1.0 Introduction

1.1 Definitions

The following definitions apply to terms used in the Design Descriptions and associated Inspections, Tests, Analyses, and Acceptance Criteria (ITAAC):

**Acceptance Criteria** means the performance, physical condition, or analysis result for a structure, system or component that demonstrates the Design Commitment is met.

**Analysis** means a calculation, mathematical computation, or engineering or technical evaluation. Engineering or technical evaluations could include, but are not limited to, comparisons with operating experience or design of similar structures, systems or components.

**As-built** means the physical properties of a structure, system, or component following the completion of its installation or construction activities at its final location at the plant site. In cases where it is technically justifiable, determination of physical properties of the as-built structure, system, or component may be based upon measurements, inspections, or tests that occur prior to installation, provided that subsequent fabrication, handling, installation, and testing do not alter the properties.

**ASME Code** means Section III of the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code, unless a different Section of the ASME Code (such as Section XI) or a separate ASME Code (such as the ASME Code for Operation and Maintenance of Nuclear Power Plants (OM Code)) is specifically referenced.

**ASME Code Data Report** means a document, which certifies that a component or system was constructed in accordance with the requirements of the ASME Code. This data report shall be recorded on a form approved by the ASME.

**Basic Configuration (for a Building)** means the arrangement of building features (e.g., floors, ceilings, walls, basemat and doorways) and of the structures, systems, or components within, as specified in the building Design Description.

**Channel** means an arrangement of components and modules are required to generate a single protective action signal when required by a plant condition. A channel loses its identity where single protective action signals are combined.
**Component**, as used for reference to ASME Code components, means a vessel, concrete containment, pump, pressure relief valve, line valve, storage tank, piping system, or core support structure that is designed, constructed, and stamped in accordance with the rules of the ASME Code. It should be noted that ASME Code Section III classifies metal containment as a vessel.

**Design Commitment** means that portion of the Design Description that is verified by ITAAC.

**Design Description** means that portion of the design that is certified.

**Division (for electrical systems)** is the designation applied to a given safety-related system or set of components which are physically, electrically, and functionally independent from other redundant sets of components.

**Division (for mechanical systems or equipment)** is the designation applied to a specific set of safety-related components within a system.

**Exist, Exists or Existence**, when used in the Acceptance Criteria, means that the item is installed in its required location and meets the design description. Detailed supporting information on what should be present to conclude that an item “exists” and meets the design description is contained in the appropriate sections of Tier 2 of the DCD. **Functional Arrangement (for a System)** means the physical arrangement of systems and components to provide the service for which the system is intended, and which is described in the system Design Description.

**Inspect or Inspection** mean visual observations, physical examinations, or reviews of records based on visual observation or physical examination that compare the structure, system, or component condition to one or more Design Commitments. Examples include walkdowns, configuration checks, measurements of dimensions, or non-destructive examinations.

**Inspect for Retrievability** means to visually observe that the specified information appears on a monitor, display, or alarm when summoned by the operator.

**Operate** means the actuation and running of equipment.
Qualified for Harsh Environment means that equipment can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of its safety function, for the time required to perform the safety function. These environmental conditions include applicable time-dependent temperature and pressure profiles, humidity, chemical effects, radiation, aging, submergence, and their synergistic effects which have a significant effect on the equipment performance. Equipment identified in the Design Description as being Qualified for Harsh Environment includes the:

a. equipment itself

b. sensors, switches and lubricants that are an integral part of the equipment

c. electrical components connected to the equipment (wiring, cabling and terminations)

Items b and c are Qualified for Harsh Environment only when they are necessary to support operation of the equipment to meet its safety-related function listed in the Design Description and to the extent such equipment is located in a harsh environment during or following a design basis accident.

Reconciliation or Reconciled means the identification, assessment, and disposition of differences between the design feature as described in the plant-specific DCD and the as-built plant design feature. For ASME Code piping systems, it is the reconciliation of differences between the approved design and the as-built piping system. For structural features, it is the reconciliation of differences between the approved design and the as-built structural feature.

Test means the actuation or operation, or establishment of specified conditions, to evaluate the performance or integrity of as-built structures, systems, or components, unless explicitly stated otherwise.

Type Test means a test on one or more sample components of the same type and manufacturer to qualify other components of that same type and manufacturer. A type test is not necessarily a test of the as-built structures, systems or components.
1.2 General Provisions

The following general provisions are applicable to the Design Descriptions and the associated ITAAC:

1.2.1 Treatment of Individual Items

The absence of any discussion or depiction of an item in the Design Description or accompanying Figures shall not be construed as prohibiting a licensee from utilizing such an item, unless it would prevent an item from performing its safety function as discussed or depicted in the Design Description or accompanying Figures.

When the term “operate”, “operates”, or “operation” is used with respect to an item discussed in the Acceptance Criteria, it refers to the actuation and running of the item.

Many of the Acceptance Criteria include the words “A report exists and concludes that…” When these words are used, it indicates that the ITAAC for that Design Commitment will be met when it is confirmed that appropriate documentation exists and the documentation shows that the Design Commitment is met. Appropriate documentation can be a single document or a collection of documents that show that the stated acceptance criteria are met. Examples of appropriate documentation include data reports, test reports, inspection reports, analysis reports, evaluation reports, design and manufacturing procedures, certified data sheets, commercial dedication procedures and records, quality assurance records, calculation notes, and equipment qualification data packages.

When the Design Commitment or ITAAC provides that some thing or some activities must comply with ASME Code Section III, ASME Code Section XI, or the ASME OM Code, this means compliance with the ASME Code, as incorporated by reference in 10 CFR 50.55a with specific conditions, or in accordance with relief granted by the NRC or alternatives authorized by the NRC pursuant to 10 CFR 50.55a.

Item numbers are used to identify structures, systems and components in Tier 1 tables, figures, and text and are not representative of an actual equipment or tag numbers.

1.2.2 Implementation of ITAAC

The ITAAC are provided in tables with the following three column format:
Each Design Commitment in the left-hand column of the ITAAC tables has an associated Inspections, Tests, or Analyses (ITA) requirement specified in the middle column of the tables.

The identification of a separate ITA entry for each Design Commitment shall not be construed to require that separate inspections, tests, or analyses must be performed for each Design Commitment. Instead, the activities associated with more than one ITA entry may be combined, and a single inspection, test, or analysis may be sufficient to implement more than one ITA entry.

An ITA may be performed by the licensee of the plant, or by its authorized vendors, contractors, or consultants. Furthermore, an ITA may be performed by more than a single individual or group, may be implemented through discrete activities separated by time, and may be performed at any time prior to fuel load (including before issuance of the Combined License for those ITAAC that do not necessarily pertain to as-built equipment). Additionally, an ITA may be performed as part of the activities that are required to be performed under 10 CFR Part 50 (including, for example, the Quality Assurance (QA) program required under Appendix B to Part 50); therefore, an ITA need not be performed as a separate or discrete activity.

Each ITA has an associated Acceptance Criteria in the third column of the tables that demonstrate that the Design Commitment in the first column has been met.

1.2.3 System Design Description Discussion of Matters Related to Operations

In some cases, the Design Descriptions in this document refer to matters that relate to operation, such as normal valve or breaker alignment during normal operation modes. Such discussions are provided solely to place the Design Description provisions in context (e.g., to explain automatic features for opening or closing valves or breakers upon off-normal conditions). Such discussions shall not be construed as requiring operators during operation to take any particular action (e.g., to maintain valves or breakers in a particular position during normal operation).
1.2.4 Interpretation of Figures

In many but not all cases, the Design Descriptions in Section 2 include one or more Figures. The Figures may represent a functional diagram, general structural representation, or other general illustration. For instrumentation and control (I&C) systems, Figures also represent aspects of the relevant logic of the system or part of the system. Unless specified explicitly, the Figures are not indicative of the scale, location, dimensions, shape, or spatial relationships of as-built structures, systems, and components. In particular, the as-built attributes of structures, systems, and components may vary from the attributes depicted on the Figures, provided that those safety functions discussed in the Design Description pertaining to the Figure are not adversely affected.

1.2.5 Rated Reactor Core Thermal Power

The rated reactor core thermal power for the APR1400 certified design is 3,983 megawatts thermal (MWt).

1.2.6 Fuel Assembly Design

The fuel assembly is designed to ensure that possible fuel damage would not result in the release of radioactive materials in excess of prescribed limits. The fuel assembly is comprised of fuel rods, grids, guide tubes, top and bottom nozzles, and holddown springs. The fuel assembly design utilized in the APR1400 shall be approved by the NRC for the reactor design.
1.3 Figure Legend, Acronym and Abbreviation List

The conventions presented in this section are employed for figures used in the Design Descriptions. The acronyms and abbreviations presented in this section are used in the Design Control Document (DCD). The figure legend and acronym and abbreviation list are part of the Tier 1 DCD.

2.0 Design Description and ITAAC

2.1 Site Parameters

This section provides the major site parameters postulated for the Certified Design. These site parameters are applied for the design of the SSCs important to safety of the Certified Design.

2.1.1 Design Description

The site characteristics of the actual site for the Certified Design will be bounded by the postulated site parameters identified in Table 2.1-1. In case of deviation, the COL applicant is to justify that the facilities installed at the actual site will be acceptable regardless of site-specific parameters which may fall outside the postulated site parameters.

2.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

This section contains no ITAAC.

1. Plant grade represents the level of ground adjacent to the nuclear island buildings and is established plant elevation of 98 ft 8 in.
2. 100-year recurrence interval; value to be used for design of seismic Category I and II structures only.
3. Bearing capacity is defined at the foundation level of the seismic Category I Structures.
4. The HRHF response spectra are provided for evaluation of site-specific ground motion response spectra which exceed the CSDRS in the high frequency range at hard rock sites.
5. Degrees Fahrenheit (°F) are the main units and temperatures in Celsius (°C) are reference values that are converted from main units.
6. The backfill material dynamic properties are used to calculate the shear strain-compatible shear wave velocity profiles for the backfill. The strain-compatible damping values of the backfill cannot be greater than 15%.

2.2 Structural and System Engineering

This section provides discussions on building structures and structural aspects of major components. The nuclear island (NI) structures, emergency diesel generator building, turbine generator building, compound building and structural aspects of reactor pressure vessel and in-core instrument guide tube system are discussed. In addition, the protection against internal and external hazards is discussed.

2.2.1 Nuclear Island Structures

2.2.1.1 Design Description

The NI structures house, protect, and support plant equipment and provide personnel and equipment access, support for systems and components under operating loads, radiation shielding, structural components to withstand loads due to design basis external and internal events, physical separation between divisions of safety-related equipment, and barriers to minimize or prevent the release of radioactive materials. The NI structures are safety-related structures that consist of the reactor containment building (RCB) and the auxiliary building (AB). The NI structures are designed to withstand the effect of an aircraft impact.

The RCB and AB are structurally separated but founded on a common reinforced concrete basemat which is embedded below the finished plant grade level. The plant grade level is established at a plant elevation of 98 ft 8 in.

The RCB structure is composed of a prestressed concrete containment, and reinforced concrete internal structures with steel structures.

The containment is a steel lined prestressed concrete structure which consists of a right cylinder with a hemispherical dome on the reinforced concrete common basemat. The cylinder and dome of the containment is prestressed by a post-tensioning system consisting of horizontal and inverted "U" vertical tendons. There are three buttresses equally spaced around the cylinder to anchor horizontal tendon. There is no structural connection between free standing portion of the containment and adjacent structures other than penetrations and their supports. The containment retains its integrity at pressure and temperature conditions associated with the most limiting design basis accident without exceeding the design leakage rate. Access to the containment is provided through
personnel air locks and an equipment hatch. Penetrations are provided for electrical and mechanical components and for the transport of nuclear fuel.

The containment internal structures consist of reinforced concrete and structural steels that support reactor vessel and reactor coolant system. The primary shield wall supports and laterally surrounds the reactor vessel. The secondary shield wall laterally surrounds the primary shield wall and is structurally connected to the primary shield wall by reinforced concrete slabs, beams, and walls. The secondary shield wall supports steam generators and pressurizer. The containment internal structures enclose a reactor cavity area below the reactor vessel which can be flooded during a postulated accident. An indirect gas vent path is provided between the reactor cavity and the free volume of the containment.

The reactor cavity has a corium debris chamber. And the reactor cavity floor is constructed with a fill concrete on steel liner plate. The reactor cavity floor area is free from obstructions to corium debris spreading.

The AB is a reinforced concrete structure which consists of the electrical and control area, the fuel handling area, the chemical and volume control system area, the main steam valve house, and the emergency diesel generator area. The AB laterally surrounds the RCB and is divided by divisional walls.

The NI structures are designed in accordance with the requirements of ASME Section III Div. 2 CC, ASME Section III Div. 1 NE, ACI 349 and ANSI/AISC N690 as described in Table 2.2.1-6.

The tolerances for the dimensions in Table 2.2.1-1 and Figure 2.2.1-1 through 2.2.1-13 shall be in accordance with ACI 117(2010 edition) for concrete structures, ANSI/AISC 303(2010 edition) for structural steel members/structures, and ASME Section III, Div. 2, Subsection CC & applicable appendices related to tolerances (2001 edition with 2003 Addenda) for containment. Any provisions in these codes which provide acceptance criteria for conditions when tolerances are exceeded shall not apply, but a licensee referencing the APR1400 DCD may deviate from the tolerances in these codes using alternative acceptance criteria, if these acceptance criteria are approved by the NRC. As-built dimensions will also be evaluated to verify compliance with the design bases and applicable codes and standards identified in Table 2.2.1-6.
The NI structures, including the critical sections and design attributes listed in Table 2.2.1-5, are seismic Category I, and are designed and constructed to withstand the design basis loads associated with:

1. Normal plant operation (including dead loads, live loads, lateral earth pressure loads, hydrodynamic loads, and equipment loads, including the effects of temperature and equipment vibration)

2. External events (including rain, snow, wind, flood, tornado or hurricane, tornado or hurricane generated missiles, and earthquake)

3. Internal events (including flooding, pipe rupture, equipment failure, and equipment failure generated missile)

Seismic classification of the building is shown in Table 2.2.1-4.

1. The basic configuration of the NI structure is as shown in Figure 2.2.1-1 through Figure 2.2.1-13.

2.a The containment, except the steel portions of the containment not backed by concrete, is designed and constructed in accordance with ASME Section III, Div. 2 requirements.

2.b The containment penetrations are designed and constructed to meet ASME Section III, Div. 1 (portions not backed by concrete) and Div. 2 (portions backed by concrete).

2.c The containment and its penetrations retain their pressure boundary integrity associated with the design pressure.

2.d The containment and its penetrations maintain the containment leakage rate less than or equal to the maximum allowable leakage rate associated with the peak containment pressure for the design basis accident in accordance with 10 CFR Part 50, Appendix J.

3. The NI structures are seismic Category I, and are designed and constructed to withstand the design basis loads.
4. The dimensions and elevations of the NI structures are as described in Table 2.2.1-1 and Figures 2.2.1-1 through 2.2.1-13.

5. Nuclear Island (NI) Structures are designed constructed in accordance with the codes and standards listed in Table 2.2.1-6.

6. The critical sections and design attributes of the NI structures are in accordance with Table 2.2.1-5.

2.2.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for nuclear island structures are specified in Table 2.2.1-3.

2.2.2 Emergency Diesel Generator Building

2.2.2.1 Design Description

The emergency diesel generator (EDG) building block is located adjacent to east side of the Nuclear Island with seismic isolation gap, and comprises two buildings, one that houses additional two generators and the other for the diesel fuel oil tank (DFOT). Both EDG and DFOT buildings are single-story structures which are composed of reinforced concrete basemat, shearwalls and slabs. The two basemats are horizontally separated by seismic isolation gap.

The EDB building block is designed in accordance with the requirements of ACI 349 and ANSI/AISC N690 as described in the Table 2.2.1-6.

The tolerances for the dimensions in Table 2.2.2-1 and Figures 2.2.2-1 through 2.2.2-2 shall be in accordance with ACI 117(2010 edition) for concrete structures and ANSI/AISC 303(2010 edition) for structural steel members/structures. Any provisions in these codes which provide acceptance criteria for conditions when tolerances are exceeded shall not apply, but a licensee referencing the APR1400 DCD may deviate from the tolerances in these codes using alternative acceptance criteria, if these acceptance criteria are approved by the NRC. As-built dimensions will also be evaluated to verify compliance with the design bases and applicable codes and standards identified in Table 2.2.1-6. The EDG building block, including the critical sections and design attributes listed in Table 2.2.1-5, is designed and constructed to withstand the structural design basis loads associated with:

1. Normal plant operation (including dead loads, live loads, lateral earth pressure loads, and equipment loads, including the effects of temperature and equipment vibration)

2. External events (including rain, snow, wind, flood, tornado or hurricane, tornado or hurricane generated missiles, and earthquake)

3. Internal events (including flooding, pipe rupture, equipment failure, and equipment failure generated missile)

   a) The basic configuration of the EDG building block is as shown in Figures 2.2.2-1 and 2.2.2-2.
b) The EDG building block is designed and constructed to withstand the structural design basis loads.

c) The dimensions and elevations of the EDG building block are as described in Table 2.2.2-1, Figure 2.2.2-1 and Figure 2.2.2-2.

d) The EDG building block is designed and constructed in accordance with the applicable codes and standards listed in Table 2.2.1-6.

e) The critical sections and design attributes of the EDG building block are in accordance with Table 2.2.1-5.

2.2.2.2 Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the EDG building block are specified in Table 2.2.2-2.

Figure 2.2.2-2  Emergency Diesel Generator Building Block Plan
2.2.3 Turbine Generator Building

2.2.3.1 Design Description

The turbine generator building is a non-safety-related seismic Category II structure located adjacent to the auxiliary building that houses the high pressure turbine, low pressure turbine, and generator driven with high temperature and pressure steam which is generated from steam generator, and also houses some related auxiliary system. The building is composed of basemat, underground shear wall, turbine generator pedestal, and superstructure, and is supported by a reinforced concrete foundation which is separated from the adjacent auxiliary building structures.

1. The seismic Category II turbine generator building structure does not impair the ability of the safety-related SSCs to perform their safety-related functions during or following an SSE.

2.2.3.2 Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the turbine generator building is specified in Table 2.2.3-1.

2.2.4 Compound Building

2.2.4.1 Design Description

The compound building is a non-safety-related seismic Category II reinforced concrete structure which is located adjacent to the auxiliary building. The compound building houses the access control area, the hot machine shop, the radwaste treatment and drum removal areas, and the operation support center (OSC). The building is composed of reinforced concrete shear walls, interior walls, concrete slabs, girders and columns. The exterior shear walls and roof slabs play a role as a radiation shielding and missile protection.

1. The seismic Category II compound building structure does not impair the ability of the safety-related SSCs to perform their safety-related functions during or following an SSE.

2.2.4.2 Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the compound building is specified in Table 2.2.4-1.

2.2.5 Protection against Hazards

2.2.5.1 Design Descriptions

2.2.5.1.1 External Flooding

The NI structures and EDG building block are designed to withstand the external flooding. The safety-related SSCs housed in the structures are ascertained to maintain their safety functions during the external flooding condition.

The as-built NI structures and EDG structure have the following protective provisions against external flooding hazards:

1. The external walls below the postulated flood level or groundwater level have a thickness of greater than or equal to 0.60 m (2 ft) to prevent in-leakage.
2. The penetrations in the exterior walls below the postulated flood level or groundwater level are water sealed.
3. Water stops are installed at all construction joints of the exterior walls and basemats below the postulated flood level or groundwater level to prevent seepage into the structures.

2.2.5.1.2 Internal Flooding

The safety-related components are protected from the effect of internal flooding due to postulated piping failure. The internal flooding sources are considered high-energy or moderate-energy piping failure, non-seismically designed component or tank failure, including the operation of fire protection system.

The design considerations such as plant arrangement, physical or distance separation, flood barrier including watertight doors and various openings and penetrations are applied to satisfy the design concepts on the internal flooding protection. Openings and penetrations through flood barriers are minimized and the safety-related equipment are located above the internal flood level so that flooding events do not affect them.

The as-built RCB, AB (except the lowest floor at El. 55 ft), EDG building, ESW building, and the CCW HX building have the following protective provisions against internal flooding hazards.
1. Divisional flood barriers are provided that protect against the internal flooding.

2. Watertight doors are provided that protect against internal flooding.

3. Penetrations in the flood barrier are sealed up to internal design flood levels and, in addition, penetrations in the divisional walls are at least 2.5 m above the floor.

4. Safety-related electrical, instrumentation and control equipment are located above the internal design flood level and at least 20 cm above the floor surface.

2.2.5.1.3 Fire Barrier

The plant is subdivided into separate fire areas by fire-rated barriers, i.e., walls, floors, and ceilings, to confine the effects of fire hazards to a single area, thereby minimizing the potential for adverse effects from fires on redundant SSC important to safety.

The protective provisions against fire hazards are as follows:

1. The redundant trains of systems, components and cables important to safety, except for the control room complex and inside containment, are separated from each other by fire barriers having a 3-hour rating.

2. Openings and penetrations through fire barriers are protected by components (such as fire doors, fire dampers, penetration seals) having fire resistance equivalent to that of the barrier.

3. MCR complex and RSR are separated from each other and other fire areas by 3-hour rated fire barriers.

4. Fire and smoke barriers exist to keep any radiological releases from a fire within the exposure criteria of 10 CFR Part 20.

2.2.5.1.4 Internally Generated Missiles (Inside and Outside Containment)

Missile protection is provided for safety-related equipment so that internally generated missiles do not cause the release of significant amount of radioactivity or prevent the safe and orderly shutdown of the reactor.
Safety-related equipment and components in the as-built RCB, AB, EDG building, ESW building, and the CCW HX building are protected against internally generated missiles by one or more of the following:

1. Design features to prevent the generation of missiles

2. Orientation of missile sources to prevent missiles from striking safety-related equipment and components

3. Local shields and barriers protect the safety-related equipment and components

   Safety-related equipment and components are designed to withstand the impact of missiles

2.2.5.2 Inspection, Tests, Analyses, and Acceptance Criteria

The inspection, tests, analyses, and associated acceptance criteria for protection against hazards are specified in Table 2.2.5-1.

2.2.6 Reactor Vessel Internals

2.2.6.1 Design Description

The reactor vessel internals consist of a core support barrel (CSB) assembly and an upper guide structure (UGS) assembly. The reactor vessel internals are safety-related.

The CSB assembly is suspended from the reactor vessel flange. The CSB assembly provides support and location positioning for the fuel assembly lower end fittings. The CSB assembly contains structural elements that provide an instrumentation guide path from the lower vessel, and hydraulic flow paths through the vessel from the inlet nozzles to the upper end of the fuel assemblies.

The CSB assembly contains a grid structure which supports the core and provides flow distribution from the lower plenum region to the bottom of the fuel assemblies. The core shroud is part of the CSB assembly and provides an envelope to direct the primary coolant flow through the core. Instrumentation nozzles in the grid structure provide a guide path for in-core instrumentation from the reactor vessel lower head to the fuel assemblies.

The UGS assembly is supported by the CSB upper flange and extends into the CSB assembly to engage the top of the fuel assemblies. The UGS assembly provides an insertion path for the control element assemblies (CEA). The UGS assembly contains structural elements which provide both a guide path and lateral support for the upper portion of the CEA and extensions shafts in the reactor vessel upper plenum region. The UGS assembly also provides guide paths for heated junction thermocouple (HJTC) assemblies.

1. The functional arrangement of the reactor vessel internals is as described in the Design Description of Subsection 2.2.6.1 and in Table 2.2.6-1 and as shown in Figures 2.2.6-1 and 2.2.6-2.

2. The ASME Code components identified in Table 2.2.6-1 are designed and constructed in accordance with ASME Section III Subsection NG requirements.

3. The seismic Category I components identified in Table 2.2.6-1 can withstand seismic design basis loads without loss of safety function.
4. The reactor vessel internals withstand the effects of flow induced vibration caused by the operation of the reactor coolant pumps.

2.2.6.2 Inspections, Tests, Analyses, and Acceptance Criteria

Figure 2.2.6-1  Core Support Barrel Assembly
Figure 2.2.6-2  Upper Guide Structure Assembly
2.2.7  In-core Instrument Guide Tube System

2.2.7.1  Design Description

The in-core instrument (ICI) guide tube system is safety-related and consists of guide tubes, supports, seal housings and a seal table.

The ICI guide tubes serve as a guide path and provide support for the in-core instrument assemblies. The ICI guide tubes connect to the bottom of the reactor vessel and terminate in a seal housing assembly located at the seal table. Pressure retaining seals are installed between the seal housing and the in-core instrument assembly at the seal housing.

The ICI guide tube supports and seal table support the ICI guide tubes and provide spacing between tubes. The seal table also seals the ICI chase from water ingress during refueling.

1. The functional arrangement of the ICI guide tubes, seal housings, supports, and seal table is as described in the Design Description of Subsection 2.2.7.1 and in Table 2.2.7-1 and as shown in Figure 2.2.7-1.

2. The ASME Code components identified in Table 2.2.7-1 are designed and constructed in accordance with ASME Section III requirements.

3. The ICI guide tubes and seal housings identified in Table 2.2.7-1 retain their pressure boundary integrity at their design pressure.

4. The seismic Category I components identified in Table 2.2.7-1, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

2.2.8 Essential Service Water Building

2.2.8.1 Design Description

The Essential Service Water (ESW) buildings are classified as seismic Category I buildings with a concrete structure. The ESW building houses essential service water pumps, cooling tower, and cooling tower basin. The structure is composed of basemat, floors, roofs, and shear walls. The ESW structure provides pump rooms that are separated by reinforced concrete walls and operating floor in which the equipment are installed.

The ESW building is designed in accordance with the requirements of ACI 349 and ANSI/AISC N690 as described in the Table 2.2.1-6.

The ESW building is designed and constructed to withstand the structural design basis loads associated with:

1. Normal plant operation (including dead loads, live loads, lateral earth pressure loads, and hydrostatic loads, hydrodynamic loads, and temperature loads)

2. External events (including rain, snow, wind, flood, tornado or hurricane, tornado or hurricane generated missiles, and earthquake)

3. Internal events (including internal flooding, pipe rupture, equipment failure, and equipment failure generated missile)

   a) The ESW building is designed and constructed to withstand the structural design basis loads.

   b) The ESW building is designed and constructed in accordance with the applicable codes and standards listed in Table 2.2.1-6.

2.2.8.2 Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the ESW building are specified in Table 2.2.8-1.

2.2.9  Component Cooling Water Heat Exchanger Building

2.2.9.1  Design Description

The component cooling water (CCW) heat exchanger buildings next to each ESW building are classified as seismic Category I buildings with a concrete structure. The CCW heat exchanger building houses CCW heat exchangers, debris filters. The structure is composed of basemat, floors, roofs, and shear walls. The load resistance of the structure consists of slabs and shear walls combined with concrete columns and beams as the structural elements.

The CCW heat exchanger building is designed in accordance with the requirements of ACI 349 and ANSI/AISC N690 as described in the Table 2.2.1-6.

The CCW heat exchanger building is designed and constructed to withstand the structural design basis loads associated with:

1. Normal plant operation (including dead loads, live loads, lateral earth pressure loads, and equipment loads, including the effects of temperature and equipment vibration)

2. External events (including rain, snow, wind, flood, tornado or hurricane, tornado or hurricane generated missiles, and earthquake)

3. Internal events (including flooding, pipe rupture, equipment failure, and equipment failure generated missile)
   a) The CCW heat exchanger building is designed and constructed to withstand the structural design basis loads.
   b) The CCW heat exchanger building is designed and constructed in accordance with the applicable codes and standards listed in Table 2.2.1-6.

2.2.9.2  Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the CCW heat exchanger building are specified in Table 2.2.9-1.

2.2.10  Seismic Analysis Methods

The seismic Category I safety-related structures of the APR1400 standard plant design are modeled as three-dimensional finite element models to perform seismic analyses for the safe shutdown earthquake. The structures for which seismic analyses are performed are as follows:

The time-history analyses with complex frequency response method considering the soil-structure interaction effects for the generic site conditions are performed to generate the seismic responses of above structures such as story shear forces and in-structure response spectra (ISRS). For structural design of the reactor containment building containment structure and internal structure, the response spectrum analyses with ISRS at the reactor containment building El. 78’-0” are performed to determine design member forces and moments due to seismic loads. For structural design of the auxiliary building, emergency diesel generator building and diesel fuel oil storage tank room, the equivalent static analyses to story shear forces are performed to determine design member forces and moments due to seismic loads.

Table 2.2.10-1 shows the key locations where comparisons of ISRS are needed by a COL applicant if a site-specific seismic analysis evaluation is required. The key locations are locations that are expected to represent the minimum and maximum seismic responses in the structure and include the basemat and roof slab elevations and the support elevation of the major equipment.

2.3 Piping Systems and Components

2.3.1 Design Description

There are four areas related to piping systems and components which are addressed in the certified plant design:

a. Piping stress analysis

b. Analysis of protection against the dynamic effects of piping rupture

c. Evaluation of leak-before-break (LBB)

d. Analysis of component stress

Piping Stress Analysis

The analysis and design of piping and piping supports are in accordance with the requirements of the ASME Section III based on Code classification and ASME Service Level. The piping stress analysis is based on the requirements of ASME Section III Subsections NB (Class 1), NC (Class 2), or ND (Class 3). Stress analysis of piping and supports considers design basis loads and load combinations applicable to each system. ASME Section III Class 1 piping subject to fatigue analysis in both air and reactor coolant environment is evaluated for failure over the design life of the plant.

Analysis of Protection against the Dynamic Effects of Piping Rupture

All safety-related SSCs are protected from the dynamic and environmental effects associated with postulated piping failures in high-energy piping systems inside and outside the containment where consideration of these dynamic effects is not eliminated by LBB. All safety-related SSCs are protected against environmental effects associated with postulated failures in moderate-energy piping systems. Each postulated piping failure shall be documented in a pipe break analysis report. Design of features that protect these SSCs considers, as applicable, pipe whip, jet impingement, flooding, compartment pressurization, and environmental conditions in the area where the piping is located. Table 2.3-2 lists high-energy and moderate-energy piping systems that are evaluated for the
dynamic and environmental effects of piping failures. Table 2.3-3 specifies the inspection, tests, analyses, and associated acceptance criteria for the pipe rupture hazard protection.

**Evaluation of Leak-Before-Break (LBB)**

The following piping systems are designed to meet leak-before-break (LBB) criteria:

a. Reactor coolant loop (RCL) piping, hot and cold legs,

b. Pressurizer surge line,

c. Shutdown cooling (SC) line from the reactor coolant system to the second isolation valve, and

d. Direct vessel injection (DVI) line from the reactor vessel to the safety injection tank and the second isolation valve.

The LBB evaluations consider normal and abnormal loads and load combinations to demonstrate compliance with the LBB design criteria.

LBB acceptance criteria are established and LBB evaluations including material properties are performed for each piping system designed to meet LBB criteria. For each piping system qualified for LBB, the as-built piping and materials are reconciled with the bases for the LBB acceptance criteria.

**Analysis of Component Stress**

Design and analysis of components are performed in accordance with the requirements of the ASME Section III on the basis of Code classification and ASME Service Level. For the component stress analysis, the requirements of the ASME Section III Subsection NB (Class 1), NC (Class 2), or ND (Class 3) code are applied. Design basis loads and load combination applicable to each system are considered in the stress analysis of components. ASME Section III Class 1 pressure boundary components are also subject to fatigue usage evaluations over the design life of the plant.

Piping system and components are designed as follows:
1. The ASME Section III Class 1 piping systems and components for systems identified in Table 2.3-1 are designed to retain their pressure integrity and functional capability under internal design and operating pressures and design basis loads.

2. The ASME Section III Class 1 piping systems and components for systems identified in Table 2.3-1 are evaluated for fatigue usage factor in both air and reactor coolant environments.

3. The ASME Section III Class 2 and 3 piping systems and components for systems identified in Table 2.3-1 are designed to retain their pressure integrity and functional capability under internal design and operating pressures and design-basis loads.

4. For each piping system qualified for LBB identified in Table 2.3-1, the as-built piping and materials are reconciled with the basis used for LBB acceptance criteria.

5. SSCs required for safe shutdown are protected from the dynamic and environmental effects of postulated high and moderate energy piping failures inside and outside the containment where consideration of these dynamic effects is not eliminated by LBB.

2.4 Reactor Systems

2.4.1 Reactor Coolant System

2.4.1.1 Design Description

The reactor coolant system (RCS) is a safety-related system which removes the heat generated in the reactor core and transfers the heat to the steam generators. The RCS forms part of the pressure and fission product boundary between the reactor coolant and the reactor containment building (RCB) atmosphere.

The RCS is located in the RCB and consists of a reactor vessel (RV), two vertical U-tube steam generators (SGs), four reactor coolant pumps (RCPs), one pressurizer (PZR), four pressurizer pilot operated safety relief valves (POSRVs), ninety three control element drive mechanisms (CEDMs), piping, heaters, controls, instrumentation, and valves.

The safety-related functions of the RCS are as follows:

a. To form a barrier against the uncontrolled release of reactor coolant and radioactive materials to the containment.

b. In conjunction with other systems, to provide cooling during all plant evolutions and anticipated operational occurrences to preclude significant reactor core damages.

c. To provide protection of the RCS from overpressure by pressure relief devices for all design basis events (DBEs).

The RCS is designed and/or constructed as follows:

1. The functional arrangement of the RCS is as described in the Design Description of Subsection 2.4.1.1 and Table 2.4.1-1 and as shown in Figures 2.4.1-1 and 2.4.1-2.

2.a The ASME Code components identified in Table 2.4.1-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping including supports identified in Table 2.4.1-1 is designed and constructed in accordance with ASME Section III requirements.
3. a Pressure boundary welds in ASME Code components identified in Table 2.4.1-2 meet ASME Section III requirements.

3. b Pressure boundary welds in ASME Code piping identified in Table 2.4.1-1 meet ASME Section III requirements.

4. a The ASME Code components identified in Table 2.4.1-2 retain their pressure boundary integrity under at their design pressure.

4. b The ASME Code piping identified in Table 2.4.1-1 retains its pressure boundary integrity under at its design pressure.

5. a The seismic Category I components and instruments identified in Tables 2.4.1-2 and 2.4.1-3, including the supports and anchorages, withstands seismic design basis loads without loss of safety function.

5. b The seismic Category I piping, including supports, identified in Table 2.4.1-1 withstands seismic design basis loads without loss of safety function.

6. a The Class 1E components and instruments identified in Tables 2.4.1-2 and 2.4.1-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6. b Each of the Class 1E components and instruments identified in Tables 2.4.1-2 and 2.4.1-3 is powered from its respective Class 1E division.

6. c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7. a The RCS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions with debris laden coolant fluids up to and including design basis accident conditions.

7. b After loss of motive power, MOVs and AOVs identified in Table 2.4.1-2 assume the indicated loss of motive power position.
8.a Controls exist in the MCR to start and stop the reactor coolant pumps and to open and close the MOVs and AOVs listed in Table 2.4.1-2.

8.b Controls exist in the RSR to start and stop the reactor coolant pumps and to open and close the MOVs and AOVs listed in Table 2.4.1-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.4.1-2 and 2.4.1-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.4.1-2 and 2.4.1-3.

8.e Controls exist in the MCR to energize and de-energize the pressurizer backup heaters listed in Table 2.4.1-2.

8.f Controls exist in the RSR to energize and de-energize the pressurizer backup heaters listed in Table 2.4.1-2.

9.a The pressurizer POSRVs provide overpressure protection for reactor coolant pressure boundary components in the RCS.

9.b Each RCP motor has a flywheel which retains its integrity at a design overspeed condition.

9.c Each RCP has rotating inertia to slow the pump flow coastdown when electrical power is disconnected.

9.d The RCPs circulate coolant at a rate which removes heat generated in the reactor core.

9.e The RCS provides properly rated pressurizer backup heaters to control system pressure.

10. The RV is equipped with holders for at least six capsules for accommodating material surveillance specimens.

11. RV material specimens taken from materials actually used in fabrication of the beltline region are inserted in the capsules and include Charpy V-notch
specimens of base metal, weld metal and heat-affected zone material, and tensile and 1/2T compact tension specimens from base metal and weld metal.

12. The piping systems identified in Table 2.4.1-1 as qualified for LBB meet the LBB acceptance criteria, or protection of safety-related SSCs from the dynamic effects associated with postulated failures of the high energy piping system is provided.

13. The nozzle dam withstands its design pressure of 50 psig under the design conditions.14. The decay heat removal function of the SCS will not be impaired by air entrainment into the SCS suction nozzle.

2.4.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.4.1-4 specifies the inspections, tests, analyses, and associated acceptance criteria for the reactor coolant system.

Figure 2.4.1-1 Reactor Coolant System
Figure 2.4.1-2  Reactor Coolant System (Pressurizer)
2.4.2 In-containment Water Storage System

2.4.2.1 Design Description

The in-containment water storage system (IWSS) is a safety-related system and includes the in-containment refueling water storage tank (IRWST) which is an integral part of containment building structures, the holdup volume tank (HVT) which is also an integral part of the containment building structures, and the cavity flooding system (CFS).

The IRWST provides borated water for the safety injection system (SIS) and the containment spray system (CSS). It is the primary heat sink for discharges from the POSRVs and the reactor coolant gas vent system (RCGVS). It is the source of water for the CFS, and for filling the refueling pool via the shutdown cooling system (SCS).

The HVT collects water released in containment during design basis events (DBEs) and returns water to the IRWST through spillways. It receives water discharged from the IRWST and transfers the water to the reactor cavity area by the CFS.

The CFS is used to provide water to flood the reactor cavity in response to beyond DBEs.

The IWSS is located in the containment.

1. The functional arrangement of the IWSS is as described in the Design Description of Subsection 2.4.2.1 and in Table 2.4.2-1 and as shown in Figure 2.4.2-1.

2.a The ASME Code components identified in Table 2.4.2-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.4.2-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.4.2-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.4.2-1 meet ASME Section III requirements.
4.a The ASME Code components identified in Table 2.4.2-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.4.2-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.4.2-2 and 2.4.2-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.4.2-1 withstands seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.4.2-2 and 2.4.2-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.4.2-2 and 2.4.2-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The IWSS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, MOVs and SOVs identified in Table 2.4.2-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close the MOVs and SOVs identified in Table 2.4.2-2.

8.b Controls exist in the RSR to open and close the MOVs and SOVs identified in Table 2.4.2-2.
8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.4.2-2 and 2.4.2-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.4.2-2 and 2.4.2-3.

9.a The IWSS provides borated water for safety injection and containment spray during design basis events.

9.b The IWSS provides post-LOCA pH control with tri-sodium phosphate (TSP).

9.c The IWSS provides protection from overpressure and vacuum of the IRWST.

10. The IWSS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.4.2.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria of the IWSS are specified in Table 2.4.2-4.

The ITAAC related to the CIVs and the piping between the CIVs of the IWSS are described in Table 2.11.3-2.

Table 2.4.2-4 (7 of 7)
Figure 2.4.2-1  In-containment Water Storage System
2.4.3 Safety Injection System

2.4.3.1 Design Description

The safety injection system (SIS) is a safety-related system which injects borated water into the reactor vessel to provide core cooling and reactivity control in response to design basis accidents. The SIS also provides core cooling during feed and bleed operation, in conjunction with the pilot operated safety relief valves (POSRVs). The major components of the SIS are four safety injection pumps (SIPs), four identical safety injection tanks (SITs), and associated valves.

The SIS is located in the auxiliary building and containment building.

1.a. The functional arrangement of the SIS is as described in the Design Description of Subsection 2.4.3.1 and in Table 2.4.3-1 and as shown in Figure 2.4.3-1.

1.b. Physical separation exists between the four redundant trains of the SIS as described in Section 6.3.1.5 of DCD Tier 2.

2.a. The ASME Code components identified in Table 2.4.3-2 are designed and constructed in accordance with ASME Section III requirements.

2.b. The ASME Code piping, including supports, identified in Table 2.4.3-1 are designed and constructed in accordance with ASME Section III requirements.

3.a. Pressure boundary welds in ASME Code components identified in Table 2.4.3-2 meet ASME Section III requirements.

3.b. Pressure boundary welds in ASME Code piping identified in Table 2.4.3-1 meet ASME Section III requirements.

4.a. The ASME Code components identified in Table 2.4.3-2 retain their pressure boundary integrity at their design pressure.

4.b. The ASME Code piping identified in Table 2.4.3-1 retains its pressure boundary integrity at its design pressure.
5.a The seismic Category I components and instruments identified in Tables 2.4.3-2 and 2.4.3-3, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.4.3-1 can withstand seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.4.3-2 and 2.4.3-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.4.3-2 and 2.4.3-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The SIS safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions with debris-laden coolant fluids up to and including design basis accident conditions.

7.b After loss of motive power, MOVs, SOVs and AOVs identified in Table 2.4.3-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to start and stop the SIPs, and to open and close the MOVs, SOVs, and AOVs identified in Table 2.4.3-2.

8.b Controls exist in the RSR to start and stop the SIPs, and to open and close the MOVs, SOVs, and AOVs identified in Table 2.4.3-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.4.3-2 and 2.4.3-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.4.3-2 and 2.4.3-3.
9.a The SIS provides RCS makeup, boration, and safety injection during design basis accidents.

9.b The SIS safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions with debris laden coolant fluids up to and including design basis accident conditions.

9.c The SI pumps have sufficient net positive suction head (NPSH).

9.d The as-built SI pumps deliver flow between 3,915 L/min (1,034 gpm) to 4,201 L/min (1,110 gpm) to the reactor vessel within 40 seconds following receipt of signals simulating ESF-SIAS or DPS-SIAS.

9.e The SI pumps can be tested at full flow during plant operation.

9.f The SIS can be manually realigned for simultaneous hot leg injection and direct vessel injection (DVI).

9.g The pumps identified in Table 2.4.3-2 start after receiving an ESF-SIAS or DPS-SIAS.

9.h A confirmatory-open interlock is provided to automatically open the SIT discharge valve upon receipt of an ESF-SIAS or DPS-SIAS.

10. The piping systems identified in Table 2.4.3-1 as qualified for LBB meets the LBB acceptance criteria, or protection of safety-related SSCs from the dynamic effects associated with postulated failures of the high energy piping system is provided.

11. The emergency core cooling function of the SIS will not be impaired by gas entrainment based on monitoring and venting at pre-determined intervals.

12. The SIS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.
2.4.3.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.4.3-4 specifies the inspections, tests, analyses, and acceptance criteria for the SIS.

Figure 2.4.3-1  Safety Injection System
2.4.4 Shutdown Cooling System

2.4.4.1 Design Description

The shutdown cooling system (SCS) is a safety-related system which removes decay heat from the reactor coolant system (RCS) and transfers the heat to the component cooling water system (CCWS) during a planned reactor shutdown operation and an accident.

The SCS is designed such that the shutdown cooling pumps (SCPs) are identical and functionally interchangeable with containment spray pumps (CSPs) for containment spray function. Provisions are made to control the valves used in the SCS/CSS interconnection. The SCS consists of heat exchangers and two pumps. One SCS pump is capable of meeting the safety-grade cooldown criteria and two SCS pumps are required to meet the normal cooldown design criteria.

The SCS is located in the containment building and auxiliary building.

1. The functional arrangement of the SCS is as described in the Design Description of Subsection 2.4.4.1 and in Table 2.4.4-1 and as shown in Figure 2.4.4-1.

2.a The ASME Code components identified in Table 2.4.4-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.4.4-1 are designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.4.4-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.4.4-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.4.4-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.4.4-1 retains its pressure boundary integrity at its design pressure.
5.a The seismic Category I components and instruments identified in Tables 2.4.4-2 and 2.4.4-3, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.4.4-1 can withstand seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.4.4-2 and 2.4.4-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.4.4-2 and 2.4.4-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The SCS safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions with debris-laden coolant fluids up to and including design basis accident conditions.

7.b After loss of motive power, MOVs identified in Table 2.4.4-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to start and stop the SCPs, and to open and close the MOVs identified in Table 2.4.4-2.

8.b Controls exist in the RSR to start and stop the SCPs, and to open and close the MOVs identified in Table 2.4.4-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.4.4-2 and 2.4.4-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.4.4-2 and 2.4.4-3.
9.a The SCS cools the reactor by removing decay heat and other residual heat from
the reactor core and the RCS during the normal plant shutdown and cool down
conditions.

9.b The SCS suction line relief valves provide RCS low temperature overpressure
protection (LTOP).

9.c The SCS safety-related pumps are functionally designed and qualified to perform
their safety-related function under the full range of fluid flow, differential
pressure, electrical, and temperature conditions with debris laden coolant fluids
up to and including design basis accident conditions.

9.d Each SCP has sufficient net positive suction head (NPSH) in each operating
configuration.

9.e Each SCP has a full flow test capability during a normal plant operating
condition when the pump suction is aligned to the IRWST and the discharge is
aligned to the IRWST.

9.f A containment spray actuation signal (CSAS) or engineered safety features-
safety injection actuation signal (ESF-SIAS) starts the SCP only when the SCP is
aligned for containment spray pump (CSP) function. The CSP in the same
division will not start on those signals.

9.g The piping of SCS contains no loop seals and maintains a horizontal or
downward slope from the RCS to the SCPs, with the exception of the section of
piping adjacent to the pump suction flange.

10. The decay heat removal function of the SCS will not be impaired by gas
entrainment based on monitoring and venting at pre-determined intervals.

11. The SCS non-metallic parts, materials, and lubricants used in safety-related
mechanical equipment perform their safety-related function up to the end of their
qualified life in the design basis harsh environmental conditions (both internal
service conditions and external environmental conditions) experienced during
normal operations, anticipated operational occurrences, design-basis accidents,
and post accident conditions.
2.4.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.4.4-4 specifies the inspections, tests, analyses, and acceptance criteria for the SCS.

## Shutdown Cooling System ITAAC

### Design Commitment

1. The functional arrangement of the SCS is as described in the Design Description of Subsection 2.4.4.1 and in Table 2.4.4-1 and as shown in Figure 2.4.4-1.

### Inspections, Tests, Analyses

1. Inspection of the as-built SCS will be conducted.

### Acceptance Criteria

1. The as-built SCS conforms with the functional arrangement as described in the Design Description of Subsection 2.4.4.1 and in Table 2.4.4-1 and as shown in Figure 2.4.4-1.

Figure 2.4.4-1  Shutdown Cooling System

Rev. 3
2.4.5 Reactor Coolant Gas Vent System

2.4.5.1 Design Description

The reactor coolant gas vent system (RCGVS) is used to discharge non-condensible gases and steam from the high point of the reactor coolant system (RCS). The RCGVS is a safety-related system and provides a safety-grade means of remotely venting non-condensible gases from the reactor vessel closure head and the pressurizer steam space during post-accident conditions when large quantities of non-condensible gases accumulate in these high spots.

The RCGVS provides a safety-grade means to depressurize the RCS in the event that pressurizer main spray and auxiliary spray systems are unavailable.

The RCGVS effluent from the pressurizer or the reactor vessel closure head is transported to the in-containment refueling water storage tank (IRWST) through the RCGVS sparger for the safety vent function. The IRWST provides a water reservoir to condense the steam effluent and collect the RCS discharge. The RCGVS effluent from the pressurizer or the reactor vessel closure head is transported to the reactor drain tank (RDT) or the IRWST for the non-safety gas vent operation during plant startup and shutdown.

The RCGVS is located in the RCB and consists of piping, valves and instrumentation to vent non-condensible gases and/or steam from the RCS to either the RDT or the IRWST.

1. The functional arrangement of the RCGVS is as described in the Design Description of Subsection 2.4.5.1 and in Table 2.4.5-1 and as shown in Figure 2.4.5-1.

2.a The ASME Code components identified in Table 2.4.5-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.4.5-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.4.5-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.4.5-1 meet ASME Section III requirements.
4.a The ASME Code components identified in Table 2.4.5-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.4.5-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.4.5-2 and 2.4.5-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.4.5-1 withstands seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.4.5-2 and 2.4.5-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.4.5-2 and 2.4.5-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The RCGVS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, SOVs indicated in Table 2.4.5-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close SOVs identified in Table 2.4.5-2.

8.b Controls exist in the RSR to open and close SOVs identified in Table 2.4.5-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.4.5-2 and 2.4.5-3.
8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.4.5-2 and 2.4.5-3.

9. The RCGVS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.4.5.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria of the RCGVS are specified in Table 2.4.5-4.

Figure 2.4.5-1 Reactor Coolant Gas Vent System

2.4-90 Rev. 3
2.4.6 Chemical and Volume Control System

2.4.6.1 Design Description

The chemical and volume control system (CVCS) controls the purity, volume, and chemistry of the reactor coolant. The portions of the CVCS which accomplish reactor normal makeup and normal reactivity control are classified at least safety Class 3.

The CVCS maintains the required volume of water in reactor coolant system (RCS) in conjunction with the pressurizer level control system. The CVCS also provides backup spray water to the pressurizer and cooling water to the RCP seals.

The CVCS also has the following safety-related functions: maintaining integrity of components (including piping and valves) in the reactor coolant pressure boundary, isolating the CVCS lines passing through the containment penetrations following a postulated DBA, and limiting the magnitude of a boron dilution source to the RCS to prevent inadvertent RCS boron dilution.

Major portion of CVCS is located in the auxiliary building and reactor containment building, except the holdup tank (HT), reactor makeup water tank (RMWT), and boric acid storage tank (BAST) are located in the yard and surrounded by a dike.

The gas stripper is operated as necessary to ensure that dose rate outside the HT remains less than 2.5 μSv/hr.

The gas stripper is operated as necessary to ensure that dose rate outside the HT remains less than the Zone 1 criteria.

1. The functional arrangement of the CVCS is as described in the Design Description of Subsection 2.4.6.1 and in Table 2.4.6-1 and as shown in Figure 2.4.6-1.
2.a The ASME Code components identified in Table 2.4.6-2 are designed and constructed in accordance with ASME Section III requirements.
2.b The ASME Code piping, including supports, identified in Table 2.4.6-1 is designed and constructed in accordance with ASME Section III requirements.
3. a Pressure boundary welds in ASME Code components identified in Table 2.4.6-2 meet ASME Section III requirements.

3. b Pressure boundary welds in ASME Code piping identified in Table 2.4.6-1 meet ASME Section III requirements.

4. a The ASME Code components identified in Table 2.4.6-2 retain their pressure boundary integrity at their design pressure.

4. b The ASME Code piping identified in Table 2.4.6-1 retains its pressure boundary integrity at its design pressure.

5. a The seismic Category I components and instruments identified in Tables 2.4.6-2 and 2.4.6-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5. b The seismic Category I piping, including supports, identified in Table 2.4.6-1 can withstand seismic design basis loads without loss of safety function.

6. a The Class 1E components and instruments identified in Tables 2.4.6-2 and 2.4.6-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6. b Each of the Class 1E components and instruments identified in Tables 2.4.6-2 and 2.4.6-3 is powered from its respective Class 1E division.

6. c Physical separation and electrical isolation are provided (1) between Class 1E divisions and (2) between Class 1E divisions and non-Class 1E divisions.

7. a The CVCS safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7. b After loss of motive power, MOVs, AOVs, and SOV identified in Table 2.4.6-2 assume the indicated loss of motive power position.
8.a Controls exist in the MCR to start and stop the charging pumps and auxiliary charging pump, and to open and close the MOVs, AOVs, and SOV identified in Table 2.4.6-2.

8.b Controls exist in the RSR to start and stop the charging pumps and auxiliary charging pump, and to open and close the MOVs, AOVs, and SOV identified in Table 2.4.6-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.4.6-2 and 2.4.6-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.4.6-2 and 2.4.6-3.

9.a The CVCS provides makeup capability to maintain the RCS volume.

9.b The CVCS supplies seal water to the RCP seals.

9.c The CVCS provides pressurizer auxiliary spray water for depressurization.

9.d The CVCS limits the magnitude of a boron dilution source to the RCS to prevent inadvertent RCS boron dilution.

9.e The charging pumps and auxiliary charging pump have net positive suction head (NPSH).

10. The CVCS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

11. A pre-holdup ion exchanger is used to limit radionuclide inventories stored in the holdup tank. A 3-to-1 cation to anion ratio provides a minimum cesium DF of 100.
2.4.6.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.4.6-4 specifies the ITAAC for the CVCS.

The ITAAC associated with the CVCS equipment, components, and piping that comprise a portion of the containment isolation system are described in Table 2.11.3-2.

Figure 2.4.6-1  Chemical and Volume Control System
2.4.7 Leakage Detection System

2.4.7.1 Design Description

The leak detection system for reactor coolant pressure boundary (RCPB) provides a means of detecting and, to the extent practical, identifying the source of reactor coolant leakage and monitoring leakage from the reactor coolant system and associated systems.

1. Indications of unidentified coolant leakage into the containment are provided by containment sump level monitors and containment airborne particulate radioactivity monitors, and containment atmosphere humidity monitors listed in Table 2.4.7-2. The instrumentation for leak detection system provides alarms and displays in the MCR indicating reactor coolant pressure boundary leakage.

2. The above listed leak detection system instrumentation is located at the following locations:

   - Containment atmosphere humidity sensors: The humidity sensors are installed at the intake of each of the reactor containment fan Coolers (RCFCs).

   - Containment airborne particulate radioactivity: The sample line inlet for radiation monitors is located on the operating level between two RCFC air intakes.

   - Containment sump level: The level monitors are installed at the ICI cavity sump and the reactor containment building sump.

2.4.7.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.4.7-1 describes the ITAAC for reactor coolant pressure boundary leakage detection system.

2.5 Instrumentation and Control

2.5.1 Reactor Trip System and Engineered Safety Features Initiation

2.5.1.1 Design Description

The reactor trip system (RTS) consists of four channels of sensors, auxiliary process cabinet-safety (APC-S) cabinets, ex-core neutron flux monitoring system (ENFMS) cabinets, and four divisions of core protection calculator system (CPCS) cabinets, the reactor protection system (RPS) portion of plant protection system (PPS) cabinets, and reactor trip switchgear system (RTSS) cabinets.

The engineered safety features (ESF) system consists of four sensors, APC-S cabinets, and four divisions of the engineered safety features actuation system (ESFAS) portion of the PPS cabinets and engineered safety features-component control system (ESF-CCS) cabinets. The ESF initiation is performed in sensors, APC-S cabinets and the ESFAS portion of the PPS cabinets.

The APC-S provides signal conditioning/splitting for the safety field sensor signals and transmits the signals to safety systems (PPS, CPCS, QIAS-P and ESF-CCS) and non-safety systems (NPCS, DPS and DIS).

The CPCS monitors pertinent reactor core conditions and calculates Departure from Nucleate Boiling Ratio (DNBR) and Local Power Density (LPD). If the calculated DNBR goes below the pre-determined trip setpoint, a DNBR trip signal is generated. If the calculated LPD exceeds the pre-determined trip setpoint, an LPD trip is generated. The DNBR and LPD trip signals are sent to the PPS for reactor trip initiation.

The ENFMS provides signal conditioning for the detector signals and transmits the signals to the PPS and CPCS.

The PPS automatically generates signals for reactor trip and ESF initiation whenever the monitored processes exceed predefined limits.

The RTSS opens the reactor trip circuit breaker to shut down the reactor upon receiving the reactor trip initiation signal from the PPS.

The Subsection 2.5.1 describes the RTS and ESF system (generation ESF initiation signal). The ESF-CCS is described in Subsection 2.5.4.
The RTS and ESF initiation equipment is located in the auxiliary building and reactor containment building.

The operator module (OM), the maintenance and test panel (MTP), and the interface and test processor (ITP) which are part of the safety I&C system, provide monitoring and testing for the safety-related plant components and instrumentation.

The RTS and ESF system (generating ESF initiation signal) are designed as follows:

1. The seismic Category I equipment, identified in Table 2.5.1-1 withstands seismic design basis loads without loss of safety function.

2. The Class 1E equipment identified in Table 2.5.1-1 (and the associated wiring, cables, and terminations) withstand lightning strikes, the electrical surge, electromagnetic interference (EMI), radio frequency interference (RFI), and electrostatic discharge (ESD) conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

3.a Class 1E equipment identified in Table 2.5.1-1 is powered from its respective Class 1E train.

3.b Redundant Class 1E divisions listed in Table 2.5.1-1 and associated field equipment are physically separated and electrically independent from each other and physically separated and electrically independent from non-Class 1E equipment. Class 1E qualified isolation devices such as fiber optic modems or interposing relays are applied at interfaces between redundant safety divisions and at interfaces between safety and non-safety systems.

3.c Communication independence is achieved between redundant divisions of the Class 1E equipment listed in Table 2.5.1-1.

3.d Communication independence is achieved between non-safety systems and Class 1E equipment listed in Table 2.5.1-1.

4.a The PPS and CPCS provide an automatic reactor trip (RT) and ESF initiation signals, for each condition listed in Tables 2.5.1-2 and 2.5.1-3, if plant process signals reach predetermined setpoints.
4.b Once RT is initiated (automatically or manually), the reactor trip breakers remain open until completion of the protective action, and do not automatically return to normal after the trip condition is reset.

4.c Manual reactor trip switches are provided in the MCR and the RSR for reactor trip.

5. The OM in the MCR displays the status information for variables listed in Tables 2.5.1-2 and 2.5.1-3.

6. Each local coincidence logic (LCL) receives trip signals from four channels of bistable processors (BPs) and utilizes a 2-out-of-4 coincidence logic to perform RPS and ESF initiation functions identified in Tables 2.5.1-2 and 2.5.1-3.

7.a The PPS provides manual trip bypasses on the MTP switch panel, for RT and ESF initiation identified in Tables 2.5.1-2 and 2.5.1-3, respectively.

7.b The PPS automatically removes the operating bypasses listed in Table 2.5.1-4 when permissive conditions are not met.

7.c The PPS provides indications of the bypassed or inoperable status indication (BISI) on the OM in the MCR for the variables identified in Tables 2.5.1-2 and 2.5.1-3 for RT and ESF initiation.

8. Each PPS division is controlled from either the MCR or the RSR as selected from master transfer switches.

9. The PPS utilizes a 2-out-of-4 coincidence logic when no channels are in trip channel bypass. The resulting logic becomes a 2-out-of-3 coincidence logic whenever a trip channel bypass is present.

10. Accuracy, response time testing, surveillance testing, and maintenance are applied to determine if setpoints for variables of RT and ESF initiation are within acceptable limits.

11. The application software for RT and ESF initiation is implemented according to each lifecycle phase in the software development process: concept phase, requirements phase, design phase, implementation phase, test phase, and installation and checkout phase. The outputs including documentation of each
lifecycle phase in the software development process conform to the requirements of that phase.

12. The cabinets listed in Table 2.5.1-1 have key locks and door open alarms, and are located in a vital area of the facility.

13. The RT logic of the PPS is designed to fail to a safe state such that a processor lock-up or loss of electrical power to a division of PPS results in a trip condition by the hardware-based window watchdog timer (from the NRC-approved safety I&C platform) located in the processor module for that division. The ESFAS logic of the PPS is designed to fail to a safe state such that loss of electrical power to a division of PPS does not result in ESF initiation for that division.

14. Redundant safety equipment listed in Table 2.5.1-1 and related field equipment are provided with means of identification.

15. The input signals of PPS through APC-S or ENFMS are derived from RT and ESF initiation measurement instrumentation that measures monitored variables identified in Tables 2.5.1-2 and 2.5.1-3.

16. The PPS provides RT and ESF initiation signals to meet the required response time for trip and initiation conditions identified in Tables 2.5.1-2 and 2.5.1-3.

17. The Class 1E equipment listed in Table 2.5.1-1 is protected from accident related hazards considered in the transient and accident analyses.

18. The RTS and ESF system instrumentation (referenced in Tables 2.5.1-2 and 2.5.1-3) monitors the normal operating, anticipated operational occurrence (AOO), and postulated accident (PA) events.

19. The Class 1E instrument identified in Table 2.5.1-1 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.
20. The PPS providing RT and ESF initiation signals has the testing function that can be initiated from the PPS MTP. This testing function verifies the functionality of the bistable processing logic and coincidence processing logic within the PPS.

21. A single channel of RTS and ESF system is bypassed to allow testing, maintenance or repair and this capability does not prevent the RTS and ESF system from performing its safety function.

22. Input sensors from each channel of the RTS and ESF system as identified in Tables 2.5.1-2 and 2.5.1-3 are compared continuously in the information processing system (IPS) to allow detection of out-of-tolerance sensors.

23. Two sets of RTSS which consists of four RTSGs are diverse each other.

24. The PPS and CPCS are installed in accordance with the dedicated process of commercial grade hardware and software.

25. The RTS is provided with the minimum number and locations of sensors for the variables that have a spatial dependence as identified and noted in Table 2.5.1-2.

26. Hardwired disconnections exist between the PPS, CPCS cabinets, and the portable workstation used to download the PPS, CPCS software. The hardwired disconnections protect the PPS, CPCS software from unintended modifications.

27. The CPCS configuration restrictions and tests for the CPU load have been implemented.

28. In order for the APR1400 Core Protection Calculator System application to run greater than 70% processor load but less than 75% processor load, the following configuration restrictions are applied:

1) No sequence of events modules or calculated events shall be used.

2) No CPU redundancy shall be used.

3) Only one CI631 module in slot 2 shall be used.

4) No more than four PM646A modules shall be used in an AC160 station.

5) No basic objects shall be used.
6) No serial protocols directly from the PM646A shall be used.
7) The CI532 and SC610 modules shall not be used.
8) The SEQ/STEP functions shall not be used.
9) No usage of scheduling strategy 252 or 255 shall be used for the PCPGM and CONTRM function blocks.
10) Boolean MDAT database elements shall not be used.
11) The CI631 shall not be configured as time synchronization master.
12) The online function of the Function Chart Builder shall not be used while the Core Protection Calculator System Channel is in service.
13) No CONTRM or PCPGM cycle times shall be less than 10 milliseconds.
14) The I/O port on the PM646A shall not be used.
15) Remote login to the PM646A using the AF100 shall not be used.

2.5.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

2.5.2 Diverse Actuation System

2.5.2.1 Design Description

The diverse actuation system (DAS) is a non-safety system which provides a diverse mechanism to decrease risk from the anticipated transients without scram (ATWS) events. The DAS also mitigates the effects of a postulated software common cause failure (CCF) within digital safety I&C systems.

The DAS consists of the diverse protection system (DPS), the diverse manual ESF actuation (DMA) switches, and the diverse indication system (DIS).

The DAS equipment are located in the auxiliary building as described in Table 2.5.2-1.

The DPS initiates reactor trip, turbine trip, auxiliary feedwater actuation, and safety injection actuation. The DPS consists of four channels of non-safety equipment.

The DMA switches are provided to permit the operator to actuate ESF systems from the MCR after a postulated software CCF of the PPS and ESF-CCS.

The DIS provides functions to monitor critical variables and to control heated junction thermocouple (HJTC) heater power when the CCF of digitalized safety I&C systems occurs.

1. The seismic Category I equipment identified in Table 2.5.2-1 withstands seismic design basis loads without loss of protective function.

2. The DPS is physically separate, electrically independent, and diverse from the PPS and ESF-CCS including a diverse method for the reactor trip, the turbine trip, the auxiliary feedwater actuation and safety injection actuation.

3. The DPS provides the automatic functions as shown in Table 2.5.2-2, if plant process signals exceed predetermined setpoints.

4. The DPS utilizes a 2-out-of-4 coincidence logic for the initiation of automatic functions shown in Table 2.5.2-2.

5. The DPS cabinets listed in Table 2.5.2-1 are located in separate rooms.

6. The DPS software is implemented according to each development phase of the software lifecycle process: concept phase, requirements phase, design phase,
implementation phase, test phase, and installation and checkout phase. The outputs, including documentations, of each development phase of the software lifecycle process are verified by inspection and analysis to conform to the requirements of that phase.

7. The DMA switches in the MCR are used to provide the functions identified in Table 2.5.2-3.

8. The DIS monitors and displays the variables listed in Table 2.5.2-4.

9. The DIS provides the HJTC heater power control for reactor vessel level detection when the QIAS-P is inoperable during a postulated CCF. Manual transfer of HJTC heater power control is performed using the DIS switch on the MCR safety console.

10. The DIS software is implemented according to each development phase of the software lifecycle process: concept phase, requirements phase, design phase, implementation phase, test phase, and installation and checkout phase. The outputs, including documentations, of each development phase of the software lifecycle process are verified by inspection and analysis to conform to the requirements of that phase.

11. The DPS initiates diverse reactor trip (RT), auxiliary feedwater actuation signal (AFAS), and safety injection actuation signal (SIAS) within the required response time for trip/initiation conditions identified in Table 2.5.2-2.

12. The DIS is diverse and independent from the QIAS-P.

2.5.2.2 Inspection, Test, Analyses, and Acceptance Criteria

Table 2.5.2-5 specifies the inspections, tests, analyses, and associated acceptance criteria for the DAS.

2.5.3 Qualified Indication and Alarm System

2.5.3.1 Design Description

The qualified indication and alarm system (QIAS) is a monitoring system that is used to display safety-related information and non-safety information.

The QIAS consists of the two subsystems as follows:

a. QIAS - P, Divisions A and B

b. QIAS - N

In this section, QIAS-N which is non-safety system is not described.

The QIAS-P equipment are located in the auxiliary building.

1. The seismic Category I equipment, identified in Table 2.5.3-1, withstands seismic design basis loads without loss of its safety function.

2. QIAS-P equipment identified in Table 2.5.3-1 (and the associated wiring, cables, and terminations) can withstand the electrical surge, electromagnetic interference (EMI), radio frequency interference (RFI), and electrostatic discharge (ESD) conditions that would exist before, during, and following a postulated accidents without loss of its safety function for the time required to perform the safety function.

3.a Class 1E equipment identified in Table 2.5.3-1 is powered from its respective Class 1E train.

3.b Redundant Class 1E divisions listed in Table 2.5.3-1, are physically separated and electrically independent from each other and physically separated and electrically independent from non-Class 1E equipment.

4. The QIAS-P monitors and displays the accident monitoring instrumentation variables identified in Table 2.5.3-2.

5. The application software for QIAS-P is implemented according to each lifecycle phase in the software development process: concept phase, requirements phase, design phase, implementation phase, test phase, and
installation and checkout phase. The outputs, including documentation, of each lifecycle phase in the software development process are verified by inspection and analysis to conform to the requirements of that phase.

6. Redundant Class 1E equipment listed in Table 2.5.3-1 are provided with means of identification.

7. The QIAS-P is installed in accordance with the dedicated process of commercial grade hardware and software.

8. The cabinets for processors listed in Table 2.5.3-1 have key locks and door open alarms, and are located in a vital area of the facility.

9. Hardwired disconnections exist between the QIAS-P cabinets, and the portable workstation used to download the QIAS-P software. The hardwired disconnections protect the QIAS-P software from unintended modifications.

2.5.3.2 Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the QIAS-P are specified in Table 2.5.3-3.

2.5.4 Engineered Safety Features-Component Control System

2.5.4.1 Design Description

The engineered safety features (ESF) system consists of sensors, auxiliary process cabinet-safety (APC-S), engineered safety features actuation system (ESFAS) portion of the plant protection system (PPS) and engineered safety features-component control system (ESF-CCS). The sensors, APC-S, and ESFAS portion of the PPS are described in Subsection 2.5.1. Subsection 2.5.4 describes the ESF-CCS.

The ESF-CCS provides automatic actuation of ESF systems. The ESF-CCS performs the nuclear steam supply system (NSSS) ESFAS function, balance of plant (BOP) ESFAS function, and emergency diesel generator (EDG) loading sequencer function.

The ESF-CCS generates the NSSS ESF actuation signals upon receipt of ESF initiation signals from the PPS. The ESF-CCS generates the BOP ESF actuation signals upon receipt of ESFAS initiation signals from the process and effluent radiation monitoring system.

The ESF-CCS generates the EDG loading sequencer signals upon receipt of loss of power to Class 1E train buses, safety injection actuation signal (SIAS), containment spray actuation signal (CSAS), and auxiliary feedwater actuation signal (AFAS).

The ESF-CCS provides the capability for manual actuation of ESF systems and manual control of ESF components.

The ESF-CCS consists of four divisions of group controller cabinets and loop controller cabinets. The ESF-CCS equipment and manual control components are identified in Table 2.5.4-1. The ESF-CCS components are located in auxiliary building. The ESF-CCS soft control modules (ESCMs) are provided in the main control room (MCR), remote shutdown room (RSR), and remote control center (RCC).

The ESF-CCS design incorporates the following features: processors arranged in primary and standby processor configurations within each ESF-CCS division. ESF actuation functions are divided into the ESF-CCS distributed segments which receive ESFAS initiation signals from the PPS through the fiber optic cable. Separation is provided for protection between ESFAS processing function and auxiliary functions of human-system interfaces, data communication, and automatic testing. The SDL supports the
transmission of protection data on a continuous cyclical basis independent of plant transients.

1. The seismic Category I equipment and components identified in Table 2.5.4-1 withstand seismic design basis loads without loss of the safety function.

2. Redundant Class 1E divisions listed in Table 2.5.4-1 and associated field equipment are physically separated and electrically isolated from each other and physically separated and electrically isolated from non-Class 1E equipment. Class 1E qualified isolation devices such as fiber optic modems or interposing relays are applied at interfaces between redundant safety divisions and at interfaces between safety and non-safety systems.

3. The Class 1E equipment and components identified in Table 2.5.4-1 are powered from its respective Class 1E train.

4. Each ESF-CCS division receives ESF initiation signals from four divisions of the PPS and performs selective 2-out-of-4 coincidence logic to perform NSSS ESF actuation functions identified in Table 2.5.4-2.

5. Each BOP ESFAS initiation signal passes through ESF-CCS division from two divisions of the RMS as shown in Tables 2.7.6.4-2 and 2.7.6.5-2 and performs 1-out-of-2 logic taken twice except the fuel handling area emergency ventilation actuation signal which has one 1-out-of-2 logic to perform the BOP ESF actuation functions identified in Table 2.5.4-2.

6. Upon receipt of an SIAS, CSAS, or AFAS, the ESF-CCS initiates an automatic start of the EDGs and automatic EDG loading sequencer of ESF loads identified in Table 2.5.4-2.

7. Upon detecting loss of power to Class 1E buses, the ESF-CCS initiates startup of the EDGs, shedding of electrical loads, transfer of Class 1E bus connections to the EDGs, and EDG loading sequencer to the reloading of safety-related loads to the Class 1E buses.

8. Each ESF-CCS division is controlled from either the MCR or RSR or either the MCR or RCC, as selected from MCR/RSR or MCR/RCC master transfer switches.
9.a Once a NSSS ESF actuation has been actuated (automatically or manually), the ESF actuation logic is latched in the actuated state and is not reset automatically when the NSSS ESF initiating condition has been cleared. After the initiating condition has been cleared, the NSSS ESF actuation is manually reset.

9.b Once a BOP ESF actuation has been actuated (automatically or manually), the ESF actuation logic is latched in the actuated state and is not reset automatically when the ESF actuation signal has been cleared. Once the initiating condition is cleared, the ESF actuation is manually reset.

10. Loss of power or a processor lock-up in an ESF-CCS division results in (1) the respective ESF-CCS division output assuming fail-safe output condition and (2) the relay output of the hardware-based window watchdog timer (from the NRC-approved safety I&C platform) being energized and generating the alarm to prompt operator action.

11. Manual ESF actuation switches are provided in the MCR and RSR for the manual ESF actuations identified in Table 2.5.4-3.

12. The operator modules (OMs) in the MCR display ESF actuation status, manual ESF actuation status, and ESF-CCS status information including the test status for ESF actuations identified in Tables 2.5.4-2 and 2.5.4-3.

13. The component interface module (CIM) provides state-based priority logic to prioritize the ESF-CCS and diverse protection system (DPS) signals.

14. The CIM provides system-based priority logic for the front panel control switch signals on the CIM, the signals generated by the diverse manual ESF actuation (DMA) switches, the signals from the ESF-CCS, and the signals from the DPS. The front panel control switches have the highest priority, and the signals from the DMA switches have priority over signals from the ESF-CCS and DPS.

15. The application software for the ESF-CCS is implemented according to each lifecycle phase in the software development process: concept phase, requirement phase, design phase, implementation phase, test phase, and installation and checkout phase. The outputs including documentation, of each lifecycle phase in the software development process conform to the requirements of that phase.
16. The ESF-CCS equipment and components identified in Table 2.5.4-1 (and the associated wiring, cables, and terminations) withstand the electrical surge, electromagnetic interference (EMI), radio-frequency interference (RFI), and electrostatic discharge (ESD) conditions that would exist before, during, and following a design basis event without loss of its safety function for the time required to perform the safety function.

17. Redundant safety equipment and components of the ESF-CCS listed in Table 2.5.4-1 and related field equipment are provided with means of identification.

18. The Class 1E equipment and components listed in Table 2.5.4-1 are protected from accident related hazards considered in the transient and accident analyses.

19. The ESF-CCS cabinets listed in Table 2.5.4-1 have key locks and door position alarms, and are located in a vital area of the facility.

20. The ESF-CCS provides ESF actuation within required response time in the accident and transient analyses for ESF functions identified in Table 2.5.4-2.

21. The ESF-CCS has the testing function to confirm the integrity of the capability to accomplish the intended safety functions.

22. The ESF-CCS provides the interlocks important to safety identified in Table 2.5.4-4.

23. Communication independence between redundant divisions of ESF-CCS and between ESCM and information flat panel display (IFPD) is achieved by use of dual-ported memory and separation of functional processor and communication processor.

24. The ESF-CCS is installed in accordance with the dedicated process of commercial grade hardware and software.

25. The ESF-CCS LC provides the priority logic to assure the actuation of automatically actuated ESFAS signals.

26. Means are provided for manual initiation and control of the protective actions that have not been selected for automatic control in Table 2.5.4-6.
27. Hardwired disconnections exist between the ESF-CCS cabinets, and the portable workstation used to download the ESF-CCS software. The hardwired disconnections protect the ESF-CCS software from unintended modifications.

28. Communication from IFPD to ESCM is implemented by using predefined data sets, protocol, and an error checking code.

2.5.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the ESF-CCS are specified in Table 2.5.4-5.

2.5.5 Control System Not Required for Safety

2.5.5.1 Design Description

Control system which is not required for safety consists of power control system (PCS) and process-component control system (P-CCS).

The PCS includes the reactor regulating system (RRS), the digital rod control system (DRCS), and the reactor power cutback system (RPCS). The P-CCS includes nuclear steam supply system (NSSS) process control system (NPCS) and balance of plant (BOP) control systems. The NPCS consists of the feedwater control system (FWCS), the steam bypass control system (SBCS), the pressurizer pressure control system (PPCS), the pressurizer level control system (PLCS), and other miscellaneous NSSS control systems which include reactor makeup control function of the chemical and volume control system (CVCS).

The PCS and P-CCS provide control of functions to maintain the plant within its normal operating range for all normal modes of plant operation.

Control and display interface devices for the PCS and P-CCS are provided in the main control room (MCR) and remote shutdown room (RSR) for control and monitoring of the PCS and P-CCS.

1. The controllers of the PCS and P-CCS are arranged in separate controller groups as identified in Table 2.5.5-1.

2. The digital equipment and software used in the PCS and P-CCS are diverse from those of the plant protection system (PPS) and engineered safety features-component control system (ESF-CCS).

3. The PCS and P-CCS are controlled from either the MCR or RSR or either the MCR or RCC, as selected from MCR/RSR or MCR/RCC master transfer switches.

The information flat panel displays (IFPDs) provide control means of PCS and P-CCS. The IFPDs are the primary human systems interface (HSI) for normal and abnormal plant conditions. They display information that is used by plant operators, including indications and alarms for critical safety and power production functions, and the performance of the
plant’s preferred non-safety and safety systems that are used to control those critical functions (i.e., the critical function success paths). The IFPDs are used for non-safety control, and safety-related component selection in conjunction with control through the ESF-CCS soft control modules (ESCM).

While the IFPDs play an important role in the integrated HSI for APR1400, they are not credited for compliance to GDC 13 for anticipated operational occurrences and accident conditions. Compliance to GDC 13 is achieved through independent Class 1E HSI devices, which consist of the qualified indication and alarm system-P (QIAS-P), the Class 1E ESCMs, and minimum inventory switches. Since the IFPDs are not the credited HSI for abnormal plant conditions, but commensurate with their use as the primary operator interface, they are designed with the software grade designated as important to availability (ITA). Also the IFPDs are qualified to seismic Category II and the interface portion of IFPD for ESCM is qualified to same seismic criteria of the plant safety systems to prevent adverse impact to safety devices in the MCR.

4. The IFPDs display information for monitoring critical safety functions, and information and safety component selections for the plant systems/components used to control those functions.

5. The IFPDs are independent from Class 1E HSI devices.

6. The application software for the IFPD is implemented according to each life cycle phase in the software development process: concept phase, requirements phase, design phase, implementation phase, test phase, and installation and checkout phase. The outputs including documentation of each lifecycle phase in the software development process conform to the requirements of that phase.

7. The IFPDs do not adversely affect safety devices in the MCR during seismic conditions that would exist before, during, and following a design basis event.

Some field equipment uses non-safety embedded digital devices. These non-safety embedded digital devices are diverse from the safety systems. In case of the ultrasonic level transmitters, these devices are used in both safety and non-safety applications. The design diversity for these devices is achieved by using different manufacturers' software and hardware designs and the functional diversity is maintained between the non-safety ultrasonic level transmitters and the safety ultrasonic level transmitters.
8. The ultrasonic level transmitters for the non-safety system are diverse from the ultrasonic level transmitters for the safety system.

2.5.5.2 Inspection, Test, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the PCS and P-CCS are specified in Table 2.5.5-2.

2.6 Electric Power

2.6.1 AC Electric Power Distribution System

2.6.1.1 Design Description

The ac electric power distribution system consists of the transmission system, the plant switchyard, main transformer (MT), two unit auxiliary transformers (UATs), two standby auxiliary transformers (SATs), a main generator (MG), a generator circuit breaker (GCB), isolated phase bus, switchgears, load centers (LCs), and motor control centers (MCCs). The electric power distribution system also includes the power, control, instrumentation cables and raceways, and electrical protection devices, such as circuit breakers and fuses.

The Class 1E ac electric power distribution system consists of two independent, redundant divisions. Each division consists of two independent trains.

Four emergency diesel generators (EDGs) provide Class 1E power to the four independent Class 1E trains respectively, during a LOOP or a LOOP concurrent with DBA. One AAC generator provides power to the permanent non-safety buses during a LOOP or to one Class 1E train during SBO.

During plant normal operation, the MG supplies power through the GCB and MT to the transmission system, and to the UATs. When the GCB is open, power is backed from the transmission system through the MT to the UATs. In the event of a loss of preferred power supply through the UATs, medium voltage (non-Class 1E 13.8 kV and Class 1E & non-Class 1E 4.16 kV) buses are powered from the SATs after performing an automatic bus transfer from the normal offsite preferred power supply to the alternate offsite preferred power supply.

The ac electric power distribution system is designed as follows:

1. The functional arrangement of ac electric power distribution system is as described in the Design Description of Subsection 2.6.1.1 and as shown in Figure 2.6.1-1.

2. The seismic Category I equipment identified in Table 2.6.1-1, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.
3.a Controls exist in the MCR to operate the electric power distribution system, specifically to open and close the 4.16 kV circuit breakers for the Class 1E buses identified in Table 2.6.1-2.

3.b Controls exist in the RSR to operate the electric power distribution system, specifically to open and close the 4.16 kV circuit breakers for the Class 1E buses identified in Table 2.6.1-2.

3.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.6.1-2.

3.d Displays and alarms exist and are retrievable in the RSR as defined in Table 2.6.1-2.

4. Class 1E medium voltage switchgears, load centers, and motor control centers located in seismic Category I structures within the auxiliary building, EDG building, and ESW buildings are located in their respective train areas.

5. MT and UATs are separated from the SATs.

6. MT, UATs, and SATs are provided with their own oil pit, drain, fire deluge system.

7.a The MG, UATs, MT, and GCB power feeders are separated from the SATs power feeders.

7.b The MG, UAT, MT, and GCB instrumentation and control circuits are separated from the SATs instrumentation and control circuits.

8. If the normal preferred offsite power supply is not available, Class 1E 4.16 kV medium voltage buses are automatically transferred to the alternate preferred offsite power supply.

9. Instrumentation and control power for Class 1E medium voltage switchgear and load centers is supplied from the Class 1E dc power system in the same train.

10.a Independence is provided between each of the four trains of Class 1E distribution equipment and circuits.
10.b Independence is provided between Class 1E distribution equipment and circuits and non-Class 1E distribution equipment and circuits.

10.c The Class 1E distribution equipment of independent trains, identified in Table 2.6.1-1, is located in separate rooms in the auxiliary building.

11. Class 1E electric power distribution system equipment and circuits are rated to withstand fault currents for the time required to clear the fault from its power source.

12. Equipment and circuits of independent trains including raceway are uniquely identified by their train color and identifying nomenclature.

13.a The raceway systems for Class 1E electric power distribution system cables are designed to meet seismic Category I requirements.

13.b Class 1E electric power distribution system cables are routed in seismic Category I structures and in their respective raceway trains.

14. Class 1E equipment is not prevented from performing its safety functions by design basis harmonic distortion waveforms.

15. Protection is provided for Class 1E equipment from degraded voltage condition.

16. There are no automatic connections between Class 1E trains.

17. Class 1E qualified isolation devices provide independence between Class 1E electric power distribution equipment and non-Class 1E loads.

18.a The switchyard power circuit breakers (PCBs) open in the event of electrical faults in either MT, GCB, UATs, SATs, or associated equipment and circuits.

18.b The GCB opens in the event of plant trip conditions, or electrical faults in either MG, MT, UATs, or associated equipment and circuits.

19. The UATs and SATs are designed and sized to meet the worst case loading conditions for all modes of plant operation and accident conditions.

20. Overcurrent protection is set for proper coordination of Class 1E ac electric distribution system.
21. The post-fire safe shutdown circuit analysis provides assurance that one success path of shutdown SSCs remains free of fire damage.

22. The Class 1E cables are sized considering derating due to ambient temperature, cable grouping, and other derating effects as applicable.

23. The open phase detection and protection (OPDP) system is capable of detecting the following open phase conditions (OPCs) over the full range of transformer loading from no load to full load:

- loss of one phase with and without a high-impedance ground fault condition; and

- loss of two phases without a high-impedance ground fault condition.

24. Upon detection of an OPC with or without a high-impedance ground fault, the OPDP system actuates an alarm in the MCR and RSR.

25. In case an OPC with or without a high-impedance ground fault on the primary side of the MT or SATs occurs and safe shutdown capability is not assured due to the OPC while the transformer(s) is (are) under loading condition, the Class 1E medium voltage switchgear buses are automatically separated from the degraded offsite power source and transferred to the alternate offsite power source or the onsite standby source as designed.

26. Transients due to failures or incidental operation of the non-Class 1E electrical equipment will not cause failure of the Class 1E loads.

2.6.1.2 Inspection, Test, Analyses, and Acceptance Criteria

Table 2.6.1-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the ac electrical power distribution system.

Figure 2.6.1-1 AC Electrical Power Distribution System
2.6.2 Emergency Diesel Generator System

2.6.2.1 Design Description

The emergency diesel generator (EDG) system is a safety-related system which has four diesel generators and their respective support systems such as fuel oil, lube oil, engine cooling, starting air, and combustion air intake and exhaust systems. Four EDGs provide Class 1E power to the four independent Class 1E trains, respectively, during a LOOP or a LOOP concurrent with DBA. EDGs are normally in stand-by mode.

The EDG system is designed as follows:

1. The functional arrangement of the EDG system is as described in the Design Description of Subsection 2.6.2.1 and in Tables 2.6.2-1 and 2.6.2-2.

2.a The ASME Code components identified in Table 2.6.2-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.6.2-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.6.2-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.6.2-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.6.2-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.6.2-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I diesel engines and generators, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I components identified in Table 2.6.2-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.
5.c The seismic Category I piping, including supports, identified in Table 2.6.2-1 withstand seismic design basis loads without loss of safety function.

6.a Controls exist in the MCR and EDG room to start and stop each EDG and to synchronize each EDG to its respective Class 1E bus.

6.b Controls exist in the RSR to start and stop each EDG and to synchronize each EDG to its respective Class 1E bus.

6.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.6.2-2.

6.d Displays and alarms exist and are retrievable in the RSR as defined in Table 2.6.2-2.

7. Each mechanical division of EDG and its support systems (A, B, C & D) is physically separated from the other divisions.

8.a Each diesel fuel oil transfer pump is capable of transferring oil from the diesel fuel oil storage tank to its corresponding day tank at sufficient pressure and flow to cover the maximum demand at EDG continuous rated load while simultaneously increasing day tank level.

8.b The diesel fuel oil transfer pumps have sufficient net positive suction head (NPSH).

9. Each EDG has fuel storage capacity to provide fuel to its EDG for a period of seven days with the EDG supplying the power requirements for the most limiting design basis event.

10. Each day tank provides fuel oil for at least 60 minutes plus a minimum additional margin of 10 percent at EDG rated load.

11. One transfer pump in each train is designed to automatically supply diesel fuel oil from the storage tank to the day tank prior to actuation of low level alarm and stops automatically on a fuel oil day tank high-level signal.

12. Each lube oil makeup tank provides lube oil to its respective EDG for seven continuous days of EDG full power rated operation.
13. The starting air system receiver tanks of each EDG have a combined air capacity for five starts of the EDG without replenishing air to the receiver tanks.

14. The air intakes for EDG combustion are separated from the EDG exhaust ducts to prevent the degradation of the EDG power output due to the recirculation of the exhaust gases.

15. A loss of power to a Class 1E medium voltage safety bus automatically starts its respective EDG and load shedding the Class 1E bus within the affected train. Following attainment of required voltage and frequency, the EDG automatically connects to its respective bus. After the EDG connects to its respective bus, the non-accident loads are automatically sequenced onto the bus.

16. The Class 1E auxiliary power for EDG support systems is supplied from the same train, respectively.

17. For a loss of power to a Class 1E medium voltage safety bus concurrent with a design basis event condition (SIAS/CSAS/AFAS), each EDG automatically starts and load shedding of the Class 1E bus within the affected train occurs. Following attainment of required voltage and frequency, the EDG automatically connects to its respective bus, and the accident loads are sequenced onto the bus.

18. When running in a test mode, an EDG is capable of responding to an automatic start signal.

19. Each Class 1E EDG is designed and sized to supply power to its train's safety-related loads after a LOOP or a LOOP concurrent with LOCA conditions.

20. When the Class 1E EDG is started by an ESF actuation signal, all Class 1E EDG protection systems, except for overspeed and generator differential current, are automatically bypassed.

21. The heat exchangers of the EDG cooling water system have the capacity to transfer heat from the diesel engine to the component cooling water system for maintaining the temperature of the diesel engine within an optimum operating range.
22. Each combustion air intake and exhaust system of the EDG is capable of supplying combustion air to the EDG and disposing of EDG exhaust gases during operation at 110% of nameplate rating.

23. The EDG system safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

24. The EDG system safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

2.6.2.2 Inspection, Test, Analyses, and Acceptance Criteria

Table 2.6.2-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the EDG system.

Figure 2.6.2-1  Emergency Diesel Generator Mechanical System
2.6.3 DC Power System

2.6.3.1 Design Description

The Class 1E 125 Vdc system consists of four independent subsystems, trains A, B, C, and D, each corresponding to one of the four reactor protection instrumentation channels A, B, C, and D. The non-Class 1E dc power system is also comprised of two separate subsystems, divisions I and II. Each Class 1E dc power system is provided with its own battery, two battery chargers (normal and standby), a dc control center, and dc distribution panels. Each non-Class 1E dc power system is provided with its own battery, a battery charger with or without a standby battery charger, a dc control center, and dc distribution panels. The Class 1E dc power system supplies reliable continuous power to the plant safety system dc loads and the Class 1E I&C system.

The Class 1E 125 Vdc batteries are located in their separate respective channelized rooms within the auxiliary building.

The Class 1E dc power system is designed as follows:

1. The functional arrangement of the Class 1E dc power system is as described in the Design Description of Subsection 2.6.3.1 and as shown in Figure 2.6.3-1.

2. The seismic Category I equipment identified in Table 2.6.3-1, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

3. The raceway systems for Class 1E dc power system cables are designed to meet seismic Category I requirements.

4. Class 1E dc power system cables are routed in seismic Category I structures and in their respective raceways.

5. The Class 1E dc power system operating voltage is within the terminal voltage range of the Class 1E equipment.

6. Each Class 1E battery is sized to supply its Design Basic Event (DBE) loads, at the end-of-installed-life, for pertinent required hours without recharging.
7. Each Class 1E battery charger is sized to supply its respective Class 1E steady-state loads while charging its respective Class 1E battery.

8. Class 1E dc power system distribution panels and dc control centers are identified according to their Class 1E trains.

9. Class 1E dc power system cables are identified according to their Class 1E trains.

10.a Independence is provided between each of the four trains of Class 1E dc distribution equipment and circuits.

10.b Independence is provided between Class 1E dc distribution equipment and circuits and non-Class 1E dc distribution equipment and circuits.

10.c Class 1E qualified isolation devices provide independence between Class 1E dc distribution equipment and non-Class 1E dc loads.

11.a Displays and alarms exist and are retrievable in the MCR as defined in Table 2.6.3-2.

11.b Displays and alarms exist and are retrievable in the RSR as defined in Table 2.6.3-2.

12. Each of the four Class 1E dc power trains has a main circuit protection device which has selective coordination with downstream protective devices.

13. The Class 1E batteries of each train are located in a separate room.

14. The Class 1E dc distribution panel, dc control center and battery charger of each train are located in a separate room.

15. The Class 1E dc power system cables are sized to carry required load currents and to provide minimum design basis voltage at load terminals, considering derating due to ambient temperature, cable grouping, and other derating effects as applicable.

16. The Class 1E protective devices (circuit breakers/fuses) in the dc power system are rated to supply their required loads and withstand fault currents for the time required to clear the fault from the power source.
2.6.3.2 Inspection, Test, Analyses, and Acceptance Criteria

Figure 2.6.3-1  Class 1E DC Power System
2.6.4 Instrumentation and Control Power System

2.6.4.1 Design description

The instrumentation and control (I&C) power system consists of Class 1E and non-Class 1E power systems. The Class 1E 120 Vac I&C power system is separated into four subsystems, trains A, B, C, and D that supply power to the plant protection system channels A, B, C, and D. The Class 1E I&C power system includes four separate and independent 120 Vac power distribution panel, and each system is powered from a 125 Vdc control center via a 125 Vdc/120 Vac static inverter.

The Class 1E I&C power system is designed as follows:

1. The functional arrangement of the I&C power system is as described in the Design Description of Subsection 2.6.4.1 and as shown in Figure 2.6.4-1.

2. The seismic Category I equipment identified in Table 2.6.4-1, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

3.a Displays and alarms exist and are retrievable in the MCR as defined in Table 2.6.4-2.

3.b Displays and alarms exist and are retrievable in the RSR as defined in Table 2.6.4-2.

4. When dc input power to the Class 1E inverter power supply unit is lost, input to the Class 1E inverter power supply unit is provided by the regulating transformer without interruption of power supply to the loads.

5. Class 1E I&C power system equipment identified in Table 2.6.4-1 is located in their respective areas.

6. Physical separation and electrical isolation are provided between the Class 1E trains.

7. Physical separation and electrical isolation are provided between Class 1E I&C power system equipment and circuits and non-Class 1E I&C power system equipment and circuits.
8. Class 1E I&C power system equipment and circuits of redundant train are uniquely identified by their train color and character.

9. Class 1E I&C power system cables are routed in seismic Category I structures and in their respective raceways.

10. Class 1E I&C power system equipment and circuits are rated to withstand fault currents for the time required to clear the fault from its power source.

11. The rating of the Class 1E I&C power system circuit breakers and fuses are designed to interrupt the fault currents.

2.6.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.6.4-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the I&C power system.

2.6.5  Containment Electrical Penetration Assemblies

2.6.5.1  Design Description

Containment electrical penetration assemblies (EPAs) are provided for electrical cables passing through the containment. Containment EPAs are classified as seismic Category I.

Containment EPA is designed as follows:

1. The electric power, control, and instrumentation cables pass through the wall of reactor containment building (RCB) via the EPAs.

2. Each EPA, including the supports and anchorages, can withstand the seismic design basis loads without loss of safety function.

3. Each EPA as being qualified for a harsh environment can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

4. Physical separation is provided between trains of EPAs and between EPAs containing Class 1E cables and EPAs containing non-Class 1E cables.

5. The primary and secondary protection devices for each EPA are designed and sized to protect EPA from overload and fault current.

6. Separate penetrations are provided for medium voltage and low voltage power, control, and instrumentation circuits.

2.6.5.2  Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.6.5-1 specifies the inspections, tests, analyses, and associated acceptance criteria for the containment EPAs.

2.6.6 Alternate AC Source

2.6.6.1 Design Description

The alternate ac (AAC) source supplies power to safety-related loads to maintain the plant in a safe shutdown condition during station blackout (SBO). The AAC source also provides power to the permanent non-safety (PNS) buses during a loss of offsite power (LOOP) condition. The AAC source can be connected to Class 1E trains and PNS trains as shown on Figure 2.6.1-1. The AAC source is a gas turbine generator (GTG) that is independent from the EDGs and the offsite power sources. The AAC GTG is provided with dedicated fuel oil storage tank, fuel oil day tank, fuel oil transfer pumps, which are designed as non-safety-related.

The AAC source is designed as follows:

1. The functional arrangement of the AAC source is as described in the Design Description of Subsection 2.6.6.1.

2. The AAC source is sized with sufficient capacity to accommodate SBO and LOOP conditions.

3. The AAC source is connected to the Class 1E train A or train B bus through two in series (one Class 1E circuit breaker at the Class 1E bus and the other non-Class 1E circuit breaker at the non-Class 1E AAC bus) circuit breakers during SBO condition.

4. The AAC source is started, brought up to the required voltage and frequency, and connected manually to the Class 1E train A or train B bus within 10 minutes of the onset of an SBO.

5. The AAC source is installed in the separate building.

6. The GTG has sufficient fuel oil storage capacity to supply power to the required SBO loads for 24 hours.

7. The GTG fuel oil system is non-safety-related and independent from that of the Class 1E EDGs.
8.a Each fuel oil transfer pump is capable of transferring oil from the fuel oil storage tank to its corresponding day tank at sufficient pressure and flow to cover the maximum demand at GTG continuous rated load while simultaneously increasing day tank level.

8.b The fuel oil transfer pumps have sufficient net positive suction head (NPSH).

9. One fuel oil transfer pump is designed to automatically supply fuel oil from the storage tank to the day tank prior to actuation of low level alarm and stops automatically on a fuel oil day tank high-level signal.

10. The air intakes for the GTG combustion are separated from the GTG exhaust ducts.

11. Controls exist in the MCR and RSR to start and stop the AAC GTG and to synchronize the AAC GTG to its respective Class 1E bus.

12. Each day tank provides fuel oil for at least 60 minutes plus a minimum additional margin of 10 percent at GTG rated load.

2.6.6.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.6.6-1 specifies the inspections, tests, analyses, and associated acceptance criteria for the AAC source.

2.6.7 Lightning Protection and Grounding System

2.6.7.1 Design Description

The grounding and lightning protection system is provided for personnel and equipment protection from the effects of transient overvoltage that can occur in electrical systems due to electrical faults or lightning strikes. The grounding and lightning protection system is divided into subsystems such as neutraling grounding, equipment grounding, instrumentation grounding, and lightning protection, and connected to the plant ground grid. The ground conductor spacing and quantity are designed to be sufficient to limit touch voltages to tolerable values.

1. The functional arrangement of the grounding and lightning protection system is as described in the Design Description of Subsection 2.6.7.1.

2. Lightning protection systems are provided for buildings, structures and transformers located outside of the buildings. Surge arrestors are provided for main transformers, auxiliary transformers.

3. Neutral grounding is installed at the ground bus of main generator, main transformer, unit auxiliary transformers, standby auxiliary transformers, load center transformers, low voltage dry-type distribution transformers, EDGs, and AAC GTG.

4. Equipment grounding is installed at all metal structures such as buildings, tanks, transformers, transmission structures, equipment enclosure including grounding busbar, and raceway.

5. The instrumentation grounding system is a separate radial ground system that consists of instrumentation ground bus and insulated cables.

6. The plant ground grid consists of buried, interconnected bare copper conductors and ground rods forming a plant ground grid that is designed to limit personnel step and touch voltages to an acceptable level during a ground fault.

2.6.8 Lighting Systems

2.6.8.1 Design Description

The plant lighting system is non-Class 1E and consists of two subsystems which are normal lighting and emergency lighting. Emergency lighting system is divided into emergency ac and dc lighting system.

1. The functional arrangement of the lighting system is as described in the Design Description of Subsection 2.6.8.1.

2. The normal lighting system provides normal levels of illumination throughout the plant and is powered from the non-Class 1E ac buses.

3. The emergency ac lighting system is powered from the Class 1E ac buses backed-up by the Class 1E emergency diesel generators during a LOOP and the non-Class 1E AAC source during an SBO.

4.a There are two configurations for lighting fixture used within the emergency dc lighting system, lighting fixtures powered from non-Class 1E station battery and self-contained battery pack unit lighting fixtures.

4.b The emergency dc lighting fixtures equipped with self-contained rechargeable battery pack are powered from Class 1E or non-Class 1E ac in accordance with area designation. The emergency illumination level is not less than an average of 1 foot-candle and at least 0.1 foot-candle at the floor level for 8 hours for access and egress route.

5. The emergency illumination levels in MCR and RSR are minimum 10 foot-candle for 8 hours.

2.6.8.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.6.8-1 specifies the inspections, tests, analyses, and associated acceptance criteria for the lighting system.

2.6.9 Communication Systems

2.6.9.1 Design Description

The plant communication systems are non-safety-related systems that provide effective intra-plant and plant-to-offsite communications. The following buildings contain communications systems:

a. Reactor containment building
b. Turbine generator building
c. Auxiliary building
d. Compound building
e. Emergency diesel generator building
f. AAC gas turbine generator building
g. ESW building
h. CCW HX building
i. Security building 1 / Security building 2
j. Main access control building

The various communication systems provide independent and alternate paths to provide reasonable assurance of the capability to communicate with plant personnel and organizations during all operating or emergency conditions.

The communication systems consist of the following independent subsystems:

a. Paging phone system
b. Evacuation alarm address system
c. Public address system
d. Sound powered telephone system
The various subsystems of the plant communication system are as stated in Subsection 2.6.9.

1. Paging phone system provides page and party communications between MCR, RSR, and other areas.

2. Sound powered telephone system provides communications between MCR, TSC, refueling areas, turbine-generator operating deck, RSR, electrical and I&C equipment areas, and other high maintenance active areas.

3. a. Evacuation alarm address system provides alarm for radiation and fire accidents throughout the plant.

3. b. Public address system provides broadcasting throughout the plant.

3. c. Telephone system provides communication throughout the plant.

3. d. Plant time synchronizing system provides standard time information throughout the plant.

3. e. LAN and VPN systems provide network throughout the plant.

3. f. Wireless communication system provides a stand-alone method of plant-wide communication throughout the plant.

2.6.9.2 Inspections, Tests, Analyses, and Acceptance Criteria

2.7 Plant Systems

2.7.1 Power Generation Systems

2.7.1.1 Turbine Generator

2.7.1.1.1 Design Description

The turbine generator (T/G) is a non-safety-related system that converts the energy of the steam produced from the steam generators into rotational energy and then electrical energy.

The T/G has favorably oriented turbines. Potential missiles from the failure of the T/G should not affect essential SSCs since they are located outside the low trajectory turbine strike zone. The low pressure turbine rotor integrity is ensured by the combination of design, material properties including fracture toughness, tests, and inspections of the rotor to limit the probability of turbine missile generation. Turbine rotor components and turbine stop and control valves will be inservice tested and inspected at intervals in accordance with industry practice or as specified by the manufacturer to meet turbine missile generation probability requirements.

The T/G is located within the turbine building and consists of:

a. One (1) double-flow high pressure (HP) turbine
b. Three (3) double-flow low pressure (LP) turbines
c. A generator and exciter
d. Two (2) sets of moisture separator and reheaters
e. Associated piping, valves, control system
f. Auxiliary systems

The main stop valves (MSVs) and control valves (CVs) are arranged in series at the HP turbine inlet and control the steam flow entering the HP turbine. The intermediate stop valves (ISVs) and intercept valves (IVs) are arranged in series at the inlet to the LP turbines, and control steam flow to the LP turbines. The non-return check valves are installed in the extraction lines to the feedwater heaters.
1.a The functional arrangement of the T/G system is as described in the Design Description of Subsection 2.7.1.1.1.

1.b The T/G has a favorable orientation to minimize the potential effects of turbine missiles on essential (as defined in Regulatory Guide 1.115, Rev. 2, Appendix A) SSCs.

2.a The mechanical overspeed trip system initiates the T/G trip by closing the MSVs, CVs, ISVs, and IVs upon reaching the overspeed setpoint.

2.b The electrical overspeed trip system, which is independent of the normal speed control system and mechanical overspeed trip system, initiates a T/G trip by closing the MSVs, CVs, ISVs, and IVs upon reaching the electrical overspeed setpoint.

3. The control system generates the electrical signals in the main control room (MCR) for T/G trip.

4. The MSVs, CVs, ISVs, and IVs close reacting to a T/G trip signal.

5. The non-return check valves on extraction lines close reacting to T/G trip signal.

6. The reactor trip signal from the plant control system initiates a T/G trip.

7. The probability of a strike by a turbine missile is sufficiently low to prevent equipment damage to essential SSCs.

8. The as-built turbine material properties, turbine rotor and blade designs, pre-service inspection and testing results and in-service testing and inspection requirements meet the requirements defined in the Turbine Missile Probability Analysis performed by the COL applicant.

2.7.1.1.2 Inspection, Tests, Analyses, and Acceptance Criteria

</table>
2.7.1.2 Main Steam System

2.7.1.2.1 Design Description

The main steam system (MSS) transports steam from the steam generators to the power conversion system and removes heat from the reactor coolant system (RCS).

The safety-related portion of the MSS consists of the main steam piping and valves located between the steam generator outlet nozzles in the containment up to and including the main steam isolation valves (MSIVs) in the main steam valve houses (MSVHs). The non-safety-related portions of the MSS, downstream of the isolation valves, are located in the auxiliary building and the turbine building.

The MSS has the following safety-related functions:

a. To supply steam to the auxiliary feedwater pump turbine

b. To protect the steam generator and pressure boundary components in the MSS from over pressurization

c. To cooldown the Reactor Coolant System through a controlled discharge of steam to the atmosphere

d. To isolate the containment and steam generator

The MSS has the following non-safety-related functions:

a. To supply steam to the main turbine

b. To provide a flow path to the turbine bypass system

The MSS is designed as follows:

1. The functional arrangement of the MSS is as described in the Design Description of Subsection 2.7.1.2.1 and in Table 2.7.1.2-1 and as shown in the Figure 2.7.1.2-1.

2.a The ASME Code components identified in Table 2.7.1.2-2 are designed and constructed in accordance with ASME Section III requirements.
2.7.1.2-1 is designed and constructed in accordance with ASME Section III requirements.

3. Pressure boundary welds in ASME Code components identified in Table 2.7.1.2-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.1.2-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.1.2-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.7.1.2-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.7.1.2-2 and 2.7.1.2-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.7.1.2-1 withstands seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.7.1.2-2 and 2.7.1.2-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.7.1.2-2 and 2.7.1.2-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The MS system safety-related valves listed in Table 2.7.1.2-2 are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.
7.b After loss of motive power, MOVs, AOVs and electro-hydraulic valves identified in Table 2.7.1.2-2, assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close the MOVs, AOVs and electro-hydraulic valves listed in Table 2.7.1.2-2.

8.b Controls exist in the RSR to open and close the MOVs, AOVs and electro-hydraulic valves listed in Table 2.7.1.2-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.1.2-2 and 2.7.1.2-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.1.2-2 and 2.7.1.2-3.

9. Each mechanical division of the MSS is physically separated from the other divisions.

10. The MSSVs, identified in the Table 2.7.1.2-2, provide overpressure protection for the secondary side of the steam generators and for pressure boundary components in the MSS.

11. The MSIVs and MSIV bypass valves identified in Table 2.7.1.2-2 close on receipt of an MSIS within the required response time.

12. The MS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.1.2.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.1.2-4 specifies the inspections, tests, analyses, and associated acceptance criteria for the MSS.

Figure 2.7.1.2-1  Main Steam System
2.7.1.3 Turbine Bypass System

No entry for this system.
2.7.1.4 Condensate and Feedwater System

2.7.1.4.1 Design Description

The condensate and feedwater system delivers feedwater from the condenser hotwells to the steam generators during startup, shutdown, normal operation, and hot standby operation.

The safety-related function of the feedwater system is to isolate feedwater to the steam generators after receipt of a main steam isolation signal (MSIS).

The safety-related portions of the feedwater system are located in the main steam valve house of the auxiliary building and reactor containment building. Non-safety-related portion is located in the turbine building.

The condensate and feedwater system is designed as follows:

1. The functional arrangement of the condensate and feedwater system is as described in the Design Description of Subsection 2.7.1.4.1 and in Table 2.7.1.4-1 and as shown in Figure 2.7.1.4-1.

2.a The ASME Code components identified in Table 2.7.1.4-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME code piping, including supports, identified in Table 2.7.1.4-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.1.4-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.1.4-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.1.4-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.7.1.4-1 retains its pressure boundary integrity at its design pressure.
5.a The seismic Category I components and instruments identified in Tables 2.7.1.4-2 and 2.7.1.4-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.7.1.4-1 withstands seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.7.1.4-2 and 2.7.1.4-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.7.1.4-2 and 2.7.1.4-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The CD and FW system safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, AOVs and electro-hydraulic valves identified in Table 2.7.1.4-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close AOVs and electro-hydraulic valves identified in Table 2.7.1.4-2.

8.b Controls exist in the RSR to open and close AOVs and electro-hydraulic valves identified in Table 2.7.1.4-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.1.4-2 and 2.7.1.4-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.1.4-2 and 2.7.1.4-3.
9. The main feedwater isolation valves (MFIVs) close on receipt of an MSIS within the required response time.

10. The FW non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.1.4.2 Inspection, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the condensate and feedwater systems are specified in Table 2.7.1.4-4.

Figure 2.7.1.4-1  Condensate and Feedwater System
2.7.1.5 Auxiliary Feedwater System

2.7.1.5.1 Design Description

The auxiliary feedwater system (AFWS) is a safety-related system. The AFWS supplies auxiliary feedwater (AFW) to the steam generators for removal of residual heat from the reactor core when the feedwater system is inoperable for transient condition or postulated accidents.

The AFWS is designed to be either manually actuated or automatically actuated by an auxiliary feedwater actuation signal (AFAS) from the engineered safety feature actuation system (ESFAS) or diverse protection system (DPS).

AFW flow to the affected steam generator is terminated manually by operator action within 30 minutes after the initiation of the secondary side pipe rupture event.

The AFWS is located within the auxiliary building and containment.

The AFWS consists of two 100 percent capacity motor-driven pumps, two 100 percent capacity turbine-driven pumps, two 100 percent auxiliary feedwater storage tanks (AFWSTs), valves, two cavitating flow-limiting venturis, and instrumentation. One motor-driven pump and one turbine-driven pump are configured into one mechanical division and joined together inside containment to feed their respective steam generator through a common auxiliary feedwater (AFW) header which connects to the steam generator downcomer feedwater line. Each common AFW header contains a cavitating venturi to restrict the maximum AFW flow rate to each steam generator.

The functional requirements of the AFWS are designed as follows:

1. The functional arrangement of the AFWS is as described in the Design Description of Subsection 2.7.1.5.1 and in Table 2.7.1.5-1 and as shown in Figure 2.7.1.5-1.

2.a The ASME Code components identified in Table 2.7.1.5-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.1.5-1 is designed and constructed in accordance with ASME Section III requirements.
3. a Pressure boundary welds in ASME Code components identified in Table 2.7.1.5-2 meet ASME Section III requirements.

3. b Pressure boundary welds in ASME Code piping identified in Table 2.7.1.5-1 meet ASME Section III requirements.

4. a The ASME Code components identified in Table 2.7.1.5-2 retain their pressure boundary integrity at their design pressure.

4. b The ASME Code piping identified in Table 2.7.1.5-1 retains its pressure boundary integrity at its design pressure.

5. a The seismic Category I components and instruments identified in Tables 2.7.1.5-2 and 2.7.1.5-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5. b The seismic Category I piping, including supports, identified in Table 2.7.1.5-1 withstand seismic design basis loads without loss of safety function.

6. a The Class 1E components and instruments identified in Tables 2.7.1.5-2 and 2.7.1.5-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6. b Each of the Class 1E components and instruments identified in Tables 2.7.1.5-2 and 2.7.1.5-3 is powered from its respective Class 1E division.

6. c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7. a The AFW system safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7. b After loss of motive power, MOVs, AOVs, and SOVs indicated in Table 2.7.1.5-2 assume the indicated loss of motive power position.
8.a Controls exist in the MCR to start and stop the AFW pumps, and to open and close the MOVs, AOVs, and SOVs identified in Table 2.7.1.5-2.

8.b Controls exist in the RSR to start and stop the AFW pumps, and to open and close the MOVs, AOVs, and SOVs identified in Table 2.7.1.5-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.1.5-2 and 2.7.1.5-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.1.5-2 and 2.7.1.5-3.

9. The two mechanical divisions of the AFWS (A/C & B/D) are physically separated.

10.a The AFW pumps have sufficient net positive suction head (NPSH).

10.b Each AFWST has sufficient capacity for eight hours of operation at hot standby condition and for subsequent cooldown of the reactor coolant system within six hours to condition that permit operation of the shutdown cooling system.

10.c The AFW system safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

11.a The AFWS is actuated by an auxiliary feedwater actuation signal (AFAS) from the ESFAS or DPS.

11.b The ESF-CCS includes logic to close the AFW isolation valves when SG water level has risen above a high level setpoint, and to re-open the AFW isolation valves when SG water level drops below a low level setpoint.

12.a Each AFW pump delivers the minimum flow to its respective steam generator for removal of core decay heat against a steam generator feedwater nozzle pressure.

12.b The cavitating flow-limiting venturis limit the maximum flow to each steam generator with both AFW pumps running in the division against a steam generator pressure.
13. The AF non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.1.5.2 Inspection, Tests, Analyses, and Acceptance Criteria

Table 2.7.1.5-4 specifies the inspections, tests, analyses, and associated acceptance criteria for the AFWS.

2.7.1.8 Steam Generator Blowdown System

2.7.1.8.1 Design Description

The steam generator blowdown system (SGBS) removes and processes steam generator fluid containing impurities, and returns the water to the feedwater and condensate system.

The SGBS performs a safety-related function of isolating the secondary side of the SG using two isolation valves in series in the blowdown lines from each SG.

The safety-related portions of the SGBS components and piping are located in the containment and the auxiliary building.

1. The functional arrangement of the SGBS is as described in the Design Description of Subsection 2.7.1.8.1 and in Table 2.7.1.8-1 and as shown in Figure 2.7.1.8-1.

2.a The ASME Code components identified in Table 2.7.1.8-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.1.8-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.1.8-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.1.8-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.1.8-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.7.1.8-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components identified in Tables 2.7.1.8-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.
5.b The seismic Category I piping, including supports, identified in Table 2.7.1.8-1 withstands seismic design basis loads without loss of its safety function.

6.a The Class 1E components identified in Table 2.7.1.8-2 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components identified in Tables 2.7.1.8-2 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The SGBS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, MOVs and AOVs identified in Table 2.7.1.8-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close the MOVs and AOVs identified in Table 2.7.1.8-2.

8.b Controls exist in the RSR to open and close the MOVs and AOVs identified in Table 2.7.1.8-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.1.8-2.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Table 2.7.1.8-2.

9. Each mechanical division of the SGBS (Divisions I, II) is physically separated from the other division.
10. The SGBS components are classified as RW-IIc in accordance with NRC RG 1.143 and designed to the corresponding requirements in order to maintain structural integrity under the design basis loads. Component Radiation Safety Classification is summarized in Table 2.7.1.8-2.

11. The SGBS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.1.8.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the steam generator blowdown system are specified in Table 2.7.1.8-3.

The ITAAC related to the CIVs and the piping between the CIVs of the SGBS are described in Table 2.11.3-2.

Figure 2.7.1.8-1  Steam Generator Blowdown System
2.7.1.9  Auxiliary Steam System

2.7.1.9.1  Design Description

The auxiliary steam system (ASS) is a non-safety-related system, with the exception of containment isolation valves (CIVs) and the piping between the CIVs that are safety-related, ASME Section III Class 2 and Seismic Category I as described in Subsection 2.11.3.

The ASS performs the containment isolation function for the ASS line penetrating the containment.

The ASS supplies auxiliary steam to all usage points through an auxiliary steam header interconnecting the main steam system and the auxiliary boiler.

2.7.1.9.2  Inspections, Tests, Analyses, and Acceptance Criteria

The ITAAC related to the CIVs and the piping between the CIVs of the ASS are described in Table 2.11.3-2.
2.7.2 Cooling Water System

2.7.2.1 Essential Service Water System

2.7.2.1.1 Design Description

The essential service water system (ESWS), in conjunction with the ultimate heat sink (UHS), provides cooling water to remove heat from the component cooling water system (CCWS).

The ESWS is a safety-related system and provides cooling water to the CCW heat exchangers.

The ESWS consists of two independent, redundant, once-through, safety-related divisions. Each division cools one of two divisions of the CCWS, which cools 100 percent of the safety-related loads. Each division of the ESWS consists of two pumps, three CCW heat exchangers, three debris filters, and associated piping, valves, controls and instrumentation.

To meet above functional requirement, the ESWS is designed as follows:

1. The functional arrangement of the ESWS is as described in the Design Description of Subsection 2.7.2.1.1 and in Table 2.7.2.1-1 and as shown in Figure 2.7.2.1-1.

2.a The ASME Code components identified in Table 2.7.2.1-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.2.1-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.2.1-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.2.1-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.2.1-2 retain their pressure boundary integrity at their design pressure.
4.b The ASME Code piping identified in Table 2.7.2.1-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.7.2.1-2 and 2.7.2.1-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.7.2.1-1 withstand seismic design basis loads without loss of safety function.

6.a Each of the Class 1E components and instruments identified in Tables 2.7.2.1-2 and 2.7.2.1-3 is powered from its respective Class 1E division.

6.b Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The ESWS safety-related valves are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, MOVs identified in Table 2.7.2.1-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to start and stop the ESW pumps, and to open and close the MOVs identified in Table 2.7.2.1-2.

8.b Controls exist in the RSR to start and stop the ESW pumps, and to open and close the MOVs identified in Table 2.7.2.1-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.2.1-2 and 2.7.2.1-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.2.1-2 and 2.7.2.1-3.

9. The two mechanical divisions of the ESWS (A/C & B/D) are physically separated.
10. The ESWS has the capacity to remove heat from the CCWS during power operation, shutdown, refueling, and design basis accident conditions.

11. The ESWS safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

12. The ESW pumps have net positive suction head (NPSH).

2.7.2.1.2 Inspections, Tests, Analysis, and Acceptance Criteria

The inspection, tests, analyses, and associated acceptance criteria for the ESWS are specified in Table 2.7.2.1-4.

### Design Commitment

1. The functional arrangement of the ESWS is as described in the Design Description of Subsection 2.7.2.1.1 and in Table 2.7.2.1-1 and as shown in Figure 2.7.2.1-1.

### Inspections, Tests, Analyses

1. Inspection of the as-built ESWS will be performed.

### Acceptance Criteria

1. The as-built ESWS conforms with the functional arrangement as described in the Design Description of Subsection 2.7.2.1.1 and in Table 2.7.2.1-1 and as shown in Figure 2.7.2.1-1.

#### 2. A.

2.a The ASME Code components identified in Table 2.7.2.1-2 are designed and constructed in accordance with ASME Section III requirements.

2. Inspection of the as-built ASME Code components identified in Table 2.7.2.1-2 will be performed and documented in the ASME data report(s).

2.a The ASME Section III data report(s) exist and conclude that the as-built ASME Code components identified in Table 2.7.2.1-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.2.1-1 is designed and constructed in accordance with ASME Section III requirements.

2.b Inspection of the as-built ASME Code piping, including supports, identified in Table 2.7.2.1-1 will be performed and documented in the ASME data report(s).

2.b The ASME Section III data report(s) exist and conclude that the as-built ASME Code piping, including supports, identified in Table 2.7.2.1-1 is designed and constructed in accordance with ASME Section III requirements.

#### 3. A.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.2.1-2 meet ASME Section III requirements.

3.a Inspections of the as-built pressure boundary welds in ASME Code components identified in Table 2.7.2.1-2 will be performed in accordance with the ASME Section III.

3.a A report exists and concludes that the ASME Section III requirements are met for non-destructive examination of the as-built pressure boundary welds in ASME Code components identified in Table 2.7.2.1-2.

#### 3. B.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.2.1-1 meet ASME Section III requirements.

3.b Inspections of the as-built pressure boundary welds in ASME Code piping identified in Table 2.7.2.1-1 will be performed in accordance with the ASME Section III.

3.b A report exists and concludes that the ASME Section III requirements are met for non-destructive examination of the as-built pressure boundary welds in ASME Code piping identified in Table 2.7.2.1-1.

</table>
Figure 2.7.2.1-1  Essential Service Water System
2.7.2.2 Component Cooling Water System

2.7.2.2.1 Design Description

The component cooling water system (CCWS) is a closed loop cooling water system that, in conjunction with the essential service water system (ESWS) and the ultimate heat sink (UHS), removes heat generated from the plant’s safety-related and non-safety-related components connected to the CCWS.

The CCWS is a safety-related system and has the following safety-related functions:

a. Removes decay heat and waste heat from safety-related equipment necessary for achieving plant safe shutdown and transfers it to the ESWS

b. Protects against leakage of service water into the nuclear island systems

c. Protects against release of radiological contamination into the ultimate heat sink

The CCWS consists of two separate, independent, redundant, closed loop, and safety-related divisions. Either division of the CCWS is capable of supporting 100 percent of the cooling functions required for a safe reactor shutdown. Each division of the CCWS includes three heat exchangers, a surge tank, two CCW pumps, a chemical addition tank, a CCW radiation monitor, piping, valves, controls, and instrumentation. There are two cross connections between divisions.

To meet above functional requirement, the CCWS is designed as follows:

1. The functional arrangement of the CCWS is as described in the Design Description of Subsection 2.7.2.2.1 and in Table 2.7.2.2-1 and as shown in Figure 2.7.2.2-1.

2.a The ASME Code components identified in Table 2.7.2.2-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.2.2-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.2.2-2 meet ASME Section III requirements.
3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.2.2-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.2.2-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.7.2.2-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.7.2.2-2 and 2.7.2.2-3, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.7.2.2-1 can withstand seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.7.2.2-2 and 2.7.2.2-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.7.2.2-2 and 2.7.2.2-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The CCWS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, MOVs and AOVs identified in Table 2.7.2.2-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to start and stop the CCW pumps and CCW makeup pumps, and to open and close the MOVs and AOVs identified in Table 2.7.2.2-2.
8.b Controls exist in the RSR to start and stop the CCW pumps and CCW makeup pumps, and to open and close the MOVs and AOVs identified in Table 2.7.2.2-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.2.2-2 and 2.7.2.2-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.2.2-2 and 2.7.2.2-3.

9. The two mechanical divisions of the CCWS (A/C & B/D) are physically separated except for the cross connection lines between the divisions.

10. The CCWS safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

11. The CCWS pumps and CCWS makeup pumps have sufficient net positive suction head (NPSH).

12. The CCWS, in conjunction with the ESWS and UHS, has the capacity to dissipate the heat loads of connected components during power operation, shutdown, refueling and design basis accident conditions for at least 7 days of operation without surge tank makeup.

13. The CCWS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.
2.7.2.2.2 Inspection, Tests, Analyses, and Acceptance Criteria

The inspection, tests, analyses, and associated acceptance criteria for the CCWS are specified in Table 2.7.2.2-4.

The ITAAC related CIVs and the piping between the CIVs of the CCWS are described in Table 2.11.3-2.

Figure 2.7.2.2-1  Component Cooling Water System
2.7.2.3 Essential Chilled Water System

2.7.2.3.1 Design Description

The essential chilled water system (ECWS) is a safety-related closed loop chilled water system that serves safety-related HVAC cooling loads. The ECWS has the safety-related function that provides chilled water to safety-related air handling units and cubicle coolers.

The ECWS consists of two divisions. Each division includes two essential chillers, two ECW pumps, an ECW compression tank, an ECW makeup pump, an ECW air separator, piping, valves, controls and instrumentation. The ECWS is located in the auxiliary building.

Makeup water to the ECWS is supplied from the demineralized water makeup system. A safety-related seismic Category I makeup line is also provided to each division from the auxiliary feedwater system.

The ECWS is designed as follows:

1. The functional arrangement of the ECWS is as described in the Design Description of Subsection 2.7.2.3.1 and in Table 2.7.2.3-1 and as shown in Figure 2.7.2.3-1.

2.a The ASME Code components identified in Table 2.7.2.3-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.2.3-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.2.3-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.2.3-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.2.3-2 retain their pressure boundary integrity at their design pressure.
4.b The ASME Code piping identified in Table 2.7.2.3-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.7.2.3-2 and 2.7.2.3-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Tables 2.7.2.3-1 withstand seismic design basis loads without loss of safety function.

6.a Each of the Class 1E components and instruments identified in Tables 2.7.2.3-2 and 2.7.2.3-3 is powered from its respective Class 1E division.

6.b Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The ECWS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, AOVs identified in Table 2.7.2.3-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to start and stop the essential chillers and pumps identified in Table 2.7.2.3-2.

8.b Controls exist in the RSR to start and stop the essential chillers and pumps identified in Table 2.7.2.3-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.2.3-2 and 2.7.2.3-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.2.3-2 and 2.7.2.3-3.

9. The two mechanical divisions of the ECWS are physically separated.
10. The ECWS safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

11. The ECW pumps and ECW makeup pumps have sufficient net positive suction head (NPSH).

12. The ECW compression tank accommodates water volume due to thermal expansion and contraction, and 7 day system operation without normal makeup.

13. The ECWS has the capability to remove heat from safety-related HVAC equipment cooling coils during plant normal, abnormal and accident conditions.

2.7.2.3.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.2.3-4 specifies the inspections, tests, analyses, and associated acceptance criteria for the essential chilled water system.

| 11. | The ECW pumps and ECW makeup pumps have sufficient net positive suction head (NPSH). | 11. Test to measure the as-built ECW pump and ECW makeup pump suction pressure will be performed. Inspection and analyses to determine NPSH available to each pump will be performed. The analyses will be performed using the vendor’s pump NPSH required test results and the following information:  
- pressure losses of pump inlet piping and components, and  
- suction head from the ECW compression tank with its operating pressure and minimum level. | 11. A report exists and concludes that the as-built calculated NPSH available exceeds each ECW pump’s and ECW makeup pump’s NPSH required. |
| 12. | The ECW compression tank accommodates liquid volume due to thermal expansion and contraction, and 7 day system operation without normal makeup. | 12. Inspection and analysis will be performed on the as-built ECW compression tank size to verify that tank accommodates water volume due to thermal expansion and contraction, and 7 day system operation without normal makeup. | 12. A report exists and concludes that the as-built ECW compression tank accommodates the water volume due to thermal expansion and contraction, and 7 day system operation without normal makeup. |
| 13. | The ECWS has the capability to remove heat from safety-related HVAC equipment cooling coils during plant normal, abnormal and accident conditions | 13.a Tests to verify the heat removal capability of the as-built ECWS will be performed. | 13.a A report exists and concludes that the heat removal capability of the as-built ECWS is greater than or equal to design value during plant normal, abnormal and accident conditions |
|   |   | 13.b Testing will be performed to measure the as-built ECW pump flow rate. | 13.b The as-built ECW pump is capable of delivering its design flow rate during plant normal, abnormal and accident conditions. |
Figure 2.7.2.3-1  Essential Chilled Water System
2.7.2.4 Plant Chilled Water System

2.7.2.4.1 Design Description

The plant chilled water system (PCWS) is a non-safety-related closed loop chilled water system that serves non-safety-related HVAC cooling loads, with the exception of containment isolation valves (CIVs) and the piping between the CIVs that are safety-related, ASME Section III Class 2 and seismic Category I as described in Subsection 2.11.3. The PCWS performs the containment isolation function for the PCW lines penetrating the containment.

The PCWS consists of central chilled water subsystem and compound building chilled water subsystem. The central chilled water subsystem is located in the auxiliary building and provides chilled water to the reactor containment fan coolers (RCFCs) and reactor cavity air handling unit (AHU) located in the reactor containment building. This subsystem also provides chilled water to AHUs and cubicle coolers located in auxiliary building and turbine generator building. The compound building chilled water subsystem is located in the compound building and provides chilled water to the AHUs, cubicle coolers and gaseous radwaste system package located in the compound building. The central chilled water subsystem consists of four chillers, two chilled water pumps, an air separator, a compression tank, a chemical additive tank, associated piping, controls and instrumentation. The compound building chilled water subsystem consists of three chillers, two chilled water pumps, an air separator, a compression tank, a chemical additive tank, associated piping, controls and instrumentation.

To meet the above functional requirements, the PCWS is designed as follows:

1. The functional arrangement of the PCWS is as described in the Design Description of Subsection 2.7.2.4.1.

2.7.2.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.2.4-1 specifies the inspections, tests, analyses, and associated acceptance criteria for plant chilled water system.

The ITAAC related to the CIVs and the piping between the CIVs of the PCWS are described in Table 2.11.3-2.

2.7.2.5 Equipment and Floor Drainage System

2.7.2.5.1 Design Description

The equipment and floor drainage system (EFDS) has no safety function except the containment isolation and flooding level detection capability. The EFDS collects radioactive and potentially radioactive liquid waste at atmospheric pressure, from equipment and floor drainage of the reactor containment building, auxiliary building, compound building, CVCS yard tanks and the turbine generator building, and transports liquid waste to the liquid waste management system (LWMS). All drainages are conveyed by gravity to their respective building sumps and are then pumped to the LWMS. Radioactive contamination in turbine generator building sump is continuously monitored by a radiation monitor and alarmed in the main control room (MCR) during normal operations for radioactivity. Upon detecting any radioactivity in the discharge, the discharge is manually terminated and is routed to the floor drain tanks of LWMS.

The EFDS has the following safety-related functions:

1. Preserve containment integrity by the one fail-closed and the one fail-lock air operated containment isolation valves of the EFDS lines penetrating the containment.

2. Preserve flooding level detection capability by means of measuring flooding level in the engineering safety feature (ESF) pump rooms and the floors of Quadrants A, B, C, and D in auxiliary building.

To meet above functional requirements, the EFDS is designed as follows:

1. The functional arrangement of the EFDS is as described in the Design Description of Subsection 2.7.2.5.1 and in Table 2.7.2.5-1 and as shown in Figure 2.7.2.5-1.

2.a The ASME Code components identified in Table 2.7.2.5-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.2.5-1 is designed and constructed in accordance with ASME Section III requirements.
3.a The seismic Category I components and instruments identified in Tables 2.7.2.5-2 and 2.7.2.5-3, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

3.b The seismic Category I piping, including supports, identified in Table 2.7.2.5-1 can withstand seismic design basis load without loss of safety function.

4. Floor drains in the auxiliary building (AB) are physically separated into quadrants (two in each division) and there are no common floor drain lines among quadrants.

5.a The Class 1E components and instruments identified in Tables 2.7.2.5-2 and 2.7.2.5-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) can withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

5.b Each of the Class 1E components and instruments identified in Tables 2.7.2.5-2 and 2.7.2.5-3 is powered from its respective Class 1E division.

5.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

6.a The EFDS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

6.b After loss of motive power, MOV and AOV identified in Table 2.7.2.5-2 assume the indicated loss of motive power position.

7.a Controls exist in the MCR to open and close the MOV and AOV identified in Table 2.7.2.5-2.

7.b Controls exist in the RSR to open and close the MOV and AOV identified in Table 2.7.2.5-2.

7.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.7.2.5-3.
7.d Displays and alarms exist and are retrievable in the RSR defined in Table 2.7.2.5-3.

8. Leak detection design for the tank house sump for holdup tank, BAST, and RMWT provides an alarm in MCR of liquid detection.

9. The EFDS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.2.5.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the equipment and floor drainage system specified in Table 2.7.2.5-4.

The ITAAC associated with the EFDS components and piping that comprise a portion of the containment isolation system are described in Table 2.11.3-2.

Figure 2.7.2.5-1  Equipment and Floor Drainage System
2.7.2.6 Process and Post-Accident Sampling System

2.7.2.6.1 Design Description

The process and post-accident sampling system (PPASS) is designed to collect samples of the various process fluids (liquid and gaseous) during normal and post-accident conditions and monitor various conditions using the collected and analyzed samples.

The PPASS does not have any safety function, and therefore has no safety design basis, except for providing containment isolation. The containment isolation function of PPASS is described in Subsection 2.11.3.

1. The functional arrangement of the PPASS is as described in the Design Description of Subsection 2.7.2.6.1 and in Table 2.7.2.6-1 and as shown in Figure 2.7.2.6-1.

2.a The ASME Code components identified in Table 2.7.2.6-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.2.6-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.2.6-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.2.6-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.2.6-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.7.2.6-1 retains its pressure boundary integrity at its design pressures.

5.a The seismic Category I components and instruments identified in Tables 2.7.2.6-2 and 2.7.2.6-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.
5.b The seismic Category I piping, including supports, identified in Table 2.7.2.6-1 withstands seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.7.2.6-2 and 2.7.2.6-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.7.2.6-2 and 2.7.2.6-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The PPASS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, MOVs and SOVs identified in Table 2.7.2.6-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close the MOVs and SOVs identified in Table 2.7.2.6-2.

8.b Controls exist in the RSR to open and close the MOVs and SOVs identified in Table 2.7.2.6-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.2.6-2 and 2.7.2.6-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.2.6-2 and 2.7.2.6-3.

9. The PPASS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during
normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.2.6.2 **Inspections, Tests, Analyses, and Acceptance Criteria**

The inspection, tests, analyses, and associated acceptance criteria for the PPASS are specified in Table 2.7.2.6-4.

The ITAAC related to the CIVs and the piping between the CIVs of the PPASS are described in Table 2.11.3-2.

2.7.3 HVAC Systems

2.7.3.1 Control Room HVAC System

2.7.3.1.1 Design Description

The control room HVAC system is a safety-related except a kitchen and toilet exhaust fan and a smoke removal fan, and maintains environmental conditions for personnel comfort, health, safety, and proper functions of equipment and controls within the control room envelope (CRE) during normal operations, abnormal and accident conditions of the plant. The control room HVAC system is located in auxiliary building.

The CRE is maintained at a positive pressure with respect to adjacent areas to prevent unfiltered in-leakage.

This system consists of two divisions. Each division has an outside air intake, louver, dampers, two air handling units (AHUs), an air cleaning unit (ACU), ductwork, instrumentation and controls.

Each outside air intake has two redundant isolation dampers, a smoke detector, and two radiation detection monitors.

The control room HVAC system is designed as follows:

1. The functional arrangement of the control room HVAC system is as described in the Design Description of Subsection 2.7.3.1.1 and as shown in Figure 2.7.3.1-1.

2. The seismic Category I components and instruments identified in Tables 2.7.3.1-1 and 2.7.3.1-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

3.a Each of the Class 1E components and instruments identified in Tables 2.7.3.1-1 and 2.7.3.1-2 is powered from its respective Class 1E division.

3.b Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.
4.a ESR dampers, PSR dampers, check dampers and tornado dampers identified in Table 2.7.3.1-1 perform an active safety function to change position as indicated in the table.

4.b After loss of motive power, the ESR dampers and PSR dampers identified in Table 2.7.3.1-1 assume the indicated loss of motive power position.

5.a Controls exist in the MCR to start and stop the ACUs and AHUs, and to open and close the ESR dampers and PSR dampers identified in Table 2.7.3.1-1.

5.b Controls exist in the RSR to start and stop the ACUs and AHUs, and to open and close the ESR dampers and PSR dampers identified in Table 2.7.3.1-1.

5.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.3.1-1 and 2.7.3.1-2.

5.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.3.1-1 and 2.7.3.1-2.

6. The two mechanical divisions of the control room HVAC system are physically separated.

7. The control room HVAC system provides the conditioned air to maintain the room temperature within the design limits for the CRE (except non-safety-related rooms) during plant normal, abnormal and accident conditions.

8. The control room HVAC system removes particulate matter and iodine, and provides system flow as required in the safety analysis.

9.a The outside air intake isolation dampers in the outside air intake with the higher radiation level close upon receipt of a high radiation signal.

9.b After the outside air intake isolation dampers are initially closed upon receipt of a high radiation signal, the closed outside air intake isolation dampers are automatically reset and reopened, and the outside air intake isolation dampers with the higher radiation level automatically close within a predetermined interval.
10. The control room emergency makeup ACU starts and the ACU inlet isolation damper, the ACU discharge flow control damper, and the ACU return air isolation dampers open upon receipt of ESFAS-SIAS or ESFAS-CREVAS.

11. The unfiltered inleakage is within the performance value limit as specified in the safety analysis.

12. The AHU inlet isolation dampers (PSR) listed in Table 2.7.3.1-1 close within their closure time before the airborne radioactive material passes through the isolation dampers.

13.a The fire dampers are installed in the fire rated barriers and have the same fire resistance rating as the barrier.

13.b The fire dampers which are required to protect safety shutdown capability close under design air flow condition.

13.c HVAC ducts that penetrate fire barriers have fire dampers in the HVAC ducts.

14. HVAC duct is installed and routed within the CRE boundary.

15. The control room HVAC system non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.3.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.3.1-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the control room HVAC system.

Figure 2.7.3.1-1  Control Room HVAC System
2.7.3.2 Fuel Handling Area HVAC System

2.7.3.2.1 Design Description

The fuel handling area HVAC system provides ventilation, heating, and cooling to fuel handling area located in the auxiliary building.

The fuel handling area HVAC system has safety-related function that provides suitable conditions for fuel handling area and maintains under a slightly negative pressure to the atmosphere.

The fuel handling area HVAC system has normal HVAC subsystem and emergency HVAC subsystem. The normal HVAC subsystem is non-safety-related and has a supply AHU, a normal exhaust ACU, ductwork, instrumentation, and controls.

The emergency HVAC subsystem is safety-related and has two emergency exhaust ACUs, two cubicle coolers, ductwork, instrumentation, and controls.

The fuel handling area HVAC system is designed as follows:

1. The functional arrangement of the fuel handling area HVAC system is as described in the Design Description of Subsection 2.7.3.2.1 and as shown in Figure 2.7.3.2-1.

2. The seismic Category I components and instruments identified in Tables 2.7.3.2-1 and 2.7.3.2-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

3.a The Class 1E components and instruments identified in Tables 2.7.3.2-1 and 2.7.3.2-2 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

3.b Each of the Class 1E components and instruments identified in Tables 2.7.3.2-1 and 2.7.3.2-2 is powered from its respective Class 1E division.

3.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.
4.a ESR dampers, PSR dampers and tornado dampers identified in Table 2.7.3.2-1 perform an active safety function to change position as identified in the table.

4.b After loss of motive power, ESR dampers and PSR dampers identified in Table 2.7.3.2-1 assume the indicated loss of motive power position.

5.a Controls exist in the MCR to start and stop the emergency exhaust ACUs and safety-related cubicle coolers, and to open and close ESR dampers and PSR dampers identified in Table 2.7.3.2-1.

5.b Controls exist in the RSR to start and stop the emergency exhaust ACUs and safety-related cubicle coolers, and to open and close ESR dampers and PSR dampers identified in Table 2.7.3.2-1.

5.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.7.3.2-2.

5.d Displays and alarms exist and are retrievable in the RSR as defined in Table 2.7.3.2-2.

6. The two mechanical divisions of the fuel handling area emergency HVAC subsystem (A/C & B/D) are physically separated.

7. The safety-related cubicle coolers identified in Table 2.7.3.2-1 provide conditioned air that is required to maintain the room temperature within the design limits for the spent fuel pool cooling heat exchanger rooms during plant normal, abnormal and accident conditions.

8. The fuel handling area HVAC system cubicle cooler fans identified in Table 2.7.3.2-1 operate automatically according to room temperature signal.

9. The emergency exhaust ACU in each division removes particulate matter and iodine.

10.a The fuel handling area emergency exhaust ACU starts upon receipt of an ESFAS-FHEVAS or high radiation signal.
10.b The air intake isolation dampers and the normal exhaust ACU isolation dampers close within their design basis closure time upon receipt of an ESFAS-FHEVAS or high radiation signal.

11.a The fire dampers are installed in the fire rated barriers and have the same fire resistance rating as the barrier.

11.b The fire dampers which are required to protect safety shutdown capability close under design air flow condition.

11.c HVAC ducts that penetrate fire barriers have fire dampers in the HVAC ducts.

12. The fuel handling area HVAC system has exhaust airflow rate greater than supply airflow rate to control the release of potential airborne radioactive materials from the fuel handling area during plant normal condition.

13. The fuel handling area HVAC system non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.3.2.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.3.2-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the fuel handling area HVAC system.

2.7.3.3 Auxiliary Building Clean Area HVAC System

2.7.3.3.1 Design Description

The auxiliary building clean area HVAC system provides ventilation, cooling and heating to the auxiliary building clean area and is located inside the auxiliary building clean area. The auxiliary building smoke removal fans are used for smoke removal.

The auxiliary building clean area HVAC system is a non-safety-related system except for safety-related cubicle coolers.

The safety-related cubicle coolers for motor-driven auxiliary feedwater (AFW) pump rooms and essential chiller rooms are cooled by the essential chilled water system.

The auxiliary building clean area HVAC system is designed as follows:

1. The functional arrangement of the auxiliary building clean area HVAC system is as described in the Design Description of Subsection 2.7.3.3.1 and as shown in Figure 2.7.3.3-1.

2. The seismic Category I components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

3.a Each of the Class 1E components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2 is powered from its respective Class 1E division.

3.b Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

4.a Controls exist in the MCR to start and stop the safety-related cubicle coolers identified in Table 2.7.3.3-1.

4.b Controls exist in the RSR to start and stop the safety-related cubicle coolers identified in Table 2.7.3.3-1.

4.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.7.3.3-2.
4.d  Displays and alarms exist and are retrievable in the RSR as defined in Table 2.7.3.3-2.

5.  The two mechanical divisions of the safety-related cubicle coolers are physically separated.

6.  The auxiliary building clean area HVAC system provides conditioned air that is required to maintain the room temperature within the design limits for the auxiliary building clean area during plant normal condition.

7.  The safety-related cubicle coolers identified in Table 2.7.3.3-1 provide conditioned air that is required to maintain the room temperature within the design limits for the motor-driven AFW pump rooms and essential chiller rooms during plant normal, abnormal and accident conditions.

8.  The auxiliary building clean area HVAC system cubicle cooler fans identified in Table 2.7.3.3-1 operate automatically according to room temperature signal.

9.a  The fire dampers are installed in the fire rated barriers and have the same fire resistance rating as the barrier.

9.b  The fire dampers which are required to protect safety shutdown capability close under design air flow condition.

9.c  HVAC ducts that penetrate fire barriers have fire dampers in the HVAC ducts.

2.7.3.3.2  Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.3.3-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the auxiliary building clean area HVAC system.

### Design Commitment

1. The functional arrangement of the auxiliary building clean area HVAC system is as described in the Design Description of Subsection 2.7.3.3.1 and as shown in Figure 2.7.3.3-1.

### Inspections, Tests, Analyses

1. Inspection of the as-built auxiliary building clean area HVAC system will be performed.

2. The seismic Category I components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

   2.a Inspections will be performed to verify that the as-built seismic Category I components and instruments are located in the seismic Category I structure.

   2.b Type tests, analyses or a combination of type tests and analyses of seismic Category I components and instruments will be performed.

   2.c Inspections will be performed to verify that the as-built seismic Category I components and instruments, including the supports and anchorages, are seismically bounded by the tested or analyzed conditions.

3. Each of the Class 1E components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2 is powered from its respective Class 1E division.

   3.a Tests will be performed by providing a test signal in only one Class 1E division at a time.

### Acceptance Criteria

1. The as-built auxiliary building clean area HVAC system conforms with the functional arrangement as described in the Design Description of Subsection 2.7.3.3.1 and as shown in Figure 2.7.3.3-1.

2.a The as-built seismic Category I components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2 are located in the seismic Category I structure.

2.b A report exists and concludes that the seismic Category I components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2 withstand seismic design basis loads without loss of safety function.

2.c A report exists and concludes that the as-built seismic Category I components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2, including the supports and anchorages, are seismically bounded by the tested or analyzed conditions.

3.a The test signal exists at the Class 1E components and instruments identified in Tables 2.7.3.3-1 and 2.7.3.3-2 as being powered from its respective Class 1E division under test.

2.7.3.5 Engineered Safety Features Ventilation System

The engineered safety features (ESF) ventilation system includes:

   a. Emergency diesel generator area HVAC system
   b. Electrical and I&C equipment areas HVAC system
   c. Auxiliary building controlled area HVAC system

2.7.3.5.1 Design Description

2.7.3.5.1.1 Emergency Diesel Generator Area HVAC System

The emergency diesel generator area HVAC system is a safety-related system that provides ventilation, cooling and heating to four emergency diesel generator areas. The emergency diesel generator area HVAC system is located inside the auxiliary building and emergency diesel generator building.

The emergency diesel generator area HVAC system consists of four divisions. Each division of the emergency diesel generator area HVAC system has an air handling unit (AHU), fans, cubicle coolers, dampers, ductwork, instrumentation and controls.

2.7.3.5.1.2 Electrical and I&C Equipment Areas HVAC System

The electrical and I&C equipment areas HVAC system is a safety-related system that provides ventilation, cooling and heating to the electrical equipment rooms and I&C equipment rooms. The electrical and I&C equipment areas HVAC system is located in the auxiliary building.

The electrical and I&C equipment areas HVAC system consists of two divisions. Each division of the electrical and I&C equipment areas HVAC system has battery room exhaust fans, RSR supply fan and RSR exhaust fan, cubicle coolers, ductwork, instrumentation and controls.

The safety-related electrical rooms and I&C equipment rooms are cooled by the safety-related cubicle coolers.
The auxiliary building controlled area HVAC system is a safety-related system that provides ventilation, cooling and heating to the auxiliary building controlled area. The auxiliary building controlled area HVAC system is located in the auxiliary building controlled area.

The auxiliary building controlled area HVAC system consists of two divisions. Each division of the auxiliary building controlled area HVAC system has air handling units, air cleaning units, cubicle coolers, dampers, ductwork, instrumentation and controls.

Each division of auxiliary building controlled area HVAC system maintains its division of the auxiliary building controlled area under a slightly negative pressure relative to the atmosphere.

The ESF ventilation system is designed as follows:

1. The functional arrangement of the emergency diesel generator area HVAC system is as described in the Design Description of Subsection 2.7.3.5.1.1 and as shown in Figure 2.7.3.5-1.

2. The functional arrangement of the electrical and I&C equipment areas HVAC system is as described in the Design Description of Subsection 2.7.3.5.1.2 and as shown in Figure 2.7.3.5-2.

3. The functional arrangement of the auxiliary building controlled area HVAC system is as described in the Design Description of Subsection 2.7.3.5.1.3 and as shown in Figure 2.7.3.5-3.

2. The seismic Category I components and instruments identified in Tables 2.7.3.5-1 and 2.7.3.5-2, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

3. The Class 1E components and instruments identified in Tables 2.7.3.5-1 and 2.7.3.5-2 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.
3.b Each of the Class 1E components and instruments identified in Tables 2.7.3.5-1 and 2.7.3.5-2 is powered from its respective Class 1E division.

3.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

4.a ESR dampers, PSR dampers and tornado dampers identified in Table 2.7.3.5-1 perform an active safety function to change position as indicated in the table.

4.b After loss of motive power, ESR dampers and PSR dampers identified in Table 2.7.3.5-1 assume the indicated loss of motive power position.

5.a Controls exist in the MCR to start and stop the ACUs, AHUs and cubicle coolers, and to open and close ESR dampers and PSR dampers identified in Table 2.7.3.5-1.

5.b Controls exist in the RSR to start and stop the ACUs, AHUs and cubicle coolers, and to open and close ESR dampers and PSR dampers identified in Table 2.7.3.5-1.

5.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.7.3.5-2.

5.d Displays and alarms exist and are retrievable in the RSR as defined in Table 2.7.3.5-2.

6.a Each mechanical division of the emergency diesel generator area HVAC system (A, B, C & D) is physically separated from the other divisions.

6.b The two mechanical divisions of the electrical and I&C equipment areas HVAC system (A/C & B/D) are physically separated.

6.c The two mechanical divisions of the auxiliary building controlled area HVAC system (A/C & B/D) are physically separated.

7.a The emergency diesel generator area HVAC system provides conditioned air that is required to maintain the room temperature within the design limits for the emergency diesel generator area during plant normal, abnormal and accident conditions.
7.b The electrical and I&C equipment areas HVAC system provides conditioned air that is required to maintain the room temperature within the design limits for the electrical and I&C equipment areas except non-safety-related equipment rooms during plant normal, abnormal and accident conditions.

7.c The auxiliary building controlled area HVAC system provides conditioned air that is required to maintain the room temperature within the design limits for the safety-related rooms in the auxiliary building controlled area during plant normal, abnormal and accident conditions.

8. The emergency diesel generator area HVAC system, the electrical and I&C equipment areas HVAC system and the auxiliary building controlled area HVAC system cubicle cooler fans identified in Table 2.7.3.5-1 operate automatically according to room temperature signal.

9. The auxiliary building controlled area emergency exhaust ACU removes particulate matter and iodine and provides a negative pressure.

10. The auxiliary building controlled area emergency exhaust ACUs start and the auxiliary building controlled area supply AHU outlet isolation dampers and the auxiliary building controlled area normal exhaust ACU inlet isolation dampers close upon receipt of an ESFAS-SIAS.

11. The electrical and I&C equipment areas HVAC system provides battery room ventilation that is required to maintain hydrogen concentration within the design limit during plant normal, abnormal and accident conditions.

12.a The fire dampers are installed in the fire rated barriers and have the same fire resistance rating as the barrier.

12.b The fire dampers which are required to protect safety shutdown capability close under design air flow condition.

12.c HVAC ducts that penetrate fire barriers have fire dampers in the HVAC ducts.

13. The auxiliary building controlled area HVAC system has exhaust airflow rate greater than supply airflow rate to control the release of potential airborne...
radioactive materials from the auxiliary building controlled area during plant normal condition.

14. The auxiliary building controlled area HVAC system non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.3.5.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.3.5-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the engineered safety features ventilation system.

Figure 2.7.3.5-2  Electrical and I&C Equipment Areas HVAC System
Figure 2.7.3.5-3  Auxiliary Building Controlled Area HVAC System
2.7.3.6 Reactor Containment Building HVAC System and Reactor Containment Building Purge System

2.7.3.6.1 Design Description

2.7.3.6.1.1 Reactor Containment Building HVAC System

The reactor containment building HVAC system is a non-safety-related system that provides cooling and air recirculation in the containment.

The reactor containment building HVAC system consists of reactor containment building cooling subsystem, reactor cavity cooling subsystem, and CEDM cooling subsystem.

The reactor containment building cooling subsystem cools and recirculates air inside the containment.

The reactor cavity cooling subsystem provides cooled air to the concrete surrounding the reactor.

The CEDM cooling subsystem maintains the temperature of the CEDM coils.

2.7.3.6.1.2 Reactor Containment Building Purge System

The reactor containment building purge system is a non-safety-related system, with the exception of containment isolation valves (CIVs) and the piping between the CIVs that are safety-related, ASME Section III Class 2 and seismic Category I as described in Subsection 2.11.3. The reactor containment building purge system performs the containment isolation function for the piping penetrating the containment.

The reactor containment building purge system provides containment pressure relief, reduces air borne radioactivity, and maintains environmental condition within the containment. The reactor containment building purge system is located in the auxiliary building and the containment building.

The reactor containment building purge system is divided into low volume purge subsystem, and high volume purge subsystem.

The high volume purge subsystem consists of one 100 percent capacity supply AHU and two 50 percent capacity exhaust ACUs, CIVs, ductwork, instrumentation and controls.
The high volume purge subsystem reduces airborne radioactivity and maintains environmental conditions within the containment to entry for maintenance or inspections during cold shutdown and refueling conditions.

The low volume purge subsystem consists of two 100 percent capacity supply fans and two 100 percent capacity exhaust ACUs, CIVs, ductwork, instrumentation and controls. The low volume purge subsystem controls the containment atmosphere pressure and removes gaseous and particulate contamination from the containment atmosphere during plant normal condition, when required.

The reactor containment building HVAC system and reactor containment building purge system are designed as follows:

1. The functional arrangement of the reactor containment building HVAC system and reactor containment building purge system are as described in the Design Description of Subsections 2.7.3.6.1.1 and 2.7.3.6.1.2.

2.a The fire dampers are installed in the fire rated barriers and have the same fire resistance rating as the barrier.

2.b The fire dampers which are required to protect safety shutdown capability close under design air flow condition.

2.c HVAC ducts that penetrate fire barriers have fire dampers in the HVAC ducts.

2.7.3.6.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.3.6-1 specifies the inspections, tests, analyses, and associated acceptance criteria for the reactor containment building HVAC system and reactor containment building purge system.

The ITAAC related to CIVs and piping penetrating the containment of the reactor containment building purge system are described in Table 2.11.3-2.
### Design Commitment

1. The functional arrangement of the reactor containment building HVAC system and reactor containment building purge system are as described in the Design Description of Subsections 2.7.3.6.1.1 and 2.7.3.6.1.2.

### Inspections, Tests, Analyses

1. Inspection of the as-built system will be conducted.

### Acceptance Criteria

1. The as-built reactor containment building HVAC system and reactor containment building purge system conforms with the functional arrangement as described in the Design Description of Subsections 2.7.3.6.1.1 and 2.7.3.6.1.2.

2.7.3.7 Compound Building HVAC System

No entry for this system.
2.7.4 New and Spent Fuel Handling System

2.7.4.1 New Fuel Storage

2.7.4.1.1 Design Description

The new fuel storage racks are non-safety-related, but treated as safety-related components in accordance with the quality assurance of the 10 CFR 50 Appendix B. In addition, the racks are designed as seismic Category I for integrity of the new fuel assemblies. The new fuel storage racks provide on-site dry storage for nuclear fuel assemblies. The new fuel storage racks are located in the new fuel storage pit in the fuel handling area of the auxiliary building. A drain system with a provision preventing backflow from other drains is included in the new fuel storage pit and curbs are installed around the top edge of the pit for preventing the water in-flow in the event of flooding in the adjacent fuel handling areas. It is designed that non-seismic Category I component located near the area of NFSP will not impact NFSP racks and stored fuel due to its failure during SSE.

The new fuel storage racks are designed and constructed to accommodate design basis load and load combinations including impact due to postulated fuel handling accidents in a sub-critical configuration. The racks are also designed and constructed to prevent tipping of the racks in the event of an SSE earthquake by means of fixation to the floor.

The new fuel storage racks are designed and constructed to maintain a $K_{\text{eff}}$ no greater than 0.95 under fully flooded conditions and no greater than 0.98 under optimum moderation conditions at a 95 percent probability with 95 percent confidence level in accordance with 10 CFR 50.68.

1. The functional arrangement of the new fuel storage facility including the new fuel storage racks is as described in the Design Description of Subsection 2.7.4.1.1.

2. The new fuel storage racks maintain the effective multiplication factor, $K_{\text{eff}}$, less than or equal to the regulatory limits in 10 CFR 50.68 during normal operation and the postulated accident conditions.
2.7.4.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.4.1-1 specifies the inspections, tests, analyses, and associated acceptance criteria for the new fuel storage racks.

2.7.4.2 Spent Fuel Storage

2.7.4.2.1 Design Description

The function of spent fuel facility is to store spent fuel in the spent fuel pool of the auxiliary building, which is seismic Category I. The spent fuel pool is designed to have sufficient dimensions to maintain the proper water level and volume for spent fuel cooling and radiation shielding. The spent fuel pool liner plate is classified as seismic Category I. The liner plate is fabricated from stainless steel material and utilizes a welded construction for minimizing potential leakage. A liner leakage collection system is provided to collect possible leakage from liner plate welds on the pool walls and floor.

The spent fuel storage racks are non-safety-related, but treated as safety-related components in accordance with the quality assurance of the 10 CFR 50 Appendix B. In addition, the racks are designed as seismic Category I for integrity of the spent fuel assemblies. The spent fuel storage racks provide on-site storage capability for a core offload during the design life. The spent fuel storage racks are located in the spent fuel pool. The spent fuel pool has no opening, gate, drain, or connection below the top of the stored fuel. The spent fuel pool gates for transferring fuel to the adjacent fuel handling area are seismic Category I. The gates are designed to minimize potential leakage and withstand the water pressure in the spent fuel pool. The water level in the spent fuel pool remains 3 m (10 ft) above the top of fuel assemblies in the event of a single gate failure. All piping penetrating the spent fuel pool are located at least 3 m (10 ft) or more above the top of irradiated fuel assemblies seated in the storage racks, and all piping extending down into the spent fuel pool have siphon breaker holes installed on the piping inside the spent fuel pool at or above this level. The spent fuel pool water level shall be 7 m (23 ft) over the top of irradiated fuel assemblies seated in the storage racks. It is designed that non-seismic Category I component located near the area of SFP will not impact SFP safety-related SSC, the racks, or stored fuel due to its failure during SSE.

The spent fuel storage racks are designed and constructed to accommodate design basis load and load combinations including impact due to postulated fuel handling accidents in a subcritical configuration.

The spent fuel storage racks are designed and constructed to maintain a $K_{eff}$ no greater than 0.95, at a 95 percent probability, 95 percent confidence level (95/95level), if flooded with
borated water, and a $K_{\text{eff}}$ of less than 1.0, at a 95/95 level, if flooded with unborated water in accordance with 10 CFR 50.68.

1. The functional arrangement of the spent fuel storage facility including the spent fuel pool liner plate, gates and racks is as described in the Design Description of Subsection 2.7.4.2.1.

2. The spent fuel storage racks maintain the effective multiplication factor, $K_{\text{eff}}$, less than or equal to the regulatory limits in 10 CFR 50.68 during normal operation and the postulated accident conditions.

2.7.4.2.2 Inspections, Tests, Analyses, and Acceptance Criteria

2.7.4.3  Spent Fuel Pool Cooling and Cleanup System

2.7.4.3.1  Design Description

The spent fuel pool (SFP) cooling system removes heat generated by the stored spent fuel assemblies in the spent fuel pool water. The SFP cleanup system purifies spent fuel pool water, refueling pool water, IRWST water, and fuel transfer canal water through filters and ion exchangers. The spent fuel pool cooling and cleanup system (SFPCCS) performs safety-related functions to maintain the SFP water temperature within limits and preserve containment integrity by isolation of the SFPCCS lines penetrating the containment. The SFP cooling system (SFPCS) is safety-related and the SFP cleanup system is non-safety-related. The SFPCCS consists of a SFP cooling system and cleanup system. The SFPCCS is located in the auxiliary building.

To meet above functional requirements, the SFPCCS is designed as follows:

1. The functional arrangement of the SFPCCS is as described in the Design Description of Subsection 2.7.4.3.1 and in Table 2.7.4.3-1 and as shown in Figure 2.7.4.3-1.

2.a The ASME Code components identified in Table 2.7.4.3-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.7.4.3-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.7.4.3-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.7.4.3-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.7.4.3-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.7.4.3-1 retains its pressure boundary integrity at its design pressure.
5.a The seismic Category I components and instruments identified in Tables 2.7.4.3-2 and 2.7.4.3-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.7.4.3-1 withstands seismic design basis loads without loss of safety function.

6.a The Class 1E components and instruments identified in Tables 2.7.4.3-2 and 2.7.4.3-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.7.4.3-2 and 2.7.4.3-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7. Check valves identified in Table 2.7.4.3-2 perform an active safety function to change position as indicated in the table.

8.a Controls exist in the MCR to start and stop the SFP cooling pumps identified in Table 2.7.4.3-2.

8.b Controls exist in the RSR to start and stop the SFP cooling pumps identified in Table 2.7.4.3-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.7.4.3-2 and 2.7.4.3-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.7.4.3-2 and 2.7.4.3-3.

9. The two mechanical divisions of the SFPCS are physically separated except for the cross-connect line between SFP cooling pump suction, discharge lines.

10. The SFPCCS provides heat removal capacity to remove the decay heat generated by spent fuel assemblies.
11. The SFPCCS safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

12. The SFP cooling pumps have sufficient net positive suction head (NPSH).

13. Spent fuel pool liner leak detection design provides visual indication of liner leak.

2.7.4.3.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the SFPCCS are specified in Table 2.7.4.3-4.

The ITAAC related to the CIVs and the piping between CIVs of the SFPCCS are described in Table 2.11.3-2.

Figure 2.7.4.3-1  Spent Fuel Pool Cooling and Cleanup System
2.7.4.4  Light Load Handling System

2.7.4.4.1  Design Description

The light load handling system (LLHS) handles, moves and stores fuel assemblies and control element assemblies (CEAs) during fuel transfer operation. The LLHS load measuring devices are designed to reduce the potential for damage to a fuel assembly. All of the LLHS equipment are classified as non-nuclear safety with the single exception of the double blind flange assembly for transfer tube penetration sleeve. The LLHS has indicator lights on the control console to verify visually the operation status for the operator. Additionally, movement of the refueling machine (RM) and the spent fuel handling machine (SFHM) bridge is audibly signaled.

The RM, CEA change platform (CEACP) and CEA elevator (CEAE) are located in the reactor containment building. The SFHM, new fuel elevator (NFE) and fuel handling hoist of overhead crane are located in the fuel handling area of the auxiliary building. The fuel transfer system (FTS) is located in both the reactor containment building and the auxiliary building.

1. The functional arrangement of the LLHS is as described in the Design Description of Subsection 2.7.4.4.1 and in Table 2.7.4.4-1.

2. The ASME Code equipment identified in Table 2.7.4.4-1 is designed and constructed in accordance with ASME Section III requirements.

3. The ASME Code equipment identified in Table 2.7.4.4-1 retains its pressure boundary integrity at its design pressure.

4. The seismic Category I equipment identified in Table 2.7.4.4-1, including the supports and anchorages, withstands seismic design basis loads without loss of safety function.

5. The seismic Category II equipment identified in Table 2.7.4.4-1 retains structural integrity and does not impair the ability of a seismic Category I equipment to perform its design basis safety function during or following a safe shutdown earthquake (SSE).
6. The RM, SFHM and CEACP hoists are provided with load measuring devices and are interlocked to interrupt hoisting and lowering if load limits are reached.

7. The RM, SFHM and CEACP hoists are interlocked to limit upward hoist travel.

8. The RM, SFHM and CEACP hoists are provided with mechanical stops. The mechanical stops restrict withdrawal of the spent fuel assemblies or CEAs above the minimum safe water cover depth (9 ft). This, along with the shielding provided by the refueling equipment, ensures that an operator on the refueling platform is not exposed to the radiation dose limit of 2.5 mrem/hr when at the lower limit of the normal operating water level.

9. During a loss of electrical power to the RM or SFHM, the RM or SFHM does not drop the fuel assembly held by its hoist.

10. The new fuel elevator is interlocked to prevent from raising the elevator with a fuel assembly in the carriage assembly.

2.7.4.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.4.4-2 specifies the inspections, tests, analyses, and associated acceptance criteria for the LLHS.

2.7.4.5 Overhead Heavy Load Handling System

2.7.4.5.1 Design Description

The overhead heavy load handling system (OHLHS) is a non-safety-related system that handles and moves any loads greater than a fuel assembly load plus its handling device. OHLHS consists of one fuel handling area overhead crane, one containment polar crane, and other cranes and hoists that handle heavy loads which may damage safe shutdown equipment in the event of accidental drop.

The containment polar crane is used to handle the reactor vessel head in the area of the reactor vessel and the fuel handling area overhead crane is used to handle new fuel containers and spent fuel casks in the fuel handling area.

The containment polar crane is designed as a single-failure-proof crane so that any single failure does not result in losing the crane’s capability to perform its own functions. The containment polar crane is also designed as seismic Category II and therefore, the dynamic effects arising from seismic events are restricted by the seismic restraints which prevent the bridge or trolley from leaving the rails during and after a safe shutdown earthquake (SSE).

The fuel handling area overhead crane, equipped with a cask handling hoist and a fuel handling hoist, is mounted on the rail that extends the entire length of the fuel handling area. Once fuel assemblies are received onsite, provisions are installed permanently to restrict movement of the crane over the spent fuel pool (SFP) area for safe heavy-load handling.

The fuel handling area overhead crane is designed as seismic Category II. During an SSE, the fuel handling area overhead crane and all its components retain structural integrity, and the bridge and trolley remain in place on their respective runways with their wheels prevented from leaving the tracks.

1. The functional arrangement of the OHLHS is as described in the Design Description of Subsection 2.7.4.5.1.

2. The OHLHS retains structural integrity and does not impair the ability of a seismic Category I equipment to perform its design basis safety function during or following an SSE.
3. The containment polar crane and fuel handling area crane have seismic restraints that prevent the bridge and trolley on their respective runways with their wheels from leaving the tracks during and after an SSE.

4. The containment polar crane has the dual reeving system and at least two holding brake system.

5. OHLHS prevents the uncontrolled lowering of a heavy load.

6. The hoists of containment polar crane and the fuel handling area overhead crane are provided with two limit switches to prevent the hoisting system from two-blocking.

7. The fuel handling hoist of fuel handling area overhead crane is interlocked to prevent moving new fuel over the spent fuel storage racks in the spent fuel pool.

8. The cask handling hoist of fuel handling area overhead crane is interlocked and equipped with mechanical stops to prevent moving a cask over the spent fuel storage racks in the spent fuel pool, and interlocked to prevent moving a cask over the new fuel storage racks.

9. The OHLHS has a control system to return to or maintain a secure holding position of critical loads in the event of a system fault.

2.7.4.5.2 Inspections, Tests, Analyses, and Acceptance Criteria

The ITAAC for the OHLHS is described in Table 2.7.4.5-1.

2.7.5 Auxiliary System

2.7.5.1 Compressed Air and Gas Systems

2.7.5.1.1 Design Description

The compressed air and gas systems are composed of the compressed air system (CAS), compressed gas system, and breathing air system. The CAS comprises the instrument air system (IAS) and the service air system (SAS). The compressed gas system is composed of nitrogen subsystem, hydrogen subsystem, and carbon dioxide subsystem.

The CAS are non-safety-related systems with the exception of the containment isolation valves (CIVs) and the piping between the CIVs that are safety-related, ASME Section III Class 2 and seismic Category I as described in Subsection 2.11.3. The CAS performs the containment isolation function for the CAS lines penetrating the containment.

2.7.5.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

The ITAAC related to the CIVs and the piping between the CIVs of the CAS are described in Table 2.11.3-2.
2.7.5.2 Fire Protection System

2.7.5.2.1 Design Description

The fire protection system (FPS) is classified as a non-safety-related system with the exception of the containment isolation function. The FPS provides fire detection and suppression capabilities and mitigates fire propagation.

The FPS consists of a water distribution system, automatic and manual suppression systems, a fire detection and alarm system, and portable fire extinguishers. Main components of the FPS are located in yard and auxiliary building. The FPS provides fire protection for containment building, auxiliary building, turbine building, and compound building. The FPS has a safety-related containment isolation function as described in Subsection 2.11.3.

Seismic Category I design is applied to the FPS located in the auxiliary building, emergency diesel generator building, and containment building containing safe shutdown equipment.

To meet functional requirements, the FPS is designed as follows:

1. The functional arrangement of the FPS is as described in the Design Description of Subsection 2.7.5.2.1 and as shown in Figure 2.7.5.2-1.

2.a The main fire water storage tank has minimum volume for design flow rate for fire fighting during 2 hours.

2.b The seismic Category I fire water storage tank has minimum volume for 2 hose station during 2 hours.

3.a There are three 50 percent capacity fire pumps: one pump is motor driven and two pumps are diesel driven.

3.b There are two 100 percent capacity seismic Category I motor driven fire pumps.

4. The FPS fire water supply is available as emergency containment spray backup source for severe accident mitigation.

5. During and after safe-shutdown earthquake loading, the stand pipe system remains functional in areas containing equipment required for safe shutdown.
6. The fuel tank for the diesel-driven fire pump is capable of holding at least equal to 5.07 L per kW (1 gal per hp) plus 10 percent volume.

7. Manual pull stations or individual fire detectors provide fire detection capability and are used to initiate fire alarms.

8.a Displays and alarms exist and are retrievable in the MCR as defined in Table 2.7.5.2-2.

8.b Displays and alarms exist and are retrievable in the RSR as defined in Table 2.7.5.2-2.

2.7.5.2.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses and associated acceptance criteria for the fire protection system are described in Table 2.7.5.2-3.

The ITAAC associated with the FPS equipment, components and piping that comprise a portion of the CIS are described in Table 2.11.3-2.

2.7.6 Radioactive Waste Management

2.7.6.1 Liquid Waste Management System

2.7.6.1.1 Design Description

The liquid waste management system (LWMS) is a non-safety-related system. The LWMS is designed to handle, process, store, and release the liquid radioactive waste generated during normal operation including anticipated operational occurrences (AOOs). The LWMS treats liquid radioactive waste using eight (8) collection tanks for segregated staging of liquids, two (2) reverse osmosis (R/O) package systems for processing, and two monitor tanks to collect treated effluent for staging confirmatory sampling and analysis. The R/O package system is designed to process liquid radioactive waste with a pretreatment module, an R/O module and a demineralizer module. By sampling from monitor tanks, LWMS provides means to monitor and confirm that the radioactivity levels in the processed liquid waste are below the release limits prior to discharge. The LWMS provides sufficient capacity, redundancy, and flexibility to treat the liquid radioactive waste in a manner to reduce the radionuclide concentrations to meet the effluent concentration and dose limits in 10 CFR Part 20, Appendix B, Table 2 and 10 CFR Part 50, Appendix I dose objectives for liquid effluents.

During plant operation, treated effluent is collected in the monitor tanks and each batch is sampled for confirmation that the effluent concentrations are within the discharge specifications prior to discharge operation. The effluent is also continuously monitored for radioactivity levels during discharge. The radiation monitor will provide alarms in the MCR and the radwaste control room for operator action in the event that the effluent exceeds a predetermined radiation setpoint, simultaneously turn off the monitor tank pump, and close the discharge valves. The tank contents will be recycled for further treatment before release.

The LWMS is located in the compound building. The component cubicles are designed with early detection features to minimize the spread of unintended contamination. The LWMS consists of equipment waste subsystem, floor drain subsystem, chemical waste subsystem and detergent waste subsystem.

1. The functional arrangement of the LWMS is as described in the Design Description of Subsection 2.7.6.1.1 and in Table 2.7.6.1-1 and as shown in Figure 2.7.6.1-1.
2. The LWMS has the sole liquid discharge line which is equipped with dual radiation monitors and an automatic discharge valve. The valve is to automatically close upon detection of a high radioactivity level in the liquid effluent that exceeds a predetermined setpoint.

3. The LWMS uses two (2) trains of industry-proven R/O technologies. The R/O trains are sized adequately to remove radionuclides to maintain radioactivity in the liquid releases within regulatory limits. Three (3) demineralizers in each demineralizer module are added to polish the permeate to further remove any residual nuclides in the effluent.

4. The LWMS uses two (2) sets of monitor tanks and pumps. The tanks are provided with eductors to thoroughly mix the tank content for sampling and analysis to confirm that the contamination level in the treated effluent is below the regulatory limits for discharge. Dual radiation monitors are provided to continuously monitor the radiation levels during discharge operation and alarm in the MCR and radwaste control room upon detection of a high radioactivity level.

5. The LWMS components are classified as RW-IIa, RW-IIb and RW-IIc in accordance with NRC RG 1.143 and designed to the corresponding requirements in order to maintain structural integrity under the design basis loads. Component Radiation Safety Classification is summarized in Table 2.7.6.1-1.

6. Dual radiation monitors and an isolation valve are provided on the LWMS sole discharge line.

7. Leak detection design for floor drain tanks provides an alarm in MCR and RCR of liquid detection.

8. Leak detection design for equipment waste tanks provides an alarm in MCR and RCR of liquid detection.

9. Leak detection design for monitor tanks provides an alarm in MCR and RCR of liquid detection.

2.7.6.1.2 **Inspections, Tests, Analyses, and Acceptance Criteria**

The ITAAC for the LWMS is described in Table 2.7.6.1-2.

Figure 2.7.6.1-1  Liquid Waste Management System
2.7.6.2 Gaseous Waste Management System

2.7.6.2.1 Design Description

The gaseous waste management system (GWMS) consists of the gaseous radwaste system (GRS) and the building ventilation HVAC systems. The design and methods of treatment for the building ventilation subsystems are discussed in Section 9.4 of this DCD, Tier 2 and the condenser vacuum subsystem is discussed in Section 10.4 of the DCD, Tier 2. This subsection covers the design of the GRS, which handles and processes reactor offgas from the chemical and volume control system (CVCS). The GRS is non-safety-related with the exception of containment penetration isolation valves and the piping. The GRS is designed to collect, store, process, sample and monitor gaseous radioactive waste generated as a result of normal operation, including anticipated operational occurrences (AOOs). The GRS ensures that gaseous waste releases comply with effluent concentration and dose limit in 10 CFR Part 20, Appendix B, and 10 CFR Part 50, Appendix I dose objectives for gaseous effluents.

The GRS is located in the compound building. The GRS is designed to process gaseous radioactive waste with charcoal delay beds having adequate charcoal mass for adsorption of nuclides for decay in order to keep releases within regulatory limits. The waste gas dryer and charcoal guard bed remove the moisture in the radioactive waste to protect the charcoal delay beds. The GRS is designed for continuous operation. Treated effluent is continuously monitored for radioactivity levels during discharge. The radiation monitor will provide alarms in the MCR and the radwaste control room in the event that the effluent exceeds a predetermined radiation setpoint, and simultaneously close the discharge valve.

The GRS is designed as follows:

1. The functional arrangement of the GRS is as described in the Design Description of Subsection 2.7.6.2.1 and in Tables 2.7.6.2-1 and 2.7.6.2-3 and as shown in Figure 2.7.6.2-1.

2. The GRS charcoal delay beds contain the appropriate type, size, and mass of charcoal needed to facilitate adsorption of radionuclides (xenon and krypton gases) for decay to ensure that the gaseous releases are within the regulatory limits. Moisture instruments are provided for the protection of the charcoal delay beds.
3. The GRS discharge valve is closed automatically upon detection of a high radiation signal from the radiation monitor at the gaseous waste discharge. The discharge valve is also automatically closed when there is insufficient or no ventilation flow.

4. An alarm from the gaseous waste discharge radiation monitor is provided in the MCR, the RSR, and the radwaste control room.

5. The nitrogen injection valve is opened automatically upon receipt of a high oxygen concentration signal above the pre-determined setpoint.

6. The GRS components are classified as RW-IIa in accordance with NRC RG 1.143 and designed to the corresponding requirements in order to maintain structural integrity under the design basis loads. Component Radiation Safety Classification is summarized in Table 2.7.6.2-3.

2.7.6.2.2 Inspections, Tests, Analysis, and Acceptance Criteria

The inspections, tests, and analyses, and associated acceptance criteria for the gaseous radwaste system is specified in Table 2.7.6.2-4 except for containment penetration isolation valves and piping.

The inspection, tests, analyses, and associated acceptance criteria for the containment penetration isolation valves and piping of GRS are specified in Table 2.11.3-2.

Figure 2.7.6.2-1  Gaseous Radwaste System
2.7.6.3 Solid Waste Management System

2.7.6.3.1 Design Description

The solid waste management system (SWMS) is designed as a non-safety-related system. The SWMS collects, packages, and temporarily stores the solid radioactive wastes prior to shipment.

The SWMS is located in the compound building. The SWMS consists of subsystems to manage various types of solid radioactive waste products, including spent resin, spent filter elements, reverse osmosis (R/O) concentrates, dry active waste (DAW).

1. The functional arrangement of the SWMS is as described in the Design Description of Subsection 2.7.6.3.1 and in Table 2.7.6.3-1.

2. The SWMS spent resin storage tanks listed in Table 2.7.6.3-1 have the capacity for radioactive spent resin storage.

3. The SWMS provides dewatering equipment for spent resin in order to meet transportation and waste acceptance criteria for disposal.

4. The SWMS provides drying equipment for R/O concentrate in order to meet transportation and waste acceptance criteria for disposal.

5. The SWMS components are classified as RW-IIa in accordance with NRC RG 1.143 and designed to the corresponding requirements in order to maintain structural integrity under the design basis loads. Component Radiation Safety Classification is summarized in Table 2.7.6.3-1.

2.7.6.3.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the SWMS are listed in Table 2.7.6.3-2.

2.7.6.4 Process and Effluent Radiation Monitoring and Sampling System

2.7.6.4.1 Design Description

The process and effluent radiation monitoring and sampling system (PERMSS) provide components to monitor liquid and gaseous effluents prior to release to unrestricted areas, and to monitor in-plant radioactivity.

The PERMSS is non-safety-related with the exception of the following, each of which is safety-related and Class 1E:

a. Main control room (MCR) air intake radiation monitors
b. Containment building operating area and upper operating area radiation monitors
c. Fuel handling area monitors
d. Containment air radiation monitors

Components of the PERMSS are located in the containment building, the auxiliary building, the compound building, and the turbine building.

1. The functional arrangement of the PERMSS is as described in the Design Description of Subsection 2.7.6.4.1 and in Table 2.7.6.4-1.

2. The PERMSS has components that provide radiation monitoring of gaseous and liquid processing systems.

3. Displays and alarms exist and are retrievable in the MCR and RSR as defined in Table 2.7.6.4-1.

4. Each PERMSS channel monitors the radiation level in its assigned area, and indicates its respective MCR alarm and local audible and visual alarm when the radiation level reaches a preset level.

5. The safety-related divisionalized cabinet (SRDC) of the PERMSS provides an automatic ESFAS initiation signals for each loop including the final component, as shown on Table 2.7.6.4-2.
6. The seismic Category I monitors identified in Table 2.7.6.4-1, including the supports and anchorages, can withstand seismic design basis loads without loss of safety function.

7. Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

8. The steam generator blowdown radiation monitor provides an alarm in the MCR of high radioactive contamination and isolation signal to blowdown valve.

9. Each monitor channel function of PERMSS identified in Table 2.7.6.4-1 is functioning.

10. The containment air radiation monitor non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (internal service conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.7.6.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.7.6.4-3 specifies the inspections, tests, analyses, and associated acceptance criteria for the process and effluent radiation monitoring and sampling system.

2.7.6.5  Area Radiation Monitoring System

2.7.6.5.1  Design Description

The area radiation monitoring system (ARMS) monitors the radiation levels in selected areas throughout the plant. The area monitors warn operators and station personnel of the visible and audible alarm when unusual radiological events occur.

Components of the ARMS are located in the containment building, the auxiliary building, and the compound building.

1. The functional arrangement of the ARMS is described in the Design Description of Subsection 2.7.6.5.1 and in Table 2.7.6.5-1.

2. The ARMS identified in table 2.7.6.5-1 provides for the indication, alarm, and recording of the defined plant area radiation levels within the MCR and RSR for operating personnel.

3. The monitors provide local readout and alarm units at the detector locations.

4. Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

5. The seismic Category I monitors of the ARMS identified in Table 2.7.6.5-1 can withstand seismic design basis loads without loss of safety function.

6. The safety-related divisionalized cabinet (SRDC) of the ARMS provides an automatic ESFAS initiation signals for each loop including the final component, as shown in Table 2.7.6.5-2.

7. The containment monitors are located in a location for each intended function as follows:

   - Upper area monitor (RE-234B) is located level just below the containment polar crane for a direct, unimpeded exposure path of the entire containment free air volume. RE-233A is located to accommodate operator's easy access, but still at an elevation that provides observation of a large fraction of the containment free air volume.
Lower area monitors (RE-231A and 232B) are located directly overhead with an unimpeded view of the refueling pool to detect fuel handling accident condition.

8. The Class 1E components and instruments identified in Table 2.7.6.5-1 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) are capable of withstanding the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

9. Each monitor channel of ARMS identified in table 2.7.6.5-1 is functioning.

2.7.6.5.2 Inspections, Tests, Analyses, and Acceptance Criteria

The ITAAC for the area radiation monitoring system is described on Table 2.7.6.5-3.

2.8 Radiation Protection

2.8.1 Design Description

Radiation protection design features in the APR1400 provide the limitation of radiation exposures to plant personnel and to the public complying with the NRC RG and as low as reasonably achievable (ALARA) principles.

The design commitments for radiation protection are as follows:

1. Shielding design of rooms, corridors, cubicles, labyrinth access, and operating areas is commensurate with the minimum shielding requirements for significant radiation sources.

2. Ventilation systems for the radiological controlled areas are designed to keep the radiation exposure below the limits specified in 10 CFR Part 20, Appendix B.

3. Design features provide radiation protection so that operators can take actions necessary to mitigate or recover from the design basis accidents.

2.8.2 Inspections, Tests, Analyses, and Acceptance Criteria

The ITACC ensure that the target dose rates of all areas are below the limits of each area’s radiation zone designations in Table 2.8-1, and Table 2.8-2 provides the ITAAC, which will be undertaken for radiation protection.

Radiation protection is to be based on the shielding design for walls and floors for individual cubicles inside RCB, AB and CB are summarized in DCD Tier 1, Tables 2.2.1-1 and 2.2.1-1a. The shield wall and floor thicknesses are designed to be the minimum for the protection of plant personnel for radiation ALARA in the corresponding radiation zone areas. Radiation protection ITAAC is to be performed in accordance with Table 2.8-2, item #1, and the wall and floor thicknesses as specified in Table 2.2.1-1 for RCB, AB and Table 2.2.1-2 for CB. In addition, the following document types are to be used for inspection and analysis of as-built shield walls and floors as applicable:

- General arrangement drawings
- Radiation zone drawings
Radiation shield barrier drawings
Concrete outline drawings
Construction reports

</table>
2.9 Human Factors Engineering

2.9.1 Design Description

The human factors engineering (HFE) program ensures that human-system interface (HSI) of the main control room, remote shutdown room, technical support center, emergency operations facility, and local control stations associated with important human actions reflects state-of-the-art HFE principles, and satisfies all specific regulatory criteria and support the operator in safely operating the plant.

The HSI is designed in accordance with the HFE program to provide reasonable assurance that the HFE design is properly developed and effectively implemented to conform to NUREG-0711, Rev. 3. The HFE program objectives for the design are that the design is human-centered, it incorporates HFE principles and methods, and is developed according to a systematic top-down integrated approach in accordance with applicable requirements and performance of the HFE program element implementation plans (IPs) and results summary reports to support ITAAC closure. ITAAC is applied to the human factors verification and validation (HF V&V) for the APR1400. The HFE program and IPs are in effect at least from the start of the design cycle through completion of initial plant startup test program. The implementation plans are complete and conform to the review criteria of NUREG-0711, Rev. 3. The COL applicant is to provide a ITAAC closure schedule for implementing the V&V ITAAC. ITAAC will be closed in accordance with applicable regulatory guidance. Any changes and departures to the implementation plans will be governed by applicable regulatory guidance and requirements included with the design certification rulemaking.

The HFE program elements for ITAAC are as follows:

1. The HF V&V determines that the final HSI design conforms to accepted HFE design principles and it enables plant personnel to successfully perform their tasks to assure plant safety and operational goals.

2. The human factors design implementation verifies that the as-built design conforms to the verified and validated design resulting from the HFE design process.

The HF V&V program element is performed to confirm that the HSI design conforms to HFE design principles and that it enables plant personnel to successfully perform tasks to achieve plant safety and other operational goals. The HF V&V of the HSI design
demonstrates operator task performance capabilities and the capabilities to perform
operator functions. All HF V&V activities are performed according to the HF V&V
Implementation Plan and it applies to all HSIs in the main control room, remote shutdown
room, and voice communications when it influences the main control room crew’s
performance, between the main control room and the technical support center, emergency
operations facility, and other offsite emergency entities. The HF V&V also includes the
HSIs on local control stations associated with the important human actions. The HF V&V
consists of the following steps: (1) Sampling of operational conditions; (2) Design
verification; (3) Integrated system validation (ISV); (4) Human engineering discrepancies;
and (5) Documentation of results of the HF V&V program.

By applying performance-based testing of the final integrated system, the ISV validates that
the final integrated design supports safe plant operation. The realistic scenarios, defined
by the sampling of operating conditions, are used to determine if human errors could occur
due to operational complexity or excessive task load. For ISV, it uses a method to reduce
the bias due to the allocation of scenarios to the operators and the learning effect from the
order in which the scenarios are run, and the test design is such that each operating team
performs all scenarios. Plant participants in the ISV are trained in APR1400 plant operation
and are divided into three crew teams. When the test personnel identify errors, loss of
situation awareness, or workload increase conditions, these conditions are compared to the
recorded plant parameters to evaluate the measure of performance. Two significant
dimensions that are measured are situation awareness and workload. Measures of
situation awareness include the use of the situation awareness rating tool and measures of
workload use the workload rating tool and situational tool. These tools are valid, reliable
and sensitive.

The situation awareness rating tool is the primary tool that is used to measure situation
awareness, along with questionnaires and debriefings. The workload rating tool is used to
measure the categories of workload, such as mental demand, physical demand, temporal
demand, performance, effort, and frustration level. Situation awareness is used to evaluate
the operator responses on each question (i.e., perception, comprehension, and projection)
and it is measured using situation awareness rating tool after the scenario is complete.
The data are sorted and compared with situation awareness data for a predecessor or
reference plant. Appropriateness of the responses is converted into a percentage point
based on a 7-point Likert scale and is compared with the value of the predecessor or
reference plant using the T-test results. If the measure is equal or higher than the
predecessor or reference plant, it is determined that the situation awareness for the ISV is appropriate. The performance of the APR1400 is acceptable when it meets or exceeds the performance of predecessors.

Workload is measured using a questionnaire based on the workload rating tool that is completed at the end of the scenario, and results are compared with the results from a predecessor or reference plant. Workload analysis is performed by quantifying the operator responses to the questions (e.g. mental, physical, temporal, performance, effort, and frustration) and then comparing it with the workload values from the predecessor or reference plant. If the measure is equal or lower than that of the predecessor or reference, it is considered that the workload rate for the ISV is appropriate. The performance of the APR1400 is acceptable when it meets or exceeds the performance of predecessors.

Plant performance measures are plant process variables that are required to confirm whether the operator has checked the plant status correctly for each scenario and to verify that the operator has controlled the plant safely. For this reason, process variables are developed separately for each scenario in the ISV and are obtained through the simulator logging system. Process variable include trend graph data values recorded from the start of a scenario until the end. Suitability criteria of the plant performance measure are based on the plant’s operating procedures, technical specifications and the DCD Tier 2, Chapters 7, 15, and 19. A requirement criterion is successful only if it is within the requirement range, and it has a pass/fail characteristic.

Primary task measures support the analysis of the plant performance measures and have a diagnostic characteristic. When a pass/fail requirement applies to the time measure, as when assessing credited manual actions and safe plant parameter envelopes, it is based on the amount of time required for an operator to execute an action. Time is measured for each scenario as applicable and includes the total execution time and partial execution time of tasks. Time measurements are taken from simulator history files or measured manually through observations of the HFE team. When time represents required normative criteria, a violation of the time required analysis from the DCD Tier 2, Chapters 7, 15, or 19, it is a pass/fail measure.

Secondary task measures are based on an operator survey, observation by HFE experts on the HFE team, and debriefing of the operators. The survey is completed by the operators after the scenario has ended, and HFE expert observations are used during the debriefing, with final questions included in the result summary report (ReSR). The observer survey
for secondary task measures will apply a questionnaire that will be developed later in the
design process, when the final user interfaces have been completed. This will be done
prior to the start of the HF V&V program. This questionnaire will be available for audit
and will be included in the HF V&V ReSR. Acceptance of the performance of a
secondary task is determined by averaging the points with all of 3 or less on a 7-point
Likert scale with the average representing a failure.

Subjective reports of participants, based on expert judgment, are obtained through a
debriefing with the operator at the completion of the ISV scenario, and through a detailed
discussion about the performance of the operator tasks. Criteria for analyzing the measure
are often based on expert judgment based on the operating plant experience of the SMEs
and the decision process. The anthropometric and physiological survey uses a 7-point
Likert scale. Operator surveys are completed by the operators when the scenario has ended.
Operators are debriefed, and HFE specialist observations are recorded at the end
of the scenario. The determination of the appropriateness of anthropometric and
physiological measures is based on an acceptable measure of 4 points on a 7-point scale
(e.g., median score agreed upon by the HFE specialists) using the data from the survey.
The performance criteria for anthropometric and physiological measures have a pass/fail
characteristic, and any unsatisfactory performance identified through any measure on
important human actions, as listed in the treatment of important human actions ReSR, is
identified as pass/fail.

2.9.2 Inspections, Tests, Analyses, and Acceptance Criteria

The ITAAC for HFE program elements are described in the Table 2.9-1.

2.10 Emergency Planning

2.10.1 Design Description

The technical support center (TSC) provides facilities for management and technical support to plant operations during emergency conditions. The operations support center (OSC) provides an assembly area where operations support personnel can assemble in an emergency. Subsections 2.7.3.1 describe a habitability of the TSC (TSC is included in control room envelope).

1. The TSC has at least 200 m² of floor space.

2. The TSC is located adjacent to the MCR in the auxiliary building.

3. The means exists for communications among the MCR, the TSC, the EOF, principal state and local emergency operations centers (EOCs), and radiological field assessment teams.

4. The means exists for communications from the MCR, the TSC, and the EOF to the NRC headquarters and regional office EOCs (including establishment of the emergency response data system (ERDS) between the onsite computer system and the NRC operations center).

5. The OSC is located in compound building, separate from the MCR and the TSC.

6. The OSC has equipment for voice communication with the MCR and the TSC.

2.10.2 Inspection, Tests, Analyses, and Acceptance Criteria

Table 2.10-1 specifies the inspections, tests, analyses, and associated acceptance criteria for emergency planning.

2.11 Containment System

2.11.1 Containment Structure

2.11.1.1 Design Description

The geometric shape of the prestressed concrete containment structure is a vertically oriented cylinder topped by a hemispherical dome with no ring girder at the dome/cylinder interface.

The containment consists of a prestressed concrete shell containing unbonded tendons and reinforcement steel. Prestressing is obtained through post-tensioning – a method of prestressing in which tendons are tensioned after concrete has hardened. Reinforcing steel is provided overall in the cylinder and dome. Additional reinforcement is provided at discontinuities, such as the cylinder-basemat interface, around penetrations and openings, at buttresses, and at other areas.

The concrete shell inner surface is lined with a minimum 1/4-in. carbon steel plate that is anchored to the concrete shell and dome to provide the required pressure boundary leak tightness. The liner plate system is not designed or considered as a structural member in providing for the overall containment load resistance. The liner plate system is attached to the containment shell with an anchorage system.

The containment is designed to accommodate conditions during and following postulated accidents.

1. The reactor cavity floor area allows for the spreading of core debris, enhancing its coolability.

2. The reactor cavity has the core debris chamber to retain core debris.

3. The concrete filled slab of the reactor cavity floor protects against containment liner plate melt through.

4. The containment design pressure provides over a 10% margin above the maximum calculated peak pressure for the design basis LOCA.

5. The design basis LOCA containment pressure at 24 hours after the postulated accident is less than 50% of its calculated maximum pressure.
6. The calculated subcompartment peak differential pressures do not exceed the
design differential pressures.

7. The as-built containment volume, heat sink areas and compositions bound the
assumptions used in the containment pressure analyses.

8. The as-built subcompartment accessway dimensions are at least as large as those
assumed in the subcompartment analyses.

2.11.1.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspection, tests, analyses, and associated acceptance criteria for the containment
structure are specified in Table 2.11.1-2.

2.11.2       Containment Spray System

2.11.2.1  Design Description

The containment spray system (CSS) is a safety-related system. It removes heat and reduces the concentration of radionuclides released from the containment atmosphere and transfers the heat to the component cooling water system following events which increase containment temperature and pressure. The CSS also remove heat from the in-containment refueling water storage tank (IRWST).

The CSS is located in the auxiliary building and the containment.

1. The functional arrangement of the CSS is as described in the Design Description of Subsection 2.11.2.1 and in Table 2.11.2-1 and as shown in Figure 2.11.2-1.

2.a The ASME Code components identified in Table 2.11.2-2 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.11.2-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.11.2-2 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.11.2-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.11.2-2 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.11.2-1 retains its pressure boundary integrity at its design pressure.

5.a The seismic Category I components and instruments identified in Tables 2.11.2-2 and 2.11.2-3, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.11.2-1 withstand seismic design basis loads without loss of safety function.
6.a The Class 1E components and instruments identified in Tables 2.11.2-2 and 2.11.2-3 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components and instruments identified in Tables 2.11.2-2 and 2.11.2-3 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The CSS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions with debris-laden coolant fluids up to and including design basis accident conditions.

7.b After loss of motive power, MOVs identified in Table 2.11.2-2 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to start and stop the CSS pumps, and to open and close the MOVs identified in Table 2.11.2-2.

8.b Controls exist in the RSR to start and stop the CSS pumps, and to open and close the MOVs identified in Table 2.11.2-2.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Tables 2.11.2-2 and 2.11.2-3.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Tables 2.11.2-2 and 2.11.2-3.

9. Two mechanical divisions of the CSS (A & B) are physically separated.

10. The CSS safety-related pumps are functionally designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions with debris laden coolant fluids up to and including design basis accident conditions.
11. The CSS pumps have sufficient net positive suction head (NPSH).

12. The CSS has heat removal capacity to control the containment atmosphere temperature and pressure.

13. The pumps identified in Table 2.11.2-2 can perform their safety functions under expected ranges of fluid flow, pump head, electrical, and temperature conditions up to and including design-basis conditions.

14. The containment heat removal function of the CSS will not be impaired by gas entrainment based on monitoring and venting at pre-determined intervals.

15. The CSS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.11.2.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspection, tests, analyses, and associated acceptance criteria for the CSS are specified in Table 2.11.2-4.

The ITAAC related to the CIVs and the piping between the CIVs of the CSS are described in Table 2.11.3-2.

**Figure 2.11.2-1** Containment Spray System
2.11.3 Containment Isolation System

2.11.3.1 Design Description

The containment isolation system (CIS) provides a safety-related means to close valves in fluid system piping that passes through containment penetrations. The CIS provides a pressure barrier at each of these containment penetrations.

The CIS has the following safety-related functions:

1. Provide automatic and leak-tight closure of those valves required to close for containment integrity following a design basis event to minimize release of any radioactive material.

2. Provide a double barrier at the containment penetration in those fluid systems that are not required to function following a design basis event.

To meet above functional requirements, the CIS is designed as follows:

1. The functional arrangement of the CIS is as described in the Design Description of Subsection 2.11.3.1 and in Table 2.11.3-1 and as shown in Figure 2.11.3-1.

2.a The ASME Code components identified in Table 2.11.3-1 are designed and constructed in accordance with ASME Section III requirements.

2.b The ASME Code piping, including supports, identified in Table 2.11.3-1 is designed and constructed in accordance with ASME Section III requirements.

3.a Pressure boundary welds in ASME Code components identified in Table 2.11.3-1 meet ASME Section III requirements.

3.b Pressure boundary welds in ASME Code piping identified in Table 2.11.3-1 meet ASME Section III requirements.

4.a The ASME Code components identified in Table 2.11.3-1 retain their pressure boundary integrity at their design pressure.

4.b The ASME Code piping identified in Table 2.11.3-1 retains its pressure boundary integrity at its design pressure.
5.a The seismic Category I components identified in Table 2.11.3-1, including the supports and anchorages, withstand seismic design basis loads without loss of safety function.

5.b The seismic Category I piping, including supports, identified in Table 2.11.3-1 withstand seismic design basis loads without loss of safety function.

6.a The Class 1E components identified in Table 2.11.3-1 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) withstand the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

6.b Each of the Class 1E components identified in Table 2.11.3-1 is powered from its respective Class 1E division.

6.c Physical separation and electrical isolation are provided (1) between Class 1E divisions, and (2) between Class 1E divisions and non-Class 1E divisions.

7.a The CIS safety-related valves are designed and qualified to perform their safety-related function under the full range of fluid flow, differential pressure, electrical, and temperature conditions up to and including design basis accident conditions.

7.b After loss of motive power, MOVs, AOVs, SOVs, and E/H Valves identified in Table 2.11.3-1 assume the indicated loss of motive power position.

8.a Controls exist in the MCR to open and close the MOVs, AOVs, SOVs, and E/H Valves identified in Table 2.11.3-1.

8.b Controls exist in the RSR to open and close the MOVs, AOVs, SOVs, and E/H Valves identified in Table 2.11.3-1.

8.c Displays and alarms exist and are retrievable in the MCR as defined in Table 2.11.3-1.

8.d Displays and alarms exist and are retrievable in the RSR as defined in Table 2.11.3-1.
9. CIV closure times to limit potential releases of radioactivity as low as reasonably achievable are as shown in Table 2.11.3-1.

10. The CIS provides a safety-related function of containment isolation to prevent or limit the release of fission products to the environment.

11. MOVs, AOVs, SOVs, and E/H valves in series on the same containment penetration (whether located inside or outside containment) are powered from different Class 1E divisions.

12. Containment isolation valves outside the containment as listed in Table 2.11.3-1 and as shown in Figure 2.11.3-1, are located as close to the containment as practical, consistent with General Design Criteria 55, 56, and 57.

2.11.3.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspection, tests, analyses, and associated acceptance criteria for the CIAS are specified in Table 2.11.3-2.

1. Dash(-) indicates not applicable.
2. Valve arrangements are shown in Figure 2.11.3-1.
3. Definition of actuation signals.
   - AFAS - Auxiliary Feedwater Actuation Signal
   - CIAS - Containment Isolation Actuation Signal
   - CPIAS - Containment Purge Isolation Actuation Signal
   - CSAS - Containment Spray Actuation Signal
   - SIAS - Safety Injection Actuation Signal
   - MSIS - Main Steam Isolation Signal

   All above signals are engineered safety feature (ESF) signal and classified as ESF valves.

2.11.4 Containment Hydrogen Control System and Monitoring System

2.11.4.1 Design Description

The containment hydrogen control system (CHCS) is a non-safety-related system. The CHCS is used to maintain hydrogen gas concentration in containment at a level which precludes an uncontrolled hydrogen and oxygen recombination within containment following beyond design basis accidents.

The CHCS consists of the passive autocatalytic recombiners (PARs) and hydrogen igniters (HIs). The PARs and HIs are designed to control and allow adiabatic controlled burning of hydrogen at fairly low concentration in containment and in-containment refueling water storage tank (IRWST) from exceeding 10 volume percent during a degraded core accident with 100 percent fuel clad metal-water reaction.

The hydrogen monitoring system (CHMS) consists of hydrogen analyzer cabinets and monitoring cabinets. Each hydrogen analyzer cabinet includes a hydrogen detector located outside the containment and performs sampling, transmission, and measurement of the hydrogen concentration from the air sample extracted from inside the containment and in-containment refueling water storage tank. The monitoring cabinet performs data collection, calculation, and automatic or manual operation of all analyzers.

To meet above functional requirements, the CHCS and the CHMS are designed as follows:

1. The functional arrangement of the CHCS is as described in the Design Description of Subsection 2.11.4.1 and in Table 2.11.4-1 and as shown in Figure 2.11.4-1.

2. The seismic Category I equipment identified in Table 2.11.4-1, including the supports and anchorages, can withstand seismic design basis loads without loss of function.

3. The CHCS provides PARs complemented by HIs to control the containment hydrogen concentration to maintain containment integrity during beyond design basis accidents.
4. Sufficient electrical power to operate the HIs can be individually supplied from each of the following sources: the Class 1E division, the emergency diesel generator, the AAC generator, and the Class 1E DC battery.

5.a Controls exist in the MCR to start and stop the HIs identified in Table 2.11.4-1.

5.b Controls exist in the RSR to start and stop the HIs identified in Table 2.11.4-1.

5.c Displays and alarms for hydrogen concentration measured by a hydrogen concentration detector of the containment hydrogen monitoring system exist and are retrievable in the MCR, as defined in Table 2.11.4-2.

5.d Displays and alarms for hydrogen concentration measured by a hydrogen concentration detector of the containment hydrogen monitoring system exist and are retrievable in the RSR, as defined in Table 2.11.4-2.

6. The Class 1E components and instruments identified in Tables 2.11.4-1 and 2.11.4-2 as being qualified for a harsh environment (and the associated wiring, cables, and terminations) are capable of withstanding the environmental conditions that would exist before, during, and following a design basis accident without loss of safety function for the time required to perform the safety function.

7. The CHCS non-metallic parts, materials, and lubricants used in safety-related mechanical equipment perform their safety-related function up to the end of their qualified life in the design basis harsh environmental conditions (both internal service conditions and external environmental conditions) experienced during normal operations, anticipated operational occurrences, design-basis accidents, and post accident conditions.

2.11.4.2 Inspections, Tests, Analyses, and Acceptance Criteria

The inspections, tests, analyses, and associated acceptance criteria for the containment hydrogen control system are specified in Table 2.11.4-3.

## Containment Hydrogen Control System ITAAC

### Design Commitment

1. The functional arrangement of the CHCS is as described in the Design Description of Subsection 2.11.4.1 and in Table 2.11.4-1 and as shown in Figure 2.11.4-1.

2. The seismic Category I equipment identified in Table 2.11.4-1, including the supports and anchorages, can withstand seismic design basis loads without loss of function.

3. The CHCS provides PARs complemented by HIs to control the containment hydrogen concentration to maintain containment integrity during beyond design basis accidents.

### Inspections, Tests, Analyses

1. Inspection of the as-built CHCS will be conducted.

2.a Inspections will be performed to verify that the as-built seismic Category I equipment is located in seismic Category I structures.

2.b Type tests, analyses, or a combination of type tests and analyses of seismic Category I equipment will be performed.

2.c Inspections will be performed to verify that the as-built seismic Category I equipment, including the supports and anchorages, are seismically bounded by the tested or analyzed conditions.

3.a Inspection of the as-built containment for the number of PARs and hydrogen igniters and their general location, as described in Table 2.11.4-1 will be performed.

### Acceptance Criteria

1. The as-built CHCS conforms with the functional arrangement as described in the Design Description of Subsection 2.11.4.1 and in Table 2.11.4-1 and as shown in Figure 2.11.4-1.

2.a The as-built seismic Category I equipment identified in Table 2.11.4-1 is located in seismic Category I structures.

2.b A report exists and concludes that the seismic Category I equipment identified in Table 2.11.4-1 can withstand seismic design basis loads.

2.c A report exists and concludes that the as-built equipment, including the supports and anchorages, are seismically bounded by the tested or analyzed conditions.

3.a At least thirty PARs and eight hydrogen igniters are provided inside containment.
Table 2.11.4-3 (2 of 4)

2.12 Physical Security Hardware

2.12.1 Design Description

The physical security system provides physical features to detect, delay, assist response to, and defend against the design basis threat (DBT) for radiological sabotage. The physical security system consists of physical barriers, intrusion detection, surveillance, communications, alarm stations, and power supplies. These design descriptions only address the portions of the design of physical security systems that are included within the scope of the APR1400 DC document, and they provide the design descriptions necessary to meet all requirements specified in the corresponding requirement of 10 CFR 73.55. Additional design descriptions will be provided by the COL applicant for items where the APR1400 design descriptions provided only address a portion of the requirement for design in 10 CFR 73.55 and other design descriptions must be further developed by a COL applicant for site-specific design of the physical security system in order to complete the physical security ITAAC. The details of the design of physical security system are categorized as sensitive security information and are further described in APR1400-E-A-NR-14002-P technical report which is incorporated by reference.

1.a Vital equipment is located only within a vital area.

1.b Access to vital equipment requires passage through the vital area barrier at least two physical barriers.

2.a Physical barriers for the protected area perimeter. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 2(a) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

2.b Penetrations through the protected area barrier. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 2(b) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

2.c Unattended openings that intersect a security boundary. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 2(c) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)
3.a Isolation zones for outdoor areas adjacent to the protected area. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 3(a) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

3.b Isolation zones will be monitored with intrusion detection and assessment equipment. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 3(b) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

3.c Areas where permanent buildings do not allow for an isolation zone will be monitored with intrusion detection equipment. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 3(c) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

4.a The perimeter intrusion detection system detects penetration or attempted penetration of the protected area perimeter barrier. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 4(a) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

4.b Included in 11.a below.

4.c The intrusion detection equipment at the protected area remains operable from a UPS during a loss of normal power. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 4(c) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

5.a Isolation zones and exterior areas within the protected area are provided with illumination to permit observation of abnormal presence or activity of persons or vehicles.

5.b The security alarm stations are provided with illumination to perform security functions.
6. The external walls, doors, ceilings, and floors in the main control room, the central alarm station, the secondary alarm station, and the location within which the last access control function for access to the protected area is performed are bullet-resistant to at least Underwrites Laboratory Ballistic Standard 752, level 4.

7. The vehicle barrier system is installed and located at the necessary standoff distance to protect against the design basis threat (DBT) vehicle bombs.

8.a Access control points will be established at the protected area to control personnel and vehicle access. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 8(a) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

8.b Access control points will have search equipment for detecting firearms, explosives, incendiary devices or other items. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 8(b) in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

9. The access control system will use a numbered photo identification badge. (This item is a site specific design description that the COL applicant will be providing and it will be similar to 9 in Appendix A to NUREG 0800 SRP 14.3.12 but the actual description will be written by the COL applicant.)

10. Vital areas are locked and alarmed with active intrusion detection systems that annunciate in the central and secondary alarm stations upon intrusion into a vital area.

11.a Security alarm annunciation and video assessment information is displayed concurrently in the central alarm station and the secondary alarm station, and the video image recording with real time playback capability can provide assessment of activities before and after each alarm annunciation within the perimeter barrier.

11.b The central and secondary alarm stations are located inside the protected area and the interior of each alarm station is not visible from the perimeter of the protected area.
11.c The alarm system will not allow the status of a detection point, locking mechanism or access control device to be changed without the knowledge and concurrence of the alarm station operator in the other alarm station.

11.d The central and secondary alarm stations are designed and equipped such that, in the event of a single act, in accordance with the design basis threat of radiological sabotage, the design enables the survivability of equipment needed to maintain the functional capability of either alarm station to detect and assess alarms and communicate with onsite and offsite response personnel.

12. Secondary security power supply system for alarm annunciator equipment and non-portable communications equipment is located within a vital area.

13.a Security alarm devices including transmission lines to annunciators are tamper indicating and self-checking (e.g., an automatic indication is provided when failure of the alarm system or a component occurs, or when on standby power). Alarm annunciation shall indicate the type of alarm (e.g., intrusion alarms and emergency exit alarm) and location.

13.b Intrusion detection and assessment systems concurrently provide visual displays and audible annunciation of alarms in the central and secondary alarm stations.

14. Recording Equipment will record onsite security alarm annunciation, including the location of the alarm, false alarm, alarm check, and tamper indication; and the type of alarm, location, alarm circuit, date, and time.

15. Emergency exits through the protected area and vital area boundaries are locked, alarmed, and equipped with a mechanism to allow for emergency egress.

16.a The central and secondary alarm stations have conventional (landline) telephone service with the main control room and local law enforcement authorities.

16.b The central and secondary alarm stations are capable of continuous communications with security personnel.

16.c Non-portable communication equipment in the central and secondary alarm stations remains operable from an independent power source in the event of loss of normal power.

2.13 Design Reliability Assurance Program

2.13.1 Design Description

The purpose of the APR1400 design reliability assurance program (RAP) is to provide reasonable assurance that:

a. A plant is designed, constructed, and operated in a manner that is consistent with the risk insights and key assumptions (e.g., SSC design, reliability, and availability) from the probabilistic, deterministic, and other methods of analysis.

b. The RAP SSCs do not degrade to an unacceptable level of reliability, availability, or condition during plant operations.

c. The frequency of transients that challenge these SSCs is minimized.

d. These SSCs will function reliably when challenged.

The risk-significant SSCs including both safety-related and non-safety-related SSCs are identified for inclusion in the RAP through the expert panel.

1. For structures, systems, and components within the scope of the reliability assurance program (RAP SSCs), the design is consistent with risk insights and key assumptions.

2.13.2 Inspections, Tests, Analyses, and Acceptance Criteria

Table 2.13-1 describes the ITAAC for the design RAP.

</table>
3.0 Interface Requirement

3.1 Electrical System

The offsite power system is site-specific. The offsite power system has interfaces with the onsite power system as follows:

a. The offsite power system is provided with a minimum of two independent offsite circuits from the transmission network to the onsite electrical distribution system.

b. The offsite transmission lines are designed to have the capacity and capability to power the required loads during steady state, transient, accident condition, and postulated events.

c. Independence is established between the onsite and offsite power systems physically and electrically.

d. The main transformer and the standby auxiliary transformers are connected to the switchyard.

e. The switchyard and its circuit breakers are sized to supply their load requirements and rated to interrupt fault currents.

f. Voltage variations of the transmission network do not cause voltage variations of more than acceptable tolerance of the normal voltage ratings of the loads.

g. The normal steady-state frequency of the offsite system is within acceptable tolerance of 60 Hz during recoverable periods of the offsite system instability.

h. The protocols are provided for the plant to remain cognizant of grid vulnerabilities.

i. Grounding and lightning protection systems are provided for the switchyard.

j. Alarms and displays are provided in order to monitor the switchyard.
3.2 Ultimate Heat Sink

The ultimate heat sink (UHS) is a safety-related and site-specific. The COL applicant is to provide the UHS design information based on the specific site characteristics including meteorological conditions. The COL applicant is to verify the following interface requirements:

a. The UHS provides the capability to reject the heat under normal and accident conditions (safe shutdown or post accident) assuming a single active failure concurrent with a loss of offsite power.

b. The UHS provides cooling capacity for at least 30 days without makeup water under worst case meteorological conditions in accordance with NRC RG 1.27.

c. The UHS provides the maximum supply temperature of 33.2 °C (91.8 °F) to the essential service water system.

d. The UHS design provides isolation between the UHS and the non-safety-related system.

e. The UHS provides the means to ensure the adequate NPSH of the ESW pumps under all operation modes if applicable to the site-specific design.

f. The UHS provides the means to prevent long-term fouling and mitigate short-term clogging anticipated at the site that may degrade system performance.

g. The UHS is designed to prevent water hammer if applicable to the site-specific design.

h. The UHS is designed to consider the evaluation of maximum evaporation and other losses if applicable to the site-specific design.

i. The components and piping, including supports, of the UHS are fabricated, installed and inspected in accordance with ASME Section III requirements if applicable to the site-specific design.

j. Pressure boundary welds in ASME Code components and piping of UHS meet ASME Section III requirements if applicable to the site-specific design.
k. The ASME Code components and piping of UHS maintain their pressure boundary integrity as its design pressure if applicable to the site-specific design.

l. The Seismic Category I structure, components, piping, including supports, and instruments of the UHS can withstand seismic design basis loads without loss of safety function if applicable to the site-specific design.

m. The Class 1E components and instruments can withstand the harsh environmental conditions during design basis accident without loss of safety function if applicable to the site-specific design.

n. Each of Class 1E components and instruments is powered from its respective Class 1E division, and separation is provided between Class 1E divisions, and between Class 1E divisions and non-Class 1E divisions if applicable to the site-specific design.

o. Alarms and indications for the UHS water temperature and level are provided in the MCR and RSR.

p. Controls required for the safety-related functions of the UHS are provided in the MCR and RSR if applicable to the site-specific design.
3.3 **Essential Service Water System**

Some of the Essential Service Water System (ESWS) are site-specific. The COL applicant is to provide the ESWS design information based on the specific site characteristics. The COL applicant is to verify the following interface requirements:

a. The ESWS piping outside the component cooling water heat exchanger building connected to the ultimate heat sink is designed and constructed in accordance with ASME Section III requirements.

b. The ESWS piping is designed and constructed to prevent the void formation in the pipe and minimize the water hammer.
