RCS by circulating reactor coolant through the RHR heat exchanger(s) where the heat is transferred to the Component Cooling Water System. The coolant is then returned to the RCS via the RCS loop "B" cold leg. Operation of the RHR System for normal cooldown or decay heat removal is manually accomplished from the control room. The heat removal rate is adjusted by controlling the flow of reactor coolant through the RHR heat exchanger(s) and bypass line(s). Mixing of the reactor coolant is maintained by this continuous circulation of reactor coolant through the RHR System.

APPLICABLE
SAFETY ANALYSES

The safety analysis for the boron dilution event during refueling assumes one RHR loop is in operation (Ref. 2). This initial assumption ensures continuous mixing of the borated coolant in the reactor vessel. The analysis also assumes the RCS is at equilibrium boron concentration and dilution occurs uniformly throughout the system. Therefore, thermal or boron stratification is not postulated. In order to ensure adequate mixing of the borated coolant, one loop of the RHR System is required to be OPERABLE, and in operation while in MODE 6, with water level \geq 23 ft above the top of the reactor vessel flange.

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

(194)

While there is no explicit analysis assumption for the decay heat removal function of the RHR System in MODE 6, if the reactor coolant temperature is not maintained, boiling of the coolant could result. Due to the water volume available in the RCS with a water level \geq 23 ft above the top of the reactor vessel flange, a significant amount of time exists before boiling of the coolant would occur following a loss of the required RHR pump. Since the loss of the required RHR pump results in the ~~suspension of requirement to suspend operations involving a reduction in reactor coolant boron concentration, a boron dilution event is very unlikely.~~ Therefore, this requirement dictates that single failures are not considered for this LCO due to the time available to operators to respond to a loss of the operating RHR pump.

(194)

The LCO permits de-energizing the required RHR pump for short durations, ~~under the condition provided no operations are permitted that they would cause a reduction in the RCS boron concentration is not reduced.~~ This conditional de-energizing of the required RHR pump does not result in a challenge to the fission product barrier or result in coolant stratification.

(169)

(194)

~~Residual Heat Removal (RHR) RHR and Coolant Circulation—High Water Circulation—Water Level \geq 23 Ft~~ satisfies criterion 42 of the NRC Policy—Statement.

LCO

(194)

Only one RHR loop is required for decay heat removal in MODE 6, with the water level \geq 23 ft above the top of the reactor vessel flange, because the volume of water above the reactor vessel flange provides backup decay heat removal capability. One RHR loop is required to be OPERABLE and in operation to provide mixing of borated coolant ~~to minimize the possibility of criticality.~~

An OPERABLE RHR loop includes an RHR pump, a heat exchanger, valves, piping, instruments, and controls to ensure an OPERABLE flow path. The flow path starts in the RCS loop "A" hot leg and is returned to the RCS loop "B" cold leg.

(continued)

BASES

LCO
(continued)

The LCO is modified by a Note that allows the required operating RHR loop to be removed from service for up to 1 hour per 8 hour period provided no operations are permitted that would cause a reduction of the RCS boron concentration. Boron reduction is prohibited because uniform concentration distribution cannot be ensured without forced circulation. This allows the operator to view the core and permits operations such as core mapping or alterations in the vicinity of the reactor vessel hot leg nozzles. This also permits operations such as RCS to RHR isolation valve testing. During this 1 hour period, decay heat is removed by natural convection to the large mass of water in the refueling cavity. Should both RHR loops become inoperable at anytime during operation in accordance with this Note, the Required Actions of this LCO should be immediately taken.

APPLICABILITY

One RHR loop must be OPERABLE and in operation in MODE 6, with the water level \geq 23 ft above the top of the reactor vessel flange, to provide decay heat removal and mixing of the borated coolant. The 23 ft water level was selected because it corresponds to the 23 ft requirement established for fuel movement in LCO 3.9.5, "Refueling Cavity Water Level."

Requirements for the RHR System in MODES 1, 2, 3, 4, and 5 are covered by LCO 3.4.4, "RCS Loops—MODE 1 $>$ 8.5% RTP;" LCO 3.4.5, "RCS Loops—MODES 1 \leq 8.5% RTP, 2 and 3;" LCO 3.4.6, "RCS Loops—MODE 4;" ~~LCO 3.4.7, "RCS Loops—MODE 5, Loops Filled;"~~ ~~LCO 3.4.7, "RCS Loops—MODE 5, Loops Filled;"~~ and LCO 3.4.8, "RCS Loops—MODE 5, Loops Not Filled." The RHR loop requirements in MODE 6 with the water level $<$ 23 ft are located in LCO ~~3.9.4~~ 3.9.5, "Residual Heat Removal (RHR) and Coolant Circulation—Water Level $<$ 23 Ft."

169

(continued)

BASES (continued)

ACTIONS

A.1, A.2, and A.3

If RHR loop requirements are not met, there will be no forced circulation to provide mixing to establish uniform boron concentrations. Reduced boron concentrations can occur by the addition of water with a lower boron concentration than that contained in the RCS. Therefore, actions that could result in a reduction in the coolant boron concentration must be suspended immediately.

With no forced circulation cooling, decay heat removal from the core occurs by natural convection to the heat sink provided by the water above the core. A minimum refueling water level of 23 ft above the reactor vessel flange provides an adequate available heat sink. Suspending any operation that would increase decay heat load, such as loading a fuel assembly, is a prudent action under this condition. Therefore, actions shall be taken immediately to suspend loading irradiated fuel assemblies in the core.

(continued)

BASES (continued)

With the plant in MODE 6 and the refueling water level \geq 23 ft above the top of the reactor vessel flange, removal of decay heat is by ambient losses only. Therefore, corrective actions shall be initiated immediately and shall continue until RHR loop requirements are satisfied.

B 3.9.4~~

~~B 3.9 REFUELING OPERATIONS~~

~~B 3.9.4 Residual Heat Removal (RHR) and Coolant Circulation Water Level
 $<$ 23 Ft~~

BASES

BACKGROUND — The purpose of the RHR System in MODE 6/2 hours is to remove decay heat sufficient considering other indications and sensible heat from alarms available to the Reactor Coolant System (RCS), and to provide mixing of the borated coolant to prevent thermal and boron stratification (Refoperator in the control room to monitor RHR loop performance).

B 3.9 REFUELING OPERATIONS

B 3.9.5 Residual Heat Removal (RHR) and Coolant Circulation - Water Level < 23 Ft

BASES

BACKGROUND The purpose of the RHR System in MODE 6 is to remove decay heat and sensible heat from the Reactor Coolant System (RCS), and to provide mixing of the borated coolant to prevent thermal and boron stratification (Ref. 1). Heat is removed from the RCS by circulating reactor coolant through the RHR heat exchanger(s) where the heat is transferred to the Component Cooling Water System. The coolant is then returned to the RCS via the RCS loop "B" cold leg. Operation of the RHR System for normal cooldown or decay heat removal is manually accomplished from the control room. The heat removal rate is adjusted by controlling the flow of reactor coolant through the RHR heat exchanger(s) and bypass line(s). Mixing of the reactor coolant is maintained by this continuous circulation of reactor coolant through the RHR System.

APPLICABLE SAFETY ANALYSES

The safety analysis for the boron dilution event during refueling assumes one RHR loop is in operation (Ref. 2). This initial assumption ensures continuous mixing of the borated coolant in the reactor vessel. The analysis also assumes the RCS is at equilibrium boron concentration and dilution occurs uniformly throughout the system. Therefore, thermal or boron stratification is not postulated.

While there is no explicit analysis assumption for the decay heat removal function of the RHR System in MODE 6, if the reactor coolant temperature is not maintained, boiling of the coolant could result. This could lead to a loss of coolant in the reactor vessel. In addition, boiling of the coolant could lead to a reduction in boron concentration in the coolant due to boron plating out on components near the areas of the boiling activity. The loss of coolant and the reduction of boron concentration in the reactor coolant could eventually challenge the integrity of the fuel cladding, which is a fission product barrier.

(continued)

BASES

(continued)

BASES

APPLICABLE
SAFETY ANALYSES
(continued)

In order to prevent a challenge to fuel cladding and to ensure adequate mixing of the borated coolant, two loops of the RHR System are required to be OPERABLE, and one loop in operation while in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange.

169

~~Residual Heat Removal (RHR) RHR and Coolant Circulation-Low Water Circulation-Water Level < 23 Ft~~ satisfies criterion 4 of the NRC Policy Statement.

LCO

Both RHR loops must be OPERABLE in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange. In addition, one RHR loop must be in operation in order to remove decay heat and provide mixing of borated coolant to minimize the possibility of criticality.

194

An OPERABLE RHR loop includes an RHR pump, a heat exchanger, valves, piping, instruments and controls to ensure an OPERABLE flow path. The flow path starts in the RCS loop "A" hot leg and is returned to the RCS loop "B" cold leg.

APPLICABILITY

Two RHR loops are required to be OPERABLE, and one RHR loop must be in operation in MODE 6, with the water level < 23 ft above the top of the reactor vessel flange, to provide decay heat removal and mixing of the borated coolant.

169

Requirements for the RHR System in MODES 1, 2, 3, 4, and 5 are covered by LCO 3.4.4, "RCS Loops-MODE 1 > 8.5% RTP;" LCO 3.4.5, "RCS Loops-MODES 1 ≤ 8.5% RTP, 2 and 3;" LCO 3.4.6, "RCS Loops-MODE 4;" ~~LCO 3.4.7, "RCS Loops-MODE 5, Loops Filled;"~~ LCO 3.4.7, "RCS Loops-MODE 5, Loops Filled;" and LCO 3.4.8, "RCS Loops-MODE 5, Loops Not Filled." The RHR loop requirements in MODE 6 with the water level ≥ 23 ft are located in LCO ~~3.9.3~~ 3.9.4, "Residual Heat Removal (RHR) and Coolant Circulation-Water Level ≥ 23 Ft."

(continued)

BASES (continued)

ACTIONS

A.1 and A.2

195

If only one RHR loop is OPERABLE and in operation, less than the required number of RHR loops are OPERABLE, redundancy for RHR is lost. Action shall be immediately initiated and continued until the RHR loop is restored to OPERABLE status and operation or until ≥ 23 ft of water level is established above the reactor vessel flange. Action must be initiated to restore either a second loop to OPERABLE status or when the water level ≥ 23 ft above the top of reactor vessel flange, the Applicability changes to that of LCO 3.9.4, and only one RHR loop is required to be OPERABLE and in operation. The An immediate Completion Time reflects the importance of maintaining the availability of two paths necessary for heat removal. An operator to initiate corrective actions.—

The actions to restore must continue until either the second RHR loop is restored to OPERABLE status or water level is established ≥ 23 ft above the top of reactor vessel flange.

1 and B.1 and B.2

195

If no RHR loop is in operation, there will be no forced circulation to provide mixing to establish uniform boron concentrations. 2

If no RHR loop is in operation or if no loop is OPERABLE all operations involving a reduction in boron concentration must be suspended and action to restore one RHR loop to OPERABLE status and operation must be initiated. The potential for reduced boron concentrations by the addition of RCS water with a lower boron concentration must be reduced than that contained in the RCS must be reduced to prevent a criticality event. To prevent boron dilution, forced circulation is required to provide proper mixing and preserve the margin to criticality. Therefore, forced circulation is required to provide proper mixing and preserve the margin to criticality. Operations involving a reduction in this type of operation RCS boron concentration must be suspended immediately. The immediate Completion Time reflects the importance of maintaining RCS boron concentration. Actions shall also be initiated immediately, and continued, to restore one RHR loop to operation for heat removal. The action to restore must continue until one loop is restored to in Conditions A and B concurrently, the restoration of two

BASES (continued)

SURVEILLANCE REQUIREMENTS SR 3.9.5.1

(195) This SR requires verification every 12 hours that one RHR loop is in operation and circulating reactor coolant. Verification includes flow rate, temperature, or pump status monitoring, which help ensure that forced flow is providing decay heat removal capability and mixing of the borated coolant to prevent thermal and boron stratification in the core. The frequency of 12 hours is sufficient considering other indications and alarms available to the operator in the control room to monitor RHR loop performance.

SR 3.9.5.2

Verification that a second RHR pump is OPERABLE ensures that an additional pump can be placed in operation, if needed, to maintain decay heat removal and reactor coolant circulation. Verification is performed by verifying proper breaker alignment and power available to the standby pump. The frequency of 7 days is considered reasonable in view of other administrative controls available and has been shown to be acceptable by operating experience.

B 3.9 REFUELING OPERATIONS

221 B 3.9.53.9.6 Refueling Cavity Water Level

BASES

BACKGROUND

The movement of irradiated fuel assemblies within containment or performance of CORE ALTERATIONS, except during latching and unlatching of control rod drive shafts, requires a minimum water level of 23 ft above the top of the reactor vessel flange. This requirement ensures a sufficient level of water is maintained in the refueling cavity or portions hydraulically connected (e.g., refueling canal) to retain iodine fission product activity resulting from a fuel handling accident in containment (Ref. 1). The retention of iodine activity by the water limits the offsite dose from the accident well within the values specified in 10 CFR 100 (Ref. 2).

APPLICABLE
SAFETY ANALYSES

During CORE ALTERATIONS and movement of irradiated fuel assemblies, the water level in the refueling cavity is an initial condition design parameter in the analysis of a fuel handling accident in containment (Ref. 1). A minimum water level of 23 ft allows a decontamination factor of 100 to be used in the accident analysis for iodine (Ref. 3). This relates to the assumption that 99% of the total iodine released from the pellet to cladding gap of all the dropped fuel assembly rods is retained by the refueling cavity water. The fuel pellet to cladding gap is assumed to contain 10% of the total fuel rod iodine inventory (Ref. 3).

With a minimum water level of 23 ft and a minimum decay time of 100 hours prior to fuel handling, the analysis and test programs demonstrate that the iodine release due to a postulated fuel handling accident is adequately captured by the water and offsite doses are maintained within allowable limits (Ref. 2).

Refueling cavity water level satisfies Criterion 2 of the NRC Policy Statement.

(continued)

BASES (continued)

LCO A minimum refueling cavity water level of 23 ft above the reactor vessel flange is required to ensure the radiological consequences of a postulated fuel handling accident inside containment are within acceptable limits and preserves the assumptions of the fuel handling accident analysis (Ref. 1). As such, it is the minimum required level during movement of fuel assemblies within containment. Maintaining this minimum water level in the refueling cavity also ensures that ≥ 23 ft of water is available in the spent fuel pool during fuel movement assuming that containment and Auxiliary Building atmospheric pressures are equal.

APPLICABILITY This LCO is applicable when moving irradiated fuel assemblies within containment. This LCO is also applicable during CORE ALTERATIONS, except during latching and unlatching of control rod drive shafts. The LCO ensures a sufficient level of water is present in the refueling cavity to minimize the radiological consequences of a fuel handling accident in containment. Requirements for fuel handling accidents in the spent fuel pool are covered by LCO 3.7.11, "Spent Fuel Pool (SFP) Water Level."

149

ACTIONS A.1 and A.2

When the initial condition assumed in the fuel handling accident cannot be met, steps should be taken to preclude the accident from occurring. With a water level of < 23 ft above the top of the reactor vessel flange, all operations involving CORE ALTERATIONS or movement of irradiated fuel assemblies within the containment shall be suspended immediately to ensure that a fuel handling accident cannot occur.

The suspension of CORE ALTERATIONS and fuel movement shall not preclude completion of movement of a component to a safe position.

(continued)

BASES (continued)

221
SURVEILLANCE
REQUIREMENTS

SR ~~3.9.5.13.9.6.1~~

Verification of a minimum refueling cavity water level of 23 ft above the top of the reactor vessel flange ensures that the design basis for the analysis of the postulated fuel handling accident during refueling operations is met. Water at the required level above the top of the reactor vessel flange limits the consequences of damaged fuel rods that are postulated to result from a fuel handling accident inside containment (Ref. 1).

The Frequency of 24 hours is based on engineering judgment and is considered adequate in view of the large volume of water and the normal procedural controls of valve positions, which make significant unplanned level changes unlikely.

(continued)

4.0 DESIGN FEATURES (continued)

4.3 Fuel Storage (continued)

4.3.2 Drainage

226 The spent fuel pool is designed and shall be maintained to prevent inadvertent draining of the pool to ~~< 23 ft above the top of the fuel assemblies pool~~ below elevation 257'0" (mean sea level).

4.3 ~~Fuel Storage (continued)~~

4.3.3 Capacity

226 The spent fuel pool is designed and shall be maintained with a storage capacity limited to no more than 2032 ~~1016~~ fuel assemblies.

5.0 ADMINISTRATIVE CONTROLS

5.1 Responsibility

5.1.1 The ~~Plant Manager~~ ~~plant manager~~ shall be responsible for overall plant operation and shall delegate in writing the succession to this responsibility during his absence.

184

The ~~Plant Manager~~ ~~plant manager~~, or his designee, shall approve prior to implementation, each proposed test, experiment or modification to structures, systems or components that affect nuclear safety.

5.1.2 The Shift Supervisor (SS) shall be responsible for the control room command function. During any absence of the SS from the control room while the plant is in MODE 1, 2, 3, or 4, an individual with an active Senior Reactor Operator (SRO) license shall be designated to assume the control room command function. During any absence of the SS from the control room while the plant is in MODE 5 or 6, an individual with an active SRO license or Reactor Operator license shall be designated to assume the control room command function.

5.0 ADMINISTRATIVE CONTROLS

5.2 Organization

5.2.1 Onsite and Offsite Organizations

Onsite and offsite organizations shall be established for plant operation and corporate management, respectively. The onsite and offsite organizations shall include the positions for activities affecting the safety of the nuclear power plant.

a. Lines of authority, responsibility, and communication shall be defined and established throughout highest management levels, intermediate levels, and all operating organization positions. These relationships shall be documented and updated, as appropriate, in organization charts, functional descriptions of departmental responsibilities and relationships, and job descriptions for key personnel positions, or in equivalent forms of documentation. These requirements, including the plant specific titles of those personnel fulfilling the responsibilities of the positions delineated in these Technical Specifications, shall be documented in the UFSAR;

b. ~~The Plant Manager shall be responsible for overall safe operation of the plant and shall have control over those onsite activities necessary for safe operation and maintenance of the plant; and~~

~~ereport to the corporate vice president specified in 5.2.1.~~

~~A specified senior corporate executive shall have corporate responsibility, shall be responsible for overall plant nuclear safety and shall take any measures needed to ensure acceptable performance safe operation of the plant, and shall have control over those onsite activities necessary for safe operation and maintenance of the staff in operating, maintaining, and providing technical support to the plant to ensure nuclear safety.~~

c.

A corporate vice president shall have corporate responsibility for overall plant nuclear safety and shall take any measures needed to ensure acceptable performance of the staff in operating, maintaining, and providing technical support to the plant to ensure nuclear safety.

(continued)

5.2 Organization (continued)

- (153) d. The individuals who train the operating staff, carry out health physics, or perform quality assurance functions may report to the appropriate onsite manager; however, these individuals shall have sufficient organizational freedom to ensure their independence from operating pressures.

(continued)

5.2 Organization (continued)

5.2.2 Plant Staff

The plant staff organization shall include the following:

- a. An auxiliary operator shall be assigned to the shift crew with fuel in the reactor. An additional auxiliary operator shall be assigned to the shift crew while the plant is in MODE 1, 2, 3 or 4.

~~5.2.2 Plant Staff (continued)~~

- b. Shift crew composition may be one less than the minimum requirement of 10 CFR 50.54(m)(2)(i) and Specifications 5.2.2.a and 5.2.2.e for a period of time not to exceed 2 hours in order to accommodate unexpected absence of on-duty shift crew members provided immediate action is taken to restore the shift crew composition to within the minimum requirements.
- c. An individual qualified in radiation protection procedures shall be on site when fuel is in the reactor. The position may be vacant for not more than 2 hours, in order to provide for unexpected absence, provided immediate action is taken to fill the required position.
- d. The amount of overtime worked by plant staff members performing safety related functions shall be limited and controlled in accordance with a NRC approved program.

- e. ~~The operations manager or operations middle manager shall hold a SRO license.~~

- f. The Shift Technical Advisor (STA) shall provide advisory technical support to the Shift Supervisor (SS) in the areas of thermal hydraulics, reactor engineering, and plant analysis with regard to the safe operation of the plant. The STA shall be assigned to the shift crew while the plant is in MODE 1, 2, 3 or 4 and shall meet the qualifications ~~specified within a NRC approved~~ STA training program.

Contained in the

Specified in VFFAR
13.2

Specified in plant procedures. Changes to the guidelines in these procedures shall be submitted to the NRC for review.

5.0 ADMINISTRATIVE CONTROLS

5.3 Plant Staff Qualifications

- 5.3.1 Each member of the plant staff shall meet or exceed the minimum qualifications of ANSI Standard N18.1-1971, as supplemented by Regulatory Guide 1.8, Revision 1, September 1975, for comparable positions.
-

5.0 ADMINISTRATIVE CONTROLS

5.4 Procedures

5.4.1 Written procedures shall be established, implemented, and maintained covering the following activities:

- a. The applicable procedures recommended in Regulatory Guide 1.33, Revision 2, Appendix A, February 1978;
 - b. The emergency operating procedures required to implement the requirements of NUREG-0737 and NUREG-0737, Supplement 1, as stated in Generic Letter 82-33;
 - c. Effluent and environmental monitoring;
 - d. Fire Protection Program implementation; and
 - e. All programs specified in Specification 5.5.
-

5.0 ADMINISTRATIVE CONTROLS

5.5 Programs and Manuals

The following programs and manuals shall be established, implemented, and maintained.

5.5.1 Offsite Dose Calculation Manual (ODCM)

- a. The ODCM shall contain the methodology and parameters used in the calculation of offsite doses resulting from radioactive gaseous and liquid effluents, in the calculation of gaseous and liquid effluent monitoring alarm and trip setpoints, and in the conduct of the radiological environmental monitoring program; and
- b. The ODCM shall also contain the radioactive effluent controls and radiological environmental monitoring activities and descriptions of the information that should be included in the Annual Radiological Environmental Operating and Radioactive Effluent Release Reports.

Licensee initiated changes to the ODCM:

- a. Shall be documented and records of reviews performed shall be retained. This documentation shall contain:
 1. sufficient information to support the change(s) together with the appropriate analyses or evaluations justifying the change(s),
 2. a determination that the change(s) maintain the levels of radioactive effluent control required by 10 CFR 20.1302, 40 CFR 190, 10 CFR 50.36a, and 10 CFR 50, Appendix I, and does not adversely impact the accuracy or reliability of effluent, dose, or setpoint calculations;
- b. Shall become effective after review and acceptance by the onsite review function and the approval of the ~~Plant~~ plant manager; and

194

(continued)

5.5 Programs and Manuals

5.5.1 ODCM (continued)

- c. Shall be submitted to the NRC in the form of a complete, legible copy of the entire ODCM as a part of or concurrent with the Radioactive Effluent Release Report for the period of the report in which any change in the ODCM was made. Each change shall be identified by markings in the margin of the affected pages, clearly indicating the area of the page that was changed, and shall indicate the date (i.e., month and year) the change was implemented.

5.5.2 Primary Coolant Sources Outside Containment Program

(169)

This program provides controls to minimize leakage from those portions of systems outside containment that could contain highly radioactive fluids during a serious transient or accident. The systems include Containment Spray, Safety Injection, and Residual Heat Removal (RHR) in the recirculation configuration. The program shall include the following:

- a. Preventive maintenance and periodic visual inspection requirements; and
- b. Integrated leak test requirements for each system at refueling cycle intervals or less.

5.5.3 Post Accident Sampling Program

This program provides controls that ensure the capability to obtain and analyze reactor coolant, radioactive gases, and particulates in plant gaseous effluents and containment atmosphere samples under accident conditions. The program shall include the following:

- a. Training of personnel;
- b. Procedures for sampling and analysis; and
- c. Provisions for maintenance of sampling and analysis equipment.

(continued)

5.5 Programs and Manuals (continued)

5.5.4 Radioactive Effluent Controls Program

This program conforms to 10 CFR 50.36a for the control of radioactive effluents and for maintaining the doses to members of the public from radioactive effluents as low as reasonably achievable. The program shall be contained in the ODCM, shall be implemented by procedures, and shall include remedial actions to be taken whenever the program limits are exceeded. The program shall include the following elements:

- a. Limitations on the functional capability of radioactive liquid and gaseous monitoring instrumentation including surveillance tests and setpoint determination in accordance with the methodology in the ODCM;
- b. Limitations on the concentrations of radioactive material released in liquid effluents to unrestricted areas, conforming to ten times the concentration values in 10 CFR 20, Appendix B, Table 2, Column 2;
- c. Monitoring, sampling, and analysis of radioactive liquid and gaseous effluents in accordance with 10 CFR 20.1302 and with the methodology and parameters in the ODCM;
- d. Limitations on the annual and quarterly doses or dose commitment to a member of the public from radioactive materials in liquid effluents released from the plant to unrestricted areas, conforming to 10 CFR 50, Appendix I;
- e. Determination of cumulative and projected dose contributions from radioactive effluents for the current calendar quarter and current calendar year in accordance with the methodology and parameters in the ODCM at least every 31 days;
- f. Limitations on the functional capability and use of the liquid and gaseous effluent treatment systems to ensure that appropriate portions of these systems are used to reduce releases of radioactivity when the projected doses in a period of 31 days would exceed 2% of the guidelines for the annual dose or dose commitment, conforming to 10 CFR 50, Appendix I;

(continued)

5.5 Programs and Manuals (continued)

5.5.4 Radioactive Effluent Controls Program (continued)

- (169)
- g. Limitations on the dose rate resulting from radioactive material released in gaseous effluents to areas beyond the site boundary conforming to the dose associated with 10 CFR 20, Appendix B, Table 112, Column 1;
 - h. Limitations on the annual and quarterly air doses resulting from noble gases released in gaseous effluents from the plant to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I;
 - i. Limitations on the annual and quarterly doses to a member of the public from iodine-131, iodine-133, tritium, and all radionuclides in particulate form with half lives > 8 days in gaseous effluents released from the plant to areas beyond the site boundary, conforming to 10 CFR 50, Appendix I; and
 - j. Limitations on the annual dose or dose commitment to any member of the public due to releases of radioactivity and to radiation from uranium fuel cycle sources, conforming to 40 CFR 190.

(156) 5.5.5 Component Cyclic or Transient Limit Program

(200) This program provides controls to track the reactor coolant system cyclic and transient occurrences specified in the UFSAR Table 5.1.4 to ensure that components are maintained within the design limits.

5.5.6 Pre-Stressed Concrete Containment Tendon Surveillance Program

(240) This program provides controls for monitoring any tendon degradation in pre-stressed concrete containments, including effectiveness of its corrosion protection medium, to ensure containment structural integrity. The Tendon Surveillance Program, inspection frequencies, and acceptance criteria shall be in accordance with a NRC approved program.

Regulatory Guide 1.35, Revision 2
The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Tendon Surveillance Program inspection frequencies.

5.5 Programs and Manuals (continued)

- d. Nothing in the ASME Boiler and Pressure Vessel Code shall be construed to supersede the requirements of any Technical Specification.

(continued)

in accordance with the Nuclear Policy Manual.
This inspection program shall define the specific
requirements of the edition and Addenda of the
ASME Boiler and Pressure Code, Section XI, as
required by 10 CFR 50.55a(g)

5.5 Programs and Manuals (continued)

5.5.95 5.8 Steam Generator (SG) Tube Surveillance Program

Each SG shall be demonstrated OPERABLE by performance of an inservice inspection program. The program shall include the following:

- 169
- a. The inspection intervals for SG tubes shall be specified in the Inservice Inspection Program.
 - b. SG tubes that have imperfections > 40% through wall, as indicated by eddy current, shall be repaired by plugging or sleeving.
 - c. SG sleeves that have imperfections > 30% through wall, as indicated by eddy current, shall be repaired by plugging.

5.5.10 ~~Ventilation Filter Testing (VFTP)~~ 5.5.9 Secondary Water Chemistry Program

A

186

~~This program shall be established to implement the following required testing of Engineered Safety Feature (ESF) filter ventilation systems to inhibit SG tube degradation. The test frequencies and methods, where practical, will be performed in accordance with Regulatory Guide 1.52.~~

~~a. Post Accident Charcoal System~~

- ~~1. Demonstrate the pressure drop across the charcoal absorber bank is < 3 inches of water at a design flow rate ($\pm 10\%$).~~
- ~~2. Demonstrate that an in-place Freon test of the charcoal absorber bank shows a penetration and system bypass < 1.0%, when tested under ambient conditions.~~
- ~~3. Demonstrate for a carbon sample that a laboratory analysis shows the iodine removal efficiency of $\geq 90\%$ of radioactive methyl iodide.~~

~~b. Containment Recirculation System~~

- ~~1. This program shall include:~~

(continued)

5.5 Programs and Manuals (continued)

- a. Identification of a sampling schedule for the critical variables and control points for these variables;
- b. Identification of the procedures used to measure the values of the critical variables;
- c. Identification of process sampling points;
- d. Procedures for the recording and management of data;
- e. Procedures defining corrective actions for all off control point chemistry conditions; and
- f. A procedure identifying the authority responsible for the interpretation of the data and the sequence and timing of administrative events, which is required to initiate corrective action.

186

(continued)

5.5 Programs and Manuals (continued)

5.5.10 Ventilation Filter Testing Program (VFTP)

A program shall be established to implement the following required testing of Engineered Safety Feature filter ventilation systems and the Spent Fuel Pool (SFP) Charcoal Adsorber System. The test frequencies and methods will be in accordance with Regulatory Guide 1.52, Revision 2, except that in lieu of 18 month test intervals, a 24 month interval will be implemented.

193
180

180

a. Containment Post-Accident Charcoal System

1. Demonstrate the pressure drop across the charcoal adsorber adsorber bank is < 3 inches of water at a design flow rate ($\pm 10\%$).

2. Demonstrate that an in-place Freon test of the charcoal adsorber adsorber bank shows a penetration and system bypass < 1.0%, when tested under ambient conditions.

3. Demonstrate for a carbon sample that a laboratory analysis shows the iodine removal efficiency of $\geq 90\%$ of radioactive methyl iodide.

156

b. Containment Recirculation Fan Cooler System

1. Demonstrate the pressure drop across the high efficiency particulate air (HEPA) filter bank is < 3 inches of water at a design flow rate ($\pm 10\%$).

5.5.10 VFTP (continued)

2. Demonstrate that an in-place dioctylphthalate (DOP) test of the HEPA filter bank shows a penetration and system bypass < 1.0%.

c. Control Room Emergency Air Treatment System (CREATS)

1. Demonstrate the pressure drop across the HEPA filter bank is < 3 inches of water at a design flow rate ($\pm 10\%$).

180

2. Demonstrate that an in-place dioctylphthalate (DOP) test of the HEPA filter bank shows a penetration and system bypass < 1.0%.

(continued)

5.5 Programs and Manuals (continued)

5.5.10 VFTP (continued)

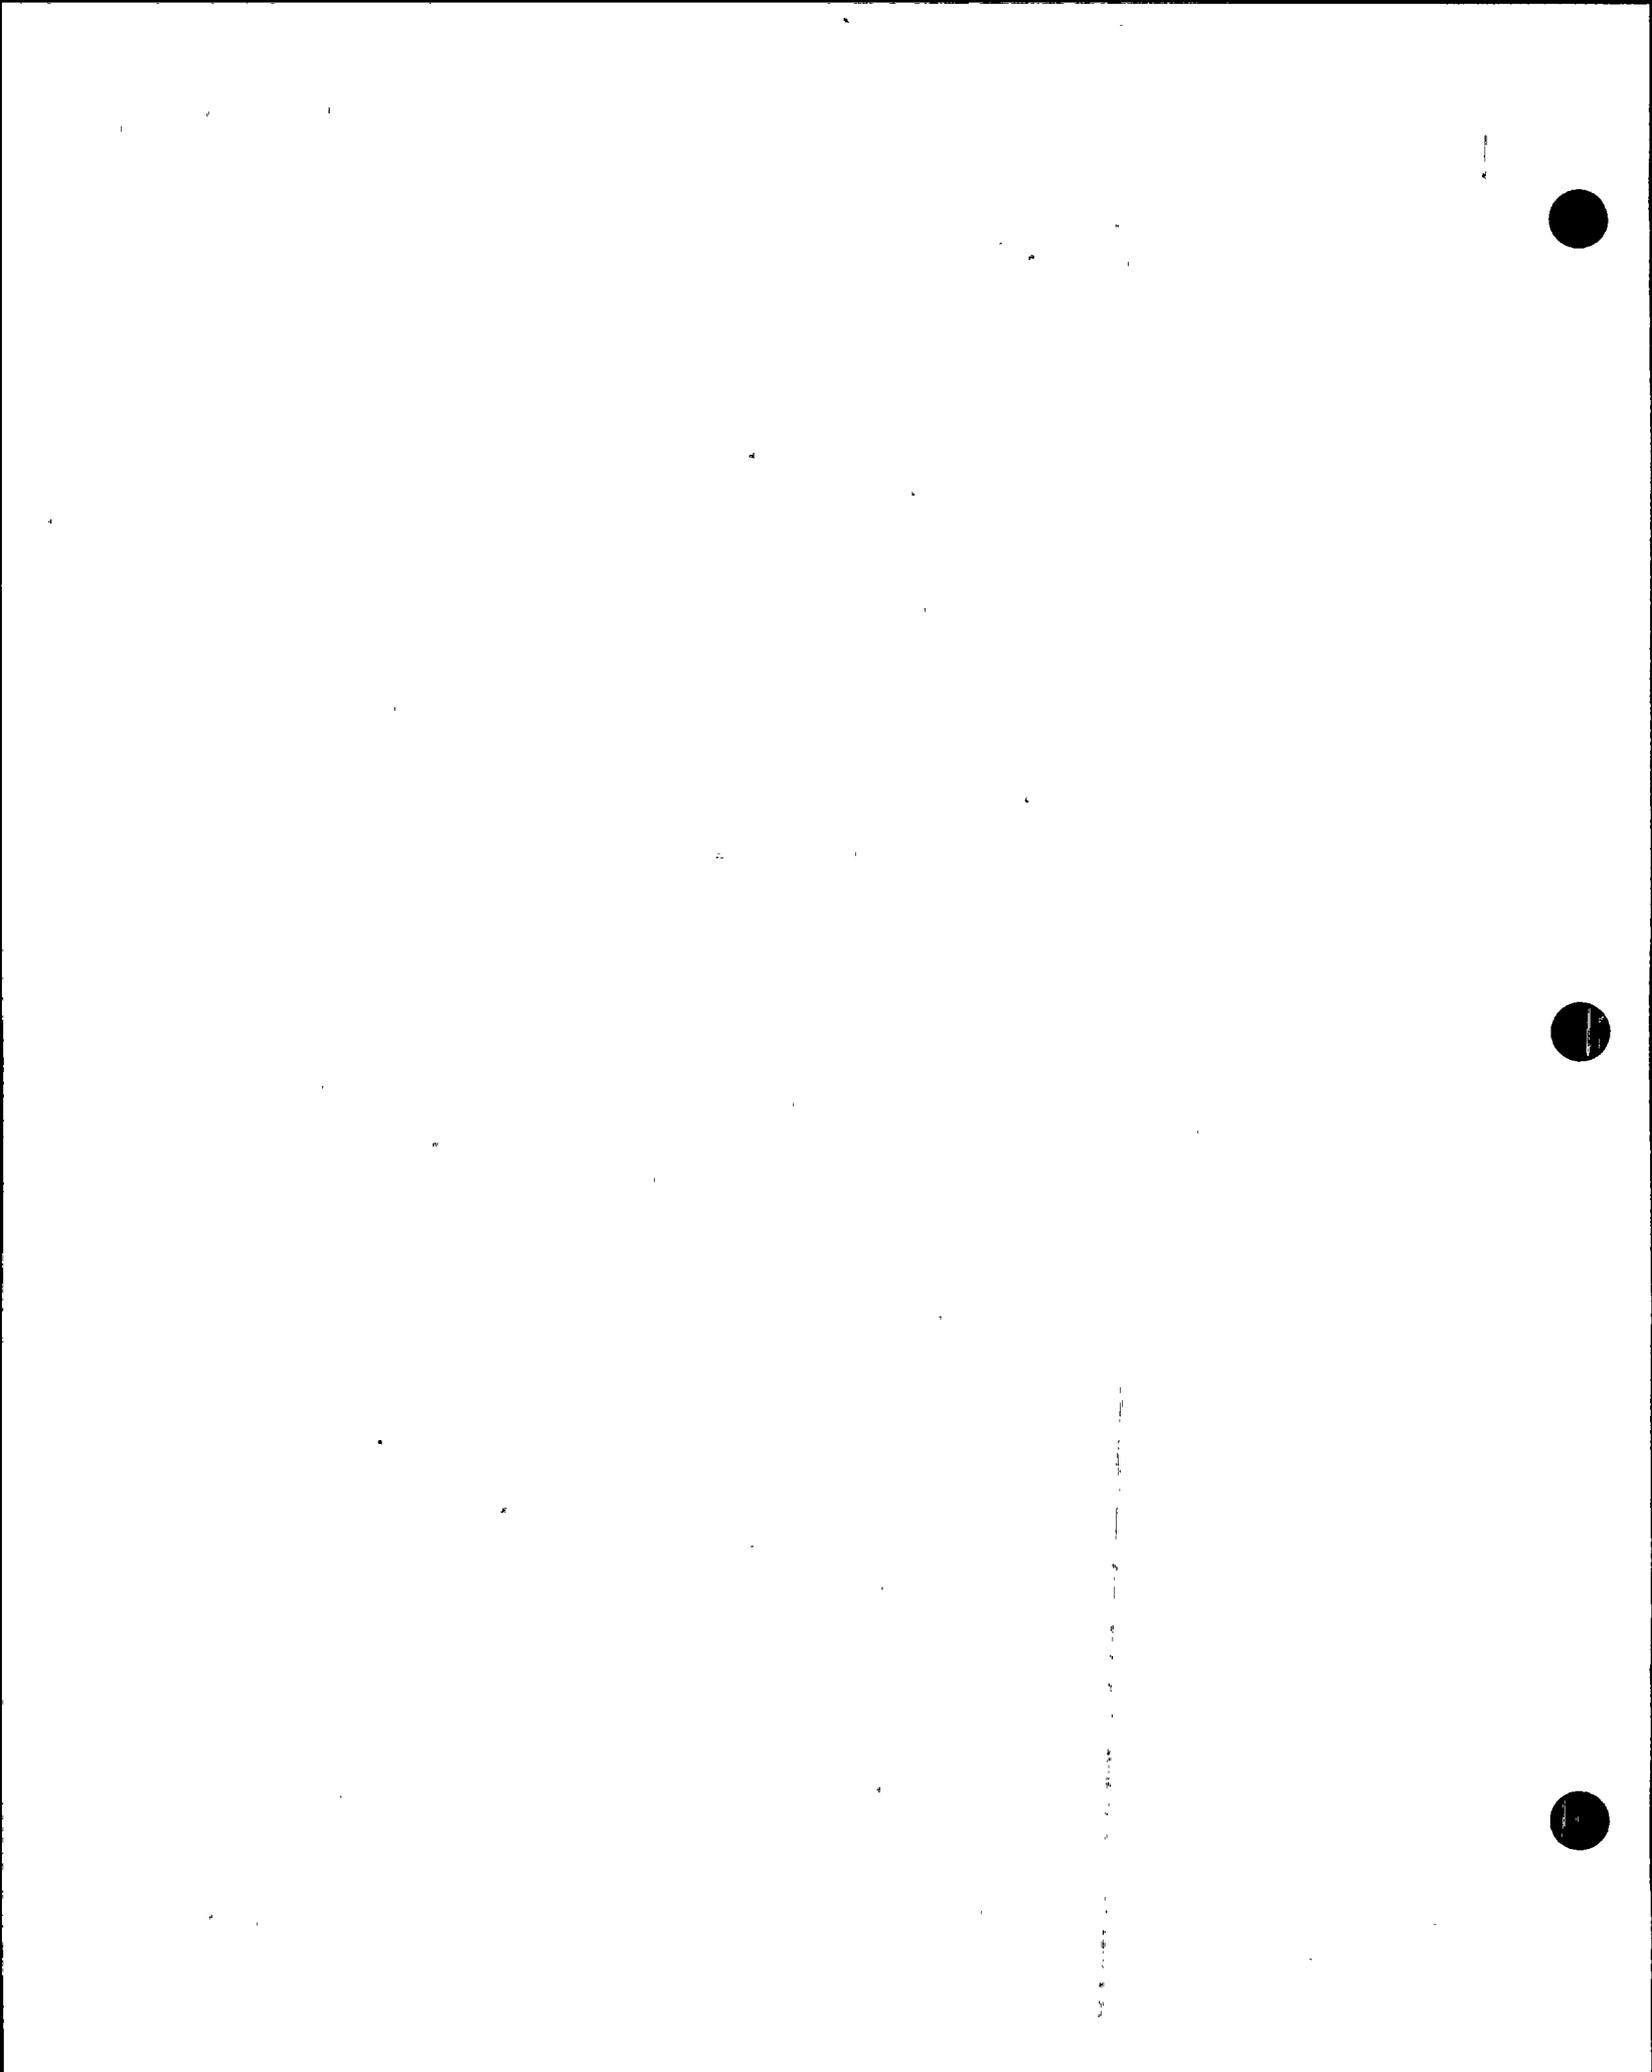

3. Demonstrate the pressure drop across the charcoal ~~adsorber~~ adsorber bank is < 3 inches of water at a design flow rate ($\pm 10\%$).
4. Demonstrate that an in-place Freon test of the charcoal ~~adsorber~~ adsorber bank shows a penetration and system bypass < 1.0%, when tested under ambient conditions.
5. Demonstrate for a carbon sample that a laboratory analysis shows the iodine removal efficiency of $\geq 90\%$ of radioactive methyl iodide.

d. Spent Fuel Pit SFP Charcoal Absorber ~~Adsorber~~ System

1. Demonstrate that the total air flow rate from the charcoal ~~absorbers~~ desorbers shows at least 75% of that measured with a complete set of new ~~absorbers~~ desorbers.
2. Demonstrate that an in-place Freon test of the charcoal ~~adsorbers~~ adsorbers bank shows a penetration and system bypass < 1.0%, when tested under ambient conditions.
3. Demonstrate for a carbon sample that a laboratory analysis shows the iodine removal efficiency of $\geq 90\%$ of radioactive methyl iodide.

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the VFTP frequencies.

(continued)

5.5 Programs and Manuals (continued)

5.5.11 Explosive Gas and Storage Tank Radioactivity Monitoring Program

This program provides controls for potentially explosive gas mixtures contained in the waste gas decay tanks and the quantity of radioactivity contained in waste gas decay tanks. The gaseous radioactivity quantities shall be determined following the methodology in NUREG-0133.

The program shall include:

- a. The limits for concentrations of hydrogen and oxygen in the waste gas decay tanks and a surveillance program to ensure the limits are maintained. Such limits shall be appropriate to the system's design criteria (i.e., whether or not the system is designed to withstand a hydrogen explosion); and
- b. A surveillance program to ensure that the quantity of radioactivity contained in each waste gas decay tank is less than the amount that would result in a whole body exposure of ≥ 0.5 rem to any individual in an unrestricted area, in the event of an uncontrolled release of the tanks' contents.

The provisions of SR 3.0.2 and SR 3.0.3 are applicable to the Explosive Gas and Storage Tank Radioactivity Monitoring Program surveillance frequencies.

5.5.12 Diesel Fuel Oil Testing Program

A diesel fuel oil testing program to implement required testing of both new fuel oil and stored fuel oil shall be established. The program shall include sampling and testing requirements, and acceptance criteria, all in accordance with ~~limits specified in Table 1 of applicable~~ ASTM D975 ~~Standards~~.

196

(continued)

~

5.5 Programs and Manuals (continued)

The purpose of the program is to establish the following:

- a. Acceptability of new fuel oil for use prior to addition to storage tanks by determining that the fuel oil has:
1. an API gravity or an absolute specific gravity within limits,
 2. a flash point and kinematic viscosity within limits for ASTM 2D fuel oil, and

(continued)

5.5 Programs and Manuals (continued)

5.5.12 Diesel Fuel Oil Testing Program (continued)

3. a clear and bright appearance with proper color; and

196
b. Within 31 days following addition of the new fuel to the storage tanks, verify that the properties of the new fuel oil, other than those addressed in a. above, are within limits for ASTM 20 fuel oil.

5.5.13 Technical Specifications (TS) Bases Control Program

This program provides a means for processing changes to the Bases of these Technical Specifications.

- a. Changes to the Bases of the TS shall be made under appropriate administrative controls and reviews.
- b. Licensees may make changes to Bases without prior NRC approval provided the changes do not involve either of the following:
 1. A change in the TS incorporated in the license; or
 2. A change to the UFSAR or Bases that involves an unreviewed safety question as defined in 10 CFR 50.59.
- c. The Bases Control Program shall contain provisions to ensure that the Bases are maintained consistent with the UFSAR.
- d. Proposed changes that meet the criteria of Specification 5.5.13.b.1 or Specification 5.5.13.b.2 shall be reviewed and approved by the NRC prior to implementation. Changes to the Bases implemented without prior NRC approval shall be provided to the NRC on a frequency consistent with 10 CFR 50.71e.

(continued)

5.5 Programs and Manuals (continued)

5.5.14 Safety Function Determination Program (SFDP)

This program ensures that a loss of safety function is detected and appropriate actions taken. Upon entry into LCO 3.0.6, an evaluation shall be made to determine if loss of safety function exists. Additionally, other appropriate actions may be taken as a result of the support system inoperability and corresponding exception to entering supported system Condition and Required Actions. ~~These appropriate actions will be stated in an exception to entering supported system Condition and Required Actions as provided in the Specifications.~~ This program implements the requirements of LCO 3.0.6. The SFDP shall contain the following:

- 187
- a. Provisions for cross train checks to ensure a loss of the capability to perform the safety function assumed in the accident analysis does not go undetected;
 - b. Provisions for ensuring the plant is maintained in a safe condition if a loss of function condition exists;
 - c. Provisions to ensure that an inoperable supported system's Completion Time is not inappropriately extended as a result of multiple support system inoperabilities; and
 - d. Other appropriate limitations and remedial or compensatory actions.

A loss of safety function exists when, assuming no concurrent single failure, a safety function assumed in the accident analysis cannot be performed. For the purpose of this program, a loss of safety function may exist when a support system ~~or train is~~ inoperable ~~(i, and:~~

- 187
- a. ~~eA required system redundant to the supported system(s) is also inoperable; or~~
 - b. ~~, the Conditions and Required Actions have been entered), and:~~
 - a. ~~A required system or train redundant to the supported system(s) or train is also inoperable; or~~
 - b. ~~A required system redundant to the system(s) or train supported by the inoperable supported system or train is also inoperable; or~~

SFDP (continued)

187

The SFDP identifies where a loss of safety function exists. If a loss of safety function is determined to exist by this program, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

5.5.15 ~~Secondary Water Chemistry Program~~

~~This program provides controls for monitoring secondary water chemistry to inhibit SG tube degradation. This program shall include:~~

- ~~a. Identification of a sampling schedule for the critical variables and control points for these variables;~~
- ~~b. Identification of the procedures used to measure the values of the critical variables;~~
- ~~c. Identification of process sampling points;~~
- ~~d. Procedures for the recording and management of data;~~
- ~~e. Procedures defining corrective actions for all off control point chemistry conditions; and~~
- ~~f. A procedure identifying the authority responsible for the interpretation of the data and the sequence and timing of administrative events, which is required to initiate~~

186

~~corrective action.~~ 5.5.15 ~~Containment Leakage Rate Testing Program~~

A program shall be established to implement the leakage rate testing of the containment as required by 10 CFR 50.54(o) and 10 CFR 50, Appendix J, Option B, as modified by approved exemptions. This program shall be in accordance with the guidelines contained in Regulatory Guide 1.163, "Performance-Based Containment Leak-Test Program," dated September 1995.

35

The peak calculated containment internal pressure for the design basis loss of coolant accident, P_0 , is 60 psig.

The maximum allowable primary containment leakage rate, L_0 , at P_0 , shall be 0.2% of containment air weight per day.

Leakage Rate acceptance criteria are:

5.5 Programs and Manuals

a. Containment leakage rate acceptance criterion is $\leq 1.0 L_a$. During the first plant startup following testing in accordance with this program, the leakage rate acceptance criteria are $\leq 0.60 L_a$ for the Type B and Type C tests and $\leq 0.75 L_a$ for Type A tests;

b. Air lock testing acceptance criteria are:

1) For each air lock, overall leakage rate is $\leq 0.05 L_a$ when tested at $\geq P_a$, and

2) For each door, leakage rate is $\leq 0.01 L_a$ when tested at $\geq P_a$.

c. Mini-purge valve acceptance criteria is $\leq 0.05 L_a$ when tested at $\geq P_a$.

The provisions of SR 3.0.2 do not apply to the test frequencies specified in the Containment Leakage Rate Testing Program.

The provisions of SR 3.0.3 do not apply to the test frequencies specified in the Containment Leakage Rate Testing Program.

5.0 ADMINISTRATIVE CONTROLS

5.6 Reporting Requirements

The following reports shall be submitted in accordance with 10 CFR 50.4.

5.6.1 Occupational Radiation Exposure Report

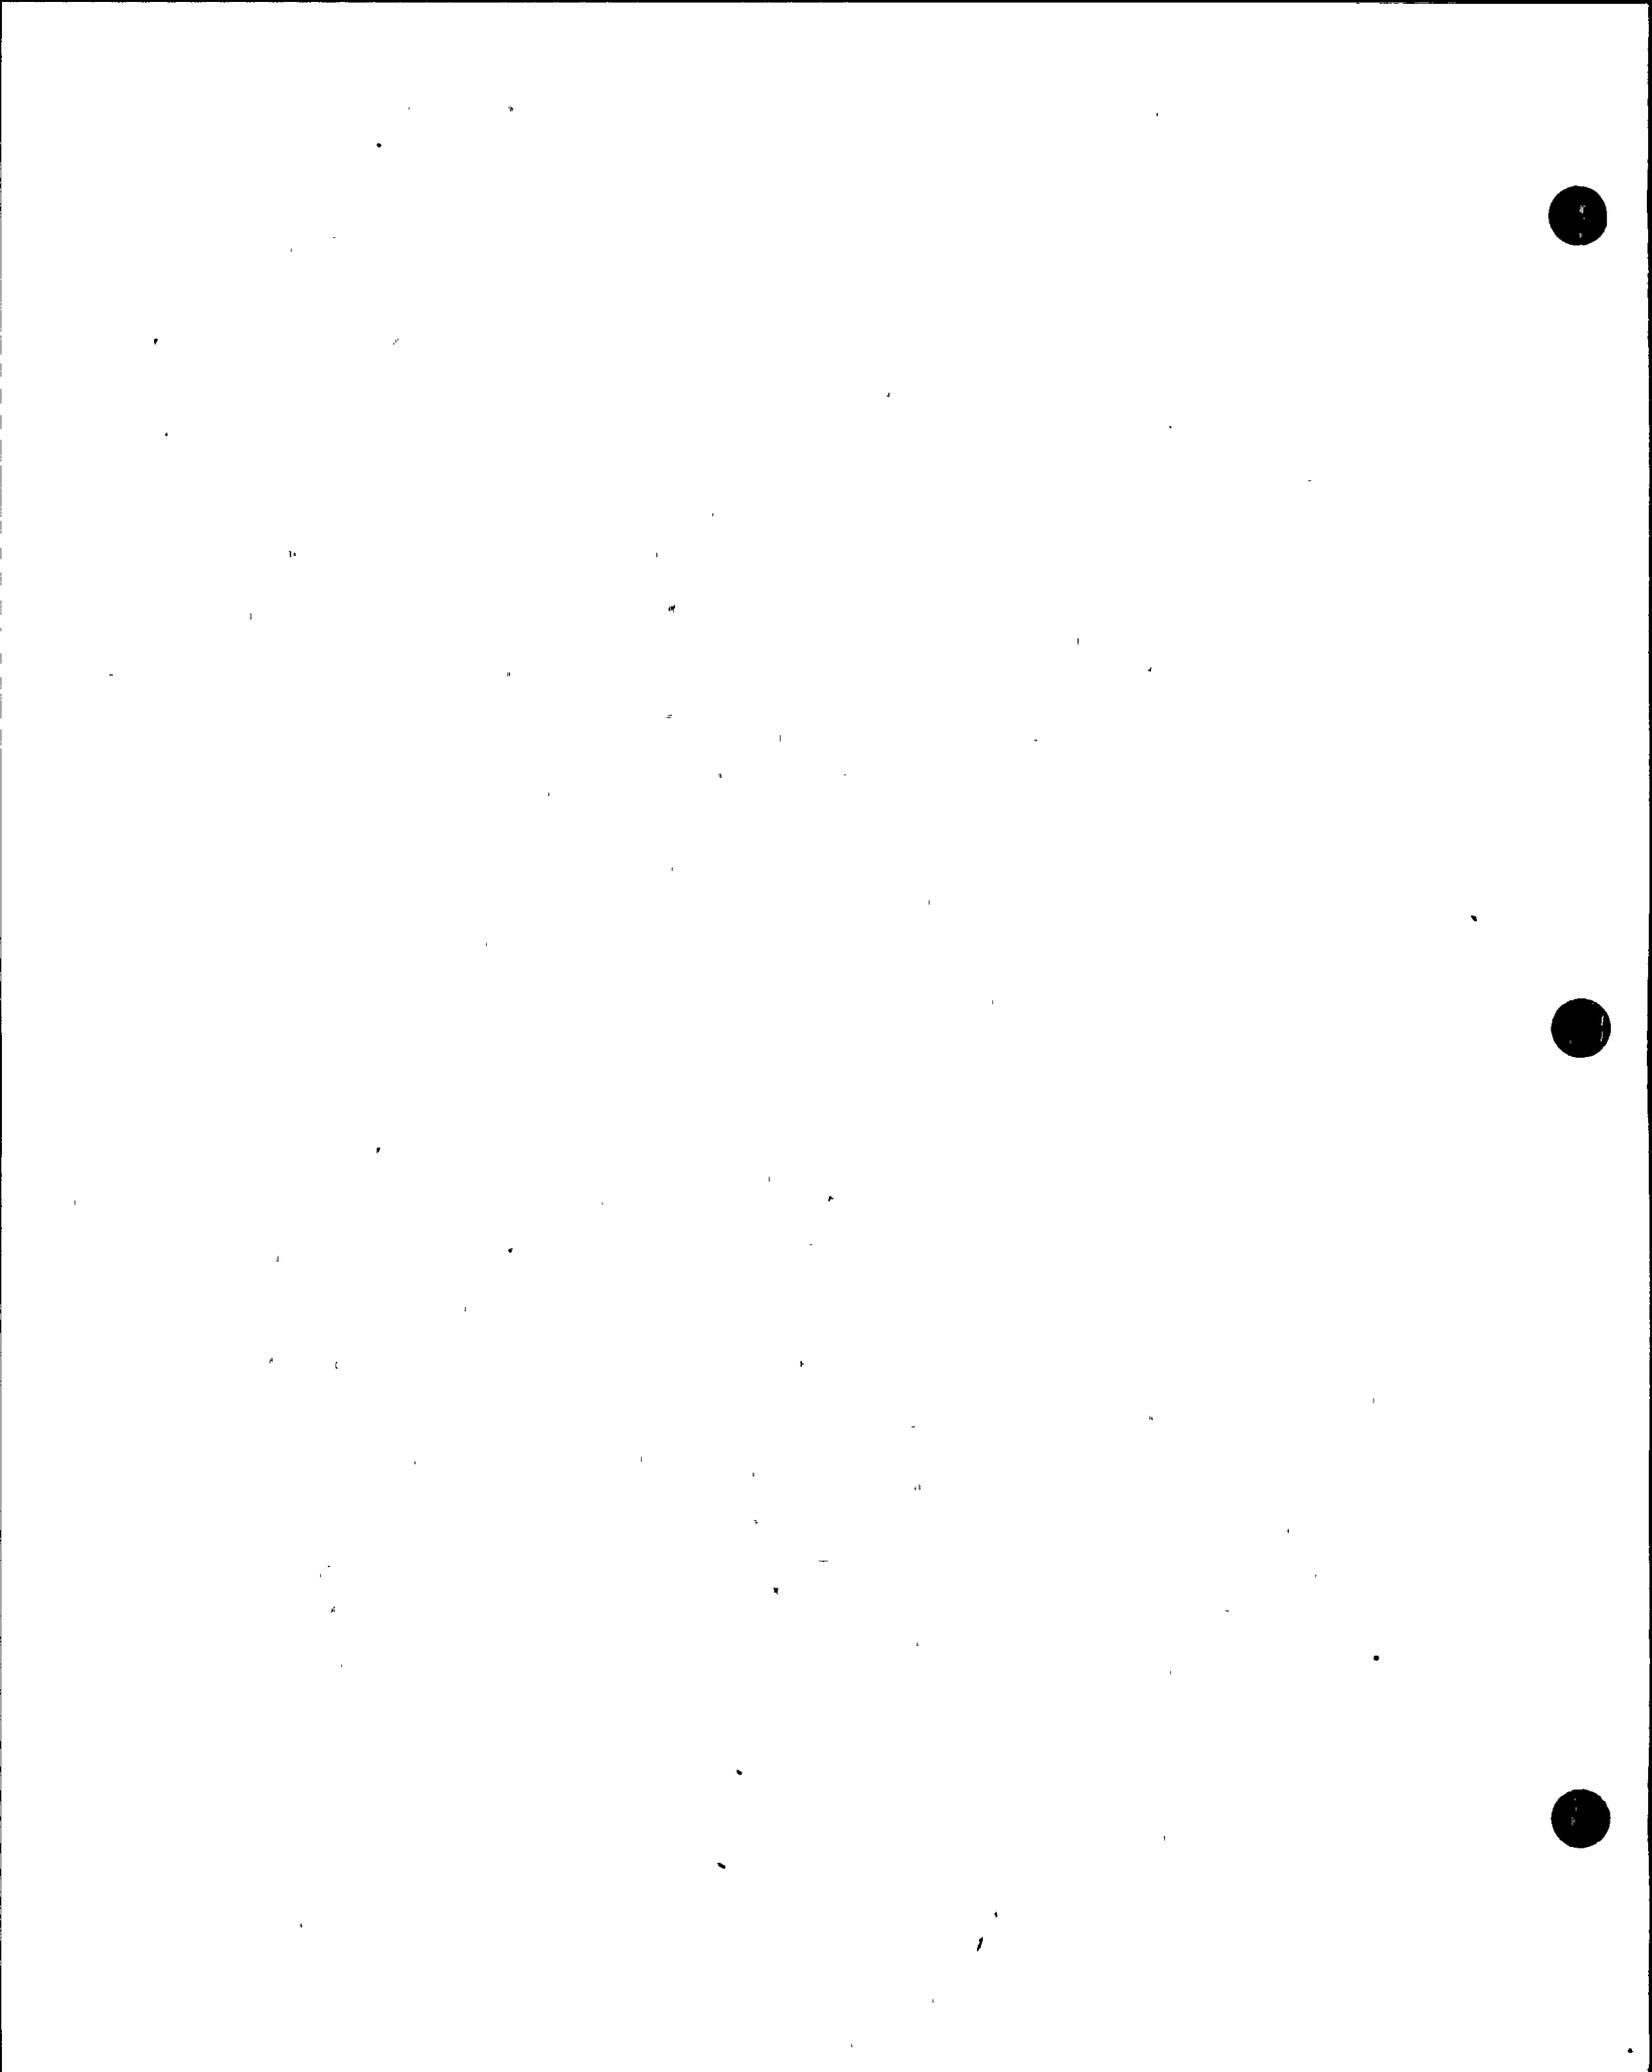

A tabulation on an annual basis of the number of station, utility, and other personnel (including contractors) receiving exposures > 100 mrem/yr and their associated man rem exposure according to work and job functions (e.g., reactor operations and surveillance, inservice inspection, routine maintenance, special maintenance, waste processing, and refueling). This tabulation supplements the requirements of 10 CFR 20.2206. The dose assignments to various duty functions may be estimated based on pocket dosimeter, thermoluminescent dosimeter (TLD), or film badge measurements. Small exposures totalling < 20% of the individual total dose need not be accounted for. In the aggregate, at least 80% of the total whole body dose received from external sources should be assigned to specific major work functions. The report shall be submitted on or before April 30 of each year.

5.6.2 Annual Radiological Environmental Operating Report

The Annual Radiological Environmental Operating Report covering the operation of the plant during the previous calendar year shall be submitted by May 15 of each year. The report shall include summaries, interpretations, and analyses of trends of the results of the radiological environmental monitoring activities for the reporting period. The material provided shall be consistent with the objectives outlined in the Offsite Dose Calculation Manual (ODCM), and in 10 CFR 50, Appendix I, Sections IV.B.2, IV.B.3, and IV.C.

The Annual Radiological Environmental Operating Report shall include the results of analyses of all radiological environmental samples and of all environmental radiation measurements taken during the period pursuant to the locations specified in the table and figures in the ODCM, as well as summarized and tabulated results of these analyses and measurements in the format of the table in the Radiological Assessment Branch Technical Position, Revision 1, November 1979. In the event that some individual results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted in a supplementary report as soon as possible.

(continued)

5.6 Reporting Requirements (continued)

5.6.3 Radioactive Effluent Release Report

The Radioactive Effluent Release Report covering the operation of the plant shall be submitted in accordance with 10 CFR 50.36a. The report shall include a summary of the quantities of radioactive liquid and gaseous effluents and solid waste released from the plant. The material provided shall be consistent with the objectives outlined in the ODCM and in conformance with 10 CFR 50.36a and 10 CFR 50, Appendix I, Section IV.B.1.

5.6.4 Monthly Operating Reports

Routine reports of operating statistics and shutdown experience, including documentation of all challenges to the pressurizer power operated relief valves or pressurizer safety valves, shall be submitted on a monthly basis no later than the 15th of each month following the calendar month covered by the report.

5.6.5 CORE OPERATING LIMITS REPORT (COLR)

- a. Core operating limits shall be established prior to each reload cycle, or prior to any remaining portion of a reload cycle, and shall be documented in the COLR for the following:

LCO 3.1.1, "SHUTDOWN MARGIN (SDM)";
 LCO 3.1.3, "MODERATOR TEMPERATURE COEFFICIENT (MTC)";
 LCO 3.1.5, "Shutdown Bank Insertion Limit";
 LCO 3.1.6, "Control Bank Insertion Limits";
 LCO 3.2.1, "Heat Flux Hot Channel Factor ($F_Q(Z)$)";
 LCO 3.2.2, "Nuclear Enthalpy Rise Hot Channel Factor ($F_{\Delta H}^N$)";

5.0 ADMINISTRATIVE CONTROLS

5.7 High Radiation Area

5.7.1 Pursuant to 10 CFR 20, paragraph 20.1601(a), in lieu of the requirements of 10 CFR 20.1601(c), each high radiation area, as defined in 10 CFR 20, in which the intensity of radiation is > 100 mrem/hr but ≤ 1000 mrem/hr at a distance of 30 cm, shall be barricaded and conspicuously posted as a high radiation area and entrance thereto shall be controlled by requiring issuance of a Radiation Work Permit (RWP). Individuals qualified in radiation protection procedures (e.g., ~~Radiation Protection Technicians~~ ~~radiation protection technicians~~) or personnel continuously escorted by such individuals may be exempt from the RWP issuance requirement during the performance of their assigned duties in high radiation areas with exposure rates ≤ 1000 mrem/hr, provided they are otherwise following plant radiation protection procedures for entry into such high radiation areas.

Any individual or group of individuals permitted to enter such areas shall be provided with or accompanied by one or more of the following:

- a. A radiation monitoring device that continuously indicates the radiation dose rate in the area.
- b. A radiation monitoring device that continuously integrates the radiation dose rate in the area and alarms when a preset integrated dose is received. Entry into such areas with this monitoring device may be made after the dose rate levels in the area have been established and personnel are aware of them.
- c. An individual qualified in radiation protection procedures with a radiation dose rate monitoring device, who is responsible for providing positive control over the activities within the area and shall perform periodic radiation surveillance at the frequency specified by the ~~radiation protection technician~~ in the RWP.

(continued)

5.7 High Radiation Area (continued)

- 5.7.2 In addition to the requirements of Specification 5.7.1, areas with radiation levels > 1000 mrem/hr at a distance of 30 cm shall be provided with locked or continuously guarded doors to prevent unauthorized entry and the keys shall be maintained under the administrative control of the Shift Supervisor on duty or radiation protection supervision. Doors shall remain locked except during periods of access by personnel under an approved RWP that shall specify the dose rate levels in the immediate work areas and the maximum allowable stay times for individuals in those areas. In lieu of the stay time specification of the RWP, direct or remote (such as closed circuit TV cameras) continuous surveillance may be made by personnel qualified in radiation protection procedures to provide positive exposure control over the activities being performed within the area.
- 5.7.3 In addition to the requirements of Specification 5.7.1, for individual high radiation areas with radiation levels of > 1000 mrem/hr at a distance of 30 cm, accessible to personnel, that are located within large areas such as reactor containment, where no enclosure exists for purposes of locking, or that cannot be continuously guarded, and where no enclosure can be reasonably constructed around the individual area, that individual area shall be barricaded and conspicuously posted, and a flashing light shall be activated as a warning device.
-

D. JUSTIFICATION (CURRENT GINNA TS)

Converting to the ITS format will provide a significant human factors improvement by locating similar requirements within the same section and also provide a standard structure. In addition, the expanded bases information will support preparation of safety evaluations and training activities. There are several types of changes that are being requested by this LAR in order to perform the conversion. These changes are with respect to both the ITS and the current Ginna Station Technical Specifications. The technical and significant administrative changes related to the current Ginna Station TS are organized into multiple categories as summarized below.

i. Relocation of Requirements Within Technical Specifications

Many current specifications are moved to support consolidation of similar requirements within the same section. Since the requirements are only being relocated within the technical specifications, there is no reduction in safety. This category is mainly used to identify multiple requirements that are consolidated into a single new specification and not for listing requirements which are only renumbered.

ii. Elimination of Duplicated Regulatory Requirements

Several specifications currently duplicate existing regulatory requirements. The removal of these specifications eliminates the need to change technical specifications when there are rule changes. Since all licensees must meet the applicable requirements contained in the Code of Federal Regulations, or have NRC approved exemptions, there are sufficient regulatory controls in place to allow elimination of duplicated requirements from technical specifications. The implementation of these requirements are contained in procedures and other licensee controlled documents.

iii. Relocation of Current Requirements To Other Controlled Documents

The relocation of certain requirements to other licensee controlled documents (i.e., UFSAR, QA Program, and plant procedures) does not eliminate the requirement. Instead, the requirements are relocated to other more appropriate documents and programs which have sufficient controls in place to manage implementation and future changes (e.g., 10 CFR 50.54(a)(3) and 10 CFR 50.59). The relocation of these items will enable RG&E to more efficiently maintain the requirements under existing regulations and reduce the need to request technical specification changes for issues which do not affect public safety.

iv. Addition of New ITS Requirements

There are several requirements contained in NUREG-1431 which are not currently in the Ginna Station Technical Specifications. These ITS requirements were added in order to provide a more complete specification. Changes within this category are further identified as either being a "more restrictive change" (iv.a) or a "less restrictive change" (iv.b).

v. Other Changes to Technical Specifications (Technical)

Several changes to existing requirements were made to provide consistency with NUREG-1431. Examples include moving requirements to LCO Notes and revising the current specified Completion Time. Also included within this category are the revision of the existing bases to reflect more current information. Changes within this category are further identified as either being a "more restrictive change" (v.a), "less restrictive change" (v.b), or an "administrative change" (v.c).

vi. Other Changes to Technical Specifications (Administrative)

Several minor changes to the technical specifications were made that are minor revisions only and do not involve any technical issues. Examples include updates of references to the Code of Federal Regulations.

The following section discusses changes to the current Ginna Station Technical Specifications which were not addressed in Section C of this attachment. This section is organized based on the existing TS chapter numbers to facilitate easier review. Each change is also identified with respect to one of the above categories (e.g., Ginna Station TS Category (i)). A marked up copy of the Ginna Station Technical Specifications is provided in Attachment B which identifies major changes only. A cross reference is provided in the margin of each specification that has been changed by use of a circle containing section numbers from below. For example, "1.i" found in the margin of the markup would refer to section 1.i below. A cross reference between the ITS and current Ginna Station Technical Specifications is also provided in Attachment E.

1. Technical Specification 1.0

- i. TS 1.2 - The definitions of operating MODES were revised as follows (these are Ginna TS Category (v.a) changes):
 - a. Refueling - see Note 1.ii below.
 - b. Cold Shutdown - The reactivity limit was revised from $\leq -1 \Delta k/k\%$ to $< 0.99 k_{eff}$ which are equivalent limits.

- c. Hot Shutdown - The reactivity limit was revised from $\leq -1 \Delta k/k\%$ to $< 0.99 k_{eff}$ which are equivalent limits. The average reactor coolant temperature was also revised from $\geq 540^\circ\text{F}$ to $\geq 350^\circ\text{F}$. This change eliminates the use of an intermediate mode of 350°F as found throughout the current TS which is not defined in TS 1.2. The expansion of this temperature range is conservative since the current TS only use the Hot Shutdown MODE in two aspects. The first method is requiring a shutdown to this mode due to plant conditions. Since the upper temperature range for Hot Shutdown remains the same (i.e., the Operating MODE temperature), there is no impact. The second method is to require certain equipment to be OPERABLE in this mode. However, lowering the temperature limit to 350°F requires that the equipment would be OPERABLE for a larger temperature range.
- d. Operating - The reactivity limit was revised from $> -1 \Delta k/k\%$ to $\geq 0.99 k_{eff}$ which are equivalent limits. The average reactor coolant temperature of $\sim 580^\circ\text{F}$ was not added since this parameter is specified in new LCO 3.4.1. In addition, the Operating MODE was separated into two modes: Operating and Startup. The only difference between these two modes is that Startup is defined when the reactor is $\leq 5\%$ Rated Thermal Power (RTP) while the Operating MODE is when the reactor is $> 5\%$ RTP.
- e. A new operating mode (Hot Standby) was provided between Hot Shutdown and Cold Shutdown. This mode is defined as when the reactivity condition is $< 0.99 k_{eff}$ and the average reactor coolant temperature is $< 350^\circ\text{F}$ and $> 200^\circ\text{F}$ when the reactor vessel head closure bolts are fully tensioned. The definition of this new mode eliminates the use of an intermediate mode of 350°F as found throughout the current TS which is not defined in TS 1.2.

- ii. TS 1.3 - This definition of refueling was deleted. The current TS 1.2 provides a definition of refueling as being the reactor mode when reactivity is $\leq -5 \Delta k/k\%$ and the average reactor coolant temperature is $\leq 140^\circ\text{F}$. TS 1.3 states that refueling is "any operation within the containment involving movement of fuel and/or control rods when the vessel head is unbolted" which is a subset of the mode defined in TS 1.2. The new TS Table 1.1-1 states that refueling is any condition in which "one or more reactor vessel head closure bolt is less than fully tensioned" with fuel in the reactor. While an average reactor coolant temperature or reactivity limit is no longer provided for the refueling mode definition, the reactor vessel head closure bolts cannot be removed at elevated reactor coolant temperatures or when the RCS is pressurized due to their design. A reactivity limit is also not required when the RCS is depressurized. Therefore, the new definition of the refueling mode is more conservative than current TS 1.3 and generally consistent with TS 1.2. This is a Ginna TS Category (v.a) change.
- iii. TS 1.5 - The definition for Operating was not added to the new specifications since it is no longer required. This definition is addressed by the new definition for OPERABLE - OPERABILITY. This is a Ginna TS Category (i) change.
- iv. TS 1.6 - The definition for Degree of Redundancy (Instrument Channels) was not added to the new specifications since it is no longer required. This definition is addressed within new TS 3.3 (Instrumentation). This is a Ginna TS Category (v.c) change.
- v. TS 1.7.1 - This was revised to specify that the CHANNEL CALIBRATION includes the required interlock and time constant functions of the channel. In addition, discussion of calibrating instrument channels with resistance temperature detectors was added for clarification. These are Ginna TS Category (v.a) changes.
- vi. TS 1.7.2 - The last sentence of this definition was revised as follows:

This determination shall include, where possible, comparison of the channel indication and/or status with to other indications and/or status derived from independent instrumentation channels measuring the same parameter.

These minor changes provide greater clarification of the defined term and are Ginna TS Category (v.c) changes.

- vii. TS 1.7.3 - The definitions for testing of analog and bistable channels were combined into one description with a new title. The only difference between the two definitions is that testing of bistable channels required injection of a simulated or source signal into the sensor versus "as close to the sensor as possible" for analog channels. Since the bistable must be actuated to determine operability, maintaining the analog channel description for the combined definition is acceptable. In addition, the combined definition was expanded to require "adjustments, as necessary, of the required alarm, interlock, and trip setpoints so that the setpoints are within the required range and accuracy." These are Ginna TS Category (v.a) changes.
- viii. TS 1.7.4 - The definition for Source Check was not added to the new specifications since it is no longer required. The performance of a Source Check is now addressed within the definition of CHANNEL CALIBRATION and CHANNEL OPERATING TEST (COT). This is a Ginna TS Category (v.c) change.
- ix. TS 1.8 - The definition for Containment Integrity was relocated to the bases of new TS 3.6.1 and 3.6.2 which essentially requires compliance with 10 CFR 50, Appendix J and the GDC. This is a Ginna TS Category (iii) change.
- x. TS 1.10 - The definition for Hot Channel Factors was not added to the new specifications since it is no longer required. The Hot Channel Factor limit is only discussed in one LCO with the limit defined in the COLR. This is a Ginna TS Category (v.c) change.
- xi. TS 1.11 - This previously deleted definition was not added to the new specifications. This is a Ginna TS Category (vi) change.
- xii. TS 1.12 - The Frequency for Surveillance Requirements is now specified in hours, days or months in the new specifications such that the current definition of Frequency Notation is no longer required. Consequently, this definition was replaced with a general description of how to use and apply the Frequency requirements. In addition, the definition of refueling Frequency was revised from 18 months to 24 months for all systems. This is discussed in Attachment H and is a Ginna TS Category (v.b.1) change.
- xiii. TS 1.13 - The definition for Offsite Dose Calculation Manual (ODCM) was moved to the ODCM program description in ITS specification 5.5.1. The change to the CTS is editorial because the program description involves reorganization or reformatting of requirements without affecting technical content. This is a Ginna TS Category (v.c) change.

- xiv. TS 1.14 - The definition for Process Control Program (PCP) was not added to the new specifications since it is no longer required. The PCP was relocated from the technical specifications to the TRM and does not need to be described within new TS 1.1. This is a Ginna TS Category (v.c) change.
- xv. TS 1.15 - The definition for Solidification was not added to the new specifications since it is no longer required. Solidification is described within the PCP which was relocated from the technical specifications to the TRM. Therefore, this definition does not need to be provided in new TS 1.1. This is a Ginna TS Category (v.c) change.
- xvi. TS 1.16 - The definition for Purge - Purging was not added to the new specifications since it is no longer required. This definition only pertains to the Containment Purge system which is described in new TS 3.6.3. This is a Ginna TS Category (v.c) change.
- xvii. TS 1.17 - The definition for Venting was not added to the new specifications since it is no longer required. This definition only pertains to the Containment Purge system which is described in new TS 3.6.3. This is a Ginna TS Category (v.c) change.
- xviii. Not used.
- xix. TS 1.19 - The definition for Reportable Event was not added to the new specifications since it is no longer required. Reportable Events are described in 10 CFR 50.72 and 50.73. This is a Ginna TS Category (ii) change.
- xx. TS 1.20 - The definition for Canisters Containing Consolidated Fuel Rods was not added to the new specifications since it is no longer required. This definition is provided in new TS 4.3 which is the only section that addresses consolidated fuel rods. This is a Ginna TS Category (v.c) change.

- xxi. TS 1.21 - The definition for Shutdown Margin was expanded to require another assumption that in MODES 1 and 2, the fuel and moderator temperatures are changed to the nominal hot zero power temperature. Also, the definition was revised to require consideration of any RCCA known to be incapable of being fully inserted. This is in addition to the existing assumptions related to a stuck fully withdrawn single RCCA with the highest reactivity worth. The definition description discussing "no changes in xenon or boron concentration" was deleted since this level of detail is not required. These clarifications, which are consistent with NUREG-1431, are Ginna TS Category (v.a) changes.
- xxii. TS 1.4 - The definition for OPERABLE -. OPERABILITY was revised to remove "supports." This phrase was added to the current definition by Reference 3 but is not consistent with the definition as provided in NUREG-1431. Therefore, to provided consistency, this was not added to the new specifications. This is a Ginna TS Category (v.c) change.
- xxiii. The following definitions were added to the new specifications since the associated terms are used throughout the document (these are Ginna TS Category (v.a) changes):
- a. ACTIONS
 - b. ACTUATION LOGIC TEST
 - c. AXIAL FLUX DIFFERENCE
 - d. CORE ALTERATION
 - e. CORE OPERATING LIMITS REPORT (COLR)
 - f. LEAKAGE
 - g. PHYSICS TESTS
 - h. PRESSURE TEMPERATURE LIMITS REPORT (PTLR)
 - i. RATED THERMAL POWER
 - j. STAGGERED TEST BASIS
 - k. TRIP ACTUATING DEVICE OPERATIONAL TEST (TADOT)
- xxiv. A new section was added to the specifications which explains the use of Logical Connectors within the new TS. This section does not provide any new requirements, only a description and examples of how to use the new ITS format. This is a Ginna TS Category (v.c) change.
- xxv. A new section was added to the specifications which explains the use of the Completion Time convention within the new TS. There are several changes from the current Ginna Station TS format which are discussed in this section (these are Ginna TS Category (v.a) changes):

- a. Completion Times in the new TS are based on the format that the clock for all Required Actions begin from the time that the Condition is entered. The Completion Times in the new specifications and the current Ginna Station TS are typically equal. For example, the new specifications may require that the plant be in MODE 3 within 6 hours and in MODE 4 within 36 hours for a specified Condition while the current Ginna Station TS require that the plant be in MODE 3 within 6 hours and in MODE 4 within an additional 30 hours for the same Condition. The intent of both the new specifications and the current Ginna Station TS is the same (i.e. be in MODE 4 within 36 hours).
- b. The new specifications restrict multiple entries into the ACTION table for separate Conditions unless it is specifically stated as acceptable. For example, if one SI pump is inoperable and during the LCO, a second SI pump is declared inoperable, the plant would enter 3.0 conditions in both the new specifications and the current Ginna Station TS. If the first SI pump were restored to OPERABLE status before entering MODE 3, the plant could resume operation in both TS. However, in the current TS, the Completion Time for restoring the second SI pump to OPERABLE status would begin from the time that it was declared inoperable. In the new specifications, the Completion Time would begin from the time the first pump was declared inoperable with an additional 24 hours allowed. This is a conservative change.

xxvi. A new section was added to the specifications which explains the use of the Frequencies specified within the SRs. This section does not provide any new requirements, only a description and examples of how to use the new ITS format. This is a Ginna TS Category (v.c) change.

2. Technical Specification 2.1

- i. The Applicability was revised to define when the reactor is in "operation" as MODES 1 and 2. This is an editorial change only since "operation" has been redefined as MODES 1 and 2 per Section D Change 1.i.d. This is a Ginna TS Category (iv.a) change.

3. Technical Specification 2.2

- i. The Applicability was revised to "MODES 1, 2, 3, 4, and 5." The proposed Applicability does not require this Safety Limit (SL) to be met when fuel is in the vessel with one or more reactor vessel head closure bolts less than fully tensioned or with the head removed. With the reactor head bolts less than fully tensioned, it is highly unlikely that the RCS can be pressurized greater than the SL pressure due to the low temperature over-pressure protection requirements. With the head removed, it is not possible to pressurize the RCS greater than the SL pressure. This is a Ginna TS Category (v.b.2) change.

4. Technical Specification 2.3

- i. This entire section was relocated to ITS Chapter 3.3, "Instrumentation." This is a Ginna TS Category (i) change.
- ii. TS 2.3 - Various limiting safety system settings (LSSS) are addressed as "Trip Setpoints," "Allowable Values," or "Applicable Modes" (as permissives) for their respective Reactor Trip System (RTS) instrumentation Functions in new LCO 3.3.1. Specific changes to the LSSS are discussed below for each of the associated Functional Units. This is a Ginna TS Category (i) change.
- iii. Not used.
- iv. TS 2.3.3.1, TS 2.3.3.2, and Figure 2.3-1 - The LSSS for the loss of voltage and degraded voltage functions were revised to provide a minimum Trip Setpoint value. Criteria for the establishment of equivalent values based on measured voltage versus relay operating time was relocated to the bases for LCO 3.3.4. This is a Ginna TS Category (iii) change.
- v. TS 2.3.2 - The listing of permissives was revised to provide requirements and setpoints for P-6, P-9, and P-10. These permissives also provide enabling and blocking features for various RTS functions. This is a Ginna TS Category (v.a) change.

5. Technical Specification 3.0

- i. A new section LCO 3.0.1 was added which explains the use of the Applicability statement in the new TS. This section does not provide any new requirements. Previous guidance provided by the NRC (e.g., Generic Letter 87-09) regarding the intent and interpretation of existing Specifications is consistent with LCO 3.0.1. This LCO provides clarifying and descriptive information for the LCOs applicability consistent with the use and format of the ITS. This is a Ginna TS Category (v.c) change.
- ii. A new section LCO 3.0.2 was added which explains the use of the associated ACTIONS upon discovery of a failure to meet an LCO in the new TS. This section does not provide any new requirements. Previous guidance provided by the NRC (e.g., Generic Letter 87-09) regarding the intent and interpretation of existing Specifications is consistent with LCO 3.0.2. This LCO provides clarifying and descriptive information for the LCOs applicability consistent with the use and format of the ITS. This is a Ginna TS Category (v.c) change.
- iii. TS 3.0.1 - This was revised to clarify the use of the actions that must be implemented when an LCO is not met and (1) an associated Required Action and Completion Time is not met and no other Condition applies, or (2) the condition of the plant is not specifically addressed by the associated ACTIONS. The current requirement that the LCO time limits apply if they are more limiting than those required by LCO 3.0.3 is deleted and an expanded discussion is provided in the Basis to clarify the applicability of this requirement. This section does not provide any new requirements except as discussed in item 5.viii below. The clarifications and examples are based on the use of the new ITS format. This is a Ginna TS Category (v.c) change.
- iv. A new section LCO 3.0.4 was added which explains the limitations on changes in MODES or other specified conditions in the Applicability when an LCO is not met in the new TS. This section provides new requirements consistent with the use and format of the ITS. This is a Ginna TS Category (iv.a) change.

- v. A new section LCO 3.0.5 was added to provide an exception to LCO 3.0.2 for instances where restoration of inoperable equipment to an OPERABLE status could not be performed while continuing to comply with Required Actions. Many Technical Specification ACTIONS require an inoperable component to be removed from service, such as: maintaining an isolation valve closed or tripping an inoperable instrument channel. To allow the performance of SRs to demonstrate the OPERABILITY of the equipment being returned to service, or to demonstrate the OPERABILITY of other equipment which otherwise could not be performed without returning the equipment to service, an exception to these Required Actions is necessary. LCO 3.0.5 is necessary to establish an allowance that, although informally utilized in restoration of inoperable equipment, is not formally recognized in the present Specifications. Without this allowance certain components could not be restored to OPERABLE status and a plant shutdown would ensue. Clearly, it is not the intent or desire that the Technical Specifications to preclude the return to service of a suspected OPERABLE component to confirm its OPERABILITY. This allowance is deemed to represent a more stable, safe operation than requiring a plant shutdown to complete the restoration and confirmatory testing. Since this requirement is informally utilized and has no licensing basis, this section is considered to provide new requirements consistent with the use and format of the ITS. This is a Ginna TS Category (iv.a) change.
- vi. TS 3.0.2 - This was deleted and replaced by LCO 3.0.6 which provides guidance regarding the appropriate ACTIONS to be taken when a single inoperability (e.g., a support system) also results in the inoperability of one or more related systems (e.g., supported system(s)). Since its function is to clarify existing ambiguities and to maintain actions within the realm of previous industry interpretations and NRC positions, this new provision does not provide any new requirements. The information contained in TS 3.0.2 was relocated to LCO 3.8.1 which allows one power source to a safeguards bus and a redundant safety features on a second bus to be inoperable for 12 hours versus 1 hour. This change is consistent with NUREG-1431. These are Ginna TS Category (v.c) and (i) changes, respectively.

- vii. A new section LCO 3.0.7 was added to provide guidance regarding Test Exceptions for LCO 3.1.8. This LCO allows specified Technical Specification requirements to be changed (i.e., made applicable in part or whole, or suspended) to permit the performance of special tests or operations which otherwise could not be performed. If this Test Exception LCO did not exist, many of the special tests and operations necessary to demonstrate select plant performance characteristics, special maintenance activities and special evolutions could not be performed. This Specification eliminates the confusion which would otherwise exist as to which LCOs apply during the performance of a special test or operation. Without this specific allowance to change the requirements of another LCO, a conflict of requirements could be incorrectly interpreted to exist. This section does not provide any new requirements. This LCO provides clarifying and descriptive information for the LCOs applicability consistent with the use and format of the ITS. This is a Ginna TS Category (v.c) change.
- viii. TS 3.0.1 - This was revised to remove the 1 hour allowance to prepare for a plant shutdown. Instead, the plant must now be in hot shutdown (i.e., MODE 3) within 6 hours of entering this LCO and cold shutdown (i.e., MODE 5) within 36 hours. No time limits are now placed on initiating the plant shutdown, only in the time frame in which the shutdown must be completed. Since the plant must now be in a lower mode in less amount of time, this is a more restrictive change. However, since no restrictions are made as to when the shutdown must commence, this is identified as a Ginna TS Category (v.c) change.

6. Technical Specification 3.1.1

- i. TS 3.1.1.1.b - This requirement was changed to require entry into MODE 1 \leq 8.5% RTP within six hours versus an immediate power reduction under administrative control. This change defines a specific number of hours to reach this condition which provides greater clarity to the operators. The remaining actions as specified by TS 3.1.1.1.b were relocated to LCO 3.4.5 and are discussed in 6.ii below. This is a Ginna TS Category (v.a) change.

- ii. TS 3.1.1.1.b, 3.1.1.1.c, and 3.1.1.1.d - These requirements were revised per new LCO 3.4.5 to require both reactor coolant loops OPERABLE with one loop in operation during MODES 1 \leq 8.5% RTP, and MODES 2 and 3, versus one in operation and the other OPERABLE for natural circulation between 350°F and 8.5% RTP. However, one RCS loop is now allowed to be inoperable for up to 72 hours provided that the shutdown margin as provided in the COLR is maintained and the non-operating RCS loop is OPERABLE (i.e., available for natural recirculation). These are all conservative changes (Ginna TS Category (iv.a) changes) since:
 - a. Two RCS loops are required to be OPERABLE.
 - b. A defined period of time is now specified for one RCS loop operation which addresses the concern raised by Reference 12. In addition, Completion Times are now specified for verifying shutdown margin and natural circulation capability.
- iii. TS 3.1.1.1.f - The exception for not requiring the RCS or RHR loops during steam generator crevice cleaning operations was not added to the new specifications since RG&E no longer performs this activity and the new SGs scheduled to be installed in 1996 do not have crevices subjected to cleaning as described in this specification. This is a conservative deletion and is a Ginna TS Category (v.a) change.
- iv. TS 3.1.1.1.g - The action to be in Cold Shutdown (i.e., < 200°F) within 24 hours was not added for the Condition with both RHR loops inoperable and only one RCS loop inoperable consistent with Condition B of LCO 3.4.6. Since RHR is the only system which provides long-term decay heat removal below 200°F, it is not prudent to bring the plant to a lower MODE until RHR is recovered. This is a Ginna TS Category (v.a) change.
- v. TS 3.1.1.1.k - This requirement was changed into a Note for LCO 3.4.6 and 3.4.7. This is a Ginna TS Category (v.c) change. The value for LTOP enable temperature with respect to the RCPs was also relocated to the PTLR. This is a Ginna TS Category (iii) change.

- vi. TS 3.1.1.1.f - This requirement was revised to require one RHR loop to be operating when in MODE 5 consistent with LCO 3.4.7 and 3.4.8. A RHR pump is required to be operating since a RCP cannot be routinely operated under these low temperature and pressure conditions. However, a SG with minimum water level of 16% can provide an alternate means of decay heat removal to the operating RHR loop in MODE 5 with the loops filled. In addition, a limit of 15 minutes (versus 1 hour) was placed on removing both RHR loops from service in MODE 5 with the loops not filled due to the reduced RCS inventory. These are conservative changes to the current requirements and are Ginna TS Category (v.a) changes.
- vii. TS 3.1.1.1.e - The note associated with the power sources for the RHR loops has been relocated to the specifications for electrical requirements during MODES 5 and 6 (i.e., LCOs 3.8.2, 3.8.5, 3.8.8, and 3.8.10). This is a Ginna TS Category (i) change.
- viii. TS 3.1.1.1.i and 3.1.1.1.j - These requirements were not added due to the expanded specifications provided in new TS 3.4.4, 3.4.5, 3.4.6, 3.4.7, and 3.4.8. The new specifications ensure that the appropriate RCS or RHR loop is available to provide forced flow for decay heat removal and boron mixing. Therefore, these requirements are no longer necessary. This is a Ginna TS Category (v.c) change.
- ix. TS 3.1.1.5.a - The lower limit for pressurizer water level (12%) was not added. This lower limit was related to the previous Safety Injection actuation logic which required a coincident low pressurizer level and low pressurizer pressure trip. This logic was modified as a result of IE Bulletin 79-06A (Ref. 45) to eliminate the coincident low pressurizer level trip (Ref. 46) such that the setpoint is no longer used in an UFSAR Chapter 15 accident analysis. Therefore, the low pressurizer water level setpoint is not required. This is a Ginna TS Category (v.b.3) change.
- x. TS 3.1.1.5.b - The current exception for not requiring the pressurizer heaters and water level setpoints during the RCS hydro test was not added to the new specifications. These hydro tests are performed with RCS temperatures below MODE 3 conditions (i.e., < 350°F). Since the new specification only requires the pressurizer to be OPERABLE in MODES 1, 2, and 3, this exception is no longer required. This is a Ginna TS Category (v.a) change.

- xi. TS 3.1.1.6 - The requirement for the reactor vessel head vents was not added to the new specifications since these vents do not meet the criteria specified in the NRC Policy Statement. This is due to the fact that the vents are used to exhaust noncondensable gases and steam from the RCS which could inhibit natural circulation following an accident with an extended loss of offsite power. However, these vents are not the primary success path and are only used by operators if both pressurizer PORVs are unavailable. These vents are not used in the safety analyses nor were identified as being risk significant in the Ginna Station Level 2 PRA (Ref. 47). This requirement will be relocated from TS to the TRM. The remaining requirements contained within this specification relate to the pressurizer PORVs and their associated block valves which are addressed in TS 3.1.1.4. These requirements were revised as discussed in Section D, items 6.xiii and 6.xiv below. This is a Ginna TS Category (iii) change.
- xii. TS 3.1.1.3.a and 3.1.1.3.b - These requirements were not added to the new specifications since the pressurizer safety valves do not provide overpressurization protection during Cold Shutdown and Refueling conditions. This is provided by the low temperature overpressure protection (LTOP) requirement as specified in current TS 3.15 and new LCO 3.4.12. Since the pressurizer safety valves do not perform a safety function during these low MODES of operation, these requirements were not retained. These changes also supersede those proposed in Reference 60. This is a Ginna TS Category (v.b.4) change.
- xiii. TS 3.1.1.4.a.i and 3.1.1.6 - These were revised to provide separate Required Actions for the PORVs based on the reason for their inoperability. A PORV which is inoperable for automatic functions but capable of manual actuation must be isolated by its block valve consistent with the current requirement. However, a PORV which is incapable of manual cycling is required to be isolated by its block valve within 1 hour and repaired within 72 hours or the plant must initiate a controlled shutdown. In addition, with both PORVs inoperable, a controlled shutdown to MODE 3 conditions with RCS < 500°F must be accomplished within 8 hours. This limit on operation with an inoperable PORV is provided since a SGTR event cannot be mitigated under this condition. The 72 hours for one inoperable PORV is allowed since the second PORV is available. These changes also supersede those proposed in Reference 60. This is a conservative revision and a Ginna TS Category (iv.a) change.

- xiv. TS 3.1.1.4.a.ii and 3.1.1.6 - This was revised to require that one inoperable block valve must be restored to OPERABLE status within 72 hours, both block valves within 7 days, or the plant must initiate a controlled shutdown. This limit on operation with an inoperable block valve is provided since a stuck open PORV cannot be isolated in this condition. The time limits provide adequate time to perform most repairs at power since the valves are located inside containment in the pressurizer cubicle. These changes also supersede those proposed in Reference 60. This is a conservative revision with respect to current requirements and a Ginna TS Category (iv.a) change.
- xv. TS 3.1.1.2 - This was not added since this temperature limit is not required for safe operation. All necessary heatup and cooldown rates are relocated to the PTLR while new LCO 3.4.1 provides limits on RCS pressure, temperature, and flow. This is a Ginna TS Category (v.b.5) change.
- xvi. TS 3.1.1.3.d - A Note was added which allows the pressurizer safety valves to be removed from service above 350°F for the purpose of setting the valves under hot (i.e., ambient) conditions consistent with NUREG-1431. This is a Ginna TS Category (v.c) change.
- xvii. TS 3.1.1.3.c - This was revised to change the pressurizer safety valve lift settings from 2485 psig $\pm 1\%$ to 2485 psig $\pm 2.4\%$, -3% . The valve lift settings are required to be set to within $\pm 1\%$ following testing; however the OPERABILITY tolerances have been revised. The increased OPERABILITY tolerances have been evaluated in the most limiting pressure transients for Ginna Station (i.e., loss of external load and locked rotor events) and found to result in acceptable results with respect to the safety limit values. This change is a result of an event in which the pressurizer safety valves were found to have drifted outside the existing $\pm 1\%$ tolerance band following testing (Ref. 58). The proposed change is within the ASME tolerances of $\pm 1\%$ following testing and $\pm 3\%$ for OPERABILITY. This is a Ginna TS Category (v.b.45) change.

7. Technical Specification 3.1.2

- i. TS 3.1.2.1.a, Figure 3.1-1, and Figure 3.1-2 - The RCS temperature and pressure curves and the RCS heatup and cooldown curves and limits were relocated from technical specifications to the PTLR which is addressed under Administrative Controls. This is a Ginna TS Category (iii) change.

- ii. TS 3.1.2.1.b - The requirement for periodically recalculating the RCS temperature and pressure curves and the RCS heatup and cooldown curves and limits was deleted from technical specifications. A periodic review is already required by 10 CFR 50, Appendix H which does not need to be restated within the technical specifications. This is a Ginna TS Category (ii) change.
- iii. TS 3.1.2.1.c.1 - The time allowed to perform an engineering analysis to determine that the RCS is acceptable to continue operation after a pressure and/or temperature limit is exceeded was increased from 6 hours to 72 hours. A duration of 6 hours is not sufficient time to accomplish the required engineering analysis, especially if the event were to occur during evening or early morning hours with limited staff support immediately available. Since NRC accepted guidance for performing the necessary calculations exists, allowing 72 hours to complete the analyses is appropriate, especially since the duration of event is very limited (i.e., controlled by LCO 3.4.3). This is a Ginna TS Category (v.b.6) change.
- iv. TS 3.1.2.2 - This was not added since this temperature limit is not required for safe operation. All necessary heatup and cooldown rates are relocated to the PTLR while new LCO 3.4.1 provides limits on RCS pressure, temperature, and flow. This is a Ginna TS Category (v.b.5) change.
- v. TS 3.1.2.3 - This was revised to relocate the pressurizer heatup and cooldown rates to the PTLR. The maximum temperature difference between the pressurizer and spray fluid was not added since this limit is controlled by the cooldown curves. These are Ginna TS Category (iii) and (v.c) changes respectively.

8. Technical Specification 3.1.3

- i. TS 3.1.3.1 - This was revised to raise the minimum temperature for criticality from 500°F to 540°F. This change was made to correct a discrepancy between the definition of reactor operating modes and this requirement. Currently, Ginna Station TS 1.2 defines Hot Shutdown as Reactivity $\leq -1 \Delta k/k\%$ and $T_{avg} \geq 540^\circ F$. In order to achieve criticality at 500°F, the Hot Shutdown condition would have to be directly bypassed. A value of 540°F was selected for the new minimum temperature for criticality based on previous operating experience during startup conditions. This is a Ginna TS Category (v.a) change.

- ii. TS 3.1.3.2 - This was not added since LCO 3.4.2 specifies the minimum temperature for criticality. The minimum temperature with respect to the reactor vessel is contained in the PTLR and is below the limit specified in LCO 3.4.2. This is a Ginna TS Category (v.c) change.
- iii. TS 3.1.3.3 - The existing action statement was revised to require that the plant be in MODE 2 with $k_{\text{off}} < 1.0$ within 30 minutes if T_{avg} for one or both RCS loops was $< 540^{\circ}\text{F}$ versus subcritical by an amount equal to or greater than the potential reactivity due to depressurization. The new requirement provides clear and precise instructions to operations and ensures that the plant is quickly brought to a condition in which the LCO is no longer applicable. This is a Ginna TS Category (v.c) change.
- iv. TS 3.1.3.1 - The MTC requirements are moved from the RCS chapter in the Ginna Station TS to the Reactivity Control Systems Chapter. This is a Ginna TS Category (i) change.
- v. TS 3.1.3.1 - This was revised to reference cycle specific MTC requirements in the COLR. This change is consistent with NUREG-1431 and provides flexibility during reload core design. The MTC maximum upper limit described in TS 3.1.3.1 remains the same in ITS LCO 3.1.4. This is a Ginna TS Category (iii) change.

9. Technical Specification 3.1.4

- i. TS 3.1.4.4 - This specification was revised to only require shutdown to MODE 3 with $T_{\text{avg}} < 500^{\circ}\text{F}$ within 8 hours versus Cold Shutdown within 40 hours consistent with the LCO Applicability. This is a Ginna TS Category (v.c) change.
- ii. TS 3.1.4.1.c - The limit on secondary coolant activity is now required to be met in MODES 1, 2, 3, and 4 and not just when the reactor is critical or RCS temperature is $> 500^{\circ}\text{F}$. The secondary coolant activity limit is based on a steam line break and the resulting dose consequences. A RCS temperature of $> 500^{\circ}\text{F}$ is based on preventing the MSSVs from lifting following a SGTR (i.e., a RCS temperature of $> 500^{\circ}\text{F}$ is only applicable to primary system activity limits not secondary limits). In addition, if the secondary coolant activity limits are not met, TS 3.1.4.4 requires entering cold shutdown (i.e., MODE 5) within 40 hours. Requiring the secondary coolant activity limits to be met for all of MODE 4 (i.e., RCS is $> 200^{\circ}\text{F}$) provides consistency with NUREG-1431 and the current Required Actions if the limit is exceeded. This is a Ginna TS Category (iv.a) change.

- iii. The time to perform a shutdown if secondary activity is not within limits was changed from 8 hours to 6 hours to reach hot shutdown and 32 hours to 30 hours to reach cold shutdown. These completion times are conservative and provide consistency with the rest of the TS. This is a Ginna TS category (v.a) change.

10. Technical Specification 3.1.5

- i. TS 3.1.5.1.1 - Added a new requirement for the containment sump "A" level or pump actuation per LCO 3.4.15. This leakage detection system replaces the containment humidity detectors and the air cooler condensate flow monitor. The containment humidity detectors do not meet the required leakage rate detection capability of 1.0 gpm within 4 hours as required by Generic Letter 84-04 (Ref. 19). In addition, the containment humidity detectors are recommended by RG 1.45 (Ref. 17) to only be used as an alarm or indirect indication of leakage to containment and not as a separate method of detecting leakage. The remaining leakage detection systems provide adequate monitoring as discussed in the new bases and Section C, item 46. These are Ginna TS Category (v.a) changes.
- ii. TS 3.1.5.1.1 and 3.1.5.1.2 - The RCS leakage detection systems are required to be OPERABLE and RCS LEAKAGE within limits above MODE 4 (200°F) and not 350°F per LCO 3.4.15 and 3.4.13. The increased LCO Applicability will address all MODES in which the RCS is at an increased temperature and pressure. This is a Ginna TS Category (iv.a) change.
- iii. TS 3.1.5.1' - Added a note which allows a change in MODE if either the containment sump monitor or both the containment atmospheric radioactivity monitors are inoperable per LCO 3.4.15. This note is appropriate considering the other instrumentation that is available to monitor RCS leakage. This is a Ginna TS Category (v.b.7) change.

11. Technical Specification 3.1.6

- i. TS 3.1.6 - This entire section was not added since RCS Chemistry does not meet the NRC Policy Statement. RCS Chemistry is controlled by plant procedures and is not required to be addressed within the technical specifications. This requirement is being relocated to the TRM. This is a Ginna TS Category (iii) change.

12. Technical Specification 3.2

- i. TS 3.2.5 - The requirement was revised to require placing a charging pump in pull-stop within 1 hour regardless of the status of the RHR pumps or the MODE. This is a conservative change which provides direct operator guidance to perform an action within a defined time period. Also, these requirements were relocated to the LTOP specification to consolidate all related requirements. The verification of the charging pump status every 12 hours was also not added since the plant is required to be in a depressurized and vented condition within 8 hours which removes the need to isolate a charging pump (i.e., a 1.1 square inch vent can mitigate a charging/letdown mismatch event). These are Ginna TS Category (v.a), (i), and (v.c) changes, respectively.

- ii. TS 3.2.1 and TS 3.2.1.1 - The requirements for the boric acid injection flow paths during cold shutdown and refueling which specifies the number of flow paths that must be OPERABLE were not added. The boration subsystem is not assumed to be OPERABLE to mitigate the consequences of a DBA or Transient. Further, the boration system is a non-significant risk contributor to core damage frequency and offsite releases. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement Technical Specification screening criteria and are relocated to the TRM. This is a Ginna TS Category (iii) change.

- iii. TS 3.2.2 and TS 3.2.4 - The requirements for the boric acid injection flow paths above cold shutdown which specifies the number of flow paths that must be OPERABLE, were not added. The boration subsystem is not assumed to be OPERABLE to mitigate the consequences of a DBA or Transient. Further, the boration system is a non-significant risk contributor to core damage frequency and offsite releases. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement Technical Specification screening criteria and are relocated to the TRM. This is a Ginna TS Category (iii) change.

- iv. TS 3.2.3 and Table 3.2-1 - The requirements for the Boric Acid Storage Tank(s) which specifies the boron concentrations, minimum volume and solution temperature, were not added. The boration subsystem is not assumed to be OPERABLE to mitigate the consequences of a DBA or Transient. Further, the boration system is a non-significant risk contributor to core damage frequency and offsite releases. Therefore, the requirements specified for this system do not satisfy the NRC Final Policy Statement Technical Specification screening criteria and are relocated to the TRM. This is a Ginna TS Category (iii) change.

13. Technical Specification 3.3

- i. TS 3.3.1.1.b and 3.3.1.3 - LCO 3.5.1 Condition A was added which allows 72 hours to restore accumulator boron concentration to within acceptable limits. The ITS bases state that allowing a longer period of time to correct boron concentration is acceptable since the volume of water in the accumulators is the critical feature. Attempting to correct boron concentration within the current 1 hour limit would create a significant burden on the operations staff. Therefore, the current 1 hour LCO was only maintained for accumulator pressure and volume. In addition, the accumulator boron concentration limit was increased to 2100 ppm to support the value used in the accident analysis for the 18 month refueling cycles. An upper limit of 2600 ppm was also added to address chemical considerations of the sump fluid following an accident. This value is also consistent with that used for 18 month refueling cycles. These are Ginna TS Category (v.b.9) and (v.a) changes, respectively.
- ii. TS 3.3.1.1.a and 3.3.1.2 - LCO 3.5.4.A was added which allows 8 hours to restore the RWST boron concentration to within acceptable limits. The ITS bases state that allowing a longer period of time to correct boron concentration is acceptable since it requires a longer period of time to perform this type of adjustment due to the large volume of water contained within the RWST. In addition, the RWST boron concentration limit was increased to 2300 ppm to support the value used in the accident analysis for the 18 month refueling cycles. An upper limit of ≤ 2600 ppm was also added to address chemical considerations of the sump fluid following an accident. This value is also consistent with that used for 18 month refueling cycles. These are Ginna TS Category (v.b.10) and (v.a) changes, respectively.

- iii. TS 3.3.1.1.c - Two notes associated with LCO 3.5.2 were added. The first note allows both SI pump flow paths to be isolated for up to 2 hours to perform pressure isolation valve testing. The ITS bases state that this is acceptable since the isolation valves can be opened from the control room. The second note allows up to 4 hours, or until the RCS cold legs exceed 375°F, to place into service ECCS pumps declared inoperable due to LTOP considerations. This note was added since the LTOP setpoint of 330°F is very close to the Mode 3 definition of $\geq 350^\circ\text{F}$. As described in the ITS bases, this note provides operator flexibility to restore the inoperable pump to OPERABLE status. These are Ginna TS Category (v.b.11) changes.
- iv. TS 3.3.1.5.d - This was revised and used as a note for LCO 3.5.2. The specification now only allows 878B and 878D to have power installed during MODE 3 for the specific purpose of performing pressure isolation valve testing. Isolation valves 878A, 878C, 896A, 896B and 856 must now have DC power removed above MODE 3 or both trains of ECCS will be declared inoperable. This change was made since there is no regularly scheduled testing of 878A, 878C, 896A, 896B, and 856 above 350°F. This is a Ginna TS Category (v.a) change.
- v. LCO 3.5.3 was added which requires one train of SI and RHR during MODE 4. This new requirement is being added to address low probability accidents which may occur during this mode of operation. This is a Ginna TS Category (iv.a) change.
- vi. TS 3.3.1.1.b - The current exception for not requiring the accumulators during hydro tests was not added to the new technical specifications. These hydro tests are performed with RCS temperatures below MODE 3 conditions (i.e., $< 350^\circ\text{F}$). Since the new specification only requires the accumulators when RCS pressure is > 1600 psig during MODE 3, this exception is no longer required. This is a Ginna TS Category (vi) change.
- vii. TS 3.3.1.1.b - The bases for TS 3.3 were revised to update the specified water volume contained in the accumulator with respect to the 50% and 82% levels. The required levels specified in TS 3.3.1.1.b have not been changed, only the corresponding water volumes provided in the bases. The new values are consistent with those used in the accident analysis (see COLR, Table 1). This is a Ginna TS Category (v.c) change.

- viii. TS 3.3.1.1.g - Motor operated isolation valves 851A and 851B were added to new SR 3.5.2.1 since these valves must remain open with AC power removed to ensure the availability of Containment Sump B to the RHR system following a LOCA. The addition of these valves is a conservative change. This is a Ginna TS Category (v.a) change.
- ix. TS 3.3.1.1.h - Check valves 877A, 877B, 878F, 878H, and motor operated isolation valves 878A and 878C were added to this requirement since the valves are required to be tested as PIVs by current Ginna Station TS 4.3.3.3. This provides a more complete specification and is a Ginna TS Category (v.a) change. The listing of valves was also relocated to the bases. This is a Ginna TS Category (iii) change.
- x. TS 3.3.1.1.h and 3.3.1.5 - These requirements were revised to require PIVs to be OPERABLE in MODES 1, 2, 3, and 4 and not just above 350°F (i.e., in MODE 3 and above). Therefore, the plant must now enter MODE 5 within 36 hours if the Required Actions cannot be accomplished. This is a conservative revision which expands the LCO Applicability. This is a Ginna TS Category (iv.a) change.
- xi. TS 3.3.1.5.e - The current requirement allows 12 hours to repair a leaking check valve if the in-series motor operated isolation valve is closed. This was revised to specify that a leaking PIV (check valve or motor operated) must be isolated within 4 hours with a leak tested valve, and that a second leak tested valve must be closed within 72 hours. This is generally a conservative change since a time limit is now specified for isolating the leaking valve and the second isolation valve must now be leak tested. The only exception is that 72 hours is now provided to perform repairs versus 12 hours. The existing allowed repair time is insufficient to perform most leakage repairs and would most likely require a reactor shutdown. Since there are three isolation valves for several flow paths, and the LCO applicability has been expanded to include MODE 4, this change is considered acceptable. This is a Ginna TS Category (v.a) change.
- xii. TS 3.3.1.7 and 3.3.1.8 - The exception for allowing the SI pumps to be OPERABLE during DG load and safeguard sequence testing was not added since the new bases allow the pumps to be OPERABLE if a discharge isolation valve is locked closed. Therefore, this exception is not required. Also, these requirements were relocated to the LTOP specification to consolidate all related requirements. These are Ginna TS Category (v.c) and (i) changes, respectively.

- xiii. TS 3.3.1.7.1 and 3.3.1.8.1 - These specifications were converted into Surveillance Requirements consistent with the ITS format and relocated to the LTOP specification to consolidate all related requirements. This is a Ginna TS Category (i) change.
- xiv. TS 3.3.1.8.2 - This requirement was not added since the new bases list the criteria for ensuring that a SI pump is incapable of injecting into the RCS. Limiting the operation to one SI pump when the PORVs provide the RCS vent path is not necessary if the isolation device requires two separate actions before providing an injection path to the RCS. Therefore, operating multiple SI pumps will not pose any threat to overpressurizing the RCS with this isolation. This is a Ginna TS Category (v.c) change.
- xv. TS 3.3.2.2 - This was revised to allow both post-accident charcoal filter trains (including the CRFC units which supply them) to be inoperable for up to 72 hours if both containment spray (CS) trains are OPERABLE. This change provides consistency with the accident analyses which demonstrate that either two CS trains, one CS train and one post-accident charcoal filter train, or two post-accident charcoal filter trains are adequate to remove radioactive iodine from the containment atmosphere following a DBA (i.e., each CS train and post-accident charcoal filter train provides 50% of the required iodine removal requirements). However, two CS trains cannot be inoperable since at least one train must operate for containment pressure and temperature control. In addition, two CRFC units can now be removed from service for up to 7 days since the accident analyses only credit two of the four cooling units as being OPERABLE with respect to containment pressure and temperature control. Finally, with one or two CRFC units inoperable and not restored within 7 days, the plant has only 36 hours to reach MODE 5 versus 84 hours due to the importance of maintaining containment pressure and temperature control. These are Ginna TS Category (v.b.12) changes.
- xvi. TS 3.3.3.1 - This was revised to specify that the CCW loop header must also be OPERABLE. The loop header is defined as the section of piping from the discharge of the heat exchangers to the first isolation valve of each supplied component. The loop header then continues from the last isolation valve on the discharge of the supplied component to the suction of the pumps. This is a Ginna TS Category (v.a) change.

- xvii. TS 3.3.3.1 - This was revised to allow one CCW heat exchanger to be removed from service for up to 31 days. As discussed in Section C, item 82.i above, the CCW heat exchangers are 100% redundant and are separated from the CCW pump trains by a section of common piping. Since there is no signal active failure which could fail the redundant heat exchanger, 31 days is considered acceptable. Also, there is only one loop header such that a passive failure of the loop header, or the remaining OPERABLE heat exchanger, has the same consequences. This is a Ginna TS Category (v.b.13) change.
- xvii. TS 3.3.3.2 - This was revised to allow 72 hours (versus 24 hours) to restore an inoperable CCW pump before requiring a plant shutdown. However, the plant is no longer allowed to remain at Hot Shutdown for 48 hours before requiring additional cooldown to Cold Shutdown conditions. As such, the total time in which a CCW pump can remain inoperable remains the same (i.e., 72 hours) but the plant is not required to begin cooldown activities after 24 hours. The only safety related functions supported by the CCW System are with respect to the RHR, SI, and CS Systems, which all allow 72 hours to restore an inoperable train. Therefore, this change provides consistency within the new specifications. This is a Ginna TS Category (v.c) change.
- xviii. TS 3.3.4.1 - This was revised to require that the six sets of motor operated isolation valves used in the SW System to be OPERABLE for the SW System to be considered OPERABLE. Credit is taken for these valves to isolate the nonessential and nonsafety related components within the SW System following a coincident safety injection and undervoltage signal. This is a conservative change which provides a clarification to licensed personnel. This is a Ginna TS Category (v.a) change.

xix. TS 3.3.4.2 - This was revised to allow one SW train comprised of two pumps and six motor operated valves supplied by the same electrical train to be inoperable for 72 hours before requiring a plant shutdown. Since the SW trains are 100% redundant, removing one of two trains only affects redundancy and does not place the plant outside the accident analyses. Since most other safety functions allow 72 hours for one train to be inoperable (e.g., ECCS trains), this change provides consistency within the new specifications. In addition, this specification was revised to address the scenario if all SW pumps or the SW loop header are inoperable. In this condition, immediate action must be initiated to restore one SW pump or the loop header to OPERABLE status; however, it may not be prudent to exit the MODE of Applicability since the SW System is required in MODE 5 for decay heat removal. Instead, Required Actions have been provided to require a cooldown to MODE 5 unless the CCW system is incapable of supporting RHR. In MODE 4, AFW is providing for decay heat removal. If AFW were lost, additional time is required before RHR (and consequently SW) would be required. These are Ginna TS Category (v.b.47) changes.

xx. TS 3.3.5.1 - This was revised to require the control room emergency air treatment system (CREATS) to be OPERABLE in MODES 1 through 6 and during movement of irradiated fuel assemblies instead of only when RCS is $\geq 350^{\circ}\text{F}$. Current Ginna Station TS 3.5.6 requires that the control room HVAC detection system (i.e., chlorine, ammonia, and radioactivity monitors) be OPERABLE at all times. However, the filtration system is only required to be OPERABLE above 350°F . The filtration system is designed to ensure that dose rates to operators are within the guidelines of GDC 19 in the event of an accident. While dose rates to operators is expected to be lower when the RCS is $< 350^{\circ}\text{F}$, no current analyses exist under these conditions. In addition, failures of the waste gas decay tanks can still occur below 350°F which also require control room isolation. Therefore, the MODE of Applicability was revised to provide consistency within the specifications and the accident analyses. This is a Ginna TS Category (iv.a) change.

- xxi. TS 3.3.5.2 - This was revised to provide requirements for an inoperable filtration train and inoperable dampers. The CREATS dampers isolate the control room in the event of a radiological event while the filtration train filters the control room atmosphere following isolation. The new specification continues to allow the filtration train to be inoperable for 48 hours before requiring a shutdown or placing the control room in the emergency radiation mode (i.e., CREATS Mode 6). If one of the two redundant dampers in each outside air flow path is inoperable, the new specifications allow 7 days to restore the damper to OPERABLE status similar to restoring one train of redundant CREFS in NUREG-1431. If both dampers are inoperable, the plant must enter LCO 3.0.3 since the control room can no longer be isolated. If both dampers are lost in MODES 5 or 6, or during fuel movement, then fuel movement and CORE ALTERATIONS must be suspended immediately. These changes provide consistency with the accident analyses and NUREG-1431. These are Ginna TS Category (v.a) changes.

14. Technical Specification 3.4

- i. TS 3.4.1 - This was revised to specifically require that all MSSVs be tested prior to entering MODE 2 versus the current wording which allows the MSSVs to be removed for testing at any time. This change is consistent with current operating practices and ensures that the MSSVs are OPERABLE before the reactor goes critical but allows the MSSVs to be tested under hot conditions (i.e., $\geq 350^{\circ}\text{F}$). In addition, the MSSV setpoints were added to the new specification since these are assumptions within the accident analyses. These are Ginna TS Category (v.a) changes.

- ii. TS 3.4.2.1.b - This was revised to be consistent with the accident analysis assumptions as discussed in the new bases. Essentially, the accident analyses treat the preferred AFW System as four trains (i.e., two motor driven trains and two turbine driven trains) such that each SG receives flow from two AFW trains. Therefore, the failure of both motor driven trains or the turbine driven train (or both flowpaths) has the same consequence (i.e., loss of one train to each SG). Since the turbine driven train is allowed to be inoperable for up to 72 hours per TS 3.4.2.2.a (and NUREG-1431), this specification was revised to allow both motor driven AFW pumps to be inoperable for up to 72 hours. In addition, if both AFW trains to a common SG are inoperable, the new specifications allow 4 hours to restore at least one train before requiring a controlled cooldown. A time limit for being in this configuration is necessary since no AFW would be available in the event of a HELB which affects the only SG able to receive AFW. Requiring an immediate cooldown in this configuration is not considered prudent since AFW provides for decay heat removal in lower MODES. These are Ginna TS Category (v.b.14) and (v.a) changes, respectively.
- iii. TS 3.4.2.3 - This was revised to require that the SAFW cross-tie be available when the SAFW System is required to be OPERABLE. This change is required since the accident analyses credit the use of the cross-tie for HELBs with a failure of one SAFW pump. Each cross-tie motor operated valve is considered part of the SAFW train which shares the same electrical power source. This is a Ginna Station TS Category (v.a) change.
- iv. TS 3.4.3 - The requirement for SW suction for the AFW and SAFW pumps were relocated to the LCO for these pumps. The CSTs provide the preferred source of condensate to the preferred AFW pumps while the SW System is the safety related source for both the preferred and standby AFW systems. The relocation of the need for a SW supply to the AFW pumps within technical specifications does not reduce the requirement. Instead, the change provides consistency within the new specifications and is easier for licensed personnel to understand. This is a Ginna TS Category (i) change.

- v. TS 3.4.3 - This was revised to require that a backup source of condensate be verified within 4 hours when the CSTs are inoperable versus demonstrating the operability of the SW System. Specifying a time limit for verifying the backup condensate source is a conservative change which now provides a clear and concise requirement for plant operators. Revising the Actions to allow any alternate source to be used as a backup source provides additional operational flexibility since other condensate sources than the SW System can be used if necessary. These sources are described in the bases for new LCO 3.7.6. These changes are consistent with NUREG-1431 and are Ginna TS Category (v.a) changes.

15. Technical Specification 3.5

- i. The following changes were made to TS 3.5.1 or Table 3.5-1:
 - a. Table 3.5-1, Columns 1, 2, and 3 - The columns for the "Total Number of Channels," the "Number of Channels to Trip," and the "Minimum Operable Channels" were not added for each of the functional units. The columns were replaced with a new column denoting "Required Channels." System design and operational details are not directly related to the OPERABILITY of the instrumentation and were relocated to the bases or are adequately described in the UFSAR. This is a Ginna TS Category (iii) change.
 - b. Table 3.5-1, Column 6 - The column for the "channel operable above" was revised consistent with the changes to the Mode table definitions in ITS Chapter 1.0. Changes to the Applicability different from those discussed in Chapter 1.0 are discussed with the specific changes to the Functional Units. This is a Ginna TS Category (vi) change.
 - c. Table 3.5-1, Functional Unit #15 - The trip Function was not added to the new specifications. Removal of this trip function is justified in Reference 44 which shows that based on the offsite power system configuration, this trip Function is not applicable to Ginna Station. Therefore, this trip Function was relocated to the TRM. This is a Ginna TS Category (iii) change.

- d. Table 3.5-1, Action Statement #1 for Functional Unit #1 - This action was revised to add requirements for operability of the Manual Reactor Trip function in Modes 3, 4, and 5 when the rods are not fully inserted and the rod control system is capable of rod withdrawal (LCO 3.3.1, Condition C). These actions ensures the plant is placed in a condition in which the trip function is no longer required for the associated modes of operation. This is a Ginna TS Category (vi) change.
- e. Table 3.5-1, Functional Unit #11 - This was revised to add the requirements for Turbine Trip on Turbine Stop Valve Closure since this was not in the CTS. The required actions with inoperable channels are the same as that for the Turbine Trip on Low Autostop Oil Pressure. This is a Ginna TS Category (iv.a) change.
- f. Table 3.5-1, Action Statement #2 for Functional Units #2 ("low setting" and "high setting"), #5, #6, and #7 - This action was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 1 hour). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- g. Table 3.5-1, Action Statement #2 for Functional Units #2 ("low setting" and "high setting"), #5, #6, and #7 - This action was revised to allow an inoperable channel to be bypassed for up to 4 hours (rather than 2 hours) during surveillance testing. This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- h. Table 3.5-1, Column 4 - This requirement was revised to associate the permissive (or bypass) details with the specific permissive (or interlock) numbers and to clarify the applicability of the Function with an associated Mode (see ITS Table 3.3.1-1, FU #16). The details of the permissible bypass conditions for the associated Functions are discussed in the UFSAR and ITS Bases. Changes to the Applicability of a Functional Unit different from those discussed in Column 4 are discussed with the specific changes to the Functional Units. This is a Ginna TS Category (v.c) change.

- i. Table 3.5-1, Channel Operable above column for Functional Units 7, 10, 14 and 15. This was revised to change the MODE of Applicability to 8.5% RTP versus 5% RTP. The permissive which enables these functions to be OPERABLE is set at 8.5% RTP per CTS 2.3.2.1. Therefore, this change provides consistency within the CTS. This is a Ginna TS Category (v.a) change.
- j. Table 3.5-1, Action Statement #3 and #4 for Functional Units #2, #3, and #4 - These actions were revised to clarify the applicability of the intermediate range neutron flux and source range neutron flux to correspond to the specific permissives. The NIS intermediate range neutron flux channels must be OPERABLE when the power level is above the capability of the source range and below the capability of the power range. The associated Required Actions ensure the plant is no longer in the applicable condition through controlled power adjustments and taking into account the low probability of an event during the period that may require the protection of the NIS trip. This change supersedes that proposed in Reference 61. This is a Ginna TS Category (v.a) change.
- k. Table 3.5-1, Action Statement #4 for Functional Unit #4 - This action was revised to clarify the Applicability and add associated Required Actions for inoperable SRMs. For Mode 2 below the permissive and only one SRM OPERABLE, positive reactivity additions must stop immediately and the inoperable channel restored in 48 hours consistent with current TS. However, with two SRMs inoperable the plant would be required to immediately open the RTBs. For Modes 3, 4, and 5, with the CRD incapable of rod withdrawal or all rods not fully inserted, an additional action was added that requires the performance of a SDM verification. These clarifications and additional restriction ensure the plant is no longer in the applicable condition or is in a more stable condition. This is a Ginna TS Category (iv.a) change.

- l. Table 3.5-1, Action Statement #5 for Functional Units #8, #9, #10 ("low flow in one loop"), #11 and #13 - This action was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 1 hour). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- m. Table 3.5-1, Action Statement #5 for Functional Units #8, #9, #10 ("low flow in one loop"), #11 and #13 - This action was revised to replace the current limitation of operation (tied to the next channel functional test of an OPERABLE channel) to allow the bypassing of an inoperable channel for up to 4 hours in order to perform surveillance testing of other channels. The current requirement limits the ability to perform channel functional tests on OPERABLE channels for Functional Units with two-out-of-three logic. Providing a note to bypass the inoperable channel provides a sufficient timeframe to perform the required surveillance testing in a safe and orderly manner. This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- n. Table 3.5-1, Action Statement #6 for Functional Units #10 ("low flow in both loops"), #14 and #15 - This action was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 1 hour). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- o. Table 3.5-1, Action Statement #6 for Functional Units #10 ("low flow in both loops"), and #14 - This action was revised to replace the current limitation of operation (tied to the next channel functional test of an OPERABLE channel) to allow the bypassing of an inoperable channel for up to 4 hours in order to perform surveillance testing of other channels. The current requirement limits the ability to perform channel functional tests on OPERABLE channels for Functional Units with two-out-of-three logic. Providing a note to bypass the inoperable channel provides a sufficient timeframe to perform the required surveillance testing in a safe and orderly manner. This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.

- p. Table 3.5-1, Functional Unit #16 - This was revised to relocate the QPTR Monitor OPERABILITY requirements to Chapter 3.2. In addition, requirements were added to verify with a calculation that the QPTR is within limits every 24 hours when the Quadrant Power Tilt Monitor is inoperable and THERMAL POWER is $< 75\%$ RTP and to verify with a full core flux map that the core power distribution is acceptable every 24 hours when the Quadrant Power Tilt Monitor is inoperable and THERMAL POWER is $\geq 75\%$ RTP. These are Ginna TS Category (i) and (iv.a) changes, respectively.
- q. Table 3.5-1, Functional Unit #17 - The trip function requirement for the Circulation Water Flood Protection was not added. The Circulation Water Flood Protection instruments only provide an anticipatory turbine trip and is not assumed in the Ginna Station safety analysis. These instruments do not monitor parameters which are initial assumptions for a DBA or transient, do not identify a significant abnormal degradation of the reactor coolant pressure boundary, and do not provide any mitigation of a design basis event. Therefore, the requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This is a Ginna TS Category (iii) change.
- r. Table 3.5-1, Functional Units #18 and #19 - The Functional Unit applicability was revised to require the instruments to be applicable in all modes associated with DG operability. This ensures that the DG can perform its function on a loss of voltage or degraded voltage to the 480 V buses. This is a Ginna TS Category (iv.a) change.
- s. Table 3.5-1, Action Statement #7 for Functional Units #18 and #19 - This action was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 1 hour). This Completion Time is sufficient to allow restoration of the channel and takes into account the redundancy of the trip channels, and the low probability of an event requiring a LOP start occurring during this interval. This is a Ginna TS Category (v.b.16) change.

- t. Table 3.5-1, Action Statement #7 for Functional Units #18 and #19 - This action was revised to replace the current limitation of operation (tied to the next channel functional test of an OPERABLE channel) to allow the bypassing of an inoperable channel (consistent with LCO 3.0.5) in order to perform surveillance testing of other channels. The current requirement limits the ability to perform channel functional tests on OPERABLE channels for Functional Units with the associated logic. Bypassing the inoperable channel provides a sufficient timeframe to perform the required surveillance testing in a safe and orderly manner. Additionally, a note was added clarifying that entry into the associated Conditions and Required Actions can be delayed for up to 4 hours for performance of required surveillance. Entering DG actions during testing is not necessary since the Completion Times for an inoperable DG is much greater than the time to perform the SR (72 hours vs 6 hours). The SR Note time of 4 hours takes into account the redundancy of the trip channels and the low probability of an event requiring a LOP start occurring during this interval. This is a Ginna TS Category (v.b.17) change.
- u. Table 3.5-1, Action Statement #7 for Functional Units #18 and #19 - This action was revised to replace the current shutdown actions with a requirement to restore channels to an OPERABLE status or to enter the applicable conditions for an inoperable DG. The actions of new LCO 3.8.1 and LCO 3.8.2 provide for adequate compensatory actions to assure plant safety. The loss of the minimum required loss of voltage or degraded voltage channels (one bus) should result in actions that are no more restrictive than actions for the loss of one DG. This is a Ginna TS Category (iv.b.1) change.
- v. Table 3.5-1, Functional Unit #18 and #19 - The number of channels was reformatted to require only two undervoltage channels per bus versus two channels of the loss of voltage function and two degraded voltage function per bus. The bus undervoltage design is a one-out-of-two taken twice logic such that one degraded voltage channel and one loss of voltage channel comprise each of the two undervoltage channels. However, due to the system design, if either of the degraded voltage or loss of voltage functions is inoperable, the entire undervoltage channel must be tripped (i.e., both the degraded voltage and loss of voltage functions are tripped). This change provides greater clarity to the operators without any reduction in the system requirements. This is a Ginna TS Category (v.b.18) change.

- w. LCO 3.3.1, Table 3.3.1-1, Function #10 was added for the RCP Breaker Position. This function anticipates the Reactor Coolant Flow - Low trips by monitoring each RCP breaker position to avoid RCS heatup that would occur before the low flow trip actuates. The function ensures that protection is provided against violating the DNBR limit due to loss of flow in either a single loop or two loop configuration. This is a Ginna TS Category (iv.a) change.
- x. LCO 3.3.1, Table 3.3.1-1, Function #14 was added for the SI Input from ESFAS. This function ensures that if a reactor trip has not already been generated by the RTS, the ESFAS automatic actuation logic will initiate a reactor trip upon any signal that initiates SI. This is a condition of acceptability for the LOCA. A reactor trip is initiated every time an SI signal is present. This is a Ginna TS Category (v.a) change.
- y. Table 3.5-1, Functional Unit #20 and associated Action Statement #14 - This requirement was reformatted to separately denote the Reactor Trip Breakers, the Reactor Trip Breaker Undervoltage and Shunt Trip Mechanisms, and the Automatic Trip Logic functions (LCO 3.3.1, Table 3.3.1-1, Functions #15, #16, and #17). This is a Ginna TS Category (vi) change.
- z. Table 3.5-1, Action Statement #14 for Functional Unit #20 (Automatic Trip Logic) - This action was revised to allow 6 hours to restore the channel to OPERABLE status in Modes 1 and 2 prior to initiating a plant shut down to Mode 3 (new LCO 3.3.1, Condition R). The restoration time of 6 hours is reasonable considering that the remaining OPERABLE channel is adequate to perform the safety function and given the low probability of an event during this interval. This is a Ginna TS Category (v.b.18) change.
- aa. Table 3.5-1, Action Statement #14 for Functional Unit #20 (Reactor Trip Breaker) - This action was revised to allow 1 hour to restore the RTB to OPERABLE status in Modes 1 and 2 prior to initiating a plant shut down to Mode 3 (new LCO 3.3.1, Condition T). The restoration time of 1 hour is reasonable considering that the remaining OPERABLE RTB is adequate to perform the safety function and given the low probability of an event during this interval. This is a Ginna TS Category (v.b.19) change.

- bb. Table 3.5-1, Action Statement #14 for Functional Unit #20 (Automatic Trip Logic) - This action was revised to allow 48 hours to restore the channel to OPERABLE status in Modes 3, 4, and 5 prior to initiating action to open the RTBs (new LCO 3.3.1, Condition W). The restoration time of 48 hours is reasonable considering that the remaining OPERABLE channel is adequate to perform the safety function and given the low probability of an event during this interval. This is a Ginna TS Category (v.b.20) change.
- cc. Table 3.5-1, Action Statement #14 for Functional Unit #20 (Reactor Trip Breaker) - This action was revised to allow 48 hours to restore the breaker to OPERABLE status in Modes 3, 4, and 5 prior to initiating action to open the RTBs (new LCO 3.3.1, Condition W). The restoration time of 48 hours is reasonable considering that the remaining OPERABLE breaker is adequate to perform the safety function and given the low probability of an event during this interval. This is a Ginna TS Category (v.b.20) change.
- dd. Table 3.5-1, Action Statement #14 for Functional Unit #20 (Reactor Trip Breaker Undervoltage and Shunt Trip Mechanisms) - This action was revised to only allow 1 hour to open the RTBs following the action to restore the RTB to OPERABLE status in Modes 3, 4, and 5 (new LCO 3.3.1, Condition X). The current Ginna Station TS allows 6 hours to perform this action but takes into account a shut down from Modes 1 and 2. The 1 hour provides sufficient amount of time to accomplish the action in Modes 3, 4, and 5 in an orderly manner. This is a Ginna TS Category (v.a) change.
- ee. Table 3.5-1, Action Statement #14 for Functional Unit #20 (Reactor Trip Breaker Undervoltage and Shunt Trip Mechanisms) - This action was revised to specify a limit of 2 hours to bypass the RTB for surveillance testing and 6 hours to bypass the RTB for maintenance on undervoltage or shunt trip mechanisms (new LCO 3.3.1, Condition T, Notes 1 and 2). The current Ginna Station TS for bypassing during maintenance does not specify a time limit. The ITS would set a limit on this time. This is a Ginna TS Category (iv.a) change.

- ii. The following changes were made to TS 3.5.2, Table 3.5-2, or Table 3.5-4:
- a. TS 3.5.2.2, 3.5.2.3 and Table 3.5-2, Columns 1, 2, and 3 - The details describing the operability acceptance criteria for Trip Setpoints including the columns for the "Total Number of Channels," the "Number of Channels to Trip," and the "Minimum Operable Channels" were not added for each of the functional units. The columns were replaced with a new column denoting "Required Channels." System design and operational details are not directly related to the operability of the instrumentation and were relocated to the bases or are described in the UFSAR. This is a Ginna TS Category (iii) change.
 - b. Table 3.5-2, Column 6 - The column for the "Channel Operable Above" was revised consistent with the changes to the Mode table definitions in ITS Chapter 1.0. Changes to the Applicability different from those discussed in Chapter 1.0 are discussed with the specific changes to the Functional Units. This is a Ginna TS Category (vi) change.
 - c. Table 3.5-2, Functional Unit #1.b - The Mode of Applicability was revised to be RCS > 200°F. The SI High Containment Pressure Function is used to actuate containment isolation below 350°F such that this Function must be operable. The Manual SI Function does not actuate Containment Isolation while the remaining functions are blocked when RCS pressure is < 2000 psig. This is a Ginna TS Category (v.a) change.
 - d. Table 3.5-2, Functional Units #1.c and #1.d - The notes or remarks which describe operational details for the Pressurizer Pressure interlock, were reformatted as Mode Applicabilities and default conditions in the new specifications. A new SR 3.3.2.6, was added to specifically denote the operability requirements for the Pressurizer Pressure interlock. This is a Ginna TS Category (iii) change.

- e. Table 3.5-2, Action Statement #9 for Functional Units #1.b, #1.c, #1.d, #3.b.i, #5.c and #6.b - This action was revised to replace the current limitation of operation (tied to the next channel functional test of an OPERABLE channel) to allow the bypassing of an inoperable channel for up to 4 hours in order to perform surveillance testing of other channels. The current requirement limits the ability to perform channel functional tests on OPERABLE channels for Functional Units with two-out-of-three logic. Providing a note to bypass the inoperable channel provides a sufficient timeframe to perform the required surveillance testing in a safe and orderly manner. This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- f. Table 3.5-2, Action Statement #9 for Functional Units #1.b, #1.c, #1.d, #3.b.i, #5.c and #6.b - This action was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 1 hour). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- g. LCO 3.3.2, Functional Units #1.b, #2.b, #3.b, #4.b, #5.a, and #6.a, "Automatic Actuation Logic and Actuation Relays," were added for the ESFAS Instrumentation. Actuation logic consists of all circuitry housed within the actuation subsystems, including relay contacts responsible for actuating the ESF equipment. This is merely a presentation change to the Technical Specifications as this logic circuitry is assumed within the operability of the specific Functions. Additionally, the automatic actuation logic and actuation relays for various Functions are required OPERABLE in Mode 4 to support system level manual initiation. This is a Ginna TS Category (iv.a) change.
- h. Table 3.5-2, Action Statement #12 for Functional Unit #3.c - The action associated with this Function was revised to allow an inoperable channel to be placed in the tripped condition within 48 hours (rather than 1 hour). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.

- i. Table 3.5-2, Action Statement #11 for Functional Unit #2.b - The action associated with this Function was revised to replace the limitation of operation (tied to the next channel functional test of an OPERABLE channel) to allow the bypassing of an inoperable channel for up to 4 hours in order to perform surveillance testing of other channels. The current requirement limits the ability to perform channel functional tests on OPERABLE channels for Functional Units with two-out-of-three logic. Providing a note to bypass the inoperable channel provides a sufficient timeframe to perform the required surveillance testing in a safe and orderly manner. This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- j. Table 3.5-2, Action Statement #11 for Functional Unit #2.b - The action associated with this Function was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 2 hours). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- k. Table 3.5-2, Functional Unit #3.a and #3.f - The actions for an inoperable Manual Initiation channel for the AFW and SAFW Systems was revised from restoring operability in 48 hours to declaring the associated pump inoperable. The Manual Initiation channels for these functions actually consist of switches in the control which only actuate one pump train. There is no switch for complete actuation of all AFW or SAFW pumps. Therefore, entering the pump inoperability requirements is consistent with the actions if the AFW pump were declared inoperable. This is a Ginna TS Category (v.b.51) change.
- l. Table 3.5-2, Action Statement #12 for Functional Units #3.b.ii, #3.c, #5.a, and 5.b - The action associated with these Functions was revised to replace the limitation of operation (tied to the next channel functional test of an OPERABLE channel) to allow the bypassing of an inoperable channel for up to 4 hours in order to perform surveillance testing of other channels. The current requirement limits the ability to perform channel functional tests on OPERABLE channels for Functional Units with two-out-of-three logic. Providing a note to bypass the inoperable channel provides a sufficient timeframe to perform the required surveillance testing in a safe and orderly manner. This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.

- m. Table 3.5-2, Action Statement #12 for Functional Units #3.b.ii, #5.a, and 5.b - The action associated with these Functions was revised to allow an inoperable channel to be placed in the tripped condition within 6 hours (rather than 1 hour). This change is discussed and justified in Reference 30. This is a Ginna TS Category (v.b.15) change.
- n. Table 3.5-2, Action Statement #6 for Functional Unit #3.e - The action associated with this Function was revised to a more restrictive restoration time of 48 hours for an inoperable channel rather than placing the channel in the tripped condition within one hour. The allowance of 48 hours to return the train to an OPERABLE status is justified in Reference 30. This is a Ginna TS Category (iv.a) change.
- o. Not used.
- p. Table 3.5-2, Functional Unit #4.2 - The requirements for the Containment Ventilation Isolation (CVI) Manual Initiation Function were not added. The current TS are misleading in that there is no manual CVI initiation function. Instead, CVI is manually initiated by the Manual CS function. The removal of this requirement provides consistency within the TS and greater clarify to the operators. This is a Ginna TS Category (v.c) change.
- q. Table 3.5-4, Functional Units #1.b, #1.d, and #2.b - These Functional Unit Allowable Values were revised to reflect the actual values used in the accident analyses. This is a Ginna TS Category (v.c) change.
- r. Table 3.5-4, Functional Units #7.a and #7.b - The Trip Setpoint for the loss of voltage and degraded voltage functions were revised to provide a minimum value. Criteria for the establishment of equivalent values based on measured voltage versus relay operating time was relocated to the bases for new LCO 3.3.4). This is a Ginna TS Category (iii) change.
- s. Table 3.5-4, Notes 1 and 2 for Functional Units #6.a and #6.c - The notes which describe design details for the Steam Generator Water Level - Low Low Function and Loss of 4 kV Function were not added. These details are relocated to the bases or are described in the UFSAR. This is a Ginna TS Category (iii) change.

t. Table 3.5-2, Functional Unit #4.2b and Action 8 to Table 3.5-5 - The actions for an inoperable CVI radiation monitor were revised to allow 4 hours to isolate the affected penetration. Current TS Table 3.5-2 does not provide a time limit, only that the valves are to be closed while Table 3.5-5 provides 1 hour to perform this action. The time limit is consistent with NUREG-1431 and the Completion Times for an inoperable containment isolation valve which the CVI signal actuates. This is a Ginna TS Category (v.b) change.

iii. The following changes were made to TS 3.5.3 or Table 3.5-3:

- a. TS 3.5.3.2, TS 3.5.3.3, and Table 3.5-3, Columns 1 and 2 - The columns for the "Total Required Number of Channels," and the "Minimum Channels Operable," were not added for each of the functional units. The columns were replaced with a new column denoting "Required Channels." System design and operational details are not directly related to the operability of the instrumentation and were relocated to the bases or are described in the UFSAR. This is a Ginna TS Category (iii) change.
- b. TS 3.5.3.2 - The restoration time requirement of 7 days for one inoperable channel (for Functions with two channels) was revised to 30 days. The 30 day Completion Time was revised based on industry operating experience and takes into account the remaining OPERABLE channel, the passive nature of the instrument, and the low probability of an event requiring PAM instrumentation during this interval. This is a Ginna TS Category (v.b.21) change.
- c. TS 3.5.3.2 - The action for one channel inoperable for more than 7 days (for Functions with two channels) was revised from requiring a plant shutdown to requiring a Special Report. Due to the passive function of these instruments and the operator's ability to respond to an accident utilizing alternate instruments and methods for monitoring, it is not appropriate to impose stringent shutdown requirements for out-of-service instrumentation. This is a Ginna TS Category (v.b.21) change.

- d. TS 3.5.3.3 - The restoration time requirement of 48 hours for two inoperable channels was revised to 7 days. The 7 day Completion Time was revised based on industry operating experience and takes into account the availability of alternate means to obtain the required information and the low probability of an event requiring PAM instrumentation during this interval. This is a Ginna TS Category (v.b.21) change.
- e. Table 3.5-3 - The Post Accident Monitoring Instrumentation Functions required by this specification were revised to include only RG 1.97, Type A and Category I variables. These functions are denoted in UFSAR Table 7.5-1 and have been previously reviewed and approved by the NRC (Ref. 59). This is a Ginna TS Category (iv.a) change.
- iv. TS 3.5.4 and Table 3.5-6 - The requirements for radiation accident monitoring instrumentation, provided to monitor radiation levels in selected plant locations following an accident, were not added. No screening criteria apply for these requirements since the monitored parameters are not part of the primary success path in the mitigation of a DBA or transient. These monitors are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA. Therefore, the requirements specified for these functions do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM. This is a Ginna TS Category (iii) change.
- v. TS 3.5.6.1 - The requirements for the chlorine gas and ammonia gas instrumentation monitors for control room habitability were not added. No screening criteria apply for these requirements since the monitored parameters are not part of the primary success path in the mitigation of a DBA or transient. These monitors are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA. Therefore, the requirements specified for these functions do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the TRM. This is a Ginna TS Category (iii) change.
- vi. LCO 3.3.5, Conditions B and C, were added for the Control Room Emergency Air Treatment System (CREATS) actuation instrumentation. These new requirements specify Required Actions for various modes of operation when the CREATS isolation dampers cannot be placed in the emergency radiation protection mode. This is a Ginna TS Category (iv.a) change.

- vii. TS 3.5.6.2 - The requirement for one detection system inoperable has been revised to allow more than one channel inoperable with an action to isolate the control room in one hour. Even with a loss of Function of the automatic actuation logic, the CREATS may still be capable of being manually isolated within 1 hour and performing its safety function. This is a Ginna TS Category (v.c) change.
- viii. TS 3.5.5 and Table 3.5-5 - The requirements for radioactive effluent monitoring instrumentation which ensures that the limits of TS 3.9.1.1 and 3.9.2.1 are not exceeded were not added (except for R-11 and R-12 which support Containment Ventilation Isolation). No screening criteria apply for these requirements since the monitored parameters are not part of the primary success path in the mitigation of a DBA or transient. These monitors are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively.
- ix. Table 3.5-5 - The Mode of Applicability for R-11 and R-12 operability was revised from "during shutdown purges" to MODES 1, 2, 3, and 4, and during MODE 6 when required by LCO 3.9.3, "Containment Penetrations." This is a conservative change which ensures that the gaseous and particulate radiation monitors are operable in all Modes in which the mini-purge or shutdown purge systems can be used. This is a Ginna TS Category (v.a) change.

16. Technical Specification 3.6

- i. TS.3.6.1 - The text allowing closed containment isolation valves to be opened on an intermittent basis under administrative controls was relocated to a LCO Note consistent with NUREG-1431. This is a Ginna TS Category (v.c) change.
- ii. TS 3.6.2 - The Applicability for maintaining containment pressure within limits was revised from reactor criticality to MODE 4. This change is necessary to provide consistency with the requirements for containment integrity (i.e., LCO 3.6.1) since exceeding these pressure limits could result in a overpressure of containment if an accident were to occur. This is a Ginna TS Category (iv.a) change. Also, the time allowed to restore containment pressure was changed from 24 hours to 8 hours. This change was made due to the short period of time it normally takes to restore containment pressure to within limits. This is a Ginna TS Category (v.a) change.

- iii. TS 3.6.3 - Three new requirements were added. The first requires that a penetration with both containment boundaries inoperable be isolated within 1 hour versus 4 hours. This change provides consistency with TS 3.6.1 since containment integrity is potentially violated. As such, verification of continued acceptable containment leakage must be initiated immediately if both barriers are declared inoperable. In addition, new requirements with respect to an inoperable airlock (including the use of an airlock with an inoperable door or interlock mechanism) and containment mini-purge penetrations with isolation valves that exceed their leakage rate acceptance criteria were added. The new requirement for the airlocks specifies that an inoperable airlock door (including an inoperable interlock mechanism) must be isolated within 1 hour and locked closed within 24 hours. However, a dedicated individual can be used in the case of an inoperable interlock mechanism to allow entry and exit through the airlock. The new specification provides specific Required Actions in the event that current Ginna Station TS 4.4.2.3.c is exceeded. The new requirement for the mini-purge penetrations specifies that the affected penetration must be isolated within 24 hours if an isolation valve exceeds its leakage limit. These new requirements provide added assurance that penetrations which can provide direct access to the outside environment are addressed quickly when their isolation barriers become inoperable. This is a Ginna TS Category (iv.a) change.
- iv. TS 3.6.3 - The use of a closed system to isolate an inoperable containment isolation barrier for up to 72 hours was added to this specification. Consequently, a closed system which must be OPERABLE to meet this specification can be used to isolate a failed isolation barrier for a limited period of time. Also, isolation devices located outside containment that were used to isolate a failed containment isolation valve are required to be verified closed once every 31 days. For isolation devices inside containment, they must be verified closed upon entry into MODE 4 from MODE 5 if it has not been performed within the last 92 days. These are Ginna TS Category (v.b.22) changes.
- v. TS 3.6.5 - The reasons for opening the mini-purge valves above 200°F were relocated to the bases for ITS 3.6.3 since these do not meet any of the four criteria and do not specify any Required Actions. Operation of the Mini-Purge System is performed under procedures such that its use is strictly controlled. Placing this information in the bases also provides similar control under 10 CFR 50.59 (i.e., the Bases Control Program). This is a Ginna TS Category (iii) change.

- vi. TS 3.6 - A new requirement was added which specifies that the average containment air temperature shall be $\leq 120^{\circ}\text{F}$ above MODE 5. This temperature limit is necessary to ensure that the resulting containment temperature following a DBA is within the assumptions used for environmental qualification of components within containment. If the average containment air temperature is $> 120^{\circ}\text{F}$, it must be restored within 24 hours. This is a Ginna TS Category (iv.a) change.
- vii. TS 3.6 - A new requirement was added which requires the hydrogen recombiners to be OPERABLE in MODES 1 and 2. The hydrogen recombiners are assumed in the accident analyses to be used to prevent a hydrogen explosion within containment that could overpressurize the containment structure. The new LCO allows 30 days to restore an inoperable recombiner and 7 days to restore two inoperable recombiners if the Mini-Purge System is OPERABLE. In addition, the plant can enter MODES 1 and 2 with an inoperable hydrogen recombiner. This is a Ginna TS Category (iv.a) change.
- viii. TS 3.6.4.1 and TS 3.6.4.3 - The Applicability for the hydrogen monitors was revised to include Mode 3 requirements. These variables are related to the diagnosis and pre-planned actions required to mitigate DBAs. The applicable DBAs are assumed to occur in Modes 1, 2, and 3. This is a Ginna TS Category (iv.a) change.
- ix. TS 3.6.4.2 - The action for one channel inoperable for more than 30 days was revised from requiring a plant shutdown to requiring a Special Report. Due to the passive function of these instruments and the operator's ability to respond to an accident utilizing alternate instruments and methods for monitoring, it is not appropriate to impose stringent shutdown requirements for out-of-service instrumentation. This is a Ginna TS Category (v.b.21) change.
- x. TS 3.6.1.b - The requirement describing the specific applicability for containment integrity if the boron concentration is less than 2000 ppm was not added. No screening criteria apply for this requirement since the boron concentration limit is only a requirement for fuel handling accidents. Since the requirements of ITS LCO 3.6.1 immediately stop all fuel movement in this condition, there is no for containment integrity. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and have been deleted. This is a Ginna TS Category (v.b.50) change..

17. Technical Specification 3.7

- i. TS 3.7.1.1.b, 3.7.1.1.d, and 3.7.1.1.e - The cold shutdown or refueling requirements (MODES 5 and 6) for the 480 V safeguards buses, batteries and DC trains, and 120 VAC instrument buses were revised from requiring only one train to be OPERABLE to require the necessary train(s) to support all other LCO requirements. Consequently, one or both trains of these systems may be required depending on other system requirements (e.g., RHR). In MODES 5 and 6, sufficient electrical power redundancy must be available to mitigate an event coincident with either a loss of offsite power, loss of all onsite standby emergency power, or a worse case single failure. This change ensures that all necessary electrical support systems are OPERABLE to respond to a DBA or a transient. This is a Ginna TS Category (iv.a) change.
- ii. TS 3.7.1.2 - Cold or refueling requirements (MODES 5 and 6) for the DG fuel oil supply and the battery parameters have been added to provide restoration times for specified conditions consistent with the ITS. These times are sufficient to complete restoration of the degraded parameter prior to declaring the component inoperable and is acceptable based on the low probability of an event during this brief period and the fact that the component remains capable of performing most required functions. This is a Ginna TS Category (v.a) change.
- iii. TS 3.7.2.1.b.2, 3.7.2.2.a, and 3.7.2.2.b - The requirements for two offsite sources were not added. The current actions allow the plant to operate indefinitely with one offsite source inoperable. The new ITS format criteria would not specify these requirements in the TS (i.e., require a component for a MODE change but allow the component to remain inoperable indefinitely once the MODE change is complete). Therefore, these requirements are relocated to the TRM. The offsite power sources are further discussed in Reference 32. This is a Ginna TS Category (iii) change.
- iv. TS 3.7.2.2.b.1 - The actions for an inoperable DG have been revised: (1) to eliminate the testing of the OPERABLE DG if, within 24 hours, it can be determined that the OPERABLE DG is not inoperable due to common cause failure, and (2) to require verification of the offsite power circuit to the affected AC distribution train. In addition, the OPERABLE DG must only be tested once during the 7 day allowed outage for the inoperable DG. The revised action for the OPERABLE DG eliminates unnecessary testing during a period in which the plant relies on only one DG. These are Ginna TS Category (iv.b.2) and (v.a) changes.

- v. TS 3.7.2.2.c - The Completion Time for the action to re-energize the 480 V safeguards bus has been revised from 1 hour to 8 hours. The time is consistent with the ITS which assumes not only restoration of the bus but also the associated load centers, motor control centers, and distribution panels which comprise the AC electrical train. This is a Ginna TS Category (v.b.24) change.
- vi. TS 3.7.2.2.d - This was revised to address the scenario with both offsite power and one DG were inoperable. In this condition, no loss of safety function exists since the remaining DG is available to provide power to one ESF train. However, the time in this Condition should be limited due to the potential to lose multiple safety functions if the remaining DG were lost. Therefore, a Completion Time of 12 hours is provided. However, if both offsite power and one DG were inoperable to the same AC electrical train, then the time would be restricted to 8 hours as discussed in Section D, item 17.v above. This is a Ginna TS Category (v.b.54) change.

18. Technical Specification 3.8

- i. TS 3.8 - The applicability was revised from "during refueling operations" to "CORE ALTERATIONS and irradiated fuel assembly movement within containment." This is an equivalent change since refueling operations can only be related to CORE ALTERATIONS and irradiated fuel assembly movement within containment. This is a Ginna TS category (v.c) change.
- ii. TS 3.8.1.b - The refueling or MODE 6 requirement for the containment radiation monitors which provide monitoring for personnel safety was not added. No screening criteria apply for this requirement because the process variable of the LCO is not an initial condition of a DBA or transient analysis. Further, the containment radiation monitors are a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to procedures or other licensee controlled documents. This is a Ginna TS Category (iii) change.

- iii. TS 3.8.1.c - The requirement describing the specific applicability of the SRMs was revised. The phrase "whenever geometry is being changed" is covered by the new TS definition of MODE 6. The requirement that one SRM be OPERABLE when core geometry "is not being changed" is covered by the Required Action for one inoperable SRM. This would restrict CORE ALTERATION and positive reactivity additions when core geometry is not being changed. Required Actions were also provided when two SRMs become inoperable or when the audible indication is lost. These new actions require verification of boron concentration every 12 hours and ensures the stabilized condition of the reactor core. These are a conservative revisions and Ginna TS Category (v.a) and (iv.a) changes, respectively.
- iv. TS 3.8.1.e - The requirement describing the specific applicability and frequency of the boron concentration sampling was revised. The phrase "immediately before reactor vessel head removal and while loading and unloading fuel from the reactor" is covered by the new TS definition of MODE 6. This would additionally require boron concentration sampling throughout MODE 6. The sampling frequency, however, was also revised to require sampling every 72 hours. These revisions consider the large volume of the refueling canal, RCS, and refueling cavity and are adequate to identify slow changes in boron concentration. Rapid changes in boron concentration, described in UFSAR 15.4.4.2, are detected by the SRM instrumentation required by new TS 3.9.2. This is a conservative revision and a Ginna TS Category (iv.a) change.
- v. TS 3.8.1.f - The requirement for communication with the control room during CORE ALTERATIONS is not added. No screening criteria apply for this requirement since communications is not part of the primary success path assumed in the mitigation of a DBA or transient. The requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to procedures or other licensee controlled documents. This is a Ginna TS Category (iii) change.
- vi. TS 3.8.1.d (footnote *) and TS 3.8.1.g (footnote *) - The requirement that either the preferred or the emergency power source may be inoperable for each residual heat removal loop is not added. This detail is encompassed in the definition of operability described in new TS 1.1 and the electric power requirements contained in Chapter 3.8. This is a Ginna TS Category (i) change.

- vii. TS 3.8.1.c - The requirement to provide SRM audible indication in the containment was not added. No screening criteria apply for this requirement since the monitored parameter (audible indication in containment) is not assumed in the refueling safety analysis. The safety analysis assumes audible indication in the control room which is denoted by new LCO 3.9.2. The audible indication is for personnel safety only. Further, the audible indication is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to procedures or other licensee controlled documents. This is a Ginna TS Category (iii) change.
- viii. TS 3.8.1.iii.1 - The isolation devices which are allowed was revised to include "or equivalent." The use of "or equivalent" for isolation of a containment penetration is consistent with NUREG-1431 and the bases for CTS 3.8 which allow the use of a "material which can provide a temporary ventilation barrier, at atmospheric pressure, for the containment penetrations during fuel movement." Therefore, this is a clarification only to the LCO. This is a Ginna TS Category (v.c) change.
- ix. TS 3.8.2 - The requirement to initiate action "to correct the violated conditions" was not added to the new specifications since this is always an option to exit the Condition. That is, the Condition is not exited, even after completion of the Required Actions, unless either the LCO is met, or the MODE of Applicability is exited. This is a Ginna TS Category (v.c) change.
- x. TS 3.8.2 - The requirement to cease "operations which may increase the reactivity of the core" was not added to LCO 3.9.3 (Containment Penetrations) since the basis for isolation of containment is with respect to a fuel handling accident. The reactivity of the core is with respect to a boron dilution event which is adequately addressed by other LCOs. This is a Ginna TS Category (v.b.48) change.

19. Technical Specification 3.9

- i. TS 3.9.1.1 - The requirements for radioactive material released in liquid effluents to unrestricted areas which are limited to the concentrations specified in 10 CFR Part 20, Appendix B, Table II, Column 2, were not added. No screening criteria apply for these requirements because the process variable of the LCO is not an initial condition of a DBA or transient analysis. Further, liquid releases during normal operation are a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- ii. TS 3.9.1.2 and TS 3.9.2.4 - The requirements for dose or dose commitment to individuals which results from cumulative liquid effluent discharges during normal operation over extended periods and is intended to assure compliance with the dose objectives of 10 CFR Part 50, Appendix I, 40 CFR 141, and 40 CFR 190 limits were not added. These limits are not related to protection of the public from any DBA or transient analysis. Further, radioactive liquid effluent dose projected value is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- iii. TS 3.9.1.3 - The requirements for the liquid radwaste treatment system which controls the release of site liquid effluents during normal operational occurrences consistent with 10 CFR Part 50, Appendix I, were not added. No loss of primary coolant is involved, neither is an accident condition assumed or implied. Further, the loss of the system is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- iv. TS 3.9.2.1 - The requirements which assure compliance with 10 CFR Part 20 for the dose rate due to radioactive material released in gaseous effluents beyond the site boundary were not added. No screening criteria apply because the process variable of the LCO is not an initial condition of a DBA or transient analysis. Further, gaseous effluent dose rate during normal operation is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- v. TS 3.9.2.2.a, TS 3.9.2.2.c, and TS 3.9.2.4 - The requirements for dose due to noble gases released in gaseous effluents during normal operation over extended periods were not added. These limits are not related to protection of the public from any DBA or transient analysis. Further, gaseous effluents dose (noble gas) values is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- vi. TS 3.9.2.2.b, TS 3.9.2.2.c, and TS 3.9.2.4 - The requirements for dose due to radioiodine, radioactive materials in particulate form, and radionuclides other than noble gases with half-lives greater than 8 days released with gaseous effluents were not added. These limits are not related to protection of the public from any DBA or transient analysis. Further, these gaseous effluents doses are a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- vii. TS 3.9.2.3 - The requirements for the gaseous waste treatment system which reduces the activity level in gaseous waste prior to discharge to the environs were not added. The ventilation exhaust system is not assumed in the analysis of any DBA or transient. Further, the system is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- viii. TS 3.9.2.5 and TS 3.9.2.6 - The specific requirements for which limit concentration of oxygen in a gas decay tank and the quantity of radioactivity contained in each waste gas decay tank were not added. The level of detail is relocated to Explosive Gas and Storage Tank Radioactivity Monitoring Program described in new Specification 5.5.11 and a more generic description is provided. This is a Ginna TS Category (iii) change.
- ix. TS 3.9.2.7 - The requirements for the solid radwaste system which processes wet radioactive waste and operates in accordance with 10 CFR Part 50, Appendix A, for effluent control were not added. The operability of the system is not assumed in the analysis of any DBA or transient. Further, radioactive waste is a non-significant risk contributor to core damage frequency and offsite release. Therefore; the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radiological Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

20. Technical Specification 3.10

- i. TS 3.10.1 - This was revised to include specific actions and Completion Times for cases when the shutdown bank insertion limits and the control bank insertion, sequence, and overlap limits are not within the limits specified in the COLR. These actions require verification within 1 hour that the SHUTDOWN MARGIN is within limits and restoring the associated value to within limits within 2 hours or be in MODE 3 within 6 additional hours. These additions were made to ensure that the control banks and the shutdown bank are available as assumed in the safety analyses. This is a Ginna TS Category (iv.a) change.

- ii. TS 3.10.1.1 - This was revised to include a specific action to initiate boration within 15 minutes when the SHUTDOWN MARGIN is not within limits. The addition of this action ensures that SHUTDOWN MARGIN is monitored and quickly restored within limits. This is a Ginna TS Category (iv.a) change.
- iii. TS 3.10.1.1 and Figure 3.10-2 - These were revised to relocate the SHUTDOWN MARGIN requirements and Figure 3.10-2 to the COLR. SHUTDOWN MARGIN can be used in fuel management and as a variable to solve plant specific problems. SHUTDOWN MARGIN impacts a number of analyses (i.e., uncontrolled boron dilution and steamline break) and is sensitive to many core related parameters such as control bank position, core power level, coolant temperature and cycle specific parameters such as fuel burnup, xenon concentration and boron concentration. The inclusion of SHUTDOWN MARGIN in the COLR provides more flexibility in plant operation, in performing the design, and in obtaining good fuel economics particularly for extended cycle operation. With the SHUTDOWN MARGIN included in the COLR, the core design can be finalized after shutdown so that the actual end of cycle burnup is known which is particularly helpful when the actual burnup differs from the projected value. This is a Ginna TS Category (iii) change.
- iv. TS 3.10.1.2 and TS 3.10.1.3 - These were revised to indicate only low power PHYSICS TEST exceptions for the shutdown and control bank insertion limits. Ginna Station currently does not perform a PHYSICS TEST in MODE 1 which would require the exception of the insertion limits. This is a Ginna TS Category (vi) change.
- v. TS 3.10.1.3 and Figure 3.10-1 - These were revised to relocate the control rod insertion limits and the sequence and overlap limits to the COLR. This change is consistent with NUREG-1431 and provides flexibility during reload core design. This is a Ginna TS Category (iii) change.
- vi. TS 3.10.1.5 - This was not added to the new specifications. None of the PHYSICS TESTS currently performed at Ginna Station currently require a relaxation of the SHUTDOWN MARGIN requirements. Therefore none of these SHUTDOWN MARGIN PHYSICS TESTS exceptions or Required Actions are necessary. This is a Ginna TS Category (vi) change.
- vii. TS 3.10.2.2 - This was revised to remove the low power PHYSICS TESTS exception since new LCO 3.2.1 and LCO 3.2.2 which contain the peaking factor requirements are only applicable in MODE 1. This is a Ginna TS Category (v.a) change.

- viii. TS 3.10.2.3 - This was revised to remove the PHYSICS TEST exceptions for the QPTR. Ginna Station currently does not perform a PHYSICS TEST in MODE 1 which would require the exception of the QPTR limit and the ITS LCO 3.2.4 which contains QPTR is only applicable in MODE 1 with THERMAL POWER \geq 50% RTP. This is a Ginna TS Category (vi) change.
- ix. TS 3.10.2.8, TS 3.10.2.9 and TS 3.10.2.10 - These were revised to remove the PHYSICS TEST exceptions for AFD. Ginna Station currently does not perform a PHYSICS TEST in MODE 1 which would require the exception of the AFD limits and the ITS LCO 3.2.3 which contains AFD is only applicable in MODE 1 with THERMAL POWER \geq 15% RTP. This is a Ginna TS Category (vi) change.
- x. TS 3.10.3.1.a - This was revised to reduce the minimum T_{avg} for the rod drop test from 540°F to 500°F. The 500°F temperature is conservative since the water will be slightly denser at the lower temperature which has the potential to slow down the dropped rods. This change would enable the plant to complete the rod drop test at an earlier time during plant startup and is consistent with NUREG-1431. This is a Ginna TS Category (v.a) change.
- xi. TS 3.10.4.1 - This was revised to indicate only low power PHYSICS TEST exceptions for control bank alignment. Ginna Station currently does not perform a PHYSICS TEST in MODE 1 which would require the exception of the alignment limits. This is a Ginna TS Category (vi) change.
- xii. TS 3.10.4.2 and TS 3.10.4.3 - These were revised to remove conditions of rod inoperability due to being immovable. The ITS Bases state that the rods are considered to be OPERABLE if they are trippable even if they are immovable. Reference to full length rods was also removed since there are no part length rods in the reactor core. This is a Ginna TS Category (v.c) change.
- xiii. TS 3.10.4.3.2 - This was revised to remove the requirement to declare a misaligned rod inoperable when the rod cannot be restored to within the alignment limits in 1 hour. The ITS Bases state that the rods are considered to be OPERABLE if they are trippable even if they are immovable. This is a Ginna TS Category (v.c) change.
- xiv. TS 3.10.4.3.2.a - This option for restoring a rod to within alignment was removed from the LCO and relocated to the Bases for ITS 3.1.4 which is controlled under the Bases Control Program. This is a Ginna TS Category (iii) change.

- xv. TS 3.10.4.3.2.b.iii and Table 3.10-1 - These were revised to remove Table 3.10-1 from the specifications. The ITS requires evaluations of accident analysis to be performed to determine that the core limits will not be exceeded during a Design Basis Accident. An evaluation of each of the analyses on Table 3.10-1 may not be required to determine that the core limits will not be exceeded. This table was relocated to the TRM. This is a Ginna TS Category (iii) change.
- xvi. TS 3.10.4.3.2.b and TS 3.10.4.3.2.c - These were revised to remove the requirement to reduce the high neutron flux trip setpoint to $\leq 85\%$ RTP when the power level is reduced to $\leq 75\%$ RTP. This required action is deleted based on agreements between the NRC and the owners groups and is consistent with WCAP-13029 (Ref. 50) which states that the safety analyses results would not be significantly affected by changes to their initial assumptions as a result of increased peaking factors caused by rod misalignment. Additionally, the peaking factor limit verification within 72 hours and the re-evaluation of the safety analysis within 5 days that are required by this specification provide further assurance that the assumptions made in the safety analysis are preserved. This is a Ginna TS Category (v.b.52) change.
- xvii. TS 3.10.4.4 - This was revised to include an action to verify SHUTDOWN MARGIN or initiate boration within 1 hour when more than one rod is out of alignment. The ITS Bases state that 1 hour is a reasonable time based on the time required for potential xenon distribution and the low probability of a accident. This is a Ginna TS Category (v.a) change.
- xviii. TS 3.10.5.1 - This was revised to add an action statement to clarify that if more than one MRPI is inoperable per group for one or more groups or more than one demand position indicator per bank is inoperable for one or more banks then the plant must enter 3.0.3 immediately. This is a Ginna TS Category (v.a) change.
- xix. TS 3.10.5.2.a - This was revised to allow 4 hours (instead of immediately) to verify rod position. The rod position cannot be determined immediately. It takes time to acquire the data and obtain the results. "Immediately" is considered a start time not a completion time. The ITS Bases state that 4 hours provides an acceptable period of time to verify the rod positions while a reduction to $\leq 50\%$ RTP will avoid undesirable power distributions that could result from continued operation at $> 50\%$ RTP with 2 or more rods misaligned. This is a Ginna TS Category (v.c) change.

- xx. TS 3.10.2.1 - This was revised to require measurement of the power distribution after each fuel reloading prior to operation of the plant at or above 75% RTP instead of prior to 50% RTP consistent with ITS. This requirement ensures that the design limits are not exceeded when RTP is achieved, since peaking factors are usually decreased as power increases. Requiring this surveillance at 75% versus 50% still provides the necessary margin to ensure that design safety limits are not exceeded and provides the operator with more flexibility during power ascension following a refueling. This is a Ginna TS Category (v.b.25) change.
- xxi. TS 3.10.2.1 - This was revised to delete the requirement to verify QPTR using movable incore detectors or core exit thermocouples with one power range detector inoperable at THERMAL POWER \geq 75% RTP and replaced with a requirement to perform a flux map to verify that hot channel factors are within limits consistent with ITS. The incore detectors are not used to verify QPTR but rather to verify that the core power distribution is acceptable. Ginna Station does not have 8 pairs of symmetric thimble plugs which are necessary to perform a partial flux map and thus would have to complete a full core flux map to verify that the core power distribution is acceptable. This change is consistent with current interpretations at Ginna Station and is preferred by Ginna Station licensed personnel. This is a Ginna TS Category (v.c) change.
- xxii. TS 3.10.2.2 - This was revised to require the hot channel factors be within limit only in MODE 1. The proposed Applicability does not require the F_Q or $F_{\Delta H}$ limits to be met in MODES 2 - 5 or during refueling. As described in the ITS Bases, F_Q and $F_{\Delta H}$ must be within limits during MODE 1; however, such limits are not necessary in MODE 2 because there is insufficient stored energy in the fuel or being transferred to the coolant to require these limits. This is a Ginna TS Category (v.b.26) change.
- xxiii. TS 3.10.2.2 - This was revised to relocate the limits for $F_Q(Z)$ and $F_{\Delta H}$ and the Figure 3.10-3 to the COLR. This change is consistent with NUREG-1431 and provides flexibility during reload core design. This is a Ginna TS Category (iii) change.
- xxiv. TS 3.10.2.2 - This was revised to include an administrative Action to reduce the AFD acceptable operational limits specified in the COLR by the percentage that F_Q exceeds the limit. This is necessary since a change in F_Q can adversely impact AFD limits. A Completion Time of 8 hours is allowed to perform this action. This is a Ginna TS Category (iv.a) change.

- xxv. TS 3.10.2.2 - This was revised to allow 72 hours (instead of 24 hours) to reduce the Overpower ΔT and the Overtemperature ΔT trip setpoints when F_Q or $F_{\Delta H}$ is not within limits consistent with NUREG-1431. This section was also revised to include a Completion Time of 72 to reduce the Power Range Neutron Flux High trip setpoints. These actions provide further protection against the consequences of severe transients with unanalyzed power distributions. The 72 hours is sufficient considering the small likelihood of a severe transient in this time period and the initial prompt reduction in THERMAL POWER. This is a Ginna TS Category (v.b.27) change.
- xxvi. TS 3.10.2.2 - This was revised to add a Required Action to be in MODE 2 within 6 hours if the Required Actions and associated Completion Times for the Condition when F_Q or $F_{\Delta H}$ is not within limits is not met. This action places the plant in a condition outside of the Applicability requirements for the Hot Channel Factor requirements. The Completion Time of 6 hours is sufficient to reach MODE 2 from full power operation in an orderly manner without challenging plant systems. This is a Ginna TS Category (iv.a) change.
- xxvii. TS 3.10.2.3 and 3.10.2.4 - These were revised to specifically define the Applicability requirements for QPTR as MODE 1 with THERMAL POWER > 50% RTP. This Applicability is consistent with the current requirements for Ginna Station since continued operation is allowed for an unlimited period of time when THERMAL POWER is < 50% RTP. The ITS Bases state that below 50% RTP there is either insufficient stored energy in the fuel or insufficient energy being transferred to the reactor coolant to require the implementation of a QPTR limit on the distribution of core power. In addition, the LCO limit of 1.12 was removed since the primary limit of 1.02 will be reached initially and actions will already be in progress to address the tilt. THERMAL POWER will continue to be reduced if the tilt ratio continues to increase. This revision is consistent with the changes made in WCAP-12159 (Ref. 51) and current industry practice. These are Ginna TS Category (v.a) changes.

- xxviii. TS 3.10.2.3 - This was revised to limit the THERMAL POWER relative to the percentage of quadrant power tilt, (i.e., limit power to 3% below RTP for each 1% by which the QPTR exceeds 1.00) instead of requiring an immediate action to go below 75% RTP. The reduction to 75% RTP essentially employs a 2% RTP reduction for each 1% the QPTR was above 1.00 up until QPTR equalled 1.12 where a reduction to 50% RTP was required. The proposed change would provide flexibility with the initial reduction, but would require at least a 3% RTP reduction for each 1% QPTR exceeded 1.00. Thus, the proposed change while requiring a smaller reduction for small tilts is more conservative for larger tilts which would suggest a more serious problem. This revision is consistent with the changes made in WCAP-12159 (Ref. 51) and current industry practice. The requirement to measure the hot channel factors when the QPTR exceeds 1.02 is changed from within 2 hours to within 24 hours since the THERMAL POWER is appropriately limited within 2 hours. The 24 hour Completion Time takes into consideration the rate at which peaking factors are likely to change, and the time required to stabilize the plant and perform a flux map. This is a Ginna TS Category (v.a) change.
- xxix. TS 3.10.2.4 - This was revised to delete the requirement to identify the cause of the tilt or limit power to < 50% RTP. Identification of the cause of the tilt is not always possible and other actions already underway are adequate to assure safe operation of the plant (e.g., surveillances). This change is consistent with WCAP-12159 (Ref 53). This is a Ginna TS Category (v.b.28) change.
- xxx. The following Required Actions were added for the Condition when QPTR is not within the limit: These are Ginna TS Category (iv.a) changes.
- a. A requirement to verify by calculation that the QPTR is within limits and limit power accordingly every 12 hours.
 - b. A requirement to recalibrate the excore detectors prior to increasing THERMAL POWER above the limit in TS 3.10.2.3. This action is modified by a Note that requires verification that the hot channel factors are within limits prior to recalibration of the excore detectors.

- c. A requirement to verify F_Q and $F_{\Delta H}$ within limits either within 24 hours after reaching RTP or within 48 hours after increasing THERMAL POWER above the limit in TS 3.10.2.3. This action is modified by several Notes. The first Note clarifies that when the QPTR alarm is due to instrumentation alignment this action does not need to be completed. The second note allows this action to be completed only after the excores have been recalibrated. The third note clarifies that the Completion Time applicable first is the one that must be met.
 - d. A requirement to reduce power to < 50% RTP within 4 hours if the initial Required Actions are not met within the associated completion time. This takes the plant out of the Applicability when the actions are not met and provides an additional action before plant shutdown is required.
- xxxi. TS 3.10.2.5 - This was deleted since the 1.12 QPTR limit no longer applies and the Applicability requirement for QPTR has been revised to > 50% RTP. Actions already in progress (i.e., limiting power by 3% below RTP for each 1% QPTR exceeds 1.00) are sufficient to address the tilt. This is a Ginna TS Category (v.c) change.
 - xxxii. TS 3.10.2.7 - This was revised to require a measurement of the target flux difference within 31 EFPD after each refueling instead of within 92 EFPD. This requirement is also modified with a note that allows the predicted beginning of cycle AFD from the cycle nuclear design to be used to determine the initial target flux difference after each refueling. The change to within 31 EFPD is more conservative than within 92 EFPD and is necessary to perform the initial monthly target flux difference update also required by TS 3.10.2.7. This is a Ginna TS Category (v.a) change.
 - xxxiii. TS 3.10.2.8 - This was revised to relocate the AFD target band to the COLR. This change is consistent with NUREG-1431 and provides flexibility during reload core design. The Applicability requirement was also revised to specify MODE 1 with THERMAL POWER > 15% RTP. As described in the ITS Bases, this Applicability is acceptable because of the low amounts of stored or transferred energy in the lower MODES. The AFD at these lower conditions does not affect the consequences of the design basis events. Additionally, the low signal levels in the excore channels may preclude obtaining valid AFD signals below 15% RTP. These are Ginna TS Category (iii) and (v.c) changes, respectively.

- xxxiv. TS 3.10.2.9 - This was revised to specify 15 minutes (instead of immediately) to restore AFD to within the target band and then immediately initiate actions to reduce THERMAL POWER to < 90% RTP if the AFD is not restored within the initial 15 minutes. This is consistent with the intent of the current Ginna Station technical specifications. "Immediately" is considered a start time not a completion time and 15 minutes is considered a sufficient amount of time to restore AFD within limits without allowing the plant to remain in an unanalyzed condition for an extended period of time prior to a reduction in power. This is a Ginna TS Category (v.c) change.
- xxxv. TS 3.10.2.10a - This was revised to relocate the AFD target band and the acceptable operation limits to the COLR. This change is consistent with NUREG-1431 and provides flexibility during reload core design. The Applicability requirement was also revised to specify MODE 1 with THERMAL POWER > 15% RTP. As described in the ITS Bases, this Applicability is acceptable because of the low amounts of stored or transferred energy in the lower MODES. The AFD at these lower conditions does not affect the consequences of the design basis events. Additionally, the low signal levels in the excore channels may preclude obtaining valid AFD signals below 15% RTP. These are Ginna TS Category (iii) and (v.c) changes respectively.
- xxxvi. TS 3.10.2.12 - This was revised to require a verification that the AFD is within limits and to log the AFD every 15 minutes with THERMAL POWER \geq 90% RTP and once every hour with THERMAL POWER < 90% RTP when the AFD monitor alarm is inoperable instead of every hour for the first 24 hours and every half hour thereafter. This modification reflects the importance of staying within the target band at above 90% RTP and is consistent with the Required Action if the AFD is outside the target band. This is a Ginna TS Category (v.c) change.

21. Technical Specification 3.11

- i. TS 3.11.1 - This was revised to require that the Auxiliary Building Ventilation System (ABVS) be OPERABLE when one or more fuel assemblies in the Auxiliary Building has decayed < 60 days since being irradiated. The specific components which are required for the ABVS to be considered OPERABLE were relocated to the bases similar with the structure of NUREG-1431 and the ITS Writer's Guide. The bases for LCO 3.7.10 now require that one of the two 100% capacity Auxiliary Building main exhaust fans, exhaust fan C, the SFP Charcoal Absorber System, and all associated ductwork, valves and dampers be OPERABLE. In addition, TS 3.11.1.c was revised to require a negative pressure within the Auxiliary Building operating floor with respect to the outside environment instead of requiring all doors, windows, and other direct openings between the operating floor area and the outside to be closed. This change provides consistency with assumptions of the fuel handling accident as described in the bases. This change also provides a much clearer specification which is easier for licensed personnel to read and understand without any reduction in actual requirements. These are Ginna TS Category (i) and (v.a) changes, respectively.
- ii. TS 3.11.2 - The requirement to continuously monitor radiation levels in the SFP area was not added to the new specifications. No screening criteria apply for this requirement because the process variable of the LCO is not an initial condition of a DBA or transient analysis. Further, the SFP radiation levels only provide a backup source to a SFP problem. Other LCOs provide adequate verification of SFP primary indications (i.e., level and boron concentration) which ensure that all accident analysis assumptions are met. Since a fuel handling accident can only occur as a result of fuel movement, personnel would be stationed within the Auxiliary Building and immediately aware of a problem. Therefore, the requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This is a Ginna TS Category (iii) change.
- iii. TS 3.11.3 and 3.11.5 - The heavy load restriction for movement of loads over the SFP was not added to the new specifications. No screening criteria apply for this requirement because the heavy load limit of this LCO is not an initial condition of a DBA or transient analysis. The requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This change is consistent with WCAP-11618 (Ref. 52) and is a Ginna TS Category (iii) change.

- iv. TS 3.11.4 - The SFP water temperature limit was not added to the new specifications. No screening criteria apply for this requirement because the SFP water temperature limit of this LCO is not an initial condition of a DBA or transient analysis. The requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This is a Ginna TS Category (iii) change.
22. Technical Specification 3.12
- i. TS 3.12.1 - The requirement for the number of thimbles per quadrant required to OPERABLE during recalibration of the excore axial off-set detection system was not added to the new specifications. The requirements for this surveillance are not an initial assumption of any DBA or transient analysis. Therefore, this specification does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This is a Ginna TS Category (iii) change.
23. Technical Specification 3.13
- i. TS 3.13 - The requirements for snubbers operability were not added. Since snubbers testing is controlled within the Inservice Testing Program, the level of detail is relocated to the Inservice Inspection Program. This is a Ginna TS Category (iii) change.
24. Technical Specification 3.14
- None.
25. Technical Specification 3.15
- i. TS 3.15.1 - The LTOP exception during secondary side hydrostatic testing was relocated as a NOTE to new LCO 3.4.12. This is a Ginna TS Category (v.c) change.
 - ii. TS 3.15.1 - The PORV setpoint during LTOP conditions was relocated to the PTLR consistent with LCO 3.4.12. This is a Ginna TS Category (iii) change.
 - iii. TS 3.15.1 - The accumulators are now required to be isolated when the accumulator pressure is greater than the maximum RCS pressure for existing cold leg temperatures as specified in the PTLR consistent with Condition C of LCO 3.4.12. This new requirement prevents an accumulator from overpressurizing the RCS and causing an actuation of the LTOP System. The operator is instructed to isolate or depressurize the affected accumulator under these conditions. This is a Ginna TS Category (iv.a) change.

- iv. TS 3.15.1.1 - A new requirement was added when a PORV is inoperable during MODES 5 and 6 due to the increased consequences from an overpressurization event under these conditions. This new requirement specifies that the PORV must be restored to OPERABLE status within 72 hours. The limit of 72 hours with one PORV inoperable is consistent with the allowed outage time for one train of ECCS equipment during MODES 1, 2 and 3. This is a Ginna TS Category (iv.a) change.
- v. TS 3.15.1.3 - The reporting requirement for the low temperature overpressure protection (LTOP) system operation was revised. The reporting requirement to include documentation of all challenges to the pressurizer power operated relief valves is detailed in proposed TS 5.6.4, "Monthly Operating Reports" and is generally included in the LER requirements to report a RCS pressure transient that exceeds expected values or that is caused by unexpected factors. This is a Ginna TS Category (i) change.
- vi. TS 3.15 - The Applicability was revised to specify that LTOP is only required in MODES 5 and 6 when the reactor vessel head is on and the SG primary system manway and pressurizer manway are closed and secured in position. This change is consistent with the current requirements for isolating the SI pumps for LTOP conditions (3.3.1.7 and 3.3.1.8) and the ITS such that there is no real change in the MODE of Applicability. This is a Ginna TS Category (v.c) change.

26. Technical Specification 3.16

- i. TS 3.16.1 and Table 3.16-1 - The requirements for the radiological environmental program which provides measurements of radiation and of radioactive materials in those exposure pathways and for specified radionuclides which lead to the highest potential radiation exposures for members of the public were not added. This program is not related to protection of the public from any DBA or transient analysis. Further, this program is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- ii. TS 3.16.2 - The requirements for the land use census which supports the measurement of radiation and of radioactive materials in those exposure pathways and for those radionuclides which lead to the highest potential radiation exposures for members of the public were not added. This program is not related to protection of the public from any DBA or transient analysis. Further, this program is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- iii. TS 3.16.3 - The requirements of the interlaboratory comparison program which confirms the accuracy of the measurements of radiation and of radioactive materials in specified exposure pathways and for those radionuclides which lead to the highest potential radiation exposures for members of the public were not added. This program is not related to protection of the public from any DBA or transient analysis. Further, this program is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

27. Technical Specification 4.0

- i. A new section SR 3.0.1 was added which establishes the requirements and limitations that the SRs must meet during the MODES or other specified conditions in the Applicability for which the requirements of the LCO apply. This section does not provide any new requirements. Previous guidance provided by the NRC (e.g., Generic Letter 87-09) regarding the intent and interpretation of existing Specifications is consistent with SR 3.0.1. This SR provides clarifying and descriptive information for the SRs applicability consistent with the use and format of the ITS. This is a Ginna TS Category (v.a) change.

- ii. TS 4.0 - This was revised to clarify the basic application of the 25% extension to routine surveillances consistent with the use and format of the ITS. The interval extension concept is based on scheduling flexibility for repetitive performances. There are clarifications provided in SR 3.0.2 for Surveillances which are not repetitive in nature and essentially have no interval as measured from the previous performance. This precludes the ability to extend these performances. The existing Specification 4.0 can be interpreted to allow the extension to apply to all Surveillances. An additional clarification provides the basis for consistency in scheduling flexibility for all performances of periodic requirements, whether they are Surveillances or Required Actions. The intent remains to perform the activity, on the average, once during each specified interval. This section does not provide any new requirements but provides clarification and a description of SRs applicability consistent with the use and format of the ITS. This is a Ginna TS Category (v.c) change.

- iii. A new section SR 3.0.3 was added which establishes the flexibility to defer declaring affected equipment inoperable or an affected variable outside the specified limits when a Surveillance has not been completed within the specified Frequency. The SR permits the declaration of the LCO-not-met to be delayed for up to 24 hours or up to the limit of the specified Frequency (whichever is less), and eliminates confusion in applying the correct ACTION time limits at the end of this 24 hour period. The vast majority of surveillances performed demonstrate that systems or components, in fact, are OPERABLE. When a Surveillance is missed, it is primarily a question of OPERABILITY that has not been verified by the performance of the required surveillance. Based on consideration of plant conditions, adequate planning, availability of personnel, the time required to perform the Surveillance and the safety significance of the delay in completing the Surveillance, the NRC has concluded that 24 hours is an acceptable time limit for completing a missed Surveillance when the allowable outage times of the ACTIONS are less than the 24 hour limit or a shutdown is required to comply with ACTIONS (Ref. 53). This section, in part, provides new requirements consistent with the use and format of the ITS. This is a Ginna TS Category (iv.a) change.

- iv. A new section SR 3.0.4 was added which establishes the requirement that all applicable SRs must be met before entry into a MODE or other specified condition in the Applicability. This section does not provide any new requirements. Previous guidance provided by the NRC (e.g., Generic Letter 87-09) regarding the intent and interpretation of existing Specifications is consistent with SR 3.0.4. This SR provides clarifying and descriptive information for the SRs applicability consistent with the use and format of the ITS. This is a Ginna TS Category (v.a) change.

28. Technical Specification 4.1

- i. The following changes were made to TS 4.1.1 or Table 4.1-1:
 - a. Table 4.1-1, Columns 2 (Calibrate) and 3 (Test) - Various calibration and testing interval requirements for RTS and ESFAS Functions were revised consistent with NUREG-1431. Changes to the testing interval requirements different from those identified and discussed in NUREG-1431 are discussed with the specific changes to the Functional Units. This is a Ginna TS Category (v.b.15) change.
 - b. The following new requirements were added to Table 4.1-1 (Ginna TS Category (iv.a) changes):
 - 1. SR 3.4.2.2 - requires verification every 30 minutes that T_{avg} for each RCS loop is $> 540^{\circ}\text{F}$ when any RCS loop T_{avg} is known to be $< 547^{\circ}\text{F}$. This surveillance is intended to ensure that the minimum temperature for criticality is not exceeded when the RCS is at less than Hot Zero Power conditions (i.e., 547°F). The surveillance is not required to be performed if the low T_{avg} alarm in each loop is reset with a setpoint $> 540^{\circ}\text{F}$.
 - 2. SR 3.4.3.1 - requires verification every 30 minutes that RCS pressure, temperature, heatup and cooldown rates are within limits. This surveillance is only required during RCS heatup and cooldown operations, and inservice leak and hydrostatic testing. The 30 minute Frequency is based on the fact that heatup and cooldown rates are specified in hourly increments which provides adequate margin to correct minor deviations.

3. SR 3.4.1.1 - requires verification every 12 hours that pressurizer pressure is within limits during MODE 1. This surveillance is similar to current Ginna TS Table 4.1-1, #7 which is performed to support reactor trip functions.
4. SR 3.4.1.2 - requires verification every 12 hours that RCS average temperature is within limits during MODE 1. This surveillance is similar to current Ginna TS Table 4.1-1, #33 which is performed to support reactor trip functions.
5. SR 3.4.1.3 - requires performance of a precision heat balance to verify that RCS flow is within limits every 24 months. This surveillance is required to be performed within 7 days of entering MODE 1 and reaching 95% RTP.
6. SR 3.1.6.1 - Requires verification within 4 hours prior to criticality that the critical control bank position is within limits in the COLR.
7. SR 3.1.6.4 - Requires verification every 12 hours when critical that the sequence and overlap limits for the control banks not fully withdrawn are within limits specified in the COLR.
8. SR 3.1.8.3 - Requires verification every 30 minutes during MODE 2 PHYSICS TESTS that THERMAL POWER \leq 5% RTP. Verification of the THERMAL POWER level will ensure that the initial conditions of the safety analyses are not violated.
9. SR 3.2.4.1 - Verification with a calculation using the power range channels every 7 days that the QPTR is within limits.
10. SR 3.4.2.1 - requires verification within 30 minutes prior to achieving criticality that T_{avg} for each RCS loop is $> 540^{\circ}F$. This surveillance is intended to ensure that the minimum temperature for criticality is not exceeded just prior to achieving criticality.

- c. Table 4.1-1, Functional Units #1, #2, #3, #8, #17, #23, #25, #38a, #38b, #39, #40, #41a, and #41b - The notes or remarks which describe an operational detail, were not added. These details were relocated to the bases or are described in the UFSAR. This is a Ginna TS Category (iii) change.
- d. LCO 3.3.1, Table 3.3.1-1, Function #10 was added for the RCP Breaker Position. This function anticipates the Reactor Coolant Flow - Low trips by monitoring each RCP breaker position to avoid RCS heatup that would occur before the low flow trip actuates. The function ensures that protection is provided against violating the DNBR limit due to loss of flow in either a single loop or two loop configuration. This is a Ginna TS Category (iv.a) change.
- e. LCO 3.3.1, Table 3.3.1-1, Function #14 was added for the SI Input from ESFAS. This function ensures that if a reactor trip has not already been generated by the RTS, the ESFAS automatic actuation logic will initiate a reactor trip upon any signal that initiates SI. This is a condition of acceptability for the LOCA. A reactor trip is initiated every time an SI signal is present. This is a Ginna TS Category (iv.a) change.
- f. SR 3.3.1.14, SR 3.3.1.15, SR 3.3.1.16, SR 3.3.1.17, SR 3.3.1.18 were added for the Reactor Trip System Interlocks (P-6 through P-10). These surveillances are provided to ensure reactor trips are in the correct configuration for the current plant status. They are provided to back up operator actions to ensure protection system Functions are not bypassed during plant conditions under which the safety analysis assumes the Functions are not bypassed. This is a Ginna TS Category (iv.a) change.
- g. Table 4.1-1, Functions #34 and #35 - The requirements for the chlorine gas and ammonia gas instrumentation monitors for control room habitability were not added. No screening criteria apply for these requirements since the monitored parameters are not part of the primary success path in the mitigation of a DBA or transient. These monitors are not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA. Therefore, the requirements specified for these functions do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the TRM. This is a Ginna TS Category (iii) change.

- h. Table 4.1-1, Functional Units #1 and 2 were revised to require a CHANNEL OPERATIONAL TEST (COT) on the power range and the intermediate range channels within 7 days prior to reactor criticality. The ITS Bases states that the 7 day time limits is sufficient to ensure that the instrumentation is OPERABLE shortly before initiating the PHYSICS TESTS. This is a Ginna TS Category (iv.a) change.
- i. Table 4.1-1, Functional Unit #4 was revised to include a note requiring a channel check every 30 minutes while implementing MODE 2 PHYSICS TEST exceptions. Verification of the RCS temperature will ensure that the initial conditions of the safety analyses are not violated. This is a Ginna TS Category (iv.a) change.
- j. Table 4.1-1, Functional Units #18, #28, and #29 - The Surveillance requirements for radiation monitors R-1 through R-9 and R-17, emergency plan radiation instruments, and environmental monitors, were not added to the new specifications. These process variables are not an initial condition of a DBA or transient analysis. Therefore, the requirements specified for these functions do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- k. Not used.
- l. Table 4.1-1, Functional Unit #3 - This was revised to add a requirement which establishes a surveillance for a SRM CHANNEL CALIBRATION in MODE 6. This calibration consists of obtaining the detector plateau or preamp discriminator curves, evaluating those curves, and comparing the curves to baseline data and is consistent with current Ginna Station procedures. This is a Ginna TS Category (iv.a) change.
- m. Table 4.1-1, Functional Units #14, #16, and #19 were relocated to the TRM for the same reasons as described in Section D, items 12.i through 12.iv. These are Ginna TS Category (iii) changes.

- ii. The following changes were made to TS 4.1.2 or Table 4.1-2:
- a. Table 4.1-2, #6a was revised to extend the surveillance Frequency of the control rod exercises from monthly to every 92 days. The ITS Bases states that the 92 day Frequency takes into consideration the other information available to the operator in the control room and the channel check which is performed more frequently and adds to the determination of rod operability. This is a Ginna TS Category (v.b.29) change.
 - b. Table 4.1-2, #5 and #6b were revised to remove reference to once every 18 months or each refueling shutdown from the Frequency. These surveillances are only performed during a plant outage or during plant startup, prior to reactor criticality after each removal of the reactor head. This is a Ginna TS Category (v.c) change.
 - c. Table 4.1-2, Functional Unit #7 was revised to relocate the surveillance Frequency of the pressurizer safety valves to the IST Program consistent with SR 3.4.10.1. The Frequency continues to remain in a program requiring NRC approval. This is a Ginna TS Category (iii) change.
 - d. Table 4.1-2, Functional Unit #10 was not added to the new specifications. The requirement for verifying the refueling system interlocks is not an initial condition of a DBA or transient analysis. This requirement does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This change is consistent with WCAP-11618 (Ref. 52) and is a Ginna TS Category (iii) change.
 - e. Table 4.1-2, Functional Unit #13 was revised per SR 3.6.6.8 to require verification of the spray additive tank NaOH concentration once every 184 days instead of monthly. This change is acceptable since the spray additive tank is normally maintained isolated at power such that changes to the NaOH concentration or level are not expected. This is a Ginna TS Category (v.b.30) change.

- f. Table 4.1-2, Functional Unit #15 was revised to require RCS water inventory balances every 72 hours during steady state operation versus daily consistent with SR 3.4.13.1. This increased surveillance interval is considered acceptable based on the leakage detection systems required to be OPERABLE by LCO 3.4.15 and the various indications available to operators (e.g., volume control tank level and radiation alarms). This is a Ginna TS Category (v.b.31) change.
- g. Table 4.1-2, Functional Unit #17 was revised to only require verification of SFP boron concentration once every 31 days when fuel is stored in the SFP and the position of fuel assemblies which were moved in the SFP have not been verified. The current monthly requirement (regardless of the status of the SFP verification) is not reflected in the fuel handling accident analysis which does not credit the availability of soluble boron. This is a Ginna TS Category (v.b.32) change.
- h. Table 4.1-2, Functional Unit #19 - The trip function requirement for the Circulation Water Flood Protection was not added. The Circulation Water Flood Protection instruments only provide an anticipatory turbine trip and is not assumed in the Ginna Station safety analysis. These instruments do not monitor parameters which are initial assumptions for a DBA or transient, do not identify a significant abnormal degradation of the reactor coolant pressure boundary, and do not provide any mitigation of a design basis event. Therefore, the requirement specified for this function does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This is a Ginna TS Category (iii) change.
- i. The following new requirements were added to Table 4.1-2 (Ginna TS Category (iv.a) changes):
 - 1. SR 3.1.1.1 - Requires verification every 24 hours that the SHUTDOWN MARGIN is within the limits. The ITS Bases state that a Frequency of every 24 hours is based on the generally slow change in boron concentration and the low probability of an event occurring without the required SDM.

2. SR 3.1.3.1 - Requires verification prior to entering MODE 1 after each refueling that MTC is within the upper limit. The ITS Bases state that meeting the limit prior to entering MODE 1 ensures that the limit will also be met at higher power levels.
3. SR 3.1.3.2 - Requires verification prior to entering MODE 1 after each refueling that MTC will be within the 70% RTP MTC upper limit. The ITS Bases state that meeting the limit prior to entering MODE 1 ensures that the limit will also be met at higher power levels.
4. SR 3.1.8.3 - Require verification every 24 hours while implementing the MODE 2 PHYSICS TESTS exceptions that the SHUTDOWN MARGIN is within the limits. The ITS Bases state that a Frequency of every 24 hours is based on the generally slow change in boron concentration and the low probability of an event occurring without the required SDM.
5. SR 3.5.1.1 - requires verification every 12 hours that each accumulator motor-operated isolation valve is fully open above 1600 psig.
6. SR 3.5.1.3 - requires verification every 12 hours of an upper limit for the nitrogen pressure blanket in the accumulators to prevent lifting of the relief valve and overpressurization of the tank. A value of 790 psig was selected since it is above the accumulator pressure upper alarm setpoint of 760 psig and below the relief valve setpoint of 800 psig.
7. SR 3.5.1.4 - requires verification every 31 days on an STAGGERED TEST BASIS of an upper limit for boron concentration in the accumulator since this limit is used in determining the time frame which boron precipitation is addressed post LOCA. The value specified in the COLR was selected since this would not create the potential for boron precipitation in the accumulator assuming a containment (and accumulator) temperature of 60°F. This is also bounded by the containment sump pH calculations and assumptions used for chemical spray effects.

8. SR 3.5.1.5 - requires verification every 31 days that power is removed from the accumulator isolation valve operator above 1600 psig. This surveillance is consistent with current TS 3.3.1.1.i. A value of 1600 psig was selected (i.e., the same value as that for accumulator operability) since the RCS pressure interlock (i.e., P-11) as discussed in NUREG-1431 does not exist at Ginna Station. Therefore, there is no interlock signal to open the isolation valves in the event that they are closed.
9. SR 3.5.4.2 - requires verification every 7 days of an upper limit for boron concentration in the RWST since this limit is used in determining the time frame which boron precipitation is addressed post LOCA. The value specified in the COLR was selected since this would not create the potential for boron precipitation in the RWST assuming an Auxiliary Building (and RWST) temperature of 50°F. This is also bounded by the containment sump pH calculations and assumptions used for chemical spray effects.
10. SR 3.6.5.1 - requires verification every 12 hours that containment average air temperature is $\leq 120^{\circ}\text{F}$.
11. SR 3.6.6.8 - requires verification every 184 days that the spray additive tank volume is ≥ 4500 gallons.
12. SR 3.7.11.1 - requires verification every 7 days that ≥ 23 feet of water is available above the top of the irradiated fuel assemblies seated in the storage racks during fuel movement in the SFP. This verification is required since the fuel handling accident assumes that at least 23 feet of water is available with respect to iodine releases.
13. SR 3.7.13.1 and SR 3.7.13.2 - verification prior to fuel movement in the SFP that the associated fuel assembly meets the necessary requirements for storage in the intended region (e.g, enrichment limit, burnable poisons present). This verification is required to limit the amount of time that a fuel assembly could be misloaded in the SFP.

14. SR 3.7.6.1 - requires verification every 12 hours that the CST volume is $\geq 22,500$ gallons. This ensures that the minimum volume of condensate is available for the preferred AFW System following an accident.
15. SR 3.7.7.1 - requires verification every 31 days that each CCW manual and power operated valve in the CCW pump train or loop header flow path, that is not locked, sealed, or otherwise secured in position, is in the correct position. This Surveillance ensures that the CCW System is capable of performing its function following a DBA to provide cooling water to safety related components.
16. SR 3.7.7.2 - requires performance of a complete cycle of each CCW motor operated isolation valve to the RHR heat exchangers in accordance with the IST Program. This ensures that the normally closed motor operated valves are capable of being opened following a DBA.
17. SR 3.7.8.2 - requires verification every 31 days that each SW manual and power operated valve in the SW pump train or loop header flow path, that is not locked, sealed, or otherwise secured in position, is in the correct position. This Surveillance ensures that the SW System is capable of performing its function following a DBA to provide cooling water to safety related components.
18. SR 3.9.4.1 and 3.9.5.1 - requires verification every 12 hours in MODE 6 that one RHR loop is in operation and circulating reactor coolant. This ensures that the RCS is being mixed as assumed for boron dilution events and that decay heat removal continues during shutdown.
19. SR 3.9.3.1 - requires verification every 7 days that all containment penetrations which communicate to the outside environment are in their required state in MODE 6. This ensures that containment is in the correct state prior to and during fuel movement.
20. SR 3.6.3.1 - requires verification every 31 days that the mini-purge valves are closed, except when the penetration flow path is being used under administrative control. This ensures that the flow paths which provide a direct path from containment to the outside environment are in the correct position.

21. SR 3.7.8.1 - requires verification every 24 hours that the greenhouse bay water level and temperature are within limits. This ensures that the ultimate heat sink source is within the assumptions of the accident analyses.
22. SR 3.7.8.3 - requires verification every 31 days that all SW loop header cross-tie valves are in the correct position. This ensures that the valves are either locked opened or closed as necessary to support the accident analyses.
23. SR 3.5.2.7 - requires a visual verification every 24 months that the RHR containment sump suction inlet line is not obstructed and that the screen shows no evidence of structural distress or abnormal corrosion. This ensures that the RHR system will not become plugged by expected debris which may exist in containment post-LOCA.
24. SR 3.1.3.3 - requires verification prior to entering MODE 1 after each refueling that MTC will be within the EOL lower MTC limit. The ITS Bases state that meeting the limit prior to entering MODE 1 ensures that the limit will also be met at higher power levels.
25. SR 3.2.3.1 - requires verification every 12 hours that the AFD monitor is OPERABLE. This ensures that the AFD monitor is available to detect changes in AFD and provide necessary indication to operators.
26. SR 3.2.4.1 - requires verification every 12 hours that the QPTR monitor is OPERABLE. This ensures that the QPTR monitor is available to detect changes in QPTR and provide necessary indication to operators.
27. SR 3.6.6.5 - requires verification every 31 days that cooling water is flowing through each CRFC unit. This ensures that the heat removal capability of the CRFC units is verified to be available as assumed in the accident analyses.
28. SR 3.5.2.3 - requires verification every 31 days that each breaker or key switch is in the correct position of valves required to be depowered or powered. This ensures that no single active failure will fail both ECCS trains.

- j. Table 4.1-2, Functional Units #1 and #2 - These were not added to the new specifications for the reasons discussed in Section D, item 11.i. This is a Ginna TS Category (iii) change.
 - k. Table 4.1-2, Functional Unit #16 - This was revised to only require a verification of DG fuel oil inventory once every 31 days instead of daily. Since the storage tanks are of passive design and are provided with various level alarms, verification every 31 days is considered adequate. This is a Ginna TS Category (v.b.33) change.
 - l. Table 4.1-2, Functional Unit #4 - This was relocated to the TRM for the same reasons as described in Section D, item 12.iv. This is a Ginna TS Category (iii) change.
 - m. Table 4.1-2, Functional Unit #12. - This was relocated to the IST Program since it does not meet any of the requirements for inclusion in the ITS. This is a Ginna TS Category (iii) change.
 - n. Table 4.1-2, Functional Unit #18 - The Frequency for determining gross specific activity of the secondary system was revised from once every 72 hours to once every 31 days. In addition, the determination of I-131 was also changed to once every 31 days independent of the last activity level since the current Ginna TS allow up to 6 months between tests. These changes are all consistent with NUREG-1431. This is a Ginna TS Category (v.b.51) change.
- iii. The following changes were made to TS 4.1.3 or Table 4.1-3:
- a. Table 4.1-3 - The Post Accident Monitoring Instrumentation Functions required by this specification were revised to include only Regulatory Guide 1.97, Type A and Category 1 variables. These Functions are denoted in UFSAR Table 7.5-1 and have been previously reviewed and approved by the NRC (Ref. 35). This is a Ginna TS Category (v.c) change.

iv. The following changes were made to TS 4.1.2 or Table 4.1-4:

- a. Table 4.1-4, Functional Unit #1 was revised per SR 3.4.16.1 to only require verification of reactor coolant gross specific activity once every 7 days when $T_{avg} \geq 500^{\circ}\text{F}$ versus once every 72 hours above Cold Shutdown (i.e., $T_{avg} \geq 200^{\circ}\text{F}$). The increased surveillance interval is acceptable based on the small probability of a gross fuel failure during the additional 4 days. Fuel failures are more likely to occur during startup or fast power changes and not during steady state power operation during which the majority of sampling is performed. Gross fuel failures will also result in Letdown radiation alarms and possibly containment radiation alarms providing additional operator indication. Only requiring this surveillance when $T_{avg} \geq 500^{\circ}\text{F}$ provides consistency with the LCO Applicability. This is a Ginna TS Category (v.b.34) change.
- b. Table 4.1-4, Functional Unit #2 was revised per SR 3.4.16.2 to require verification of DOSE EQUIVALENT I-131 when $T_{avg} \geq 500^{\circ}\text{F}$ instead of above 5% reactor power. This conservative change provides consistency with the LCO Applicability. This is a Ginna TS Category (v.a) change.
- c. Table 4.1-4, Functional Unit #3 was revised per SR 3.4.16.3 to delay determination of E until 31 days after a minimum of 2 effective full power days and 20 days of MODE 1 operation following the reactor being subcritical for ≥ 48 hours. The 31 days was added to ensure that radioactive materials are at equilibrium in order to provide a true representative sample for E determination and eliminate possible false samples. This is a Ginna TS Category (v.b.53) change.

v. The following changes were made to TS 4.1.4 or Table 4.1-5:

- a. Table 4.1-5, Functional Unit #3b was revised to require a channel check of particulate sampler R-11 every 12 hours versus weekly. This is required since R-11 is being used to monitor RCS leakage and may be the only installed system OPERABLE to perform this task for up to 30 days per new LCO 3.4.15.

- b. TS 4.1.4 and Table 4.1-5 - The Radioactive Effluent Monitoring Instrument Functions required by this specification were not added to the new specifications since these process variables are not an initial condition or a DBA or transient analysis. Therefore, the requirements specified for these functions do not satisfy the NRC Final Policy Statement technical specification screening criteria and were relocated to the ODCM and the Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- c. TS 4.1-5, Functional Unit #3a and #3b were revised to only require the functional test of the valves actuated by R-11 and R-12 once every 24 months versus quarterly. This change is consistent with NUREG-1431 and is considered acceptable since these channels are redundant to the containment isolation signal. As such the accident analysis do not take specific credit for R-11 and R-12 to isolate the containment purge valves. Also, a functional test of the channels (minus actuation of the valves) is to be done quarterly. This is a Ginna TS Category (v.b.49) change.
- d. The CHANNEL CHECK of R-11 was revised from weekly to daily in MODES 1, 2, 3, and 4, and during MODE 6 when required by LCO 3.9.3. This is a conservative change which requires R-11 and r-12 to be checked at the same frequency. This is a Ginna TS Category (v.a) change.
- e. Table Note 5 was deleted since requiring that the CHANNEL CALIBRATION be traced back to the National Bureau of Standards is not a necessary level of detail to be contained in TS. NUREG-1431 does not contain this level of detail since it does not meet any of the four criteria. Therefore, this Note is relocated to plant procedures. This is a Ginna TS Category (iii) change.

29. Technical Specification 4.2

- i. TS 4.2.1 - The specific requirements for the Inservice Inspection Program, which include Quality Groups A, B, and C components, high energy piping outside of containment, snubbers and steam generator tubes, were not added. The level of detail is relocated to licensee controlled documents (Ginna Station QA Manual, Appendix B) and a more generic description is provided. This is a Ginna TS Category (iii) change.

- ii. TS 4.2.1 - The title of the "Ginna Station QA Manual" was changed to "Nuclear Policy Manual" since this is the location of the IST Program per Reference 64. This is a Ginna TS Category (vi) change.

30. Technical Specification 4.3

- i. TS 4.3.5.6 - This surveillance was not added for the reasons discussed under Section C, item 6.xi. This Surveillance has been relocated to the TRM. This is a Ginna TS Category (iii) change.
- ii. TS 4.3.5.3.b - This surveillance was not added since performance of pump testing in accordance with the Inservice Testing program should not be required for an operating RHR pump. The status of a non-operating RHR pump is assured by new SR 3.4.6.3 which requires the verification of the breaker alignment and indicated power available to the pump. The Inservice Testing program testing is mainly performed to ensure adequate performance during accident conditions which far exceeds the requirements during shutdown conditions. This test is not necessary to ensure operability during MODE 4 operations. However, this Surveillance is required for ECCS during MODE 4 (see new SR 3.5.3.1) This is a Ginna TS Category (v.c) change.
- iii. TS 4.3 - The following new requirements were added (Ginna TS Category (iv.a) change):
 - a. SR 3.4.6.3, 3.4.7.3 and 3.4.8.2 - Requires the verification of correct breaker alignment for the non-operating, but required, RHR pump in MODES 4 and 5.
 - b. SR 3.4.9.2 - Requires verification that the total capacity of the pressurizer heaters is ≥ 100 KW once every 92 days.
 - c. SR 3.4.11.2 - Requires a complete cycle of each PORV using the nitrogen system once every 24 months.

- iv. TS 4.3.3.1, 4.3.3.2, and 4.3.3.3 - The requirement that the leakage tests be performed with a minimum test differential pressure of 150 psid was not added to the new specifications. The bases for new LCO 3.4.14 reference ASME, Section XI (Ref. 53) which provides acceptable guidance for performing these leakage tests. This includes adjusting the observed leakage rates for tests that are not conducted at the maximum differential pressure by assuming that leakage is directly proportional to the pressure differential to the one half power. This is a conservative change in most cases since it requires that the PIVs be tested under the maximum differential pressure conditions. This is a Ginna TS Category (v.c) change.
- v. TS 4.3.3.4 - The allowed leakage rates for PIVs was adjusted from a single value for all valves to a value based on valve size consistent with SR 3.4.14.1 and SR 3.4.14.2. This change provides greater information of valve degradation and removes an unjustified penalty on larger valves (Ref. 54). This is a Ginna TS Category (v.c) change.
- vi. TS 4.3.5.5 - This surveillance was not added during MODE 1 operation since there is a reactor trip function which protects the SG level. This is a Ginna TS Category (i) change.
- vii. TS 4.3.1.1 - This requirement was not added to the new specifications since it only states that the reactor vessel must be tested in accordance with 10 CFR 50, Appendix H. Since this requirement is already specified in the CFR, it does not have to be retained with the TS and was deleted. This is a Ginna TS Category (ii) change.
- viii. TS 4.3.3.1 - This was modified to remove the requirement to test the SI cold leg injection and RHR RCS PIVs each cold shutdown. At Ginna Station, these flowpaths are only used for emergency injection (i.e., they are not relied upon or used during cold shutdown conditions). Since the valves are maintained closed at all times, requiring a leak test within 24 hours of being opened or having maintenance performed, and once every 24 months provides adequate protection. A leakage test every 24 months is also consistent with NRC approved OMa-1988. This is a Ginna TS Category (v.b.35) change.
- ix. TS 4.3.4.2 - This was revised to limit the exclusion for testing of the PORV block valves from when "the valve is closed," to "when the valve is closed due to PORV leakage > 10 gpm." This ensures that the block valve is tested under all conditions except those that could potentially result in a plant transient. This is a conservative change. This is a Ginna TS Category (v.a) change.

31. Technical Specification 4.4

- i. TS 4.4.4 - The requirements for the tendon stress surveillances were not added. The level of detail is relocated to the Pre-stressed Concrete Containment Tendon Surveillance Program described in new Specification 5.5.6 and a more generic program description is provided. This is a Ginna TS Category (iii) change.
- ii. TS 4.4.3 - The requirements for the testing of the portion of the RHR system in the recirculation configuration were not added. The level of detail is relocated to the Primary Coolant Sources Outside Containment Program described in new Specification 5.5.2 and a more generic program description is provided. This is a Ginna TS Category (iii) change.
- iii. TS 4.4.1 (except definition for L_a), 4.4.2.1, 4.4.2.2, and 4.4.2.4 - These were not added to the new specifications since this information is contained in 10 CFR 50, Appendix J and does not need to be retained within technical specifications. SRs 3.6.1.1 and 3.6.1.2 provide for the necessary relation from technical specifications to Appendix J (see also Reference 63). These are Ginna TS Category (ii) changes.
- iv. TS 4.4.2.3.a and 4.4.2.3.b - These were revised to require that if the allowed 10 CFR 50, Appendix J leakage limits are exceeded, they must be restored within 1 hour versus 48 hours consistent with LCO 3.6.1. However, the leakage limit of $< 0.6 L_a$ was revised to be consistent with the new Appendix J rule and implementation guidance (i.e., the leakage limit is $< 0.6 L_a$ on a maximum pathway leakage rate basis prior to entering MODE 4 for the first time following each refueling outage and $< 0.6 L_a$ on a minimum pathway leakage rate basis for all other time periods) (see also Reference 63). This is a Ginna TS Category (v.a) change.
- v. TS 4.4.2.4.c - A specified air lock leakage acceptance criteria of $\leq 0.05L_a$ when tested at $\geq P_a$ was added to the new specifications. This acceptance criteria is required to be retained within technical specifications by 10 CFR 50, Appendix J, Section III.D.2(iv) and is consistent with NUREG-1431 and current testing requirements. In addition, a new Surveillance was added to verify that only one door in each airlock can be opened at a time once every 24 months. This test is necessary to ensure that the OPERABILITY of the airlocks, as defined in the new bases for LCO 3.6.2 is maintained. These are Ginna Category (iv.a) changes.

- vi. TS 4.4.2.3.c - The requirement to perform an engineering evaluation if the mini-purge supply and exhaust lines isolation valve leakage exceeds 0.05 L_g was revised to require isolation of the affected penetration within 24 hours. In addition, the affected penetration must be verified isolated once every 31 days if it is outside containment, or once every 92 days if it is inside containment. These changes provide direct guidance to operators which are consistent with NUREG-1431. This is a Ginna TS Category (v.c) change.
- vii. TS 4.4.5.1 - Two new surveillances (SR 3.6.3.2 and SR 3.6.3.3) were added which require verification of the correct position of containment isolation barriers located outside containment once every 92 days and inside containment prior to entering MODE 4 from MODE 5 if it has not been performed within the previous 92 days. These surveillances ensure that the containment isolation barriers remain OPERABLE above MODE 5. These are Ginna TS Category (iv.a) changes.
- viii. TS 4.4.6.2 - The Surveillance Frequency for automatic containment isolation valves has been revised from 18 to 24 months (see Section D, item 1.xii). The response times for CIVs is discussed in the bases for new LCO 3.6.3. This is a Ginna TS Category (v.b.1) change.
- ix. TS 4.4 - Two new Surveillances were added with respect to the hydrogen recombiners (SR 3.6.7.1 and SR 3.6.7.2). The first new Surveillance requires a functional check of the hydrogen recombiners once every 24 months. The second new Surveillance requires that a CHANNEL CALIBRATION be performed on the hydrogen recombiner actuation and control channels once every 24 months. The performance of these SRs ensures that the hydrogen recombiners are OPERABLE and capable of performing their post-accident function. These are Ginna TS Category (iv.a) changes.
- x. TS 4.4.7 - The Frequency for performance of a CHANNEL CHECK of the hydrogen monitors was revised from daily to monthly. In addition, the Frequency for CHANNEL CALIBRATIONS was revised from quarterly to every 24 months. These changes are consistent with NUREG-1431 and are justified by industry experience. These are Ginna TS Category (v.b.21) changes.

32. Technical Specification 4.5

- i. TS 4.5.1.1.a - This was revised to delete the statement that the SI and RHR pumps are prevented from starting during this test. Since these components have recirculation lines available, this statement is not required. This is a Ginna TS Category (v.c) change.
- ii. TS 4.5.2.1 - This was revised to relocate all SI, RHR, and CS pump testing frequencies and discharge pressure requirements to the Inservice Testing program described in new Specification 5.5.8 consistent with the ITS. These are Ginna TS Category (iii) changes, respectively.
- iii. TS 4.5.2.2.c - The test related to accumulator check valve testing for operability every refueling shutdown was relocated to the Ginna Station Inservice Testing program. The valves are currently partially stroke tested quarterly and refurbished every six years. Leakage associated with these check valves is addressed by SR 3.5.1.2. This is a Ginna TS Category (iii) change.
- iv. The following new ITS testing requirements were added (Ginna TS Category (iv.a) change):
 - a. SR 3.5.2.1 - requires verification every 12 hours that ECCS related isolation valves are in their required position. These valves are currently specified in TS 3.3.1.1.g, 3.3.1.1.i, and 3.3.1.1.j.
 - b. SR 3.5.2.2 - requires verification every 31 days that ECCS related valves which are not locked, sealed, or otherwise secured in position are in their correct position.
- v. TS 4.5.2.3 - The requirements denoting the Frequency and conditions of the air filtration system tests were not added to the new specifications. This level of detail is relocated to the Ventilation Filter Testing Program described in new Specification 5.5.10. In addition, the remaining requirements were all relocated to the Administrative Controls section. These are Ginna TS Category (iii) and (i) changes, respectively.
- vi. TS 4.5.2.3.6.a - These test requirements were revised to clarify that two separate tests are performed. A HEPA filter test and a charcoal adsorber bank test are separately performed with each requiring a limit of less than 3 inches of water. This is essentially equivalent to a combined test of less than 6 inches of water and is consistent with specified testing standards. This is a Ginna TS Category (vi) change.

- vii. TS 4.5.1.2 - Two new Surveillances (SR 3.6.6.1 and SR 3.6.6.2) were added to verify the correct position of each manual, power operated, and automatic valve in the NaOH and CS flowpath that is not locked, sealed, or otherwise secured in position. This Surveillance ensures that the NaOH and CS Systems are OPERABLE in accordance with the LCO. These are Ginna TS Category (iv.a) changes.
- viii. TS 4.5.1.2.b - The Frequency of performing the spray nozzle gas test was revised from once every 5 years to once every 10 years consistent with SR 3.6.6.14. The increased surveillance interval is considered acceptable due to the passive nature of the spray nozzles and previous acceptable results. This is a Ginna TS Category (v.b.36) change.
- ix. TS 4.5.2.3.5 - This was revised to only require actuation of the post-accident charcoal filter dampers from an actual or simulated SI signal once every 24 months to ensure that the system aligns itself correctly (SR 3.6.6.15). The post-accident charcoal filter dampers must still be opened at least once per 31 days to allow the system to operate for ≥ 15 minutes. Consequently, only the frequency of the automatic alignment of the dampers is being revised to provide consistency with other specifications. This is a Ginna TS Category (v.b.37) change.
- x. TS 4.5.2.2.a - This was revised to adjust the testing Frequency of the spray additive valves from monthly to once every 24 months consistent with SR 3.6.6.16. This increased testing interval is acceptable since the system only needs to be verified that it can actuate on an actual or simulated SI signal on a refueling basis similar to the SI and RHR systems. Any additional valve testing is addressed by the IST program. In addition, a new Surveillance (SR 3.6.6.12) was added to verify that the CS motor operated isolation valves actuate to their correct position once every 24 months following an actual or simulated SI signal. Finally, a new Surveillance (SR 3.6.6.17) was added to verify that the spray additive flow rate is within limits once every 5 years. These changes ensure that the CS and spray additive tank LCOs continue to be met. These are Ginna TS Category (v.b.38) changes.
- xi. TS 4.5.2.3.3 and 4.5.2.3.4 - These were revised to require that each CRFC unit be operated for ≥ 15 minutes once every 31 days (SR 3.6.6.4). This test will ensure that the CRFC units are OPERABLE in accordance with the LCO. In addition, a new Surveillance is also required once every 24 months to ensure that the CRFC units start on an actual or simulated SI signal. These tests will ensure that the CRFC units are OPERABLE in accordance with the LCO. These are Ginna TS Category (v.a) changes.

xii. TS 4.5.2.3.9 - This was revised to require a test of the automatic actuation capability of the CREATS once every 24 months. This verification is necessary to ensure that the control room environment can be isolated in the event of a radiological release. This is a Ginna TS Category (iv.a) change.

33. Technical Specification 4.6

i. TS 4.6.1.a - The cold or refueling requirements (MODES 5 and 6) for demonstrating DG operability have been revised to include (1) verification of DG day tank fuel oil level, (2) verification of the onsite supply of fuel oil, and (3) operation of the fuel oil transfer system. These are consistent with the required surveillances for DG operability in MODES 1, 2, 3, and 4 and provide assurance that the DG is OPERABLE. This is a Ginna TS Category (iv.a) change.

ii. TS 4.6.1.b.6 - The requirement to verify that the DG is aligned to provide standby power to the associated emergency buses was not added. This requirement is within the definition of an OPERABLE DG and is denoted in the bases of new TS 3.8.1. This is a Ginna TS Category (i) change.

iii. TS 4.6.1.c - The requirement to perform the tests in Specification 4.6.1.b prior to exceeding cold shutdown was not added. This requirement was replaced with a general provision (new SR 3.0.4) that restricts entry into a MODE or other specified condition in the Applicability of an LCO unless the LCO's surveillances have been met. This is a Ginna TS Category (i) change.

iv. TS 4.6.1.d - The diesel fuel oil test requirements were relocated to new TS 5.5.12 and are proposed to be identified as a "program" consistent with the format of NUREG-1431. In addition, the fuel oil testing program was revised to expand the testing requirements consistent with NUREG-1431 and delete the 92 day test of the stored fuel oil. The fuel oil must now be tested before being placed in the storage tanks such that testing of viscosity, water, and sediment after being placed in the storage tanks is no longer required. This is a conservative change which reduces the potential to harm the safety related diesel generators from "bad" fuel oil. This is a Ginna TS Category (v.a) change.

- v. TS 4.6.1.e.1 - The requirement to inspect the DG in accordance with the manufacturer's recommendations was not added. No screening criteria apply for this requirement since DG inspections are not part of the primary success path assumed in the mitigation of a DBA or transient. The requirement does not satisfy the NRC Final Policy Statement technical specification screening criteria and is relocated to the TRM. This is a Ginna TS Category (iii) change.
- vi. TS 4.6.1.e.3(b) - The requirement for DG testing simulating a loss of offsite power in conjunction with a safety injection test signal was revised. Details of the test acceptance criteria were relocated to plant procedures since this level of detail is not typically specified in the SR. This is a Ginna TS Category (iii) change.
- vii. TS 4.6.2.a and 4.6.2.b - The station battery testing requirements were revised to add acceptance criteria, parameters, and associated actions for battery operability supporting DC electrical power subsystems. These requirements are provided in the SRs and enhance the current criteria specified in the TS and is a conservative change regarding the definition of battery OPERABILITY. In addition, the electrolyte temperature is only to be measured every 92 days versus monthly consistent with IEEE-450 requirements. These are Ginna TS Category (iv.a) and (v.a) changes, respectively.
- viii. TS 4.6.2.f. - The details denoting battery degradation were moved to the bases and were revised to include expected life parameters of the battery when compared to a capacity criteria of 100% of the manufacturer's rating. This criteria is used in conjunction with identifying when the surveillance Frequency must be increased and is consistent with ITS. These are Ginna TS Category (iii) and (v.a) changes, respectively.
- ix. TS 4.6.2 - Two new surveillances (SR 3.8.4.1 and SR 3.8.5.1) were added which require verification every 7 days that the battery terminal voltage is ≥ 129 V of float voltage during operating and shutdown conditions. This surveillance ensures that the required battery charger remains capable of maintaining DC system loads and a float charge on the battery. This is a Ginna TS Category (iv.a) change.
- x. TS 4.6.2.c - The requirement for trending battery test data was not added to the new specifications since this is trending must be performed to meet the Frequency requirements for SR 3.8.6.2 and SR 3.8.4.3. Therefore, this requirement is relocated to plant procedures. This is a Ginna TS Category (iii) change.

- xi. TS 4.6.1.b.4 - this was revised to require that the one hour monthly DG run must be performed after successful performance of the monthly DG start (i.e., TS 4.6.1.b.4) or the refueling outage test (i.e., TS 4.6.1.e.4). This ensures that the DG is not being unnecessarily started for the performance of the one hour run. This change is consistent with current testing practices and NUREG-1431. This is a Ginna TS Category (iv.a) change.
- xii. TS 4.6.1.b.4, 4.6.1.e.2, and 4.6.1.e.3 - These were revised to add a note to the surveillance which specifically states that credit may be taken for unplanned events that satisfies these SRs. This is consistent with current operating practice and NUREG-1431 since if a loss of offsite power were to occur requiring a DG run, it should be able to satisfy the surveillance if it meets all of the testing requirements. This also prevents unnecessary tests of the DGs which can lead to potential degradation. This is a Ginna TS Category (v.c) change.

34. Technical Specification 4.7

- i. TS 4.7 was revised to include a surveillance to ensure that each MSIV can close on an actual or simulated actuation signal every 24 months consistent with NUREG-1431 and current Ginna Station TS Table 3.5-2 which require that the isolation signals to the MSIVs be OPERABLE. In addition, Required Actions were provided in the event that the MSIVs cannot close as required by this Surveillance. These actions require restoration of, or closure of an inoperable MSIV, within 24 hours. In the event that both MSIVs are inoperable, the plant must enter LCO 3.0.3. Finally, requirements for the main steam non-return check valves were added. These are Ginna TS Category (iv.a) changes.

35. Technical Specification 4.8

- i. TS 4.8.1 and 4.8.2 - The Frequency of the AFW pump tests was changed from monthly to as defined in the Inservice Testing Program consistent with ASME, Section XI requirements. The acceptance criteria was also relocated to Inservice Testing Program consistent with NUREG-1431. This program provides sufficient control for these testing activities. In addition, all OPERABILITY requirements (e.g., required pump flowrates) were relocated to the LCO bases consistent with the ITS Writer's Guide. These are Ginna TS Category (iii) and (i) changes, respectively.

- ii. TS 4.8.3 - This Surveillance was revised to relocate the Frequency of testing the AFW suction and discharge valves to the Inservice Testing Program which provides sufficient control of these testing activities. In addition, the cross-over motor operated isolation valves were not added to the new specifications since these valves are not credited in the accident analyses (see bases for new LCO 3.7.5). These are Ginna TS Category (iii) and (v.b.39) changes, respectively.
- iii. TS 4.8.4 - The Frequency of the SAFW pump tests was changed from monthly to as defined in the Inservice Testing Program consistent with ASME, Section XI requirements. The acceptance criteria was also relocated to Inservice Testing Program consistent with NUREG-1431. This program provides sufficient control for these testing activities. In addition, all OPERABILITY requirements (e.g., required pump flowrates) were relocated to the LCO bases consistent with the ITS Writer's Guide. These are Ginna TS Category (iii) and (i) changes, respectively.
- iv. TS 4.8.5 - This Surveillance was revised to relocate the Frequency of testing the SAFW suction, discharge, and cross-over valves to the Inservice Testing Program which provides sufficient control of these testing activities consistent with NUREG-1431. This is a Ginna TS Category (iii) change.
- v. TS 4.8.6 - This was revised to relocate the acceptance criteria for the AFW and SAFW tests to the actual procedures performing these tests. The new bases identify what is required for OPERABILITY of the AFW and SAFW Systems such that specifying this acceptance criteria is unnecessary. In addition, both the bases and test procedures are controlled under 10 CFR 50.59. This is a Ginna TS Category (iii) change.
- vi. TS 4.8 - A new Surveillance was added requiring verification every 31 days of the correct position of each AFW and SAFW manual, power operated and automatic valve in the flow path that is not locked, sealed or otherwise secured in position. This verification is required to ensure that the AFW and SAFW Systems are OPERABLE when not in service. This is a Ginna TS Category (iv.a) change.
- vii. TS 4.8.10-- The requirement to measure the response time of the AFW pumps and valves to be ≤ 10 minutes once every 18 months was not added to the new specifications. The time requirements for the AFW System are described in the new bases. While some accidents do not require AFW for 10 minutes, the small break LOCA and loss of feedwater transients require AFW within much shorter time frames. Therefore, this Surveillance is not accurate and is not required. This is a Ginna TS Category (v.b.40) change.

36. Technical Specification 4.9

- i. TS 4.9 - This was revised to include an LCO requirement that the measured core reactivity be within 1% $\Delta k/k$ of the predicted values and to add a specific surveillance Frequency of every 31 EFPD after the initial normalization. The Surveillance Requirement was divided into two surveillances to clarify the difference between the initial normalization and the monthly verification. These are Ginna TS Category (v.c) changes.

37. Technical Specification 4.10

- i. TS 4.10.1 and Table 4.10-1 - The requirements for the radiological environmental program which provides measurements of radiation and of radioactive materials in specified exposure pathways and for those radionuclides which lead to the highest potential radiation exposures for members of the public were not added. This program is not related to protection of the public from any DBA or transient analysis. Further, this program is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.
- ii. TS 4.10.2 - The requirements for the land use census which supports the measurement of radiation and of radioactive materials in those exposure pathways and for those radionuclides which lead to the highest potential radiation exposures for members of the public were not added. This program is not related to protection of the public from any DBA or transient analysis. Further, this program is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- iii. TS 4.10.3 - The requirements of the interlaboratory comparison program which confirms the accuracy of the measurements of radiation and of radioactive materials in specified exposure pathways and for those radionuclides which lead to the highest potential radiation exposures for members of the public were not added. This program is not related to protection of the public from any DBA or transient analysis. Further, this program is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

38. Technical Specification 4.11

- i. TS 4.11.1 - The requirements denoting the Frequency and conditions of the SFP filtration system tests were not added. The level of detail is relocated to the VFTP described in new Specification 5.5.10. This is a Ginna TS Category (iii) change.
- ii. TS 4.11.1.1.a, 4.11.1.1.b, and 4.11.1.1.c - These charcoal adsorber system testing requirements were relocated to the VFTP described in the Administrative Controls (TS 5.5.10). This is a Ginna TS Category (i) change.
- iii. TS 4.11.1.1.d - This was not added to the new specifications since this verification is not required to ensure that initial assumptions of the accident analyses are still met. The SFP Charcoal Absorber System does not utilize heaters. The bases for SR 3.7.13.1 state that operating the ventilation system for ≥ 15 minutes every 31 days for systems without heaters is to ensure system operation. In accordance with new LCO 3.7.10 (NUREG-1431 LCO 3.7.13), the ABVS is required to be in operation during fuel movement within the Auxiliary Building. As such, the ABVS is not a standby system at Ginna Station (i.e., the system must be both OPERABLE and in operation during its MODE of Applicability). Therefore, a monthly verification provides no verification of any accident analysis assumption. Instead, two new Surveillances were added which require verification every 24 hours that the Auxiliary Building operating floor level is at a negative pressure with respect to the outside environment and that the ventilation system is in operation. These verifications are consistent with plant practices and ensures that initial assumptions of the fuel handling accident are being maintained. The change is also consistent with Reference 55. This is a Ginna TS Category (v.c) change.

- iv. TS 4.11.2.1 - This was revised to only require verification of RHR pump OPERABILITY once every 12 hours versus 4 hours consistent with SR 3.9.3.1. A Frequency of 12 hours is adequate due to the alarms and indications available to the operators with respect to RHR pump and loop performance. This is a Ginna TS Category (v.b.41) change.
- v. TS 4.11.2.2 - This was revised to remove the requirement for an Inservice Test of the RHR pumps. An Inservice Test should not be required for an operating pump. The status of a non-operating RHR pump is assured by new SR 3.9.4.2 which requires the verification of the breaker alignment and indicated power available to the pump. The Inservice Testing program test is mainly performed to ensure adequate performance during accident conditions which far exceeds the requirements during normal conditions. This test is not necessary to ensure OPERABILITY during MODE 6 operations. This is a Ginna TS Category (v.b.42) change.
- vi. TS 4.11.3.1 - This was revised to only require a verification of the water level in the reactor cavity within 24 hours of fuel movement versus 2 hours. The new TS usage rules state that a SR is to be continuously performed at its required Frequency. However, the SR is only required to be performed when in the MODE of Applicability. Therefore, a SR with a Frequency of 24 hours must have been performed within 24 hours before entering the MODE of Applicability. A Frequency of 24 hours is acceptable due to the large volume of water available and the procedural controls in place. This is a Ginna TS Category (v.c) change.

39. Technical Specification 4.12

- i. TS 4.12.1.1 and Table 4.12-1 - The requirements for radioactive material released in liquid effluents to unrestricted areas which are limited to the concentrations specified in 10 CFR Part 20, Appendix B, Table II, Column 2, were not added. No screening criteria apply for these requirements because the process variable of the LCO is not an initial condition of a DBA or transient analysis. Further, liquid releases during normal operation are a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- ii. TS 4.12.1.2 - The requirements for the liquid radwaste treatment system which controls the release of site liquid effluents during normal operational occurrences consistent with 10 CFR Part 50, Appendix A, GDC 60 and 10 CFR Part 50, Appendix I, Section II.D, were not added. No loss of primary coolant is involved, neither is an accident condition assumed or implied. Further, the loss of the system is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- iii. TS 4.12.2.1 and Table 4.12-2 - The requirements which assure compliance with 10 CFR Part 20 for the dose rate due to radioactive material released in gaseous effluents beyond the site boundary were not added. No screening criteria apply because the process variable of the LCO is not an initial condition of a DBA or transient analysis. Further, gaseous effluent dose rate during normal operation is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- iv. TS 4.12.2.2 - The requirements for dose due to noble gases released in gaseous effluents during normal operation over extended periods were not added. These limits are not related to protection of the public from any DBA or transient analysis. Further, gaseous effluents dose (noble gas) values is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

- v. TS 4.12.3 - The requirements for the gaseous waste treatment system which reduces the activity level in gaseous waste prior to discharge to the environs were not added. The ventilation exhaust system is not assumed in the analysis of any DBA or transient. Further, the system is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM and the Radioactive Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. This is a Ginna TS Category (iii) change.

40. Technical Specification 4.13

- i. TS 4.13 - The requirements for periodic testing of leakage for radioactive sources were not added. The source leak test are not assumed in the analysis of any DBA or transient. Further, the leakage from radioactive sources is a non-significant risk contributor to core damage frequency and offsite release. Therefore, the requirements specified for this function do not satisfy the NRC Final Policy Statement technical specification screening criteria and are relocated to the ODCM. This is a Ginna TS Category (iii) change.

41. Technical Specification 4.14

- i. TS 4.14 - The requirements for the testing of snubbers were not added. Since snubbers testing is controlled within the Inservice Testing Program, the level of detail is relocated to Inservice Testing Program described in new Specification 5.5.7 and more generic program description is provided. This is a Ginna TS Category (iii) change.

42. Technical Specification 4.15

None.

43. Technical Specification 4.16

- i. TS 4.16 - A new surveillance was added which requires verification once within 12 hours and every 12 hours thereafter that an accumulator's motor operated isolation valve is closed when its pressure is greater than or equal to the pressure allowed by the P/T limit curves provided in the PTLR consistent with SR 3.4.12.3. In addition, a verification once within 12 hours and every 31 days thereafter that power is removed to these isolation valves is also added. These verifications are needed to ensure that the accumulator does not discharge into the RCS and cause an overpressure event which challenges the LTOP System. This is a Ginna TS Category (iv.a) change.

- ii. TS 4.16.1.a - This surveillance was revised to delay performance of the PORV functional channel test until 12 hours after decreasing to the LTOP enable temperature specified in the PTLR instead of within 31 days prior to entering the LTOP System Applicability. This change eliminates the performance of the functional test when RCS is between 330°F (the LTOP enable temperature) and 350°F (MODE 3 lower limit) during forced shutdowns. Instead, the test can be performed within 12 hours of entering the specified condition and reduces the immediate operator burden. This is a Ginna TS Category (v.b.43) change.
44. Technical Specification 5.1
- i. TS 5.1.1, TS 5.1.2, and Figure 5.1-1 - The description and figure of the site area boundary was not added to the new specifications consistent with Traveller CEOG-03, C.1. Since the description of this design feature does not meet the criteria for Design Features described in 10 CFR 50.36, this description is relocated to licensee controlled documents (i.e., UFSAR, Section 2.1.2). The figure and description of the exclusion area boundary was also replaced with a table describing this feature consistent with Traveller CEOG-03, C.1. There are Ginna TS Category (iii) changes.
45. Technical Specification 5.2
- i. TS 5.2 - The description of the containment design features was not added. Specific containment features are covered in the Technical Specification LCO's and, therefore, does not meet the criteria for Design Features described in 10 CFR 50.36(c)(4). Therefore, this description is relocated to licensee controlled documents (i.e., UFSAR Sections 3.8.1 and 6.2). This is a Ginna TS Category (iii) change.
46. Technical Specification 5.3
- i. TS 5.3.1.a and TS 5.3.1.c - The description of the reactor core design features was revised consistent with the standard guideline of NUREG-1431. The section now includes the amount, kind, and source of nuclear material related to the reactor core. This is a Ginna TS Category (v.c) change.
 - ii. TS 5.3.1.b - The description of the fuel storage design feature with respect to the maximum enrichment weight percent was revised and relocated to new Specification 4.3.1. The changes are in accordance with the changes discussed in item 47.ii, below. These are Ginna TS Category (v.c) and (i) changes, respectively.

- iii. TS 5.3.2 - The description of the reactor coolant system (RCS) design features was not added. Specific RCS features are covered in the Technical Specification LCO's and, therefore, does not meet the criteria for Design Features described in 10 CFR 50.36(c)(4). Therefore, this description is relocated to licensee controlled documents (i.e., UFSAR Section 3.7.1 and Chapter 5). This is a Ginna TS Category (iii) change.
- iv. TS 5.3.1.b - This was revised to increase the fuel enrichment limit from 4.25 weight percent to 5.05 weight percent. This change has been evaluated and found to be acceptable with respect to postulated fuel handling accidents (Ref. 29). This is a Ginna TS Category (v.b.46) change.

47. Technical Specification 5.4

- i. TS 5.4.1, 5.4.2, 5.4.6, and Figures 5.4-1 and 5.4-2 - The description of the fuel storage design features denoting spent fuel storage regions and borated water concentrations were relocated to Chapters 3.7 and 3.9. These features are discussed in LCOs 3.7.11, 3.7.12, 3.7.13, and 3.9.1 as appropriate. In addition, appropriate Required Actions were added in the event that SFP water level, boron concentration, or SFP region storage requirements are not met. This is a Ginna TS Category (i) change.
- ii. TS 5.4.2 - The description of the fuel storage design features was revised. The revision to these features are based on a revised criticality analysis supporting the proposed 18 month fuel cycle (Reference 29). The description of these features follow the standard guideline of NUREG-1431 which would include the amount, kind, and source of special nuclear material with the exception that nominal center to center spacing between the fuel assemblies was not added. This is a Ginna TS Category (v.c) change.

- iii. TS 5.4.3 - The description of the fuel storage design feature denoting the 60-day limit on storage of discharged fuel assemblies in Region 2 was not added. No screening criteria applies for the time limit on storage of discharged fuel assemblies in Region 2. The current 60-day limit was established to provide sufficient margin in spent fuel pool temperature calculations as a result of decay heat loads in Region 2 from discharged fuel assemblies (Reference 39). Although the spent fuel pool cooling system and, thus, the associated restriction on heat load prevent structural integrity damage to the spent fuel pool, they are not assumed to function to mitigate the consequences of a design basis accident (DBA). The restriction on heat load is not used for, nor capable of, detecting a significant abnormal degradation of the reactor coolant pressure boundary prior to a DBA. The restriction on heat load is a non-significant risk contributor to core damage frequency and offsite doses. Since this does not meet the criteria for Design Features described in 10 CFR 50.36(c)(4) and no NRC Final Policy Statement technical specification screening criteria apply, this requirement is relocated to the TRM. This is a Ginna TS Category (iii) change.
- iv. TS 5.4.4 and 5.4.5 - These were revised consistent with References 29 and 39 to provide the amount, kind, and source of material which is stored in the canisters. This is a Ginna TS Category (v.c) change.
- v. TS 5.4 - This was revised to include descriptions of the SFP drainage system and capacity. This information is currently contained in the bases for this section. Since NUREG-1431, Chapter 4 does not contain any bases, this information has been relocated to the specification. This is a Ginna TS Category (i) change.

48. Technical Specification 5.5

- i. TS 5.5 - The description of the waste treatment systems design features was not added. No screening criteria apply for the description of these features. Specific waste treatment systems features are either covered in the Technical Specification LCO's or have been relocated to other licensee controlled documents and, therefore, do not meet the criteria for Design Features described in 10 CFR 50.36(c)(4). Since the description of these design features does not satisfy the NRC Final Policy Statement technical specification screening criteria, this description is relocated to licensee controlled documents (i.e., UFSAR Chapter 11). This is a Ginna TS Category (iii) change.

49. Technical Specification 6.1

- i. TS 6.1.1 - The requirement was revised to include a statement that the plant manager shall approve each proposed test, experiment or modification to structures, systems or components that affect nuclear safety. This is a Ginna TS Category (iv.a) change.
- ii. TS 6.1 - A new requirement (Specification 5.1.2) was added which establishes the requirement for Shift Supervisor responsibility. This is a Ginna TS Category (iv.a) change.
- iii. The plant manager title was revised to be more generic consistent with Reference 62. See also item 50.ii below. This is a Ginna TS Category (vi) change.

50. Technical Specification 6.2

- i. Cross references to existing regulatory requirements are redundant and generally not incorporated into NUREG-1431. This is a Ginna TS Category (ii) change.
- ii. Plant specific management position titles in the current Technical Specifications are replaced with generic titles consistent with Reference 62. Personnel who fulfill these positions are required to meet specific qualifications as detailed in proposed TS 5.3, and compliance details relating to the plant specific management position titles are identified in the UFSAR. The two major specific replacements are the generic "plant manager" for the manager level individual responsible for the overall safe operation of the plant and the generic descriptive use of "a corporate vice president" in place of the specific Vice President position. The plant specific titles fulfilling the duties of these generic positions will continue to be defined, established, documented and updated in the UFSAR which has specific regulatory review requirements for changes. This change does not eliminate any of the qualifications, responsibilities or requirements for these personnel or the positions. This is a Ginna TS Category (vi) change.
- iii. TS 6.2.1.d - The requirement describing the capability of training, health physics and quality assurance to have direct access to responsible corporate management was modified to be consistent with NUREG-1431. These modifications are editorial changes only which do not change the intent or requirements of this specification. This is a Ginna TS Category (vi) change.

- iv. TS 6.2.2.b - The requirements describing the required operating crew compositions were not added. These requirements are specified in 10 CFR 50.54(k), (l), and (m) and proposed TS 5.2.2.a, 5.2.2.b, and 5.2.2.e. This is a Ginna TS Category (ii) change.
- v. TS 6.2.2.d - The requirement was revised to clarify that the individual qualified in radiation protection procedures is allowed to be absent for not more than two hours. This is consistent with the requirements for shift crew composition. This is a Ginna TS Category (v.c) change.
- vi. TS 6.2.2.e - The requirement describing the overtime requirement for plant staff who perform safety related functions was revised to reference a NRC approved program for controlling overtime. This is a Ginna TS Category (vi) change.
- vii. A new requirement was added which specifies that the Operations Manager or Operations middle manager shall hold a SRO. This change is consistent with NUREG-1431 and ensures that at least one operations manager holds a SRO. This is a Ginna TS Category (iv.a) change.

51. Technical Specification 6.3

- i. TS 6.3.1 - The reference to the RG&E letter dated December 30, 1980, was replaced with wording considered more appropriate. The current STA program at Ginna Station is discussed in References 40 and 42 and was reviewed and approved by the NRC. The revised wording eliminates the need to revise the Technical Specifications if the STA program is later revised, but still requires NRC approval of these changes. This is a Ginna TS Category (vi) change.

52. Technical Specification 6.4

- i. TS 6.4 - The requirements for a Training Program were not added. The requirements are either adequately addressed by other Section 5.0 administrative controls or are addressed by 10 CFR 55 requirements. Therefore, these requirements are relocated to the UFSAR. This is a Ginna TS Category (iii) change.

53. Technical Specification 6.5

None.

54. Technical Specification 6.6

None.

55. Technical Specification 6.7

- i. TS 6.7.1.a - The initial operator actions for Safety Limit (SL) violations were revised as follows:
 - a. For violation of the Reactor Core or RCS Pressure SL in MODES 1 and 2, the requirement to immediately shutdown the reactor (effectively to be in MODE 3) was revised to allow 1 hour to restore compliance and place the unit in MODE 3. Immediately shutting down the reactor could infer action to immediately trip the reactor. The revision provides the necessary time to shutdown the unit in a more controlled and orderly manner than immediately tripping the reactor which could result in a plant transient. The proposed time continues to minimize the time allowed to operate in MODE 1 or 2 with a SL not met. This is a Ginna TS Category (v.b.44) change.
 - b. For violation of the RCS Pressure SL in MODES 3, 4, and 5, an additional action was added which requires restoring compliance with the SL within 5 minutes. Specifying a time limit for operators to restore compliance provides greater guidance to plant staff. This is a Ginna TS Category (v.a) change.
- ii. TS 6.7.1.b - The requirement for notification to management personnel and the offsite review function of a SL violation was not added to the new specifications. Notification requirements are relocated to the TRM. This is a Ginna TS Category (iii) change. The requirement for notification to the NRC of a SL violation was not added to the new specifications since this requirement is denoted in 10 CFR 50.36 and 10 CFR 50.72. This is a Ginna TS Category (ii) change.
- iii. TS 6.7.1.c - The requirement that a Safety Limit Violation Report be prepared was not added to the new specifications. This is a duplication of requirements denoted in 10 CFR 50.36 and 10 CFR 50.73. This is a Ginna TS Category (ii) change. The requirement for the onsite review committee to review the Safety Limit Violation Report was not added to the new specifications. The responsibilities of the onsite review committee are relocated to the TRM. This is a Ginna TS Category (iii) change. SL violations are reported to the NRC in accordance with the provisions of 10 CFR 50.73. The details describing the requirements for content of the Safety Limit Violation Report is, therefore, controlled by the provisions of 10 CFR 50.73 and does not need to be specified in TS. This is a Ginna TS Category (ii) change.

- iv. TS 6.7.1.d - The requirement for the submittal of a Safety Limit Violation Report to the NRC was not added to the new specifications. This is a duplication of requirements denoted in 10 CFR 50.36 and 10 CFR 50.73. This is a Ginna TS Category (ii) change. The requirement for the submittal of a Safety Limit Violation Report to management personnel and the offsite review function was not added to the new specifications. The distribution of reports submitted in accordance with 10 CFR 50.73 are relocated to the TRM. This is a Ginna TS Category (iii) change.

56. Technical Specification 6.8

- i. TS 6.8.1.d - The Offsite Dose Calculation Manual implementation is covered by a more generic item which is specified in Section 5.5. It is not necessary to specifically identify each program under procedures (see Section D, item 56.iv). Since the requirements remain, this is considered to be a change in the method of presentation only. This is a Ginna TS Category (i) change.
- ii. TS 6.8.1.e - The PCP description was not added since this program only implements the requirements of 10 CFR 20, 10 CFR 61, and 10 CFR 71 and does not impose any new regulations. The detailed description of the PCP is provided in licensee controlled documents. This is a Ginna TS Category (iii) change.
- iii. TS 6.8.1 - A new specification (TS 5.4.1.b) was added which establishes the requirement for written emergency operating procedures implementing the requirements of NUREG-0737 and NUREG-0737, Supplement 1. This is a Ginna TS Category (iv.a) change.

- iv. TS 6.8.1 - A new specification (TS 5.4.1.e) was added which establishes the requirement for written procedures for programs and manuals denoted in new Specification 5.5. These Programs include:

<u>ITS</u>	<u>Current TS</u>	<u>Program</u>
5.5.1	1.13 & 6.15	Offsite Dose Calculation Manual
5.5.2	4.4.3	Primary Coolant Sources Outside Containment
5.5.3	New	Post Accident Sampling Program
5.5.4	3.9 & 3.16	Radioactive Effluent Controls Program
5.5.5	New	Component Cyclic or Transient Limit
5.5.6	4.4.4	Pre-Stressed Concrete Containment Tendon Surveillance Program
5.5.7	4.2	Inservice Testing Program
5.5.8	4.2	Steam Generator (SG) Tube Surveillance Program
5.5.10	4.5.2.3 & 4.11.1	Ventilation Filter Testing Program
5.5.11	3.9.2.5 & 3.9.2.6	Explosive Gas and Storage Tank Radioactive Monitoring Program
5.5.12	4.6.1.d	Diesel Fuel Oil Testing Program
5.5.13	New	Technical Specification Bases Control
5.5.14	New	Safety Function Determination Program
5.5.15	New	Containment Leakage Rate Testing Program

The technical content of several requirements are being moved from other chapters of the current Technical Specifications and are proposed to be identified as Programs in accordance with the format of NUREG-1431. This is a Ginna TS Category (i) change. Other programs were added, except as discussed below, to ensure consistency in the implementation of required programs within the current licensing basis. The Radioactive Effluent Controls Program was added due to the relocation of the radiological Technical Specifications consistent with Generic Letter 89-01 and the changes to 10 CFR 20. The Bases Control program was added to specifically delineate the appropriate methods and reviews necessary for a change to the Technical Specification Bases. The Safety Function Determination Program was added to support implementation of the support system operability characteristics of the Technical Specifications (new LCO 3.0.6). These are Ginna TS Category (iv.a) changes:

- v. TS 6.8.1.c - The radiological environmental monitoring program is covered by a more generic item which is specified in specification 5.5. It is not necessary to specifically identify each program under procedures (see Section D, item 56.iv). Since the requirements remain, this is considered to be a change in the method of presentation only. This is a Ginna TS category (i) change.

57. Technical Specification 6.9

- i. TS 6.9 - The reference to reporting requirements were revised consistent with 10 CFR 50.4. This is a Ginna TS Category (vi) change.
- ii. TS 6.9.1.1 - The requirement to submit a Startup Report was not added. The Startup Report is more appropriately addressed in the NRC Safety Evaluation Report authorizing an Operating License, increased power level, installation of a new nuclear fuel design or manufacturer, or modifications which significantly alter the nuclear, thermal, or hydraulic performances of the plant. The Startup Report is required to be submitted within 90 days following completion of the above activities and does not require NRC approval. Therefore, inclusion of the requirement for this report in Technical Specifications is not necessary to assure safe plant operation. This is a Ginna TS Category (ii) change.
- iii. TS 6.9.1.2 - The requirements describing the details of the monthly report were not added. These details are appropriately relocated to procedures or other licensee controlled documents. This is a Ginna TS Category (iii) change.
- iv. TS 6.9.1.3, TS 6.9.1.4, Table 6.9-1 and Table 6.9-2 - The details and methods implementing these specifications were not added. These details are appropriately relocated to the ODCM and the Effluent Controls Program described in new Specifications 5.5.1 and 5.5.4, respectively. The submittal date was also changed to May 15th to allow the submittal of the Annual Radiological Environmental Operating Report to correspond with the Monthly Operating Report submittal date. This is a Ginna TS Category (iii) change.
- v. TS 6.9.1.4 - The specific date referenced for the annual submittal was revised consistent with the requirements of 10 CFR 50.36a. This is a Ginna TS Category (vi) change.
- vi. TS 6.9.1.5 - The requirement for the reporting of challenges to pressurizer PORVs or safety valves was revised from an annual to a monthly report and relocated to the Monthly Operating Report (new Specification 5.6.4). This is a Ginna TS Category (v.c) change.
- vii. TS 6.9.2.1 - The reporting requirement related to sealed sources was not added since this is specified in 10 CFR 30.50. The detailed description of these reporting requirements are provided in licensee controlled documents. This is a Ginna TS Category (iii) change.

- viii. TS 6.9.2.4 - The reporting requirement for reactor overpressure protection system operation was revised. The reporting requirement is detailed in proposed Specification 5.6.4, and is generally included in the LER requirements to report a RCS pressure transient that exceeds expected values or that is caused by unexpected factors. Since the criteria identified in 10 CFR 50.73 includes the area of degraded boundaries that necessitates reporting, any minor differences are negligible with regard to safety. This is a Ginna TS Category (ii) change.
- ix. A new requirement TS 5.6.5 was added which establishes the reporting requirement for the COLR. The COLR is required due to the removal of existing Technical Specification core operating limits. This is a Ginna TS Category (iv.a) change.
- x. A new requirement TS 5.6.6 was added which establishes the reporting requirement for the RCS PTLR. The PTLR is required due to the removal of existing Technical Specification pressure and temperature operating limits. This is a Ginna TS Category (iv.a) change.

58. Technical Specification 6.10

None.

59. Technical Specification 6.11

None.

60. Technical Specification 6.12

None.

61. Technical Specification 6.13

- i. TS 6.13.1 - Plant-specific position titles in the current Ginna Station TS were replaced with generic titles (i.e., radiation protection technician). The plant specific titles fulfilling the duties of these generic positions will continue to be defined, established, documented and updated in the UFSAR which has specific regulatory review requirements for changes. This change does not eliminate any of the qualifications, responsibilities or requirements for these personnel or the positions. This is a Ginna TS Category (vi) change.

62. Technical Specification 6.14

None.

63. Technical Specification 6.15

- i. TS 6.15.1.b - The approval process for ODCM changes was revised to clarify that the effective changes be approved by the plant manager instead of the onsite review function. Since the onsite review function reports to the Plant Manager, this is a conservative change. This is a Ginna TS Category (v.a) change.

64. Technical Specification 6.16

- i. TS 6.16 - The process for changes to the PCP was not added to the new specifications since this program only implements the requirements of 10 CFR Part 20, 10 CFR Part 61, and 10 CFR Part 71 and does not impose any new requirements. The detailed description of the PCP is provided in licensee controlled documents. This is a Ginna TS Category (iii) change.

65. Technical Specification 6.17

- i. TS 6.17 - The requirements for major changes to radioactive waste treatment systems was not added. Changes to these systems are controlled by 10 CFR 50.59. NRC notification of significant changes to these systems is addressed by 10 CFR 50.59(b)(2). Therefore, this specification is relocated to the TRM. This is a Ginna TS Category (iii) change.

66. New Requirements (Ginna TS Category (iv.a) Changes)

- i. LCO 3.4.1 and the associated surveillance requirements were added for DNB limits. This new requirement places limits on pressurizer pressure, RCS average temperature, and RCS total flow rate to ensure that the minimum DNBR will be met for all analyzed transients.
- ii. LCO 3.7.3 and the associated surveillances were added for the MFW pump discharge valves (MFPDVs), MFW regulating valves, and the associated bypass valves. This new requirement specifies an isolation time of 80 seconds for the MFPDVs and 10 seconds for the remaining valves and requires them to be OPERABLE above MODE 4 to provide isolation capability as assumed in the accident analyses.
- iii. LCO 3.7.4 and the associated surveillance were added for the atmospheric relief valves (ARVs). The LCO requires that the ARVs be OPERABLE when RCS average temperature is > 500°F in MODE 3 to provide cooldown capability following a SGTR event as assumed in the accident analyses. A Surveillance to verify that each ARV is capable of opening and closing once every 24 months was also added.

iv. A COLR was developed which contains the actual limits for LCOs associated with reactor physic parameters that may change with each refueling. To prevent the need to revise Technical Specifications for parameters which are calculated using NRC approved methodology, Generic Letter 88-16 (Ref. 56) allows these limits to be relocated from the technical specifications. A copy of the proposed Ginna Station COLR is provided in Attachment F. The following parameters were relocated to the COLR:

- a. SHUTDOWN MARGIN
- b. MODERATOR TEMPERATURE COEFFICIENT
- c. Shutdown Bank Insertion Limit
- d. Control Bank Insertion Limits
- e. Heat Flux Hot Channel Factor
- f. Nuclear Enthalpy Rise Hot Channel Factor
- g. AXIAL FLUX DIFFERENCE
- h. Not used
- i. RCS Pressure, Temperature and Flow Departure from Nucleate Boiling (DNB) Limits
- j. Not used
- k. Not used
- l. Not used
- m. Refueling Boron Concentration

v. A RCS PTLR was developed which contains the actual limits for LCOs associated RCS pressure and temperature limits and LTOP. To prevent the need to revise Technical Specifications for parameters which are calculated using NRC approved methodology, NUREG-1431 allows these limits to be relocated from the technical specifications. A copy of the proposed Ginna Station PTLR is provided in Attachment G. The following parameters were relocated to the PTLR:

- a. RCS Pressure and Temperature Limits
- b. Low Temperature Overpressure Protection (LTOP) System Enable Temperature
- c. LTOP Setpoint

67. License

- i. The license was revised to relocate requirements associated with Secondary Water Chemistry Monitoring Program, Systems Integrity, and Iodine Monitoring to Appendix A of the license (i.e., TS). Changes to both the license and TS require NRC approval such that there is no reduction in commitment with respect to this change. This is a Ginna TS Category (i) change.
- ii. Minor editorial changes were made to provide consistency within the license. These are administrative changes only which do not change the intent of the license. These are Ginna TS Category (vi) changes.

- iii. The exemption to 10 CFR 50.48(c)(4) was removed from the license since this exemption expired in 1986 and is no longer required. This is a Ginna TS Category (vi) change.
- iv. The exemption to 10 CFR 50.46(a)(1) was removed from the license since this exemption is no longer required since the ECCS models for Ginna Station have since been revised. This is a Ginna TS Category (vi) change.

E. SIGNIFICANT HAZARDS CONSIDERATION EVALUATION

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D are organized into 6 categories and subcategories as necessary. These categories of changes are evaluated with respect to 10 CFR 50.92(c) and shown to not involve a significant hazards consideration as described below.

E.1 SIGNIFICANT HAZARDS CONSIDERATION EVALUATION - ADMINISTRATIVE CHANGES

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (i), (ii), (v.c), or (vi) changes do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed changes does not involve a significant increase in the probability or consequences of an accident previously evaluated. The proposed changes involve either (1) the relocation of requirements within the Technical Specifications to support consolidation of similar requirements, (2) the reformatting, renumbering or rewording of the existing Technical Specifications to provide consistency with NUREG-1431, (3) the deletion of duplicate regulatory requirements, or (4) minor changes to the Technical Specifications such that the changes do not involve any technical issues. As such, this change is administrative in nature and does not impact initiators of analyzed events or assumed mitigation of accident or transient events. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.
2. Operation of Ginna Station in accordance with the proposed changes does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed changes do not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or changes in methods governing normal plant operation. The proposed changes will not impose any new or different requirements. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Operation of Ginna Station in accordance with the proposed changes does not involve a significant reduction in a margin of safety. The proposed changes will not reduce a margin of safety because the changes do not impact any safety analysis assumptions. These changes are administrative in nature. As such, no question of safety is involved, and the change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

E.2 SIGNIFICANT HAZARDS CONSIDERATION EVALUATION - RELOCATED SPECIFICATIONS

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (iii) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed changes does not involve a significant increase in the probability or consequences of an accident previously evaluated. The proposed changes relocates requirements and surveillances for structures, systems, components or variables which did not meet the criteria for inclusion in Technical Specifications. The affected structures, systems, components or variables are not assumed to be initiators of analyzed events and are not assumed to mitigate accident or transient events. The requirements and surveillances for these affected structures, systems, components or variables will be relocated from the Technical Specifications to an appropriate administratively controlled document (e.g., Technical Requirements Manual or UFSAR) which will continue to be maintained pursuant to 10 CFR 50.59. In addition, the affected structures, systems, components or variables are addressed in existing surveillance procedures which are also controlled by 10 CFR 50.59 and subject to the change control provisions in the Administrative Controls Section of the Technical Specifications. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.
2. Operation of Ginna Station in accordance with the proposed changes does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed changes do not involve a physical alteration of the plant (no new or different type of equipment will be installed) or changes in methods governing normal plant operation. The proposed changes will not impose or eliminate any requirements and adequate control of existing requirements will be maintained. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Operation of Ginna Station in accordance with the proposed changes does not involve a significant reduction in a margin of safety. The proposed changes will not reduce a margin of safety because the changes do not impact any safety analysis assumptions. In addition, the relocated requirements and surveillances for the affected structure, system, component or variable remain the same as the existing Technical Specifications. Since any future changes to these requirements or the surveillance procedures will be evaluated per the requirements of 10 CFR 50.59, no reduction (significant or insignificant) in a margin of safety will be allowed.

The existing requirement for NRC review and approval of revisions, in accordance with 10 CFR 50.92, to these details proposed for relocation, does not have a specific margin of safety upon which to evaluate. However, the majority of changes are consistent with the Westinghouse Standard Technical Specification, NUREG-1431, which has been approved by the NRC Staff. Therefore, revising the Technical Specifications to reflect the approved level of detail ensures no significant reduction in the margin of safety. For those requirements proposed to be relocated which are retained within NUREG-1431, the relocated items are similar in nature to other relocated requirements or are not credited in the accident analyses for Ginna Station.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

E.3 SIGNIFICANT HAZARDS CONSIDERATION EVALUATION - MORE RESTRICTIVE CHANGES

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (iv.a) and (v.a) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed changes does not involve a significant increase in the probability or consequences of an accident previously evaluated. The proposed changes provide more stringent requirements for operation of the facility. These more stringent requirements do not result in operation that will increase the probability of initiating an analyzed event and do not alter assumptions relative to mitigation of an accident or transient event. The more restrictive requirements continue to ensure process variables, structures, systems and components are maintained consistent with the safety analyses and licensing basis. Therefore, this change does not involve a significant increase in the probability or consequences of an accident previously evaluated.

2. Operation of Ginna Station in accordance with the proposed changes does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed changes do not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or changes in the methods governing normal plant operation. The proposed changes do impose different requirements. However, these changes are consistent with assumptions made in the safety analysis and licensing basis. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed changes does not involve a significant reduction in a margin of safety. The imposition of more restrictive requirements either has no impact on or increases the margin of plant safety. As provided in the discussion of the change in Section D, each change in this category is by definition providing additional restrictions to enhance plant safety. The change maintains requirements within safety analyses and licensing bases. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

E.4 SIGNIFICANT HAZARDS CONSIDERATION EVALUATION - LESS RESTRICTIVE CHANGES

LESS RESTRICTIVE CHANGE CATEGORY (iv.b.1)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (iv.b.1) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Required Actions of the Diesel Generator (DG) Loss of Power (LOP) start instrumentation (current Table 3.5-1, Functional Units # 18 and #19) from an action to shutdown to an action to restore the channel to an OPERABLE status or enter the applicable conditions for an inoperable DG. The start instrumentation function is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The change does not further degrade the capability of the OPERABLE start instrumentation channels from performing their intended function. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change results in actions that are no more restrictive than actions for the loss of one DG. The change maintains requirements within safety analyses and licensing bases. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (iv.b.2)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (iv.b.2) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the actions for an inoperable DG to: (1) eliminate the testing of the OPERABLE DG if, within 24 hours, it can be determined that the OPERABLE DG is not inoperable due to a common cause failure, and (2) eliminate the requirement to test the OPERABLE DG once every 24 hours until the second DG is restored to OPERABLE status (TS 3.7.2.2.b.1). The testing requirements for an OPERABLE DG are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The change does not degrade the capability of the OPERABLE DG from performing its intended function since some DG failures can be conclusively determined not to apply to a second DG without requiring excessive testing. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change results in actions that prevent unnecessary DG starts which can potentially adversely affect DG reliability. The change maintains DG OPERABILITY requirements within the safety analyses and licensing bases. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.1)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.1) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Refueling Frequency which is used to define CHANNEL CALIBRATION and other testing intervals, from 18 months to 24 months (TS 1.12 and 4.4.6.2). The Frequency between CHANNEL CALIBRATIONS is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. TS required equipment is current maintained under a Reliability Centered Maintenance program such that their failures are tracked and trended. In addition, instrumentation setpoints and equipment history have been verified to be acceptable with respect to this change. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The equipment testing intervals are increased, but they still must be maintained OPERABLE consistent with their TS requirements. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.2)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.2) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the applicability associated with the RCS Safety Limits (SL) in MODE 6 (current TS 2.2). Adequate margin exists such that it is not possible to pressurize the RCS greater than the SL pressure while in MODE 6. Therefore, this change does not significantly increase the probability of a previously analyzed accident. Further, these limits are not credited for mitigation of any accident in the omitted condition. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since it is not possible to pressurize the RCS greater than the SL pressure while in MODE 6. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.3)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.3) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement for the pressurizer water level lower limit of 12% (current TS 3.1.1.5.a). This requirement relates to a reactor trip function that was removed at Ginna Station as a result of IE Bulletin 79-06A (Ref. 45). Therefore, this change does not significantly increase the probability of a previously analyzed accident nor significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant since the trip function has already been removed. The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
- 3.. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since the pressurizer low level trip function is no longer credited. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.4)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.4) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the applicability and deletes requirements associated with the overpressurization protection function of the pressurizer safety valves in MODES 5 and 6 (current TS 3.1.1.3.a and TS 3.1.1.3.b). The pressurizer safety valves do not perform a safety function in the omitted conditions. Therefore, this change does not significantly increase the probability of a previously analyzed accident. Further, these limits are not credited for mitigation of any accident in the omitted conditions. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since these valves do not perform a safety function in MODES 5 and 6. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.5)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.5) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change deletes the requirements associated with SG temperature and pressure variables (current TS 3.1.1.2 and TS 3.1.2.2). The temperature and pressure variables are not specifically modeled in the safety analysis except through the variables of RCS pressure, temperature, and flow which are addressed in the heatup and cooldown rates in the PTLR. Therefore, this change does not significantly increase the probability of a previously analyzed accident. Further, these SG variables are not credited for mitigation of any accident. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since all necessary heatup and cooldown rates are addressed by the PTLR. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.6)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.6) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the period of time (from 6 hours to 72 hours) continued operation is allowed prior to confirming through the performance of an engineering evaluation, the structural integrity of the RCS after exceeding pressure or temperature limits (current TS 3.1.2.1.c.1). The requirement is associated with a function that is not an assumed initiator for any accidents previously evaluated since the exceeded limits are subsequently restored. Therefore, this change does not significantly increase the probability of a previously analyzed accident. Further, this function is not credited for mitigation of any accident. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The proposed change does not alter the manner in which safety limits, limiting safety system settings, or limiting conditions for operation are determined. The change maintains requirements within current safety analyses since the time that out-of-condition limits are restore is not changed. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.7)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.7) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change provides a Note allowing the plant to change MODES if either the containment sump monitor or both the containment atmospheric radioactivity monitors are inoperable (current TS 3.1.5.1). The RCS LEAKAGE detection system is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. This change does not further degrade the capability of the system to perform its required function since some form of LEAKAGE detection must always remain OPERABLE under these circumstances or a plant shutdown commenced. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since some form of RCS LEAKAGE detection must remain OPERABLE in MODES 1, 2, 3, and 4. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.8)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.8) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows an additional 4 hours to correct administrative and other similar discrepancies in the SG Tube Surveillance Program before commencing a reactor shutdown (current TS 3.1.5.2.2). Administrative discrepancies in the SG Tube Surveillance Program are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The change does not further degrade the capability of the SG tubes to perform their intended function since the limit on SG tube leakage remains. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change results in actions that allow restoration of minor administrative discrepancies without affecting any safety analysis assumptions with respect to SG tube leakage. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.9)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.9) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows 72 hours to restore accumulator boron concentration to within acceptable limits versus 1 hour (current TS 3.3.1.1.b and 3.3.1.3). The accumulator boron concentration is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. This change does not further degrade the capability of the accumulator to perform its required function under these circumstances since it will only allow additional time to restore the system to an OPERABLE status prior to initiating a plant shutdown. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The accumulator boron concentration is not as critical feature as other accumulator parameters (e.g., water volume) such that additional time for restoration does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.10)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.10) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows 72 hours to restore accumulator boron concentration to within acceptable limits versus 1 hour (current TS 3.3.1.1.a and 3.3.1.2). The RWST boron concentration is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. This change does not further degrade the capability of the RWST to perform its required function under these circumstances since it will only allow additional time to restore the system to an OPERABLE status prior to initiating a plant shutdown. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The RWST boron concentration is not as critical feature as other RWST parameters (e.g., water volume) such that additional time for restoration does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.11)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.11) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change: (1) allows both SI pump flow paths to be isolated for up to 2 hours to perform pressure isolation valve testing, and (2) allows up to 4 hours, or until the RCS cold legs exceed 375°F, to place into service ECCS pumps declared inoperable due to LTOP considerations (current TS 3.3.1.1.c). The ECCS System is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The change allows required testing to be performed on the ECCS and reduces the potential for a transient to challenge the LTOP System. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change allows required testing to be performed on the ECCS, reduces the potential for a transient to challenge the LTOP Systems, and are consistent with NUREG-1431. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.12)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.12) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change provides an AOT of 72 hours for two inoperable post-accident charcoal filter trains (current TS 3.3.2.2). The system is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. This change does not further degrade the capability of the system to perform its required function under these circumstances. This will allow an additional time to restore the system to an OPERABLE status prior to initiating a plant shutdown. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since the CRFC units which supply the post-accident charcoal filter trains may be removed from service for up to 7 days prior to initiating a plant shutdown. In addition, the 100% redundant CS trains must remain OPERABLE in this condition. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.13)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.13) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the CCW heat exchanger requirements to allow 1 heat exchanger to be inoperable for up to 31 days versus 24 hours (current TS 3.3.3.1). The CCW System is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. This change does not further degrade the capability of the CCW system to perform its required function under these circumstances since the heat exchanger is a passive device similar to the CCW piping. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since the CCW piping is also a passive device, which if it were to fail, would result in the loss of the entire CCW System which has been analyzed with acceptable results. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.14)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.14) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the AOT for two motor driven AFW pumps, from 24 hours to 72 hours, to be consistent with that for the turbine driven AFW pump (current TS 3.4.2.1.b). The AFW system is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. This change does not further degrade the capability of the AFW system to perform its required function under these circumstances since the turbine driven AFW pump is fully capable of supplying both SGs. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change maintains requirements within current safety analyses since the turbine driven AFW pump is fully capable of supplying both SGs. In addition, for accident conditions in which AFW is not immediately required (i.e., not required for 10 minutes), the SAFW System is available. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.15)

Not used (see Reference 30).

LESS RESTRICTIVE CHANGE CATEGORY (v.b.16)

Not used (see Reference 3.0).

LESS RESTRICTIVE CHANGE CATEGORY (v.b.17)

Not used (see Reference 3.0).

LESS RESTRICTIVE CHANGE CATEGORY (v.b.18)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.18) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the required channels for Diesel Generator (DG) Loss of Power (LOP) start instrumentation (current Table 3.5-1, Functional Units # 18 and #19) from individually specifying the loss of voltage and degraded voltage channels to requiring two channels of undervoltage per 480 V safeguards bus. The start instrumentation function is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The change does not further degrade the capability of the OPERABLE DG LOP instrumentation channels from performing their intended function. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed) or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change only clarifies the actual design of the DG LOP instrumentation without affecting the safety function of the specified channels. The requirement for a loss of voltage and degraded voltage function is specified in the surveillance requirement for this LCO. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.19)

Not used (see Reference 30).

LESS RESTRICTIVE CHANGE CATEGORY (v.b.20)

Not used (see Reference 30).

LESS RESTRICTIVE CHANGE CATEGORY (v.b.21)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.21) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the current AOT to restore inoperable Post Accident Monitors (PAMs), revises the actions for inoperable PAMs that are not restored to service within the AOT, and revises the PAM testing frequencies (current TS 3.5.3, 3.6.4.2, and 4.4.7). The PAMs are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function under these circumstances. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The PAMs are not required to provide automatic response to any design basis accident. The additional time and surveillance frequencies has been evaluated and determined by the NRC to not significantly affect the contribution of the monitors to risk reduction. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.22)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.22) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows the use of a closed system to be used to isolate a penetration with a failed containment isolation valve for up to 72 hours (current TS 3.6.3). The containment isolation system is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the containment isolation system to perform its required function under these circumstances since the closed system is a passive device which is missile protected. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The containment isolation system remains capable of performing its intended function since the closed system is missile protected, leak tested, and capable of maintaining containment integrity in the event of an accident. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.23)

Not used.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.24)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.24) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the AOT for an inoperable 480 V safeguards bus from 1 hour to 8 hours before requiring a plant shutdown (current TS 3.7.2.2.c). The 480 V safeguards buses are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the 480 V safeguards buses to perform their required function under these circumstances since a redundant train is available. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. Allowing additional time to restore an inoperable 480 V safeguards bus does not adversely affect the accident analyses since a redundant train is available. The increased time is also consistent with NUREG-1431. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.25)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.25) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the requirement to verify power distribution after each refueling from prior to reaching 50% RTP to < 75% RTP (current TS 3.10.2.1). Peaking factors are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function under these circumstances. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. Allowing power ascension to 75% RTP before verifying power distribution still provides the necessary margin to ensure design limits are met since peaking factors are most decreased near 100% RTP. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.26)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.26) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the requirement to maintain F_Q and F_{AH} within limits at all times to only in MODE 1 (current TS 3.10.2.2). These power distribution limits are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function under these circumstances. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. These power distribution limits are not necessary to be met during MODE 2 since there is insufficient energy in the fuel to require these limits. In MODES 3, 4, 5, and 6, the reactor is not critical and, as such, these limits are not required. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.27)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.27) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Completion Time, from 24 hours to 72 hours, to reduce the Overpower ΔT , Overtemperature ΔT , and Power Range Neutron Flux - High trip setpoints when F_Q or F_{AH} is not within limits (current TS 3.10.2.2). These power distribution limits are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function under these circumstances since the Required Actions for these power distribution limits already require a power reduction in direct relationship to the percentage that the limit was exceeded. The reduction of trip setpoints only provides additional protection. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. Allowing additional time to reduce the setpoints for associated reactor trip functions only provides secondary protection with respect to potential unanalyzed power distributions since reactor power has already been reduced. Therefore, this change does not involve a significant reduction in a margin of safety. The change for Overpower ΔT is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.28)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.28) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change deletes the requirement to identify the cause of QPTR exceeding 1.02 or limit power to < 50% RTP (current TS 3.10.2.4). The QPTR is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. If the QPTR is not within limits, thermal power is required to be reduced proportional to the percentage that QPTR is outside the limits to compensate for the tilt and flux mapping must be initiated. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. Removing the requirement to identify the cause of the tilt or reduce power to < 50% RTP does not adversely affect the accident analyses since a power reduction proportional to the percentage that QPTR is outside the limit is required. It is not always possible to identify the cause of the tilt and the remaining Required Actions already underway are adequate to assure safe operation of the plant. This power change is consistent with NUREG-1431 and WCAP-12159 (Ref. 51). Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.29)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.29) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for performance of control rod exercises from monthly to every 92 days (current Table 4.1-2, Functional Unit #6a). Control Rods are only considered as an initiator for rod ejection accidents which are not related to this Surveillance. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function since this Surveillance only confirms normal operational indications of control rod OPERABILITY. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. Control Rod OPERABILITY is normally verified by normal operational practices such that increasing the allowed Surveillance interval does not involve a significant reduction in a margin of safety. The change is also consistent with NUREG-1431 and NUREG-1366 (Ref. 8).

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.30)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.30) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for verifying the NaOH concentration in the spray additive tank from monthly to once every 184 days (current Table 4.1-2, Functional Unit #13). The spray additive tank is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function since the tank is passive with available level indications to the operators which would indicate a change in concentration. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the spray additive tank from performing its intended safety function. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.31)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.31) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for performing an RCS water inventory balance from daily to once every 72 hours (current Table 4.1-2, Functional Unit #15). Verifying RCS water inventory is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of operations to identify LEAKAGE in the RCS since other indications, including letdown, are available. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not degrade the capability of operations to identify LEAKAGE in the RCS since other indications are available. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.32)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.32) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for performing verification of the SFP boron concentration from once every 31 days to once every 31 days if a verification of fuel storage has not been complete (current Table 4.1-2, Functional Unit #17). Verifying SFP boron concentration is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not affect the accident analyses since boron concentration is only credited during a fuel handling accident prior to the time which the fuel has been verified to be correctly stored. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not affect the assumptions used for a fuel handling accident. Therefore, this change does not involve a significant reduction in a margin of safety. This change (with the exception of the 31 day Frequency) is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.33)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.33) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for verifying the DG fuel oil inventory from daily to once every 31 days (current Table 4.1-2, Functional Unit #16). The DG fuel oil tank is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the system to perform its required function since the tank is passive with available level indications to the operators which would indicate a change in inventory. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the DG fuel oil tank from performing its intended safety function since other indicators are available to operators. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.34)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.34) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for verifying RCS gross specific activity from once every 72 hours to once every 7 days (current Table 4.1-4, Functional Unit #1). Verifying RCS gross specific activity is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of operations to identify fuel failures since other indications, including radiation alarms, are available. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not degrade the capability of operations to identify gross fuel failure since other indications are available. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.35)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.35) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement to test the SI cold leg injection and RHR RCS PIVs each cold shutdown greater than 7 days (current TS 4.3.3.1). These valves are normally maintained closed (i.e., they are not relied upon or used during power operation or cold shutdown conditions). Performing testing on these PIVs should only be required once every 24 months or within 24 hours of their being opened since more frequent testing would not likely provide any additional information. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the PIVs to perform their required function since the valves are maintained closed. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the RCS PIVS from performing their intended safety function since they will be tested a minimum of once every 24 months. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.36)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.36) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for performing the spray nozzle gas test from once every 5 years to once every 10 years (current TS 4.5.1.2.b). The spray ring nozzles are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the CS System to perform its required function since the nozzles are passive and located in a generally unaccessible area. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the CS System from performing its intended safety function. Therefore, this change does not involve a significant reduction in a margin of safety. The revised Frequency is also consistent with NUREG-1431 and NUREG-1366 (Ref. 8).

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.37)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.37) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for performing actuation testing of the post-accident charcoal filter dampers from monthly to once every 24 months (current TS 4.5.2.3.5). The post-accident charcoal filters are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the post-accident charcoal filters to perform their required function since the dampers have demonstrated a high degree of reliability and the CS System provides a 100% redundant iodine removal capability. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the post-accident filters from performing their intended safety function. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.38)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.38) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for performing the spray additive valves from monthly once every 24 months (current TS 4.5.2.2.a). The spray additive valves are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the spray additive system from performing its required function since have demonstrated a high degree of reliability and the post-accident charcoal filters provide 100% redundant iodine removal capability. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the spray additive system from performing its intended safety function. The revised Frequency is also consistent with NUREG-1431. Therefore, this change does not involve a significant reduction in a margin of safety. The revised Frequency is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.39)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.39) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement to test the AFW motor driven pump cross-over motor operated isolation valves (current TS 4.8.3). The AFW System is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the AFW System since the cross-over isolation valves are not credited in the accident analysis. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The deletion of the AFW cross-over isolation valves testing requirements does not prevent the AFW System from performing its intended safety function since the valves are not credited in the accident analysis. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.40)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.40) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change eliminates the need to perform a verification that the AFW pumps can start within 10 minutes once every 18 months (current TS 4.8.10). The AFW System is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the AFW System from performing its required function since this verification is not consistent with the accident analysis times. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The deletion of this Surveillance does not prevent the AFW System from performing its intended safety function since the 10 minute verification is not consistent with the accident analysis assumptions. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.41)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.41) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the Frequency for verifying a RHR pump, is providing forced flow in MODE 6 from once every 4 hours to once every 12 hours (current TS 4.11.2.1). Verification of RHR pump OPERABILITY is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the RHR System to provide decay heat removal since there are numerous indications available to plant operators of a loss of an RHR pump. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change in Surveillance Frequency does not prevent the RHR System from performing its intended safety function. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.42)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.42) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement to perform Inservice Testing surveillances of the RHR pumps during MODES 5 and 6 (current TS 4.11.2.2). At least one RHR pump is operating and the breakers of the second pump are verified during these conditions such that performance of this test is only a duplication of existing surveillances. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change does not further degrade the capability of the RHR System to provide decay heat removal since there are alternate Surveillances verifying pump OPERABILITY. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The deletion of this Surveillance does not prevent the RHR System from performing its intended safety function since the Inservice Testing Surveillance is mainly performed to verify pump operation at high pressures which do not exist in MODES 5 and 6. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.43)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.43) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change delays performance of the PORV functional channel test until 12 hours after decreasing to the LTOP enable temperature specified in the PTLR instead of within 31 days prior to entering this condition (current TS 4.16.1.a). The PORVs are only considered as an initiator for a previously analyzed accident with respect to spuriously opening. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The proposed change only provides a short period of time to verify that the PORV is OPERABLE for its LTOP functions since the PORV provides alternate functions, with different setpoints, in higher MODES. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The short period provided to perform the PORV testing ensures that the PORV remains capable of performing its multiple functions through all required MODES. This period of time is consistent with NUREG-1431. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.44)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.44) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows 1 hour to restore compliance for violations of the Reactor Core or RCS Pressure SL in MODES 1 and 2 instead of requiring an immediate shutdown of the plant (current TS 6.7.1.a). Since this change affects the Required Actions following a violation of SLs, this change does not significantly increase the probability of a previously analyzed accident. The proposed change only provides a short period of time to restore compliance before performing a shutdown of the plant in order to limit the potential for additional damage. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The short period provided to restore compliance provides operators with time to stabilize the plant before requiring a shutdown. Therefore, this change does not involve a significant reduction in a margin of safety. This change is also consistent with NUREG-1431 which has been approved by the NRC Staff.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.45)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.45) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change increases the OPERABILITY tolerance for the pressurizer safeties from $\pm 1\%$ to $+ 2.4\%$, -3% (current TS 3.1.1.3.c.). Since the pressurizer safety valve setpoint remains above the normal operating pressure and the PORV setpoint, this change does not significantly increase the probability of a previously analyzed accident. The change has been evaluated with respect to the most limiting pressure transients and shown to be acceptable. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation since the pressurizer safety valve setpoints following testing remain $\pm 1\%$. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The increased OPERABILITY tolerance allows for setpoint drift which has been demonstrated to exist at Ginna Station. The increased tolerances have been analyzed for the most limiting pressure transients with safety limits still being met. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.46)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.46) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change increases the fuel enrichment limit from 4.25 weight percent to 5.05 weight percent (current TS 5.3.1.b). The fuel enrichment limit is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The change has been evaluated with respect to fuel handling accidents and shown to be acceptable with respect to offsite doses and 10 CFR 100. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.

2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The increased fuel enrichment limit allows for Ginna Station to convert to 18 month cycles. The change has been analyzed and shown that all safety limits are still met. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.47)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.47) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows two SW pumps from the same electrical source to be inoperable for up to 72 hours (current TS 3.3.4.2). The inoperability of one SW train is not considered as an initiator for an accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. Systems supported by SW and using the same electrical train as the two SW pumps are currently allowed 72 hours or more to restore one inoperable train. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change only provides consistency within the TS between the SW system and systems which it supports. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.48)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.48) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement to "cease operations which may increase the reactivity of the core" (current TS 3.8.2) if the necessary containment penetrations are not isolated during refueling activities. Containment isolation is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The required actions for not meeting the containment isolation provisions during refueling is to stop all CORE ALTERATIONS and fuel movement. This action precludes a fuel handling accident for which containment isolation prevents an offsite release. Requiring that all operations which may increase the reactivity of the core is not necessary since containment does not protect against this accident. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.

3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. No accident analyses are affected by the removal of this requirement. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.49)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.49) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises the testing requirements of radiation monitors R-11 and R-12 to only require a functional test of the purge valves on a refueling outage basis (every 24 months) versus quarterly (current TS Table 4.1-5, Functional Units #3a and #3b). The radiation monitors are not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The radiation monitors actuate the Containment Ventilation Isolation System which is not credited in the accident analyses since it only serves to back up the containment isolation system. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The radiation monitors are not credited in any accident analysis. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.50)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.50) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement to isolate containment if the RCS boron concentration is not maintained above 2000 ppm during refueling (current TS 3.6.1.b). Containment isolation is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The required actions for not meeting the boron concentration limits is to stop all CORE ALTERATIONS and movement of irradiated fuel. This action precludes a fuel handling accident for which containment isolation prevents an offsite release. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. No accident analyses are affected by the removal of this requirement. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.51)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.51) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change revises current requirements from restoring an inoperable manual AFW or SAFW pump initiation channel within 48 hours to declare the association pump train inoperable (current TS Table 3.5-2, Functional Unit #3.a and #3.f). The manual actuation of the AFW and SAFW pumps is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. Since the manual initiation functions only affect one AFW or SAFW pump, entering the LCO for the affected pump is consistent with all other pump operability requirements. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. The change provides consistency within the TS without allowing a pump to be inoperable for a period greater than is currently allowed. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.52)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.52) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change removes the requirement to reduce the high neutron flux trip setpoint to $\leq 85\%$ RTP when power is reduced to $\leq 75\%$ RTP with a misaligned rod (current TS 3.10.4.3.2.b and 3.10.4.3.2.c). The accident analyses are performed assuming that one rod remains fully withdrawn following operation at full power conditions. Since reducing power to $\leq 75\%$ RTP and verifying peaking limits are still maintained must also be performed, the accident analyses remain valid. Therefore, this change does not significantly increase the probability of a previously analyzed accident and does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. All safety limits and accident analyses assumptions are still met. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.53)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.53) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change delays the determination of \bar{E} until 31 days after a minimum of 2 EFPDs and 20 days of MODE 1 operation following the reactor being subcritical for ≥ 48 hours (current TS Table 4.1-4, Functional Unit #3). The determination of \bar{E} is not considered as an initiator for any accidents previously analyzed. Therefore, this change does not significantly increase the probability of a previously analyzed accident. The allowance of an additional 31 days ensures that a true representative sample is obtained such that the potential for false readings is reduced. The actual value of \bar{E} is not changed. Therefore, this change does not significantly increase the consequences of a previously analyzed accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. All safety limits and accident analysis assumptions are still met. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

LESS RESTRICTIVE CHANGE CATEGORY (v.b.54)

The proposed changes to the Ginna Station Technical Specifications as discussed in Section D and denoted by Category (v.b.54) do not involve a significant hazards consideration as discussed below:

1. Operation of Ginna Station in accordance with the proposed change does not involve a significant increase in the probability or consequences of an accident previously evaluated. The change allows one diesel generator to be inoperable with no offsite power available for up to 12 hours (current TS 3.7.2.2.d). Since the loss of all offsite power and the failure of a diesel generator are assumptions of most accident analysis, this change does not significantly increase the consequences of an accident. The probability of an accident previously analyzed is not increased since offsite power and the diesel generators only mitigate an accident.
2. Operation of Ginna Station in accordance with the proposed change does not create the possibility of a new or different kind of accident from any accident previously evaluated. The proposed change does not involve a physical alteration of the plant (i.e., no new or different type of equipment will be installed). The proposed change introduces no new mode of plant operation or changes in the methods governing normal plant operation. Thus, this change does not create the possibility of a new or different kind of accident from any accident previously evaluated.
3. Operation of Ginna Station in accordance with the proposed change does not involve a significant reduction in a margin of safety. All safety limits and accident analysis assumptions are still met. Therefore, this change does not involve a significant reduction in a margin of safety.

Based upon the above information, it has been determined that the proposed changes to the Ginna Station Technical Specifications do not involve a significant increase in the probability or consequences of an accident previously evaluated, does not create the possibility of a new or different kind of accident previously evaluated, and does not involve a significant reduction in a margin of safety. Therefore, it is concluded that the proposed changes meet the requirements of 10 CFR 50.92(c) and do not involve a significant hazards consideration.

F. ENVIRONMENTAL CONSIDERATION

RG&E has evaluated the proposed changes and determined that:

1. The changes do not involve a significant hazards consideration as documented in Section D above;

2. The changes do not involve a significant change in the types or significant increase in the amounts of any effluents that may be released offsite since all specifications related to offsite releases are retained, addressed by existing regulations, or relocated to a licensee controlled program subject to the current regulations; and
3. The changes do not involve a significant increase in individual or cumulative occupational radiation exposure since no new or different type of equipment are required to be installed as a result of this LAR, and the frequency of required testing which may result in radiation exposure is to be optimized consistent with industry practices.

Accordingly, the proposed changes meet the eligibility criteria for categorical exclusion set forth in 10 CFR 51.22(c)(9). Therefore, pursuant to 10 CFR 51.22(b), an environmental assessment of the proposed changes is not required.

ATTACHMENT B

Marked Up Copy of R.E. Ginna Nuclear Power Plant
Technical Specifications

Included pages:

All pages in Full-Term Operating License and Appendix A to that license up to, and including, Amendment No. 59. These are organized with respect to the proposed new ITS provided in Attachment C.

The following pages have been revised since the May 26, 1995 submittal:

License: 2, 4, and 5

Chapter 1.0: 1.0-5, -8, -9, and -10

Chapter 2.0: None

Chapter 3.0: 3.0-1

Chapter 3.1: 3.1-36

Chapter 3.2: 3.2-1 and 3.2-17a

Chapter 3.3: 3.3-2, -3, -4, -13, -14, -15, -19 through -29, -31, -33 through -37, -50, -52, -54, and -55

Chapter 3.4: 3.4-4, -25, -45, -47, and -55

Chapter 3.5: 3.5-1, and -9

Chapter 3.6: 3.6-5, -6, -9, -10, -11, -29, -30, and -31

Chapter 3.7: 3.7-2, -4, -5, -18, -19, -28, -32 through -36

Chapter 3.8: 3.8-14, -15, and -17

Chapter 3.9: 3.9-1 through -8, -10, -14a, and -14b

Chapter 4.0: 4.0-2, -2a, and -12

Chapter 5.0: 5.0-7, -8, -40, -42, -43, -92, -93, -94, -95, -100

UNITED STATES
NUCLEAR REGULATORY COMMISSION
WASHINGTON, D. C. 20555

ROCHESTER GAS AND ELECTRIC CORPORATION

DOCKET NO. 50-244

R. E. GINNA NUCLEAR POWER PLANT

FACILITY OPERATING LICENSE

License No. DPR-18

1. The Nuclear Regulatory Commission (the Commission) has found that:
 - A. The application complies with the requirements of the Atomic Energy Act of 1954, as amended (the Act), and the regulations of the Commission set forth in 10 CFR Chapter I and all required notifications to other agencies or bodies have been duly made;
 - B. Construction of the R. E. Ginna Nuclear Power Plant (the facility) has been substantially completed in conformity with Construction Permit No. CPPR-19, as amended, and the application, the provisions of the Act, and the rules and regulations of the Commission;
 - C. The facility will operate in conformity with the application, the provisions of the Act, and the rules and regulations of the Commission; *(excepted as exempted from compliance in Section 2.D below)*
 - D. There is reasonable assurance (i) that the facility can be operated at power levels up to 1520 megawatts (thermal) without endangering the health and safety of the public; and (ii) that such activities will be conducted in compliance with the regulations of the Commission;
 - E. The applicant is technically and financially qualified to engage in the activities authorized by this operating license in accordance with the rules and regulations of the Commission;
 - F. The applicant has furnished proof of financial protection that satisfies the requirements of 10 CFR Part 140; and
 - G. The issuance of this license will not be inimical to the common defense and security or to the health and safety of the public.
2. The Provisional Operating License dated September 19, 1969, is superseded by Facility Operating License No. DPR-18 hereby issued to Rochester Gas and Electric Corporation to read as follows:
 - A. This license applies to the R. E. Ginna Nuclear Power Plant, a closed cycle, pressurized, light-water-moderated and cooled reactor, and electric generating equipment (herein referred to as "the

facility") which is owned by the Rochester Gas and Electric Corporation (hereinafter "the licensee" or "RG&E"). The facility is located on the licensee's site on the south shore of Lake Ontario, Wayne County, New York, about 16 miles east of the City of Rochester and is described in license application Amendment No. 6, "Final Facility Description and Safety Analysis Report," and subsequent amendments thereto, and in the application for power increase notarized February 2, 1971, and Amendment Nos. 1 through 4 thereto (herein collectively referred to as "the application").

B. Subject to the conditions and requirements incorporated herein, the Commission hereby licenses RG&E:

(1) Pursuant to Section 104b of the Act and 10 CFR Part 50, "Domestic Licensing of Production and Utilization Facilities," to possess, use, and operate the facility at the designated location in Wayne County, New York, in accordance with the procedures and limitations set forth in this license;

(2) Pursuant to the Act and 10 CFR Part 70, to receive, possess, and use at any time special nuclear material or reactor fuel, in accordance with the limitations for storage and amounts required for reactor operation as described in the Final Safety Analysis Report, as amended, and Commission Safety Evaluations dated November 15, 1976, October 5, 1984, ~~and~~ November 14, 1984, and August 30, 1985

Fuel enrichment
SER

(a) Pursuant to the Act and 10 CFR Part 70, to receive and store four (4) mixed oxide fuel assemblies in accordance with the licensee's application dated December 14, 1979 (transmitted by letter dated December 20, 1979);

(b) Pursuant to the Act and 10 CFR Part 70, to possess and use four (4) mixed oxide fuel assemblies in accordance with the licensee's application dated December 14, 1979 (transmitted by letter dated December 20, 1979), as supplemented February 20, 1980 and March 5, 1980;

(3) Pursuant to the Act and 10 CFR Parts 30, 40, and 70 to receive, possess, and use at any time any byproduct, source, and special nuclear material as sealed neutron sources for reactor startup, sealed sources for reactor instrumentation and radiation monitoring equipment calibration, and as fission detectors in amounts as required;

(4) Pursuant to the Act and 10 CFR Parts 30, 40, and 70, to receive, possess, and use in amounts as required any byproduct, source, or special nuclear material without restriction to chemical or physical form, for sample analysis or instrument calibration or associated with radioactive apparatus or components; and

(5) Pursuant to the Act and 10 CFR Parts 30 and 70, to possess, but not separate, such byproduct and special nuclear materials as may be produced by the operation of the facility.

C. This license shall be deemed to contain and is subject to the conditions specified in the following Commission regulations in 10 CFR Part 20, Section 30.34 of Part 30, Section 40.41 of Part 40, Sections 50.54 and 50.59 of Part 50, and Section 70.32 of Part 70; and is subject to all applicable provisions of the Act and rules, regulations and orders of the Commission now or hereafter in effect; and is subject to the additional conditions specified below:

(1) Maximum Power Level

RG&E is authorized to operate the facility at steady-state power levels up to a maximum of 1520 megawatts (thermal).

(2) Technical Specifications

The Technical Specifications contained in Appendix A, are hereby incorporated in the license. The licensee shall operate the facility in accordance with the Technical Specifications.

(3) Fire Protection

(a) The licensee shall implement and maintain in effect all fire protection features described in the licensee's submittals referenced in and as approved or modified by the NRC's Fire Protection Safety Evaluation (SE) dated February 14, 1979 and SE supplements dated December 17, 1980, February 6, 1981, June 22, 1981, February 27, 1985 and March 21, 1985 or configurations subsequently approved by the NRC, subject to provision (b) below.

(b) The licensee may make changes to the approved fire protection program without prior approval of the Commission only if those changes would not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire.

67.ii

~~(c) Deleted~~

S.5.10

67.ii

(4) Secondary Water Chemistry Monitoring Program

The licensee shall implement a secondary water chemistry monitoring program to inhibit steam generator tube degradation. This program shall be described in the plant procedures and shall include:

- (a) Identification of a sampling schedule for the critical parameters and control points for these parameters;
- (b) Identification of the procedures used to measure the values of the critical parameters;
- (c) Identification of process sampling points;
- (d) Procedure for the recording and management of data;
- (e) Procedures defining corrective actions for off control point chemistry conditions; and
- (f) A procedure identifying (i) the authority responsible for the interpretation of the data, and (ii) the sequence and timing of administrative events required to initiate corrective action.

(5) Systems Integrity

S.5.2

67.i

The licensee shall implement a program to reduce leakage from systems outside containment that would or could contain highly radioactive fluids during a serious transient or accident to as low as reasonably achievable levels. This program shall include the following:

5.5.2

67.i

- (a) Provisions establishing preventive maintenance and periodic visual inspection requirements; and
- (b) Leak test requirements for each system at a frequency not to exceed refueling cycle intervals.

5.5.3

(6) Iodine Monitoring

The licensee shall implement a program which will ensure the capability to accurately determine the airborne iodine concentration in vital areas under accident conditions. This program shall include the following:

- (a) Training of personnel;
- (b) Procedures for monitoring; and
- (c) Provisions for maintenance of sampling and analysis equipment.

D.

67.iv

The facility requires exemptions from certain requirements of ~~10 CFR 50.46(a)(1), 50.48(c)(4), and Appendix J to 10 CFR Part 50.~~ These include: (1) an exemption from 50.46(a)(1), that ECCS performance be calculated in accordance with an acceptable calculational model which conforms to the provisions in Appendix K (SER dated April 18, 1978). The exemption will expire upon receipt and approval of revised ECCS calculations; (2) certain exemptions from Appendix J to 10 CFR Part 50 section III.A.4.(a) maximum allowable leakage rate for reduced pressure tests, section III.B.1 acceptable technique for performing local (Type B) leakage rate tests, section III.D.1 scheduling of containment integrated leakage rate tests, and section III.D.2 testing interval for containment airlocks (SER dated March 28, 1978); and (3) an exemption to the scheduler requirements for the alternative shutdown system as set forth in 10 CFR 50.48(c)(4) (NRC letter dated May 10, 1984). The exemption is effective until startup from the 1986 refueling outage. The aforementioned exemptions are authorized by law and will not endanger life or property or the common defense and security and are otherwise in the public interest. Therefore, the exemptions are hereby granted pursuant to 10 CFR 50.12.

Delete Appendix J exemptions per 11/27/95 LAR

67.iii

E. Physical Protection - The licensee shall maintain in effect and fully implement all provisions of the following Commission-approved documents, including amendments and changes made pursuant to the authority of 10 CFR 50.54(p), which are being withheld from public disclosure pursuant to 10 CFR 73.21:

- E. The licensee shall fully implement and maintain in effect all provisions of the Commission-approved physical security, guard training and qualification, and safeguards contingency plans including amendments made pursuant to provisions of the Miscellaneous Amendments and Search Requirements revisions to 10 CFR 73.55 (51 FR 27827 and 27822) and to the authority of 10 CFR 50.90 and 10 CFR 50.54(p). The plans, which contain Safeguards Information protected under 10 CFR 73.21, are entitled: "Robert Emmet Ginna Nuclear Plant Physical Security Plan," with revisions submitted through August 18, 1987; "Robert Emmet Ginna Nuclear Plant Guard Training and Qualification Plan" with revisions submitted through July 30, 1981; and "Robert Emmet Ginna Nuclear Plant Safeguards Contingency Plan" with revisions submitted through April 14, 1981. Changes made in accordance with 10 CFR 73.55 shall be implemented in accordance with the schedule set forth therein.
- F. This license is effective as of the date of issuance and shall expire at midnight, September 18, 2009.

1. xxv

1. xxvi

TECHNICAL SPECIFICATIONS1.0 DEFINITIONS

The following terms are defined for uniform interpretation of the specifications.

1.1 Thermal Power

1.1 The rate that the thermal energy generated by the fuel is accumulated by the coolant as it passes through the reactor vessel.

1.2 Reactor Operating Modes

1.1

Table 1.1-1

Mode	Reactivity $\Delta k/k\%$	Coolant Temperature (°F)
Refueling	≤ -5	$T_{avg} \leq 140$
Cold Shutdown	≤ -1	$T_{avg} \leq 200$
Hot Shutdown	≤ -1	$T_{avg} \geq 540$
Operating	> -1	$T_{avg} \sim 580$

1.3 Refueling

1.1

Table 1.1-1

1.1.1 Any operation within the containment involving movement of fuel and/or control rods when the vessel head is unbolted.

1-1

1.4

Operable-Operability

A system, subsystem, train, component or device shall be operable or have operability when it is capable of performing its specified function(s). Implicit in this definition shall be the assumption that all necessary attendant instrumentation, controls, normal or emergency electrical power sources (subject to Section 3.0.2), cooling or seal water, lubrication, supports, or other auxiliary equipment that are required for the system, subsystem, train, component or device to perform its function(s) are also capable of performing their related support function(s).

1.5 Operating

Performing all intended functions in the intended manner.

1.6 Degree of Redundancy (Instrument Channels)

The difference between the number of operable channels and the number of channels which, when tripped, will cause an automatic system trip.

1.7 Instrument Surveillance

1.7.1 Channel Calibration

The adjustment, as necessary, of the channel output so that it responds with the necessary range and accuracy to known values of the parameter which the channel monitors. The Channel Calibration shall encompass the entire channel including the sensor and alarm and/or trip functions, and shall include the Channel Functional Test. The Channel Calibration may be performed by any series of sequential, overlapping or total channel steps so that the entire channel is calibrated.

1.7.2 Channel Check

The qualitative assessment of channel behavior during operation by observation. This determination shall include, where possible, comparison of the channel indication and/or status with other indications and/or status derived from independent instrumentation channels measuring the same parameter.

1.7.3

Channel Functional Test

- a. Analog channels - the injection of a simulated or source signal into the channel as close to the sensor as practicable to verify operability including alarm and/or trip functions.
- b. Bistable channels - the injection of a simulated or source signal into the sensor to verify operability including alarm and/or trip function.

1.vii

1.7.4

Source Check

The qualitative assessment of channel response when the channel sensor is exposed to a radioactive source.

1.viii

1.8

Containment Integrity

Containment integrity is defined to exist when:

- a. All non-automatic containment isolation valves which are not required to be open during accident conditions are closed and blind flanges are installed where required.
- b. The equipment door is properly closed and sealed.
- c. At least one door in each personnel air lock is properly closed and sealed.
- d. All automatic containment isolation valves are operable, secured in the closed position or isolated by closed manual valves or flanges as permitted by Limiting Conditions for Operation.
- e. The containment leakage satisfies Technical Specification 4.4.

1.1x

Relocated to bases for 3.6.1 and 3.6.2

1.9

Quadrant Power Tilt

1.1

The ratio of highest average nuclear power in any quadrant to the average nuclear power in the four quadrants. If one excor detector is out of service, the three inservice units are used in computing the average.

1.10

Hot Channel Factors

F_Q , Heat Flux Hot Channel Factor, is defined as the maximum local heat flux in the surface of a fuel rod divided by the average fuel rod heat flux allowing for manufacturing tolerances on fuel pellets and rods.

F_Q^N , Nuclear Heat Flux Hot Channel Factor, is defined as the maximum local fuel rod linear power density divided by the average fuel rod linear power density assuming nominal fuel pellet and rod dimensions.

F_Q^E , Engineering Heat Flux Hot Channel factor,, is defined as the ratio between F_Q and F_Q^N and is the allowance on heat flux required for manufacturing tolerances.

$F_{\Delta H}^N$, Nuclear Enthalpy Rise Hot Channel Factor, is defined as the ratio of the integral of linear power along the rod on which minimum DNBR occurs to the average rod power.

1.12

Frequency Notation

The frequency notation specified for the performance of surveillance requirements shall correspond to the intervals defined below.

<u>Notation</u>	<u>Frequency</u>
S, Each Shift	At least once per 12 hours
D, Daily	At least once per 24 hours
Twice per week	At least once per 4 days and at least twice per 7 days
W, Weekly	At least once per 7 days
B/W, Biweekly	At least once per 14 days
M, Monthly	At least once per 31 days
B/M, Bimonthly	At least once per 62 days
Q, Quarterly	At least once per 92 days
SA, Semiannually	At least once per 6 months
A, Annually	At least once per 12 months
R	At least once per 18 months
S/U	Prior to each startup
N.A.	Not Applicable
P	Prior to each startup if not done previous week
PR	Within 12 hours prior to each release

Offsite Dose Calculation Manual (ODCM)

The ODCM is a manual containing the methodology and parameters to be used for calculating the offsite

See Chapter 5.02

See Chapter
5.0

doses due to liquid and gaseous radiological effluents, in calculation of liquid and gaseous effluent monitoring instrumentation alarm/trip setpoints, and in the conduct of the environmental radiological monitoring program.

1.14 Process Control Program (PCP)

The PCP is a manual outlining the method for processing wet solid wastes and for solidification of liquid wastes. It shall include the process parameters and evaluation methods used to assure meeting the requirements of 10 CFR Part 71 prior to shipment of containers of radioactive waste from the site.

1.xiv

1.15 Solidification

Solidification shall be the conversion of radioactive wastes from liquid systems to a homogeneous solid.

1.xv

1.16 Purge-Purging

Purge or purging is the controlled process of discharging air or gas from a confined space to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air or gas is required to purify the confined space.

1.xvi

1.17 Venting

Venting is the controlled process of discharging air or gas from a confined space to maintain temperature, pressure, humidity, concentration or other operating condition, in such a manner that replacement air is not provided or required.

1.xvii

1.18 Dose Equivalent I-131

1.1

The dose equivalent I-131 shall be that concentration of I-131 which alone would produce the same thyroid dose as the quantity and isotopic mixture of I-131, I-132, I-133, I-134 and I-135 actually present. The dose conversion factors used for this calculation shall be those for the adult thyroid dose via inhalation, contained in NRC Regulatory Guide 1.109 Rev. 1 October 1977.

1.19 Reportable Event

1.xix

A Reportable Event shall be any of those conditions specified in Section 50.73 to 10CFR Part 50.

1.20 Canisters Containing Consolidated Fuel Rods

1.xx

Canisters containing consolidated fuel rods are stainless steel canisters containing the fuel rods of no more than two fuel assemblies which have decayed at least five years and are capable of being stored in a storage cell of the spent fuel pool.

1.21 Shutdown Margin

1.1

1.xx1

Shutdown margin shall be the amount of reactivity by which the reactor is subcritical, or would be subcritical from its present condition assuming all rod cluster control assemblies (shutdown and control) are fully inserted except for the single rod cluster control assembly of highest reactivity worth which is assumed to be fully withdrawn, and assuming no changes in xenon or boron concentration.

2.0 SAFETY LIMITS AND LIMITING SAFETY SYSTEM SETTINGS

2.1 Safety Limit - Reactor Core

Applicability:

2.1

Applies to the limiting combinations of thermal power, reactor coolant system pressure and coolant temperature during operation ← MODES 1 and 2

Objective:

To maintain the integrity of the fuel cladding.

Specification:

The combination of thermal power level, coolant pressure and coolant temperature shall not exceed the limits shown in Figure 2.1-1. The safety limit is exceeded if the point defined by the combination of reactor coolant system average temperature and power level is at any time above the appropriate pressure line.

2.1.1

Basis:

~~To maintain the integrity of the fuel cladding and prevent fission product release, it is necessary to prevent overheating of the cladding under all operating conditions. This is accomplished by operating within the nucleate boiling regime of heat transfer; wherein the heat transfer coefficient is very large and the clad surface temperature is only a few degrees Fahrenheit above the coolant temperature. The upper boundary of the nucleate boiling regime is termed departure from nucleate boiling (DNB) and at this point there is a sharp reduction of the heat transfer coefficient which would result in high clad temperatures and the possibility of clad failure. DNB is not, however, an observable~~

parameter during reactor operation. Therefore, the observable parameters, thermal power, reactor coolant temperature and pressure have been related to DNB through the W-3 and/or WRB-1 DNB correlation. These DNB correlations have been developed to predict the DNB flux and the location of DNB for axially uniform and non-uniform heat flux distributions. The local DNB heat flux ratio, defined as the ratio of the heat flux that would cause DNB at a particular core location to the local heat flux, is indicative of the margin to DNB. A minimum value of the DNB ratio, MDNBR, is specified so that during steady state operation, normal operational transients and anticipated transients, there is a 95% probability at a 95% confidence level that DNB will not occur. (1) The curves of Figure 2.1-1 represent the loci of points of thermal power, coolant system pressure and average temperature for which this minimum DNB value is satisfied. The area of safe operation is below these lines.

Since it is possible to have somewhat greater enthalpy rise hot channel factors at part power than at full power due to the deeper control bank insertion which is permitted at part power, a conservative allowance has been made in obtaining the curves in Figure 2.1-1 for an increase in $F_{\Delta H}^N$ with decreasing power levels. Rod withdrawal block and load runback occurs before reactor trip set points are reached.

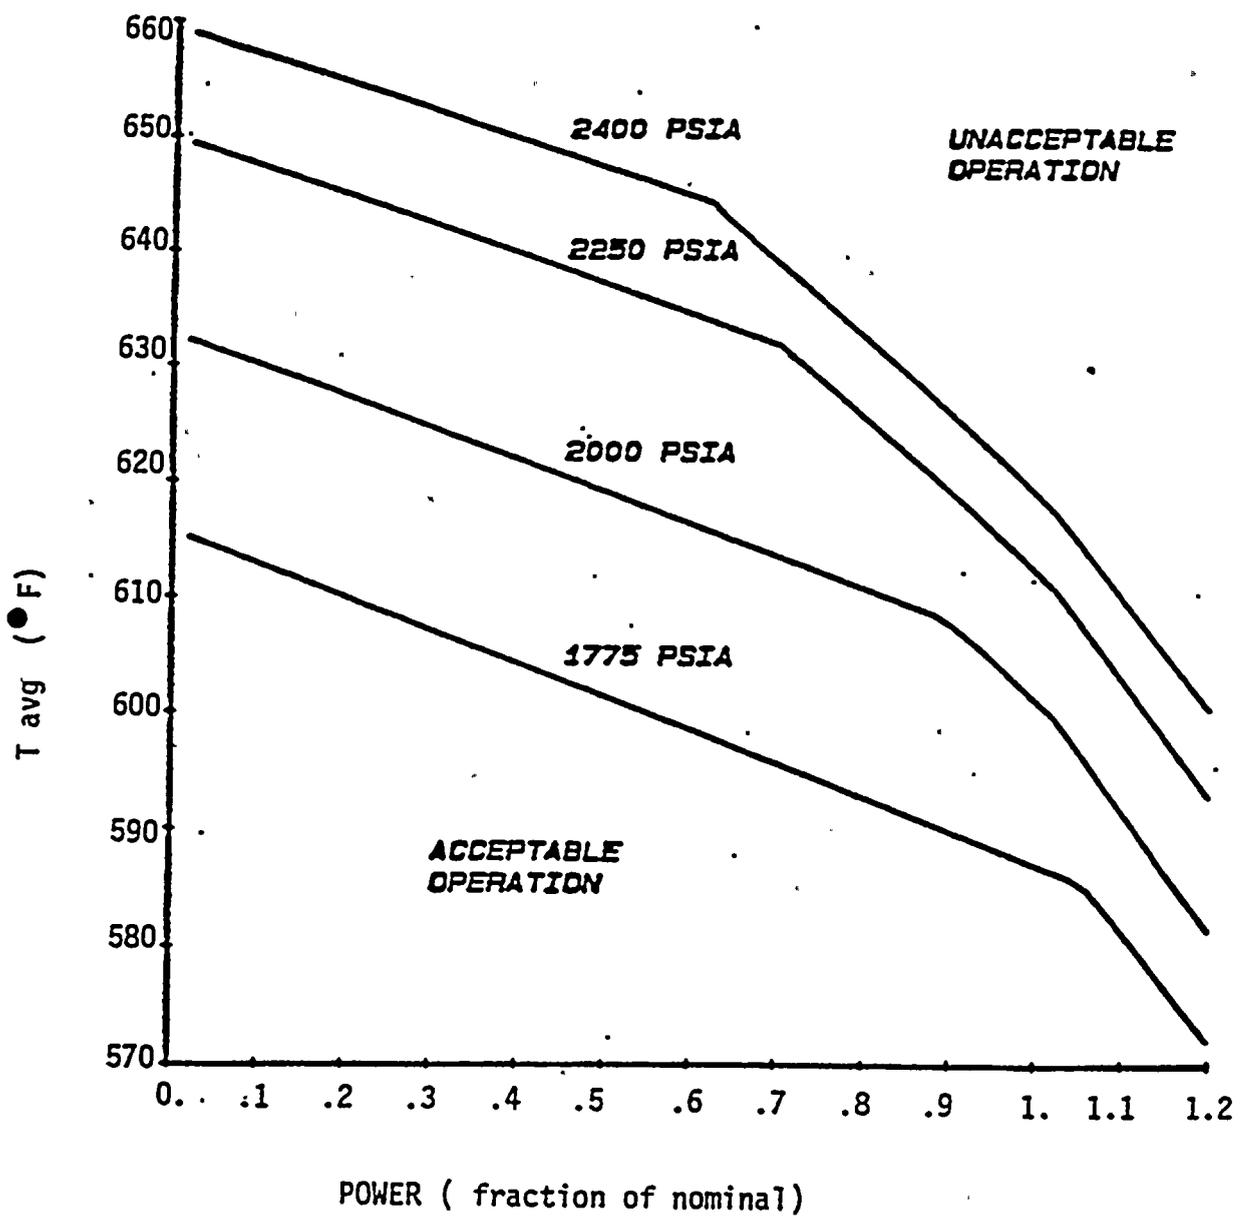

The Reactor Control and Protective System is designed to prevent any anticipated combination of transient conditions for reactor coolant system temperature, pressure and thermal power level that

would result in there being less than a 95% probability at a 95% confidence level that DNB would not occur. (2)

2.1.1-1
FIGURE ~~2.1.1~~
CORE DNB SAFETY LIMITS
2 LOOP OPERATION

~~2.1.4~~

2.2 Safety Limit - Reactor Coolant System Pressure

Applicability:
 Applies to the limit on Reactor Coolant System pressure.

Objective:
 To maintain the integrity of the Reactor Coolant System.

2.1.2

Specification:
 The Reactor Coolant System pressure shall not exceed 2735 psig with fuel assemblies installed in the reactor vessel.

3.i

Basis:
 The Reactor Coolant System⁽¹⁾ serves as a barrier preventing radio-nuclides contained in the reactor coolant from reaching the atmosphere. In the event of a fuel cladding failure, the Reactor Coolant System is the primary barrier against the release of fission products. By establishing a system pressure limit, the continued integrity of the reactor coolant system and fuel cladding is assured. The maximum transient pressure allowable in the reactor coolant system pressure vessel under the ASME Code, Section III, is 110% of design pressure. The maximum transient pressure allowable in the reactor coolant system piping, valves and fittings under USAS Section B31.1 is 120% of design pressure. Thus, the safety limit of 2735 psig (110% of design pressure) has been established.⁽²⁾

The settings of the power-operated relief valves (2335 psig), the reactor high pressure trip (2385 psig), and the safety valves (2485 psig) have been established to assure never reaching the Reactor Coolant System pressure safety limit. The initial hydrostatic test was conducted at 3110 psig to assure the integrity of the Reactor Coolant System.

6.7 SAFETY LIMIT VIOLATION

6.7.1 The following actions shall be taken in the event a Safety Limit is violated:

2.2
SS.i

a. The provisions of 10 CFR 50.36(c)(1)(i)(A) shall be complied with immediately.

SS.ii

b. The Safety Limit violation shall be reported to the Senior Vice President, Customer Operations*, to the offsite review function, and to the NRC immediately.

SS.iii

c. A Safety Limit Violation Report shall be prepared. The report shall be reviewed by the onsite review function. This report shall describe (1) applicable circumstances preceding the violation, (2) effects of the violation upon facility components, systems or structures, and (3) corrective action taken to prevent recurrence.

SS.iv

d. The Safety Limit Violation Report shall be submitted to the NRC, the offsite review function, and the Senior Vice President, Customer Operations* within two weeks of the violation.

SS.ii

SS.iv

* An alternate title may be designated for this position in accordance with 10 CFR 50.54(a)(3). All requirements of these Technical Specifications apply to the position with the alternate title as apply with the specified title. Alternate titles shall be specified in the Updated Final Safety Analysis Report.

3.0 Add 100 3.0.1
3.0 Add 100 3.0.2

LIMITING CONDITION FOR OPERATION

APPLICABILITY

3.0.1

In the event a Limiting Condition for Operation and/or associated action requirements cannot be satisfied because of circumstances in excess of those addressed in the specification, within 1 hour action shall be initiated to place the unit in at least hot shutdown within the next 6 hours (i.e., a total of seven hours), and in at least cold shutdown within the following 30 hours (i.e., a total of 37 hours) unless corrective measures are completed that permit operation under the permissible action statements for the specified time interval as measured from initial discovery or until the reactor is placed in a mode in which the specification is not applicable. If the action statement corresponding to the Limiting Condition for Operation that was exceeded contains time limits to hot and cold shutdown that are less than those specified above, these more limiting time limits shall be applied. Exceptions to these requirements shall be stated in the individual specifications.

100 3.0.3
5.vii
5.viii

3.0.2

When a system, subsystem, train, component or device is determined to be inoperable solely because its emergency power source is inoperable, or solely because its preferred power source is inoperable, it may be considered operable for the purpose of satisfying the requirements of its applicable Limiting Condition for Operation, provided:

100 3.0.4
5.vi

5.iv Add 100 3.0.4
5.v Add 100 3.0.5

3.0.7

5.vi

(1) its corresponding preferred or emergency power source is operable; and (2) all of its redundant system(s), subsystems(s), train(s), component(s) and device(s) are operable, or likewise satisfy the requirements of this specification. Unless both conditions (1) and (2) are satisfied within 1 hour, the unit shall be placed in at least hot shutdown within the next 6 hours, and in at least cold shutdown within the following 30 hours. This specification is not applicable in cold shutdown or refueling modes.

Basis

Specification 3.0.1 delineates the ACTION to be taken for circumstances not directly provided for in the ACTION statements and whose occurrence would violate the intent of the specification. For example, Specification 3.3.2 requires two Containment Spray Pumps to be operable and provides explicit action requirements if one spray pump is inoperable. Under the terms of Specification 3.0.1, if both of the required Containment Spray Pumps are inoperable, the unit is required to be in at least hot shutdown within the following 6 hours and in at least cold shutdown in the next 30 hours. These time limits apply because the time limits for one spray pump inoperable (6 hours to hot shutdown, wait 48 hours then 30 hours to cold shutdown) are less limiting. As a further example, Specification 3.3.1 requires each Reactor Coolant System accumulator to be operable and provides explicit action requirements if one accumulator is inoperable. Under the terms of Specification 3.0.1, if more than one accumulator is inoperable, within 1 hour action shall be initiated to place the unit in at least hot shutdown within 6 hours and cold shutdown within an additional 30 hours. The time limit of 6 hours

to hot shutdown and 30 hours to cold shutdown do not apply because the time limits for 1 accumulator inoperable are more limiting. It is assumed that the unit is brought to the required mode within the required times by promptly initiating and carrying out the appropriate action statement.

Specification 3.0.2 delineates what additional conditions must be satisfied to permit operation to continue, consistent with the action statements for power sources, when a preferred or emergency power source is not operable. It allows operation to be governed by the time limits of the action statement associated with the Limiting Condition for Operation for the preferred or emergency power source, not the individual action statements for each system, subsystem, train, component or device that is determined to be inoperable solely because of the inoperability of its preferred or emergency power source.

For example, Specification 3.7.2.1.a requires in part that two emergency diesel generators be operable. The action statement provides for a maximum out-of-service time when one emergency diesel generator is not operable. If the definition of operable were applied without consideration of Specification 3.0.2, all systems, subsystems, trains, components and devices supplied by the inoperable emergency power source would also be inoperable. This would dictate invoking the applicable action statements for each of the applicable Limiting Conditions for Operation. However, the provisions of Specification 3.0.2 permit the time limits for continued operation to be consistent with the action statement for the inoperable emergency diesel generator instead, provided the other specified conditions are satisfied. In this case, this would mean that the corresponding

preferred power source must be operable, and all redundant systems, subsystems, trains, components, and devices must be operable, or otherwise satisfy Specification 3.0.2 (i.e., be capable of performing their design function and have at least one preferred or one emergency power source operable). If they are not satisfied, shutdown is required in accordance with this specification.

27.iii — Add SR 3.0.3

27.iv — Add SR 3.0.4

4.0 SURVEILLANCE REQUIREMENTS

SR 3.0.2
27.ii Specified intervals may be adjusted plus or minus 25% to accommodate normal test schedules.

4.1 Operational Safety Review

Applicability:

Applies to items directly related to safety limits and limiting conditions for operation:-

Objective:

To specify the minimum frequency and type of surveillance to be applied to plant equipment and conditions.

Specification:

- 4.1.1 Calibration, testing, and checking of analog channel and testing of logic channel shall be performed as specified in Table 4.1-1.
- 4.1.2 Equipment and sampling tests shall be conducted as specified in Table 4.1-2 and 4.1-4.
- 4.1.3 Each accident monitoring instrumentation channel shall be demonstrated operable by performance of the channel check and channel calibration operations at the frequencies shown in Table 4.1-3.
- 4.1.4 Each radioactive effluent monitoring instrumentation channel shall be demonstrated operable by performing the channel check, source check, channel functional test, and channel calibration at the frequency shown in Table 4.1-5.

See all other chapters

3.1.3 Minimum Conditions for Criticality

8.IV

3.1.3.1 Except during low power physics tests, the reactor shall not be made critical at a temperature below 500°F, and if the moderate temperature coefficient is more positive than

LCO 3.1.3
LCO 3.1.8

8.V

- a. 5 pcm/°F (below 70 percent of rated thermal power)
- b. 0 pcm/°F (at or above 70 percent of rated thermal power)

3.1.3.2 In no case shall the reactor be made critical above and to the left of the criticality limit line shown on Figure 3.1-1 of these specifications.

See Chapter 3.4

3.1.3.3 When the reactor coolant temperature is below the minimum temperature specified above, the reactor shall be subcritical by an amount equal to or greater than the potential reactivity insertion due to depressurization.

Basis

~~Previous safety analyses have assumed that for Design Basis Events (DBE) initiated from the hot zero power or higher power condition, the moderator temperature coefficient (MTC) was either zero or negative. (1)(2) Beginning in Cycle 14, the safety analyses have assumed that a maximum MTC of +5 pcm/°F can exist up to 70% power. Analyses have shown that the design criteria can be satisfied for the DBE's with this assumption. (3) At greater than 70% power the MTC must be zero or negative.~~

~~The limitations on MTC are waived for low power physics tests to permit measurement of the MTC and other physics design parameters of interest. During these tests special operating precautions will be taken.~~

See
Chapter
3.4

The requirement that the reactor is not to be made critical above and to the left of the criticality limit provides increased assurance that the proper relationship between reactor coolant pressure and temperature will be maintained during system heatup and pressurization. Heatup to this temperature will be accomplished by operating the reactor coolant pumps.

If the specified shutdown margin is maintained, there is no possibility of an accidental criticality as a result of an increase in moderator temperature or a decrease of coolant pressure.

3.2 Chemical and Volume Control System

Applicability

Applies to the operational status of the chemical and volume control system.

Objective

To define those conditions of the chemical and volume control system necessary to assure safe reactor operation.

Specification

3.2.1

12.ii

During cold shutdown or refueling with fuel in the reactor there shall be at least one flow path to the core for boric acid injection. The minimum capability for boric acid injection shall be equivalent to that supplied from the refueling water storage tank.

3.2.1.1

With this flow path unavailable, immediately suspend all operations involving core alterations or positive reactivity changes and return a flow path to operable status as soon as possible.

3.2.2

12.iii

When the reactor is above cold shutdown, two boron injection flow paths shall be operable with one operable charging pump for each operable flow path, and one operable boric acid transfer pump for each operable flow path from the boric acid storage tank(s).

3.2.3

12.iv

If required by specification 3.2.2 above, the Boric Acid Storage Tank(s) shall satisfy the concentration, minimum volume and solution temperature requirements of Table 3.2-1.

3.2.4

(12.iii)

With only one of the required boron injection flow paths to the RCS operable, restore at least two boron injection flow paths to the RCS to operable status within 72 hours, or within the next 6 hours be in at least hot shutdown and borated to a shutdown margin equivalent to at least 2.45% delta k/k at cold, no xenon conditions. If the requirements of 3.2.2 are not satisfied within an additional 7 days, then be in cold shutdown within the next 30 hours.

3.2.5

See
Chapter
3.4

Whenever the RCS temperature is greater than 200°F and is being cooled by the RHR system and the over-pressure protection system is not operable, at least one charging pump shall be demonstrated inoperable at least once per 12 hours by verifying that the control switch is in the pull-stop position.

Table 3.2-1

Boric Acid Storage Tank(s)

Minimum-Volume-Temperature-Concentration⁽²⁾

Concentration ppm boron	Minimum Volume gal.	Minimum Solution Temperature °F
4700 to less than 5000	8400	40
5000 to less than 6000	7800	52
6000 to less than 7000	6400	62
7000 to less than 8000	5400	70
8000 to less than 9000	4700	78
9000 to less than 10000	4200	85
10000 to less than 11000	3800	91
11000 to less than 12000	3500	97
12000 to less than 13000	3200	103
13000 to less than 14000	3000	108
14000 to less than 15000	2700	113
15000 to less than 16000	2500	118
16000 to less than 17000	2400	123
17000 to less than 18000	2200	127
18000 to less than 19000	2100	131
19000 to less than 20000	2000	137
20000 to less than 21000	1900	140
21000 to less than 22000	1800	143
22000 to less than 23000	1800	145

Basis

The chemical and volume control system provides control of the reactor system boron inventory.⁽¹⁾ This is normally accomplished by using one or more charging pumps in series with one of the two boric acid transfer pumps.

Above cold shutdown conditions, a minimum of two of four boron injection flowpaths are required to insure single functional capability in the event that an assumed single active failure renders one of the flow paths inoperable. The boration volume available through any flow path is sufficient to provide the required shutdown margin at cold conditions from any expected operating condition and to compensate for shrinkage of the primary coolant from the cooldown process. The maximum volume requirement is associated with boration from just critical, hot zero power, peak xenon with control rods at the insertion limit, to cold shutdown with single reactor coolant loop operation. This requires 26,000⁽²⁾ gallons of 2000 ppm borated water from the refueling water storage tank or the concentrations and volumes of borated water specified in Table 3.2-1 from the boric acid storage tanks. Two boric acid storage tanks are available. One of the two tanks may be out of service provided the required volume of boric acid is available to the operable flow paths.

Above cold shutdown, two of the following four flow paths must be operable with one operable charging pump for each operable flow path, and one operable boric acid transfer pump for each operable flow path from the boric acid storage tanks.

- (1) Boric acid storage tanks via one boric acid transfer pump through the normal makeup (FCV 110A) flow path to the suction of the charging pumps.
- (2) Boric acid storage tanks via one boric acid transfer pump through the emergency boration flow path (MOV 350) to the suction of the charging pumps.
- (3) Refueling water storage tank via gravity feed through AOV 112B to the suction of the charging pumps.

refueling water storage tank via gravity feed through manual bypass valve 358 to the suction of the charging pumps. 3.1-7

Available flow paths from the charging pumps to the reactor coolant system include the following:

- (1) Charging flow path through AOV 392A to the RCS Loop B hot leg.
- (2) Charging flow path through AOV 294 to the RCS Loop B cold leg.
- (3) Seal injection flow path to the reactor coolant pumps.

The rate of boric acid injection must be sufficient to offset the maximum addition of positive reactivity from the decay of xenon after a trip from full power. This can be accomplished through the operation of one charging pump at minimum speed with suction from the refueling water storage tank. Also the time required for boric acid injection allows for the local alignment of manual valves to provide the necessary flow paths.

The quantity of boric acid specified in Table 3.2-1 for each concentration is sufficient at any time in core life to borate the reactor coolant to the required cold shutdown concentration and provide makeup to maintain RCS inventory during the cooldown. The temperature limits specified on Table 3.2-1 are required to maintain solution solubility at the upper concentration in each range. The temperatures listed on Table 3.2-1 are taken from Reference (4). An arbitrary 5°F is added to the Reference (4) for margin. Heat tracing may be used to maintain solution temperature at or above the Table 3.2-1 limits. If the solution temperature of either the flow path or the borated water source is not maintained at or above the minimum temperature specified, the affected flow path must be declared inoperable and the appropriate actions specified in 3.2.4 followed.

Placing a charging pump in pull-stop whenever the reactor coolant system temperature is $\geq 200^\circ\text{F}$ and is being cooled by RHR without the overpressure protection system operable will prevent inadvertent overpressurization of the RHR system should letdown be terminated.⁽³⁾

~~3.10 Control Rod and Power Distribution Limits~~

~~Applicability~~

~~Applies to the operation of the control rods and power distribution limits.~~

~~Objective~~

~~To ensure (1) core subcriticality after a reactor trip, (2) limited potential reactivity insertions from a hypothetical control rod ejection, and (3) an acceptable core power distribution during power operation.~~

~~Specification~~

3.10.1 Control Rod Insertion Limits.

20.i

3.10.1.1 When the reactor is subcritical prior to startup, the hot shutdown margin shall be at least that shown in

LCO 3.1.1
LCO 3.1.2

20.ii
20.iii

Figure 3.10-2. The shutdown margin as used here is defined as the amount by which the reactor core would be subcritical at hot shutdown conditions (547°F) if all control rods were tripped, assuming that the highest worth control rod remained fully withdrawn, and assuming no changes in xenon or boron.

specified in the COLR.

~~Amendment No. 10, 24
March 30, 1976~~

3.10.1.2
LCD 3.1.5
LCD 3.1.8

When the reactor is critical except for physics tests and control rod exercises, the shutdown control rods shall be fully withdrawn (indicated position).

20.iv

low power

20.iv

low power

3.10.1.3
LCD 3.1.6
LCD 3.1.8

When the reactor is critical, except for physics tests and control rod exercises, each group of control rods shall be inserted no further than the limits shown by the lines on Figure 3.10-1 and moved sequentially with a 100 (+5) step (demand position) overlap between successive banks.

Specified in the COLR.

20.v

Relocate to COLR

3.10.1.4
LCD 3.1.5
LCD 3.1.6

During control rod exercises indicated in Table 4.1-2, the insertion limits need not be observed but the Figure 3.10-2 must be observed.

3.10.1.5

~~During measurement of control rod worth and shutdown margin, the shutdown margin requirement, Specification 3.10.1.1, need not be observed provided the reactivity equivalent to at least the highest estimated control rod worth is available for trip insertion. Each full length control rod not fully inserted, that is, the rods available for trip insertion, shall be demonstrated capable of full insertion when tripped from at least the 50% withdrawn position (indicated) within 24 hours prior to reducing the shutdown margin to less than the limits of Specification 3.10.1.1. The position of each full length rod not fully inserted, that is, available for trip insertion, shall be determined at least once per 2 hours.~~

20.vi

3.10.2 Power Distribution Limits and Misaligned Control Rod

3.10.2.1 The movable detector system shall be used to measure power distribution after each fuel reloading prior to operation of the plant at 50% of rated power to ensure that design limits are not exceeded.

If the core is operating above 75% power with one excore nuclear channel out of service, then the quadrant to average power tilt ratio shall be determined once a day by at least one of the following means:

- a. Movable detectors
- b. Core-exit thermocouples

See Chapter 3.2

3.10.2.2 Power distribution limits are expressed as hot channel factors. At all times, ~~except during low power physics tests~~ the hot channel factors must meet the following limits:

20.vii

$$F_Q(Z) = (2.32/P)*K(Z) \quad \text{for } P \geq .5$$

$$F_Q(Z) = 4.64*K(Z) \quad \text{for } P \leq .5$$

$$F_{\Delta H}^N = 1.66 [1 + .3(1-P)] \quad \text{for } 0 \leq P \leq 1.00$$

Where P is the fraction of rated power at which the core is operating, K(Z) is the function given by Figure 3.10-3, and Z is the height in the core. The measured F_Q shall be increased by three percent to yield F_Q . If the measured F_Q or $F_{\Delta H}^N$ exceeds the limiting value, with due allowance for measurement error, the maximum allowable reactor power level and the Nuclear Overpower Trip set point shall be reduced one percent for each percent with $F_{\Delta H}^N$ or F_Q exceeds the limiting value, whichever is more restrictive. If the hot channel factors cannot be reduced below the

See Chapter 3.2

limiting values within one day, the Overpower ΔT trip setpoint and the Overtemperature ΔT setpoint shall be similarly reduced.

20.viii

3.10.2.3 ~~Except for physics tests,~~ If the quadrant to average power tilt ratio exceeds 1.02 but is less than 1.12, then within two hours:

see Chapter 3.2

- a. Correct the situation, or
- b. Determine by measurement the hot channel factors, and apply Specification 3.10.2.2, or
- c. Limit power to 75% of rated power.

3.10.2.4 If the quadrant to average power tilt ratio exceeds 1.02 but is less than 1.12 for a sustained period of more than 24 hours without known cause, or if such a tilt recurs intermittently without known cause, the reactor power level shall be restricted so as not to exceed 50% of rated power. If the cause of the tilt is determined, continued operation at a power level consistent with 3.10.2.2 above, shall be permitted.

3.10.2.5 Except for physics test, if the quadrant to average power tilt ratio is 1.12 or greater, within 2 hours either reduce the quadrant to average power tilt ratio to within its limit or reduce power to less than 50% of rated power. Within an additional 4 hours, either reduce the ratio to within its limit or be at hot shutdown. Subsequent operation for the purpose of measuring and correcting the tilt is permitted provided the power level does not exceed 50% of rated power and the Nuclear Overpower Trip setpoint is reduced by 50%.

3.10.2.6 Following any refueling and at least every effective full power month thereafter, flux maps, using the movable detector system, shall be made to confirm that

the hot channel factor limits of Specification 3.10.2.2 are met.
The reference equilibrium indicated axial flux difference as a function of power level (called the target flux difference) shall be measured at least once per equivalent full power quarter. The target flux difference must be updated at least each equivalent full power month using a measured value or by linear interpolation using the most recent measured value and the predicted value at the end of the cycle life.

3.10.2.7

See Chapter 3.2

20.1x

3.10.2.8

Except during ~~physics tests~~, control rod exercises, excore detector calibration, and except as modified by 3.10.2.9 through 3.10.2.12, the indicated axial flux difference shall be maintained within ±5% of the target flux difference (defines the target band on axial flux difference). Axial flux difference for power distribution control is defined as the average value for the four excore detectors. If one excore detector is out of service, the remaining three shall be used to derive the average.

See Chapter 3.2

20.1x

3.10.2.9

Except during ~~physics tests~~, control rod exercises, or excore calibration, at a power level greater than 90 percent of rated power, if the indicated axial flux difference deviates from its target band. The flux difference shall be returned to the target band immediately or the reactor power shall be reduced to a level no greater than 90 percent of rated power.

See Chapter 3.2

2D. IX

3.10.2.10 Except during ~~physics tests~~, control rod exercises, or excore calibration, at a power level less than or equal to 90 percent of rated power:

- a. The indicated axial flux difference may deviate from its $\pm 5\%$ target band for a maximum of one hour (cumulative) in any 24 hour period, however, the flux difference shall not exceed an envelope bounded by -11 percent and $+11$ percent at 90% power and increasing by -1 percent and $+1$ percent for each 2 percent of rated power below 90% power.
- b. If Specification 3.10.2.10a is violated, then the reactor power shall be immediately reduced to no greater than 50% power.
- c. A power increase to a level greater than 90 percent of rated power is contingent upon the indicated axial flux difference being within its target band.

See
Chapter
3.2

3.10.2.11 A power increase to a level greater than 50% of rated power is contingent upon the indicated axial flux difference not being outside its target band for more than two hours (cumulative) out of the preceding 24 hour period. One half the time the indicated axial flux difference is out of its target band up to 50% of rated power is to be counted as contributing to the one hour cumulative maximum the flux difference may deviate from its target band at a power level less than or equal to 90 percent of rated power.

3.10.2.12 When the reactor is critical and thermal power is less than or equal to 90% of rated power, an alarm is provided to indicate when the axial flux difference has been outside the target band for more than one hour (cumulative) out of any 24 hour period. In addition, when thermal power is greater than 90% of rated power, an alarm is provided to indicate when the axial flux difference is outside the target band. If either alarm is out of service, the flux difference shall be logged hourly for the first 24 hours the alarm is out of service and half-hourly thereafter.

see
Chapter
3.2

3.10.3 Control Rod Drop Time

3.10.3.1 While critical, the individual full length (shutdown and control) rod drop time from the fully withdrawn position (indicated) shall be less than or equal to 1.8 seconds from beginning of decay of stationary gripper coil voltage to dashpot entry with:

SR 3.1.4.4

20.x

- a. T_{avg} greater than or equal to $540^{\circ}F$ and
b. All reactor coolant pumps operating.

500 °F

3.10.3.2: With the drop time of any full length rod determined to exceed the above limit, restore the rod drop time to within the above limit prior to criticality.

SR 3.1.4.4

20.xi

3.10.4 Control Rod Group Height

3.10.4.1 While critical, and except for physics testing, all full length (shutdown and control) rods shall be operable and positioned within ± 12 steps (indicated position) of their group step counter demand position.

LCO 3.1.4

LCO 3.1.8

low power

3.10.4.2 With any ~~full-length rod inoperable due to being~~
 LCD 3.1.4 ~~immovable as a result of excessive friction or mechanical~~
 (20.xii) ~~interference or known to be untripable, determine that~~
 the shutdown margin requirement of Specification
 3.10.1.1 is satisfied within 1 hour and be in hot
 shutdown within 6 hours.

3.10.4.3 With one ~~full-length rod inoperable due to causes~~
 LCD 3.1.4 ~~other than addressed by 3.10.4.2, above, or misaligned~~
 (20.xii) ~~from its group step counter demand position by more~~
 than ± 12 steps (indicated position), operation may
 continue provided that within one hour either:

3.10.4.3.1 The rod is restored to operable status within the
 LCD 3.1.4 above alignment requirements, or

(20.xiii) 3.10.4.3.2 The ~~rod is declared inoperable and the~~ shutdown margin
 LCD 3.1.4 requirement of Specification 3.10.1.1 is satisfied.
 Operations may then continue provided either:

(20.xiv) LCD 3.1.4 Bases a. The remainder of the rods in the group with the
 inoperable rod are aligned to the same indicated
 position as the inoperable rod within one hour, while
 maintaining the limit of Specification 3.10.1.3: or

LCD 3.1.4 b. The power level is reduced to less than or equal
 to 75% of rated power within the next one hour,
 and ~~the high neutron flux trip setpoint is reduced~~
~~to less than or equal to 85% rated power within~~
~~the next four hours (total of six hours) and the~~
 following evaluations are performed:

(20.xvi) (i) The shutdown margin requirement of Specification
 3.10.1.1 is determined at least once per 12 hours.

LCD 3.1.4

(ii) A power distribution map is obtained from the movable incore detectors and $F_Q(2)$ and $F_{\Delta H}^N$ are verified to be within their limits within 72 hours.

LCD 3.1.4

20.XV

(iii) A reevaluation of each accident analysis ~~of Table 3.10.1~~ is performed within 5 days; this reevaluation shall confirm that the previously analyzed results of these accidents remain valid for the duration of operation under these conditions.

~~c. If power has been restricted in accordance with (b) above, then following completion of the evaluation identified in (b), the power level and high neutron flux trip setpoint may be readjusted based on the results of the evaluation provided the shutdown margin requirement of Specification 3.10.1.1 is determined at least once per 12 hours.~~

LCD 3.1.4

20.XVII

With two or more full length rods inoperable or misaligned from the group step counter demand position by more than ± 12 steps (indicated position), be in hot shutdown within 6 hours.

3.10.5

Control Rod Position Indication Systems

3.10.5.1

LCD 3.1.7

20.XVIII

While critical, the rod position indication system and the step counters shall be operable and capable of determining the control rod positions within ± 12 steps.

3.10.5.2
LCD 3.1.7

With a maximum of one rod position indication per bank inoperable either:

20.XIX

- a. Determine the position of the non-indicating rod(s) indirectly by the movable incore detectors at least once per 8 hours and immediately after any motion of the non-indicating rod which exceeds 24 steps (demand position) in one direction since the last determination of the rod's position, or
- b. Reduce the power to less than 50% of rated power within 8 hours.

3.10.5.3
LCD 3.1.7

With a maximum of one step counter per bank inoperable either:

- a. Verify that position indication for each rod of the affected bank is operable and that the rods of the bank are at the same indicated position at least once per 8 hours, or
- b. Reduce the power to less than 50% of rated power within 8 hours.

Basis

~~The reactivity control concept is that reactivity changes accompanying changes in reactor power are compensated by control rod motion. Reactivity changes associated with xenon, samarium, fuel depletion, and large changes in reactor coolant temperature (operating temperature to cold shutdown) are compensated by changes in the soluble boron concentration. During power operation the shutdown groups are fully withdrawn~~

and control of reactor power is by the control groups. A reactor trip occurring during power operation will put the reactor into the hot shutdown condition. The control rod insertion limits provide for achieving hot shutdown by reactor trip at any time, assuming the highest worth control rod remains fully withdrawn with sufficient margins to meet the assumptions used in the accident analysis.⁽¹⁾ In addition, they provide a limit on the maximum inserted rod worth in the unlikely event of a hypothetical rod ejection, and provide for acceptable nuclear peaking factors.

The lines shown on Figure 3.10-1 meet the shutdown requirement. The maximum shutdown margin requirement occurs at end-of-cycle life and is based on the value used in analysis of the hypothetical steam break accident. Early in cycle life, less shutdown margin is required, and Figure 3.10-2 shows the shutdown margin equivalent to that which is required at end-of-life with respect to an uncontrolled cooldown. All other accident analyses are based on 1% reactivity shutdown margin.

An upper bound envelope of 2.32 times the normalized peaking factor axial dependence of Figure 3.10-3 has been determined from extensive analyses considering operating maneuvers consistent with the Technical Specifications on power distribution control as given in Section 3.10. The results of the loss of coolant accident analyses based on this upper bound envelope

demonstrate compliance with the Final Acceptance Criteria limit for Emergency Core Cooling Systems. When an F_Q measurement is taken, both experimental error and manufacturing tolerance must be allowed for. Five percent is the appropriate allowance for a full core map taken with the movable incore detector flux mapping system and three percent is the appropriate allowance for manufacturing tolerance. When a measurement of $F_{\Delta H}^N$ is taken, experimental error must be allowed for and 4 percent is the appropriate allowance for a full core map with the movable incore detector flux mapping system.

Measurements of the hot channel factors are required as part of startup physics tests, at least each full power month of operation and whenever abnormal power distribution conditions require a reduction of core power to a level based on measured hot channel factors. The incore map taken following initial loading provides confirmation of the basic nuclear design bases including proper fuel loading pattern. The periodic incore mapping provides additional assurance that the nuclear design bases remain inviolate and identifies operational anomalies which might, otherwise, affect these bases.

For normal operation, it is not necessary to measure these quantities. Instead it has been determined that, provided certain conditions are observed, the hot channel factor limits will be met; these

conditions are as follows:

1. Control rods in a single bank move together with no individual rod insertion differing by more than 25 steps from the bank demand position.
2. Control rod banks are sequenced with overlapping banks as described in Specification 3.10.
3. The full length control bank insertion limits are not violated.
4. Axial power distribution limits which are given in terms of flux difference limits and control bank insertion limits are observed. Flux difference is $q_T - q_B$ as defined in Specification 2.3.1.2d.

The permitted relaxation in $F_{\Delta H}^N$ with reduced power allows radial power shape changes with rod insertion to the insertion limits. It has been determined that provided the above conditions 1 through 4 are observed, these hot channel factors limits are met. In Specification 3.10, F_Q is arbitrarily limited for $P < 0.5$ (except for lower power physics tests).

The limits on axial power distribution specified to above are designed to minimize the effects of xenon redistribution on the axial power distribution during load-follow maneuvers. Basically, control of flux difference is required to limit the difference between the current value of Flux Difference (ΔI) and a reference value which corresponds to the full power equilibrium

value of Axial Offset (Axial Offset = ΔI /fractional power). The reference value of flux difference varies with power level and burnup but expressed as axial offset it varies primarily with burnup. The technical specifications on power distribution assure that the F_Q upper bound envelope of 2.32 times Figure 3.10-3 is not exceeded and xenon distributions are not developed which, at a later time, could cause greater local power peaking even though the flux difference is then within the limits.

The target (or reference) value of flux difference is determined as follows. At any time that equilibrium xenon conditions have been established, the indicated flux difference is noted with part length rods withdrawn from the core and with control Bank D more than 190 steps (indicated position) withdrawn. This value, divided by the fraction of full power at which the core was operating is the full power value of the target flux difference.

Values for all other core power levels are obtained by multiplying the full power value by the fractional power. Since the indicated equilibrium value was noted, no allowances for excore detector error are necessary and indicated deviation of ± 5 percent ΔI is permitted from the indicated reference value.

During periods where extensive load following is

~~required, it may be impossible to establish the required
core conditions for measuring the target flux difference
every month. For this reason, two methods are~~

~~3.10-14a~~

~~Amendment No. 22~~

permissible for updating the target flux difference. Strict control of the flux difference (and rod position) is not as necessary during part power operation. This is because xenon distribution control at part power is not as significant as the control at full power and allowance has been made in predicting the heat flux peaking factors for less strict control at part power. Strict control of the flux difference is not possible during certain physics tests, control rod exercises, or during the required periodic excore calibration which require larger flux differences than permitted. Therefore, the specifications on power distribution are not applicable during physics tests, control rod exercises, or excore calibrations; this is acceptable due to the extremely low probability of a significant accident occurring during these operations. Excore calibration includes that period of time necessary to return to equilibrium operating conditions. In some instances of rapid plant power reduction automatic rod motion will cause the flux difference to deviate from the target band when the reduced power level is reached. This does not necessarily affect the xenon distribution sufficiently to change the envelope of peaking factors which can be reached on a subsequent return to full power within the target band, however, to simplify the specification, a limitation of one hour in any period of 24 hours is placed on operation outside the band. This ensures

that the resulting xenon distributions are not significantly different from those resulting from operation within the target band. The instantaneous consequence of being outside the band, provided rod insertion limits are observed, is not worse than a 10 percent increment in peaking factor for flux difference in the range +14 percent to -14 percent (+11 percent to -11 percent indicated) increasing by +1 percent of each 2 percent decrease in rated power. Therefore, while the deviation exists the power level is limited to 90 percent or lower depending on the indicated flux difference.

If, for any reason, flux difference is not controlled within the ± 5 percent band for as long a period as one hour, then xenon distributions may be significantly changed and operation at 50 percent is required to protect against potentially more severe consequences of some accidents.

As discussed above, the essence of the limits is to maintain the xenon distribution in the core as close to the equilibrium full power condition as possible. This is accomplished, without part length rods, by using the chemical volume control system to position the full length control rods to produce the required indication flux difference.

The effect of exceeding the flux difference band at or below half power is approximately half as great as it would be at 90% of rated power, where the effect of deviation has been evaluated.

The reason for requiring hourly logging is to provide continued surveillance of the flux difference if the normal alarm functions are out of service. It is intended that this surveillance would be temporary until the alarm functions are restored.

The quadrant power tilt ratio limit assures that the radial power distribution satisfies the design values used in the power capability analysis. Radial power distribution measurements are made during startup testing and periodically during power operation. The limit of 1.02 at which corrective action is required provides DNB and linear heat generation rate protection with x-y plane power tilts. A limiting tilt of 1.025 can be tolerated before the margin for uncertainty in F_Q is depleted. Therefore, the limiting tilt has been set as 1.02. To avoid unnecessary power changes, the operator is allowed two hours in which to verify the tilt reading and/or to determine and correct the cause of the tilt. Should this action verify a tilt in excess of 1.02 which remains uncorrected, the margin for uncertainty in F_Q^N and $F_{\Delta F}^N$ is reinstated by reducing the power by 2% for each percent of tilt above 1.0, in accordance with the 2 to 1 ratio above, or as required by the restriction on peaking factors.

The two hours in 3.10.2.3 are acceptable since complete rod misalignment (full-length control rod 12

- feet out of alignment with its bank) does not result in exceeding core safety limits in steady state operation at rated power and is short with respect to probability of an independent accident. If instead of determining the hot channel factors, the operator decides to reduce power, the specified 75% power maintains the design margin to core safety limits for up to 1.12 power tilt, using the 2 to 1 ratio. Reducing the overpower trip set point ensures that the protection system basis is maintained for sustained plant operation. A tilt ratio of 1.12 or more is indicative of a serious performance anomaly and a plant shutdown is prudent. The maximum rod drop time restriction is consistent with the assumed rod drop time used in the safety analyses. Measurement with T_{avg} greater than or equal to 540°F and with both reactor coolant pumps operating ensures that the measured drop times will be representative of insertion times experienced during a reactor trip at operating conditions. The various control rod banks (shutdown banks, control banks A, B, C, and D) are each to be moved as a bank; that is, with all rods in the bank within one step (5/8 inch) of the bank position. Position indication is provided by two methods: a digital count of actuation pulses which shows the

demand position of the banks and a microprocessor rod position indication (MRPI) system which indicates the actual rod position. The digital counters are known as the step counters.

Operability of the control rod position indication is required to determine control rod positions and thereby ensure compliance with the control rod alignment and insertion limits. The 12 step permissible demand to indicated misalignment and the 0 step rod to rod indicated misalignment ensures that the 25 step misalignment assumed in the safety analysis is met. The MRPI system displays the position of all rods on a CRT. A failure of the CRT would result in loss of position indication of the rods even though the MRPI system is still operable. Since the MRPI system also transmits rod position information to the Plant Process Computer System (PPCS), the PPCS can be used for rod position indication until the CRT is made operable.

The action statements which permit limited variations from the basic requirements are accompanied by additional restrictions which ensure that the original design criteria are met. Misalignment of a rod requires measurement of peaking factors or a

restriction in power; either of these restrictions provide assurance of fuel rod integrity during continued operation. In addition, those safety analyses affected by a misaligned rod are reevaluated to confirm that the results remain valid during future operation.

Reactivity Anomalies

Applicability

Applies to potential reactivity anomalies.

Objective

To require evaluation of reactivity anomalies within the reactor.

Specification

36i

SR 3.1.2.2

Following a normalization of the computed boron concentration as a function of burnup, the actual boron concentration of the coolant shall be periodically compared with the predicted value.

Basis

To eliminate possible errors in the calculations of the initial reactivity of the core and the reactivity depletion rate, the predicted relation between fuel burn-up and the boron concentration, necessary to maintain adequate control characteristics, must be adjusted (normalized) to accurately reflect actual core conditions. When full power is reached initially, and with the control rod groups in the desired positions, the boron concentration is measured and the predicted curve is adjusted to this point. As power operation proceeds, the measured boron concentration is compared with the predicted concentration and the slope of the curve relating burn-up and reactivity is compared with that

~~predicted.~~ This process of normalization should be completed after

SR 3.1.2.1

about 10% of the total core burn-up. Thereafter, actual boron concentration can be compared with predicted, and the reactivity status of the core can be continuously evaluated. Any reactivity anomaly greater than 1% would be unexpected, and considered an abnormal condition; its occurrence would be thoroughly investigated and evaluated.

LCO 3.1.2

The methods employed in calculating the reactivity of the core vs. burn-up and the reactivity worth of boron vs. burn-up are given in the FSAR. (1)

LCO 3.1.2

The value of 1% is considered a safe limit since a shutdown margin of at least 1% with the most reactive rod in the fully withdrawn position is always maintained.

relocated to the COLR

SEE CHAPTER 3.1
3.10.2.9
LCD 3.2.3

Except during physics tests, control rod exercises, or excore calibration, at a power level greater than 90 percent of rated power, if the indicated axial flux difference deviates from its target band. The flux difference shall be returned to the target band immediately or the reactor power shall be reduced to a level no greater than 90 percent of rated power.

within 15 minutes

20.XXXiv

SEE CHAPTER 3.1

3.10.2.10 Except during physics tests, control rod exercises, or excore calibration, at a power level less than or equal to 90 percent of rated power:

20.XXXV

LCO 3.2.3b

Relocate to the COLR

a.- The indicated axial flux difference may deviate from its $\pm 5\%$ target band for a maximum of one hour (cumulative) in any 24 hour period, however, the flux difference shall not exceed an envelope bounded by -11 percent and +11 percent at 90% power and increasing by -1 percent and +1 percent for each 2 percent of rated power below 90% power.

LCO 3.2.3

b. If Specification 3.10.2.10a is violated, then the reactor power shall be immediately reduced to no greater than 50% power.

LCO 3.2.3

c. A power increase to a level greater than 90 percent of rated power is contingent upon the indicated axial flux difference being within its target band.

3.10.2.11 A power increase to a level greater than 50% of rated power is contingent upon the indicated axial flux difference not being outside its target band for more

LCO 3.2.3c (NOTE)

than two hours (cumulative) out of the preceding 24 hour period. One half the time the indicated axial flux difference is out of its target band up to 50% of rated power is to be counted as contributing to the one hour cumulative maximum the flux difference may deviate from its target band at a power level less than or equal to 90 percent of rated power.

- 3.10.2.12 When the reactor is critical and thermal power is less than or equal to 90% of rated power, an alarm is provided to indicate when the axial flux difference has been outside the target band for more than one hour (cumulative) out of any 24 hour period. In addition, when thermal power is greater than 90% of rated power, an alarm is provided to indicate when the axial flux difference is outside the target band. If either alarm is out of service, the flux difference shall be logged hourly for the first 24 hours the alarm is out of service and half-hourly thereafter.

20.XXXVI

3.10.3

Control Rod Drop Time

3.10.3.1

While critical, the individual full length (shutdown and control) rod drop time from the fully withdrawn position (indicated) shall be less than or equal to 1.8 seconds from beginning of decay of stationary gripper coil voltage to dashpot entry with:

- a. T_{avg} greater than or equal to 540°F, and
- b. All reactor coolant pumps operating.

3.10.3.2

With the drop time of any full length rod determined, to exceed the above limit, restore the rod drop time to within the above limit prior to criticality.

3.10.4

Control Rod Group Height

3.10.4.1

While critical, and except for physics testing, all full length (shutdown and control) rods shall be operable and positioned within ± 12 steps (indicated position) of their group step counter demand position.

SEE
CHAPTER
3.1

and control of reactor power is by the control groups. A reactor trip occurring during power operation will put the reactor into the hot shutdown condition. The control rod insertion limits provide for achieving hot shutdown by reactor trip at any time, assuming the highest worth control rod remains fully withdrawn with sufficient margins to meet the assumptions used in the accident analysis.⁽¹⁾ In addition, they provide a limit on the maximum inserted rod worth in the unlikely event of a hypothetical rod ejection, and provide for acceptable nuclear peaking factors.

The lines shown on Figure 3.10-1 meet the shutdown requirement. The maximum shutdown margin requirement occurs at end-of-cycle life and is based on the value used in analysis of the hypothetical steam break accident. Early in cycle life, less shutdown margin is required, and Figure 3.10-2 shows the shutdown margin equivalent to that which is required at end-of-life with respect to an uncontrolled cooldown. All other accident analyses are based on 1% reactivity shutdown margin.

~~An upper bound envelope of 2.32 times the normalized peaking factor axial dependence of Figure 3.10-3 has been determined from extensive analyses considering operating maneuvers consistent with the Technical Specifications on power distribution control as given in Section 3.10. The results of the loss of coolant accident analyses based on this upper bound envelope~~

SEE
CHAPTER
3.1

demonstrate compliance with the Final Acceptance Criteria limit for Emergency Core Cooling Systems. When an F_Q measurement is taken, both experimental error and manufacturing tolerance must be allowed for. Five percent is the appropriate allowance for a full core map taken with the movable incore detector flux mapping system and three percent is the appropriate allowance for manufacturing tolerance. When a measurement of $F_{\Delta H}^N$ is taken, experimental error must be allowed for and 4 percent is the appropriate allowance for a full core map with the movable incore detector flux mapping system.

Measurements of the hot channel factors are required as part of startup physics tests, at least each full power month of operation, and whenever abnormal power distribution conditions require a reduction of core power to a level based on measured hot channel factors. The incore map taken following initial loading provides confirmation of the basic nuclear design bases including proper fuel loading pattern. The periodic incore mapping provides additional assurance that the nuclear design bases remain inviolate and identifies operational anomalies which might, otherwise, affect these bases.

For normal operation, it is not necessary to measure these quantities. Instead it has been determined that, provided certain conditions are observed, the hot channel factor limits will be met; these

conditions are as follows:

1. Control rods in a single bank move together with no individual rod insertion differing by more than 25 steps from the bank demand position.
2. Control rod banks are sequenced with overlapping banks as described in Specification 3.10.
3. The full length control bank insertion limits are not violated.
4. Axial power distribution limits which are given in terms of flux difference limits and control bank insertion limits are observed. Flux difference is $q_T - q_B$ as defined in Specification 2.3.1.2d.

The permitted relaxation in $F_{\Delta H}^N$ with reduced power allows radial power shape changes with rod insertion to the insertion limits. It has been determined that provided the above conditions 1 through 4 are observed, these hot channel factors limits are met. In Specification 3.10, F_Q is arbitrarily limited for $P < 0.5$ (except for lower power physics tests).

The limits on axial power distribution described to above are designed to minimize the effects of xenon redistribution on the axial power distribution during load-follow maneuvers. Basically, control of flux difference is required to limit the difference between the current value of Flux Difference (ΔI) and a reference value which corresponds to the full power equilibrium

value of Axial Offset (Axial Offset = ΔI /fractional power). The reference value of flux difference varies with power level and burnup but expressed as axial offset it varies primarily with burnup. The technical specifications on power distribution assure that the F_Q upper bound envelope of 2.32 times Figure 3.10-3 is not exceeded and xenon distributions are not developed which, at a later time, could cause greater local power peaking even though the flux difference is then within the limits.

The target (or reference) value of flux difference is determined as follows. At any time that equilibrium xenon conditions have been established, the indicated flux difference is noted with part length rods withdrawn from the core and with control Bank D more than 190 steps (indicated position) withdrawn. This value, divided by the fraction of full power at which the core was operating is the full power value of the target flux difference.

Values for all other core power levels are obtained by multiplying the full power value by the fractional power. Since the indicated equilibrium value was noted, no allowances for excore detector error are necessary and indicated deviation of ± 5 percent ΔI is permitted from the indicated reference value. During periods where extensive load following is

~~required, it may be impossible to establish the required core conditions for measuring the target flux difference every month. For this reason, two methods are~~

permissible for updating the target flux difference. Strict control of the flux difference (and rod position) is not as necessary during part power operation. This is because xenon distribution control at part power is not as significant as the control at full power and allowance has been made in predicting the heat flux peaking factors for less strict control at part power. Strict control of the flux difference is not possible during certain physics tests, control rod exercises, or during the required periodic excore calibration which require larger flux differences than permitted. Therefore, the specifications on power distribution are not applicable during physics tests, control rod exercises, or excore calibrations; this is acceptable due to the extremely low probability of a significant accident occurring during these operations. Excore calibration includes that period of time necessary to return to equilibrium operating conditions. In some instances of rapid plant power reduction automatic rod motion will cause the flux difference to deviate from the target band when the reduced power level is reached. This does not necessarily affect the xenon distribution sufficiently to change the envelope of peaking factors which can be reached on a subsequent return to full power within the target band, however, to simplify the specification, a limitation of one hour in any period of 24 hours is placed on operation outside the band. This ensures

that the resulting xenon distributions are not significantly different from those resulting from operation within the target band. The instantaneous consequence of being outside the band, provided rod insertion limits are observed, is not worse than a 10 percent increment in peaking factor for flux difference in the range +14 percent to -14 percent (+11 percent to -11 percent indicated) increasing by +1 percent of each 2 percent decrease in rated power. Therefore, while the deviation exists the power level is limited to 90 percent or lower depending on the indicated flux difference.

If, for any reason, flux difference is not controlled within the ± 5 percent band for as long a period as one hour, then xenon distributions may be significantly changed and operation at 50 percent is required to protect against potentially more severe consequences of some accidents.

As discussed above, the essence of the limits is to maintain the xenon distribution in the core as close to the equilibrium full power condition as possible. This is accomplished, without part length rods, by using the chemical volume control system to position the full length control rods to produce the required indication flux difference.

The effect of exceeding the flux difference band at or below half power is approximately half as great as it would be at 90% of rated power, where the effect of deviation has been evaluated.

The reason for requiring hourly logging is to provide continued surveillance of the flux difference if the normal alarm functions are out of service. It is intended that this surveillance would be temporary until the alarm functions are restored.

The quadrant power tilt ratio limit assures that the radial power distribution satisfies the design values used in the power capability analysis. Radial power distribution measurements are made during startup testing and periodically during power operation. The limit of 1.02 at which corrective action is required provides DNB and linear heat generation rate protection with x-y plane power tilts. A limiting tilt of 1.025 can be tolerated before the margin for uncertainty in F_q is depleted. Therefore, the limiting tilt has been set as 1.02. To avoid unnecessary power changes, the operator is allowed two hours in which to verify the tilt reading and/or to determine and correct the cause of the tilt. Should this action verify a tilt in excess of 1.02 which remains uncorrected, the margin for uncertainty in F_Q^N and $F_{\Delta H}^N$ is reinstated by reducing the power by 2% for each percent of tilt above 1.0, in accordance with the 2 to 1 ratio above, or as required by the restriction on peaking factors.

The two hours in 3.10.2.3 are acceptable since complete rod misalignment (full-length control rod 12

feet out of alignment with its bank) does not result in exceeding core safety limits in steady state operation at rated power and is short with respect to probability of an independent accident. If instead of determining the hot channel factors, the operator decides to reduce power, the specified 75% power maintains the design margin to core safety limits for up to 1.12 power tilt, using the 2 to 1 ratio. Reducing the overpower trip set point ensures that the protection system basis is maintained for sustained plant operation. A tilt ratio of 1.12 or more is indicative of a serious performance anomaly and a plant shutdown is prudent.

The maximum rod drop time restriction is consistent with the assumed rod drop time used in the safety analyses. Measurement with T_{avg} greater than or equal to 540°F and with both reactor coolant pumps operating ensures that the measured drop times will be representative of insertion times experienced during a reactor trip at operating conditions. The various control rod banks (shutdown banks, control banks A, B, C, and D) are each to be moved as a bank; that is, with all rods in the bank within one step (5/8 inch) of the bank position. Position indication is provided by two methods: a digital count of actuation pulses which shows the

- f. Low reactor coolant flow - $\geq 90\%$ of normal indicated flow.
- g. Low reactor coolant pump frequency - ≥ 57.5 Hz.

2.3.1.3 Other reactor trips

FU# 8

- a. High pressurizer water level - $\leq 88\%$ of span.

FU# 13

- b. Low-low steam generator water level - $\geq 6\%$ of narrow range instrument span

2.3.2 Protective instrumentation settings for reactor trip interlocks shall be as follows:

- 2.3.2.1 Remove bypass of "at power" reactor trips at high power (low pressurizer pressure and low reactor coolant flow) for both loops:

FU# 16.b

- Power range nuclear flux - $\leq 8.5\%$ of rated power
(1) (Note: During cold rod drop tests; the pressurizer high level trip may be bypassed.)

- 2.3.2.2 Remove bypass of single loss of flow trip at high power:

FU# 16.c

- Power range nuclear flux - $\leq 50\%$ rated power
Relay operating will be tested to insure that they perform according to their design characteristics which must fall in within the ranges defined below:

- 2.3.3.1 Loss of voltage relay operating time ≤ 8.5 seconds for 480 volt safeguards bus voltages ≤ 368 volts.

SR 3.3.4.2

Measured values shall fall at least 5% below the theoretical limit. This 5% margin is shown as the 5% tolerance curve in Figure 2.3-1.

4.iv

2.3.3:2 Acceptable degraded voltage relay operating times and setpoints, for 480 volt safeguards bus voltages ≤ 414 volts and > 368 volts are defined by the safeguard

equipment thermal capability curve shown in Figure

2.3-1. Measured values shall fall at least 5% below

the theoretical limit. This 5% margin is shown as the 5% tolerance curve in Figure 2.3-1.

4.iv

Basis:

The high flux reactor trip (low set point) provides redundant protection in the power range for a power excursion beginning from low power. This trip value was used in the safety analysis. (1) In the power range of operation, the overpower nuclear flux reactor trip protects the reactor core against reactivity excursions which are too rapid to be protected by temperature and pressure protective circuitry. The overpower limit criteria is that core power be prevented from reaching a value at which fuel pellet centerline melting would occur. The reactor is prevented from reaching the overpower limit condition by action of the nuclear overpower and overpower ΔT trips. The high and low pressure reactor trips limit the pressure range in which reactor operation is permitted. The high pressurizer pressure reactor trip is also a backup to the pressurizer code safety valves for overpressure protection, and is therefore set lower than the set pressure for these valves (2485 psig). The low pressurizer pressure reactor trip also trips the reactor in the unlikely event of a loss of coolant accident. (3)

The overtemperature ΔT reactor trip provides core protection against DNB for all combinations of pressure, power, coolant temperature, and axial power distribution, provided only that:

(1) the transient is slow with respect to the thermal capacity of the reactor coolant system to respond to power increases (1)(2) and (2) pressure is within the range between the high and low pressure reactor trips. With normal axial power distribution, the reactor trip limit, with allowance for errors, (2) is always below the core safety limit as shown in Figure 2.1-1. If axial peaks are greater than design, as indicated by difference between top and bottom power range nuclear detectors, the reactor trip limit is automatically reduced. (4)

The overpower ΔT reactor trip prevents power density anywhere in the core from exceeding a value at which fuel pellet centerline melting would occur as described in Section 7.2 of the UFSAR. This setpoint includes corrections for axial power distribution, change in density and heat capacity of water with temperature, and dynamic compensation for piping delays from the core to the loop temperature detectors. The specified set points meet this requirement and include allowance for instrument errors. (1)

The low flow reactor trip protects the core against DNB in the event of a sudden loss of power to one or both reactor coolant pumps. The set points specified are consistent with the value used in the accident analysis. (1)

The underfrequency reactor trip protects against a decrease in flow caused by low electrical frequency. The specified set point assures a reactor trip signal before the low flow trip point is reached.

The high pressurizer water level reactor trip protects the pressurizer safety valves against water relief. Approximately 700 ft.³ of water corresponds to 92% of span. A trip at this set point contains margin for both normal instrument error and transient overshoot of level beyond this trip setting. An additional 4% instrument error has been assumed to account for the effects of elevated temperatures on level measurement in accordance with IE Bulletin 79-21.⁽¹²⁾ Therefore a trip setpoint of 88% prevents the water level from reaching the safety valves.⁽⁴⁾

The low-low steam generator water level reactor trip protects against loss of feedwater flow accidents. A set point of 5% is equivalent to at least 40,000 lbs. of water and assures that there will be sufficient water inventory in the steam generators at the time of trip to allow for starting delays for the auxiliary feedwater system.⁽⁵⁾ An additional 11% has been added to the set point to account for error which may be introduced into the steam generator level system at a containment temperature of 286°F as determined by evaluation performed for temperature effects on level measurements required by IE Bulletin 79-21.

The specified reactor trips are blocked at low power where they are not required for protection and would otherwise interfere with normal plant operations. The prescribed set point above which these trips are unblocked assures their availability in the power range where needed.

Operation with one pump will not be permitted above 130 MWT (8.5%). An orderly power reduction to less than 130 MWT (8.5%) will be accomplished if a pump is lost while operating between 130 MWT (8.5%) and 50%. Automatic protection is provided so that a power-to-flow ratio is maintained equal to or less than one, which insures that the minimum DNB ratio increases at lower flow because the maximum enthalpy rise does not increase. For this reason the single pump loss of flow trip can be bypassed below 50% power.

The loss of voltage and degraded voltage trips ensure operability of safeguards equipment during a postulated design basis event concurrent with a degraded bus voltage condition. (9)(10)(11)

The undervoltage set points have been selected so that safeguards motors will start and accelerate the driven loads (pumps) within the required time and will be able to perform for long periods of time at degraded conditions above the trip set points without significant loss of design life. All control circuitry or safety related control centers and load centers, except for motor control centers M and L, are d.c. Therefore, degraded grid voltages do not affect these control centers and load centers. Motor control centers M and L, which supply the Standby Auxiliary Feedwater System, are fully protected by the undervoltage set points. Further, the Standby System is normally not in service and is manually operated only in total loss of feedwater and auxiliary feedwater.

The 5% tolerance curve in Figure 2.3-1 and the requirements of specifications 2.3.3.1 and 2.3.3.2 include 5% allowance for measurement error. Thus, providing the measurement error is less than 5%, measured values may be directly compared to the curve. If measurement error exceeds 5%, appropriate allowance shall be made.

3.5 Instrumentation Systems

Objective

To delineate the conditions of the plant instrumentation and safety circuits.

Specification

- LCO 3.3.1 3.5.1 Protection System Instrumentation
- 3.5.1.1 The Protection System Instrumentation shown on Table 3.5-1 shall be operable whenever the conditions specified in Column 6 are exceeded.
- LCO 3.3.1 3.5.1.2 In the event the number of channels of a particular sub-system falls below the limits given in the columns 1 or 3 of Table 3.5-1, action shall be taken according to the requirements shown in column 5 of Table 3.5-1.
(15.i.a)
- 3.5.2 Engineered Safety Feature Actuation Instrumentation
- LCO 3.3.2 3.5.2.1 The Engineered Safety Feature Actuation System (ESFAS) instrumentation channels shown in Table 3.5-2 shall be operable with their trip setpoints set consistent with the values shown in the Trip Setpoint column of Table 3.5-4, whenever the conditions specified in column 6 of Table 3.5-2 are exceeded.
- LCO 3.3.2 3.5.2.2 In the event the number of channels of a particular subsystem falls below the limits given in columns 1 or 3 of Table 3.5-2, action shall be taken according to the requirements of column 5 of Table 3.5-2.
(15.ii.a)
- 3.5.2.3 ~~With an instrumentation channel trip setpoint less conservative than the value shown in the Allowable Values column of Table 3.5-4, declare the channel inoperable and take action according to the requirements of column 5 of Table 3.5-2 until the channel is restored to operable status with the trip setpoint adjusted consistent with the Trip Setpoint value.~~
(15.ii.b)
- LCO 3.3.3 3.5.3 Accident Monitoring Instrumentation
- 3.5.3.1 The accident monitoring instrumentation channels shown in Table 3.5-3 shall be operable whenever the reactor is at or above hot shutdown.

3.5.3.2
 LCO 3.3.3
 Cond A
 Cond C (15.iii.a)

When required by 3.5.3.1, with the number of operable accident monitoring instrumentation channels less than the Total Number of Channels shown in Table 3.5-3, either restore the inoperable channel(s) to operable status within 30 days (15.iii.b), or be in at least hot shutdown within the next 12 hours. (15.iii.c) Cond C

Cond B
 Cond C/G (for Functions with only one channel)

3.5.3.3
 LCO 3.3.3
 Cond D (15.iii.a)

When required by 3.5.3.1, with the number of operable accident monitoring instrumentation channels less than the Minimum Channels Operable requirements of Table 3.5-3 either restore the inoperable channel(s) to operable status within 7 days (15.iii.d) or be in at least hot shutdown within the next 12 hours. (one inoperable channel)

Cond G

3.5.4 (15.iv)

The radiation accident monitoring instrumentation channels shown in Table 3.5-6 shall be operable, whenever the reactor is at or above hot shutdown. With one or more radiation monitoring channels inoperable, take the action shown in Table 3.5-6. Startup may commence or continue consistent with the action statement.

3.5.5 Radioactive Effluent Monitoring Instrumentation

3.5.5.1 The radioactive effluent monitoring instrumentation shown in Table 3.5-5 shall be operable at all times with alarm and/or trip setpoints set to insure that the limits of Specification 3.9.1.1 and 3.9.2.1 are not exceeded. Alarm and/or trip setpoints shall be established in accordance with calculational methods set forth in the Offsite Dose Calculation Manual.

For R-11 and R-12 only. All other instrumentation addressed in 5.0

For R-11 and R-12 only.
All others addressed in
5.0

3.5.5.2 If the setpoint for a radioactive effluent monitor alarm and/or trip is found to be higher than required, one of the following three measures shall be taken immediately:

- (i) the setpoint shall be immediately corrected without declaring the channels inoperable; or
- (ii) immediately suspend the release of effluents monitored by the effected channel; or
- (iii) declare the channel inoperable.

3.5.5.3 If the number of channels which are operable is found to be less than required, take the action shown in Table

3.5-5. Exert best efforts to return the instruments to OPERABLE status within 31 days and, if unsuccessful, explain in the next Radioactive Effluent Release Report why the inoperability was not corrected in a timely manner.

Reverted
to 3.3.4

3.5.6 Control Room HVAC Detection Systems

3.5.6.1 During all modes of plant operation, detection systems

for ~~chlorine gas, ammonia gas and~~ radioactivity in the

15.V

control room HVAC intake shall be operable with setpoints to isolate air intake adjusted as follows:

Table 3.3.5-1

(15.v)

chlorine, < 5 ppm
ammonia, < 35 mg/m³radioactivity, particulate $\leq 1 \times 10^{-8}$ μ Ci/cciodine $\leq 9 \times 10^{-9}$ μ Ci/ccnoble gas $\leq 1 \times 10^{-5}$ μ Ci/cc

(15.vii)

3.5.6.2

LCO 3.3.5

Cond A and

R.F. Note

With one of the detection systems inoperable, within 1 hour isolate the control room HVAC air intake. Maintain the air intake isolated except for short periods, not to exceed 1 hour a day, when fresh air makeup is allowed to improve the working environment in the control room.

Add Cond B
Cond C

(15.vi)

Basis

During plant operations, the complete instrumentation system will normally be operable. Reactor safety is provided by the Reactor Protection System, which automatically initiates appropriate action to prevent exceeding established limits. Safety is not compromised, however, by continuing operation with certain instrumentation channels inoperable since provisions were made for this in the plant design. This specification outlines limiting conditions for operation necessary to preserve the effectiveness of the reactor control and protection system when any one or more of the channels is inoperable.

Almost all reactor protection channels are supplied with sufficient redundancy to provide the capability for channel calibration and test at power. Exceptions are backup channels such as reactor coolant pump breakers. The removal of one trip channel is accomplished by placing that channel bistable in a tripped mode; e.g., a two-out-of-three circuit becomes a one-out-of-two circuit. Testing does not trip the system unless a trip condition exists in a concurrent channel.

The operability of the accident monitoring instrumentation ensures that sufficient information is available on selected plant parameters to monitor and assess these variables during and following an accident. This capability is consistent with the recommendations of NUREG-0578, "TMI-2 Lessons Learned Task Force Status Report and Short-Term Recommendations".

The radioactive liquid effluent instrumentation is provided to monitor and/or control, as applicable, the releases of radioactive materials in liquid effluents. The alarm and/or trip setpoints for these instruments are calculated in accordance with the ODCM to ensure that alarm and/or trip will occur prior to exceeding the limits of 10 CFR Part 20. The operability and use of this instrumentation is consistent with the requirements of General Design Criteria 60, 63 and 64 of Appendix A to 10 CFR Part 50.

The radioactive gaseous effluent instrumentation is provided to monitor and control, as applicable, the releases of radioactive materials in gaseous effluents. The alarm and/or trip setpoints for these instruments are calculated in accordance with the ODCM to ensure that alarm and/or trip will occur prior to exceeding the limits of 10 CFR Part 20. This instrumentation also includes provisions for monitoring the concentrations of potentially explosive gas mixtures in the waste gas holdup system. The operability and use of this instrumentation is consistent with the requirements of General Design Criterion 64 of Appendix A to 10 CFR Part 50.

Control Room HVAC detection systems are designed to prevent the intake of chlorine, ammonia and radiation at concentrations which may prevent plant operators from performing their required functions. Concentrations which initiate isolation of the control room HVAC system have been established using the guidance of several established references (2-4).

The chlorine isolation setpoint is 1/3 of the toxicity limit of reference 2 but slightly greater than the short term exposure limit of reference 4. The ammonia setpoint is established at approximately 1/3 of the toxicity limit for anhydrous ammonia in reference 2 and equal to the short term exposure limit of reference 4.

The setpoints for radioactivity correspond to the

6.5

maximum permissible concentrations of reference 3 for Cs-137, I-131 and Kr-85.

The mini-purge system is connected to the plant vent. 10 CFR Part 100 type releases via mini-purge are limited by an isolation signal generated from SI. 10 CFR Part 20 releases from mini-purge are considered to be similar to other plant ventilation releases and are monitored by R-10B, R-13, and R-14. R-14A may be a substitute for R-10B. Automatic isolation of mini-purge for 10 CFR Part 20 type releases is considered unnecessary due to the low flow associated with mini-purge and the continuous monitoring. However, the automatic isolation provisions using R-11 or R-12 provide additional margin for 10 CFR Part 20 type releases. Therefore, R-11 or R-12 is required to sample containment during mini-purge operation. To ensure the containment sample monitored by R-11 or R-12 is representative of the containment atmosphere, at least one recirculation fan is required to be in operation during mini-purge operation. Should R-11 and/or R-12 become inoperable, a 1 hour limit is chosen to be consistent with the generally accepted time for prompt action.

Amendment No. 79, 43

TABLE 3.5-5 (Continued)Table Notation

Action 1 - If the number of operable channels is less than required by the Minimum Channels Operable requirement, effluent releases from the tank may continue for up to 14 days, provided that prior to initiating a release:

1. At least two independent samples of the tank's contents are analyzed, in accordance with Specification 4.12.1.1.a, and
2. At least two technically qualified members of the Facility Staff independently verify the release rate calculations and discharge line valving;

Addressed with
Chapter 5.0

Otherwise, suspend release of radioactive effluents via this pathway.

Action 2 - When Steam Generator Blowdown is being released (not recycled) and the number of channels operable is less than required by the Minimum Channels Operable requirements, effluent releases via this pathway may continue provided grab samples are analyzed for gross radioactivity (beta or gamma) at a limit of detection of at most 10⁻⁷ uCi/gram:

1. At least once per 8 hours when the concentration of the secondary coolant is > 0.01 uCi/gram dose equivalent I-131.
2. At least once per 24 hours when the concentration of the secondary coolant is ≤ 0.01 uCi/gram dose equivalent I-131.

Action 3 - If the number of operable channels is less than required by the Minimum Channels operable requirement, effluent releases via this pathway may continue provided that at least once per 24 hours grab samples are analyzed for gross radioactivity (beta or gamma) at a limit of detection of at most 10⁻⁷ uCi/gm.

Action 4 - If the number of operable channels is less than required by the Minimum Channels Operable requirement, effluent releases via this pathway may continue provided grab samples are taken at least once per 8 hours and these samples are analyzed for isotopic activity within 24 hours or R14A is operable and readings are reviewed at least once per 8 hours.

~~3.5-21~~

TABLE 3.5-5 (Continued)

Table Notation

- Action 5 - If the number of operable channels is less than required by the Minimum Channels Operable requirements, effluent releases via this pathway may continue provided samples are continuously collected as required by Table 4.12-2 Item E with auxiliary sampling equipment.
- Action 6 - If the number of operable channels is less than required by the Minimum Channels Operable and the Secondary Activity is $\leq 1 \times 10^{-4}$ uCi/gm, effluent releases may continue via this pathway provided grab samples are analyzed for gross radioactivity (beta or gamma) at least once per 24 hours. If the secondary activity is greater than 1×10^{-4} uCi/gm, effluent releases via this pathway may continue for up to 31 days provided grab samples are taken every 8 hours and analyzed within 24 hours.
- Action 7 - If the channel is inoperable, a sample of the gas from the in service gas decay tank shall be analyzed for oxygen content at least once every 4 hours.

Action 8 - If the number of operable channels is less than required by the Minimum Channels Operable, or at least one containment fan cooler is not operating, within 4 hour terminate the purge.

3.6.3 Containment Isolation Boundaries

3.6.3.1 With a containment isolation boundary inoperable for one or more containment penetrations, either:

Addressed w/
Chapter 3.6

- a. Restore each inoperable boundary to OPERABLE status within 4 hours, or
- b. Isolate each affected penetration within 4 hours by use of at least one deactivated automatic valve secured in the isolation position, one closed manual valve, or a blind flange, or
- c. Be in at least hot shutdown within the next 6 hours and in cold shutdown within the following 30 hours.

LC0333 3.6.4 Combustible Gas Control

Table 3.3-1
FU #11

3.6.4.1 16.viii When the reactor is critical, at least two independent containment hydrogen monitors shall be operable. One of the monitors may be the Post Accident Sampling System.

Cond A
Cond B

3.6.4.2 16.ix With only one hydrogen monitor operable, restore a second monitor to operable status within 30 days or be in at least hot shutdown within the next 6 hours.

Cond E
Cond G

3.6.4.3 16.viii With no hydrogen monitors operable, restore at least one monitor to operable status within 72 hours or be in at least hot shutdown within the next 6 hours.

3.6.5 Containment Mini-Purge

Whenever the containment integrity is required, emphasis will be placed on limiting all purging and venting times to as low as achievable. The mini-purge isolation valves will remain closed to the maximum extent practicable but may be open for pressure control, for ALARA, for respirable air quality considerations for personnel entry, for surveillance tests that may require the valve to be open or other safety related reasons.

Addressed with
Chapter 3.6

3.12 Movable In-Core Instrumentation

Applicability:

Applies to the operability of the movable detector instrumentation system.

Objective:

To specify functional requirements on the use of the in-core instrumentation systems for the recalibration of the excore axial off-set detection system.

Specification:

3.12.1 A minimum of 2 thimbles per quadrant and sufficient movable in-core detectors shall be operable during recalibration of the excore axial off-set detection system.

SR 3.3.1.6

22i

3.12.2 Power shall be limited to 90% of rated power if the calibration requirements for excore axial off-set detection system, identified in Table 4.1-1, are not met.

SR 3.3.1.6

Basis:

(1)

The Movable In-Core Instrumentation System has four drives, four detectors, and 36 thimbles in the core. Each detector can be routed to nineteen or more thimbles. Consequently, the full system has a great deal more capability than would be needed for the calibration of the excore detectors.

To calibrate the excore detector channels, it is only necessary that the

Movable In-Core System be used to determine the gross power distribution in the core as indicated by the power balance between the top and bottom halves of the core.

After the excore system is calibrated initially, recalibration is needed only infrequently to compensate for changes in the core, due for example to fuel depletion, and for changes in the detectors.

If the recalibration is not performed, the mandated power reduction assures safe operation of the reactor since it will compensate for an error of 10% in the excore protection system. Experience at Beznau (Switzerland) and Ginna has shown that drift due to changes in the core or instrument channels is very slight. Thus, the 10% reduction is considered to be very conservative.

Reference:

- (1) FSAR - Section 7.6

4.0 SURVEILLANCE REQUIREMENTS

Specified intervals may be adjusted plus or minus 25% to accommodate normal test schedules.

4.1 Operational Safety Review

Applicability:

Applies to items directly related to safety limits and limiting conditions for operation:-

Objective:

To specify the minimum frequency and type of surveillance to be applied to plant equipment and conditions.

Specification:

4.1.1 Calibration, testing, and checking of analog channel and testing of logic channel shall be performed as specified in Table 4.1-1.

LCO 3.3.1
LCO 3.3.2
LCO 3.3.4
LCO 3.3.5

4.1.2 Equipment and sampling tests shall be conducted as specified in Table 4.1-2 and 4.1-4.

4.1.3 Each accident monitoring instrumentation channel shall be demonstrated operable by performance of the channel check and channel calibration operations at the frequencies shown in Table 4.1-3.

LCO 3.3.3

4.1.4 Each radioactive effluent monitoring instrumentation channel shall be demonstrated operable by performing the channel check, source check, channel functional test, and channel calibration at the frequency shown in Table 4.1-5.

Addressed with Chapter 50

Basis:Check

Failures such as blown instrument fuses, defective indicators, faulted amplifiers which result in "upscale" or "downscale" indication can be easily recognized by simple observation of the functioning of an instrument or system. Furthermore, such failures are, in many cases, revealed by alarm or annunciator action, and a check supplements this type of built-in surveillance.

Based on experience in operation of both conventional and nuclear plant systems, when the plant is in operation, the minimum checking frequency of once per shift is deemed adequate for reactor and steam system instrumentation.

Control Room procedures require a check of the Radiation Monitoring System (RMS) panel meters and strip chart recorders for proper readout once each shift. A daily surveillance log is also maintained in the Control Room for manual entry of RMS readouts, and is independently reviewed by Health Physics supervision at least weekly.

A radiation monitor downscale failure will result in a conspicuous visual indication on the RMS panel (no audible alarm). Radiation monitor control switches are spring-returned to the "operate" mode after being turned to any other test or check mode. Therefore, together with the design features of the RMS, plant surveillance procedures ensure the continued availability of each radiation monitor to perform its intended function.

Calibration

Calibrations are performed to ensure the presentation and acquisition of accurate information.

The nuclear flux (linear level) channels are calibrated daily against a heat balance standard to account for errors induced by changing rod patterns and core physics parameters.

Other channels are subject only to the "drift" errors induced within the instrumentation itself and, consequently, can tolerate longer intervals between calibration. Process system instrumentation errors induced by drift can be expected to remain within acceptable tolerances if recalibration is performed at intervals of each refueling shutdown.

Substantial calibration shifts within a channel (essentially a channel failure) will be revealed during routine checking and testing procedures.

Thus, minimum calibration frequencies of once-per-day for the nuclear flux (linear level) channels, and once each refueling shutdown for the process system channels is considered acceptable.

Testing

The minimum testing frequency for those instrument channels connected to the safety system is based on an average unsafe failure rate of 2.5×10^{-6} failure/hr. per channel. This is based on operating experience at conventional and nuclear plants. An "unsafe failure" is defined as one which negates channel operability and which, due to its nature, is revealed only when the channel is tested or attempts to respond to a bona fide signal.

For the specified one month test interval, the average unprotected time is 360 hours in case of a failure occurring between test intervals. Thus, the probability of failure of one channel between test intervals is $360 \times 2.5 \times 10^{-6}$ or $.9 \times 10^{-3}$. Since two channels must fail in order to negate the safety function, the probability of simultaneous failure of two-out-of-three channels is $3(.9 \times 10^{-3})^2 = 2.4 \times 10^{-6}$. This represents the fraction of time in which each three-channel system would have one operable and two inoperable channels and equals $2.4 \times 10^{-6} \times 8760$ hours per year, or (approximately) 1 minute/year.

Because of their greater degree of redundancy, the 1/3 and 2/4 logic arrays provide an even greater measure of protection and are thereby acceptable for the same testing interval. Those items specified for monthly testing are associated with process components where other means of verification provide additional assurance that the channel is operable, thereby requiring less frequent testing.

TABLE 4.1-1

SR 3.3.1.14 through SR 3.3.1.18 (28.i.f)

NOTE 1: Logic trains will be tested on alternate months corresponding to the reactor trip breaker testing. Monthly logic testing will verify the operability of all sets of reactor trip logic actuating contacts on that train (See Note 3). Refueling shutdown testing will verify the operability of all sets of reactor trip actuating contacts on both trains. In testing, operation of one set of contacts will result in a reactor trip breaker trip; the operation of all other sets of contacts will be verified by the use of indication circuitry. (28.i.c)

NOTE 2: Testing shall be performed monthly, unless the reactor trip breakers are open or shall be performed prior to startup if testing has not been performed within the last 30 days.

NOTE 3: The source range trip logic may be excluded from monthly testing provided it is tested within 30 days prior to startup.

NOTE 4: When BAST is required to be operable.

TABLE 4.1-5 (Continued)

TABLE NOTATION

28.v.c

(1) The Channel Functional Test shall also demonstrate that automatic isolation of this pathway and control room alarm occur if any of the following conditions exist:

- 1. Instrument indicates measured levels above the alarm and/or trip setpoint.
- 2. Power failure.

(2) The Channel Functional Test shall also demonstrate that control room alarm occurs if any of the following conditions exist:

- 1. Instrument indicates measured levels above the alarm setpoint.
- 2. Power failure.

(3) The Channel Calibration shall include the use of standard gas samples containing a nominal:

- 1. Zero volume percent oxygen; and
- 2. Three volume percent oxygen.

(4) This check may require the use of an external source due to high background in the sample chamber.

(5) Source used for the Channel Calibration shall be traceable to the National Bureau of Standards (NBS) or shall be obtained from suppliers (e.g. Amersham) that provide sources traceable to other officially-designated standards agencies.

28.v.c

(6) Flow rate for main plant ventilation exhaust and containment purge exhaust are calculated by the flow capacity of ventilation exhaust fans in service and shall be determined at the frequency specified.

(7) Applies only during releases via this pathway. 28.ii.d

See Chapter 5.0

See Chapter
3.6

the tendon containing 6 broken wires) shall be inspected. The accepted criterion then shall be no more than 4 broken wires in any of the additional 4 tendons. If this criterion is not satisfied, all of the tendons shall be inspected and if more than 5% of the total wires are broken, the reactor shall be shut down and depressurized.

4.4.4.2 Pre-Stress Confirmation Test

- a. Lift-off tests shall be performed on the 14 tendons identified in 4.4.4.1a above, at the intervals specified in 4.4.4.1b. If the average stress in the 14 tendons checked is less than 144,000 psi (60% of ultimate stress), all tendons shall be checked for stress and retensioned, if necessary, to a stress of 144,000 psi.
- b. Before reseating, a tendon, additional stress (6%) shall be imposed to verify the ability of the tendon to sustain the added stress applied during accident conditions.

4.4.5 Containment Isolation Valves

- 4.4.5.1 Each containment isolation valve shall be demonstrated to be OPERABLE in accordance with the Ginna Station Pump and Valve Test program submitted in accordance with 10 CFR 50.55a.

4.4.6 Containment Isolation Response

- 4.4.6.1 Each containment isolation instrumentation channel shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION, and CHANNEL FUNCTIONAL TEST operations for the MODES and at the frequencies shown in Table 4.1-1.

Table 3.3.2-1
F.V. 3a, b, c

- 4.4.6.2 The response time of each containment isolation valve shall be demonstrated to be within its limit at least once per 18 months. The response time includes only the valve travel time for those valves which the safety analysis assumptions take credit for a change in valve position in response to a containment isolation signal.

See Chapter
3.6

4.4.7 Containment Hydrogen Monitors

4.4.7.1 Demonstrate that two hydrogen monitors are operable at least daily by verifying that the unit is on or in standby. monthly

31.x

4.4.7.2 At least once per quarter perform a channel calibration using two sample gases containing known concentrations of hydrogen. 24 months

31.x

Basis:

The containment is designed for an accident pressure of 60 psig. ⁽¹⁾ While the reactor is operating, the internal environment of the containment will be air at approximately atmospheric pressure. The maximum temperature of the steam-air mixture at the peak accident pressure of 60 psig is calculated to be 286° F.

See Chapter
3.7

4.8.8 At least once per 18 months during shutdown:

- a. Verify that each automatic valve in the flow path for each auxiliary feedwater pump actuates to its correct position upon receipt of each auxiliary feedwater actuation test signal.
- b. Verify that each auxiliary feedwater pump starts as designed automatically upon receipt of each auxiliary feedwater actuation test signal.

4.8.9 Each instrumentation channel shall be demonstrated operable by the performance of the Channel Check, Channel Calibration, and Channel Functional Test operations for the modes and at the frequencies shown in Table 4.1-1.

Table 3.3.2-1
F.V.#6

4.8.10 ~~The response time of each pump and valve required for the operation of each "train" of auxiliary feedwater shall be demonstrated to be within the limit of 10 minutes at least once per 18 months.~~

35.vii

Basis

The monthly testing of the auxiliary feedwater pumps by supplying feedwater to the steam generators will verify their ability to meet minimum required flowrates. The capacity of any one of the three auxiliary feedwater pumps is sufficient to meet decay heat removal requirements.⁽¹⁾ Proper functioning of the steam turbine admission valve and the feedwater pumps start will demonstrate the integrity of the steam driven pump.⁽²⁾

Monthly testing of the standby auxiliary feedwater pumps by supplying water from a condensate supply tank to the steam generators will verify their ability to meet minimum required flowrates.

The standby auxiliary feedwater pumps would be used only if all three auxiliary feedwater pumps were unavailable.⁽³⁾ One of the two standby pumps would be sufficient to meet decay heat removal requirements. Proper functioning of the suction valves from the service water system, the discharge valves, and the crossover valves will demonstrate their operability. The operability of the standby auxiliary feedwater pump flow paths between the pumps and the steam generators is demonstrated using water from the test tank. Testing of the auxiliary feedwater pumps using their primary source of water supply will verify the operability of the auxiliary feedwater flow path.

Verification of correct operation will be made both from instrumentation within the main control room and by direct visual observation of the pumps.

3.1 Reactor Coolant System

Applicability:

Applies to the operating status of the Reactor Coolant System when fuel is in the reactor.

Objective:

To specify those conditions of the Reactor Coolant System which must be met to assure safe reactor operation.

Specification:

3.1.1 Operational Components

3.1.1.1 Reactor Coolant Loops

- a. When the reactor power is above 130 MWT (8.5%), both reactor coolant loops and their associated steam generators and reactor coolant pumps shall be in operation.
- b. If the conditions of 3.1.1.1.a are not met, then immediate power reduction shall be initiated under administrative control. If the shutdown margin meets the one loop requirements of Figure 3.10-2, then the power shall be reduced to less than 130 MWT. If the one loop shutdown margin of Figure 3.10-2 is not met, the plant shall be taken to the hot shutdown condition and the one loop shutdown margin shall be met.
- c. Except for special tests, when the RCS temperature is at or above 350°F with the reactor power less than or equal to 130 MWT (8.5%), at least one reactor coolant loop and its associated steam generator and reactor coolant pump shall be in

LCO 3.4.4

(6.i)

LCO 3.4.5
(6.ii)

operation. The other loop and its associated steam generator must be operable so that heat could be removed via natural circulation. However, both reactor coolant pumps may be de-energized for up to 1 hour provided (1) no operations are permitted that would cause dilution of the reactor coolant system boron concentration, and (2) core outlet temperature is maintained at least 10°F below saturation temperature.

- d. If the conditions of 3.1.1.1.c are not met, then
- (i) if one loop is in operation, but the other loop is not operable, restore the inoperable loop to operable status within 72 hours or take the plant to the hot shutdown condition and reduce the RCS temperature to less than 350°F within the next 12 hours, or
 - (ii) if neither loop is in operation suspend all operations involving a reduction in boron concentration in the Reactor Coolant System and immediately initiate corrective action to return a coolant loop to operation.

LCO 3.4.5

(6.ii)

LCO 3.4.3

(6.ii)

- e. When the RCS temperature is less than 350°F, at least two of the following coolant loops shall be operable:

LCO 3.4.6

LCO 3.4.7

LCO 3.4.2

(6.vii)

- (i) reactor coolant loop A and its associated steam generator and reactor coolant pump.
- (ii) reactor coolant loop B and its associated steam generator and reactor coolant pump.

- (iii) residual heat removal loop A.*
- (iv) residual heat removal loop B.*

(6.iii)
 (6.vi)

f. ~~Except during steam generator crevice cleaning operations~~ at least one of the coolant loops listed in paragraph 3.1.1.1.e shall be in operation while RCS temperature is less than 350°F. However, both reactor coolant pumps and residual heat removal pumps may be de-energized for up to 1 hour provided 1) no operations are permitted that would cause dilution of the reactor coolant system boron concentration, and 2) core outlet temperature is maintained at least 10°F below saturation temperature.

LCO 3.4.7
 LCO 3.4.6
 LCO 3.4.8

(6.iv)

g. If the conditions of 3.1.1.1.e are not met, immediately initiate corrective action to return the required loops to operable status, and if not in cold shutdown already, be in cold shutdown within 24 hours.

LCO 3.4.6
 LCO 3.4.7
 LCO 3.4.8

h. If the conditions of 3.1.1.1.f are not met, then suspend all operations involving a reduction in boron concentration of the Reactor Coolant System and immediately initiate corrective action to return the required coolant loop to operation.

*The preferred or emergency power source may be inoperable while in cold shutdown.

6.vii

i. At least one reactor coolant pump or the residual heat removal system shall be in operation when a reduction is made in the boron concentration of the reactor coolant.

6.viii

j. At least one reactor coolant pump shall be in operation for a planned transition from one Reactor Operating Mode to another involving an increase in the boron concentration of the reactor coolant, except for emergency boration.

LCO 3.4.7
LCO 3.4.6

6.v

Reference to P11C

k. A reactor coolant pump shall not be started with one or more of the RCS cold leg temperatures $\leq 330^{\circ}\text{F}$ unless 1) the pressurizer water volume is less than 324 cubic feet (38% level) or 2) the secondary water temperature of each steam generator is less than 50°F above each of the RCS cold leg temperatures.

3.1.1.2 Steam Generator

6.xv

a. The temperature difference across the tube sheet shall not exceed 100°F .

3.1.1.3 Safety Valves

6.xii

a. During cold shutdown or refueling when the reactor head is bolted on the vessel, at least one pressurizer code safety valve shall be operable with a lift setting of $2485 \text{ psig} \pm 1\%$.

6.xiii

b. If the conditions of 3.1.1.3.a are not met, immediately suspend all operations involving positive reactivity changes and place an operable RHR loop into operation in the shutdown cooling mode.

c. Whenever the reactor is at or above an RCS temperature of 350°F, both pressurizer code safety valves shall be operable with a lift setting of 2485 psig $\pm 1\%$.

LCO 3.4.10

G.Xvii

d. If one pressurizer code safety valve is not operable while the reactor is at or above an RCS temperature of 350°F, then either restore the inoperable valve to operable status within 15 minutes or be in at least hot shutdown within 6 hours and below an RCS temperature of 350°F within an additional 6 hours.

LCO 3.4.10.

G.Xvi

3.1.1.4 Relief Valves

a. Both pressurizer power operated relief valves (PORVs) and their associated block valves shall be operable whenever the reactor is at or above an RCS temperature of 350°F, or

(i). with one or more PORV(s) inoperable, within 1 hour either restore the PORV(s) to operable status or close the associated block valve(s); otherwise, be in at least hot shutdown within the next 6 hours and below an RCS temperature of 350°F within the following 6 hours, or

(ii) with one or more block valve(s) inoperable, within 1 hour either restore the block valve(s) to operable status or close the block valve(s) and remove power from the block valve(s);

LCO 3.4.11

G.Xiii

LCO 3.4.11

G.Xiv

otherwise, be in at least hot shutdown within the next 6 hours and below an RCS temperature of 350°F within the following 6 hours.

3.1.1.5 Pressurizer

LCO 3.4.3

G.ix

- a. Whenever the reactor is at or above an RCS temperature of 350°F the pressurizer shall have at least 100 kw of heaters operable and a water level maintained between 12% and 87% of level span. If the pressurizer is inoperable due to heaters or water level, restore the pressurizer to operable status within 6 hrs. or have the reactor below an RCS temperature of 350°F and the RHR system in operation within an additional 6 hrs.

G.x

- ~~b. This requirement shall not apply during performance of RCS hydro test provided the test is completed and the pressurizer is operable per 3.1.1.5a within 16 hours.~~

3.1.1.6 Reactor Coolant System Vents

LCO 3.4.1

G.xiii

G.xiv

G.xi

- a. When the reactor is at hot shutdown or critical, at least one reactor coolant system vent path consisting of two valves in series shall be operable and closed* at each of the following locations:

~~1. Reactor Vessel head~~

2. Pressurizer steam space

*The PORV block valve is not required to be closed but must be operable if the PORV is capable of being opened.

b. With one or more vents at the above reactor coolant system vent path locations inoperable, startup may commence and/or power operation may continue provided at least one vent path is operable and the inoperable vent paths are maintained closed with motive power removed from the valve actuator of all the valves in the inoperable vent paths. If the requirements of 3.1.1.6a are not met within 30 days, be in hot shutdown within 6 hours and below 350°F within the following 30 hours.

260 3.4.11

G.xi

G.xiii

G.xiv

c. With all of the above reactor coolant system vent paths inoperable; maintain the inoperable vent paths closed with power removed from the valve actuators of all the valves in the inoperable vent paths, and restore at least one of the vent paths to operable status within 72 hours or be in hot shutdown within 6 hours and below 350°F within the following 30 hours.

260 3.4.11

G.xi

G.xiii

G.xiv

Bases

The plant is designed to operate with all reactor coolant loops in operation and maintain the DNBR above the limit value during all normal

operations and anticipated transients. Heat transfer analyses⁽¹⁾ show that reactor heat equivalent to 130 MWT (8.5%) can be removed by natural circulation alone. Therefore operation with one operating reactor coolant loop while below 130 MWT provides adequate margin.

The specification permits an orderly reduction in power if a reactor coolant pump is lost during operation between 130 MWT and 50% of rated power.⁽²⁾ Above 50% power, an automatic reactor trip will occur if either pump is lost. The power-to-flow ratio will be maintained equal to or less than one which ensures that the minimum DNB ratio increases at lower flow since the maximum enthalpy rise does not increase.

When the reactor coolant system average temperature is above 350°F, a single reactor coolant loop provides sufficient heat removal capability for removing decay heat; however, single failure considerations require one loop be in operation and the other loop be capable of removing heat via natural circulation.

When the reactor coolant system average temperature is between 200°F and 350°F or while in cold shutdown, a single reactor coolant loop or RHR loop provides sufficient heat removal capability for removing decay heat; but single failure considerations require that at least two loops be operable. Thus, if the reactor coolant loops are not operable, this specification requires two RHR loops to be operable.

When the boron concentration of the reactor coolant system is to be reduced the process must be uniform to prevent sudden reactivity

changes in the reactor. Mixing of the reactor coolant will be sufficient to prevent a sudden increase in reactivity if at least one reactor coolant pump or one residual heat removal pump is running while the change is taking place. The residual heat removal pump will circulate the primary system volume in approximately one half hour. The pressurizer is of no concern because of the low pressurizer volume and because the pressurizer boron concentration will be higher than that of the rest of the reactor coolant. When the boron concentration of the reactor coolant system is to be increased, the process must be uniform to prevent sudden reactivity increases in the reactor during subsequent startup of the reactor coolant pumps. Mixing of the reactor coolant will be sufficient to maintain a uniform boron concentration if at least one reactor coolant pump is running while the change is taking place. Emergency boration without a reactor coolant pump in operation is not prohibited by this specification.

Prohibiting reactor coolant pump starts without a large void in the pressurizer or without a limited RCS temperature differential will prevent RCS overpressurization due to expansion of cooler RCS water as it enters a warmer steam generator. A 38% level in the pressurizer will accommodate the swell resulting from a reactor coolant pump start with a RCS temperature of 140°F and steam generator secondary side temperature of 340°F, or the maximum temperature which usually exists prior to cooling the reactor with the RHR system.

Temperature requirements for the steam generator correspond with measured NDT for the shell and allowable thermal stresses in the tube sheet.

Each of the pressurizer code safety valves is designed to relieve 288,000 lbs. per hr. of saturated steam at the valve set point. Below 350°F and 350 psig in the reactor coolant system, the residual heat removal system can remove decay heat and thereby control system temperature and pressure. If no residual heat were removed by any of the means available, the amount of steam which could be generated at safety valve relief pressure would be less than half the valves' capacity. One valve, therefore, provides adequate defense against overpressurization.

The power operated relief valves (PORVs) operate to relieve RCS pressure below the setting of the pressurizer code safety valves. These relief valves have remotely operated block valves to provide a positive shutoff capability should a relief valve become inoperable. The electrical power for both the relief valves and the block valves is capable of being supplied from an emergency power source to ensure the ability to seal this possible RCS leakage path. The requirement that 100 kw of pressurizer heaters and their associated controls be capable of being supplied electrical power from an emergency bus provides assurance that these heaters can be energized during a loss of offsite power condition to maintain natural circulation at hot shutdown and during cooldown. (3)

Reactor Coolant System Vents

Reactor Coolant System Vents are provided to exhaust noncondensable gases and/or steam from the primary system that could inhibit natural circulation core cooling. The operability of at least one reactor coolant system vent path from the reactor vessel head and one from the pressurizer steam space ensures the capability exists to perform this function.

The valve redundancy of the reactor coolant system vent paths serves to minimize the probability of inadvertent or irreversible actuation while ensuring that a single failure of a vent valve, power supply or control system does not prevent isolation of the vent path.

The function, capabilities, and testing requirements of the reactor coolant system vent systems are consistent with the requirements of Item II.B.1 of NUREG-0737, "Clarification of TMI Action Plan Requirements", November 1980.

3 1.2

Heatup and Cooldown Limit Curves for Normal Operation

3.1.2.1

The reactor coolant temperature and pressure and system heatup and cooldown rates (with the exception of the pressurizer) shall be limited in accordance with Figures 3.1-1 and 3.1-2 for the first 21.0 effective full power years.

LCO 3.4.3

(7.i)

a. Allowable combinations of pressure and temperature for specific temperature change rates are below and to the right of the limit lines shown. The heatup and cooldown rates shall not exceed 60°F/hr and 100°/hr, respectively. Limit lines for cooldown rates between those presented may be obtained by interpolation.

LCO 3.4.3

(7.i)

b. Figures 3.1-1 and 3.1-2 define limits to assure prevention of non-ductile failure only. The limit lines shown in Figures 3.1-1 and 3.1-2 shall be recalculated periodically using methods discussed in the Basis Section.

LCO 3.4.3

(7.ii)

c. If the limits on Figures 3.1-1 and 3.1-2 are exceeded, restore the temperature and/or pressure to within the limit within 30 minutes; and either

- 1) within ⁷²8 hours, perform an engineering evaluation to determine the effects of the out-of-limit condition on the structural integrity of the Reactor Coolant System and determine that the Reactor Coolant System remains acceptable for continued operation, or

LCO 3.4.3

(7.iii)

LCO 3.4.3

2) within 6 hours be in at least HOT SHUTDOWN, and within the next 30 hours reduce RCS temperature and pressure to less than 200°F and 500 psig, respectively.

3.1.2.2 The secondary side of the steam generator must not be pressurized above 200 psig if the temperature of the steam generator vessel is below 70°F.

7.iv

3.1.2.3 The pressurizer heatup and cooldown rates shall not exceed 100°F/hr and 200°F/hr, respectively. The spray shall not be used if the temperature difference between the pressurizer and the spray fluid is greater than 320°F.

7.v

Basis:

Fracture Toughness Properties

The fracture toughness properties of the ferritic materials in the reactor vessel are determined in accordance with the Summer 1965 Section III of the ASME Boiler and Pressure Vessel Code, Reference (1), and ASTM E185, Reference (2), and in accordance with additional reactor vessel requirements. These properties are then evaluated in accordance with Appendix G of the 1972 Summer Addenda to Section III of the ASME Boiler and Pressure Vessel Code, Reference (3) and the calculation methods described in Reference (4). The results are reported in Reference (5) for Capsule T.

The heatup and cooldown curves are based on nominal pressure-temperature indications. Sufficient conservatism exists in the algorithm from which the curves were derived to account for instrument uncertainties.

TEXT DELETED

The temperature requirements for the steam generator corresponds with the measured NDT for the shell of the steam generator.

A temperature difference of 320°F between the pressurizer and reactor coolant system maintains stresses within the pressurizer spray nozzle below design limits.

3.1.3 Minimum Conditions for Criticality

3.1.3.1 Except during low power physics tests, the reactor shall not be made critical at a temperature below 500°F, and if the moderate temperature coefficient is more positive than

- a. 5 pcm/°F (below 70 percent of rated thermal power)
- b. 0 pcm/°F (at or above 70 percent of rated thermal power)

8.i 8.iv

LCO 3.4.2

3.1.3.2 ~~In no case shall the reactor be made critical above and to the left of the criticality limit line shown on Figure 3.1-1 of these specifications.~~

8.ii

3.1.3.3 When the reactor coolant temperature is below the minimum temperature specified above, the reactor shall be subcritical by an amount equal to or greater than the potential reactivity insertion due to depressurization.

LCO 3.4.2

8.iii

Basis

~~Previous safety analyses have assumed that for Design Basis Events (DBE) initiated from the hot zero power or higher power condition, the moderator temperature coefficient (MTC) was either zero or negative. (1)(2) Beginning in Cycle 14, the safety analyses have assumed that a maximum MTC of +5 pcm/°F can exist up to 70% power. Analyses have shown that the design criteria can be satisfied for the DBE's with this assumption. (3) At greater than 70% power the MTC must be zero or negative.~~

The limitations on MTC are waived for low power physics tests to permit measurement of the MTC and other physics design parameters of interest. During these tests special operating precautions will be taken.

The requirement that the reactor is not to be made critical above and to the left of the criticality limit provides increased assurance that the proper relationship between reactor coolant pressure and temperature will be maintained during system heatup and pressurization. Heatup to this temperature will be accomplished by operating the reactor coolant pumps.

If the specified shutdown margin is maintained, there is no possibility of an accidental criticality as a result of an increase in moderator temperature or a decrease of coolant pressure.

3.1.4 Maximum Coolant Activity

Specifications

3.1.4.1 Whenever the reactor is critical or the reactor coolant average temperature is greater than 500°F:

LCO 3.4.16
Condition C

a. The total specific activity of the reactor coolant shall not exceed $84/\bar{E}$ $\mu\text{Ci/gm}$, where \bar{E} is the average beta and gamma energies per disintegration in Mev.

LCO 3.4.16
Condition A

b. The I-131 equivalent of the iodine activity in the reactor coolant shall not exceed 0.2 $\mu\text{Ci/gm}$.

c. The I-131 equivalent of the iodine activity on the secondary side of a steam generator shall not exceed 0.1 $\mu\text{Ci/gm}$. *See Chapter 3.7*

LCO 3.4.16
Condition C

3.1.4.2 If the limit of 3.1.4.1.a is exceeded, then be subcritical with reactor coolant average temperature less than 500°F within .8 hours.

LCO 3.4.16
Condition A

3.1.4.3 a. If the I-131 equivalent activity in the reactor coolant exceeds the limit of 3.1.4.1.b but is less than the allowable limit shown on Figure 3.1.4-1, operation may continue for up to 168 hours.

The reactor may be taken critical or reactor coolant average temperature may be increased above a 500°F with the I-131 equivalent activity greater than the limit of 3.1.4.1.b as long as the provisions of this paragraph are met.

- b. If the I-131 equivalent activity exceeds the limit of 3.1.4.1.b for more than 168 hours during one continuous time interval or exceeds the limit shown on Figure 3.1.4-1, be subcritical with reactor coolant average temperature less than 500°F within 8 hours.
- c. If the I-131 equivalent activity exceeds the limit of 3.1.4.1.b, then perform sampling and analysis as required by Table 4.1-4, item 4a, until the activity is reduced to less than the limit of 3.1.4.1.b.

LCO 3.4.16

LCO 3.4.16

- 3.1.4.4 If the limit of 3.1.4.1.c is exceeded, then be at hot shutdown within 8 hours and in cold shutdown within the following 32 hours.

LCO 3.4.16

(9.1)

Basis:

The total activity limit for the primary system corresponds to operation with the plant design basis of 1% fuel defects.⁽¹⁾
Radiation shielding and the radioactive waste disposal systems

(3.1-22)

were designed for operation with 1% defects⁽²⁾. The limit for secondary iodine activity is conservatively established with respect to the limits on primary system iodine activity and primary-to-secondary leakage (Specification 3.1.5.2). If the activity should exceed the specified limits following a power transient the major concern would be whether additional fuel defects had developed bringing the total to above 1% defects. Appropriate action to be taken to bring the activity within specification include one or more of the following: gradual decrease in power to a lower base power, increase in letdown flow rate, and venting of the volume control tank gases to the gas decay tanks.

The specified activity limits provide protection to the public against the potential release of reactor coolant activity to the atmosphere, as demonstrated by the analysis of a steam generator tube rupture accident.⁽³⁾

The 500°F temperature in the specification corresponds at saturation to 681 psia, which is below the set point of the secondary side relief valves. Therefore, potential primary to secondary leakage at a temperature below 500°F can be contained by closing the steam line isolation valves.

Figure 3.1.4-1

I-131 Equivalent Reactor Coolant Specific Activity Limit Versus Percent of Rated Thermal Power

3.1.5 RCS Leakage3.1.5.1 Detection Systems

3.1.5.1.1 With an RCS temperature greater than 350°F, two of the following leak detection systems, including one system sensitive to radioactivity, shall be in operation.

LCO 3.4.15

(10.i)

(10.ii)

(10.iii)

- a. The containment air particulate monitor
- b. The containment radiogas monitor
- c. The containment atmosphere humidity detector
- d. The containment water inventory monitoring system

3.1.5.1.2 When a system sensitive to radioactivity is not operable, operation may continue for up to 30 days provided grab samples of the containment atmosphere are obtained and analyzed at least once every 24 hours. Otherwise be in hot shutdown within the next 6 hours and have the RCS temperature less than 350°F within the following 6 hours.

LCO 3.4.15

(10.ii)

3.1.5.2 RCS Leakage Limits

3.1.5.2.1 With the RCS temperature at or above 350°F, RCS leakage shall be limited to:

LCO 3.4.13

- a. No leakage, if known to be through an RCS pressure boundary such as a pipe, vessel or valve body,
- b. 10 gpm from a known leakage source other than the above,
- c. 1 gpm from an unidentified leakage source,
- d. .1 gpm tube leakage in one steam generator when averaged over 24 hours.

3.1.5.2.2 If the limits specified above are exceeded the following action is required.

- CCO 3.4.13
- a. With any RCS pressure boundary leakage, as defined in 3.1.5.2.1.a, be at hot shutdown within 6 hours and at an RCS temperature less than 350°F in the following 6 hours.
- CCO 3.4.13
- b. With leakage in excess of 3.1.5.2.1 b or c, reduce leakage rate to within limits within 4 hours or be in hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the following 6 hours.
- CCO 3.4.13
- c. With steam generator tube leakage in excess of 3.1.5.2.1d, be at hot shutdown within 6 hours and at an RCS temperature less than 350°F within the following 6 hours. If more than six months have elapsed since the last steam generator inspection, perform an inspection in accordance with the requirements of Technical Specification 4.2.

Basis

Water inventory balances, monitoring equipment, boric acid crystalline deposits, and physical inspections can disclose reactor coolant leaks. Any leak of radioactive fluid, whether or not it is from the reactor coolant system pressure boundary, can be a serious problem with respect to in-plant radioactivity contamination or it could develop into a still more serious problem if the leakage rate is of sufficient magnitude to effect cooling of the reactor core; and, therefore, first indications of such leakage should be investigated as soon as practicable.

If leakage is to the containment, its presence may be indicated by one or more of the following methods:

- a. The containment air particulate monitor is sensitive to low leak rates. The rate of leakage to which the instrument is sensitive is 0.013 gpm within twenty minutes, assuming the presence of corrosion product activity.
- b. The containment radiogas monitor is less sensitive but can be used as a backup to the air particulate monitor. The sensitivity range of the instrument is approximately 2 gpm to greater than 10 gpm.
- c. The humidity detector provides a backup to a. and b. The sensitivity range of this instrument is from approximately 2 gpm to 10 gpm.
- d. A leakage detection system which determines leakage from water and steam systems within the containment collects and measures moisture condensed from the containment atmosphere by cooling coils of the main recirculation units. This system provides a dependable and accurate means of determining total leakage, including leaks from the cooling coils. This system can detect leakage from approximately 1/2 gpm to 10 gpm.

Indication of leakage from the above sources should be cause for an investigation and could require a containment entry and limited inspection at power of the reactor coolant system. Visual inspection procedures, i.e., looking for steam, floor wetness or boric acid crystalline formations, would be used.

It should be noted that detection systems sensitive to radioactivity will have an indication that is sensitive to the coolant activity and the location of the leak as well as the leak rate. Also since leakage directly into the containment could be from a variety of sources, such as the component cooling system, the service water system, the secondary system, the reactor make-up water system, the chemical and volume control system, the seal injection system, the sampling system, as well as the primary coolant system, an increase in containment air moisture or sump actuation does not necessarily mean a primary system leak. Water inventory balances, liquid waste activities and tritium content can all be used in determining the nature of a leak inside the containment.

If leakage is to another system, it will be detected by the plant radiation monitors and/or water inventory control.

When the source of leakage has been investigated, the situation can be evaluated to determine if operation can be continued safely. This evaluation will be within the criteria of this specification.

- a. A leak of any magnitude in a pipe, vessel, or valve body in the coolant system pressure boundary compromises the integrity of that system and significantly alters the probability of a loss-of-coolant accident occurring. Therefore, prompt shutdown of the reactor or isolation of the leaking component is required to reduce the consequences of this event or prevent its occurrence.
- b. The identified leakage rate is restricted to less than 25% of the coolant make-up capability with the minimum charging capacity powered by emergency power. This does allow for further degradation of the system during the evaluation and shutdown process with assurance that adequate cooling make-up capability exists. If the maximum allowable coolant activity existed, the 10 gpm leak rate would not result in doses in excess of the annual average allowed by 10 CFR Part 20.

Should a postulated transient or accident occur (such as a rod ejection or steam line break accident), then, if the primary to secondary leak rate is limited to 0.1 gpm per steam generator, the site boundary dose would be maintained well within the guidelines and all steam generator tubes would maintain their integrity. Continuous operability of two systems of diverse principles is desired to assure some surveillance of coolant leakage. However,

due to the redundancy of systems designed to monitor degradation of the reactor coolant pressure boundary, provisions for short term degradation of one system or long term substitution of a system do not materially alter the degree of safety.

3.1.6 Maximum Reactor Coolant Oxygen, Fluoride, and Chloride Concentration

3.1.6.1 With an RCS temperature above 200°F, the RCS chemistry shall be maintained within the following limits.

<u>Contaminant</u>	<u>Steady-State Limit (ppm)</u>	<u>Transient Limit (ppm)</u>
*Oxygen	0.10	1.00
Chloride	0.15	1.50
Fluoride	0.15	1.50

3.1.6.2 With any one or more of the chemistry parameters in excess of its Steady State Limit, but within its Transient Limit, restore the parameter to within its Steady State Limit within 24 hours or be in at least hot shutdown within 6 hours and below an RCS temperature of 200°F within the following 30 hours.

3.1.6.3 With any one or more of the chemistry parameters in excess of its Transient Limit, be in at least hot shutdown within 6 hours and below an RCS temperature of 200°F within the following 30 hours and perform an engineering evaluation in accordance with 3.1.6.5.

3.1.6.4 With the RCS temperature at or below 200°F, the RCS chemistry shall be maintained within the following limits.

<u>Contaminant</u>	<u>Normal Limit (ppm)</u>	<u>Transient Limit (ppm)</u>
Oxygen	Saturated	Saturated

* Limits for Oxygen not applicable below 250°F.

11.1

Chloride	0.15	1.50
Fluoride	0.15	1.50

3.1.6.5 If the concentration of chloride or fluoride exceeds the Steady State Limit for more than 48 hours, or exceeds the Transient Limit, maintain the RCS pressure less than 500 psig and perform an engineering evaluation of the effects of the out of limit conditions on the structural integrity of the RCS. This evaluation shall determine that the RCS remains acceptable for continued operation prior to increasing RCS temperature and pressure above 200°F and 500 psig respectively.

Basis:

By maintaining the oxygen, chloride and fluoride concentrations in the reactor coolant below the normal limits as specified, the integrity of the Reactor Coolant System is assured under all operating conditions (1). If normal limits are exceeded, measures can be taken to correct the condition, e.g., replacement of ion exchange resin, the addition of hydrazine during subcritical operation, or adjustment of the hydrogen concentration in the volume control tank (2) during power operation. Because of the time dependent nature of any adverse effects arising from oxygen, chloride, and fluoride concentration in excess of the limits, it is unnecessary to shut down immediately since the condition can be corrected. Thus, the period of 24 hours for corrective action to restore concentrations within the limits has been established. If the corrective action has not been effective at the end of the

24 hour period, then the RCS will be brought below 200°F and the corrective action will continue. The effects of contaminants in the reactor coolant are temperature dependent. It is consistent, therefore, to permit a steady state concentration in excess of limit to exist for a longer period of time at the colder RCS temperatures and still provide the assurance that the integrity of the primary coolant system will be maintained. In order to restore the contaminant concentrations to within specification limits in the event such limits were exceeded, mixing of the primary coolant with the reactor coolant pumps may be required. This will result in a small heatup of short duration and will not increase the average coolant temperature above 250°F.

See Chapter 3.1

3.2.4 With only one of the required boron injection flow paths to the RCS operable, restore at least two boron injection flow paths to the RCS to operable status within 72 hours, or within the next 6 hours be in at least hot shutdown and borated to a shutdown margin equivalent to at least 2.45% delta k/k at cold, no xenon conditions. If the requirements of 3.2.2 are not satisfied within an additional 7 days, then be in cold shutdown within the next 30 hours.

3.2.5 Whenever the RCS temperature is greater than 200°F and is being cooled by the RHR system and the over-pressure protection system is not operable, at least one charging pump shall be demonstrated inoperable at least once per 12 hours by verifying that the control switch is in the pull-stop position.

LCO 3.4.12

12.i

(4) Refueling water storage tank via gravity feed through manual bypass valve 358 to the suction of the charging pumps.

Available flow paths from the charging pumps to the reactor coolant system include the following:

- (1) Charging flow path through AOV 392A to the RCS Loop B hot leg.
- (2) Charging flow path through AOV 294 to the RCS Loop B cold leg.
- (3) Seal injection flow path to the reactor coolant pumps.

See Chapter 3.12

The rate of boric acid injection must be sufficient to offset the maximum addition of positive reactivity from the decay of xenon after a trip from full power. This can be accomplished through the operation of one charging pump at minimum speed with suction from the refueling water storage tank. Also the time required for boric acid injection allows for the local alignment of manual valves to provide the necessary flow paths.

The quantity of boric acid specified in Table 3.2-1 for each concentration is sufficient at any time in core life to borate the reactor coolant to the required cold shutdown concentration and provide makeup to maintain RCS inventory during the cooldown. The temperature limits specified on Table 3.2-1 are required to maintain solution solubility at the upper concentration in each range. The temperatures listed on Table 3.2-1 are taken from Reference (4). An arbitrary 5°F is added to the Reference (4) for margin. Heat tracing may be used to maintain solution temperature at or above the Table 3.2-1 limits. If the solution temperature of either the flow path or the borated water source is not maintained at or above the minimum temperature specified, the affected flow path must be declared inoperable and the appropriate actions specified in 3.2.4 followed.

~~Placing a charging pump in pull-stop whenever the reactor coolant system temperature is $\geq 200^\circ\text{F}$ and is being cooled by RHR without the overpressure protection system operable will prevent inadvertent overpressurization of the RHR system should letdown be terminated. (3)~~

- d. At or above an RCS temperature of 350°F, two residual heat removal pumps are operable.
- e. At or above an RCS temperature of 350°F, two residual heat removal heat exchangers are operable.
- f. At the conditions required in a through e above, all valves, interlocks and piping associated with the above components which are required to function during accident conditions are operable.
- g. At or above an RCS temperature of 350°F, A.C. power shall be removed from the following valves with the valves in the open position: safety injection cold leg injection valves 878B and D. A.C. power shall be removed from safety injection hot leg injection valves 878A and C with the valves closed. D.C. control power shall be removed from refueling water storage tank delivery valves 896A, 896B and 856 with the valves open.

See
Chapter
3.5

- h. At or above an RCS temperature of 350°F, check valves 853A, 853B, 867A, 867B, 878G, and 878J shall be operable with less than 5.0 gpm leakage each. The leakage requirements of Technical Specification 3.1.5.2.1 are still applicable.

LC0 3.4.14

13.ix

13.x

- i. Above a reactor coolant system pressure of 1600 psig, except during performance of RCS hydro test, A.C. power shall be removed from accumulator isolation valves 841 and 865 with the valves open.
- j. At or above an RCS temperature of 350° F, A.C. power shall be removed from Safety Injection suction valves 825A and B with the valves in the open position, and from valves 826A, B, C, D with the valves in the closed position.

See
Chapter
3.5

3.3.1.2 If the conditions of 3.3.1.1a are not met, then satisfy the condition within 1 hour or be at hot shutdown in the next 6 hours and at least cold shutdown within an additional 30 hours.

3.3.1.3 The requirements of 3.3.1.1b and 3.3.1.1i may be modified to allow one accumulator to be inoperable or isolated for up to one hour. If the accumulator is not operable or is still isolated after one hour, the reactor shall be placed in hot shutdown within the following 6 hours and below a RCS pressure of 1600 psig within an additional 6 hours.

See Chapter 3.5

3.3.1.4 The requirements of 3.3.1.1c may be modified to allow one safety injection pump to be inoperable for up to 72 hours. If the pump is not operable after 72 hours, the reactor shall be placed in hot shutdown within the following 6 hours and below a RCS temperature less than 350°F within an additional 6 hours.

3.3.1.5 The requirements of 3.3.1.1d through h. may be modified to allow components to be inoperable at any one time. More than one component may be inoperable at any one time provided that one train of the ECCS is operable. If the requirements of 3.3.1.1d through h. are not satisfied within the time period specified below, the reactor shall be placed in hot shutdown within 6 hours and at an RCS temperature less than 350°F in an additional 6 hours.

LCW 3.4.14

13.x

a. One residual heat removal pump may be out of service provided the pump is restored to operable status within 72 hours.

See Chapter 3.5

- b. One residual heat removal heat exchanger may be out of service for a period of no more than 72 hours.
- c. Any valve, interlock, or piping required for the functioning of one safety injection train and/or one low head safety injection train (RHR) may be inoperable provided repairs are completed within 72 hours (except as specified in e. below).
- d. Power may be restored to any valve referenced in 3.3.1.1g for the purposes of valve testing provided no more than one such valve has power restored and provided testing is completed and power removed within 12 hours.
- e. Those check valves specified in 3.3.1.1h may be inoperable (greater than 5.0 gpm leakage) provided the inline MOVs are de-energized closed and repairs are completed within 12 hours.

See
Chapter
3.5

LC0 3.4.14

13.xi

~~3.3.1.6 Deleted~~

3.3.1.7

Except during diesel generator load and safeguard sequence testing or when the vessel head is removed, or the steam generator primary system manway is open, no more than one safety injection pump shall be operable whenever the overpressurization protection is provided by a RCS vent of ≥ 1.1 sq. in. (3.15.1.b).

CCO 3.4.12

13.xii

3.3.1.7.1

Whenever only one safety injection pump may be operable by 3.3.1.7, at least two of the three safety injection pumps shall be verified inoperable, as defined in the Basis for this section, a minimum of once per twelve hours.

SR 3.4.12.1

13.xiii

3.3.1.8

Except during diesel generator load and safeguard sequence testing or when the vessel head is removed, or the steam generator primary system manway is open, all three safety injection pumps shall be inoperable and safety injection discharge paths to the RCS isolated whenever overpressure protection is provided by the pressurizer PORVs (3.15.1.a).

CCO 3.4.12

13.xi

3.3.1.8.1

Whenever safety injection pumps are required to be inoperable by 3.3.1.8, the safety injection pumps shall be verified inoperable, as defined in the Basis of this section, a minimum of once per twelve hours. Similarly safety injection discharge paths to the RCS shall be verified to be isolated a minimum of once per twelve hours.

SR 3.4.12.2

13.xiii

3.3.1.8.2

The requirements of 3.3.1.8 may be modified to allow operation of one SI pump provided the associated paths to the RCS are isolated by A.C. power being removed to the discharge MOVs in the closed position, or the manual isolation valves closed. Isolation of the discharge paths shall be verified at least once per 12 hours.

SR 3.4.12.2

13.xiv

See
Chapter
3.7

3.3.5 Control Room Emergency Air Treatment System

3.3.5.1 The RCS temperature shall not be at or above 350°F unless the control room emergency air treatment system is operable.

3.3.5.2 The requirements of 3.3.5.1 may be modified to allow the control room emergency air treatment system to be inoperable for a period of 48 hours. If the system is not made operable within those 48 hours, the reactor shall be placed in hot shutdown within the next 6 hours and the RCS temperature less than 350°F in an additional 12 hours.

Basis

~~The normal procedure for starting the reactor is, first to heat the~~

reactor coolant to near operating temperature by running the Reactor Coolant Pumps. The reactor is then made critical by withdrawing control rods and/or diluting boron in the coolant. ⁽¹⁾ With this mode of startup, the energy stored in the reactor coolant during the approach to criticality is substantially equal to that during power operation and therefore all engineered safeguards and auxiliary cooling systems, with the one exception of one fan cooler, as discussed below, are required to be fully operable. During low temperature physics tests, there is a negligible amount of stored energy in the reactor coolant, therefore an accident comparable in severity to the Design Basis Accident is not possible, and the engineered safeguards systems are not required. The operable status of the various systems and components is to be demonstrated by periodic tests in the Specifications. A large fraction of these tests will be performed while the reactor is operating in the power range. If a component is found to be inoperable, it will be possible in most cases to effect repairs and restore the system to full operability within a relatively short time. For a single component to be inoperable does not negate the ability of the system to perform its function, but it reduces the redundancy provided in the reactor design and thereby limits the ability to tolerate additional equipment failures. To provide maximum assurance that the redundant component(s) will

operate if required to do so, the redundant component(s) are to be tested prior to initiating repair of the inoperable component. If it develops that (a) the inoperable component is not repaired within the specified allowable time period or (b) a second component in the same or related system is found to be inoperable, the reactor will initially be put in the hot shutdown condition to provide for reduction of the decay heat from the fuel, and consequent reduction of cooling requirements after a postulated loss-of-coolant accident. This will also permit improved access for repairs in some cases. After a limited time in hot shutdown, if the malfunction(s) are not corrected, the reactor will be placed in the cold shutdown condition, utilizing normal shutdown and cooldown procedures. In the cold shutdown condition, there is no possibility of an accident that would release fission products or damage the fuel elements.

The plant operating procedures will require immediate action to effect repairs of an inoperable component, and therefore in most cases repairs will be completed in less than the specified allowable repair times. Furthermore, the specified repair times do not apply to regularly scheduled maintenance of the engineered safeguards systems, which is normally to be performed during refueling shutdowns. The limiting times to repair are based on:

- (1) Assuring with high reliability that the safeguard system will function properly if required to do so.

See
Chapter
2.5

3.15 Overpressure Protection System

Applicability

LCO 3.4.12

25.vi

Applies whenever the temperature of one or more of the RCS cold legs is $\leq 330^\circ\text{F}$, or the Residual Heat Removal System is in operation.

Objective

To prevent overpressurization of the reactor coolant system and the residual heat removal system.

Specification

3.15.1

LCO 3.4.12

25.i

25.ii

25.iii

Except during secondary side hydrostatic tests in which RCS pressure is to be raised above the PORV setpoint, at least one of the following over-pressure protection systems shall be operable:

- a. Two pressurizer power operated relief valves (PORVs) with a lift setting of ≤ 424 psig, or
- b. A reactor coolant system vent of ≥ 1.1 square inches:

3.15.1.1

LCO 3.4.12

25.v

With one PORV inoperable, either restore the inoperable PORV to operable status within 7 days or depressurize and vent the RCS through a 1.1 square inch vent(s) within the next 8 hours; maintain the RCS in a vented condition until both PORVs have been restored to operable status.

3.15.1.2

LCO 3.4.12

With both PORVs inoperable, depressurize and vent the RCS through a 1.1 square inch vent(s) within 8 hours; maintain the RCS in a vented condition until both PORVs have been restored to operable status.

3.15.1.3

25.v

~~Use of the overpressure protection system to mitigate an RCS or RHRS pressure transient shall be reported in accordance with 6.9.2.~~

Basis

~~At RCS vent opening of greater than 1.1 square inches ensures that the RCS will be protected from pressure transients which could exceed the limits of Appendix G to 10 CFR Part 50 when one or more of the RCS cold legs are $\leq 330^\circ\text{F}$ ⁽¹⁾. This relief capacity will~~

ensure that no overpressurization of the RHR system could occur. The vent opening protects the RCS and RHRS from overpressurization when the transient is limited to either 1) the start of an idle RCP with the secondary water temperature of the steam generator $\leq 50^{\circ}\text{F}$ above the RCS cold leg temperature or 2) the start of a safety injection pump and its injection into a water solid RCS⁽²⁾.

The operability of two pressurizer PORVs ensures that the RCS will be protected from pressure transients which could exceed the limits of Appendix G to 10 CFR Part 50 when one or more of the RCS cold legs are $\leq 330^{\circ}\text{F}$ ⁽²⁾. This relief capacity will also ensure that no overpressurization of the RHR system could occur. Either PORV has adequate relieving capability to protect the RCS and RHRS from overpressurization when the transient is limited to either 1) the start of an idle RCP with the secondary water temperature of the steam generator $\leq 50^{\circ}\text{F}$ above the RCS cold leg temperature or 2) charging/letdown mismatch with three charging pumps in operation⁽³⁾.

4.3 Reactor Coolant System

Applicability

Applies to surveillance of the reactor coolant system and its components.

Objective

To ensure operability of the reactor coolant system and its components.

Specifications:

4.3.1 Reactor Vessel Material Surveillance Testing

30.vii

4.3.1.1 ~~The reactor vessel material surveillance specimens shall be removed and examined to determine changes in their material properties, as required by Appendix H to 10 CFR Part 50.~~

4.3.2 Pressurizer

4.3.2.1 The pressurizer water level shall be verified to be within its limits at least once per 12 hours during power operation and hot shutdown.

SR 3.4.9.1

4.3.3 Check Valves

4.3.3.1 Leakage testing of check valves 853A, 853B, 867A, 867B, 878G and 878J shall be accomplished prior to criticality, except for low power physics testing, following (1) refueling, ~~(2) cold shutdown,~~ and (3) maintenance, repair or replacement work on the valves. Leakage may be measured indirectly from the performance of pressure indicators, system volume measurements or by direct measurement. Minimum test differential pressure shall be greater than 150 psid. See 4.3.3.4 for allowable leakage rates.

SR 3.4.14.1

30.iv

30.viii

4.3.3.2 Check valves 878G and 878J will be tested for leakage following each safety injection flow test. Minimum test differential pressure shall be greater than 150 psid. See 4.3.3.4 for allowable leakage rates.

SR 3.4.14.1

30.iv

4.3.3.3 Motor-operated valves 878A and 878C and check valves 877A, 877B, 878F, and 878H shall be tested at the first refueling outage following the date of this order* to individually assure integrity of at least two of the three pressure boundaries in each hot leg high-head safety injection path. Testing shall also be performed after any opening of either motor-operated valve and at a minimum, once every 40 months. Opening of the motor-operated valves, and testing, are to be performed at a test pressure less than that of the

SR 3.4.14.2

30.v

lowest design pressure of any portion of the high-head safety injection system which may be pressurized during the test. Minimum test differential pressure shall be greater than 150 psid. See 4.3.3.4 for allowable leakage rates.

4.3.3.4 Allowable check valve leakage rates are as follows:

SR 3.4.14.1

30.v

- (a) Leakage rates less than or equal to 1.0 gpm are considered acceptable.
- (b) Leakage rates greater than 1.0 gpm but less than or equal to 5.0 gpm are considered acceptable if the latest measured rate has not exceeded the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and the maximum permissible rate of 5.0 gpm by 50% or greater.
- (c) Leakage rates greater than 1.0 gpm but less than or equal to 5.0 gpm are considered unacceptable if the latest measured rate exceeded the rate determined by the previous test by an amount that reduces the margin between measured leakage rate and the maximum permissible rate of 5.0 gpm by 50% or greater.
- (d) Leakage rates greater than 5.0 gpm are considered unacceptable.

4.3.4 Relief Valves

4.3.4.1 Each PORV shall be demonstrated operable at least once per 18 months by performance of a CHANNEL CALIBRATION.

SE 3.4.4.2.6

4.3.4.2 Except during cold and refueling shutdown each block valve shall be demonstrated operable at least once per 92 days by operating the valve through one complete cycle of full travel unless the valve is already closed.

SR 3.4.4.1

4.3.5 Reactor Coolant Loops

30. ix

due to PORV leakage > 10 gpm

4.3.5.1 When reactor power is above 130 MWt (8.5%), the reactor coolant pumps shall be verified to be in operation and circulating reactor coolant at least once per 12 hours.

SR 3.4.4.1

4.3.5.2 When the average coolant temperature is above 350°F but the reactor is not critical, when the reactor is at hot shutdown, or when the reactor is critical but reactor power is less than or equal to 130 MWt (8.5%):

SE 3.4.5.1

a) the operating reactor coolant pump(s) shall be verified to be in operation and circulating reactor coolant at least once per 12 hours, and

SR 3.4.5.2

b) if a reactor coolant pump is not operating, but must be operable, it shall be demonstrated operable once per 7 days by verifying correct breaker alignments and indicated power availability.

4.3.5.3 When the reactor is at cold shutdown or when the average coolant temperature is between 200°F and 350°F, and fuel is in the reactor, the following shall be performed to demonstrate a loop is operable. Tests need not be performed if a loop is not relied upon to satisfy the requirements of Specification 3.1.1.1.e.

SR 3.4.1.2 a) to demonstrate a reactor coolant loop operable, the reactor coolant pump(s), if not in operation, shall be demonstrated operable at least once per 7 days by verifying correct breaker alignments and indicated power availability.

30.ii

~~b) to demonstrate a residual heat removal pump is operable, the surveillance specified in the Inservice Pump and Valve Test Program prepared pursuant to 10 CFR 50.55a shall be performed.~~

SR 3.4.5.1
SR 3.4.5.2
SR 3.4.8.1
4.3.5.4 When the reactor is at cold shutdown or when the average coolant temperature is between 200°F and 350°F and fuel is in the reactor, at least one coolant loop shall be verified to be in operation and circulating reactor coolant at least once per 12 hours.

SR 3.4.5.2
SR 3.4.5.2
SR 3.4.7.2
4.3.5.5 In addition to the above requirements, in order to demonstrate that a reactor coolant loop is operable, the steam generator water level shall be greater than or equal to 16% of the narrow range instrument span.

30.i

~~4.3.5.6 Each reactor coolant system vent path shall be demonstrated operable at least once per 18 months by:~~

- ~~1. Verifying all manual isolation valves in each vent path are locked in the open position.~~
- ~~2. Verifying flow through the reactor coolant vent system vent paths using either liquid or gas.~~

Basis:

~~This material surveillance program monitors changes in the fracture toughness properties of ferritic materials in the reactor vessel beltline region of the reactor resulting from exposure to~~

neutron irradiation and the thermal environment. The test data obtained from this program will be used to determine the conditions under which the reactor vessel can be operated with adequate margins of safety against fracture throughout its service life.

The surveillance requirements on pressurizer equipment will assure proper performance of the pressurizer function and give early indication of malfunctions.

4.16 Overpressure Protection System

Applicability:

Applies to the reactor coolant system overpressure protection system.

43.i

Objective:

To verify that the overpressure protection system will function properly if needed.

Specification

4.16.1 Each PORV shall be demonstrated operable by:

SR 3.4.12.5

43.ii

a. Performance of a channel functional test on the PORV actuation channel, but excluding valve operation, within 31 days prior to entering a condition in which the PORV is required operable and at least once per 31 days thereafter when the PORV is required operable.

SR 3.4.12.8

b. Performance of a channel calibration on the PORV actuation channel at least once per 18 months.

SR 3.4.12.4

c. Verifying the PORV isolation valve is open at least once per 72 hours when the overpressure protection system is required to be operable.

4.16.2 The RCS vent(s) shall be verified to be open at least once per 12 hours when the vent(s) is being used for overpressure protection except when the vent pathway is provided with a valve which is locked, sealed, or otherwise secured in the open position. Then verify these valves open at least once per 31 days.

SR 3.4.12.3

SR 3.4.12.7

} 43.i

LCO 3.5.2 (13.v)

3.3

Emergency Core Cooling System, Auxiliary Cooling Systems, Air Recirculation Fan Coolers, Containment Spray, and Charcoal/HEPA Filters

Objective

To define those conditions for operation that are necessary: (1) to remove decay heat from the core in emergency or normal shutdown situations, (2) to remove heat from containment in normal operating and emergency situations, (3) to remove airborne iodine from the containment atmosphere following a postulated Design Basis Accident, and (4) to minimize containment leakage to the environment subsequent to a Design Basis Accident.

Specification

3.3.1 Safety Injection and Residual Heat Removal Systems

3.3.1.1 The reactor shall not be taken above the mode indicated unless the following conditions are met:

- a. Above cold shutdown, the refueling water storage tank contains not less than 300,000 gallons of water, with a boron concentration of at least ~~2000~~ ²³⁰⁰ ppm, and ~~≤ 2000 ppm~~ ^{≤ 2300 ppm}.
- b. Above a reactor coolant system pressure of 1600 psig, except during performance of RCS hydro test, each accumulator is pressurized to at least 700 psig with an indicated level of at least 50% and a maximum of 82% with a boron concentration of at least ~~1800~~ ²¹⁰⁰ ppm, and ~~≤ 2100 ppm~~ ^{≤ 2400 ppm}.
- c. At or above a reactor coolant system temperature of 350°F, three safety injection pumps are operable.

(13.ii)
LCO 3.5.4
SR 3.5.4.1
SR 3.5.4.2

LCO 3.5.1
(13.i)
(13.vi)
(13.vii)

LCO 3.5.2
(13.iii)

LCO 3.5.2 d. At or above an RCS temperature of 350°F, two residual heat removal pumps are operable.

LCO 3.5.2 e. At or above an RCS temperature of 350°F, two residual heat removal heat exchangers are operable.

LCO 3.5.1
LCO 3.5.2
LCO 3.5.4 f. At the conditions required in a through e above, all valves, interlocks and piping associated with the above components which are required to function during accident conditions are operable.

LCO 3.5.2 g. At or above an RCS temperature of 350°F, A.C. power shall be removed from the following valves with the valves in the open position: safety injection cold leg injection valves 878B and D. A.C. power shall be removed from safety injection hot leg injection valves 878A and C with the valves closed. D.C. control power shall be removed from refueling water storage tank delivery valves 896A, 896B and 856 with the valves open.

13.viii

See Chapter 3.4

h. At or above an RCS temperature of 350°F, check valves 853A, 853B, 867A, 867B, 878G, and 878J shall be operable with less than 5.0 gpm leakage each. The leakage requirements of Technical Specification 3.1.5.2.1 are still applicable.

LCO 3.5.1
LCO 3.5.15 i. Above a reactor coolant system pressure of 1600 psig, except during performance of RCS hydro test, A.C. power shall be removed from accumulator isolation valves 841 and 865 with the valves open.

LCO 3.5.2 j. At or above an RCS temperature of 350° F, A.C. power shall be removed from Safety Injection suction valves 825A and B with the valves in the open position, and from valves 826A, B, C, D with the valves in the closed position.

3.3.1.2 If the conditions of 3.3.1.1a are not met, then satisfy the condition within 1 hour or be at hot shutdown in the next 6 hours and at least cold shutdown within an additional 30 hours.

LCO 3.5.4

13.2

3.3.1.3 The requirements of 3.3.1.1b and 3.3.1.1i may be modified to allow one accumulator to be inoperable or isolated for up to one hour. If the accumulator is not operable or is still isolated after one hour, the reactor shall be placed in hot shutdown within the following 6 hours and below a RCS pressure of 1600 psig within an additional 6 hours.

LCO 3.5.1

13.4

3.3.1.4 The requirements of 3.3.1.1c may be modified to allow one safety injection pump to be inoperable for up to 72 hours. If the pump is not operable after 72 hours, the reactor shall be placed in hot shutdown within the following 6 hours and below a RCS temperature less than 350°F within an additional 6 hours.

LCO 3.5.2

3.3.1.5 The requirements of 3.3.1.1d through h. may be modified to allow components to be inoperable at any one time. More than one component may be inoperable at any one time provided that one train of the ECCS is operable. If the requirements of 3.3.1.1d through h. are not satisfied within the time period specified below, the reactor shall be placed in hot shutdown within 6 hours and at an RCS temperature less than 350°F in an additional 6 hours.

LCO 3.5.2

- a. One residual heat removal pump may be out of service provided the pump is restored to operable status within 72 hours.

LCO 3.5.2

LCO 3.5.2 b. One residual heat removal heat exchanger may be out of service for a period of no more than 72 hours.

LCO 3.5.2 c. Any valve, interlock, or piping required for the functioning of one safety injection train and/or one low head safety injection train (RHR) may be inoperable provided repairs are completed within 72 hours (except as specified in e. below).

LCO 3.5.2 (Note) 13.iv d. Power may be restored to any valve referenced in 3.3.1.1g for the purposes of valve testing provided no more than one such valve has power restored and provided testing is completed and power removed within 12 hours.

~~e. Those check valves specified in 3.3.1.1h may be inoperable (greater than 5.0 gpm leakage) provided the inline MOVs are de-energized closed and repairs are completed within 12 hours.~~

~~3.3.1.6 Deleted~~

operate if required to do so, the redundant component(s) are to be tested prior to initiating repair of the inoperable component. If it develops that (a) the inoperable component is not repaired within the specified allowable time period or (b) a second component in the same or related system is found to be inoperable, the reactor will initially be put in the hot shutdown condition to provide for reduction of the decay heat from the fuel, and consequent reduction of cooling requirements after a postulated loss-of-coolant accident. This will also permit improved access for repairs in some cases. After a limited time in hot shutdown, if the malfunction(s) are not corrected, the reactor will be placed in the cold shutdown condition, utilizing normal shutdown and cooldown procedures. In the cold shutdown condition, there is no possibility of an accident that would release fission products or damage the fuel elements.

The plant operating procedures will require immediate action to effect repairs of an inoperable component, and therefore in most cases repairs will be completed in less than the specified allowable repair times. Furthermore, the specified repair times do not apply to regularly scheduled maintenance of the engineered safeguards systems, which is normally to be performed during refueling shutdowns. The limiting times to repair are based on:

- (1) Assuring with high reliability that the safeguard system will function properly if required to do so.

(2) Allowances of sufficient time to effect repairs using safe and proper procedures.

Assuming the reactor has been operating at full rated power for at least 100 days, the magnitude of the decay heat decreases as follows after initiating hot shutdown.

<u>Time After Shutdown</u>	<u>Decay Heat % of Rated Power</u>
1 min.	4.5
30 min.	2.0
1 hour	1.62
8 hours	0.96
48 hours	0.62

Thus, the requirement for core cooling in case of a postulated loss-of-coolant accident while in the hot shutdown condition is significantly reduced below the requirements for a postulated loss-of-coolant accident during power operation. Putting the reactor in the hot shutdown condition, significantly reduces the potential consequences of a loss-of-coolant accident; and also allows more free access to some of the engineered safeguards components in order to effect repairs.

Failure to complete repairs within 48 hours of going to the hot shutdown condition is considered indicative of a requirement for major maintenance and therefore in such a case the reactor is to be put into the cold shutdown condition.

See Chapter 3.4

With respect to the core cooling function, there is some functional re-

See Chapter
3.7

The facility has four service water pumps. Only one is needed during the injection phase, and two are required during the recirculation phase of a postulated loss-of-coolant accident.⁽⁸⁾ The control room emergency air treatment system is designed to filter the control room atmosphere during periods when the control room is isolated and to maintain radiation levels in the control room at acceptable levels following the Design Basis Accident.⁽⁹⁾ Reactor operation may continue for a limited time while repairs are being made to the air treatment system since it is unlikely that the system would be needed. Technical Specification 3.3.5 applies only to the equipment necessary to filter the control room atmosphere. Equipment necessary to initiate isolation of the control room is covered by another specification.

~~The limits for the accumulator pressure and volume assure the required amount of water injection during an accident, and are based on values used for the accident analyses. The indicated level of 50% corresponds to 1108 cubic feet of water in the accumulator and the indicated level of 82% corresponds to 1134 cubic feet.~~

~~The limitation of no more than one safety injection pump to be operable when overpressure protection is being provided by a RCS vent of ≥ 1.1 sq. in. insures~~

Notes:

- (1) Also required for specifically affected individual rods following any maintenance on or modification to the control rod drive system which could affect the drop time of those specific rods.
- (2) Not required during a cold or refueling shutdown.
- (3) An isotopic analysis for I-131 equivalent activity is required at least monthly whenever the gross activity determination indicates iodine concentration greater than 10% of the allowable limit but only once per 6 months whenever the gross activity determination indicates iodine concentration below 10% of the allowable limit.
- (4) When BAST is required to be operable.

4.3.4 Relief Valves

4.3.4.1 Each PORV shall be demonstrated operable at least once per 18 months by performance of a CHANNEL CALIBRATION.

4.3.4.2 Except during cold and refueling shutdown each block valve shall be demonstrated operable at least once per 92 days by operating the valve through one complete cycle of full travel unless the valve is already closed.

4.3.5 Reactor Coolant Loops

4.3.5.1 When reactor power is above 130 Mwt (8.5%), the reactor coolant pumps shall be verified to be in operation and circulating reactor coolant at least once per 12 hours.

4.3.5.2 When the average coolant temperature is above 350°F but the reactor is not critical, when the reactor is at hot shutdown, or when the reactor is critical but reactor power is less than or equal to 130 Mwt (8.5%):

- a) the operating reactor coolant pump(s) shall be verified to be in operation and circulating reactor coolant at least once per 12 hours, and
- b) if a reactor coolant pump is not operating, but must be operable, it shall be demonstrated operable once per 7 days by verifying correct breaker alignments and indicated power availability.

See
Chapter
3.4

4.3.5.3 When the ~~reactor is at cold shutdown or when the~~ average coolant temperature is between 200°F and 350°F, and fuel is in the reactor, the following shall be performed to demonstrate a loop is operable. Tests need not be performed if a loop is not relied upon to satisfy the requirements of Specification 3.1.1.1.e.

See Chapter
3.4

a) ... to demonstrate a reactor coolant loop operable, the reactor coolant pump(s), if not in operation, shall be demonstrated operable at least once per 7 days by verifying correct breaker alignments and indicated power availability.

b) to demonstrate a residual heat removal pump is operable, the surveillance specified in the Inservice Pump and Valve Test Program prepared pursuant to 10 CFR 50.55a shall be performed.

SR 3.5.3.1

See
Chapter
3.4

4.3.5.4 When the reactor is at cold shutdown or when the average coolant temperature is between 200°F and 350°F and fuel is in the reactor, at least one coolant loop shall be verified to be in operation and circulating reactor coolant at least once per 12 hours.

4.3.5.5 In addition to the above requirements, in order to demonstrate that a reactor coolant loop is operable, the steam generator water level shall be greater than or equal to 16% of the narrow range instrument span.

4.3.5.6 Each reactor coolant system vent path shall be demonstrated operable at least once per 18 months by:

1. Verifying all manual isolation valves in each vent path are locked in the open position.
2. Verifying flow through the reactor coolant vent system vent paths using either liquid or gas.

Basis:

This material surveillance program monitors changes in the fracture toughness properties of ferritic materials in the reactor vessel beltline region of the reactor resulting from exposure to

SR 3.5.2.1 }
SR 3.5.2.2 } (32.iv)

4.5 Safety Injection, Containment Spray and Iodine Removal

Systems Tests

Applicability:

Applies to testing of the Safety Injection System, the Containment Spray System, and the Air Filtration System inside Containment.

Objective:

To verify that the subject systems will respond promptly and perform their intended functions, if required.

Specification:

4.5.1 Safety Tests

4.5.1.1 Safety Injection System

- a. System tests shall be performed at each reactor refueling interval. The test shall be performed in accordance with the following:

SR 3.5.2.5

(32.i)

With the reactor coolant system pressure less than or equal to 350 psig and temperature less than or equal to 350°F, a test safety injection signal will

be applied to initiate operation of the system. The safety injection and residual heat removal pump motors are prevented from starting during the test.

SR 3.5.2.5

b. The system test will be considered satisfactory if control board indication and visual observations indicate that all valves have received the Safety Injection signal and have completed their travel. The proper sequence and timing of the rotating components are to be verified in conjunction with Section 4.6.1 b.

See Chapter 3.6

4.5.1.2 Containment Spray System

- a. System tests shall be performed at each reactor refueling interval. The test shall be performed with the isolation valves, in the spray supply lines, at the containment blocked closed. Operation of the system is initiated by tripping the normal actuation instrumentation.
- b. The spray nozzles shall be checked for proper functioning at least every five years.
- c. The test will be considered satisfactory if visual observations indicate all components have operated satisfactorily.

4.5.2 Component Tests

4.5.2.1 Pumps

- a. Except during cold or refueling shutdowns the safety injection pumps, residual heat removal pumps, and containment spray pumps shall be started at intervals not to exceed one month. The pumps shall be tested prior to startup if the time since the last test exceeds 1 month.

SR 3.5.3.1
SR 3.5.2.4

32.ii

SR 3.5.3.1
SR 3.5.2.4
SR 3.5.2.3
32.22

b. Acceptable levels of performance for the pumps shall be that the pumps start, operate, and develop the minimum discharge pressure for the flows listed in the table below:

PUMPS	RECYCLE FLOW RATE	DISCHARGE PRESSURE
Containment Spray Pumps	35 gpm	240 psig
Residual Heat Removal Pumps	[200 gpm] 450 gpm	[140 psig] 138 psig
Safety Injection Pumps	[50 gpm] 150 gpm	[1420 psig] 1356 psig

Notes

(1)

(2)

Table 4.5-1

Notes

- (1) Items in square brackets are effective until the installation of the new residual heat removal minimum flow recirculation system.
- (2) Items in square brackets are effective until installation of the new safety injection minimum flow recirculation system.

See Chapter 3.6

4.5.2.2 Valves

a. Except during cold or refueling shutdowns the spray additive valves shall be tested at intervals not to exceed one month. With the pumps shut down and the valves upstream and downstream

of the spray additive valves closed, each valve will be opened and closed by operator action. This test shall be performed prior to startup if the time since the last test exceeds one month.

- 3. The accumulator check valves shall be checked for operability during each refueling shutdown.

32.iii

4.5.2.3 Air Filtration System

4.5.2.3.1 At least once every 18 months or after every 720 hours of charcoal filtration system operation since the last test, or following painting, fire or chemical release in any ventilation zone communicating with the system, the post accident charcoal system shall have the following conditions demonstrated.

- a. The pressure drop across the charcoal adsorber bank is less than 3 inches of water at design flow rate ($\pm 10\%$).
- b. In place Freon testing, under ambient conditions, shall show at least 99% removal.
- c. The iodine removal efficiency of at least one charcoal filter cell shall be measured. The filter cell to be tested shall be selected randomly from those cells with the longest in-bank residence time. The minimum acceptable value for filter efficiency is 90% for removal of methyl iodide when tested at at least 286°F and 95% RH and at 1.5 to 2.0 mg/m³ loading with tagged CH₃I.

See Chapter 5.0

- See Chapter 3.8
- c. The tests in Specification 4.6.1b will be performed prior to exceeding cold shutdown if the time since the last test exceeds 31 days.
 - d. At least once per 92 days by verifying that a sample of diesel fuel from the fuel storage tank is within the acceptable limits specified in Table 1 of ASTM D975-78 when checked for viscosity, water and sediment.
 - e. At least once per 18 months during shutdown by:
 1. Inspecting the diesel in accordance with the manufacturer's recommendations for this class of standby service.
 2. Verifying the generator capability to reject a load of 295 KW without tripping.
 3. Simulating a loss of offsite power in conjunction with a safety injection test signal and:
 - (a) Verifying de-energization of the emergency buses and load shedding from the emergency buses.
 - (b) Verifying the diesel starts from normal standby condition on the auto-start signal, energizes the automatically connected emergency loads with the following maximum breaker closure times after the initial starting signal for Trains A and B not being exceeded

SR 3.5.2.6

(33.vi)

	A	B
Diesel plus Safety Injection Pump plus RHR Pump	20 sec	22 sec
All Breakers	40 sec	42 sec

and operates for \geq five minutes while its generator is loaded with emergency loads.

- See Chapter 3.8
- (c) Verifying that all diesel generator trips, except engine overspeed, low lube oil pressure, and overcrank, are automatically bypassed upon a safety injection actuation signal.

3.3.2 Containment Cooling and Iodine Removal

3.3.2.1 The reactor shall not be taken above cold shutdown unless the following conditions are met:

- 3.6.6
- a. The spray additive tank contains not less than 4500 gallons of solution with a sodium hydroxide concentration of not less than 30% by weight.
 - b. Both containment spray pumps are operable.
 - c. Four recirculation fan cooler units including the associated HEPA filter units with demisters are operable.
 - d. Both post accident charcoal filter units are operable.
 - e. All valves and piping associated with the above components which are required to function during accident conditions are operable.

3.3.2.2 The requirements of 3.3.2.1 may be modified to allow components to be inoperable at any one time provided that 1) the time limits and other requirements specified in a through f below are satisfied, and 2) at least 1 containment spray pump, ~~1~~² fan cooler units, ~~1~~² HEPA filter units with demisters, and 1 charcoal filter unit and all required valves and piping associated with these components are operable. If these requirements are not satisfied, the reactor shall be in hot shutdown within 6 hours. If the requirements are not satisfied within an additional 48 hours, be in cold shutdown within the next 30 hours.

- 3.6.6
- (13.xv)
- a. One ^{or 2} HEPA filter unit or demister and/or associated recirculation fan cooler may be inoperable for a period of no more than 7 days.

3.6.6 b. One containment spray pump may be inoperable provided the pump is restored to operable status within 3 days.

3.6.6 c. Any valve or piping in a system, required to function during accident conditions, may be inoperable provided it is restored to operable status within 72 hours.

3.6.6 d. One post accident charcoal filter unit and/or its associated fan cooler may be inoperable provided the unit is restored to operable status within 7 days.

(13.xv)

Two post-accident charcoal filter trains may be inoperable up to 72 hours if both CS trains are available.

3.6.6 e. The spray additive system may be inoperable for a period of no more than 3 days provided that both charcoal filter units are operable.

3.3.3 Component Cooling System

3.3.3.1 The reactor shall not be taken above cold shutdown unless the following conditions are met:

- a. Both component cooling pumps are operable.
- b. Both component cooling heat exchangers are operable.
- c. All valves, interlocks and piping associated with the above components which are required to function during accident conditions are operable.

3.3.3.2 The requirements of 3.3.3.1 may be modified to allow one of the following components to be inoperable at any one time. If the system is not restored to meet the conditions of 3.3.3.1 within the time period

Addressed in chapter 3.3

3.3-6

redundancy for certain ranges of break sizes. (2)

The containment cooling and iodine removal functions are provided by two independent systems: (a) fan-coolers plus post accident charcoal filters and (b) containment spray with sodium hydroxide addition. During normal power operation, only two of the four fan-coolers are required to remove heat lost from equipment and piping within containment. (3) In the event of a Design Basis Accident, any one of the following will serve to reduce airborne iodine activity and maintain doses within the values calculated in the FSAR: (1) two containment spray pumps and sodium hydroxide addition, (2) two fan-coolers and two post accident charcoal filters, or (3) one containment spray pump and sodium hydroxide addition plus one fan-cooler and one post accident charcoal filter. (4) In addition, the containment integrity analysis assumes that one containment spray pump and two fan-coolers operate to reduce containment pressure following a Design Basis Accident. (9) Because of the difficulty of access to make repairs to a fan-cooler and because of the low probability of a Design Basis Accident during that time, an additional seven days operation with an inoperable fan-cooler is permitted. The containment spray pumps and spray additive system are located outside containment and are, therefore, less difficult to repair. Therefore, three days with an inoperable containment spray pump or spray additive system is deemed acceptable.

The Component Cooling System is different from the other systems discussed above in that the components are so located in the Auxiliary Building as to be accessible for repair after a loss-of-coolant accident. (5) In addition, if during the post-accident phase the component cooling water supply is lost, core and containment cooling could be maintained until repairs were effected. (6)(7)

3.6 Containment System

Applicability:

Applies to the integrity of reactor containment.

Objective:

To define the operating status of the reactor containment for plant operation.

Specification:

3.6.1 Containment Integrity

3.6.1
14.i

a. Except as allowed by 3.6.3, containment integrity shall not be violated unless the reactor is in the cold shutdown condition. Closed valves may be opened on an intermittent basis under administrative control.

Note 1 →

Addressed
in Chapter
3.9

b. The containment integrity shall not be violated when the reactor vessel head is removed unless the boron concentration is greater than 2000 ppm.

c. Positive reactivity changes shall not be made by rod drive motion or boron dilution whenever the containment integrity is not intact unless the boron concentration is greater than 2000 ppm.

3.6.2 Internal Pressure

3.6.4
16.ii

If the internal pressure exceeds 1 psig or the internal vacuum exceeds 2.0 psig, the condition shall be corrected within ~~24~~ hours or the reactor rendered subcritical.

8

3.6.3 Containment Isolation Boundaries

3.6.3.1 With a containment isolation boundary inoperable for one or more containment penetrations, either:

LCO 3.6.2
LCO 3.6.3

- a. Restore each inoperable boundary to OPERABLE status within 4 hours, or
- b. Isolate each affected penetration within 4 hours by use of at least one deactivated automatic valve secured in the isolation position, one closed manual valve, or a blind flange, or
- c. Be in at least hot shutdown within the next 6 hours and in cold shutdown within the following 30 hours.

16.iii

16.iv

3.6.4 Combustible Gas Control

3.6.4.1 When the reactor is critical, at least two independent containment hydrogen monitors shall be operable. One of the monitors may be the Post Accident Sampling System.

3.6.4.2 With only one hydrogen monitor operable, restore a second monitor to operable status within 30 days or be in at least hot shutdown within the next 6 hours.

3.6.4.3 With no hydrogen monitors operable, restore at least one monitor to operable status within 72 hours or be in at least hot shutdown within the next 6 hours.

Addressed in Chapter 3.3

3.6.5 Containment Mini-Purge

LCO 3.6.3

16.v

Whenever the containment integrity is required, emphasis will be placed on limiting all purging and venting times to as low as achievable. The mini-purge isolation valves will remain closed to the maximum extent practicable but may be open for pressure control, for ALARA, for respirable air quality considerations for personnel entry, for surveillance tests that may require the valve to be open or other safety related reasons.

Under Admin control

16.vi

- LCO 3.6.5

16.vii

- LCO 3.6.3

referred to base for LCO 3.6.3

Basis:

The reactor coolant system conditions of cold shutdown assure that no steam will be formed and hence there would be no pressure buildup in the containment if the reactor coolant system ruptures.

The shutdown margins are selected based on the type of activities that are being carried out. The (2000 ppm) boron concentration provides shutdown margin which precludes criticality under any circumstances. When the reactor head is not to be removed, a cold shutdown margin of 1%Δk/k precludes criticality in any occurrence.

Regarding internal pressure limitations, the containment design pressure of 60 psig would not be exceeded if the internal pressure before a major steam break accident were as much as 1 psig.⁽¹⁾ The containment is designed to withstand an internal vacuum of 2.5 psig.⁽²⁾ The 2.0 psig vacuum is specified as an operating limit to avoid any difficulties with motor cooling.

In order to minimize containment leakage during a design basis accident involving a significant fission product release, penetrations not required for accident mitigation are provided with isolation boundaries. These isolation boundaries consist of either passive devices or active automatic valves and are listed in a procedure under the control of the Quality Assurance Program. Closed manual valves, deactivated automatic valves secured in their closed position (including check valves with flow through the valve secured), blind flanges and closed systems are considered passive devices. Automatic isolation valves designed to close following an accident without operator action, are considered active devices. Two isolation devices are provided for each mechanical penetration, such that no single credible failure or malfunction of an active component can cause a loss of isolation, or result in a leakage rate that exceeds limits assumed in the safety analyses⁽³⁾.

In the event that one isolation boundary is inoperable, the affected penetration must be isolated with at least one boundary that is not affected by a single active failure. Isolation boundaries that meet this criterion are a closed and deactivated automatic containment isolation valve, a closed manual valve, or a blind flange.

The opening of closed containment isolation valves on an intermittent basis under administrative control includes the following considerations: (1) stationing an individual qualified in accordance with station procedures, who is in constant communication with the control room, at the valve controls, (2) instructing this individual to close these valves in an accident situation, and (3) assuring that environmental conditions will not preclude access to isolate the boundary and that this action will prevent the release of radioactivity outside the containment.

TABLE 4.1-2

MINIMUM FREQUENCIES FOR EQUIPMENT AND SAMPLING TESTS

	<u>Test</u>	<u>Frequency</u>
1.	Reactor Coolant Chemistry Samples Chloride and Fluoride Oxygen	3 times/week and at least every third day 5 times/week and at least every second day except when below 250°F
2.	Reactor Coolant Boron	Boron Concentration Weekly
3.	Refueling Water Storage Tank Water Sample	Boron Concentration Weekly
4.	Boric Acid Storage Tank	Boron Concentration Twice/Week ⁽⁴⁾
5.	Control Rods	Rod drop times of all full length rods After vessel head removal and at least once per 18 months (1)
6a.	Full Length Control Rod	Move any rod not fully inserted a sufficient number of steps in any one direction to cause a change of position as indicated by the rod position indication system Monthly
6b.	Full Length Control Rod	Move each rod through its full length to verify that the rod position indication system transitions occur Each Refueling Shutdown
7.	Pressurizer Safety Valves	Set point Each Refueling Shutdown
8.	Main Steam Safety Valves	Set point Each Refueling Shutdown
9.	Containment Isolation Trip	Functioning Each Refueling Shutdown
10.	Refueling System Interlocks	Functioning Prior to Refueling, Operations

See Chapters 3.1 → 3.9 (except for 3.6)

See Chapter 3.7

	<u>Test</u>	<u>Frequency</u>
11. Service Water System	Functioning	Each Refueling Shutdown
12. Fire Protection Pump and Power Supply	Functioning	Monthly
13. Spray Additive Tank <i>SE 3.4.4.8</i>	NaOH Concent	<u>Monthly</u> 184 days
14. Accumulator <i>28.11.6</i>	Boron Concentration	Bi-Monthly
15. Primary System Leakage	Evaluate	Daily
16. Diesel Fuel Supply	Fuel Inventory	Daily
17. Spent Fuel Pit	Boron Concentration	Monthly
18. Secondary Coolant Samples	Gross Activity	72 hours (2) (3)
19. Circulating Water Flood Protection Equipment	Calibrate	Each Refueling Shutdown

Notes:

- (1) Also required for specifically affected individual rods following any maintenance on or modification to the control rod drive system which could affect the drop time of those specific rods.
- (2) Not required during a cold or refueling shutdown.
- (3) An isotopic analysis for I-131 equivalent activity is required at least monthly whenever the gross activity determination indicates iodine concentration greater than 10% of the allowable limit but only once per 6 months whenever the gross activity determination indicates iodine concentration below 10% of the allowable limit.
- (4) When BAST is required to be operable.

SR 3.6.7.1
SR 3.6.7.2

4.4 Containment Tests

Applicability

Applies to containment leakage and structural integrity.

Objective

To verify that potential leakage from the containment and the pre-stressing tendon loads are maintained within specified values.

Specification

4.4.1 Integrated Leakage Rate Test

4.4.1.1 Definitions

31.iii

SR 3.6.1.1

Pa (psig) is the containment vessel design pressure of 60 psig.

Pt (psig) is the containment vessel reduced test pressure for periodic testing.

Lt (weight percent/24 hours) is the maximum allowable leakage rates of the containment vessel test atmosphere at pressure Pt.

La (weight percent/24 hours) is the maximum allowable leakage rate of the containment vessel test atmosphere at pressure Pa; 0.2%/24 hrs.

1.1

Lam and Ltm (weight percent/24 hours) are the total measured containment leakage rates of the containment vessel test atmosphere at pressures Pa and Pt respectively.

4.4.1.2 Pretest Requirements

31.iii

SR 3.6.1.1

- a. A visual examination of the accessible interior and exterior surfaces of the containment structure shall be performed to uncover any evidence of structural deterioration which may affect either the containment structure integrity or leak-tightness. If there is evidence of structural deterioration, integrated leak rate testing shall not be performed until appropriate corrective action has been taken. Except for repairs to correct structural deterioration, however, no repairs or adjustments shall be made during the period between the initiation of the inspection and the performance of the test.
- b. Closure of containment isolation valves shall be accomplished by normal operation and without any preliminary exercising or adjustments.

4.4.1.3

Conduct of Tests

- a. All integrated leak rate tests shall be conducted in accordance with the provisions of American National Standard N45.4-1972, Leakage Rate Testing of Containment Structures for Nuclear Reactors, March 16, 1972.
- b. The accuracy of each integrated leak rate test shall be verified by a supplemental test which confirms the accuracy of the test instrumentation and calculational methods by determining a leak rate which is within 0.25Lt of the test result. If results are not within 0.25Lt the reason shall be determined, corrective action taken and a successful supplemental test performed.
- c. Integrated leak rate tests shall be conducted at an initial pressure (beginning of test) $P_t \geq 35$ psig.
- d. If during the test, including the supplemental test, potentially excessive leakage paths are identified which will interfere with satisfactory completion of the test, or which result in the test not meeting the acceptance criteria, the test shall be terminated and the leakage through such paths shall be measured using local leakage testing methods. Repairs and/or adjustments to equipment shall be made and an integrated leak rate test performed.

(31.iii)

SR 3.6.1.1

4.4.1.4 Acceptance Criteria

- 31.iii
SR 3.6.1.1
- a. The leakage rate L_{tm} shall be $<0.75 L_t$ at P_t . P_t is defined as the containment vessel reduced test pressure which is greater than or equal to 35 psig. L_{tm} is defined as the total measured containment leakage rate at pressure P_t . L_t is defined as the maximum allowable leakage rate at pressure P_t .
- b. L_t shall be determined as $L_t = L_a \left(\frac{P_t}{P_a} \right)^{1/2}$ which equals .1528 percent weight per day at 35 psig. P_a is defined as the calculated peak containment internal pressure related to design basis accidents which is greater than or equal to 60 psig. L_a is defined as the maximum allowable leakage rate at P_a which equals .2 percent weight per day.
- c. The leakage rate at P_a (L_{am}) shall be $<0.75 L_a$. L_{am} is defined as the total measured containment leakage rate at pressure P_a .

4.4.1.5 Test Frequency

- 31.iii
SR 3.6.1.1
- a. A set of three integrated leak rate tests shall be performed at approximately equal intervals during each 10-year service period. The third test of each set shall be conducted in the final year of the 10-year service period or one year before or after the final year of the 10-year service period provided:
- i. the interval between any two Type A tests does not exceed four years,
 - ii. following each in-service inspection, the containment airlocks, the steam generator inspection/maintenance penetration, and the equipment hatch are leak tested prior to returning the plant to operation, and
 - iii. any repair, replacement, or modification of a containment barrier resulting from the inservice inspections shall be followed by the appropriate leakage test.

b. If any test fails to meet the acceptance criteria of 4.4.1.4.a the test schedule for subsequent regularly scheduled inservice tests shall be submitted to the Commission for review and approval.

c. If two consecutive tests fail to meet the acceptance criteria of 4.4.1.4.a, a retest shall be performed at each refueling shutdown or approximately every 18 months, whichever comes first, until two consecutive tests meet the acceptance criteria of 4.4.1.4.a, after which time the retest schedule of 4.4.1.5.a may be resumed.

31.iii

SR 3.4.1.1

4.4.1.6 Additional Requirements

a. A summary technical report shall be submitted to the Commission after the conduct of each integrated leak rate test. Information on any valve closure malfunction or valve leakage that requires corrective action before the test shall be included in the report.

4.4.2 Local Leak Detection Tests

4.4.2.1 Test

a. Local leakage rate tests shall be performed at intervals specified in 4.4.2.4 below and at a pressure of not less than 60 psig.

31.iii

SR 3.4.1.1

- b. The local leakage rate shall be measured for each of the following components:
 - i. Containment penetrations that employ resilient seals, gaskets, or sealant compounds, piping penetrations with expansion bellows and electrical penetrations with flexible metal seal assemblies.
 - ii. Air lock and equipment door seals.
 - iii. Fuel transfer tube.
 - iv. Isolation valves on the testable fluid systems lines penetrating the containment.
 - v. Other containment components, which require leak repair in order to meet the acceptance criterion for any integrated leakage rate test.

31.iii

SR 3.6.1.1

4.4.2.2 Acceptance Criterion

Containment isolation boundaries are inoperable from a leakage standpoint when the demonstrated leakage of a single boundary or cumulative total leakage of all boundaries is greater than 0.60 La.

4.4.2.3 Corrective Action

- a. If at any time it is determined that the total leakage from all penetrations and isolation boundaries exceeds 0.60 La, repairs shall be initiated immediately.

CCO 3.6.1

31.iv

b. If repairs are not completed and conformance to the acceptance criterion of 4.4.2.2 is not demonstrated within 48 hours, the reactor shall be shutdown and depressurized until repairs are effected and the local leakage meets the acceptance criterion.

CCO 3.6.1

31.iv

c. If it is determined that the leakage through a mini-purge supply and exhaust line is greater than 0.05 La an engineering evaluation shall be performed and plans for corrective action developed.

SR 3.6.3.4

CCO 3.6.3

31.vi

4.4.2.4 Test Frequency

- a. Except as specified in b. and c. below, individual penetrations and containment isolation valves shall be tested in accordance with 10 CFR 50, Appendix J, as modified by approved exemptions.
- b. The containment equipment hatch, fuel transfer tube, steam generator inspection/maintenance penetration, and shutdown purge system flanges shall be tested at each refueling shutdown or after each use, if that be sooner.

31.iii

SR 3.3.1.1

SR 3.6.2.1
SR 3.6.2.2
LCO 3.6.2

31.iii

31.v

c. The containment air locks shall be tested at intervals of no more than six months by pressurizing the space between the air lock doors. In addition, following opening of the air lock door during the interval, a test shall be performed by pressurizing between the dual seals of each door opened, within 48 hours of the opening, unless the reactor was in the cold shutdown condition at the time of the opening or has been subsequently brought to the cold shutdown condition. A test shall also be performed by pressurizing between the dual seals of each door within 48 hours of leaving the cold shutdown condition, unless the doors have not been open since the last test performed either by pressurizing the space between the air lock doors or by pressurizing between the dual door seals.

- c. Visual inspection shall be made for excessive leakage from components of the system. Any significant leakage shall be measured by collection and weighing or by an equivalent method.

4.4.3.2 Acceptance Criterion

The maximum allowable leakage from the recirculation heat removal systems components (which includes valve stems, flanges and pump seals) shall not exceed two gallons per hour.

4.4.3.3 Correction Action

- a. Repairs shall be made as required to maintain leakage within the acceptance criterion of 4.4.3.2.
- b. If repairs are not completed within 24 hours, the reactor shall be shut down and depressurized until repairs are effected and the acceptance criterion of 4.4.3.2 is satisfied.

4.4.3.4 Test Frequency

Tests of the recirculation heat removal system shall be conducted at intervals not to exceed 12 months.

SR 3.6.1.2 4.4.4 Tendon Stress Surveillance

~~4.4.4.1 Inspection for Broken Wires~~

- ~~a. Fourteen specific tendons, equally spaced around the~~

31.i

See
Chapter
5.0

containment shall be inspected periodically for the presence of broken wires.

- b. The inspection intervals, measured from the date of the initial structural test, shall be as follows:

6 months

1 year

3 years

8 years and 5 years intervals thereafter.

- c. The acceptance criteria for the inspection are that no more than a total of 38 wires (in 14 tendons) are broken and that not more than 6 broken wires exist in any one tendon. If more than 38 broken wires are found, all tendons shall be inspected. If inspection reveals more than 5% of the total wires broken, the reactor shall be shut down and depressurized.

- d. If more than 20 wires (in 14 tendons) have been broken since the last inspection, all tendons shall be inspected. If inspection reveals more than 5% of the total wires broken, the reactor shall be shut down and depressurized.

- e. If as many as 6 broken wires are found in any one tendon, four immediately adjacent tendons (two on each side of

31.1

the tendon containing 6 broken wires) shall be inspected. The accepted criterion then shall be no more than 4 broken wires in any of the additional 4 tendons. If this criterion is not satisfied, all of the tendons shall be inspected and if more than 5% of the total wires are broken, the reactor shall be shut down and depressurized.

31.i

4.4.4.2 Pre-Stress Confirmation Test

- a. Lift-off tests shall be performed on the 14 tendons identified in 4.4.4.1a above, at the intervals specified in 4.4.4.1b. If the average stress in the 14 tendons checked is less than 144,000 psi (60% of ultimate stress), all tendons shall be checked for stress and retensioned, if necessary, to a stress of 144,000 psi.
- b. Before reseating a tendon, additional stress (6%) shall be imposed to verify the ability of the tendon to sustain the added stress applied during accident conditions.

4.4.5 Containment Isolation Valves

4.4.5.1 Each containment isolation valve shall be demonstrated to be OPERABLE in accordance with the Ginna Station Pump and Valve Test program submitted in accordance with 10 CFR 50.55a.

SR 3.4.3.3

31.vii

4.4.6 Containment Isolation Response

4.4.6.1 Each containment isolation instrumentation channel shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION, and CHANNEL FUNCTIONAL TEST operations for the MODES and at the frequencies shown in Table 4.1-1.

Addressed in chapter 3.3

4.4.6.2 The response time of each containment isolation valve shall be demonstrated to be within its limit at least once per 18 months. The response time includes only the valve travel time for those valves which the safety analysis assumptions take credit for a change in valve position in response to a containment isolation signal.

SR 3.4.3.5

31.viii

Addressed in
chapter 3.3

4.4.7 Containment Hydrogen Monitors

- 4.4.7.1 Demonstrate that two hydrogen monitors are operable at least daily by verifying that the unit is on or in standby.
- 4.4.7.2 At least once per quarter perform a channel calibration using two sample gases containing known concentrations of hydrogen.

Basis:

The containment is designed for an accident pressure of 60 psig. (1) While the reactor is operating, the internal environment of the containment will be air at approximately atmospheric pressure. The maximum temperature of the steam-air mixture at the peak accident pressure of 60 psig is calculated to be 286° F.

Prior to initial operation, the containment was strength tested at 69 psig and then was leak tested. The acceptance criterion for this pre-operational leakage rate test was established as 0.1% per 24 hours at 60 psig. This leakage rate was believed consistent with the construction of the containment, (2) which is equipped with independent leak-testable penetrations and contains channels over all containment liner welds, which were independently leak tested during construction.

Safety analyses have been performed on the basis of a leakage rate of 0.20% per 24 hours at 60 psig. With this leakage rate and with minimum containment engineered safeguards operating (i. e., either 2 filter units and no spray, or 1 filter unit and 1 spray, or no filter units and 2 sprays) the public exposure would be well below 10 CFR 100 values in the event of the design basis accident. (3)

Performance of the integrated leakage rate test provides an over-all assessment of potential leakage from the containment in case of an accident that would pressurize the interior of the containment. In order to provide a realistic appraisal of the integrity of the containment under accident conditions, the test is to be performed without preliminary leak detection surveys or leak repairs, and containment isolation valves are to be closed in the normal manner. The test pressure of 35 psig for the integrated leakage rate test is sufficiently high to provide an accurate measurement of the leakage rate and it duplicates the preoperational leakage rate test at 35 psig.

The Specification also allows for possible deterioration of the leakage rate between tests, by requiring that the total measured leakage rate be only 75% of the maximum allowable leakage rate.

The duration and methods for the integrated leakage rate test established by ANSI N45.4-1972 provide a minimum level of accuracy and allow for daily cyclic variation in temperature and thermal radiation. The frequency of the integrated leakage rate test is keyed to the refueling schedule for the reactor, because these tests can best be performed during refueling shutdowns. Refueling shutdowns are scheduled at approximately one year intervals.

The specified frequency of integrated leakage rate tests is based on three major considerations. First is the low probability of leaks in the liner, because of (a) the use of weld channels to test the leaktightness of the welds during erection, (b) conformance of the complete containment to a 0.1% per day leak rate at 60 psig during preoperational testing, and (c) absence of any significant stresses in the liner during reactor operation. Second is the more frequent testing, at the full accident pressure, of those portions of the containment envelope that are most likely to develop leaks during reactor operation (penetrations and isolation valves) and the low value (0.60 La) of the total leakage that is specified as acceptable. Third is the tendon stress surveillance program, which provides assurance that an important part of the structural integrity of the containment is maintained.

The basis for specification of a total leakage of 0.60 La from penetrations and isolation boundaries is that only a portion of the allowable integrated leakage rate should be from those sources in order to provide assurance that the integrated leakage rate would remain within the specified limits during the intervals between integrated leakage rate tests. Because most leakage during an integrated leak rate test occurs through penetrations and isolation valves, and because for most penetrations and isolation valves a smaller leakage rate would result from an integrated leak test than from a local test, adequate assurance of maintaining the integrated leakage rate within the specified limits is provided. The limiting leakage rates from the Recirculation Heat Removal Systems are judgement values based primarily on assuring that the components could operate without mechanical failure for a period on the order of 200 days after a design basis accident. The test

pressure, 350 psig, achieved either by normal system operation or by hydrostatic testing, gives an adequate margin over the highest pressure within the system after a design basis accident. Similarly, the hydrostatic test pressure for the containment sump return lines and the reactor coolant drain tank piping connections to the residual heat removal system of 100 psig gives an adequate margin over the highest pressure within the lines after a design basis accident. (4)

A recirculation system leakage of 2 gal. /hr will limit offsite exposure due to leakage to insignificant levels relative to those calculated for leakage directly from the containment in the design basis accident. The dose calculated as a result of this leakage is 7.7 mr for a 2-hr exposure at the site boundary. (5)

In case of failure to meet the acceptance criteria for leakage from the residual heat removal system or the penetrations, it may be possible to effect repairs within a short time. If so, it is considered unnecessary and unjustified to shut down the reactor. The times allowed for repairs are consistent with the times developed in Specification 3.3.

The tendon surveillance program is based on assuring that, on the average, the load-carrying capability of the tendons is maintained at approximately 95% design.

See Chapter 5.0

See Chapter 5.0

The pre-stress confirmation test provides a direct measure of the load-carrying capability of the tendon.

If the surveillance program indicates by extensive wire breakage or tendon stress relation that the pre-stressing tendons are not behaving as expected, the situation will be evaluated immediately. The specified acceptance criteria are such as to alert attention to the situation well before the tendon load-carrying capability would deteriorate to a point that failure during a design basis accident might be possible. Thus the cause of the incipient deterioration could be evaluated and corrective action studied without need to shut down the reactor. The containment is provided with two readily removable tendons that might be useful to such a study. In addition, there are 40 tendons, each containing a removable wire which will be used to monitor for possible corrosion effects.

Operability of the containment isolation boundaries ensures that the containment atmosphere will be isolated from the outside environment in the event of a release of radioactive material to the containment atmosphere or pressurization of the containment. Performance of cycling tests and verification of isolation times associated with automatic containment isolation valves is covered by the Pump and Valve Test Program. Compliance with Appendix J to 10 CFR 50 is addressed under local leak testing requirements.

in Chapter
3.5

b. The system test will be considered satisfactory if control board indication and visual observations indicate that all valves have received the Safety Injection signal and have completed their travel. The proper sequence and timing of the rotating components are to be verified in conjunction with Section 4.6.1 b.

4.5.1.2 Containment Spray System

SR 3.4.6.13

a. System tests shall be performed at each reactor refueling interval. The test shall be performed with the isolation valves, in the spray supply lines, at the containment blocked closed. Operation of the system is initiated by tripping the normal actuation instrumentation.

SR 3.4.6.2
SR 3.6.6.1
32.vii

b. The spray nozzles shall be checked for proper functioning at least every ~~five~~ ^{ten} years.

SR 3.6.6.18
32.viii

c. The test will be considered satisfactory if visual observations indicate all components have operated satisfactorily.

4.5.2 Component Tests

4.5.2.1 Pumps

SR 3.4.6.7

32.ii

a. Except during cold or refueling, shutdowns the safety injection pumps, residual heat removal pumps, and containment spray pumps shall be started at intervals not to exceed one month. The pumps shall be tested prior to startup if the time since the last test exceeds 1 month.

SR 3.6.6.7

32.11

See also chapter 3.5

b. Acceptable levels of performance for the pumps shall be that the pumps start, operate, and develop the minimum discharge pressure for the flows listed in the table below:

PUMPS	RECYCLE FLOW RATE	DISCHARGE PRESSURE
Containment Spray Pumps	35 gpm	240 psig
Residual Heat Removal Pumps	[200 gpm] 450 gpm	[140 psig] 138 psig
Safety Injection Pumps	[50 gpm] 150 gpm	[1420 psig] 1356 psig

SR 3.6.6.12
SR 3.6.6.16
SR 3.6.6.17

32.x

a. Except during cold or refueling shutdowns the spray additive valves shall be tested at intervals not to exceed ^{24 months} one month. With the pumps shut down and the valves upstream and downstream

32.x

of the spray additive valves closed, each valve will be opened and closed by operator action. This test shall be performed prior to startup if the time since the last test exceeds one month.

See Chapter 3.5

3. The accumulator check valves shall be checked for operability during each refueling shutdown.

4.5.2.3 Air Filtration System

SR 3.6.6.4
SR 3.6.6.14

4.5.2.3.1 At least once every 18 months or after every 720 hours of charcoal filtration system operation since the last test, or following painting, fire or chemical release in any ventilation zone communicating with the system, the post accident charcoal system shall have the following conditions demonstrated.

SR 3.6.6.10

See also Chapter 5.0

- a. The pressure drop across the charcoal adsorber bank is less than 3 inches of water at design flow rate ($\pm 10\%$).
- b. In place Freon testing, under ambient conditions, shall show at least 99% removal.
- c. The iodine removal efficiency of at least one charcoal filter cell shall be measured. The filter cell to be tested shall be selected randomly from those cells with the longest in-bank residence time. The minimum acceptable value for filter efficiency is 90% for removal of methyl iodide when tested at at least 286°F and 95% RH and at 1.5 to 2.0 mg/m³ loading with tagged CH₃I.

4.5.2.3.2 After each replacement of a charcoal drawer or after any structural maintenance on the housing for the post accident charcoal system, the condition of Specification 4.5.2.3.1.b shall be demonstrated for the affected portion of the system.

SR 3.6.6.5
See also Chapter 5.0

4.5.2.3.3 At least every 18 months or following painting, fire, or chemical release in any ventilation zone communicating with the system, the containment recirculation system shall have the following conditions demonstrated.

SR 3.6.6.6

32.xi

- a. The pressure drop across the HEPA filter bank is less than 3 inches of water at design flow rate ($\pm 10\%$).
- b. In place thermally generated DOP testing of the HEPA filters shall show at least 99% removal.

See also Chapter 5.0

4.5.2.3.4 After each complete or partial replacement of the HEPA filter bank or after any structural maintenance on a housing for the containment recirculation system, the condition of Specification 4.5.2.3.3.b shall be demonstrated for the affected portion of the system.

4.5.2.3.5 Except during cold or refueling shutdowns the post accident charcoal filter isolation valves shall be tested at intervals not greater than one month to verify operability and proper orientation and flow shall be maintained through the system for at least 15 minutes. The test shall be performed prior to startup if the time since the last test exceeds 1 month.

SR 3.6.6.3

SR 3.6.6.12

32.ix

See also Chapter 5.0

4.5.2.3.9 Except during cold or refueling shutdowns the automatic initiation of the control room emergency air treatment system shall be tested at intervals not to exceed one month to verify operability and proper orientation and flow shall be maintained through the system for at least 15 minutes. The test shall be performed prior to startup if the time since the last test exceeds one month.

chapter
2.2

Basis:

The Safety Injection System and the Containment Spray System are principal plant safeguards that are normally inoperative during reactor operation.

Complete systems tests cannot be performed when the reactor is operating because a Safety Injection signal causes containment isolation and a Containment Spray System test requires the system to be temporarily disabled. The method of assuring operability of these systems is therefore to combine systems tests to be performed during annual plant shutdowns, with more frequent component tests, which can be performed during reactor operation.

The annual systems tests demonstrate proper automatic operation of the Safety Injection and Containment Spray Systems. With the pumps blocked from starting, a test signal is applied to initiate automatic action

and verification made that the components receive the safety injection in the proper sequence. The test demonstrates the operation of the valves, pump, circuit breakers, and automatic circuitry.⁽¹⁾

During reactor operation, the instrumentation which is depended on to initiate safety injection and containment spray is generally checked daily and the initiating circuits are tested monthly. In addition, the active components (pumps and valves) are to be tested monthly to check the operation of the starting circuits and to verify that the pumps are in satisfactory running order and develop the minimum required pressure to meet accident conditions.⁽²⁾ The minimum discharge pressure values listed in Table 4.5-1 are based on an assumed degradation of the pump head-capacity (characteristic) curve adjusted to water temperature of 60°F as follows:

Containment Spray Pumps	5%*
Residual Heat Removal Pumps	5%*
Safety Injection Pumps	3%*

*Percentage is based on the head at the best efficiency point of flow.

The test interval of one month is based on the judgement that more frequent testing would not significantly increase the reliability (i.e., the probability that the component would operate when required) and would result in increased wear over long periods of time.

Other systems that are also important to the emergency cooling function are the accumulators, the component cooling system, the service water system and the containment fan coolers. The accumulators are a passive safeguard. In accordance with the specifications, the water volume and pressure in the accumulators are checked periodically. The other systems mentioned operate when the reactor is in operation and by these means are continuously monitored for satisfactory performance. The reactor coolant drain tank pumps operate intermittently during reactor operation, and thus are also monitored for satisfactory performance.

The air filtration portion of the containment air recirculation system is a passive safeguard which is isolated from the cooling air flow during normal reactor operation. Hence the charcoal should have a long useful lifetime. The filter frames that house the charcoal are stainless steel and should also last indefinitely. The pressure drop, filter efficiency, and valve operation test frequencies will assure that the system can operate to meet its design function under accident conditions. As the adsorbing charcoal is normally isolated, the test schedule, related to hours of operation as well as elapsed time, will assure that it does not degrade below the required adsorption.

~~efficiency. The test conditions for charcoal sample adsorbing efficiency are those which might be encountered under an accident situation.⁽³⁾~~

See Chapter 3.2

The control room air treatment system is designed to filter the control room atmosphere (recirculation and intake air) during control room isolation conditions. HEPA filters are installed before the charcoal filters to remove particulate matter and prevent clogging of the iodine adsorbers. The charcoal filters reduce the airborne radioiodine in the control room. Bypass leakage must be at a minimum in order for these filters to perform their designed function. If the performances are as specified the calculated doses will be less than those analyzed.⁽⁴⁾

~~Retesting of the post accident charcoal system or the control room emergency air treatment system in the event of painting, fire, or chemical release is required only if the system is operating and is providing filtration for the area in which the painting, fire, or chemical release occurs.~~

~~Testing of the air filtration systems will be, to the extent it can, given the configuration of the systems, in accordance with ANSI N510-1975, "Testing of Nuclear Air-Cleaning Systems."~~

3.1.4 Maximum Coolant Activity Specifications

3.1.4.1 Whenever the reactor is critical or the reactor coolant average temperature is greater than 500°F:

- See Chapter 3.4
- a. The total specific activity of the reactor coolant shall not exceed $84/\bar{E}$ $\mu\text{Ci/gm}$, where \bar{E} is the average beta and gamma energies per disintegration in Mev.
 - b. The I-131 equivalent of the iodine activity in the reactor coolant shall not exceed 0.2 $\mu\text{Ci/gm}$.
 - c. The I-131 equivalent of the iodine activity on the secondary side of a steam generator shall not exceed 0.1 $\mu\text{Ci/gm}$.
- See Chapter 3.4

See Chapter 3.4

3.1.4.2 If the limit of 3.1.4.1.a is exceeded, then be subcritical with reactor coolant average temperature less than 500°F within 8 hours.

See Chapter 3.4

3.1.4.3 a. If the I-131 equivalent activity in the reactor coolant exceeds the limit of 3.1.4.1.b but is less than the allowable limit shown on Figure 3.1.4-1, operation may continue for up to 168 hours.

The reactor may be taken critical or reactor coolant average temperature may be increased above a 500°F with the I-131 equivalent activity greater than the limit of 3.1.4.1.b as long as the provisions of this paragraph are met.

- b. If the I-131 equivalent activity exceeds the limit of 3.1.4.1.b for more than 168 hours during one continuous time interval or exceeds the limit shown on Figure 3.1.4-1, be subcritical with reactor coolant average temperature less than 500°F within 8 hours.
- c. If the I-131 equivalent activity exceeds the limit of 3.1.4.1.b, then perform sampling and analysis as required by Table 4.1-4, item 4a, until the activity is reduced to less than the limit of 3.1.4.1.b.

3.1.4.4 If the limit of 3.1.4.1.c is exceeded, then be at hot shutdown within ⁶ hours and in cold shutdown within the following ³⁰ ~~32~~ hours.

Basis:

The total activity limit for the primary system corresponds to operation with the plant design basis of 1% fuel defects. (1)

Radiation shielding and the radioactive waste disposal systems

See
Chapter 2.4

were designed for operation with 1% defects⁽²⁾. The limit for secondary iodine activity is conservatively established with respect to the limits on primary system iodine activity and primary-to-secondary leakage (Specification 3.1.5.2). If the activity should exceed the specified limits following a power transient the major concern would be whether additional fuel defects had developed bringing the total to above 1% defects. Appropriate action to be taken to bring the activity within specification include one or more of the following: gradual decrease in power to a lower base power, increase in letdown flow rate, and venting of the volume control tank gases to the gas decay tanks.

See
Chapter
3.4

The specified activity limits provide protection to the public against the potential release of reactor coolant activity to the atmosphere, as demonstrated by the analysis of a steam generator tube rupture accident.⁽³⁾

The 500°F temperature in the specification corresponds at saturation to 681 psia, which is below the set point of the secondary side relief valves. Therefore, potential primary to secondary leakage at a temperature below 500°F can be contained by closing the steam line isolation valves.

3.6

- b. One containment spray pump may be inoperable provided the pump is restored to operable status within 3 days.
- c. Any valve or piping in a system, required to function during accident conditions, may be inoperable provided it is restored to operable status within 72 hours.
- d. One post accident charcoal filter unit and/or its associated fan cooler may be inoperable provided the unit is restored to operable status within 7 days.
- e. The spray additive system may be inoperable for a period of no more than 3 days provided that both charcoal filter units are operable.

3.3.3 Component Cooling System

3.3.3.1 The reactor shall not be taken above cold shutdown unless the following conditions are met:

CCO 3.7.7

- a. Both component cooling pumps are operable.
- b. Both component cooling heat exchangers are operable.
- c. All valves, interlocks and piping associated with the above components which are required to function during accident conditions are operable. (i.e., loop hoister)

13. xvi

3.3.3.2 The requirements of 3.3.3.1 may be modified to allow one of the following components to be inoperable at any one time. If the system is not restored to meet the conditions of 3.3.3.1 within the time period

CCO 3.7.7

13. xvii

specified, the reactor shall be in hot shutdown within the next 6 hours. ^{and} If the requirements of 3.3.3.1 are not satisfied within an additional 48 hours, the reactor shall be in the cold shutdown condition within the following 30 hours. If neither component cooling water loop is operable, ^{or the loop header is inoperable} the reactor shall be maintained below a reactor coolant system temperature of 350°F instead of at cold shutdown and corrective action shall be initiated to restore a component cooling water loop to operable status as soon as possible.

LCO 3.7.7

13.xvii

a. One component cooling pump may be out of service provided the pump is restored to operable status within ⁷²~~24~~ hours.

b. One heat exchanger or other passive component may be out of service provided the system may still operate at 100% capacity and repairs are completed within ~~24 hours~~ ^{31 days}

114

13.xvii

3.3.4 Service Water System

3.3.4.1 The reactor shall not be taken above cold shutdown unless the following conditions are met:

LCO 3.7.8

13.xviii

a. At least two service water pumps, one on bus 17 and one on bus 18, ^{Six sets of isolation valves} and one loop header are operable.

b. All valves, interlocks, and piping associated with the operation of two pumps are operable.

3.3.4.2 Any time that the conditions of 3.3.4.1 above cannot be met, the reactor shall be placed in hot shutdown within ^{components shall be restored within 72 hours on the} 6 hours and in cold shutdown within an additional 30 hours.

LCO 3.7.8

12.xix

3.3.5 Control Room Emergency Air Treatment System

3.3.5.1 The ~~RCS temperature shall not be at or above 350°F~~
~~unless the~~ control room emergency air treatment system ^{Shut off}

LCO 3.7.9

13.xx

~~is~~ operable ^{in MODES 1 → 6 and during movement of irradiated fuel assemblies}

LCO 3.7.9

13.xxi

inoperable for a period of 48 hours. If the system is not made operable within those 48 hours, the reactor shall be placed in hot shutdown within the next 6 hours and ~~the RCS temperature less than 350°F~~ ³⁰ in an additional ¹² hours. ← ^{Cold shutdown}

Basis

The normal procedure for starting the reactor is, first to heat the

If one isolation damper is inoperable, replace within 7 days.

If both isolation dampers are inoperable, enter LCO 3.0.3 and immediately stop all fuel movement.

See Chapter 3.6

dundancy for certain ranges of break sizes. (2)

The containment cooling and iodine removal functions are provided by two independent systems: (a) fan-coolers plus post accident charcoal filters and (b) containment spray with sodium hydroxide addition. During normal power operation, only two of the four fan-coolers are required to remove heat lost from equipment and piping within containment. (3) In the event of a Design Basis Accident, any one of the following will serve to reduce airborne iodine activity and maintain doses within the values calculated in the FSAR: (1) two containment spray pumps and sodium hydroxide addition, (2) two fan-coolers and two post accident charcoal filters, or (3) one containment spray pump and sodium hydroxide addition plus one fan-cooler and one post accident charcoal filter. (4) In addition, the containment integrity analysis assumes that one containment spray pump and two fan-coolers operate to reduce containment pressure following a Design Basis Accident. (9) Because of the difficulty of access to make repairs to a fan-cooler and because of the low probability of a Design Basis Accident during that time, an additional seven days operation with an inoperable fan-cooler is permitted. The containment spray pumps and spray additive system are located outside containment and are, therefore, less difficult to repair. Therefore, three days with an inoperable containment spray pump or spray additive system is deemed acceptable.

~~The Component Cooling System is different from the other systems discussed above in that the components are so located in the Auxiliary Building as to be accessible for repair after a loss-of-coolant accident. (5) In addition, if during the post-accident phase the component cooling water supply is lost, core and containment cooling could be maintained until repairs were effected. (6)(7)~~

The facility has four service water pumps. Only one is needed during the injection phase, and two are required during the recirculation phase of a postulated loss-of-coolant accident.⁽⁸⁾ The control room emergency air treatment system is designed to filter the control room atmosphere during periods when the control room is isolated and to maintain radiation levels in the control room at acceptable levels following the Design Basis Accident.⁽⁹⁾ Reactor operation may continue for a limited time while repairs are being made to the air treatment system since it is unlikely that the system would be needed. Technical Specification 3.3.5 applies only to the equipment necessary to filter the control room atmosphere. Equipment necessary to initiate isolation of the control room is covered by another specification.

The limits for the accumulator pressure and volume assure the required amount of water injection during an accident, and are based on values used for the accident analyses. The indicated level of 50% corresponds to 1108 cubic feet of water in the accumulator and the indicated level of 82% corresponds to 1134 cubic feet.

The limitation of no more than one safety injection pump to be operable when overpressure protection is being provided by a RCS vent of ≥ 1.1 sq. in. insures

3.4 TURBINE CYCLEApplicability

Applies to the operating status of turbine cycle.

Objective

To define conditions of the turbine cycle steam-relieving capacity, and to define the Auxiliary Feedwater System and supporting Service Water System operation as necessary to ensure the capability to remove core decay heat. The Standby Auxiliary Feedwater System provides additional assurance of capability to remove core decay heat should the Auxiliary Feedwater System be unavailable.

3.4.1 MAIN STEAM SAFETY VALVES

Specification

Except during testing of the main steam safety valves, with the RCS temperature at or above 350°F, a minimum turbine cycle code approved steam relieving capability of eight (8) main steam safety valves shall be available.

In MODE 3

14.i

LCO 3.7.1

Action

With one or more main steam code safety valves inoperable, restore the inoperable valve(s) to operable status within 4 hours or be in hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the following 6 hours.

3.4.2 AUXILIARY FEEDWATER

3.4.2.1. MOTOR-DRIVEN AUXILIARY FEEDWATER SYSTEM

Specification

With the RCS temperature at or above 350°F, both motor-driven auxiliary feedwater pumps must be operable, each with an operable flow path from the condensate storage tanks to its respective steam generator.

LCO 3.7.5

Action

- a. With one motor-driven auxiliary feedwater pump inoperable and at least one turbine-driven auxiliary feedwater pump flowpath operable, restore the pump to operable status within 7 days or be in at least hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the following 6 hours.

to the opposite SG

- b. With both motor-driven ^(both) auxiliary feedwater pumps inoperable, and ~~at least one~~ turbine-driven auxiliary feedwater pump flowpath operable (see 3.4.2.2), or with a motor-driven and turbine-driven pump ~~(or both flow paths)~~ inoperable, restore a pump to operable status within ~~6~~ ⁽¹²⁾ hours or be in at least hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the following 6 hours.
If all AFW to one or more SGs is inoperable, restore within 4 hours.
- c. With all auxiliary feedwater pumps inoperable (motor-driven, turbine-driven, and standby), immediately initiate corrective action to restore any of these pumps to operable status as soon as possible.

(14.i)

3.4.2.2 TURBINE-DRIVEN AUXILIARY FEEDWATER SYSTEM

Specification

With the RCS temperature at or above 350°F, the turbine-driven auxiliary feedwater pump associated flow paths from the condensate storage tanks to the steam generators, and flow paths of steam from each steam generator to the pump turbine, must be operable. The turbine-driven auxiliary feedwater pump must be shown to be operable prior to exceeding 5% power.

LCO 3.7.5
SR 3.7.5.2

Action

- a. With the turbine-driven auxiliary feedwater pump and/or both associated flow paths inoperable, restore the pump (and at least one flow path) to operable status within 72 hours or be in at least hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the next 6 hours.
- b. With one associated flow path of the turbine-driven auxiliary feedwater pump inoperable, restore to operable status within 7 days or be in at least hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the next 6 hours.

3.4.2.3 STANDBY AUXILIARY FEEDWATER SYSTEM

Specification

With the RCS temperature at or above 350°F, two standby auxiliary feedwater pumps each with an associated flow path from the service water system to ~~its respective~~ steam generator, shall be operable. ^(both)

LCO 3.7.5
(14.iii)

Action

- a. With one standby auxiliary feedwater pump inoperable restore the pump to operable status within 14 days or be in hot shutdown within the next 6 hours and at an RCS temperature less than 350°F within the following 6 hours.

- b. With both standby auxiliary feedwater pumps inoperable restore at least one standby auxiliary feedwater pump to operable status within 7 days or be in at least hot shutdown within 6 hours and at an RCS temperature less than 350°F in the following 6 hours.

3.4.3 SOURCES OF AUXILIARY FEEDWATER

Specification

- a. With the RCS temperature at or above 350°F, the following sources of auxiliary feedwater shall be operable:

LCO 3.7.4 (1) One or more condensate storage tanks with a minimum of 22,500 gallons of water, and

LCO 3.7.5 (14.1v) (2) Service water as the primary supply to the standby auxiliary feedwater pumps.

Action

- a. With the condensate storage tanks inoperable, within 4 hours either:

1) restore the condensate storage tanks to operable status, or be in at least hot shutdown within the following 6 hours and at an RCS temperature less than 350°F within the following 6 hours, OR.

LCO 3.7.4

(14.v)

2) demonstrate the operability of the service water system as a water supply to the motor-driven and turbine-driven auxiliary feedwater pumps and restore the condensate storage tanks to operable status within 7 days, or be in at least hot shutdown within the following 6 hours and at an RCS temperature less than 350°F within the following 6 hours.

- b. With the service water system to one or both standby auxiliary feedwater pump(s) inoperable, declare the standby auxiliary feedwater pump(s) inoperable and comply with Specification 3.4.2.3.

LCO 3.7.5

(14.1v)

Basis

A reactor shutdown from power requires removal of core decay heat. Immediate decay heat removal requirements are normally satisfied by the steam bypass to the condenser. Therefore, core decay heat can be continuously dissipated via the steam bypass to the condenser as feedwater in the steam generator is converted to steam by heat absorption. Normally, the capability to return feedwater flow to the steam generators is provided by operation of the turbine cycle feedwater system.

In the event of a reactor and turbine trip, together with a loss of offsite power, immediate decay heat removal is effected via the main steam safety valves. The eight main steam safety valves have a total combined rated capability of 6,580,000 lbs/hr. This capability exceeds the total full-power steam flow of 6,577,279 lbs/hr.

Following reactor/turbine trip, the motor-driven auxiliary feedwater system is automatically initiated on low-low level in one steam generator, a Safety Injection signal, or a trip of both main feedwater pumps. The turbine-driven auxiliary feedwater pump is initiated on low-low steam generator level in both steam generators, or a loss of power to electrical buses 11A and 11B. The motor-driven auxiliary feedwater system has two 100% capacity pumps, each normally serving one steam generator.

Their sources of water include the normally-aligned but non-safety-related and non Seismic Category I condensate storage tanks, and the safety-related service water system. The turbine-driven auxiliary feedwater system consists of one 200% capacity pump, two steam supply flow paths (one from each steam generator), a normal source of water from the non-safety-related condensate storage tanks, and a backup source of water from the safety-related service water system.⁽¹⁾

The Ginna Station accident analyses⁽²⁾ assume 200 gpm is delivered to an operable steam generator, in order to remove the required decay heat. The combination of motor-driven and turbine-driven auxiliary feedwater pumps assures operability of the system to meet these requirements, even assuming a single failure.

In the event of a high energy line break outside containment,⁽³⁾ the operability of the motor-driven and turbine-driven auxiliary feedwater systems cannot be ensured, since the systems are not qualified for the ensuing harsh environment. The standby auxiliary feedwater system, which consists of two redundant pumps, a discharge flow path to each steam generator and suction from both loops of the safety-related service water system, performs this function. Operator action from the control room is required to effect operation of the SAFW system. The worst-case analysis, a feedwater line break,⁽⁴⁾ has been performed, and the consequences were found to be acceptable.

The minimum amount of water in the condensate storage tanks is the amount needed to remove decay heat for 2 hours after reactor trip from full power.⁽⁵⁾ An unlimited source for auxiliary feedwater is available using the safety-related service water system.

3.11 Fuel Handling in the Auxiliary Building

Applicability

Applies to limitations while moving irradiated fuel in the operating floor area of the auxiliary building.

Objective

To limit doses in the event an irradiated fuel assembly is damaged significantly.

Specification

3.11.1 During handling of fuel assemblies in the auxiliary building when either the fuel being handled or the fuel stored in the spent fuel storage pool has decayed less than 60 days since irradiation, the following conditions shall be satisfied:

LCO 2.7.10

21.1

- a. One auxiliary building main exhaust fan shall be operating.
- b. The auxiliary building exhaust fan 1C, which takes suction from the spent fuel storage pool area, shall be operating.
- c. ~~All doors, windows, and other direct openings between the operating floor area and the outside shall be closed except that the personnel door may be opened for access as required.~~
- d. Roughing filters shall be installed at the inlet to the adsorbers.

Shall have a negative pressure with respect to

3.11.1

Amendment No. 19

LCO 3.7.10

21.i

e. Charcoal adsorbers shall be installed in the ventilation system exhaust from the spent fuel storage pool area and shall be operable.

21.ii

3.11.2 Radiation levels in the spent fuel storage area shall be monitored continuously.

21.iii

3.11.3 A load in excess of one fuel assembly and its handling tool shall never be stationed or permitted to pass over storage racks containing spent fuel.

21.iv

3.11.4 The spent fuel pool temperature shall be limited to 150°F.

21.v

3.11.5 The restriction of 3.11.3 above shall not apply to the movement of canisters containing consolidated fuel rods if the spent fuel rack beneath the transported canister contain only spent fuel that has decayed at least 60 days since reactor shutdown.

Basis:

Charcoal adsorbers will reduce significantly the consequences of a refueling accident which considers the clad failure of a single irradiated fuel assembly. Therefore, charcoal adsorbers should be employed whenever recently irradiated fuel is being handled. This requires that the ventilation system should be operating and drawing air through the adsorbers. The only exception to the requirement occurs when the fuel being handled, or any fuel in the storage pool, has decayed at least 60 days since irradiation. The consequences of a fuel handling accident in this case without operation of the charcoal adsorbers is significantly less than the guidelines of 10CFR100.³

Amendment No. 6, 10, 12, 19

Amendment No.

The desired air flow path, when handling irradiated fuel, is from the outside of the building into the operating floor area, toward the spent fuel storage pool, into the area exhaust ducts, through the adsorbers, and out through the ventilation system exhaust to the facility vent. Operation of a main auxiliary building exhaust fan assures that air discharged into the main ventilation system exhaust duct will go through a HEPA and be discharged to the facility vent. Operation of the exhaust fan for the spent fuel storage pool area causes air movement on the operating floor to be toward the pool. Proper operation of the fans and setting of dampers would result in a negative pressure on the operating floor which will cause air leakage to be into the building. Thus, the overall air flow is from the location of low activity (outside the building) to the area of highest activity (spent fuel storage pit). The exhaust air flow would be through a roughing filter and charcoal before being discharged from the facility. The roughing filter protects the adsorber from becoming fouled with dirt; the adsorber removes iodine, the isotope of highest radiological significance, resulting from a fuel handling accident. The effectiveness of charcoal for removing iodine is assured by having a high throughput and a high removal efficiency. The throughput is attained by operation of the exhaust fans. The high removal efficiency is attained by minimizing the amount of iodine that bypasses the charcoal and having charcoal with a high potential for removing the iodine that does pass through the charcoal.

The spent fuel pool temperature is limited to 150°F because if the spent fuel pool cooling system is not at that temperature, sufficient time (approximately 7 hours) is available to provide backup cooling, assuming the maximum anticipated heat load (full core discharge & previously stored fuel), until a temperature of 180°F is reached, the temperature at which the structural integrity of the pool was analyzed and found acceptable.

The requirement of 3.11.5 insures that should a handling accident occur during the movement of a consolidated fuel cannister (as described in 5.4.) the dose at the exclusion area boundary would satisfy the requirements of 10CFR100.

 SR 3.7.9.2
 SR 3.7.9.1

32.xii

See Chapters 3.5 and 3.6

Basis:

The Safety Injection System and the Containment Spray System are principal plant safeguards that are normally inoperative during reactor operation.

Complete systems tests cannot be performed when the reactor is operating because a Safety Injection signal causes containment isolation and a Containment Spray System test requires the system to be temporarily disabled. The method of assuring operability of these systems is therefore to combine systems tests to be performed during annual plant shutdowns, with more frequent component tests, which can be performed during reactor operation.

The annual systems tests demonstrate proper automatic operation of the Safety Injection and Containment Spray Systems. With the pumps blocked from starting a test signal is applied to initiate automatic action

See Chapter 3.4

efficiency. The test conditions for charcoal sample adsorbing efficiency are those which might be encountered under an accident situation.⁽³⁾

The control room air treatment system is designed to filter the control room atmosphere (recirculation and intake air) during control room isolation conditions. HEPA filters are installed before the charcoal filters to remove particulate matter and prevent clogging of the iodine adsorbers. The charcoal filters reduce the airborne radiiodine in the control room. Bypass leakage must be at a minimum in order for these filters to perform their designed function. If the performances are as specified the calculated doses will be less than those analyzed.⁽⁴⁾

Retesting of the post accident charcoal system or the control room emergency air treatment system in the event of painting, fire, or chemical release is required only if the system is operating and is providing filtration for the area in which the painting, fire, or chemical release occurs.

Testing of the air filtration systems will be, to the extent it can, given the configuration of the systems, in accordance with ANSI N510-1975, "Testing of Nuclear Air-Cleaning Systems."

4.7 Main Steam Isolation Valves

Applicability

Applies to periodic testing of the main steam isolation valves.

Objective

To verify the ability of the main steam isolation valves to close upon signal.

MODES 1, 2, and 3

Specification

SR 3.7.2.2
SR 3.7.2.1

34.i

The main steam isolation valves shall be tested at each refueling interval. Closure time of five seconds or less shall be verified. The valves are tested under no flow and at no

load conditions. ← The MSIVs shall be tested on an actual or simulated close signal once every 24 months

Basis

The main steam isolation valves serve to limit an excessive reactor coolant system cooldown rate and resultant reactivity insertion following a main steam break incident. Their ability to close upon signal should be verified at each scheduled refueling shutdown. A closure time of five seconds was selected as being consistent with expected response time for instrumentation as detailed in the steam line break incident analysis.

35.vi - SR 3.7.5.1

4.8 AUXILIARY FEEDWATER SYSTEMS

Applicability

Applies to periodic testing requirements of the turbine-driven, motor-driven auxiliary feedwater pumps, and of the standby auxiliary feedwater pumps.

Objective

To verify the operability of the auxiliary feedwater system and the standby auxiliary feedwater system and their ability to respond properly when required.

Specification

4.8.1 Except when below 350°F each motor-driven auxiliary feedwater pump, unless it is declared inoperable without testing, will be started at intervals not to exceed ~~one month~~ ^{three} and a flowrate of ~~200 gpm~~ established.

4.8.2 Except when below 350°F the steam turbine-driven auxiliary feedwater pump, unless it is declared inoperable without testing, will be started at intervals not to exceed ~~one month~~ ^{three} and a flowrate of ~~400 gpm~~ established. If one discharge flow path is inoperable in accordance with Specification 3.4.2.2, a flow of 200 gpm must be established. Once the inoperable discharge flow path is returned to operable status, a flow of 400 gpm must be established within 72 hours thereafter.

4.8.3 Except when below 350°F the auxiliary feedwater pumps suction, discharge, ~~and crossover motor operated valves~~ shall be exercised at intervals ~~not to exceed one month~~.

4.8.4 Except when below 350°F each standby auxiliary feedwater pump, unless it is declared inoperable without testing, will be started at intervals not to exceed ~~one month~~ ^{Specified in the Inservice Testing Program} and a flowrate of ~~200 gpm~~ established.

4.8.5 Except when below 350°F the ~~suction, discharge, and crossover motor operated valves~~ for the standby auxiliary feedwater pumps shall be exercised at intervals ~~not to exceed one month~~.

4.8.6 These tests shall be considered satisfactory if control board indication and subsequent visual observation of the equipment demonstrate that all components have operated properly. These tests shall be performed prior to exceeding 5% power during startup ~~if the time since the last test exceeds one month~~.

4.8.7 At least once per ~~18~~ ²⁴ months, control of the standby auxiliary feed system pumps and valves from the control room will be demonstrated.

Specified in the IST Program

4.8.8 At least once per ⁽²⁴⁾ months during shutdown:

See 3.7.5.5

a. Verify that each automatic valve in the flow path for each auxiliary feedwater pump actuates to its correct position upon receipt of each auxiliary feedwater actuation test signal.

See 3.7.5.6

b. Verify that each auxiliary feedwater pump starts as designed automatically upon receipt of each auxiliary feedwater actuation test signal.

See Chapter 3.2

4.8.9 Each instrumentation channel shall be demonstrated operable by the performance of the Channel Check, Channel Calibration, and Channel Functional Test operations for the modes and at the frequencies shown in Table 4.1-1.

4.8.10 The response time of each pump and valve required for the operation of each "train" of auxiliary feedwater shall be demonstrated to be within the limit of 10 minutes at least once per 18 months.

Basis

The monthly testing of the auxiliary feedwater pumps by supplying feedwater to the steam generators will verify their ability to meet minimum required flowrates. The capacity of any one of the three auxiliary feedwater pumps is sufficient to meet decay heat removal requirements.⁽¹⁾ Proper functioning of the steam turbine admission valve and the feedwater pumps start will demonstrate the integrity of the steam driven pump.⁽²⁾

Monthly testing of the standby auxiliary feedwater pumps by supplying water from a condensate supply tank to the steam generators will verify their ability to meet minimum required flowrates.

The standby auxiliary feedwater pumps would be used only if all three auxiliary feedwater pumps were unavailable.⁽³⁾ One of the two standby pumps would be sufficient to meet decay heat removal requirements. Proper functioning of the suction valves from the service water system, the discharge valves, and the crossover valves will demonstrate their operability. The operability of the standby auxiliary feedwater pump flow paths between the pumps and the steam generators is demonstrated using water from the test tank. Testing of the auxiliary feedwater pumps using their primary source of water supply will verify the operability of the auxiliary feedwater flow path.

Verification of correct operation will be made both from instrumentation within the main control room and by direct visual observation of the pumps.

4.11 Refueling

Applicability

Applies to refueling and to fuel handling in the spent fuel pool.

Specification

4.11.1 Spent Fuel Pit Charcoal Adsorber System

4.11.1.1 Within 60 days prior to any operation of the spent fuel pool charcoal adsorber system as required by Section 3.11, the following conditions shall be demonstrated. After the conditions have been demonstrated, the occurrence of painting, fire, or chemical release in any ventilation zone communicating with the spent fuel pool charcoal adsorber system shall require that the following conditions be redemonstrated, before fuel handling may continue, if operation of the spent fuel pool charcoal adsorber system is required per section 3.11

- a. The total air flow rate from the charcoal adsorbers shall be at least 75% of that measured with a complete set of new absorbers.
- b. In-place Freon testing, under ambient conditions, shall show at least 99% removal.
- c. The results of laboratory analysis on a carbon sample shall show 90% or greater radioactive methyl iodide removal when tested at least 150°F and 95% RH and at 1.5 to 2.0 mg/m³ loading with tagged CH₃I.

See Chapter 5.0

SR 3.7.10.2

3.7.iii SR 3.7.10.1

SR 3.7.10.3

3.7.iii

- d. Flow shall be maintained through the system using either the filter or ~~bypass~~ flow path for at least 15 minutes each month.

4.11.1.2 After each replacement of a charcoal filter drawer or after any structural maintenance on the charcoal housing for the spent fuel pit charcoal adsorber system, the condition of Specification 4.11.1.1.b shall be demonstrated for the affected portion of the system.

4.11.2 Residual Heat Removal and Coolant Circulation

4.11.2.1 When the reactor is in the refueling mode and fuel is in the reactor, at least one residual heat removal loop shall be verified to be in operation and circulating reactor coolant at least once per 4 hours.

4.11.2.2 When the water level above the top of reactor vessel flange is less than 23 feet, both RHR pumps shall be verified to be operable by performing the surveillance specified in the Inservice Pump and Valve Test Program prepared pursuant to 10 CFR 50.55a.

4.11.3 Water Level - Reactor Vessel

4.11.3.1 The water level in the reactor cavity shall be determined to be at least its minimum required depth within 2 hours prior to the start of and at least once per 24 hours thereafter during movement of fuel assemblies or control rods in containment.

Basis

The measurement of the air flow assures that air is being withdrawn from the spent fuel pit area and passed through the adsorbers. The flow is measured prior to employing the adsorbers to establish that

See Chapter 5.0

See Chapter 3.9

~~there has been no gross change in performance since the system was last used.~~ The Freon test provides a measure of the amount of leakage from around the charcoal adsorbent.

The ability of charcoal to adsorb iodine can deteriorate as the charcoal ages and weathers. Testing the capacity of the charcoal to adsorb iodine assures that an acceptable removal efficiency under operating conditions would be obtained. The difference between the test requirement of a removal efficiency of 90% for methyl iodine and the percentage assumed in the evaluation of the fuel handling accident provides adequate safety margin for degradation of the filter after the tests.

Retesting of the spent fuel pit charcoal adsorber system in the event of painting, fire, or chemical release is required only if the system is operating and is providing filtration for the area in which the painting, fire, or chemical release occurs.

Testing of the air filtration systems will be tested, to the extent it can be given the configuration of the systems, in accordance with ANSI NS10-1975, "Testing of Nuclear Air-Cleaning Systems".

The operability requirements for residual heat removal loops will ensure adequate heat removal while in the refueling mode. The requirement for 23 feet of water above the reactor vessel flange while handling fuel and fuel components in containment is consistent with the assumptions of the fuel handling accident analysis.

5.4 Fuel Storage Specification

5.4.1 The new and spent fuel pit structures are designed to withstand the anticipated earthquake loadings as Class I structures. The spent fuel pit has a stainless steel liner to ensure against loss of water.

5.4.2 The new and spent fuel storage racks are designed so that it is impossible to insert fuel assemblies in other than the prescribed locations. The spent fuel storage racks are divided into two regions as depicted on Figure 5.4-1. The

47.i

fuel is stored vertically in an array with sufficient center to center distance between assemblies to assure $K_{eff} \leq$

4.3.1.1.a
4.3.1.1.b

0.95 for (1) unirradiated fuel assemblies delivered prior to January 1, 1984 (Region 1-15) ~~containing no~~ ^{with initial enrichment} ~~more than 39.0 gms U-235 per axial cm,~~ ~~no greater than 3.50 weight percent U-235~~

47.ii

and (2) unirradiated fuel assemblies delivered after January 1, 1984 ~~containing~~ ^{with initial enrichment} ~~no more than 41.9 gms U-235 per axial cm,~~ ~~enrichment no greater than 4.05 weight percent U-235~~

Both cases assume unborated water used in the pool.

5.4.3 In Region 2 of the spent fuel storage racks, fuel is stored in a close packed array utilizing fixed neutron poisons in each of the stored locations. For discharged fuel assemblies to be stored in Region 2, (1) 60 days

47.iii

must have elapsed since the core reached hot shutdown prior to discharge and (2) the combination of assembly

30.17

average burnup and initial U-235 enrichment must be such that the point identified by these two parameters on Figure 5.4-2 is above the line applicable to the particular fuel assembly design, therefore assuring that $K_{eff} \leq 0.95$.

5.4.4

Cannisters containing consolidated fuel rods may be stored in either Region 1 or 2 provided that:

4.3.1.1.c

a. the average burnup and initial enrichment of the fuel assemblies from which the rods were removed satisfy the requirements of 5.4.2 and 5.4.3 above, and

47.iv

b. the average decay heat of the fuel assembly from which the rods were removed is less than 2150 BTU/hr

5.4.5

4.3.1.1.c

The requirements of 5.4.4a may be excepted for those consolidated fuel assemblies of Region RGAF2.

5.4.6

3.9.1

47.L

The spent fuel storage pit is filled with borated water at a concentration to match that used in the reactor cavity and refueling canal during refueling operations whenever there is fuel in the pit.

Basis

The center to center spacing of Region 1 insures that $K_{eff} \leq 0.95$ for the enrichment limitations specified in 5.4.2¹, and for a postulated missile impact the resulting dose at the EAB would be within the guidelines of 10CFR100².

In Region 2, $K_{eff} \leq 0.95$ is insured by the addition of fixed neutron poison (boraflex) in each of the Region 2 storage locations, and a minimum burnup requirement as a function of initial enrichment for each fuel assembly design. The 60 day cooling time requirement insures that for a postulated missile impact the resulting dose at the EAB would be within the guidelines of 10CFR100.

The two curves of Figure 5.4-2 divide the fuel assembly designs into two groups. The first group is all fuel delivered prior to January 1, 1984. This incorporates all Exxon and Westinghouse HIPAR designs used at Ginna.⁴ The second curve is for the Westinghouse Optimized Fuel Assembly design delivered to Ginna beginning in February 1984.³

The assembly average burnup is calculated using INCORE generated power sharing data and the actual plant operating history. The calculated assembly average burnup should be reduced by 10% to account for uncertainties. An uncertainty of 4% is associated with the measurement of power sharing. The additional 6% provides additional margin to bound the burnup uncertainty associated with the time between measurements and updates of core burnup. The curves of Figure 5.4-2 incorporate the uncertainties of the calculation of assembly reactivity.³

The calculations of fuel assembly burnup for comparison to the curves of Figure 5.4-2 to determine the acceptability for storage in Region 2 shall be independently checked. The record of these calculations shall be kept for as long as fuel assemblies remain in the pool.

The fuel storage cannisters are designed so that, normally, they can contain the equivalent number of fuel rods from two fuel assemblies in a close packed array, and can be stored in either Region 1 or Region 2 rack locations. The close packed array will insure the K_{∞} of the rack configuration containing any number of cannisters will be less than that for stored fuel assemblies at the same burnup and initial enrichment. The exception

of paragraph 5.4.5 is possible because the consolidated configuration is substantially less reactive than that of a fuel assembly. The maximum decay heat requirement will insure that local and film boiling will not occur between the close packed fuel rods if the pool temperature is maintained at or below 150°F. The decay heat of the assembly will be determined using ANS 5.1, ASB 9-2 or other acceptable substitute standards.

With the addition of the storage of consolidated fuel cannisters, the theoretical storage capacity of the pool would be increased to 2032 fuel assemblies (2x1016). However, due to limitation on the heat removal capability of the spent fuel pool cooling system, the storage capacity is limited to 1016 fuel assemblies.⁵

3.0

LIMITING CONDITION FOR OPERATION

Chapter
3.0

APPLICABILITY

3.0.1

In the event a Limiting Condition for Operation and/or associated action requirements cannot be satisfied because of circumstances in excess of those addressed in the specification, within 1 hour action shall be initiated to place the unit in at least hot shutdown within the next 6 hours (i.e., a total of seven hours), and in at least cold shutdown within the following 30 hours (i.e., a total of 37 hours) unless corrective measures are completed that permit operation under the permissible action statements for the specified time interval as measured from initial discovery or until the reactor is placed in a mode in which the specification is not applicable. If the action statement corresponding to the Limiting Condition for Operation that was exceeded contains time limits to hot and cold shutdown that are less than those specified above, these more limiting time limits shall be applied. Exceptions to these requirements shall be stated in the individual specifications.

3.0.2

When a system, subsystem, train, component or device is determined to be inoperable solely because its emergency power source is inoperable, or solely because its preferred power source is inoperable, it may be considered operable for the purpose of satisfying the requirements of its applicable Limiting Condition for Operation, provided:

See 3.8.1

S.vi

(1) its corresponding preferred or emergency power source is operable; and (2) all of its redundant system(s), subsystems(s), train(s), component(s) and device(s) are operable, or likewise satisfy the requirements of this specification. Unless both conditions (1) and (2) are satisfied within ~~1 hour~~ ^{12 hours}, the unit shall be placed in at least hot shutdown within the next 6 hours, and in at least cold shutdown within the following 30 hours. This specification is not applicable in cold shutdown or refueling modes.

CCO 3.8.1
 S.vi

See Chapter 3.6

Basis

Specification 3.0.1 delineates the ACTION to be taken for circumstances not directly provided for in the ACTION statements and whose occurrence would violate the intent of the specification. For example, Specification 3.3.2 requires two Containment Spray Pumps to be operable and provides explicit action requirements if one spray pump is inoperable. Under the terms of Specification 3.0.1, if both of the required Containment Spray Pumps are inoperable, the unit is required to be in at least hot shutdown within the following 6 hours and in at least cold shutdown in the next 30 hours. These time limits apply because the time limits for one spray pump inoperable (6 hours to hot shutdown, wait 48 hours then 30 hours to cold shutdown) are less limiting. As a further example, Specification 3.3.1 requires each Reactor Coolant System accumulator to be operable and provides explicit action requirements if one accumulator is inoperable. Under the terms of Specification 3.0.1, if more than one accumulator is inoperable, within 1 hour action shall be initiated to place the unit in at least hot shutdown within 6 hours and cold shutdown within an additional 30 hours. The time limit of 6 hours

See Chapter
3.0

to hot shutdown and 30 hours to cold shutdown do not apply because the time limits for 1 accumulator inoperable are more limiting. It is assumed that the unit is brought to the required mode within the required times by promptly initiating and carrying out the appropriate action statement.

Specification 3.0.2 delineates what additional conditions must be satisfied to permit operation to continue, consistent with the action statements for power sources, when a preferred or emergency power source is not operable. It allows operation to be governed by the time limits of the action statement associated with the Limiting Condition for Operation for the preferred or emergency power source, not the individual action statements for each system, subsystem, train, component or device that is determined to be inoperable solely because of the inoperability of its preferred or emergency power source.

For example, Specification 3.7.2.1.a requires in part that two emergency diesel generators be operable. The action statement provides for a maximum out-of-service time when one emergency diesel generator is not operable. If the definition of operable were applied without consideration of Specification 3.0.2, all systems, subsystems, trains, components and devices supplied by the inoperable emergency power source would also be inoperable. This would dictate invoking the applicable action statements for each of the applicable Limiting Conditions for Operation. However, the provisions of Specification 3.0.2 permit the time limits for continued operation to be consistent with the action statement for the inoperable emergency diesel generator instead, provided the other specified conditions are satisfied. In this case, this would mean that the corresponding

preferred power source must be operable, and all redundant systems, subsystems, trains, components, and devices must be operable, or otherwise satisfy Specification 3.0.2 (i.e., be capable of performing their design function and have at least one preferred or one emergency power source operable). If they are not satisfied, shutdown is required in accordance with this specification.

3.7 AUXILIARY ELECTRICAL SYSTEMS

Applicability

Applies to the availability of electrical power for the operation of plant auxiliaries.

Objective

To define those conditions of electrical power availability necessary to provide for the continuing availability of engineered safeguards.

3.7.1 Specification

3.7.1.1 When in cold shutdown or refueling, with fuel in the reactor vessel, the following conditions are to be met:

- LCO 3.8.2 a. One independent offsite power source operable, or backfeed through unit auxiliary transformer 11; and
- LCO 3.8.10 b. One train of 480-volt buses (14 and 18, or 16 and 17) operable; and
- LCO 3.8.2 c. One diesel generator operable with onsite supply of 5,000 gallons of fuel available and either buses 14 and 18, or 16 and 17, capable of being supplied from that diesel generator.
- LCO 3.8.5 d. One battery and one dc system, and at least 150 amps of battery charger capacity to the battery must be operable.
- LCO 3.8.8 e. Either 120 volt A.C. Instrument Bus 1A or 1C energized from its associated inverter.

3.7.1.2 Actions To Be Taken If Conditions of 3.7.1.1. Are Not Met:

With less than the above minimum required power source operable, immediately suspend all operations involving positive reactivity changes, core alterations, movement of

- RA A.3 3. Re-energize the bus from its associated inverter within 72 hours, OTHERWISE
- Cond C 4. Reduce to a mode equal to or below hot shutdown within the next 6 hours and be in cold shutdown within the following 30 hours.

- LCO 3.8.7 g. With Instrument Bus 1B not energized from its associated constant voltage transformer (CVT) from MCC 1C:
- RA E.1 1. Re-energize the bus within 2 hours (maintenance supply), AND
- RA E.2 2. Re-energize the bus from its associated CVT from MCC 1C within 7 days, OTHERWISE
- Cond C 3. Reduce to a mode equal to or below hot shutdown within the next 6 hours and be in cold shutdown within the following 30 hours.

Basis for 3.7.1 and 3.7.2:

The electrical systems equipment is arranged so that no single failure can inactivate enough safeguards equipment to jeopardize the plant safety. The 480-volt safeguards equipment is arranged on 4 safeguards buses. The 4160-volt equipment (none of which is safety-related), is supplied from 4 buses.

Two separate offsite sources supply station service power to the plant.

The plant auxiliary equipment is arranged electrically so that redundant safeguards loads receive power from separate sources. In the event that 1 offsite source is not available, the remaining offsite source is capable of supplying both trains of safeguards loads. Safeguards loads such as safety injection pumps, containment fans, residual heat removal pumps, and motor control centers 1C and 1D are divided between the 480-volt buses No. 14 and 16. Redundant loads including service water pumps are supplied by buses No. 18 and 17. Together these buses form the Train A and B redundant Class 1E sources.

AC power for safeguards equipment originates from both offsite and onsite sources. The operability of these power sources and associated distribution systems ensures that sufficient power will be available to supply the safety-related equipment required for (1) the

safe shutdown of the plant, and (2) the mitigation and control of accident conditions within the plant.

When the RCS is above cold shutdown, both emergency diesel generators are required to be operable. The two diesel generators have sufficient capacity to start and run all the engineered safeguards equipment at design loads. The safeguards equipment operated from one diesel generator can adequately cool the core and maintain the containment pressure within the design value for any loss of coolant incident. The minimum diesel fuel oil inventory is maintained to assure that both diesels can operate at their design ratings for 24 hours. This assures that both diesels can carry the design loads of required engineered safeguards equipment for any loss of coolant accident conditions for at least 40 hours, or for one engineered safety feature train for 80 hours.⁽¹⁾ Commercial oil supplies and trucking facilities exist to assure deliveries within 8 hours.

The offsite power source consists of separate dedicated 34.5 kv-4160 volt station service transformers served by dedicated 34.5 kv lines (12A transformer with dedicated circuit 751, or 12B transformer with dedicated circuit 767) in operable status. Either offsite source of power can supply all auxiliary loads and transfer can be accomplished within the time constraints of GDC 17. Thus, GDC 17 is explicitly met.

With fuel in the reactor vessel a minimum of one offsite source, one onsite source of AC power and one DC power train are required. The offsite power source may be provided by one of three configurations:

1. Transformer 12A served by a dedicated 34.5 kv line (circuit 751),
or
2. Transformer 12B served by a dedicated 34.5 kv line (circuit 767),
or
3. Backfeed through unit auxiliary transformer 11.

The offsite power source is the preferred source of AC power. Operability of an offsite source requires that one station service transformer served by a dedicated 34.5 kv line is operating and providing power to the unit. The emergency diesel generator provides power upon loss of the offsite source. One emergency diesel generator with 5,000 gallons of fuel can provide power to a minimum level of engineered safeguards equipment for 40 hours (the required safeguards loads at cold shutdown/refueling are significantly less than during power operation). One operable diesel fuel oil transfer pump is required to supply fuel from one of the two fuel storage tanks to the day tank of the operable diesel generator. With less than one offsite AC power source, and one onsite AC power source, one DC power train, and one battery backed instrument bus available, no operations involving positive reactivity changes, core alterations, and movement of irradiated fuel shall occur.

Battery chargers with at least 150 amps capacity shall be in service for each battery so that the batteries will always be at full charge. This ensures that adequate dc power will be available.

The plant can be safely shutdown without the use of offsite power since all vital loads (safety systems, instruments, etc.) can be supplied from the emergency diesel generators and the station batteries. Instrument Buses 1A, 1B, and 1C provide power to vital plant instrumentation. All three buses are backed up by safety related emergency supplies; bus 1A from battery 1A, bus 1C from battery 1B, and bus 1B from diesel generator 1A.

The two diesel generators, each capable of supplying safeguards loads, and the station auxiliary transformers provide four separate sources of power immediately available for operation of these loads. Thus, the power supply meets the single failure criteria.

4.6 Preferred and Emergency Power Systems Periodic Tests

Applicability

Applies to periodic testing and surveillance requirements of the preferred and emergency power systems.

Objective

To verify that the preferred and emergency power systems will respond promptly and properly when required.

Specification

The following tests and surveillance shall be performed as stated:

4.6.1 Diesel Generators

At least one diesel generator shall be demonstrated operable:

a. During cold or refueling shutdown at least once per 31 days by:

SR 3.8.2.1

33.i

- 1. Verifying the diesel starts from normal standby conditions, and attains rated voltage and frequency.

Each diesel generator shall be demonstrated operable:

b. Except during cold or refueling shutdown at least once per 31 days by:

SR 3.8.1.1

- 1. Verifying the fuel level in the day tank.

SR 3.8.3.1

- 2. Verifying a minimum oil storage of 5,000 gallons for each generator that is onsite.

SR 3.8.1.5

- 3. Verifying the fuel transfer pump can be started and transfer fuel from the storage system to the day tank.

SR 3.8.1.2

- 4. Verifying the diesel starts from normal standby conditions, and attains rated voltage and frequency.

SR 3.8.1.3

33.xi

33.xii

- 5. Verifying the generator is synchronized, loaded to at least 1950 kw but less than the 2 hour rating of 2250 kw and operates for at least 60 minutes but less than 120 minutes. (Must be performed after test on e.3)

LCO 3.8.1

33.ii

- 6. Verifying the diesel generator is aligned to provide standby power to the associated emergency buses.

SR 3.8.4

33.iii

c. The tests in Specification 4.6.1b will be performed prior to exceeding cold shutdown if the time since the last test exceeds 31 days.

SR 3.8.3.2

33.iv

See Chapter 5.0

d. At least once per 92 days by verifying that a sample of diesel fuel from the fuel storage tank is within the acceptable limits specified in Table 1 of ASTM D975-78 when checked for viscosity, water and sediment.

33.v

e. At least once per ~~6~~⁽²⁴⁾ months during shutdown by:
1. Inspecting the diesel in accordance with the manufacturer's recommendations for this class of standby service.

SR 3.8.1.7

33.xii

2. Verifying the generator capability to reject a load of 295 KW without tripping.

SR 3.8.1.9

33.xii

3. Simulating a loss of offsite power in conjunction with a safety injection test signal and:

SR 3.8.1.9.a

SR 3.8.1.9.b

(a) Verifying de-energization of the emergency buses and load shedding from the emergency buses.

SR 3.8.1.9.c

(b) Verifying the diesel ^{permanently and} starts from normal standby condition on the auto-start signal, energizes the automatically connected emergency loads with the following maximum

33.vi

breaker closure times after the initial starting signal for Trains A and B not being exceeded

	A	B
Diesel plus Safety Injection	20 sec	22 sec
Pump plus RHR Pump		
All Breakers	40 sec	42 sec

SR 3.8.1.8

(c) Verifying that all diesel generator trips, except engine overspeed, low lube oil pressure, and overcrank, are automatically bypassed upon a safety injection actuation signal.

SR 3.8.1.2.
NOTE 1

4. This test may also serve to concurrently meet the requirements of 4.6.1.a and b.

4.6.2 Station Batteries

SR 3.8.6.4
SR 3.8.6.2
SR 3.8.6.1
SR 3.8.6.3

33.vii

SR 3.8.6.1
SR 3.8.6.6
SR 3.8.6.5

33.vii

- a. Every month the voltage of each cell (to the nearest 0.01 volt), the specific gravity and temperature of a pilot cell in each battery shall be measured and recorded. → 92 days
- b. Every 3 months the specific gravity of each cell, the temperature reading of every fifth cell, the height of electrolyte, and the amount of water added shall be measured and recorded.

33.ix

SR 3.8.4.1
SR 3.8.5.1

Verify battery terminal voltage
is $\geq 129V$ on float charge every
7 days.

33. x c. At each time data is recorded, new data shall be compared with old to detect signs of deterioration.

24 months d. Each battery shall be subjected to a load test within a twelve-month period from the last load test; however, to permit the load test to coincide with a scheduled refueling, the period may extend for an additional three months. The battery voltage as a function of

SR 3.8.4.2 time shall be monitored to establish that the battery performs as expected during heavy discharge and that all electrical connections are tight.

SR 3.8.4.3 e. Each battery shall be subject to a discharge test at least once per 60 months. The purpose of this test is to show that the battery capacity is at least 80% of the manufacturer's recommendations. When performed,

SR 3.8.4.2 Note 1 this discharge test may substitute for the load test.

SR 3.8.4.3 f. The discharge test shall be performed annually for any battery that shows signs of degradation. Degradation

33. viii is indicated when the battery capacity drops more than 10% of rated capacity from its average on previous discharge tests, or is below 90% of the manufacturer's rating.

4.6.3 Preferred (Offsite) Power Supplies

Each offsite power source shall be demonstrated operable:

a. At least once per 7 days by:

- SR 3.8.1.1 SR 3.8.2.i 1. Verifying nominal voltage indications on the high-voltage side of transformers 12A and 12B; and on the 4160 volt buses 12A and 12B.
- 2. Verifying 4160 volt circuit breakers 12AX or 12BX, AND 12AY or 12BY are open.

SR 3.8.9.1 3. Verifying tie breakers 52/BT16-14 and 52/BT17-18 are open when plant mode is above 200°F.

SR 3.8.1.6 b. At least once per 18 (24) months by transferring unit power supply to 4160 volt buses 12A and 12B from the normal circuit, i.e., transformer 12A for bus 12A and transformer 12B for bus 12B to the alternate circuit, i.e., transformer 12B for bus 12A and transformer 12A for bus 12B.

4.6.4 Instrument Buses

Each safety related instrument bus required to be operable, shall be demonstrated operable at least once per 7 days by:

SR 3.8.9.1
SR 3.8.10.1

1. Verifying nominal voltage indications on the Instrument Buses 1A, 1B, 1C.

SR 3.8.6.2 SR 3.8.7.1
SR 3.8.9.1 SR 3.8.7.2
SR 3.8.10.1 SR 3.8.8.1

2. Verifying proper supply breaker alignment for Instrument Buses 1A, 1B, and 1C.

SR 3.8.7.1
SR 3.8.8.1

3. Verifying proper static switch alignment for Instrument Buses 1A and 1C.

Basis

The tests specified are designed to demonstrate that the diesel generators will provide power for operation of equipment. They also assure that the emergency generator system controls and the control systems for the safeguards equipment will function automatically in the event of a loss of all normal 480V AC station service power. (1)

The testing frequency specified will be often enough to identify and correct any mechanical or electrical deficiency before it can result in a system failure. The fuel supply and starting circuits and controls are continuously monitored and any faults are indicated by alarm. An abnormal condition in these systems can be identified without having to test the diesel generators.

Periodic tests are also specified to demonstrate that the offsite power sources will provide power for operation of equipment.

Offsite power source operability requires correct breaker alignment and indicated power availability from the two preferred power circuits, 767 and 751, to the 4160 volt buses. These requirements are met by monitoring nominal voltage indications on the high-voltage side of transformers 12A and 12B; and on the 4160 volt buses 12A and 12B.

Offsite power source independence requires separate 4160 volt circuits supplying power to the 4160 volt buses. Interlocks prevent concurrent closure of 12AX and 12BX, OR 12AY and 12BY; and surveillance is specified to ensure separation is maintained.

Instrument bus power source operability requires correct breaker alignment and indicated power availability. These requirements are met by monitoring nominal voltage indications on the buses and proper breaker alignment.

Furthermore, to assure independence between redundant Class 1E 480 volt buses 14 and 18 (Train A) and buses 16 and 17 (Train B), tie breakers 52/BT16-14 and 52/BT17-18 are required to be open when the plant mode is above 200°F. Once tie breakers are open, interlocks prevent closure when independent and redundant buses are energized.

Station batteries may deteriorate with time, but precipitous failure is extremely unlikely. The surveillance specified is that which has been demonstrated over the years to provide an indication of a cell becoming unserviceable long before it fails, and to ensure that the battery capacity is acceptable.

The equalizing charge, as recommended by the manufacturer, is vital to maintaining the ampere-hour capability of the battery. As a check upon the effectiveness of the equalizing charge, the battery should be loaded rather heavily and the voltage monitored as a function of time. If a cell has deteriorated or if a connection is loose, the voltage under load will drop excessively indicating replacement or maintenance.

The minimum permissible on-site fuel inventory, 10,000 gallons, (5,000 gallons for each generator), is sufficient for operation under loss-of-coolant accident conditions of two engineered safety features trains for 40 hours, or for one train for 80 hours, or for operation of both diesel generators at their design ratings for 24 hours. 3.6 Containment System

Applicability:

Applies to the integrity of reactor containment.

Objective:

To define the operating status of the reactor containment for plant operation.

Specification:

Addressed in Chapter 3.6

3.6.1 Containment Integrity

a. Except as allowed by 3.6.3, containment integrity shall not be violated unless the reactor is in the cold shutdown condition. Closed valves may be opened on an intermittent basis under administrative control.

~~b. The containment integrity shall not be violated when the reactor vessel head is removed unless the boron concentration is greater than 2000 ppm.~~

16.x

c. Positive reactivity changes shall not be made by rod drive motion or boron dilution whenever the containment integrity is not intact unless the boron concentration is greater than 2000 ppm.

LCO 3.9.1 Condition A

3.6.2 Internal Pressure

If the internal pressure exceeds 1 psig or the internal vacuum exceeds 2.0 psig, the condition shall be corrected within 24 hours or the reactor rendered subcritical.

Addressed in Chapter 3.6

3.8

REFUELING

Applicability

Applies to operating limitations during refueling operations

CORE ALTERATIONS and irradiated fuel assembly movement with containment

18.i

Objective

To ensure that no incident could occur during refueling operations that would affect public health and safety

Specification

3.8.1 During refueling operations the following conditions shall be satisfied.

a. Containment penetrations shall be in the following status:

LCO 3.9.3.a

i. The equipment hatch shall be in place with at least one access door closed, or the closure plate that restricts air flow from containment shall be in place,

LCO 3.9.3.b

ii. At least one access door in the personnel air lock shall be closed, and

iii. Each penetration providing direct access from the containment atmosphere to the outside atmosphere shall be either:

18.viii

1. Closed by an automatic isolation valve, blind flange, or manual valve, or or equivalent

2. Be capable of being closed by an OPERABLE automatic shutdown purge or mini-purge valve. Containment Purge and Exhaust Isolation System

18.ii

b. Radiation levels in the containment shall be monitored continuously.

LCO 3.9.2

c. Core subcritical neutron flux shall be continuously monitored by at least two source range neutron monitors, each with continuous visual indication in the control room and one with audible indication in the containment and control room available whenever

18.vii
18.iii

core geometry is being changed. When core geometry is not being changed at

18.iii

least one source range neutron flux monitor shall be in service.

LCO 39.4 d.

At least one residual heat removal loop shall be in operation.*

LCO 39.1 18.iv

Immediately before reactor vessel head removal and while loading and unloading fuel from the reactor, the minimum boron concentration of 2000 ppm shall be maintained in the primary coolant system and checked by sampling twice each

SR 39.1 18.iv

shift every 72 hours

18.v

f. Direct communication between the control room and the refueling cavity manipulator crane shall be available whenever changes in core geometry are taking place.

LCO 39.5 g.

In addition to the requirements of paragraph 3.8.1.d, while in the refueling mode with less than 23 feet of water above the top of the reactor vessel flange, two residual heat removal loops shall be operable.*

LCO 39.6 h.

During movement of fuel or control rods within the reactor vessel cavity, at least 23 feet of water shall be maintained over the top of the reactor vessel.

18.vi

* Either the preferred or the emergency power source may be inoperable for each residual heat removal loop.

Added LCO 3.9.2 RA B.2
RA C.3

18.iii

LCO 3.9.5

flange. If this condition is not met, all operations involving movement of fuel or control rods in the reactor vessel shall be suspended.

3.8.2

If any of the specified limiting conditions for refueling is not met, refueling of the reactor shall cease; work shall be initiated to correct the violated conditions so that the specified limits are met; no operations which may increase the reactivity of the core shall be made.

- LCO 3.9.1, Cond A
- LCO 3.9.2, Cond A/B/C
- LCO 3.9.3, Cond A
- LCO 3.9.4, Cond A
- LCO 3.9.5, Cond A/B
- LCO 3.9.6, Cond A

18. ix

18. x

3.8.3

If the conditions of 3.8.1.d are not met, then in addition to the requirements of 3.8.2, isolate the shutdown purge and mini-purge penetrations within 4 hours.

LCO 3.9.4

LCO 3.9.5

Basis:

The equipment and general procedures to be utilized during refueling are discussed in the UFSAR. Detailed instructions, the above specified precautions, and the design of the fuel handling equipment incorporating built-in interlocks and safety features, provide assurance that no incident could occur during the refueling operations that would result in a hazard

28. ii. i

New surveillance requirements:

- SR 3.9.3.1
- SR 3.9.4.1
- SR 3.9.5.1

to public health and safety. (1) Whenever changes are not being made in core geometry one flux monitor is sufficient. This permits maintenance of the instrumentation. Continuous monitoring of radiation levels and neutron flux provides immediate indication of an unsafe condition. The residual heat pump is used to maintain a uniform boron concentration. The shutdown margin as indicated will keep the core subcritical, even if all control rods were withdrawn from the core. During refueling, the reactor refueling cavity is filled with approximately 230,000 gallons of borated water. The boron concentration of this water at 2000 ppm boron is sufficient to maintain the reactor subcritical by at least 5% $\Delta k/k$ in the cold condition with all rods inserted (best estimate of 10% subcritical), and will also maintain the core subcritical even if no control rods were inserted into the reactor. (2) Periodic checks of refueling water boron concentration insure the proper shutdown margin. Communication requirements allow the control room operator to inform the manipulator operator of any impending unsafe condition detected from the main control board indicators during fuel movement. In addition to the above safeguards, interlocks are utilized during refueling to insure safe handling. An excess weight interlock is

provided on the lifting hoist to prevent movement of more than one fuel assembly at a time. The spent fuel transfer mechanism can accommodate only one fuel assembly at a time. In addition, interlocks on the auxiliary building crane will prevent the trolley from being moved over stored racks containing spent fuel.

The operability requirements for residual heat removal loops will ensure adequate heat removal while in the refueling mode. The requirement for 23 feet of water above the reactor vessel flange while handling fuel and fuel components in containment is consistent with the assumptions of the fuel handling accident analysis.

The analysis⁽³⁾ for a fuel handling accident inside containment establishes acceptable offsite limiting doses following rupture of all rods of an assembly operated at peak power. No credit is taken for containment isolation or effluent filtration prior to release. Requiring closure of penetrations which provide direct access from containment atmosphere to the outside atmosphere establishes additional margin for the fuel handling accident and establishes a seismic envelope to protect against the potential consequences of seismic events during refueling. Isolation of these penetrations may be achieved by an OPERABLE shutdown purge or mini-purge valve, blind flange, or isolation valve. An OPERABLE shutdown purge or mini-purge valve is capable of being automatically isolated by R11 or R12. Penetrations which do not provide direct access from containment atmosphere to the outside atmosphere support containment integrity by either a closed system, necessary isolation valves, or a material which can provide a temporary ventilation barrier, at atmospheric pressure, for the containment penetrations during fuel movement.

TABLE NOTATIONSee Chapter
3.3

28.v.c

(1) The Channel Functional Test shall also demonstrate that automatic isolation of this pathway and control room alarm occur if any of the following conditions exist:

1. Instrument indicates measured levels above the alarm and/or trip setpoint.
2. Power failure.

(2) The Channel Functional Test shall also demonstrate that control room alarm occurs if any of the following conditions exist:

1. Instrument indicates measured levels above the alarm setpoint.
2. Power failure.

(3) The Channel Calibration shall include the use of standard gas samples containing a nominal:

1. Zero volume percent oxygen; and
2. Three volume percent oxygen.

(4) This check may require the use of an external source due to high background in the sample chamber.

(5) Source used for the Channel Calibration shall be traceable to the National Bureau of Standards (NBS) or shall be obtained from suppliers (e.g. Amersham) that provide sources traceable to other officially-designated standards agencies.

(6) Flow rate for main plant ventilation exhaust and containment purge exhaust are calculated by the flow capacity of ventilation exhaust fans in service and shall be determined at the frequency specified.

(7) Applies only during releases via this pathway.

See Chapters 3.3
and 5.0

28.v.c

(ia) The test shall also demonstrate that automatic isolation of the purge valves.

See Chapter 3.7

d. Flow shall be maintained through the system using either the filter or bypass flow path for at least 15 minutes each month.

4.11.1.2 After each replacement of a charcoal filter drawer or after any structural maintenance on the charcoal housing for the spent fuel pit charcoal adsorber system, the condition of Specification 4.11.1.1.b shall be demonstrated for the affected portion of the system.

4.11.2 Residual Heat Removal and Coolant Circulation

SR 3.9.4.1
SR 3.9.3.1

38.iv

4.11.2.1 When the reactor is in the refueling mode and fuel is in the reactor, at least one residual heat removal loop shall be verified to be in operation and circulating reactor coolant at least once per 12 hours.

SR 3.9.4.1
SR 3.9.4.2

38.v

4.11.2.2 When the water level above the top of reactor vessel flange is less than 23 feet, both RHR pumps shall be verified to be operable by performing the surveillance specified in the Inservice Pump and Valve Test Program prepared pursuant to 10 CFR 50.55a.

4.11.3 Water Level - Reactor Vessel

SR 3.9.5.1

38.vi

4.11.3.1 The water level in the reactor cavity shall be determined to be at least its minimum required depth within 24 hours prior to the start of and at least once per 24 hours thereafter during movement of fuel assemblies or control rods in containment.

Basis

The measurement of the air flow assures that air is being withdrawn from the spent fuel pit area and passed through the adsorbers. The flow is measured prior to employing the adsorbers to establish that

See Chapter 3.7

there has been no gross change in performance since the system was last used. The Freon test provides a measure of the amount of leakage from around the charcoal adsorbent.

The ability of charcoal to adsorb iodine can deteriorate as the charcoal ages and weathers. Testing the capacity of the charcoal to adsorb iodine assures that an acceptable removal efficiency under operating conditions would be obtained. The difference between the test requirement of a removal efficiency of 90% for methyl iodine and the percentage assumed in the evaluation of the fuel handling accident provides adequate safety margin for degradation of the filter after the tests.

Retesting of the spent fuel pit charcoal adsorber system in the event of painting, fire, or chemical release is required only if the system is operating and is providing filtration for the area in which the painting, fire, or chemical release occurs.

Testing of the air filtration systems will be tested, to the extent it can be given the configuration of the systems, in accordance with ANSI N510-1975, "Testing of Nuclear Air-Cleaning Systems".

~~The operability requirements for residual heat removal loops will ensure adequate heat removal while in the refueling mode. The requirement for 23 feet of water above the reactor vessel flange while handling fuel and fuel components in containment is consistent with the assumptions of the fuel handling accident analysis.~~

45.1

5.2 Containment Design Features

5.2.1 Reactor Containment

- a. The reactor containment completely encloses the entire reactor and reactor coolant system and ensures that an acceptable upper limit for leakage of radioactive materials to the environment is not exceeded even if gross failure of the reactor coolant system occurs. The structure provides biological shielding for both normal and accident situation.
- b. The containment structure is designed for an internal pressure of 60 psig, plus the loads resulting from an earthquake producing .08g in the vertical and horizontal planes simultaneously. The containment is also structurally designed to withstand an external pressure 2.5 psi higher than the internal pressure. (1)

5.2.2 Penetrations

- a. All penetrations through the containment reinforced concrete pressure barrier for pipe, electrical conductors, ducts and access hatches are of the double barrier type. (2)
- b. The automatically actuated containment isolation valves are designed to close upon high pressure in the containment (setpoint no higher than 6 psig) or high radiation

5.2.1

in the containment vessel. The actuation system is designed such that no single component failure will prevent containment isolation if required.

5.2.3 Containment Systems

- a. The containment vessel has an internal spray system which is capable of providing a distributed borated water spray of at least 1200 gpm. During the initial period of spray operation, sodium hydroxide would be added to the spray water to increase the removal of iodine from the containment atmosphere. (3)
- b. The containment vessel has an internal air recirculation system which consists of four ventilation fans and air coolers capable of a total heat removal capability of 55,600 Btu/sec under conditions following a loss of coolant accident. Two of the fan cooler units are equipped with activated charcoal filters to remove volatile iodine following an accident. (4)

5.3 Reactor Design Features

5.3.1 Reactor Core

4.2.1

46.i

a. The reactor core contains approximately 45 metric tons of uranium in the form of uranium dioxide pellets... The pellets are encapsulated in Zircaloy 4 tubing to form fuel rods. The reactor core is made up of 121 fuel assemblies⁽¹⁾ with each fuel assembly containing 179 fuel rod locations. Fuel rod locations at any time during plant life, may consist of fuel rods clad with Zircaloy -4 or filler rods fabricated from Zircaloy -4 or stainless steel if justified by cycle-specific reload analysis. Should more than 30 rods in the core, or 10 rods in any assembly be replaced per refueling, a report describing the number of rods replaced and associated cycle-specific evaluation shall be submitted to the Commission prior to criticality. Each fuel assembly also contains 16 guide tubes and one instrumentation thimble all arranged in a 14 x 14 array to form a fuel assembly.

4.3.1.2.a

46.ii

46.iii

b. The enrichment of reload fuel shall be no more than 3.5 weight per cent U-235 for regions delivered prior to January 1, 1984 (Regions 1-15), ^{5.05}4.25 weight per cent U-235 for regions delivered after January 1, 1984, or their equivalents in terms of reactivity.

4.2.2

46.i

c. There are 29 full-length assemblies in the reactor core. Each RCC assembly contains 16 144 inch lengths of silver-indium-cadmium alloy clad with stainless steel which act as neutron absorbers when inserted into the core.⁽²⁾

Basis

The DNBRs for the reconstituted assemblies are conservatively determined by assuming the filler rods are operating at the highest power in the reconstituted fuel assembly.

(46.ii)

5.3.2

Reactor Coolant System

- a. The design of the reactor coolant system complies with the code requirements. (3)
- b. All piping, components and supporting structures of the reactor coolant system are designed to Class I requirements, and have been designed to withstand:
 - i. The design seismic ground acceleration, 0.08g, with stresses maintained within code allowable working stresses.
 - ii. The maximum potential seismic ground acceleration, 0.2g, acting in the horizontal and vertical directions simultaneously with no loss of function.
- c. The nominal liquid volume of the reactor coolant system, at rated operating conditions, is 6236 cubic feet.

4b, iii

5.4 Fuel Storage
Specification

5.4.1 The new and spent fuel pit structures are designed to withstand the anticipated earthquake loadings as Class I structures. The spent fuel pit has a stainless steel liner to ensure against loss of water.

5.4.2 The new and spent fuel storage racks are designed so that it is impossible to insert fuel assemblies in other than the prescribed locations. The spent fuel storage racks are divided into two regions as depicted on Figure 5.4-1. The

47.i

fuel is stored vertically in an array with sufficient center to center distance between assemblies to assure $K_{eff} < 0.95$ for (1) unirradiated fuel assemblies delivered prior to January 1, 1984 (Region 1-15) ^{with initial enrichment} ~~containing no~~ ~~more than 39.0 gms U-235 per axial cm~~ ^{no greater than 3.50 weight percent U-235} and (2) unirradiated fuel assemblies delivered after January 1, 1984 ^{with initial enrichment} ~~containing~~ ~~no more than 41.9 gms U-235 per axial cm~~ ^{enrichment no greater than 4.05 weight percent U-235}. Both cases assume unborated water used in the pool.

4.3.1.1.a
4.2.1.1.b

47.ii

5.4.3 In Region 2 of the spent fuel storage racks, fuel is stored in a close packed array utilizing fixed neutron poisons in each of the stored locations. For discharged fuel assemblies to be stored in Region 2, (1) 60 days

must have elapsed since the core reached hot shutdown

47.iii

prior to discharge and (2) the combination of assembly average burnup and initial U-235 enrichment must be such that the point identified by these two parameters on Figure 5.4-2 is above the line applicable to the particular fuel assembly design, therefore assuring that $K_{eff} < 0.95$.

32.3

5.4.4

Cannisters containing consolidated fuel rods may be stored in either Region 1 or 2 provided that:

4.3.11.c

a. the average burnup and initial enrichment of the fuel assemblies from which the rods were removed satisfy the requirements of 5.4.2 and 5.4.3 above, and

47.iv

b. the average decay heat of the fuel assembly from which the rods were removed is less than 2150 BTU/hr

5.4.5

4.3.11.c

The requirements of 5.4.4a may be excepted for those consolidated fuel assemblies of Region RGAF2.

5.4.6

3.9.1

47.L

The spent fuel storage pit is filled with borated water at a concentration to match that used in the reactor cavity and refueling canal during refueling operations whenever there is fuel in the pit.

Basis

The center to center spacing of Region 1 insures that $K_{eff} \leq 0.95$ for the enrichment limitations specified in 5.4.2¹, and for a postulated missile impact the resulting dose at the EAB would be within the guidelines of 10CFR100².

In Region 2, $K_{eff} \leq 0.95$ is insured by the addition of fixed neutron poison (boraflex) in each of the Region 2 storage locations, and a minimum burnup requirement as a function of initial enrichment for each fuel assembly design. The 60 day cooling time requirement insures that for a postulated missile impact the resulting dose at the EAB would be within the guidelines of 10CFR100.

The two curves of Figure 5.4-2 divide the fuel assembly designs into two groups. The first group is all fuel delivered prior to January 1, 1984. This incorporates all Exxon and Westinghouse HIPAR designs used at Ginna.⁴ The second curve is for the Westinghouse Optimized Fuel Assembly design delivered to Ginna beginning in February 1984.³

The assembly average burnup is calculated using INCORE generated power sharing data and the actual plant operating history. The calculated assembly average burnup should be reduced by 10% to account for uncertainties. An uncertainty of 4% is associated with the measurement of power sharing. The additional 6% provides additional margin to bound the burnup uncertainty associated with the time between measurements and updates of core burnup. The curves of Figure 5.4-2 incorporate the uncertainties of the calculation of assembly reactivity.³

The calculations of fuel assembly burnup for comparison to the curves of Figure 5.4-2 to determine the acceptability for storage in Region 2 shall be independently checked. The record of these calculations shall be kept for as long as fuel assemblies remain in the pool.

The fuel storage cannisters are designed so that, normally, they can contain the equivalent number of fuel rods from two fuel assemblies in a close packed array, and can be stored in either Region 1 or Region 2 rack locations. The close packed array will insure the K_{∞} of the rack configuration containing any number of cannisters will be less than that for stored fuel assemblies at the same burnup and initial enrichment. The exception

of paragraph 5.4.5 is possible because the consolidated configuration is substantially less reactive than that of a fuel assembly. The maximum decay heat requirement will insure that local and film boiling will not occur between the close packed fuel rods if the pool temperature is maintained at or below 150°F. The decay heat of the assembly will be determined using ANS 5.1, ASB 9-2 or other acceptable substitute standards.

With the addition of the storage of consolidated fuel cannisters, the theoretical storage capacity of the pool would be increased to 2032 fuel assemblies (2x1016). However, due to limitation on the heat removal capability of the spent fuel pool cooling system, the storage capacity is limited to 1016 fuel assemblies.⁵

5.5 Waste Treatment Systems

5.5.1 Radioactive Liquid Waste Treatment.

The liquid waste treatment system consists of a Waste Holdup Tank, a Waste Evaporator and a mixed bed demineralize. Portions of the system may be bypassed and still meet the release limits.

5.5.2 Gaseous Radwaste Treatment

The gaseous radwaste system is designed to collect off-gas from the primary coolant system and hold for radioactive decay prior to release to the environment.

The gaseous radwaste treatment system consists of four (4) Gas Decay Tanks and two (2) gas compressors. Only one compressor and three Gas Decay Tanks are necessary to the system.

5.5.3 Ventilation Exhaust System

The ventilation exhaust is treated to reduce gaseous radioiodine and material in particulate form by passing through charcoal adsorbers and/or HEPA filters. This system has no effect on noble gas effluents. The components of the ventilation exhaust system are:

- Auxiliary Building HEPA filters
- Auxiliary Building "G" Charcoal & HEPA filters
- Auxiliary Building "A" Charcoal Adsorbers
- Containment Purge Charcoal & HEPA filters

5.5.4 Solid Radwaste System

The solid radwaste system consists of piping and valves in the Drumming Station whereby waste evaporator concentrates

are transferred into prepared drums by means of the waste evaporator feed pump. Alternatively, liquid wastes may be solidified and prepared for shipment by a contractor.

Chapter 1.0

See Chapter
3.3

3.5.3.2 When required by 3.5.3.1, with the number of operable accident monitoring instrumentation channels less than the Total Number of Channels shown in Table 3.5-3, either restore the inoperable channel(s) to operable status within 7 days, or be in at least hot shutdown within the next 12 hours.

3.5.3.3 When required by 3.5.3.1, with the number of operable accident monitoring instrumentation channels less than the Minimum Channels Operable requirements of Table 3.5-3 either restore the inoperable channel(s) to operable status within 48 hours or be in at least hot shutdown within the next 12 hours.

3.5.4 The radiation accident monitoring instrumentation channels shown in Table 3.5-6 shall be operable, whenever the reactor is at or above hot shutdown. With one or more radiation monitoring channels inoperable, take the action shown in Table 3.5-6. Startup may commence or continue consistent with the action statement.

3.5.5 Radioactive Effluent Monitoring Instrumentation

3.5.5.1 The radioactive effluent monitoring instrumentation shown in Table 3.5-5 shall be operable at all times, with alarm and/or trip setpoints set to insure that the limits of Specification 3.9.1.1 and 3.9.2.1 are not exceeded. Alarm and/or trip setpoints shall be established in accordance with calculational methods set forth in the Offsite Dose Calculation Manual.

15.viii

3-5-2

15.viii

3.5.5.2 If the setpoint for a radioactive effluent monitor alarm and/or trip is found to be higher than required, one of the following three measures shall be taken immediately:

- (i) the setpoint shall be immediately corrected without declaring the channels inoperable; or
- (ii) immediately suspend the release of effluents monitored by the effected channel; or
- (iii) declare the channel inoperable.

3.5.5.3 If the number of channels which are operable is found to be less than required, take the action shown in Table 3.5-5. Exert best efforts to return the instruments to OPERABLE status within 31 days and, if unsuccessful, explain in the next Radioactive Effluent Release Report why the inoperability was not corrected in a timely manner.

3.5.6 Control Room HVAC Detection Systems

3.5.6.1 During all modes of plant operation, detection systems for chlorine gas, ammonia gas and radioactivity in the control room HVAC intake shall be operable with setpoints to isolate air intake adjusted as follows:

See Chapter 3.2

See Chapter
3.3

chlorine, < 5 ppm
 ammonia, < 35 mg/m³
 radioactivity, particulate $\leq 1 \times 10^{-8}$ μ Ci/cc
 iodine $\leq 9 \times 10^{-9}$ μ Ci/cc
 noble gas $\leq 1 \times 10^{-5}$ μ Ci/cc

- 3.5.6.2 With one of the detection systems inoperable, within 1 hour isolate the control room HVAC air intake. Maintain the air intake isolated except for short periods, not to exceed 1 hour a day, when fresh air makeup is allowed to improve the working environment in the control room.

Basis

During plant operations, the complete instrumentation system will normally be operable. Reactor safety is provided by the Reactor Protection System, which automatically initiates appropriate action to prevent exceeding established limits. Safety is not compromised, however, by continuing operation with certain instrumentation channels inoperable since provisions were made for this in the plant design. This specification outlines limiting conditions for operation necessary to preserve the effectiveness of the reactor control and protection system when any one or more of the channels is inoperable.

Almost all reactor protection channels are supplied with sufficient redundancy to provide the capability for channel calibration and test at power. Exceptions are backup channels such as reactor coolant pump breakers. The removal of one trip channel is accomplished by placing that channel bistable in a tripped mode; e.g., a two-out-of-three circuit becomes a one-out-of-two circuit. Testing does not trip the system unless a trip condition exists in a concurrent channel.

The operability of the accident monitoring instrumentation ensures that sufficient information is available on selected plant parameters to monitor and assess these variables during and following an accident. This capability is consistent with the recommendations of NUREG-0578, "TMI-2 Lessons Learned Task Force Status Report and Short-Term Recommendations".

~~The radioactive liquid effluent instrumentation is provided to monitor and/or control, as applicable, the releases of radioactive materials in liquid effluents. The alarm and/or trip setpoints for these instruments are calculated in accordance with the ODCM to ensure that alarm and/or trip will occur prior to exceeding the limits of 10 CFR Part 20. The operability and use of this instrumentation is consistent with the requirements of General Design Criteria 60, 63 and 64 of Appendix A to 10 CFR Part 50.~~

The radioactive gaseous effluent instrumentation is provided to monitor and control, as applicable, the releases of radioactive materials in gaseous effluents. The alarm and/or trip setpoints for these instruments are calculated in accordance with the ODCM to ensure that alarm and/or trip will occur prior to exceeding the limits of 10 CFR Part 20. This instrumentation also includes provisions for monitoring the concentrations of potentially explosive gas mixtures in the waste gas holdup system. The operability and use of this instrumentation is consistent with the requirements of General Design Criterion 64 of Appendix A to 10 CFR Part 50.

See Chapter 2.2

Control Room HVAC detection systems are designed to prevent the intake of chlorine, ammonia and radiation at concentrations which may prevent plant operators from performing their required functions. Concentrations which initiate isolation of the control room HVAC system have been established using the guidance of several established references (2-4).

The chlorine isolation setpoint is 1/3 of the toxicity limit of reference 2 but slightly greater than the short term exposure limit of reference 4. The ammonia setpoint is established at approximately 1/3 of the toxicity limit for anhydrous ammonia in reference 2 and equal to the short term exposure limit of reference 4. The setpoints for radioactivity correspond to the

IS.viii

15.viii

TABLE 3.5-5 (Continued)

Table Notation

Action 1 - If the number of operable channels is less than required by the Minimum Channels Operable requirement, effluent releases from the tank may continue for up to 14 days, provided that prior to initiating a release:

- 1. At least two independent samples of the tank's contents are analyzed, in accordance with Specification 4.12.1.1.a, and
- 2. At least two technically qualified members of the Facility Staff independently verify the release rate calculations and discharge line valving;

Otherwise, suspend release of radioactive effluents via this pathway.

Action 2 - When Steam Generator Blowdown is being released (not recycled) and the number of channels operable is less than required by the Minimum Channels Operable requirements, effluent releases via this pathway may continue provided grab samples are analyzed for gross radioactivity (beta or gamma) at a limit of detection of at most 10^{-7} uCi/gram:

- 1. At least once per 8 hours when the concentration of the secondary coolant is > 0.01 uCi/gram dose equivalent I-131.
- 2. At least once per 24 hours when the concentration of the secondary coolant is ≤ 0.01 uCi/gram dose equivalent I-131.

Action 3 - If the number of operable channels is less than required by the Minimum Channels operable requirement, effluent releases via this pathway may continue provided that at least once per 24 hours grab samples are analyzed for gross radioactivity (beta or gamma) at a limit of detection of at most 10^{-7} uCi/gm.

Action 4 - If the number of operable channels is less than required by the Minimum Channels Operable requirement, effluent releases via this pathway may continue provided grab samples are taken at least once per 8 hours and these samples are analyzed for isotopic activity within 24 hours or R14A is operable and readings are reviewed at least once per 8 hours.

15. VIII

TABLE 3.5-5 (Continued)Table Notation

- Action 5 - If the number of operable channels is less than required by the Minimum Channels Operable requirements, effluent releases via this pathway may continue provided samples are continuously collected as required by Table 4.12-2 Item E with auxiliary sampling equipment.
- Action 6 - If the number of operable channels is less than required by the Minimum Channels Operable and the Secondary Activity is $\leq 1 \times 10^{-4}$ uCi/gm, effluent releases may continue via this pathway provided grab samples are analyzed for gross radioactivity (beta or gamma) at least once per 24 hours. If the secondary activity is greater than 1×10^{-4} uCi/gm, effluent releases via this pathway may continue for up to 31 days provided grab samples are taken every 8 hours and analyzed within 24 hours.
- Action 7 - If the channel is inoperable, a sample of the gas from the in service gas decay tank shall be analyzed for oxygen content at least once every 4 hours.
- Action 8 - If the number of operable channels is less than required by the Minimum Channels Operable, or at least one containment fan cooler is not operating, within 1 hour terminate the purge.

3.9

Plant EffluentsApplicability

Applies to the controlled release of radioactive liquids and gases from the plant.

Objective

To define the conditions for release of radioactive liquid and gaseous wastes.

Specifications

19.i 3.9.1

Liquid Effluents

3.9.1.1 Concentration

3.9.1.1.a The release of radioactive liquid effluents shall be such that the concentration in the circulating water discharge does not exceed the limits specified in accordance with Appendix B, Table II, Column 2 and Notes thereto of 10CFR20. For dissolved or entrained noble gases the total activity due to dissolved or entrained noble gases shall not exceed 2×10^{-4} uCi/ml.

3.9.1.1.b If the concentration of radioactive material in the circulating water discharge exceeds the limits of 3.9.1.1.a, measures shall be initiated to restore the concentration to within those limits as soon as practicable.

3.9.1.2 Dose

3.9.1.2.a The dose or dose commitment to an individual as calculated in the ODCM from radioactive materials in liquid effluents released to unrestricted areas shall be limited:

19.ii

3.9.1

19.ii

- (i) During any calendar quarter to ≤ 1.5 mrem to the total body and to ≤ 5 mrem to any organ, and
- (ii) During any calendar year to ≤ 3 mrem to the total body and to ≤ 10 mrem to any organ.

3.9.1.2.b Whenever the calculated dose resulting from the release of radioactive materials in liquid effluents exceeds the quarterly limits of 3.9.1.2.a(i), a Special Report shall be submitted to the Commission within thirty days which includes the following information:

- (i) Identification of the cause for exceeding the dose limit.
- (ii) Corrective actions taken and/or to be taken to reduce the releases of radioactive material in liquid effluents to assure that subsequent releases will remain within the above limits.
- (iii) The results of the radiological analyses of the nearest public drinking water source, and an evaluation of the radiological impact due to licensee releases on finished drinking water with regard to the requirements of 40 CFR 141 Safe Drinking Water Act.

3.9.1.3 Liquid Waste Treatment

3.9.1.3.a The liquid waste treatment system shall be used to reduce the radioactive materials in liquid wastes prior to their discharge, if necessary, to assure that the cumulative dose due to liquid effluent releases when averaged

19.iii

19.iii

over 31 days does not exceed 0.06 mrem to the total body or 0.2 mrem to any organ.

3.9.1.3.b If the liquid radwaste treatment system is not operable for more than 31 days and if radioactive liquid waste is being discharged without treatment resulting in doses in excess of Specification 3.9.1.3.a, a Special Report shall be submitted to the Commission within thirty days which includes the following information:

- (i) Identification of equipment or subsystems not operable and the reasons.
- (ii) Action(s) taken to restore the inoperable equipment to operable status.
- (iii) Summary description of action(s) taken to prevent a recurrence.

3.9.2 Gaseous Wastes

3.9.2.1 Dose Rate

3.9.2.1.a The instantaneous dose rate, as calculated in the ODCM, due to radioactive materials released in gaseous effluents from the site shall be limited to the following values:

- (i) The dose rate for noble gases shall be ≤ 500 mrem/yr to the total body and ≤ 3000 mrem/yr to the skin, and
- (ii) The dose rate for all radioiodines, radioactive materials in particulate form, and radionuclides other than noble gases with half-lives greater than 8 days shall be ≤ 1500 mrem/yr to any organ.

19. iv

19. iv

3.9.2.1.b For unplanned release of gaseous wastes, compliance with 3.9.2.1.a may be determined by averaging over a 24-hour period.

3.9.2.1.c If the calculated dose rate of radioactive materials released in gaseous effluents from the site exceeds the limits of 3.9.2.1.a or 3.9.2.1.b, measures shall be initiated to restore releases to within those limits as soon as practicable.

3.9.2.1.d Compliance with 3.9.2.1.a and 3.9.2.1.b shall be determined by considering the applicable ventilation system flow rates. These flow rates shall be determined at the frequency required by Table 4.1-5.

3.9.2.2 Dose (10 CFR Part 50, Appendix I)

3.9.2.2.a The air dose, as calculated in the ODCM, due to noble gases released in gaseous effluents from the site shall be limited to the following:

- (i) During any calendar quarter to \leq 5 mrad for gamma radiation and to \leq 10 mrad for beta radiation.
- (ii) During any calendar year to \leq 10 mrad for gamma radiation and to \leq 20 mrad for beta radiation.

3.9.2.2.b The dose to an individual, as calculated in the ODCM, from radioiodine, radioactive materials in particulate form and radionuclides other than noble gases with half-lives greater than eight days released with gaseous effluents from the site shall be limited to the following:

19.v

19.vi

19.v

(i) During any calendar quarter to ≤ 7.5 mrem to any organ.

(ii) During any calendar year to ≤ 15 mrem to any organ.

3.9.2.2.c Whenever the calculated dose to an individual resulting from noble gases or from radionuclides other than noble gases exceeds the quarterly limits of 3.9.2.2.a(i) or 3.9.2.2.b(i) a Special Report shall be submitted to the Commission within thirty days which includes the following information:

19.v

19.vi

(i) Identification of the cause for exceeding the dose limit.

(ii) Corrective actions taken and/or to be taken to reduce releases of radioactive material in gaseous effluents to assure that subsequent releases will be within the above limits.

3.9.2.3 Gaseous Waste Treatment

3.9.2.3.a The gaseous radwaste treatment system shall be used to reduce radioactive materials in gaseous waste prior to their discharge, if necessary, to assure that the cumulative air dose due to gaseous effluent releases to unrestricted areas when averaged over 31 days does not exceed 0.2 mrad for gamma radiation and 0.4 mrad for beta radiation to the maximally exposed individual.

3.9.2.3.b The appropriate portions of the ventilation exhaust system shall be used to reduce radioactive materials in gaseous waste prior to their discharge, if necessary,

19.vii

19.vii

to assure that the cumulative dose due to gaseous effluent releases from the site when averaged over 31 days does not exceed 0.30 mrem to any organ.

3.9.2.3.c If the gaseous radwaste treatment system or ventilation exhaust system is inoperable for more than 31 days and if gaseous waste is being discharged without treatment resulting in doses in excess of Specifications 3.9.2.3.a or 3.9.2.3.b, a Special Report shall be submitted to the Commission within thirty days which includes the following information:

- (i) Identification of equipment or subsystems not operable and the reasons.
- (ii) Action(s) taken to restore the inoperable equipment to operable status.
- (iii) Summary description of action(s) taken to prevent a recurrence.

3.9.2.4 Dose (40 CFR Part 190)

3.9.2.4.a If the calculated dose from the release of radioactive materials from the plant in liquid or gaseous effluents exceeds twice the limits of Specifications 3.9.1.2.a, 3.9.2.2.a, or 3.9.2.2.b, a Special Report shall be submitted to the Commission within thirty days and subsequent releases shall be limited so that the dose or dose commitment to a real individual is limited to ≤ 25 mrem to the total body or any organ (except thyroid, which is limited to ≤ 75 mrem) for the calendar year that includes the release(s) covered by this report.

19.Li
19.v
19.vi

3.9.6

19.ii, 19.v, 19.vi

This report shall include an analysis which demonstrates that radiation exposures to all real individuals from the plant are less than the 40 CFR Part 190 limits in accordance with methods set forth in the ODCM. Otherwise, the report shall request a variance from the Commission to permit releases to exceed 40 CFR Part 190. Submittal of the report is considered a timely request, and a variance is granted until staff action on the request is complete.

5.5.11

3.9.2.5 Explosive Gas Mixture

3.9.2.5.a The concentration of oxygen in each gas decay tank shall be limited to ~~≤ 2% by volume.~~

3.9.2.5.b If the concentration of oxygen in a gas decay tank is > 2% by volume but ≤ 4% by volume, restore the concentration of oxygen to within the limit within 48 hours.

3.9.2.5.c If the concentration of oxygen in a gas decay tank is > 4% by volume, immediately remove that tank from "reuse" or "in service" status and reduce the concentration of oxygen to ≤ 2% within 48 hours if such measures do not conflict with other radiological limits or procedures.

19.viii

3.9.2.6 Waste Gas Decay Tanks

5.5.11

3.9.2.6.a The quantity of radioactivity contained in each waste gas decay tank shall be limited to less than or equal to 100,000 curies of noble gas (considered as Xe-133) at all times.

3.9.2.6.b If the quantity of radioactive material in any waste gas decay tank exceeds the limit of 3.9.2.6.a, immediately suspend all additions of radioactive material to the

19.viii

tank and reduce the tank contents within 48 hours if such measures do not conflict with other radiological limits or procedures.

3.9.2.7 Solid Radioactive Waste

- 3.9.2.7.a The solid radwaste system shall be used as applicable in accordance with the Process Control Program for the solidification and packaging of radioactive waste to ensure meeting the requirements of 10CFR Part 71 prior to shipment of radioactive wastes from the site.
- 3.9.2.7.b If the packaging requirements of 10 CFR Part 71 are not satisfied, suspend shipments of deficiently packaged solid radioactive wastes from the site until appropriate corrective measures have been taken.

Basis

Liquid wastes from the Radioactive Waste Disposal System are diluted in the Circulating Water System discharge prior to release to the lake.⁽¹⁾ With two pumps operating, the capacity of the Circulating Water System is approximately 400,000 gpm. Operation of a single circulating water pump reduces the nominal flow rate by about 50%. The circulating water flow under various operating conditions has been calculated from the head differential across the pumps and the manufacturer's head-capacity curves. Because of the low radioactivity levels in the circulating water discharge, the concentration of liquid radioactive effluents at this point is not measured directly. The concentration

19.ix

in the circulating water discharge is calculated from the measured concentration in the Waste Condensate Tank, the flow rate of the Waste Condensate Pumps, and the flow in the Circulating Water System. Radioactive effluents released to unrestricted areas on the basis of gross beta-gamma analysis are based on the assumption that I-129 and radium are not present. Accordingly, Appendix B, Table II, Column 2 of 10CFR20 will permit a concentration up to 1×10^{-7} uCi/ml in the circulating water discharge. Otherwise, if controlled on a radionuclide basis, the permitted discharge concentration will be in accordance with Note 1 of 10CFR20, Appendix B, Table II, Column 2. If the concentration of liquid wastes in the circulating water discharge equals the Maximum Permissible Concentration (MPC) as specified, the average concentration at the intake of the nearest public water supply at Ontario, New York, would be well below MPC. (2) Thus, these limitations provide additional assurance that the concentrations of water-borne radioactivity will result in only minimal potential public exposures within (1) Section II.A of Appendix I, 10 CFR Part 50, and (2) the limits of 10CFR Part 20.106(e).

The concentration limit for noble gases is based upon the assumption that Xe-135 is the controlling radioisotope and its MPC in air was converted to an equivalent concentration in water using ICRP Publication 2 methodology.

The Specifications which limit the dose to an individual from radioactive liquid effluents are provided to implement the requirements of Sections II.A, III.A and IV.A of 10 CFR Part 50, Appendix I. The Limiting Condition for Operation implements the guides set forth in Section II.A of 10 CFR Part 50, Appendix I. The Specifications provide the required operating flexibility and at the same time implement the guides set forth in Section IV.A of 10 CFR Part 50, Appendix I. The dose calculations in the ODCM implement the requirements in Section III.A of 10 CFR Part 50, Appendix I that conformance with the guides of Appendix I is to be shown by calculational procedures based on such models and data that the actual exposure of a real individual through appropriate pathways is unlikely to be substantially underestimated. Also, there is reasonable assurance that the operation of the plant will not result in waterborne radionuclide discharges which cause the potential exposure from the finished drinking water ingestion to exceed the requirements of 40CFR 141.

The requirements that the appropriate portions of the liquid radwaste treatment system be used when specified provided assurance that the releases of radioactive materials in liquid effluents will be kept "as low as is reasonably achievable." This specification implements the requirements of 10 CFR Part 50.36a, General

Design Criterion 60 of Appendix A to 10 CFR Part 50 and design objective Section II.D of Appendix I. The limits governing the use of appropriate portions of the liquid radwaste treatment system were specified as a suitable fraction of the guide set forth in Section II.A of 10 CFR Part 50, Appendix I for liquid effluents. The cumulative maximum dose to an offsite individual from waterborne radioactive effluents is determined in order to verify that the average dose over a 31-day period is reasonably small, even if the liquid radwaste treatment system is not operated during that period. However, a cumulative dose which exceeds the stated limit does not necessarily imply that all portions of the liquid radwaste treatment system be used; certain subsystems may have only minimal effects on reducing doses.

The limit for dose rate is provided to ensure that the dose rate at any time at the site boundary from gaseous effluents will be within the annual dose limits of 10 CFR Part 20 for unrestricted areas. The annual dose limits are the doses associated with the concentrations of 10 CFR Part 20, Appendix B, Table II. These limits provide reasonable assurance that radioactive material discharged in gaseous effluents will not result in the exposure of an individual in an unrestricted area, to annual average concentrations exceeding the limits

specified in Appendix B, Table II of 10 CFR Part 20 (10 CFR Part 20.106(b)). For individuals who may at times be within the site boundary, these occupancy times will be sufficiently small to compensate for any increase in the atmospheric diffusion factor above that for the site boundary.

The Specifications which limit the dose from radioactive gaseous effluents are provided to implement the requirements of Sections II.B, II.C, III.A and IV.A of 10 CFR Part 50, Appendix I. The Limiting Condition for Operation implements the guides set forth in Sections II.B and II.C of 10 CFR Part 50, Appendix I. The Specifications provide the required operating flexibility and at the same time implement the guides set forth in Section IV.A of 10 CFR Part 50, Appendix I.

The requirement that the appropriate portions of the gaseous radwaste treatment system and the ventilation exhaust treatment system be used when specified provides reasonable assurance that the releases of radioactive materials in gaseous effluents will be kept "as low as is reasonably achievable." This specification implements the requirements of 10 CFR Part 50.36a, General Design Criterion 60 of Appendix A to 10 CFR Part 50, and design objective Section II.D of Appendix I. The limits governing the use of appropriate portions of

the systems were specified as a suitable fraction of the guide set forth in Sections II.B and II.C of 10 CFR Part 50, Appendix I, for gaseous effluents. The cumulative maximum dose to an offsite individual from airborne radioactive effluents is determined in order to verify that the average dose over a 31-day period is reasonably small, even in the unlikely event that the gaseous radwaste treatment or ventilation exhaust systems are not operated during that period.

However, a cumulative dose which exceeds the stated limit does not necessarily imply that all portions of the gaseous and ventilation exhaust treatment systems be used; certain subsystems may have only minimal effect on reducing doses.

The Specification on dose (40 CFR Part 190) is provided to meet the reporting requirements of 40 CFR Part 190. Since the plant is well removed from other fuel cycle facilities, it is sufficient to apply the Specification only to the plant in accordance with methods provided in the ODCM.

The Specification on explosive gas mixture is provided to ensure that the concentration of potentially explosive gas mixtures contained in the gas decay tanks are maintained below the flammability limit of oxygen. Maintaining the concentration of oxygen below its flammability limits provides assurance that the releases

of radioactive materials will be controlled in conformance with the requirements of General Design Criterion 60 of Appendix A to 10 CFR Part 50.

The waste gas decay tank curie limit is provided in order to assure that in the unlikely event of an uncontrolled release of a gas decay tank's contents, the resulting total body gamma exposure to an individual at the nearest exclusion area boundary will not exceed 0.5 rem.

The requirement pertaining to solid radioactive waste is provided to assure that the solid radioactive waste system will be used as appropriate for the processing and packaging of solid radioactive wastes. The specification also establishes the Process Control Program which includes the process parameters and evaluation methods used to ensure meeting the requirements of 10 CFR Part 71 prior to being shipped offsite.

- (3) FSAR, Sections 2.6 and 2.7

3.13

Snubbers

(23.i)

Limiting Condition for Operation

3.13.1

With RCS conditions above cold shutdown, all safety-related

5.5.8

snubbers shall be operable. This specification does not

apply to those snubbers installed on non safety-related systems if the snubber failure, and a resulting failure of the supported non safety-related system shown to be caused by that snubber failure, would have no adverse effect on any safety-related system.

(23.i)

Action

3.13.2

With one or more snubbers inoperable, within 72 hours replace or restore the inoperable snubber(s) to operable status and perform an engineering evaluation per Specification 4.14.1f on the supported component or declare the supported system inoperable and follow the appropriate action statement for that system.

Basis

Snubbers are required to be operable to ensure that the structural integrity of the reactor coolant system and all other safety-related systems is maintained during and following a seismic or other event initiating dynamic loads.

Snubbers may be replaced by rigid structural supports (bumpers) provided an analysis is performed to demonstrate that appropriate acceptance criteria are satisfied for design basis seismic and pipe break events and provided that the bumpers are inspected periodically in a manner appropriate for rigid structural supports.

~~3.14 (DELETED)~~

~~INTENTIONALLY LEFT BLANK~~

~~Amendment No. 49 3.14-1~~

3.15 Overpressure Protection System

Applicability

Applies whenever the temperature of one or more of the RCS cold legs is $\leq 330^{\circ}\text{F}$, or the Residual Heat Removal System is in operation.

Objective

To prevent overpressurization of the reactor coolant system and the residual heat removal system.

Specification

3.15.1 Except during secondary side hydrostatic tests in which RCS pressure is to be raised above the PORV setpoint, at least one of the following over-pressure protection systems shall be operable:

- a. Two pressurizer power operated relief valves (PORVs) with a lift setting of ≤ 424 psig, or
- b. A reactor coolant system vent of ≥ 1.1 square inches.

3.15.1.1 With one PORV inoperable, either restore the inoperable PORV to operable status within 7 days or depressurize and vent the RCS through a 1.1 square inch vent(s) within the next 8 hours; maintain the RCS in a vented condition until both PORVs have been restored to operable status.

3.15.1.2 With both PORVs inoperable, depressurize and vent the RCS through a 1.1 square inch vent(s) within 8 hours; maintain the RCS in a vented condition until both PORVs have been restored to operable status.

5.6.4

3.15.1.3 Use of the overpressure protection system to mitigate an RCS or RHRS pressure transient shall be reported in accordance with 6.9/2.

(25.v)

Basis

An RCS vent opening of greater than 1.1 square inches ensures that the RCS will be protected from pressure transients which could exceed the limits of Appendix G to 10 CFR Part 50 when one or more of the RCS cold legs are $\leq 330^{\circ}\text{F}$. This relief capacity will

26.i

3.16 Radiological Environmental Monitoring

Applicability

Applies to routine testing of the plant environs.

Objective

To establish a program which will assure recognition of changes in radioactivity or exposure pathways in the environs.

Specification

3.16.1 Monitoring Program

3.16.1.1 The radiological environmental monitoring program shall be conducted as specified in Table 3.16-1 at the locations given in the ODCM.

3.16.1.2 If the radiological environmental monitoring program is not conducted as specified in Table 3.16-1, prepare and submit to the Commission, in the Annual Radiological Environmental Operating Report, a description of the reasons for not conducting the program as required and the plans for preventing a recurrence. (Deviations are permitted from the required sampling schedule if specimens are unobtainable due to hazardous conditions, seasonal availability, or to malfunction of automatic sampling equipment. If the latter, efforts shall be made to complete corrective action prior to the end of the next sampling period.)

3.16.1.3 If the level of radioactivity in an environmental sampling medium at one or more of the locations specified in the ODCM exceeds the reporting levels of Table

26.i

6.9-2 when averaged over any calendar quarter, a Special Report shall be submitted to the Commission within thirty days which includes an evaluation of any release conditions, environmental factors or other aspects which caused the reporting levels of Table 6.9-2 to be exceeded.

When more than one of the radionuclides in Table 6.9-2 are detected in the sampling medium, this report shall be submitted if:

$$\frac{\text{concentration (1)}}{\text{limit level (1)}} + \frac{\text{concentration (2)}}{\text{limit level (2)}} + \dots \geq 1.0$$

When radionuclides other than those in Table 6.9-2 are detected and are the result of plant effluents, this report shall be submitted if the potential annual dose to an individual is greater than the calendar year limit of Specifications 3.9.1.2.a or 3.9.2.2.b. This report is not required if the measured level of radioactivity was not the result of plant effluents; however, in such an event, the condition shall be reported and described in the Annual Radiological Environmental Operating Report.

3.16.1.4 If milk or fresh leafy vegetable samples are unavailable for more than one sample period from one or more of the sampling locations indicated by the ODCM, a discussion shall be included in the Radioactive Effluent Release Report which identifies the cause of the unavailability of samples and identifies locations for

26.ii

obtaining replacement samples. If a milk or leafy vegetable sample location becomes unavailable, the locations from which samples were unavailable may then be deleted from the ODCM, provided that comparable locations are added to the environmental monitoring program.

3.16.2 Land Use Census

3.16.2.1 A land use census shall be conducted and shall identify the location of the nearest milk animal and the nearest residence in each of the 16 meteorological sectors within a distance of five miles.

3.16.2.2 An onsite garden located in the meteorological sector having the highest historical D/Q may be used for broad leaf vegetation sampling in lieu of a garden census; otherwise the land use census shall also identify the location of the nearest garden of greater than 500 square feet in each of the 16 meteorological sectors within a distance of five miles. D/Q shall be determined in accordance with methods described in the ODCM.

3.16.2.3 If a land use census identifies a location(s) which yields a calculated dose or dose commitment greater than that of the maximally exposed individual currently being calculated in Specification 3.12.2.2, the new identified location(s) shall be reported in the Semi-annual Radioactive Release Report.

26.ii

26.ii

3.16.2.4 If a land use census identifies a milk location(s) which yields a calculated dose or dose commitment greater than that at a location from which samples are currently being obtained in accordance with Specification 3.16.1, the new identified location(s) shall be reported in the Semiannual Radioactive Release Report. The new location shall be added to the radiological environmental monitoring program within thirty days, if possible. The milk location having the lowest calculated dose or dose commitment may be deleted from this monitoring program after October 31 of the year in which this land use census was conducted.

3.16.3 Interlaboratory Comparison Program

3.16.3.1 Analyses shall be performed on applicable radioactive environmental samples supplied as part of an interlaboratory comparison program which has been approved by NRC, if such a program exists.

3.16.3.2 If analyses are not performed as required above, report the corrective actions taken to prevent a recurrence in the Annual Radiological Environmental Operating Report.

26.iii

Basis

The radiological monitoring program required by this specification provides measurements of radiation and of radioactive materials in those exposure pathways and for those radionuclides which lead to the highest potential radiation exposures of individuals resulting

from the station operation. This monitoring program thereby supplements the radiological effluent monitoring program by verifying that the measurable concentrations of radioactive materials and levels of radiation are not higher than expected on the basis of the effluent measurements and modeling of the environmental exposure pathways. The initially specified monitoring program will be effective for at least three years. Following this period, program changes may be initiated based on operational experience. The detection capabilities required by Table 4.10-1 are state-of-the-art for routine environmental measurements in industrial laboratories. Lower limits of detection (LLDs) are intended as a priori (before-the-fact) limits, and analyses will be conducted in such a manner that the stated LLDs will be achieved under routine conditions. The land use census requirement is provided to ensure that changes in the use of unrestricted areas are identified and that modifications to the monitoring program are made if required by the results of this census. A garden census is not required if an onsite garden is located in the meteorological sector having the highest historical D/Q is used for broad leaf vegetation sampling. This census satisfies the requirements of Section IV.B.3 of Appendix I to 10 CFR Part 50.

The requirement for participation in an interlaboratory comparison program is provided to ensure that independent checks on the precision and accuracy of the measurements of radioactive material in environmental sample matrices are performed as part of a quality assurance program for environmental monitoring in order to demonstrate that the results are reasonably valid. Only samples with radioactivity levels comparable to levels in environmental samples need be analyzed.

TABLE 3.16-1

RADIOLOGICAL ENVIRONMENTAL MONITORING PROGRAM

<u>Exposure Pathway and/or Sample</u>	<u>Number of Samples and Sample Locations</u>	<u>Sampling and Collection Frequency</u>	<u>Type and Frequency of Analysis</u>
1. AIRBORNE			
a. Radioiodine	2 indicator 2 control	Continuous operation of sampler with sample collection at least once per 10 days.	Radioiodine canister. Analyze within 7 days of collection of I-131
b. Particulates	7 indicator 5 control	Same as above.	Particulate sampler. Analyze for gross beta radioactivity \geq 24 hours following filter change. Perform gamma isotopic analysis on each sample for which gross beta activity is > 10 times the mean of offsite samples. Perform gamma isotopic analysis on composite (by location) sample at least once per 92 days.
2. DIRECT RADIATION	18 indicator 10 control 11 placed greater than 5 miles from plant site	TLDs at least quarterly.	Gamma dose quarterly.

4. INGESTION			
a. Milk	1 control 3 indicator June thru October each of 3 farms	At least once per 15 days.	Gamma isotopic and I-131 analysis of each sample.
	1 control 1 indicator November thru May one of the farms	At least once per 31 days.	Gamma isotopic and I-131 analysis of each sample.
b. Fish	4 control 4 indicator (Off shore at Ginna)	Twice during fishing season including at least four species.	Gamma isotopic analysis on edible portions of each sample.
c. Food Products	1 control 2 indicator (On site)	Annual at time of harvest. Sample from two of the following: 1. apples 2. cherries 3. grapes	Gamma isotopic analysis on edible portion of sample.
	1 control 2 indicator (On site garden or nearest offsite garden within 5 miles in the highest D/Q meteorological sector)	At time of harvest. One sample of: 1. broad leaf vegetation 2. other vegetable	Gamma isotopic analysis on edible portions of each sample.

3-16-9

See Chapter 3.3

4.0 SURVEILLANCE REQUIREMENTS

Specified intervals may be adjusted plus or minus 25% to accommodate normal test schedules.

4.1 Operational Safety Review

Applicability:

Applies to items directly related to safety limits and limiting conditions for operation.

Objective:

To specify the minimum frequency and type of surveillance to be applied to plant equipment and conditions.

Specification:

4.1.1 Calibration, testing, and checking of analog channel and testing of logic channel shall be performed as specified in Table 4.1-1.

4.1.2 Equipment and sampling tests shall be conducted as specified in Table 4.1-2 and 4.1-4.

4.1.3 Each accident monitoring instrumentation channel shall be demonstrated operable by performance of the channel check and channel calibration operations at the frequencies shown in Table 4.1-3.

~~4.1.4 Each radioactive effluent monitoring instrumentation channel shall be demonstrated operable by performing the channel check, source check, channel functional test, and channel calibration at the frequency shown in Table 4.1-5.~~

28.v.b

See Chapter 3.3

Basis:

Check

Failures such as blown instrument fuses, defective indicators, faulted amplifiers which result in "upscale" or "downscale" indication can be easily recognized by simple observation of the functioning of an instrument or system. Furthermore, such failures are, in many cases, revealed by alarm or annunciator action, and a check supplements this type of built-in surveillance.

Based on experience in operation of both conventional and nuclear plant systems, when the plant is in operation, the minimum checking frequency of once per shift is deemed adequate for reactor and steam system instrumentation.

Control Room procedures require a check of the Radiation Monitoring System (RMS) panel meters and strip chart recorders for proper readout once each shift. A daily surveillance log is also maintained in the Control Room for manual entry of RMS readouts, and is independently reviewed by Health Physics supervision at least weekly.

~~A radiation monitor downscale failure will result in a conspicuous visual indication on the RMS panel (no audible alarm). Radiation monitor control switches are spring-returned to the "operate" mode after being turned to any other test or check mode. Therefore, together with the design features of the RMS, plant surveillance procedures ensure the continued availability of each radiation monitor to perform its intended function.~~

28.v.b

TABLE 4.1-5 (Continued)

TABLE NOTATION

- (1) The Channel Functional Test shall also demonstrate that automatic isolation of this pathway and control room alarm occur if any of the following conditions exist:
 - 1. Instrument indicates measured levels above the alarm and/or trip setpoint.
 - 2. Power failure.
- (2) The Channel Functional Test shall also demonstrate that control room alarm occurs if any of the following conditions exist:
 - 1. Instrument indicates measured levels above the alarm setpoint.
 - 2. Power failure.
- (3) The Channel Calibration shall include the use of standard gas samples containing a nominal:
 - 1. Zero volume percent oxygen; and
 - 2. Three volume percent oxygen.
- (4) This check may require the use of an external source due to high background in the sample chamber.
- (5) Source used for the Channel Calibration shall be traceable to the National Bureau of Standards (NBS) or shall be obtained from suppliers (e.g. Amersham) that provide sources traceable to other officially-designated standards agencies.
- (6) Flow rate for main plant ventilation exhaust and containment purge exhaust are calculated by the flow capacity of ventilation exhaust fans in service and shall be determined at the frequency specified.
- (7) Applies only during releases via this pathway.

4.2 Inservice Inspection

Applicability

Applies to the inservice inspection of Quality Groups A, B, and C Components, High Energy Piping Outside of Containment, Snubbers and Steam Generator tubes. It also applies to inservice pump and valve testing.

29.i

Objectives

To provide assurance of the continuing structural and operational integrity of the structures, components and systems in accordance with the requirements of 10 CFR 50.55a(g).

Specification

4.2.1 The inservice inspection program for Quality Groups A, B, and

5.5.7 and
5.5.8

C Components, High Energy Piping Outside of Containment,

Snubbers and Steam Generator tubes shall be in accordance with

Appendix B of the Ginna Station Quality Assurance Manual.

29.i

This inservice pump and valve testing program shall be in accordance with Appendix C of the Ginna Station Quality Assurance Manual. These inservice inspection programs shall

define the specific requirements of the edition and Addenda of the ASME Boiler and Pressure Vessel Code, Section XI, which are applicable for the forty month period of the ten year inspection interval. The programs' ten year inspection interval shall be based on the following commencing dates.

The Nelson Policy Manual.

4.2.1.1 The inspection interval for Quality Group A components shall be ten year intervals of service commencing on January 1, 1970.

4.2.1.2 The inspection intervals for Quality Group B and C Components shall be ten year intervals of service commencing with May 1, 1973, January 1, 1980, 1990 and 2000, respectively.

4.2.1.3 The inspection intervals for the High Energy Piping Outside of Containment shall be ten year intervals of service commencing May 1, 1973, January 1, 1980, 1990 and 2000, respectively. The inspection program during each third of the first inspection interval provides for examination of all welds at design basis break locations and one-third of all welds at locations where a weld failure would result in unacceptable consequences. During each succeeding inspection interval, the program shall provide for an examination of each of the design basis break location welds, and each of the welds at locations where a weld failure would result in unacceptable consequences.

4.2.1.4 The inspection intervals for Steam Generator Tubes shall be specified in the "Inservice Inspection Program" for the applicable forty month period commencing with May 1, 1973.

5.5.8.a

(29.i)

4.2.1.4.a Steam generator tubes that have imperfections greater than 40% through wall, as indicated by eddy current, shall be repaired by plugging or sleeving.

5.5.8.b

4.2.1.4.b Steam generator sleeves that have imperfections greater than 30% through wall, as indicated by eddy current, shall be repaired by plugging.

5.5.8.c

4.2.1.5 Inservice Inspection of ASME Code Class 1, Class 2 and Class 3 components (Quality Groups A, B, and C) shall be performed in accordance with Section XI of the ASME Boiler and Pressure Vessel Code and applicable Addenda as required by 10 CFR 50, Section 50.55a(g), except where specific written relief has been granted by the NRC pursuant to 10 CFR 50, Section 50.55a(g)(6)(i).

29.i- 4.2.1.6 The inspection interval for the Inservice Pump and Valve Testing Program shall be ten year intervals commencing with January 1, 1981, 1990 and 2000.

4.2.1.7 The inspection intervals for Snubbers shall be as defined in Specification 4.14.

Basis

The inservice inspection program provides assurance for the continued structural integrity of the structures, components and systems of Ginna Station. The programs comply with the ASME Boiler and Vessel Code Section XI "Rules for Inservice Inspection of Nuclear Power Plant Components" as practicable, with due consideration to the design and physical access of the structures, components and systems as manufactured and constructed. This compliance will constitute an acceptable basis for satisfying the requirements of General Design Criterion 32, Appendix A of 10 CFR Part 50 and the requirements of Section 50.55a, paragraph g of 10 CFR Part 50.

The repair criteria of 4.2.1.4.a and 4.2.1.4.b are based on the requirements of USNRC Regulatory Guide 1.121, "Bases for Plugging Degraded PWR Steam Generator Tubes" as implemented by RG&E (Reference 1). This guide describes a method acceptable to the NRC staff for establishing the limiting safe conditions of tube degradation of steam generator tubing. The repair criteria is based on structural allowances, an allowance for eddy current measurement error and an allowance for degradation during the operating period. These allowances are added together to determine the repair criteria which is typically 40% for steam generator tubes. Based on calculations the appropriate sleeve plugging limit is a 42% thru wall defect. In order to allow for conservatism, a 30% plugging limit for sleeves will be utilized.

~~Amendment No. 35~~

~~Correction letter of July 3, 1990 4.2-4~~

4.4.3 Recirculation Heat Removal Systems

4.4.3.1 Test

5.5.2

- a. The portion of the residual heat removal system that is outside the containment shall ~~either~~ be tested by use in normal operation or hydrostatically tested at 350 psig at the interval specified in 4.4.3.4.
- b. Suction piping from containment sump B to the reactor coolant drain tank pump and the discharge piping from the pumps to the residual heat removal system shall be hydrostatically tested at no less than 100 psig at the interval specified in 4.4.3.4.

31:ii

31.ii

- c. Visual inspection shall be made for excessive leakage from components of the system. Any significant leakage shall be measured by collection and weighing or by an equivalent method.

4.4.3.2 Acceptance Criterion

The maximum allowable leakage from the recirculation heat removal systems components (which includes valve stems, flanges and pump seals) shall not exceed two gallons per hour.

4.4.3.3 Correction Action

- a. Repairs shall be made as required to maintain leakage within the acceptance criterion of 4.4.3.2.
- b. If repairs are not completed within 24 hours, the reactor shall be shut down and depressurized until repairs are effected and the acceptance criterion of 4.4.3.2 is satisfied.

4.4.3.4 Test Frequency

Tests of the recirculation heat removal system shall be conducted at intervals not to exceed 12 months.

5.5.6 4.4.4 Tendon Stress Surveillance

4.4.4.1 Inspection for Broken Wire

31.i

- a. Fourteen specific tendons, equally spaced around the

containment shall be inspected periodically for the presence of broken wires.

- b. The inspection intervals, measured from the date of the initial structural test, shall be as follows:
- 6 months
 - 1 year
 - 3 years
 - 8 years and 5 years intervals thereafter.
- c. The acceptance criteria for the inspection are that no more than a total of 38 wires (in 14 tendons) are broken and that not more than 6 broken wires exist in any one tendon. If more than 38 broken wires are found, all tendons shall be inspected. If inspection reveals more than 5% of the total wires broken, the reactor shall be shut down and depressurized.
- d. If more than 20 wires (in 14 tendons) have been broken since the last inspection, all tendons shall be inspected. If inspection reveals more than 5% of the total wires broken, the reactor shall be shut down and depressurized.
- e. If as many as 6 broken wires are found in any one tendon, four immediately adjacent tendons (two on each side of

31.0.2

31.27

the tendon containing 6 broken wires) shall be inspected. The accepted criterion then shall be no more than 4 broken wires in any of the additional 4 tendons. If this criterion is not satisfied, all of the tendons shall be inspected and if more than 5% of the total wires are broken, the reactor shall be shut down and depressurized.

4.4.4.2 Pre-Stress Confirmation Test

- a. Lift-off tests shall be performed on the 14 tendons identified in 4.4.4.1a above, at the intervals specified in 4.4.4.1b. If the average stress in the 14 tendons checked is less than 144,000 psi (60% of ultimate stress), all tendons shall be checked for stress and retensioned, if necessary, to a stress of 144,000 psi.
- b. Before reseating, a tendon, additional stress (6%) shall be imposed to verify the ability of the tendon to sustain the added stress applied during accident conditions.

4.4.5 Containment Isolation Valves

4.4.5.1 Each containment isolation valve shall be demonstrated to be OPERABLE in accordance with the Ginna Station Pump and Valve Test program submitted in accordance with 10 CFR 50.55a.

4.4.6 Containment Isolation Response

4.4.6.1 Each containment isolation instrumentation channel shall be demonstrated OPERABLE by the performance of the CHANNEL CHECK, CHANNEL CALIBRATION, and CHANNEL FUNCTIONAL TEST operations for the MODES and at the frequencies shown in Table 4.1-1.

4.4.6.2 The response time of each containment isolation valve shall be demonstrated to be within its limit at least once per 18 months. The response time includes only the valve travel time for those valves which the safety analysis assumptions take credit for a change in valve position in response to a containment isolation signal.

Addressed with Chapter 3.6

pressure, 350 psig, achieved either by normal system operation or by hydrostatic testing, gives an adequate margin over the highest pressure within the system after a design basis accident. Similarly, the hydrostatic test pressure for the containment sump return lines and the reactor coolant drain tank piping connections to the residual heat removal system of 100 psig gives an adequate margin over the highest pressure within the lines after a design basis accident. (4)

A recirculation system leakage of 2 gal./hr will limit offsite exposure due to leakage to insignificant levels relative to those calculated for leakage directly from the containment in the design basis accident. The dose calculated as a result of this leakage is 7.7 mr for a 2-hr exposure at the site boundary. (5)

In case of failure to meet the acceptance criteria for leakage from the residual heat removal system or the penetrations, it may be possible to effect repairs within a short time. If so, it is considered unnecessary and unjustified to shut down the reactor. The times allowed for repairs are consistent with the times developed in Specification 3.3.

The tendon surveillance program is based on assuring that, on the average, the load-carrying capability of the tendons is maintained at approximately 95% design.

This is consistent with the design criteria for the tendons, which allow for uniform capacity reduction of 0.95 and which contemplate that a small fraction of the individual wires 0.03--0.5% may break during tensioning. (6)

Periodic visual inspection is the method to be used to determine loss of load-carrying capability because of wire breakage. Since the tendon is under a stress of approximately 144,000 psi, should a wire break, the button head will rise above the top anchor head where it can be readily observed. Assuming that 38 broken wires are observed in 14 tendons (90 wires per tendon), which corresponds to a mean breakage of 3% (97% design load-carrying capability), it can be stated with 95% confidence that the fraction of broken wires in the total containment is between 2.1 and 4.0%. This is based on reliability tables developed by North American Aviation, (7) for statistical situations that can be represented by a Poisson distribution. A condition for fitting a Poisson distribution is that the possibility of wire breakage is constant and small. The specification relating to as many as 6 broken wires in one tendon (6.6%) provides that the assumption of a constant probability of occurrence is not significantly violated. The design load can be carried even if three adjacent tendons fail completely. (8) The specification has the purpose of alerting against possible deterioration at any time in the plant operating 1st time.

The pre-stress confirmation test provides a direct measure of the load-carrying capability of the tendon.

If the surveillance program indicates by extensive wire breakage or tendon stress relation that the pre-stressing tendons are not behaving as expected, the situation will be evaluated immediately. The specified acceptance criteria are such as to alert attention to the situation well before the tendon load-carrying capability would deteriorate to a point that failure during a design basis accident might be possible. Thus the cause of the incipient deterioration could be evaluated and corrective action studied without need to shut down the reactor. The containment is provided with two readily removable tendons that might be useful to such a study. In addition, there are 40 tendons, each containing a removable wire which will be used to monitor for possible corrosion effects.

Operability of the containment isolation boundaries ensures that the containment atmosphere will be isolated from the outside environment in the event of a release of radioactive material to the containment atmosphere or pressurization of the containment. Performance of cycling tests and verification of isolation times associated with automatic containment isolation valves is covered by the Pump and Valve Test Program. Compliance with Appendix J to 10 CFR 50 is addressed under local leak testing requirements.

of the spray additive valves closed, each valve will be opened and closed by operator action. This test shall be performed prior to startup if the time since the last test exceeds one month.

c. The accumulator check valves shall be checked for operability during each refueling shutdown.

4.5.2.3 Air Filtration System

4.5.2.3.1

At least once every 18 months or after every 720 hours of charcoal filtration system operation since the last test, or following painting, fire or chemical release in any ventilation zone communicating with the system, the post accident

32.v

5.5.10.a

charcoal system shall have the following conditions demonstrated:

- a. The pressure drop across the charcoal adsorber bank is less than 3 inches of water at design flow rate ($\pm 10\%$).
- b. In place Freon testing, under ambient conditions, shall show at least 99% removal.

32.v

c. The iodine removal efficiency of at least one charcoal filter cell shall be measured. The filter cell to be tested shall be selected randomly from those cells with the longest in-bank residence time. The minimum

32.v

acceptable value for filter efficiency is 90% for removal of methyl iodide when tested at at least 286°F

32.v

and 95% RH and at 1.5 to 2.0 mg/m³ loading with tagged CH₃I.

32.v

4.5.2.3.2 After each replacement of a charcoal drawer or after any structural maintenance on the housing for the post accident charcoal system, the condition of Specification 4.5.2.3.1.b shall be demonstrated for the affected portion of the system.

32.v

4.5.2.3.3 At least every 18 months or following painting, fire, or chemical release in any ventilation zone communicating with the system, the containment recirculation system shall have the following conditions demonstrated.

32.v

5.5.10.b a. The pressure drop across the HEPA filter bank is less than 3 inches of water at design flow rate ($\pm 10\%$).

32.v

32.v

b. In place ~~thermally generated~~ DOP testing of the HEPA filters shall show at least 99% removal.

4.5.2.3.4 After each complete or partial replacement of the HEPA filter bank or after any structural maintenance on a housing for the containment recirculation system, the condition of Specification 4.5.2.3.3.b shall be demonstrated for the affected portion of the system.

32.v

4.5.2.3.5 Except during cold or refueling shutdowns the post accident charcoal filter isolation valves shall be tested at intervals not greater than one month to verify operability and proper orientation and flow shall be maintained through the system for at least 15 minutes. The test shall be performed prior to startup if the time since the last test exceeds 1 month.

Addressed w/
Chapter 3.6

4.5.2.3.6

At least once every 18 months or after every 720 hours of charcoal filtration system operation since the last test, or following painting, fire or chemical release in any ventilation zone communicating with the system, the control room emergency air treatment system shall have the following conditions demonstrated.

32.v

5.5.10.c

32.vi

32.v

a. The pressure drop across the combined HEPA filters and charcoal adsorber banks is less than 6" of water at design flow rate ($\pm 10\%$).

b. In place Freon testing, under ambient conditions, shall show at least 99% removal.

32.v

c. In place ~~thermally generated~~ DCP testing of the HEPA filters shall show at least 99% removal.

d. The results of laboratory analysis on a carbon sample shall show 90% or greater radioactive methyl iodide removal when tested at at least 125°F and 95% RH and at

32.v

32.v

1.5 to 2.0 mg/m³ loading with tagged CH₃I.

4.5.2.3.7

After each complete or partial replacement of the HEPA filter bank or after any structural maintenance on the HEPA housing for the control room emergency air treatment system, the condition of Specification 4.5.2.3.6.c shall be demonstrated for the affected portion of the system.

4.5.2.3.8

After each replacement of a charcoal drawer or after any structural maintenance on the charcoal housing for the control room emergency air treatment system, the condition of Specification 4.5.2.3.6.b shall be demonstrated for the affected portion of the system.

Addressed in
Chapter 3.7

4.5.2.3.9 Except during cold or refueling shutdowns the automatic initiation of the control room emergency air treatment system shall be tested at intervals not to exceed one month to verify operability and proper orientation and flow shall be maintained through the system for at least 15 minutes. The test shall be performed prior to startup if the time since the last test exceeds one month.

Basis:

The Safety Injection System and the Containment Spray System are principal plant safeguards that are normally inoperative during reactor operation.

Complete systems tests cannot be performed when the reactor is operating because a Safety Injection signal causes containment isolation and a Containment Spray System test requires the system to be temporarily disabled. The method of assuring operability of these systems is therefore to combine systems tests to be performed during annual plant shutdowns, with more frequent component tests, which can be performed during reactor operation.

The annual systems tests demonstrate proper automatic operation of the Safety Injection and Containment Spray Systems. With the pumps blocked from starting, a test signal is applied to initiate automatic action

and verification made that the components receive the safety injection in the proper sequence. The test demonstrates the operation of the valves, pump circuit breakers, and automatic circuitry.⁽¹⁾

During reactor operation, the instrumentation which is depended on to initiate safety injection and containment spray is generally checked daily and the initiating circuits are tested monthly. In addition, the active components (pumps and valves) are to be tested monthly to check the operation of the starting circuits and to verify that the pumps are in satisfactory running order and develop the minimum required pressure to meet accident conditions.⁽²⁾ The minimum discharge pressure values listed in Table 4.5-1 are based on an assumed degradation of the pump head-capacity (characteristic) curve adjusted to water temperature of 60°F as follows:

Containment Spray Pumps	5%*
Residual Heat Removal Pumps	5%*
Safety Injection Pumps	3%*

*Percentage is based on the head at the best efficiency point of flow.

The test interval of one month is based on the judgement that more frequent testing would not significantly increase the reliability (i.e., the probability that the component would operate when required) and would result in increased wear over long periods of time.

Other systems that are also important to the emergency cooling function are the accumulators, the component cooling system, the service water system and the containment fan coolers. The accumulators are a passive safeguard. In accordance with the specifications, the water volume and pressure in the accumulators are checked periodically. The other systems mentioned operate when the reactor is in operation and by these means are continuously monitored for satisfactory performance. The reactor coolant drain tank pumps operate intermittently during reactor operation, and thus are also monitored for satisfactory performance.

The air filtration portion of the containment air recirculation system is a passive safeguard which is isolated from the cooling air flow during normal reactor operation. Hence the charcoal should have a long useful lifetime. The filter frames that house the charcoal are stainless steel and should also last indefinitely. The pressure drop, filter efficiency, and valve operation test frequencies will assure that the system can operate to meet its design function under accident conditions. As the adsorbing charcoal is normally isolated, the test schedule, related to hours of operation as well as elapsed time, will assure that it does not degrade below the required adsorption

efficiency. The test conditions for charcoal sample adsorbing efficiency are those which might be encountered under an accident situation.⁽³⁾

The control room air treatment system is designed to filter the control room atmosphere (recirculation and intake air) during control room isolation conditions. HEPA filters are installed before the charcoal filters to remove particulate matter and prevent clogging of the iodine adsorbers. The charcoal filters reduce the airborne radioiodine in the control room. Bypass leakage must be at a minimum in order for these filters to perform their designed function. If the performances are as specified the calculated doses will be less than those analyzed.⁽⁴⁾

Retesting of the post accident charcoal system or the control room emergency air treatment system in the event of painting, fire, or chemical release is required only if the system is operating and is providing filtration for the area in which the painting, fire, or chemical release occurs.

Testing of the air filtration systems will be, to the extent it can, given the configuration of the systems, in accordance with ANSI N510-1975, "Testing of Nuclear Air-Cleaning Systems."

and operates for \geq five minutes while its generator is loaded with emergency loads.

- (c) Verifying that all diesel generator trips, except engine overspeed, low lube oil pressure, and overcrank, are automatically bypassed upon a safety injection actuation signal.

37.1

4.10 Radiological Environmental Monitoring

Applicability - Applies to routine testing of plant environs.

Objective - To establish a sampling and analysis program which will assure recognition of changes in radioactivity in the environs.

Specification

4.10.1 The radiological environmental monitoring samples shall be collected pursuant to Table 3.16-1. Acceptable locations are shown in the ODCM. Samples shall be analyzed pursuant to the requirements of Tables 3.16-1 and 4.10-1.

37.1

4.10.2 A land use census shall be conducted annually (between June 1 and October 1).

37.1

4.10.3 A summary of the results obtained as part of the required Interlaboratory Comparison Program shall be included in the Annual Radiological Environmental Operating Report.

Basis

The environmental survey has been designed to utilize the knowledge about dilution in the atmosphere and in the lake which has been gained during the pre-operational and operational period of study.

The radiological monitoring program provides measurements of radiation and of radioactive materials in those exposure pathways and for those radionuclides which lead to the highest potential radiation exposures of individuals resulting from the station operation. This

monitoring program thereby supplements the radiological effluent monitoring program by verifying that the measurable concentrations of radioactive materials and levels of radiation are not higher than expected on the basis of the effluent measurements and modeling of the environmental exposure pathways.

The detection capabilities required by Table 4.10-1 are state-of-the-art for routine environmental measurements in industrial laboratories. The specified lower limits of detection for I-131 in water, milk, and other food products correspond to approximately one-quarter of the 10 CFR Part 50 Appendix I design objective dose-equivalent of 15 mrem/year for atmospheric releases and 10 mrem/year for liquid releases to the maximally exposed organ and individual.

Participation in an approved interlaboratory comparison program assures that the adequacy of environmental laboratory measurements is maintained on a continuing basis through independent cross-checking.

TABLE 4.10-1

MAXIMUM VALUES FOR THE LOWER LIMITS OF DETECTION (LLD)^a

To be achieved on 98% of analyses

371

TABLE 4.10-1 (Continued)

TABLE NOTATION

a - The LLD is the smallest concentration of radioactive material in a sample that will be detected with 95% probability with only 5% probability of falsely concluding its presence.

For a particular measurement system (which may include radiochemical separation):

$$LLD = \frac{4.66 s_b}{E \cdot V \cdot 2.22 \cdot Y \cdot \exp(-\lambda \Delta t)}$$

where

LLD is the lower limit of detection as defined above (as pCi per unit mass or volume)

s_b is the standard deviation of the background counting rate or of the counting rate of a blank sample as appropriate (as counts per minute).

E is the counting efficiency (as counts per transformation)

V is the sample size (in units of mass or volume)

2.22 is the number of transformations per minute per picocurie

Y is the fractional radiochemical yield (when applicable)

λ is the radioactive decay constant for the particular radionuclide

Δt is the elapsed time between sample collection and analysis

The value of s_b used in the calculation of the LLD for a detection system shall be based on the actual observed variance of the background counting rate or of the counting rate of the blank samples (as appropriate) rather than on an unverified theoretically predicted variance. In calculating the LLD for a radionuclide determined by gamma-ray spectrometry, the background shall include the typical contributions of other radionuclides normally present in the samples (e.g., potassium-40 in milk samples). Typical values of E, V, Y and Δt should be used in the calculations.

Analyses shall be performed in such a manner that the stated LLDs will be achieved under routine conditions. Occasionally background fluctuations, unavoidably small

37.2

TABLE 4.10-1 (Continued)

TABLE NOTATION

sample sizes, the presence of interfering nuclides, or other uncontrollable circumstances may render these LLDs unachievable. In such cases, the contributing factors will be identified and described in the Annual Radiological Environmental Operating Report.

The LLD is defined as an a priori (before the fact) limit representing the capability of a measurement system and not as a posteriori (after the fact) limit for a particular measurement.

- b - LLD for drinking water.
- c - Total for parent and daughter.

4.11

Refueling

Applicability

Applies to refueling and to fuel handling in the spent fuel pool.

Specification

4.11.1

Spent Fuel Pit Charcoal Adsorber System

4.11.1.1

Within 60 days prior to any operation of the spent fuel pool charcoal adsorber system as required by Section

38.c

5.5.10

3.11, the following conditions shall be demonstrated.

After the conditions have been demonstrated, the occurrence of painting, fire, or chemical release in any ventilation zone communicating with the spent fuel pool charcoal adsorber system shall require that the following conditions be redemonstrated, before fuel handling may continue, if operation of the spent fuel pool charcoal adsorber system is required per section 3.11

38.i

a. The total air flow rate from the charcoal adsorbers shall be at least 75% of that measured with a complete set of new absorbers.

38.ii

b. In-place Freon testing, under ambient conditions, shall show at least 99% removal.

c. The results of laboratory analysis on a carbon sample shall show 90% or greater radioactive methyl iodide removal when tested at least 150°F and 95% RH and at 1.5 to 2.0 mg/m³ loading with tagged CH₃I.

38.i

4.11

Addressed w/
Chapter 3.7

- d. Flow shall be maintained through the system using either the filter or bypass flow path for at least 15 minutes each month.

38.i 4.11.1.2 After each replacement of a charcoal filter drawer or after any structural maintenance on the charcoal housing for the spent fuel pit charcoal adsorber system, the condition of Specification 4.11.1.1.b shall be demonstrated for the affected portion of the system.

4.11.2 Residual Heat Removal and Coolant Circulation

4.11.2.1 When the reactor is in the refueling mode and fuel is in the reactor, at least one residual heat removal loop shall be verified to be in operation and circulating reactor coolant at least once per 4 hours.

4.11.2.2 When the water level above the top of reactor vessel flange is less than 23 feet, both RHR pumps shall be verified to be operable by performing the surveillance specified in the Inservice Pump and Valve Test Program prepared pursuant to 10 CFR 50.55a.

4.11.3 Water Level - Reactor Vessel

4.11.3.1 The water level in the reactor cavity shall be determined to be at least its minimum required depth within 2 hours prior to the start of and at least once per 24 hours thereafter during movement of fuel assemblies or control rods in containment.

Basis

The measurement of the air flow assures that air is being withdrawn from the spent fuel pit area and passed through the adsorbers. The flow is measured prior to employing the adsorbers to establish that

Addressed w/
Chapter 3.9

there has been no gross change in performance since the system was last used. The Freon test provides a measure of the amount of leakage from around the charcoal adsorbent.

The ability of charcoal to adsorb iodine can deteriorate as the charcoal ages and weathers. Testing the capacity of the charcoal to adsorb iodine assures that an acceptable removal efficiency under operating conditions would be obtained. The difference between the test requirement of a removal efficiency of 90% for methyl iodine and the percentage assumed in the evaluation of the fuel handling accident provides adequate safety margin for degradation of the filter after the tests.

Retesting of the spent fuel pit charcoal adsorber system in the event of painting, fire, or chemical release is required only if the system is operating and is providing filtration for the area in which the painting, fire, or chemical release occurs.

Testing of the air filtration systems will be tested, to the extent it can be given the configuration of the systems, in accordance with ANSI N510-1975, "Testing of Nuclear Air-Cleaning Systems".

The operability requirements for residual heat removal loops will ensure adequate heat removal while in the refueling mode. The requirement for 23 feet of water above the reactor vessel flange while handling fuel and fuel components in containment is consistent with the assumptions of the fuel handling accident analysis.

Addressed w/ Chapter 3.9

39.i

4.12 Effluent Surveillance

Applicability

Applies to the periodic test and record requirements of the plant effluents.

Objective

To ascertain that radioactive liquid and gaseous releases from the plant are within allowable limits.

Specifications

4.12.1 Liquid Effluents

4.12.1.1 Concentration

4.12.1.1.a The radioactivity content of each batch of radioactive liquid waste to be discharged shall be determined prior to release by sampling and analysis in accordance with Table 4.12-1. The results of pre-release analyses shall be used with the calculational methods in the ODCM to assure that the concentration at the point of release is limited to the values in Specification 3.9.1.1.a.

4.12.1.1.b Post-release analyses of samples composited from batch releases shall be performed in accordance with Table 4.12-1. The results of the post-release analyses shall be used with the calculational methods in the ODCM to assure that the does commitments from liquids were limited to the values in Specification 3.9.1.2.a.

~~4.12.1.2 Dose, Liquid Waste Treatment~~

39.ii

39.ii

4.12.1.2.a Cumulative dose contributions from liquid effluents shall be determined in accordance with the ODCM at least once per 31 days.

4.12.2 Gaseous Wastes

39.iii

4.12.2.1 Release Rate

4.12.2.1.a The effluent continuous monitors as listed in Table 3.5-6 having provisions for the automatic termination of gas decay tank, shutdown purge or mini-purge releases, shall be used to limit releases within the values established in Specification 3.9.2.1 when monitor setpoint values are exceeded.

4.12.2.1.b The dose rate due to radioactive materials, other than noble gases, in gaseous effluents shall be determined in accordance with the methods of the ODCM by obtaining representative samples and performing analyses in accordance with the sampling and analysis program, specified in Table 4.12-2.

39.iv

4.12.2.2 Dose (10 CFR Part 50, Appendix I); Gaseous Waste Treatment.

4.12.2.2.a Cumulative dose contributions from gaseous effluents shall be determined in accordance with the ODCM at least once every 31 days.

4.12.3 Waste Gas Decay Tanks

The quantity of radioactive material contained in each waste gas decay tank shall be determined to be

39.v

4.12-3

(39.v)²

within the limit specified in 3.9.2.6.a at least once per 24 hours if the total primary coolant noble gas concentration exceeds 250 $\mu\text{Ci}/\text{gram}$ and primary coolant gas is being transferred to the gaseous radwaste treatment system.

Basis:

Sufficient tests will be made to be certain that radioactive materials are not released to the environment in quantities greater than allowable. Installed radiation monitoring equipment in the plant will be used in conjunction with laboratory analyses to maintain surveillance of normal effluents.

Sufficient records will be maintained to determine the concentration of radioactive materials in unrestricted areas. Isotopic analysis of representative samples will serve to verify the accuracy of routine samples by identification of significant energy peaks.

The quantity of radioactivity in each gas decay tank is determined when the noble gas concentration in the primary coolant system increases significantly enough to potentially contribute an appreciable quantity of noble gas activity to the gaseous radwaste system.

The required surveillance will be initiated at a primary noble gas concentration level which, if attained will still allow sufficient margin below the specified curie limit for a single gas decay tank.

Determination of tank curie content may be performed by sampling and/or calculation.

39.1

TABLE 4.12-1

RADIOACTIVE LIQUID WASTE SAMPLING AND ANALYSIS PROGRAM

* If **gross** beta is performed for batch releases, then a weekly composite shall also be analyzed for Principal Gamma Emitters and I-131.

**Service water samples shall be taken and analyzed once per 12 hours if alarm setpoint is reached on continuous monitor.

39.1

TABLE 4.12-1 (Continued)

TABLE NOTATION

a. The LLD is the smallest concentration of radioactive material in a sample that will be detected with 95% probability with 5% probability of falsely concluding its presence.

For a particular measurement system (which may include radiochemical separation):

$$LLD = \frac{4.66 s_b}{E \cdot V \cdot 2.22 \times 10^6 \cdot Y \cdot \exp(-\lambda \Delta t)}$$

where

LLD is the lower limit of detection as defined above (as uCi per unit mass or volume)

s_b is the standard deviation of the background counting rate or of the counting rate of a blank sample as appropriate (as counts per minute).

E is the counting efficiency (as counts per transformation)

V is the sample size (in units of mass or volume)

2.22×10^6 is the number of transformations per minute per microcurie

Y is the fractional radiochemical yield (when applicable)

λ is the radioactive decay constant for the particular radionuclide

Δt is the elapsed time between midpoint of sample collection and time of counting (for plant effluents, not environmental samples).

The value of s_b used in the calculation of the LLD for a detection system shall be based on the actual observed variance of the background counting rate or of the counting rate of the blank samples (as appropriate) rather than on an unverified theoretically predicted variance. In calculating the LLD for a radionuclide determined by gamma-ray spectrometry, the background shall include the typical contributions of other radionuclides normally present in the samples. Typical values of E, V, Y and Δt should be used in the calculation.

39.1

The background count rate is calculated from the background counts that are determined to be within \pm one FWHM energy band about the energy of the gamma ray peak used for the quantitative analysis for this radionuclide.

The LLD is defined as an a priori (before the fact) limit representing the capability of a measurement system and not as a posteriori (after the fact) limit for a particular measurement.

Analyses shall be performed in such a manner that the stated LLDs will be achieved under routine conditions. Occasionally background fluctuations, unavoidably small sample sizes, the presence of interfering nuclides, or other uncontrollable circumstances may render these LLDs unachievable. When circumstances result in LLDs higher than required, the reasons shall be documented in the Semiannual Radioactive Effluent Report.

- b. A batch release is the discharge of liquid wastes of a discrete volume.
- c. A composite sample is one in which the quantity of liquid sampled is proportional to the quantity of liquid waste discharged and in which the method of sampling employed results in a specimen which is representative of the liquids released.
- d. The principal gamma emitters for which the LLD specification will apply are exclusively the following radionuclides: Mn-54, Fe-59, Co-58, Co-60, Zn-65, Cs-134, Cs-137, and Ce-141. This list does not mean that only these nuclides are to be detected and reported. Other peaks which are measurable and identifiable, together with the above nuclides, shall also be identified and reported. Nuclides which are below the LLD for the analyses should be reported as less than the LLD and should not be reported as being present at the LLD level. The less than values should not be used in the required dose calculations. When unusual circumstances result in LLDs higher than required, the reasons shall be documented in the Semiannual Radioactive Effluent Release Report.
- e. A continuous release is the discharge of liquid wastes of a non-discrete volume; e.g. from a volume of system that has an input flow during the continuous release.

3111

4-12

TABLE 4.12-2 (Continued)

TABLE NOTATION

- a. The lower limit of detection (LLD) is defined in Table Notation a. of Table 4.12-1.
- b. Analyses shall also be performed when the monitor on the continuous sampler reaches its setpoint.
- c. Tritium grab samples shall be taken at least three times per week when the reactor cavity is flooded.
- d. The ratio of the sample flow rate to the sampled stream flow rate shall be known for the time period covered by each dose or dose rate calculation made in accordance with specifications 3.9.2.1.a, 3.9.2.2.a and 3.9.2.2.b.
- e. The principal gamma emitters for which the LLD specification will apply are exclusively the following radionuclides: Kr-85m, Xe-133, Xe-133m, and Xe-135 for gaseous emissions and Mn-54, Fe-59, Co-58, Co-60, Zn-65, Mo-99, Cs-134, Cs-137, Ce-141 and Ce-144 for particulate emissions. This list does not mean that only these nuclides are to be detected and reported. Other peaks which are measurable and identifiable, together with the above nuclides, shall also be identified and reported. Nuclides which are below the LLD for the analyses should not be reported as being present at the LLD level for that nuclide. When unusual circumstances result in LLDs higher than required, the reasons shall be documented in the Semiannual Effluent Release Report.
- f. Air ejector samples are not required during cold or refueling shutdowns.
- g. Air ejector tritium sample not required if the secondary activity is less than 1×10^{-4} $\mu\text{Ci/gm}$.
- h. Air ejector iodine samples shall be taken and analyzed weekly if the secondary coolant activity exceeds 1×10^{-4} $\mu\text{Ci/gm}$.

39.iii

4.13 Radioactive Material Source Leakage Test

Applicability

Applies to the periodic test for leakage of radioactive material sources performed by the licensee or by other persons specifically authorized by the Commission or the state.

Objective

To ascertain that any leakage from radioactive material sources is sufficiently low.

Specifications

4.13.1 Sources which contain quantities of by-product material that exceed the quantities listed in 10 CFR 30.71 Schedule B and all other sources (including alpha emitters) containing greater than 0.1 microcuries shall be leak tested as follows:

- a. Except for sealed sources that are stored and not being used, and except for startup sources, each sealed source containing radioactive material, other than Hydrogen 3, with a half-life greater than 30 days and in any form other than gas shall be tested for leakage and/or contamination at intervals not to exceed six months.

40.6

40.0

- b. Sealed sources that are stored and not being used shall be tested for leakage prior to use or transfer to another user unless they have been tested within six months prior to the date of use or transfer. Sealed sources received from a transferor shall, in the absence of a certificate from the transferor indicating that a test has been performed within six months prior to the transfer, be tested prior to use.
- c. Startup sources shall be leak tested prior to and following any repair or maintenance and before being subjected to core flux.

4.13.2 The leakage test shall be capable of detecting the presence of 0.005 microcuries of radioactive material on the test sample. If the test reveals the presence of 0.005 microcuries or more of removable contamination, it shall immediately be withdrawn from use, decontaminated, and repaired, or be disposed of in accordance with Commission regulations.

Basis

Ingestion or inhalation of source material may give rise to total body or organ irradiation. This specification assures that leakage from radioactive material sources does not exceed allowable limits. In the unlikely event that those

quantities of radioactive by-product materials of interest to this specification which are exempt from leakage testing are ingested or inhaled, they represent less than one maximum permissible body burden for total body irradiation. The limits for all other sources (including alpha emitters) are based upon 10 CFR 70.39 (c) limits for plutonium.

4.14

Snubber Surveillance Requirements

4.14.1

Each snubber required by Specification 3.13 to be OPERABLE shall be demonstrated OPERABLE by the performance of the following inservice inspection program in addition to the requirements of Specification 4.2.

a. Inspection Types

As used in this specification, "type of snubber" shall mean snubbers of the same design and manufacturer, irrespective of capacity.

b. Visual Inspections

Snubbers are categorized as inaccessible or accessible during reactor operation. Each of these categories (inaccessible and accessible) may be inspected independently according to the schedule determine by Table 4.14-1. The visual inspection interval for each type of snubber shall be determined based upon the criteria provided in Table 4.14-1.

c. Visual Inspection Acceptance Criteria

Visual inspections shall verify that (1) the snubber has no visible indications of damage or impaired OPERABILITY, (2) attachments to the foundation or

41.i

4.14.1.c. (continued)

supporting structure are functional, and (3) fasteners for the attachment of the snubber to the component and to the snubber anchorage are functional. Snubbers which appear inoperable as a result of visual inspections shall be classified as unacceptable and may be reclassified acceptable for the purpose of establishing the next visual inspection interval, provided that: (1) the cause of the rejection is clearly established and remedied for that particular snubber and for other snubbers, irrespective of type that may be generically susceptible; and (2) the affected snubber is functionally tested in the as-found condition and determined OPERABLE per Specification 4.14.1e. All snubbers found connected to an inoperable common hydraulic fluid reservoir shall be counted as unacceptable for determining the next inspection interval. A review and evaluation shall be performed and documented to justify continued operation with an unacceptable snubber. If continued operation cannot be justified, the snubber shall be declared inoperable and the ACTION requirement shall be met.

41.i

41:2

TABLE 4.14-1

SNUBBER VISUAL INSPECTION INTERVAL

NUMBER OF UNACCEPTABLE SNUBBERS (Ref. Note 7)

Population or Category (Notes 1 and 2)	Column A	Column B	Column C
	Extend Interval (Notes 3 and 6)	Repeat Interval (Notes 4 and 6)	Reduce Interval (Notes 5 and 6)
1	0	0	1
80	0	0	2
100	0	1	4
150	0	3	8
200	2	5	13
300	5	12	25
400	8	18	36
500	12	24	48
750	20	40	78
1000 or greater	29	56	109

Note 1: The next visual inspection interval for a snubber population or category size shall be determined based upon the previous inspection interval and the number of unacceptable snubbers found during that interval. Snubbers may be categorized, based upon their accessibility during power operation, as accessible or inaccessible. These categories may be examined separately or jointly. However, this decision must be

TABLE 4.14-1 (continued)

documented before any inspection and shall be used as the basis upon which to determine the next inspection interval for that category.

Note 2: Interpolation between population or category sizes and the number of unacceptable snubbers is permissible. Use next lower integer for the value of the limit for Columns A, B, or C if that integer includes a fractional value of unacceptable snubbers as determined by interpolation.

Note 3: If the number of unacceptable snubbers is equal to or less than the number in Column A, the next inspection interval may be twice the previous interval but not greater than 48 months.

Note 4: If the number of unacceptable snubbers is equal to or less than the number in Column B but greater than the number in Column A, the next inspection interval shall be the same as the previous interval.

Note 5: If the number of unacceptable snubbers is equal to or greater than the number in Column C, the next inspection interval shall be two-thirds of the previous interval. However, if the number of unacceptable snubbers is less than the number in Column C but greater than the number in Column B, the next interval shall be reduced proportionally by interpolation, that is, the previous interval shall be reduced by a factor that is one-third of the ratio of the difference between the number of unacceptable snubbers found during the previous interval and the number in Column B to the difference in the numbers in Column B and C.

Note 6: The provisions of Specification Section 4.0 are applicable for all inspection intervals up to and including 48 months.

Note 7: To determine the next surveillance interval, an unacceptable snubber may be reclassified as acceptable if it can be demonstrated that the snubber is operable in its as-found condition by performance if a functional test and if it satisfies the acceptance criteria for functional testing.

41.i

4.14.1.d Functional Tests

At least once per 18 months during shutdown, a representative sample (at least 10% of the snubbers required by Specification 3.13) shall be functionally tested either in place or in a bench test. For each snubber that does not meet the functional test acceptance criteria of Specification 4.14.1e, an additional 10% of the snubbers shall be functionally tested until no more failures are found or until all snubbers have been functionally tested. The representative sample selected for functional testing shall, as far as practical, include the various configurations, operating environments, range of sizes and capacities of snubbers.

In addition to the regular sample, snubbers placed in the same locations as snubbers which failed the previous functional test shall be retested at the time of the next functional test. Additionally, if a failed snubber has been repaired and reinstalled in another location, that failed snubber shall also be retested. These snubbers shall not be included in the regular sample.

If during the functional testing, additional sampling is required due to failure of only one type of snubber, the functional testing results shall be reviewed at that time to determine if additional samples should be limited to the type of snubber which has failed the functional testing.

41.i

4.14.1.e.

Functional Test Acceptance Criteria

The snubber functional test shall verify that:

- 1) Activation (restraining action) is achieved within the specified range in both tension and compression;
- 2) Snubber bleed, or release rate where required, is present in both tension and compression, within the specified range;
- 3) Where required, the force required to initiate or maintain motion of the snubber is within the specified range in both directions of travel; and
- 4) For snubbers specifically required not to displace under continuous load, the ability of the snubber to withstand load without displacement is verified.

Testing methods may be used to measure parameters indirectly or parameters other than those specified if those results can be correlated to the specified parameters through established methods.

f. Functional Test Failure Analysis

An analysis shall be made of each failure to meet the functional test acceptance criteria to determine the cause of the failure. The results of this analysis

41.i

4.14.1.f. (continued)

shall be used, if applicable, in selecting snubbers to be tested in an effort to determine the operability of other snubbers, irrespective of type, which may be subject to the same failure mode. For the specific case of a snubber selected for functional testing which either fails to activate or fails to move, i.e., frozen-in-place, the cause will be evaluated and, if caused by manufacturer or design deficiency, all snubbers of the same type subject to the same defect shall be functionally tested or evaluated in a manner to ensure their operability. Any testing performed as part of this requirement shall be independent of the requirements stated in Specification 4.14.1d for snubbers not meeting the functional test acceptance criteria.

For any snubbers found inoperable, an engineering evaluation shall be performed on the components to which the inoperable snubbers are attached. The purpose of this engineering evaluation shall be to determine if the components to which the inoperable snubbers are attached were adversely affected by the inoperability of the snubbers in order to ensure that the component remains capable of meeting the designed service.

41.i ~

4.14.1.g Snubber Seal Service Life Monitoring

The seal service life of hydraulic snubbers shall be monitored and seals replaced as required to ensure that the service life is not exceeded between surveillance inspections during a period when the snubber is required to be operable. The seal replacements shall be documented and the documentation shall be retained in accordance with Technical Specification 6.10.2

(4.13)

Basis

Snubbers are provided to ensure that the structural integrity of the reactor coolant system and all other safety related systems is maintained during and following a seismic or other event initiating dynamic loads. The visual inspection frequency is based on the number of unacceptable snubbers found during the previous inspection in proportion to the sizes of the various snubber populations or categories. A snubber is considered unacceptable if it fails the acceptance criteria delineated by Specification 4.14.1.c. The visual inspection interval is based upon the previous inspection interval and may be as long as two fuel cycles, not to exceed 48 months, depending on the number of unacceptable snubbers found during the previous visual inspection.

Basis (continued)

Unacceptable snubbers shall be evaluated to determine if they are inoperable. For inoperable snubbers the applicable action requirements shall be met. When a snubber is found inoperable, an engineering evaluation of the supported component is performed in order to determine if any safety-related component or system has been adversely affected by the inoperability of the snubber. This evaluation is in addition to the determination of the snubber mode of failure. The engineering evaluation shall determine whether or not the snubber failure has imparted a significant effect on or caused degradation of the supported component or system, to ensure they remain capable of meeting the designed service.

When the cause of the rejection of a snubber is clearly established and remedied for that snubber and for any other snubbers that may be generically susceptible, and verified by inservice functional testing, that snubber may be exempted from being counted as inoperable. Generically susceptible snubbers are those which are of a specific make or model and have the same design features directly related to the snubber rejected or are those which are similarly located or exposed to the same environmental conditions such as temperature, radiation, and vibration. To determine the next surveillance interval, an unacceptable snubber may be reclassified as acceptable if it can be demonstrated that the snubber is operable in its as-found condition by performance of a functional test and if it satisfies the acceptance criteria for functional testing.

Basis (continued)

To provide assurance of snubber functional reliability, a representative sample of the installed snubbers will be functionally tested during plant shutdowns at less than or equal to 18 month intervals. Observed failures of these sample snubbers shall require functional testing of additional units.

Hydraulic snubbers and mechanical snubbers may each be treated as a different entity for the above surveillance programs. The service life of a snubber is evaluated via manufacturer input and engineering information through consideration of the snubber service conditions and functional design requirements. The only snubber components with service lives not expected to exceed plant life are seals and o-rings fabricated from certain seal materials. Therefore, a seal replacement program is required to monitor snubber seal and o-ring service life to assure snubber operability is not degraded due to exceeding component service life.

~~4.15 (DELETED)~~

~~INTENTIONALLY LEFT BLANK~~

~~Amendment No. 49 4.15-1]~~

6.0 ADMINISTRATIVE CONTROLS

6.1 RESPONSIBILITY

6.1.1 The Plant Manager, Ginna Station shall be responsible for overall on-site Ginna Station operation and shall delegate in writing the succession to this responsibility during his absence.

49.iii
5.1.1

49.ii

49.ii — Add TS 5.1.2

6.2 ORGANIZATION

6.2.1 Onsite and Offsite Organization

5.2.1

An onsite and an offsite organization shall be established for unit operation and corporate management. The onsite and offsite organization shall include the positions for activities affecting the safety of the nuclear power plant.

5.2.1.a

a. Lines of authority, responsibility and communication shall be established and defined from the highest management levels through intermediate levels to and including all Plant management positions. Those relationships shall be documented and updated, as appropriate, in the form of organization charts. These organization charts ~~will~~

including the plant specific titles of those personnel fulfilling the responsibilities of the positions delineated in these technical specifications shall

50.ii

be documented in the UFSAR and updated in accordance with 10 CFR 50.71.

50.i

b. ~~The Senior Vice President, Customer Operations*~~

5.2.1.c

50.ii

shall have corporate responsibility for overall Plant nuclear safety, and shall take any measures needed to assure acceptable performance of the staff in operating, maintaining, and providing technical support in the Plant so that continued nuclear safety is assured.

A corporate vice president

* An alternate title may be designated for this position in accordance with 10 CFR 50.54(a)(3). All requirements of these Technical Specifications apply to the position with the alternate title as apply with the specified title. Alternate titles shall be specified in the Updated Final Safety Analysis Report.

50.ii

Shall report to the Corporate Vice President specified in 5.2.1.c,

5.2.1.b

c. The Plant Manager, Ginna Station shall have responsibility for overall unit operation and shall have control over those resources necessary for safe operation and maintenance of the Plant.

Individuals who train the operating staff, carry out

d. The persons responsible for the training, health physics, ^{or} and quality assurance functions may report to ^{the} an appropriate manager onsite, ^{however, these individuals} but shall have

50.iii

direct access to responsible corporate management at a level where action appropriate to the mitigation of training, health physics and quality assurance concerns can be accomplished.

Sufficient organizational freedom to ensure their independence from operating procedures.

6.2.2 Facility Staff

The Facility organization shall include the following:

5.2.2.a

a. An auxiliary operator shall be assigned to the shift crew with fuel in the reactor. An additional auxiliary operator shall be assigned to the shift crew above Cold Shutdown.

50.iv

b. At least one licensed operator shall be present in the control room when fuel is in the reactor. In addition, above Cold shutdown, at least one licensed Senior Reactor Operator (SRO) shall be present in the control room.

5.2.2.b

c. Shift crew composition may be less than the minimum requirements of 10 CFR 50.54(m)(2)(i) and Specifications 6.2.2.a and 6.2.2.f for a period of time not to exceed 2 hours in order to accommodate unexpected absence of on-duty shift crew members provided immediate action is taken to restore shift crew composition to within the minimum requirement.

5.2.2.c

50.v

d. An individual qualified in radiation protection procedures shall be on site when fuel is in the reactor.

5.2.2.d

50.vi

e. Adequate shift coverage shall be maintained without routine heavy use of overtime. Administrative procedures shall be developed and implemented to limit the working hours of unit staff who perform safety-related functions including senior reactor operators, reactor operators, health physicists*, auxiliary operators, and key maintenance personnel. Changes to the guidelines for the administrative procedures shall be submitted to the NRC for review.

5.2.2.f

f. The Shift Technical Advisor (STA) shall provide advisory technical support to the Shift Supervisor (SS) in the areas of thermal hydraulics, reactor engineering, and plant analysis with regard to the safe operation of the unit. The STA shall be assigned to the shift crew above Cold Shutdown.

50.vii

5.2.2.e The operations manager or operations middle manager shall hold a SRO license.

50.ii

* An alternate title may be designated for this position. All requirements of these Technical Specifications apply to the position with the alternate title as apply with the specified title. Alternate titles shall be specified in the Updated Final Safety Analysis Report.

6.3 STATION STAFF QUALIFICATIONS

6.3.1 Each member of the facility shall meet or exceed the
 5.3.1 minimum qualifications of ANSI Standard N18.1-1971,
 "Selection and Training of Nuclear Power Plant Personnel",
 as supplemented by Regulatory Guide 1.8, September
 1975, for comparable positions, except for the Shift
 5.2.2: 51.i - Technical Advisor.¹

(5.6.iv) — Add TS 5.4.1.2

6.9

Reporting Requirements

5.6

In addition to the applicable reporting requirements of Title 10, Code of Federal Regulations, the following identified reports shall be submitted to the Regional Administrator of the USNRC, Region 1, unless otherwise noted.

57.0

6.9.1

Routine Reports

6.9.1.1

Startup Report. A summary report of plant startup and power escalation testing shall be submitted following (1) receipt of an operating license, (2) amendment to the license involving a planned increase in power level, (3) installation of fuel that has a different design or has been manufactured by a different fuel supplier, and (4) modifications that may have significantly altered the nuclear, thermal, or hydraulic performance of the plant. The report shall address each of the tests performed and shall in general include a description of the measured values of the operating conditions or characteristics obtained during the test program and a comparison of these values with design predictions and specifications. Any corrective actions that were required to obtain satisfactory operation shall also be described. Any additional specific details required in license conditions based on other commitments shall be included in this report.

57.ii

57.ii

~~Startup reports shall be submitted within (1) 90 days following completion of the startup test program, or (2) 90 days following resumption of commercial power operation, whichever is earliest. If the Startup Report does not cover both events (i.e., completion of startup test program, and resumption of commercial power operation), supplementary reports shall be submitted at least every three months until both events have been completed.~~

5.6.4

6.9.1.2

Monthly Operating Report. Routine reports of operating statistics and shutdown experience shall be submitted ~~in accordance with 10 CFR 50.4 on a monthly basis to the Director, Office of Management Information and Program Control, U.S. Nuclear Regulatory Commission, Washington, D.C. 20555~~ by the fifteenth of each month following the calendar month covered by the report.

57.iii

~~The monthly report shall include a narrative summary of operating experience describing the operation of the facility, including major safety related maintenance for the monthly period, except that safety related maintenance performed during the refueling outage may be reported in the monthly report for the month following the end of the outage rather than each month during the outage.~~

5.6.5

6.9.1.3

Annual Radiological Environmental Operating Report

A radiological environmental operating report covering the operation of the unit during the previous calendar year shall be submitted prior to May ²/₁₅ of each year.

5.3.2

The annual radiological environmental report shall include summaries, interpretations, and analysis of trends of the results of the radiological environmental surveillance activities for the report period, including a comparison with background (control) samples and previous environmental surveillance reports and an assessment of the observed impacts of the plant operation on the environment. The reports shall also include the results of land use censuses as required.

57.2v

5.6.2

The annual radiological environmental operating report shall include summarized and tabulated results in the format of Table 6.9-1 of all radiological environmental samples taken during the report period. In the event that some results are not available for inclusion with the report, the report shall be submitted noting and explaining the reasons for the missing results. The missing data shall be submitted as soon as possible in a supplementary report. In addition, the annual report

57.2v

shall include a discussion which identifies the circumstances which prevent any required detection limits for environmental sample analyses from being met, and a discussion of all deviations from the sample schedule of Table 3.16-1. The report shall also include the following: a summary description of the radiological environmental monitoring program including a map of all sampling locations keyed to a table giving distances

57.iv

and directions from the reactor, and the results of the participation in an interlaboratory comparison program.

6.9.1.4 Radioactive Effluent Release Report

5.6.3

57.v

Routine radioactive effluent release reports covering the operation of the unit during the previous twelve months of operation shall be submitted by May 1 of each year. This report shall include a summary, on a quarterly basis, of the quantities of radioactive liquid and gaseous effluents and solid waste released as outlined in Regulatory Guide 1.21, Revision 1.

57.iv

This report shall include an assessment of radiation doses from the radioactive liquid and gaseous effluents released from the unit during each of the previous four calendar quarters as outlined in Regulatory Guide 1.21, Revision 1. In addition, the site boundary maximum noble gas gamma air and beta air doses shall be evaluated. The assessment of radiation doses shall be performed in accordance with the ODCM. This same report shall include an annual summary of hourly meteorological data collected over the previous calendar year. Alternatively, the licensee has the option of retaining this summary on site in a file that shall be provided to the NRC upon request.

Also, the report shall include any nearby location(s) identified by the land use census which

yield a calculated dose or dose commitment greater than those forming the basis of Specifications 4.12.2.2 or 3.16.1. The report shall also contain a discussion which identifies the causes of the unavailability of milk or leafy vegetable samples and identifies locations for obtaining replacement samples in accordance with Specification 3.16.1.4.

The radioactive effluent release report shall include a discussion which identifies the circumstances which prevent any required detection limits for effluent sample analyses from being met.

57.iv

The radioactive effluent release reports shall include any changes made during the reporting period to the ODCM as specified in Section 6.15, and to the Process Control Program as specified in Section 6.16. The radioactive effluent release reports shall also include a discussion of any major changes to radioactive waste treatment systems in accordance with Specification 6.17.2.1.

6.9.1.5 Pressurizer Relief and Safety Valve Challenges

5.6.4 Challenges to the pressurizer power operated relief valves or safety valves shall be reported no less frequently than on an annual basis.

57.vi

~~6.9.2 Unique Reporting Requirements~~

6.9.2.1 ~~Annually: Results of required leak test performed on sources if the tests reveal the presence of 0.005 microcurie or more of removable contamination.~~

57.vii

6.9.2.2 Annually: A tabulation on an annual basis of the number of station, utility and other personnel (including contractors) receiving exposures greater than 100 mrem/yr and their associated man-rem exposure according to work and job functions, e.g., reactor operations and surveillance, in-service inspection, routine maintenance, special maintenance (describe maintenance), waste processing, and refueling. The dose assignment to various duty functions may be estimates based on pocket dosimeter, TLD, or film badge measurements. Small exposures totalling less than 20% of the individual total dose need not be accounted for. In the aggregate, at least 80% of the total whole body dose received from external sources shall be assigned to specific major work functions. (NOTE: This tabulation supplements the requirements of Section 20.407 of 10CFR Part 20)

6.9.2.3 ~~(Deleted)~~

5.6.1

6.9.2.4 Reactor Overpressure Protection System Operation

In the event either the PORVs or the RCS vent(s) are used to mitigate a RCS pressure transient, a Special Report shall be prepared and submitted to the Commission within thirty days. The report shall describe the circumstances initiating the transient, the effect of the PORVs or vent(s) on the transient and any other corrective action necessary to prevent recurrence.

6.13 HIGH RADIATION AREA

6.13.1 In lieu of the "control device" or "alarm signal" required by paragraph 20.203(c)(2) of 10 CFR Part 20:

5.7.1

a. Each High Radiation Area in which the intensity of radiation is 1000 mrem/hr or less shall be barricaded and conspicuously posted as a high radiation area and entrance thereto shall be controlled by requiring issuance of a Radiation Work Permit* (RWP). Any individual or group of individuals permitted to enter such areas shall be provided with one or more of the following:

(1) A radiation monitoring device which continuously indicates the radiation dose rate in the area.

(2) A radiation monitoring device which continuously integrates the radiation dose rate in the area and alarms when a preset integrated dose is received. Entry into such areas with this monitoring device may be made after the dose rate levels in the area have been established and personnel have been made knowledgeable of them.

* Radiation Protection** personnel shall be exempt from the RWP issuance requirement during the performance of their assigned radiation protection duties, providing they are following plant radiation protection procedures for entry into high radiation areas.

** An alternate title may be designated for this position. All requirements of these Technical Specifications apply to the position with the alternate title as apply with the specified title. Alternate titles shall be specified in the Updated Final Safety Analysis Report.

6.13

5.7.1

(3) A Qualified health physicist* (i.e., qualified in radiation protection procedures) with a radiation dose rate monitoring device who is responsible for providing positive control over the activities within the area and who will perform periodic radiation surveillance at the frequency specified in the HPWP. The surveillance frequency will be established by a plant health physicist*.

5.7.2
5.7.3

b. Each High Radiation Area in which the intensity of radiation is greater than 1000 mrem/hr shall be subject to the provisions of 6.13.1 a. above, and in addition, locked doors shall be provided to prevent unauthorized entry into these areas and the keys to unlock these locked doors shall be maintained under the administrative control of the Shift Supervisor on duty.

* An alternate title may be designated for this position. All requirements of these Technical Specifications apply to the position with the alternate title as apply with the specified title. Alternate titles shall be specified in the Updated Final Safety Analysis Report.

6.15 Offsite Dose Calculation Manual (ODCM)

6.15.1 Any changes to the ODCM shall be made by the following method:

6.15.1.a Licensee initiated changes shall be submitted to the Commission with the Radioactive Effluent Release Report for the period in which the change(s) was made and shall contain:

5.5.1.c
5.5.1.a

- (i) sufficiently detailed information to support the rationale for the change.
- (ii) a determination that the change will not reduce the accuracy or reliability of dose calculations or setpoint determinations; and
- (iii) documentation of the fact that the change has been reviewed and found acceptable by the onsite review function.

5.5.1

6.15.1.b Licensee initiated changes shall become effective after review and acceptance by the onsite review function on

5.5.1.b

43.i a date specified by the licensee.

6.16 Process Control Program (PCP)

6.16.1 Any changes to the PCP shall be made by the following method:

6.16.1.a Licensee initiated changes shall be submitted to the Commission with the Radioactive Effluent Release Report for the period in which the change(s) was made and shall contain:

- (i) sufficiently detailed information to support the rationale for the change;
- (ii) a determination that the change will not reduce the overall conformance of the solidified waste product to existing criteria for solid wastes; and
- (iii) documentation of the fact that the change has been reviewed and found acceptable by the onsite review function.

6.16.1.b Licensee initiated changes shall become effective after review and acceptance by the onsite review function on a date specified by the licensee.

6.17 Major Changes to Radioactive Waste Treatment Systems
(Liquid, Gaseous and Solid)

FUNCTION

- 6.17.1 The radioactive waste treatment systems (liquid, gaseous and solid) are those systems defined in Technical Specification 5.5.
- 6.17.2 Major changes to the radioactive waste systems (liquid and gaseous) shall be reported by the following method. For the purpose of this specification, "major changes" is defined in Specification 6.17.3 below.
 - 6.17.2.1 The Commission shall be informed of all major changes by the inclusion of a suitable discussion or by reference to a suitable discussion of each change in the Radioactive Effluent Release Report for the period in which the changes were made. The discussion of each change shall contain:
 - a) a summary of the evaluation that led to the determination that the change could be made (in accordance with 10 CFR 50.59);
 - b) sufficient detailed information to support the reason for the change;
 - c) a detailed description of the equipment, components and processes involved and the interfaces with other plant systems;
