Dear Mr. Dotson:

SUBJECT: PALISADES PLANT-CABLE TRAY SUPPORTS

In June 1985 you expressed a concern regarding the adequacy of some cable tray supports at the Palisades Plant to the NRC resident inspector. This concern was raised because of apparent overloading of cable trays by added cables for plant modifications; attachments made to cable trays such as conduit, small piping, or instrument racks as part of plant modifications; and possibly overloading of cable trays during initial construction. The NRC and the licensee met with you and other representatives of Bechtel Power Corporation at the plant site on July 15, 1985. As a result of that meeting, Consumers Power Company committed to certain follow-on activities to address your areas of concern.

Enclosed is a copy of the Consumers Power Company internal correspondence that reports on the results of their on-going efforts in this matter (Memorandum from K. A. Toner to J. L. Kuemin dated September 19, 1985). On page 5, the additional actions planned by the licensee are listed. Upon completion of Item 2, the licensee's analyses from Item 1 and the evaluations of Item 2 will be treated by the NRC as evaluations pursuant to 10 CFR 50.59, that is, an evaluation to determine whether an unreviewed safety question is involved for "changes in the facility as described in the safety analysis report." We intend to review the results of the licensee's evaluation and may select certain of the analyses for worst case loading to review in detail.

As you can see from the enclosed report, the 30 percent fill criterion in the FSAR was not adhered to and the as-built drawings and raceway schedules were not up-to-date. Thank you for bringing this to our attention. Based on the results of the SEP Owners Group Testing Program and the industrial experience of cable tray systems from previous earthquakes, we do not believe that the conditions found present an immediate safety concern. However, we intend to follow up on this to determine that the licensee effects an acceptable resolution. If you have any further comments or concerns, please feel free to contact us.

Sincerely,

Thomas V. Wambach, Project Manager PWR Project Directorate #8 Division of PWR Licensing

Dear Mr. Dotson:

SUBJECT: PALISADES PLANT-CABLE TRAY SUPPORTS

In June 1985 you expressed a concern regarding the adequacy of some cable tray supports at the Palisades Plant to the NRC resident inspector. This concern was raised because of apparent overloading of cable trays by added cables for plant modifications; attachments made to cable trays such as conduit, small piping, or instrument racks as part of plant modifications; and possibly overloading of cable trays during initial construction. The NRC and the licensee met with you and other representatives of Bechtel Power Corporation at the plant site on July 15, 1985. As a result of that meeting, Consumers Power Company committed to certain follow-on activities to address your areas of concern.

Enclosed is a copy of the Consumers Power Company internal correspondence that reports on the results of their on-going efforts in this matter (Memorandum from K. A. Toner to J. L. Kuemin dated September 19, 1985). On page 5, the additional actions planned by the licensee are listed. Upon completion of Item 2, the licensee's analyses from Item 1 and the evaluations of Item 2 will be treated by the NRC as evaluations pursuant to 10 CFR 50.59, that is, an evaluation to determine whether an unreviewed safety question is involved for "changes in the facility as described in the safety analysis report." We intend to review the results of the licensee's evaluation and may select certain of the analyses for worst case loading to review in detail.

As you can see from the enclosed report, the 30 percent fill criterion in the FSAR was not adhered to and the as-built drawings and raceway schedules were not up-to-date. Thank you for bringing this to our attention. Based on the results of the SEP Owners Group Testing Program and the industrial experience of cable tray systems from previous earthquakes, we do not believe that the conditions found present an immediate safety concern. However, we intend to follow up on this to determine that the licensee effects an acceptable resolution. If you have any further comments or concerns, please feel free to contact us.

Sincerely,

Thomas V. Wambach, Project Manager PWR Project Directorate #8 Division of PWR Licensing

As part of a recent Auxiliary Feedwater Project, Bechtel Corporation was charged with the responsibility of investigating the structural capability of cable tray supports in the southeast corner of the 1C Switchgear Room to carry additional fireproofing loads (Attachment 1). Bechtel's structural analysis concluded that the existing supports were not adequately designed for seismic loads. The analysis also concluded that supports west of the trays to be fireproofed were not adequately designed (Reference 1). The purpose of this letter is to describe the actions that Consumers Power Company has taken to resolve the Bechtel concern, to respond to subsequent NRC questions related to this issue, and to resolve the issue of cable tray support adequacy at Palisades.

In response to the conclusions reached in Bechtel's analysis, Consumers Power Company authorized Bechtel to strengthen the supports for only those trays designated to be fireproofed. The additional tray support was installed by Bechtel prior to fireproofing the trays; a project which was closed out on June 18, 1984 (Attachment 1).

Regarding the trays running east to west from the fireproofed tray section (eg, trays XU012, XU014, XU016, etc), Consumers Power Company elected to rely on a continuing Systematic Evaluation Program Owners Group (SEPOG) effort for resolution of the tray supports issue. Plant representative cable tray support systems, selected from detailed plant walkdowns, were evaluated and tested for the SEPOG by URS/Blume & Associates. Based on the results of these evaluations and tests, reports of which were submitted to the NRC (References 2 and 3), the SEPOG concluded that the existing raceway systems in SEP plants possess substantial seismic resistance, and the seismic qualification of raceway systems is not a significant safety issue. This conclusion was submitted to the NRC on October 15, 1984 (Reference 4). <u>We are presently</u>. awaiting a final Safety Evaluation Report by the NRC on the SEPOG submittal (Reference_5).

Not satisfied with the timeliness of the SEP treatment of this issue, Bechtel
 informed CPCo of its intent to inform the NRC of a potential 10CFR21 condition
 (References 6 and 7). Upon notification of Bechtel's concern, the NRC Resident
 Inspector on June 20, 1985, questioned the plant staff as to the effectiveness
 of design control procedures to ensure that structural evaluations are per formed prior to adding weight to cable trays during plant modifications. In
 addition to the one-time application of a significant load to a tray such as
 fireproofing, the NRC Resident Inspector was concerned about the addition of
 individual cables and the accumulation of a significant load on the trays over

WY: at

ړ. د In response to the inspector's questions, the plant staff provided the following information:

- Existing design input documents have been and are effective in prompting an engineer to perform evaluations and make modifications, if necessary, of support systems prior to a substantial load being added to raceway. Attachments 2 and 3 are portions of major and minor modifications and design procedures, respectively. These documents show that design structural loads are required to be evaluated prior to modification implementation.
- 2. Specification change design procedures are less clear in describing the requirement to evaluate structural loads prior to performing work. As evidenced in Attachment 4, the specification change checklist does, however, require that prior to modification implementation the engineer identify and document any analyses which support the modification design. Nevertheless, the specification change procedures are being revised to --- provide design structural loading evaluation requirements to a degree of detail consistent with the major and minor modifications' design procedures.
- 3. A review of recent design changes which added substantial weight to cable trays confirms our belief in that design procedures have been effective in prompting the engineer to perform required structural evaluations. Attachments 5 and 6 provide design documentation for two recent specification changes in which fireproofing was added to cable trays. In each case, the engineer assured that structural evaluations were completed in advance of installing the fireproofing material.
- 4. Existing design procedures do not specifically require that structural loading evaluations be performed prior to installing an individual cable within a given tray. (It is our opinion that design procedures should not be so prescriptive as to inadvertently narrow the engineer's design considerations to set of "rules" outlined in cookbook fashion.) Therefore, structural evaluations would not be expected to have been performed for such installations. In the absence of this information, a review of current fill levels of cable in a limited sample of trays in the 1C Switchgear Room was performed to address the Resident Inspector's concern. The current raceway schedule shows trays adjacent to the fire-proofed tray section to be filled to approximately 30% by cross-section; an upper fill limit provided in the original FSAR for trays carrying Engineered Safeguards circuits (Attachment 7).
- 5. <u>The 30% fill requirement is considered conservative since the 1984</u> <u>National Electric Code allows a fill of 50% for trays carrying multi-</u> conductor control and signal cables only, as do the trays sampled.

6. A visual inspection of the raceway running east to west from the fireproofed tray section was conducted on June 19, 1985. Accessible raceway support were specifically inspected for evidence of raceway overloading (eg, broken concrete around the point where the raceway vertical support strut is affixed to the ceiling, or misaligned struts). Our inspection, which consisted of engineers climbing up into the tray systems, failed to reveal any signs of tray overload.

Only July 15, 1985 members of the NRC's SEP and Operating Reactors Branches visited the plant site to be briefed on the Bechtel concern. During the meeting Consumers Power Company provided the NRC with a review of the information previously given to the Resident Inspector (Items #1 through #5 above). In addition, the NRC was provided with our preliminary structural evaluations which indicated that the trays running east to west from the fireproofed tray section are adequately supported.

In response to an NRC request made during the meeting, Consumers committed to performing a review of recent design changes to identify the modification which resulted in the attachment of specific conduit to trays located within the section to be fireproofed as part of the Auxiliary Feedwater Project. According to Bechtel, this conduit was not part of the original design of the plant and resulted in additional loading on the tray supports. The NRC staff requested that Consumers attempt to identify whether or not design controls were effective in ensuring that a structural analysis was completed for the conduit installation. In addition, Consumers committed to conducting final structural evaluations for the trays running east to west from the fireproofed section.

In response to the NRC requests, Consumers performed the following:

- Bechtel was contacted to identify the specific conduit that had been reported as supported by the trays within the fireproofed section. Given the conduit designations, the conduit was identified on the applicable layout drawing and the revision record block was then reviewed in an attempt to identify a facility change which may have resulted in conduit installation. <u>Unfortunately. the drawing depicted no such change.</u> Consumers is of the opinion, however, that Attachments 5 and 6 provide ample evidence of design control effectiveness for significant load additions.
- 2. Final structural (seismic and static) evaluations of the trays running east to west from the fireproofed section were completed (Reference 8) with the results confirming the preliminary evaluations that the tray supports are not overloaded. As part of these evaluations, the raceway schedules were reviewed to identify the fill level for all of the trays in the 1C Switchgear Room. During this review of a sample of trays much larger than previously surveyed, <u>approximately 13 trays were identified as being in excess of the original FSAR's 30% limit; with the greatest fill level documented at 41% by cross-section.</u>

IC0985-0666A-TC01

Prompted by this new tray fill information, a review of all trays within the plant was conducted by referring to the raceway schedules. The schedules reveal that approximately 8% of all plant trays are filled greater than 30%, and 2% of all plant trays are filled greater than 40% by cross-section. The greatest individual tray fill was identified as 59%. In an effort to extract a subset of the total plant tray population which represents trays carrying safety-related cable, the unique identifiers for the partitioned trays (ie, trays with a metal barrier separating one side of the tray from the other so as to separate individual channels of a particular safety train) serving the Reactor Protection System (RPS) cables were used. Raceway schedules for these trays show that 12% of the RPS trays are filled greater than 30% and 5% are filled greater than 40% with the greatest overall tray fill (ie, the fill considering both partitioned sides together) being 54% by cross-section.

4

Since the raceway schedules were observed to indicate that a number of trays are filled above 30% and the review also identified specific sides of certain RPS trays being filled in excess of 100%, a walkdown was performed to visually inspect the trays and their supports. Trays selected for inspection were those shown by the schedules to be those filled the most. Trays showing the greatest fills in the plant are RPS trays located in the Cable Spreading Room. Inspections conducted on two occasions (August 1 and August 19, 1985) of approximately five partitioned trays, having fills for a specific tray section ranging from 83% to 111%, revealed the following:

- Although filled greater than 85% in a given section (per raceway schedule), the trays showed no signs of their supports being overloaded. There was no indication of the support struts breaking away from contact points on the ceiling nor evidence of support strut or tray deformation.
- 2. There was no indication of cables overheating. All cables were comfortable to the touch and temperature measurements with a probe inserted into the cable bundle showed a maximum temperature of 89°F (cables are typically rated at 90°C).
- 3. The as-built condition, with regards to fill, differs significantly from the information contained in the raceway schedules. The schedules for the trays inspected show one side of the partitioned tray to be filled in excess of 85% and the other side filled less than 5%. Field inspection, however, reveals that in the case of several trays, both sides of the partition have significant fill levels. Specifically, partitioned tray XR301/3XR301 is filled on both sides of the partition to levels above the tray side-rails. The schedules show the tray sections to be filled to 106% and 1%, respectively.

IC0985-0666A-TC01

In response to the aforementioned observations, Consumers plans on taking the following actions:

5

- 1. By November to have reviewed and analyzed those trays selected as "outliers" in terms of percent fill. For these trays, analyses will be conducted to confirm that the tray supports are capable of carrying the structural loads. In addition, cables in the trays will be monitored to determine if overheating is occurring due to self-generated and ambient temperatures. Finally, a review will be conducted to determine if the cables at the bottom of the tray can support the long-term dead weight. It is expected that this work will be instrumental in reconfirming that the plant trays and supports are capable of supporting cable for all expected or postulated plant conditions.
- On a schedule yet to be determined, which takes into account both available resources and the importance of this issue, develop an administrative limit for cable tray fill and include the limit in appropriate design
 control procedures. It is expected that the limit will be determined by performing a walkdown of representative tray systems and performing structural evaluations of such systems in order to correlate existing tray fills to reserve load-carrying capability of the tray supports.

Completion delle 4/1/86 per D-NL -85-02C (B) pg 3,6

3. Upon completion of Item 2, either revise the raceway schedules such that identified fill reflects accurately as-built conditions or delete such information from the schedules.

With reference to Specification Change SC-64-043, I have performed structural analysis on the J-box support due to adding $1/2^{\circ}$ Thermo-lag at 3.5 $1h/ft^2$, and found that the supports are adequate.

The structural analysis I performed was based on the J-box and support configuration as shown on the attached sketch. The dimensions shown on the shutch were provided to me by you, either orally or on sketches dated 1/6/84. In the analysis, I considered only the dead load and seismic load of the box, conduit, and supports. A copy of the calculation (calculation #5221-CE-1) is filed in FMADP file #5221-140.

If you have any quastions, please call me.

circuits and how separation is to be effected. Scheme numbers and relay numbers are coded with odd numbers indicating Channel 1 and even numbers for Channel 2. The allocation for the power source is shown for each scheme. The cables are routed by an engineer and printed by computer with the computer output being carefully reviewed. The computer also prints a cable routing card and connection cards for each interconnecting cable installed in the plant. The cards are sent to the field as the official installation documents. The routing cards are signed and returned to the design engineer for record and to verify that cable was installed in accordance with the design. In the field, the Bechtel Electrical Field Inspector checks that all cables have been pulled in as required on the routing card. The Bechtel Quality Assurance Engineer and Consumers Power Company Quality Assurance Engineer spot-check the routing of all reactor protective and engineered safeguards cables.

The cable and wire connected to devices and instrumentation which are required to operate during a DBA has been prooftested to assure satisfactory operation through and following the accident.

Tray fill will generally be limited to 30% by cross section. Tray fill greater than 30% by cross section is carefully reviewed to assure that cable damage, either mechanical or thermal will not take place. In the case of large diameter cables, fill may exceed 30% but will be limited to a single cable layer.

Conduit fill will be limited to values as stated in Chapter 9 of the NEC.

Cables are installed in ventilated trays and are thermally sized, in accordance with IPCEA ampacity values of three conductor concentric stranded rubber insulated cable in 40° C air for the conductor operating temperature of the insulation. If ambient temperatures above 40° C are encountered, or multiple power cables are in a tray, the cables are further derated as outlined by IPCEA.

Cables installed in conduit are thermally sized in accordance with IPCEA ampacity values of three identical single-conductor cables in isolated conduit in 40° C air or three-conductor cable in isolated conduit in 40° C air, depending on the cables used. Cables are further derated if the ambient exceeds 40° C or when multiple power cables are pulled into a conduit.
