APR1400
DESIGN CONTROL DOCUMENT TIER 2

CHAPTER 3
DESIGN OF STRUCTURES, SYSTEMS, COMPONENTS, AND EQUIPMENT

APR1400-K-X-FS-14002-NP
REVISION 3
AUGUST 2018
This document was prepared for the design certification application to the U.S. Nuclear Regulatory Commission and contains technological information that constitutes intellectual property of Korea Hydro & Nuclear Power Co., Ltd.

Copying, using, or distributing the information in this document in whole or in part is permitted only to the U.S. Nuclear Regulatory Commission and its contractors for the purpose of reviewing design certification application materials. Other uses are strictly prohibited without the written permission of Korea Electric Power Corporation and Korea Hydro & Nuclear Power Co., Ltd.

3.1.22 Criterion 26 – Reactivity Control System Redundancy and Capability ................................................................. 3.1-18
3.1.23 Criterion 27 – Combined Reactivity Control Systems Capability .... 3.1-19
3.1.24 Criterion 28 – Reactivity Limits ...................................................... 3.1-20
3.1.25 Criterion 29 – Protection Against Anticipated Operational Occurrences .................................................................. 3.1-20
3.1.26 Criterion 30 – Quality of Reactor Coolant Pressure Boundary .......... 3.1-21
3.1.27 Criterion 31 – Fracture Prevention of Reactor Coolant Pressure Boundary ................................................................ 3.1-21
3.1.28 Criterion 32 – Inspection of Reactor Coolant Pressure Boundary ............................................................ 3.1-23
3.1.29 Criterion 33 – Reactor Coolant Makeup ........................................ 3.1-23
3.1.30 Criterion 34 – Residual Heat Removal ........................................ 3.1-24
3.1.31 Criterion 35 – Emergency Core Cooling ........................................ 3.1-25
3.1.32 Criterion 36 – Inspection of Emergency Core Cooling System .......... 3.1-26
3.1.34 Criterion 38 – Containment Heat Removal .................................... 3.1-27
3.1.35 Criterion 39 – Inspection of Containment Heat Removal System .... 3.1-29
3.1.36 Criterion 40 – Testing of Containment Heat Removal System ........ 3.1-29
3.1.37 Criterion 41 – Containment Atmosphere Cleanup .......................... 3.1-30
3.1.38 Criterion 42 – Inspection of Containment Atmosphere Cleanup Systems ............................................................................ 3.1-31
3.1.40 Criterion 44 – Cooling Water ......................................................... 3.1-32
3.1.41 Criterion 45 – Inspection of Cooling Water System ....................... 3.1-33
3.1.42 Criterion 46 – Testing of Cooling Water System ............................ 3.1-33
3.1.43 Criterion 50 – Containment Design Basis ..................................... 3.1-34
3.1.44 Criterion 51 – Fracture Prevention of Containment Pressure Boundary ............................................................................ 3.1-35
3.1.45 Criterion 52 – Capability for Containment Leakage Rate Testing ...... 3.1-35
3.1.46 Criterion 53 – Provisions for Containment Testing and Inspection .... 3.1-36
3.1.47 Criterion 54 – Piping Systems Penetrating Containment ................. 3.1-36
3.1.48 Criterion 55 – Reactor Coolant Pressure Boundary Penetrating Containment ........................................................................... 3.1-37
3.1.49 Criterion 56 – Primary Containment Isolation ........................................ 3.1-38
3.1.50 Criterion 57 – Closed System Isolation Valves .................................. 3.1-39
3.1.51 Criterion 60 – Control of Releases of Radioactive Material to the Environment .............................................................................. 3.1-39
3.1.52 Criterion 61 – Fuel Storage and Handling and Radioactivity Control ......................................................................................... 3.1-40
3.1.53 Criterion 62 – Prevention of Criticality in Fuel Storage and Handling ......................................................................................... 3.1-41
3.1.54 Criterion 63 – Monitoring Fuel and Waste Storage ............................................. 3.1-41
3.1.55 Criterion 64 – Monitoring Radioactivity Releases ................................... 3.1-42
3.1.56 Combined License Information .......................................................... 3.1-43
3.1.57 References ......................................................................................... 3.1-43

3.2 Classification of Structures, Systems, and Components ....................... 3.2-1
  3.2.1 Seismic Classification ........................................................................ 3.2-2
  3.2.2 System Quality Group Classification ................................................. 3.2-5
  3.2.3 Safety Class ....................................................................................... 3.2-8
  3.2.4 Classification Listings ........................................................................ 3.2-12
  3.2.5 Combined License Information ......................................................... 3.2-12

  3.3.1 Wind Loadings .................................................................................. 3.3-1
    3.3.1.1 Design Wind Velocity and Recurrence Interval ....................... 3.3-1
    3.3.1.2 Determination of Applied Forces .............................................. 3.3-1
  3.3.2 Tornado Loadings ............................................................................ 3.3-2
    3.3.2.1 Applicable Design Parameters .............................................. 3.3-2
    3.3.2.2 Determination of Forces on Structures .................................. 3.3-3
    3.3.2.3 Effect of Failure of Structures or Components Not Designed for Extreme Wind Loads ......................................................... 3.3-4
  3.3.3 Combined License Information ......................................................... 3.3-5
  3.3.4 References ....................................................................................... 3.3-5

3.4 Water Level (Flood) Design ................................................................ 3.4-1
  3.4.1 Flood Protection and Evaluation ..................................................... 3.4-1
3.4.1.1 Design Bases ................................................................. 3.4-1
3.4.1.2 Flood Protection from External Sources ..................... 3.4-2
3.4.1.3 Flood Protection from Internal Sources ...................... 3.4-3
3.4.1.4 Evaluation of External Flooding ............................... 3.4-5
3.4.1.5 Evaluation of Internal Flooding ............................... 3.4-6
3.4.2 Analysis Procedures ........................................................... 3.4-18
3.4.3 Combined License Information ............................................. 3.4-18
3.4.4 References ........................................................................ 3.4-19

3.5 Missile Protection .................................................................. 3.5-1
3.5.1 Missile Selection and Description ........................................ 3.5-1
    3.5.1.1 Internally Generated Missiles (Outside the Containment) ........................................................................ 3.5-2
    3.5.1.2 Internally Generated Missiles (Inside Containment) .................................................................. 3.5-7
    3.5.1.3 Turbine Missiles ............................................................ 3.5-9
    3.5.1.4 Missiles Generated by Tornadoes and Extreme Winds .................................................................. 3.5-11
    3.5.1.5 Site Proximity Missiles (Except Aircraft) ........................ 3.5-13
    3.5.1.6 Aircraft Hazards ............................................................ 3.5-13
3.5.2 Structures, Systems, and Components to be Protected from Externally Generated Missiles ........................................... 3.5-13
3.5.3 Barrier Design Procedures.................................................... 3.5-14
    3.5.3.1 Evaluation of Local Structural Effects ............................ 3.5-14
    3.5.3.2 Overall Damage Prediction ............................................. 3.5-17
3.5.4 Combined License Information ............................................. 3.5-17
3.5.5 References ........................................................................ 3.5-18

3.6 Protection against Dynamic Effects Associated with the Postulated Rupture of Piping ........................................................................ 3.6-1
3.6.1 Plant Design for Protection against Postulated Piping Failures in Fluid Systems Inside and Outside the Containment .......................................................... 3.6-2
    3.6.1.1 Design Basis ................................................................. 3.6-2
    3.6.1.2 Safety Evaluation ........................................................... 3.6-5
    3.6.1.3 Postulated Failures Associated with Site-Specific Piping ........................................................................ 3.6-8
3.6.2 Determination of Break Locations and Dynamic Effects
Associated with the Postulated Rupture of Piping ............................................. 3.6-8
3.6.2.1 Criteria Used to Define Rupture Locations and Configurations ................................................................. 3.6-8
3.6.2.2 Guard Pipe Assembly Design Criteria ........................................ 3.6-19
3.6.2.3 Analytical Methods to Define Forcing Functions and Response Models .............................................. 3.6-19
3.6.2.4 Dynamic Analysis Methods to Verify Integrity and Operability ................................................................. 3.6-22
3.6.3 Leak-Before-Break Evaluation Procedure ................................................................. 3.6-28
3.6.3.1 Application of Leak-Before-Break ........................................... 3.6-29
3.6.3.2 Piping Design for Leak-Before-Break Application .................. 3.6-29
3.6.3.3 Criteria for Leak-Before-Break ........................................... 3.6-32
3.6.3.4 Potential Failure Mechanisms ............................................. 3.6-34
3.6.3.5 Analysis ............................................................................... 3.6-40
3.6.3.6 Results ................................................................................. 3.6-50
3.6.4 Combined License Information ........................................................................ 3.6-52
3.6.5 References .................................................................................. 3.6-53

3.7 Seismic Design ........................................................................................................ 3.7-1
3.7.1 Seismic Design Parameters ........................................................................ 3.7-1
3.7.1.1 Design Ground Motion .......................................................... 3.7-1
3.7.1.2 Percentage of Critical Damping Values ................................. 3.7-7
3.7.1.3 Supporting Media for Seismic Category I Structures ............ 3.7-7
3.7.2 Seismic System Analysis ........................................................................... 3.7-8
3.7.2.1 Seismic Analysis Methods ..................................................... 3.7-9
3.7.2.2 Natural Frequencies and Responses ...................................... 3.7-13
3.7.2.3 Procedures Used for Analytical Modeling ......................... 3.7-14
3.7.2.4 Soil-Structure Interaction .................................................. 3.7-17
3.7.2.5 Development of In-Structure Response Spectra ............... 3.7-18
3.7.2.6 Three Components of Earthquake Motion ....................... 3.7-18
3.7.2.7 Combination of Modal Responses .................................... 3.7-19
3.7.2.8 Interaction of Non-Seismic Category I Structures with Seismic Category I Structures ............................................. 3.7-20
3.7.2.9 Effects of Parameter Variations on Floor Response Spectra .............................................................. 3.7-22
3.7.2.10 Use of Constant Vertical Static Factors .................. 3.7-23
3.7.2.11 Methods Used to Account for Torsional Effects ........ 3.7-23
3.7.2.12 Comparison of Responses .................................. 3.7-23
3.7.2.13 Methods for Seismic Analysis of Dams .................... 3.7-23
3.7.2.14 Determination of Dynamic Stability of Seismic Category I Structures .................................. 3.7-24
3.7.2.15 Analysis Procedure for Damping ................................ 3.7-24

3.7.3 Seismic Subsystem Analysis ........................................ 3.7-25
3.7.3.1 Seismic Analysis Methods .................................... 3.7-25
3.7.3.2 Procedure Used for Analytical Modeling .............. 3.7-26
3.7.3.3 Analysis Procedures for Damping ......................... 3.7-27
3.7.3.4 Three Components of Earthquake Motion ............. 3.7-27
3.7.3.5 Combination of Modal Responses ....................... 3.7-27
3.7.3.6 Use of Constant Vertical Static Factors .................. 3.7-27
3.7.3.7 Buried Seismic Category I Conduits and Tunnels .......... 3.7-28
3.7.3.8 Methods for Seismic Analysis of Category I Concrete Dams ...................................................... 3.7-29
3.7.3.9 Methods for Seismic Analysis of Above-ground Tanks ................................................................. 3.7-29
3.7.3.10 Basis for Selection of Frequencies .................... 3.7-30
3.7.3.11 Interaction of Other Systems with Seismic Category I Systems ................................................... 3.7-30
3.7.3.12 Multiply-Supported Equipment and Components with Distinct Inputs ...................................... 3.7-30
3.7.3.13 Torsional Effects of Eccentric Masses ................... 3.7-31

3.7.4 Seismic Instrumentation ............................................. 3.7-31
3.7.4.1 Comparison with NRC Regulatory Guide 1.12 ........ 3.7-32
3.7.4.2 Location and Description of Instrumentation .......... 3.7-32
3.7.4.3 Main Control Room Operator Notification ............ 3.7-35
3.7.4.4 Comparison with NRC Regulatory Guide 1.166 ........ 3.7-35
3.7.4.5 Instrument Surveillance ........................................ 3.7-36
3.7.4.6 Program Implementation ................................................................. 3.7-37
3.7.5 Combined License Information ................................................................. 3.7-37
3.7.6 References ................................................................................................. 3.7-39

APPENDIX 3.7A – SOIL-STRUCTURE INTERACTION ANALYSIS
METHODOLOGY AND RESULTS ................................................................. 3.7A-1

APPENDIX 3.7B – EVALUATION FOR HIGH FREQUENCY
SEISMIC INPUT ................................................................................................. 3.7B-1

3.8 Design of Category I Structures ................................................................. 3.8-1

3.8.1 Concrete Containment ............................................................................... 3.8-1
3.8.1.1 Description of the Containment ............................................................. 3.8-1
3.8.1.2 Applicable Codes, Standards, and Specifications .............................. 3.8-5
3.8.1.3 Loads and Load Combinations ............................................................. 3.8-6
3.8.1.4 Design and Analysis Procedures ......................................................... 3.8-13
3.8.1.5 Structural Acceptance Criteria ............................................................ 3.8-21
3.8.1.6 Materials, Quality Control, and Special Construction Techniques ................. 3.8-31
3.8.1.7 Testing and Inservice Inspection Requirements ...................................... 3.8-34

3.8.2 Steel Containment ...................................................................................... 3.8-38
3.8.2.1 Description of Containment ................................................................. 3.8-38
3.8.2.2 Applicable Codes, Standards, and Specifications .............................. 3.8-41
3.8.2.3 Loads and Load Combinations ............................................................. 3.8-41
3.8.2.4 Design and Analysis Procedures ......................................................... 3.8-42
3.8.2.5 Structural Acceptance Criteria ............................................................ 3.8-47
3.8.2.6 Materials, Quality Control, and Special Construction Techniques ................. 3.8-48
3.8.2.7 Testing and Inservice Inspection Requirements ...................................... 3.8-49

3.8.3 Concrete and Steel Internal Structures of Steel or Concrete Containment ................................................................. 3.8-50
3.8.3.1 Description of the Internal Structures .................................................... 3.8-50
3.8.3.2 Applicable Codes, Standards, and Specifications .............................. 3.8-55
3.8.3.3 Loads and Load Combinations ............................................................. 3.8-56
3.8.3.4 Design and Analysis Procedures ......................................................... 3.8-57
3.8.3.5 Structural Acceptance Criteria ........................................ 3.8-59
3.8.3.6 Materials, Quality Control, and Special Construction
Techniques .............................................................................. 3.8-60
3.8.3.7 Testing and Inservice Inspection Requirements .......... 3.8-61
3.8.4 Other Seismic Category I Structures .................................... 3.8-61
  3.8.4.1 Description of the Structures ........................................ 3.8-62
  3.8.4.2 Applicable Codes, Standards, and Specifications .......... 3.8-65
  3.8.4.3 Loads and Load Combinations ...................................... 3.8-66
  3.8.4.4 Design and Analysis Procedures ................................. 3.8-77
  3.8.4.5 Structural Acceptance Criteria .................................... 3.8-81
  3.8.4.6 Material, Quality Control, and Special Construction
      Techniques ........................................................................... 3.8-82
  3.8.4.7 Testing and Inservice Inspection Requirements .......... 3.8-86
3.8.5 Foundations ..................................................................... 3.8-88
  3.8.5.1 Description of the Foundations ................................. 3.8-88
  3.8.5.2 Applicable Codes, Standards, and Specifications .......... 3.8-89
  3.8.5.3 Loads and Load Combinations ...................................... 3.8-89
  3.8.5.4 Design and Analysis Procedures ................................. 3.8-90
  3.8.5.5 Structural Acceptance Criteria .................................... 3.8-96
  3.8.5.6 Material, Quality Control, and Special Construction
      Techniques ........................................................................... 3.8-99
  3.8.5.7 Testing and Inservice Inspection Requirements .......... 3.8-99
  3.8.5.8 SSCs between structures ............................................. 3.8-99
3.8.6 Combined License Information ......................................... 3.8-100
3.8.7 References ..................................................................... 3.8-105

APPENDIX 3.8A – STRUCTURAL DESIGN SUMMARY ....................... 3.8A-1

3.9 Mechanical Systems and Components .................................... 3.9-1
  3.9.1 Special Topics for Mechanical Components .................. 3.9-1
      3.9.1.1 Design Transients ................................................. 3.9-1
      3.9.1.2 Computer Programs Used in Stress Analyses ............ 3.9-20
      3.9.1.3 Experimental Stress Analyses ............................... 3.9-26
3.9.1.4 Consideration for the Evaluation of the Faulted Condition............................................................................. 3.9-27
3.9.2 Dynamic Testing and Analysis of Systems, Components, and Equipment .......................................................... 3.9-28
  3.9.2.1 Piping Vibration, Thermal Expansion, and Dynamic Effects............................................................................. 3.9-28
  3.9.2.2 Seismic Analysis and Qualification of Seismic Category I Mechanical Equipment........................................... 3.9-33
  3.9.2.3 Dynamic Response Analysis for Reactor Internals under Operational Flow Transients and Steady-State Conditions ........................................................................... 3.9-36
  3.9.2.4 Preoperational Flow Induced Vibration Testing of Reactor Internals.................................................................. 3.9-40
  3.9.2.5 Dynamic System Analysis of the Reactor Internals under Faulted Conditions .................................................... 3.9-42
  3.9.2.6 Correlations of Reactor Internals Vibration Tests with the Analytical Results.......................................................... 3.9-48
  3.9.2.7 Dynamic System Analysis of the CEDM........................................................................................................... 3.9-48
3.9.3 ASME Code Class 1, 2 and 3 Components, Component Supports, and Class CS Core Support Structures .................................................. 3.9-49
  3.9.3.1 Loading Combinations, Design Transients, and Stress Limits........................................................................................................ 3.9-51
  3.9.3.2 Design and Installation of Pressure Relief Devices .............................................................................................................. 3.9-55
  3.9.3.3 Pump and Valve Functionality Assurance .................................................................................................................. 3.9-57
  3.9.3.4 Component Supports .................................................................................................................................................. 3.9-63
3.9.4 Control Element Drive Mechanisms .......................................................................................................................... 3.9-65
  3.9.4.1 Descriptive Information of Control Element Drive Mechanism ........................................................................................... 3.9-65
  3.9.4.2 Applicable CEDM Design Specifications .......................................................................................................................... 3.9-70
  3.9.4.3 Design Loads, Stress Limits and Allowable Deformations ................................................................................................. 3.9-70
  3.9.4.4 CEDM Operability Assurance Program ....................................................................................................................... 3.9-71
3.9.5 Reactor Pressure Vessel Internals ........................................................................................................................................ 3.9-73
  3.9.5.1 Design Arrangements .................................................................................................................................................. 3.9-73
  3.9.5.2 Loading Conditions .................................................................................................................................................. 3.9-79
3.9.6 Functional Design, Qualification, and Inservice Testing
Programs for Pumps, Valves, and Dynamic Restraints

3.9.6.1 Functional Design and Qualification of Pumps,
Valves, and Dynamic Restraints

3.9.6.2 Inservice Testing Program for Pumps

3.9.6.3 Inservice Testing Program for Valves

3.9.6.4 Inservice Testing Program for Dynamic Restraints

3.9.6.5 Relief Requests and Alternative Authorizations to
ASME OM Code

3.9.7 [Reserved]

3.9.8 [Reserved]

3.9.9 Combined License Information

3.9.10 References

APPENDIX 3.9A – SUPPLEMENTAL INFORMATION ON CRITERIA
OF THE APR1400 DISTRIBUTION SYSTEMS

APPENDIX 3.9B –-reactor coolant system analysis

3.10 Seismic and Dynamic Qualification of Mechanical and Electrical
Equipment

3.10.1 Seismic Qualification Criteria

3.10.1.1 Qualification Codes and Standards

3.10.1.2 Input Motion

3.10.1.3 Selection of Qualification Method

3.10.2 Methods and Procedures for Qualifying Mechanical and Electrical
Equipment and Instrumentation

3.10.2.1 Qualification by Analysis

3.10.2.2 Qualification by Test

3.10.2.3 Operability of Active Equipment

3.10.3 Methods and Procedures of Analysis or Testing of Supports of
Mechanical and Electrical Equipment and Instrumentation

3.10.4 Test and Analysis Results and Experience Database

3.10.4.1 Implementation Program and Milestones
3.10.4.2 Experience-based Qualification ........................................... 3.10-15
3.10.5 Combined License Information .................................................. 3.10-15
3.10.6 References .................................................................................. 3.10-16

3.11 Environmental Qualification of Mechanical and Electrical Equipment .... 3.11-1

3.11.1 Equipment Location and Environmental Conditions ..................... 3.11-2
  3.11.1.1 Equipment Location ......................................................... 3.11-2
  3.11.1.2 Definition of Environmental Conditions ............................... 3.11-2
  3.11.1.3 Equipment Operability Times ........................................... 3.11-3
3.11.2 Qualification Tests and Analyses ................................................. 3.11-4
  3.11.2.1 Environmental Qualification during Normal Operation ............ 3.11-7
  3.11.2.2 Environmental Qualification during and after a Design Basis Accident .................................................. 3.11-7
  3.11.2.3 Environmental Qualification Method .................................. 3.11-10
3.11.3 Qualification Test Results .......................................................... 3.11-15
  3.11.3.1 Electrical and I&C Equipment .......................................... 3.11-15
  3.11.3.2 Mechanical Equipment .................................................... 3.11-16
3.11.4 Loss of Ventilation ...................................................................... 3.11-17
3.11.5 Estimate Chemical and Radiation Environment ......................... 3.11-18
  3.11.5.1 Chemical Environment ................................................... 3.11-18
  3.11.5.2 Radiation Environment .................................................... 3.11-18
3.11.6 Qualification of Mechanical Equipment ..................................... 3.11-20
3.11.7 Combined License Information .................................................. 3.11-21
3.11.8 References .................................................................................. 3.11-22

3.12 Piping Design Review ...................................................................... 3.12-1

3.12.1 Introduction .................................................................................. 3.12-1
3.12.2 Codes and Standards .................................................................. 3.12-1
  3.12.2.1 ASME Boiler and Pressure Vessel Code ............................. 3.12-1
  3.12.2.2 ASME Code Cases ............................................................ 3.12-2
3.12.3 Piping Analysis Methods ............................................................. 3.12-3
3.12.3.1 Experimental Stress Analysis Method ................................................. 3.12-3
3.12.3.2 Modal Response Spectrum Method .................................................. 3.12-3

CHAPTER 3 – DESIGN OF STRUCTURES, SYSTEMS, COMPONENTS, AND EQUIPMENT

3.1 Conformance with Nuclear Regulatory Commission General Design Criteria

3.1.1 Criterion 1 – Quality Standards and Records

“Structures, systems, and components important to safety shall be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be identified and evaluated to determine their applicability, adequacy, and sufficiency and shall be supplemented or modified as necessary to assure a quality product in keeping with the required safety function. A quality assurance program shall be established and implemented in order to provide adequate assurance that these structures, systems, and components will satisfactorily perform their safety functions. Appropriate records of the design, fabrication, erection, and testing of structures, systems, and components important to safety shall be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit.”

Response:

The structures, systems, and components (SSCs) described in the Design Control Document (DCD) are classified according to their importance to safety, including the prevention and mitigation of accidents using the classification system described in ANSI/ANS 51.1 (Reference 1). Each component is given a safety class designation. The codes, standards, and quality control applicable to each component and safety class designation are identified in Section 3.2. The design and fabrication of SSCs conform with 10 CFR 50.55a (Reference 2) as applicable. The quality assurance program conforms with the requirements of 10 CFR Part 50, Appendix B (Reference 3), and is addressed in Section 17.5. Chapter 14 describes the initial tests and operations that are conducted on installed equipment to provide reasonable assurance that the performance of the equipment is commensurate with the importance of the safety function.

The design, fabrication, and quality programs for components not included in the American National Standards Institute (ANSI) classification system are governed by industry codes
appropriate to the application. Additional details are described in the relevant DCD sections.

3.1.2 Criterion 2 – Design Bases for Protection Against Natural Phenomena

“Structures, systems, and components important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. The design bases for these structures, systems, and components shall reflect: (1) Appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated, (2) appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena and (3) the importance of the safety functions to be performed.”

Response:

The SSCs important to safety are designed to accommodate, without loss of capability, the effects of the design basis natural phenomena along with appropriate combinations of normal and accident conditions, as described in this chapter. Additional design information is provided in the sections that describe the individual SSCs.

3.1.3 Criterion 3 – Fire Protection

“Structures, systems, and components important to safety shall be designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions. Noncombustible and heat resistant materials shall be used wherever practical throughout the unit, particularly in locations such as the containment and control room. Fire detection and fighting systems of appropriate capacity and capability shall be provided and designed to minimize the adverse effects of fires on structures, systems, and components important to safety. Firefighting systems shall be designed to assure that their rupture or inadvertent operation does not significantly impair the safety capability of these structures, systems, and components.”

Response:

The pressure boundary components and structures and the attendant auxiliary systems in the APR1400 design scope are designed to minimize the probability and effects of fires and
explosions. High-grade noncombustible and fire-resistant materials are used for components located in the containment, components of engineered safety feature systems, and throughout the plant wherever practical. The fire protection system is described in Subsection 9.5.1.

3.1.4 Criterion 4 – Environmental and Dynamic Effects Design Bases

“Structures, systems, and components important to safety shall be designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including loss-of-coolant accidents. These structures, systems, and components shall be appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit. However, dynamic effects associated with postulated pipe ruptures in nuclear power units may be excluded from the design basis when analyses reviewed and approved by the Commission demonstrate that the probability of fluid system piping rupture is extremely low under conditions consistent with the design basis for the piping.”

Response:

SSCs important to safety are designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including a LOCA as described in Section 3.11.

Where appropriate, design bases include design requirements that provide reasonable assurance that SSCs are appropriately protected against dynamic effects such as missiles, pipe whipping, fluid discharges that could result from equipment failures, postulated accidents, and events and conditions outside the nuclear power plant.

The design concept of leak-before-break (LBB) is applied to the reactor coolant piping including surge line, safety injection, and shutdown cooling piping inside containment. The LBB concept eliminates the dynamic effects of postulated pipe ruptures from the design basis and is carried out in accordance with SRP 3.6.3 (Reference 4) and NUREG-1061 (Reference 5), Volume 3. The applications of LBB provisions are described in Subsection 3.6.3.
3.1.5  **Criterion 5 – Sharing of Structures, Systems, and Components**

“Structures, systems, and components important to safety shall not be shared among nuclear power units unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions, including, in the event of an accident in one unit, an orderly shutdown and cooldown of the remaining units.”

**Response:**

SSCs that perform safety-related functions are not shared between two units because the APR1400 is a single-unit plant.

3.1.6  **Criterion 10 – Reactor Design**

“The reactor core and associated coolant, control, and protection systems shall be designed with appropriate margin to assure that specified acceptable fuel design limits are not exceeded during any condition of normal operation, including the effects of anticipated operational occurrences.”

**Response:**

Specified acceptable fuel design limits (SAFDLs) are described in Subsection 4.4.1. Operation within the limiting conditions for operation (LCOs) specified by the Technical Specifications keeps the reactor fuel within the SAFDLs for normal operation, including anticipated operational occurrences (AOOs).

The plant is designed so that operation within the LCOs and limiting safety system settings (LSSSs) prescribed in the Technical Specifications results in confidence that SAFDLs are not exceeded as a result of an AOO. Operator action, aided by control systems and monitored by plant instrumentation, maintains the plant within LCO limits during normal operation.

Additional information is provided in the following sections:

a.  Section 4.2, Fuel System Design
b.  Chapter 5, Reactor Coolant System and Connecting Systems
c.  Subsection 5.4.7, Shutdown Cooling System
d. Section 7.2, Reactor Trip System

e. Chapter 15, Transient and Accident Analyses

f. Chapter 16, Technical Specifications

3.1.7 **Criterion 11 – Reactor Inherent Protection**

“The reactor core and associated coolant systems shall be designed so that in the power operating range the net effect of the prompt inherent nuclear feedback characteristics tends to compensate for a rapid increase in reactivity.”

**Response:**

In the power operating range, the combined response of the fuel temperature coefficient (FTC), moderator temperature coefficient (MTC), moderator void coefficient, and moderator pressure coefficient to an increase in reactor power is a decrease in reactivity (i.e., the inherent nuclear feedback characteristics are not positive).

The reactivity coefficients for this reactor are described in Subsection 4.3.1.4.

3.1.8 **Criterion 12 – Suppression of Reactor Power Oscillations**

“The reactor core and associated coolant, control, and protection systems shall be designed to assure that power oscillations which can result in conditions exceeding specified acceptable fuel design limits are not possible or can be reliably and readily detected and suppressed.”

**Response:**

Total reactor power oscillations of the fundamental mode stability is provided by the negative power coefficient of reactivity (GDC 11, Subsection 3.1.7) and the coolant temperature program maintained by regulating rods. Power level is continuously monitored by neutron flux detectors (Chapter 7).

Power distribution oscillations are detected by neutron flux detectors. Axial mode oscillations are suppressed by means of part-strength or full-strength neutron absorber rods. All other modes of oscillation are expected to be convergent. Monitoring and protective
requirements imposed by GDC 10 and 20 are described in Subsections 3.1.6 and 3.1.16 and Chapter 4.

3.1.9 Criterion 13 – Instrumentation and Control

“Instrumentation shall be provided to monitor variables and systems over their anticipated ranges for normal operation, for anticipated operational occurrences, and for accident conditions as appropriate to assure adequate safety, including those variables and systems that can affect the fission process, the integrity of the reactor core, the reactor coolant pressure boundary, and the containment and its associated systems. Appropriate controls shall be provided to maintain these variables and systems within prescribed operating ranges.”

Response:

Instrumentation is provided to monitor significant process variables that can affect the fission process, the integrity of the reactor core, the reactor coolant pressure boundary (RCPB), and their associated systems. Controls are provided to maintain these variables within the limits prescribed for safe operation. Instrumentation and control for the containment and its associated systems are described in Chapters 6 through 12. The principal process variables to be monitored and controlled are:

a. Neutron flux level (reactor power)

b. Control element assembly (CEA) positions

c. Neutron flux distribution (at various axial positions)

d. Reactor coolant temperature and pressure

e. Reactor coolant pump (RCP) speed

f. Pressurizer (PZR) level

g. Steam generator (SG) level and pressure

The departure from nucleate boiling ratio (DNBR) margin and local power density (LPD) margin (kW/cm) are also monitored.
The plant protection system (PPS) consists of the reactor protection system (RPS) and engineered safety features actuation system (ESFAS). The RPS is designed to monitor nuclear steam supply system (NSSS) operating conditions and initiate reliable and rapid reactor shutdown if monitored variables or combinations of monitored variables deviate from the permissible operating range to a degree that a safety limit may be reached. The ESFAS is designed to monitor plant variables and to actuate ESF systems during a design basis event (DBE).

The following systems and equipment are provided to monitor and maintain control over the fission process during transient and steady-state periods over the life of the core:

a. Redundant channels of ex-core nuclear instrumentation as the primary means of monitoring the fission process for protection, control, and low power operation

b. Redundant and diverse CEA position-indicating systems

c. Manual and automatic control of reactor power by means of CEAs

d. Manual regulation of boron concentration in the reactor coolant

e. A boronometer to determine boron concentration in the reactor coolant by neutron absorption as a backup to routine sampling and analysis

f. In-core instrumentation, provided to supplement information on core power distribution and enable calibration of ex-core flux detectors

The non-nuclear instrumentation measures temperatures, pressures, flows, and levels in the reactor coolant, main steam, and auxiliary systems and is used to maintain these variables within the prescribed limits. The instrumentation and control (I&C) systems are described in Chapter 7. The boronometer is described in Subsections 7.7.1.1 and 9.3.4.2. The process radiation monitor is described in Subsection 9.3.4.2.

When a variable is to be monitored during and after a DBE, in addition to normal operation, the event analysis results are used to provide reasonable assurance that the instruments provided cover the range anticipated for the event conditions.
3.1.10 Criterion 14 – Reactor Coolant Pressure Boundary

“The reactor coolant pressure boundary shall be designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture.”

Response:

The RCPB is defined in accordance with 10 CFR 50.2 and ANSI/ANS 51.1, as described in the response to GDC 55, Subsection 3.1.48.

Reactor coolant system (RCS) components are designed to meet the requirements of ASME Section III. To establish operating pressure and temperature limitations during startup and shutdown of the RCS, the fracture toughness rules defined in ASME Section III are followed. Quality control, inspection, and testing are performed as required by ASME Section III and allowable reactor pressure-temperature operations are specified to provide reasonable assurance of the integrity of the RCS.

The RCPB is designed to accommodate the system pressures and temperatures attained under all expected modes of unit operation, including anticipated transients, and maintain the stresses within applicable limits.

Piping and equipment pressure parts of the RCPB are assembled and erected by welding unless applicable codes permit flanged or screwed joints. Welding procedures that produce welds of complete fusion and free of unacceptable defects are followed. All welding procedures, welders, and welding machine operators are qualified in accordance with the requirements of ASME Section IX for the materials to be welded. Qualification records, including the results of the procedure and performance qualification tests and identification symbols assigned to each welder, are maintained.

The pressure boundary has provisions for in-service inspection in accordance with ASME Section XI to provide reasonable assurance of the continuance of the structural and leak-tight integrity of the boundary, as described in the response to GDC 32, Subsection 3.1.28. For the reactor vessel, a material surveillance program conforming to the requirements of 10 CFR Part 50, Appendix H, is provided.
3.1.11 Criterion 15 – Reactor Coolant System Design

“The reactor coolant system and associated auxiliary, control, and protection systems shall be designed with sufficient margin to assure that the design conditions of the reactor coolant pressure boundary are not exceeded during any condition of normal operation, including anticipated operational occurrences.”

Response:

The design criteria and bases for the RCPB are described in the response to GDC 14.

The operating conditions for normal steady-state and transient plant operations are established conservatively. Normal operating limits are selected so that an adequate margin exists between normal operating limits and design limits. The plant control systems are designed to provide reasonable assurance that plant variables are maintained well within established operating limits. The plant transient response characteristics and pressure and temperature distributions during normal operations are considered in the design as well as the accuracy and response of the instruments and controls. These design techniques provide reasonable assurance that a satisfactory margin is maintained between normal operating conditions, including design transients, and design limits for the RCPB.

Plant control systems function to minimize the deviations from normal operating limits in the event of AOOs. When the control system is inadequate or fails to respond upon demand, the plant protection system starts functioning to mitigate the consequences of such events.

The plant protection system functions to mitigate the consequences in the event of accidents. Analyses show that design limits for the RCPB are not exceeded in the event of any ANSI/ANS 51.1 conditions.

3.1.12 Criterion 16 – Containment Design

“Reactor containment and associated systems shall be provided to establish an essentially leak-tight barrier against the uncontrolled release of radioactivity to the environment and to assure that the containment design conditions important to safety are not exceeded for as long as postulated accident conditions require.”
Response:

The containment design incorporates a post-tensioned concrete containment with a steel liner to enclose the nuclear steam supply system completely. The containment system is designed to protect the public from the consequences of a LOCA, based on the equivalent energy release of a postulated break of reactor coolant piping up to and including a double-ended break of the largest reactor coolant pipe.

The containment building and the associated engineered safety feature systems are designed to safely withstand all internal and external environmental conditions that may reasonably be expected to occur during the life of the plant, including both short- and long-term effects of a LOCA.

The design criteria and methods of analysis for the containment structure are described in Subsections 3.8.1 and 3.8.2. The leak-tightness of the containment system and short- and long-term performance following a LOCA are described in Section 6.2.

3.1.13 Criterion 17 – Electrical Power Systems

“An onsite electric power system and an offsite electric power system shall be provided to permit functioning of structures, systems, and components important to safety. The safety function for each system (assuming the other system is not functioning) shall be to provide sufficient capacity and capability to assure that (1) specified acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded as a result of anticipated operational occurrences and (2) the core is cooled and containment integrity and other vital functions are maintained in the event of postulated accidents.

The onsite electric power supplies, including the batteries, and the onsite electric distribution system, shall have sufficient independence, redundancy, and testability to perform their safety functions assuming a single failure.

Electric power from the transmission network to the onsite electric distribution system shall be supplied by two physically independent circuits (not necessarily on separate rights of way) designed and located so as to minimize to the extent practical the likelihood of their simultaneous failure under operating and postulated accident and environmental conditions. A switchyard common to both circuits is acceptable. Each of these circuits shall be designed to be available in sufficient time following a loss of all onsite alternating current power supplies and the other offsite electric power circuit, to assure that specified
acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded. One of these circuits shall be designed to be available within a few seconds following a loss-of-coolant accident to assure that core cooling, containment integrity, and other vital safety functions are maintained.

Provisions shall be included to minimize the probability of losing electric power from any of the remaining supplies as a result of, or coincident with, the loss of power generated by the nuclear power unit, the loss of power from the transmission network, or the loss of power from the onsite electric power supplies.”

Response:

The APR1400 design is provided with an onsite electric power system and an offsite electric power system to permit functioning of SSCs important to safety in conformance with the requirements of this GDC, as described in Chapter 8.

The onsite electric power system consists of separate, redundant, and independent distribution systems and dedicated power supplies with sufficient capacity, capability, and testability to perform associated safety functions assuming a single failure.

The offsite electric power is supplied to the plant from the transmission network by at least two independent circuits through the site-specific switchyard. Each circuit is immediately available and has sufficient capacity and capability to perform the associated safety function.

Provisions are made to minimize the probability of losing electric power from any of the remaining supplies as a result of, or coincident with, the loss of power generated by the nuclear power unit.

3.1.14 Criterion 18 – Inspection and Testing of Electrical Power Systems

“Electric power systems important to safety shall be designed to permit appropriate periodic inspection and testing of important areas and features, such as wiring, insulation, connections, and switchboards, to assess the continuity of the systems and the condition of their components. The systems shall be designed with a capability to test periodically (1) the operability and functional performance of the components of the systems, such as onsite power sources, relays, switches, and buses, and (2) the operability of the systems as a whole and, under conditions as close to design as practical, the full operation sequence that
brings the systems into operation, including operation of applicable portions of the protection system, and the transfer of power among the nuclear power unit, the offsite power system, and the onsite power system.”

Response:

Electrical power systems important to safety are designed to permit appropriate periodic inspection and testing of important areas and features, such as wiring, insulation, connections, and switchboards, to assess the continuity of the systems and to detect deterioration, if any, of their components. Capability is provided to periodically test the operability and functional performance of the system components. The diesel generator sets are started and loaded periodically on a routine basis, and relays, switches, and buses are inspected and tested for operation and availability.

Transfer from normal to emergency sources of power is performed to check system operability and the full operational sequence that brings the systems into operation.

Further information is provided in Subsections 8.3.1 and 8.3.2 and in Chapter 16.

3.1.15 Criterion 19 – Control Room

“A control room shall be provided from which actions can be taken to operate the nuclear power unit safely under normal conditions and to maintain it in a safe condition under accident conditions, including loss of coolant accidents. Adequate radiation protection shall be provided to permit access and occupancy of the control room under accident conditions without personnel receiving radiation exposures in excess of 5 rem whole body, or its equivalent to any part of the body, for the duration of the accident. Equipment at appropriate locations outside the control room shall be provided (1) with a design capability for prompt hot shutdown of the reactor, including necessary instrumentation and controls to maintain the unit in a safe condition during hot shutdown, and (2) with a potential capability for subsequent cold shutdown of the reactor through the use of suitable procedures.

Applicants for and holders of construction permits and operating licenses under this part who apply on or after January 10, 1997, applicants for design approvals or certifications under part 52 of this chapter who apply on or after January 10, 1997, applicants for and holders of combined licenses or manufacturing licenses under part 52 of this chapter who do not reference a standard design approval or certification, or holders of operating licenses
using an alternative source term under § 50.67, shall meet the requirements of this criterion, except that with regard to control room access and occupancy, adequate radiation protection shall be provided to ensure that radiation exposures shall not exceed 0.05 Sv (5 rem) total effective dose equivalent (TEDE) as defined in § 50.2 for the duration of the accident.”

Response:

All control and monitoring equipment necessary to operate or shut the unit down and maintain safe control of the facility is located in the main control room (MCR).

The design of the MCR permits safe occupancy during abnormal conditions. The use of non-combustible and fire-retardant materials in the construction of the MCR, the limitation of combustible supplies, the location of firefighting equipment, and the continuous presence of a trained operator minimize the possibility that the MCR will become uninhabitable. Radiation exposure levels following design basis accidents are maintained below allowable levels by proper design of shielding and ventilation. The MCR ventilation system is designed to allow access to occupancy of the MCR under accident conditions without personnel receiving radiation exposures in excess of 0.05 Sv (5 rem) TEDE during the accident. Fission product removal is performed by the MCR heating, ventilation and air conditioning (HVAC) system to remove iodine and particle matter, thereby minimizing the dose that could result from the accident. Radiation detectors and alarms are provided. MCR habitability features are described in Section 6.4. Emergency lighting is described in Subsection 9.5.3.

If the MCR is inaccessible, alternate local controls and instruments are available for equipment required to establish and maintain a hot standby condition, as well as cold shutdown. Hot and cold shutdown capability is addressed in Section 7.4 for the systems required for safe shutdown. The MCR is described in Subsection 7.7.1.2. Human factors issues are addressed in Chapter 18.

Radiation protection for the plant’s control facilities is addressed in Section 6.4 and Chapter 2.

3.1.16 Criterion 20 – Protection System Functions

“The protection system shall be designed (1) to initiate automatically the operation of appropriate systems including the reactivity control systems, to assure that specified acceptable fuel design limits are not exceeded as a result of anticipated operational
occurrences and (2) to sense accident conditions and to initiate the operation of systems and components important to safety.”

Response:

A plant protection system (PPS), consisting of a reactor protection system (RPS) and an engineered safety features actuation system (ESFAS), is provided. The RPS automatically initiates a reactor trip when any of the monitored process variables reaches a trip setpoint. The ESFAS automatically actuates engineered safety feature (ESF) systems and their support systems when any of the monitored process variables reaches a predetermined setpoint.

The trip setpoints of the RPS are selected to provide reasonable assurance that DBEs that are expected to occur once or more during the life of the nuclear generating station do not cause violation of SAFDLs. The reactor trips also help the ESF systems in mitigating the consequences of DBEs that are expected to occur once during the life of several plants as well as arbitrary combinations of unplanned events and degraded systems that are never expected to occur, to within acceptable limits.

Reactor trip is accomplished by de-energizing the control element drive mechanism (CEDM) coils through the interruption of the CEDM power supply either automatically or manually. The CEDM power supply is a pair of full-capacity motor-generator sets. The path to the CEDMs is interrupted by opening the reactor trip switchgear. With the CEDM coils de-energized, the CEAs are released to drop into the core by gravity, rapidly inserting negative reactivity to shut the reactor down. The CEDMs are addressed in Subsection 3.9.4 and specific reactor trips are addressed in Section 7.2.

The ESF systems are actuated to minimize the effects of incidents that could occur. Controls are provided for manual actuation of the ESF system. The ESF systems are addressed in Chapter 6. The process variables that automatically actuate the ESF system and the logic for the ESFAS are addressed in Section 7.3.

The SAFDLs on linear heat rate and DNBR are intended to enforce the principal thermal-hydraulic design bases given in Subsection 4.4.1 (i.e., the avoidance of thermally induced fuel damage during normal steady-state operations and AOOs).
3.1.17 Criterion 21 – Protection System Reliability and Testability

“The protection system shall be designed for high functional reliability and inservice testability commensurate with the safety functions to be performed. Redundancy and independence designed into the protection system shall be sufficient to assure that (1) no single failure results in loss of the protection function and (2) removal from service of any component or channel does not result in loss of the required minimum redundancy unless the acceptable reliability of operation of the protection system can be otherwise demonstrated. The protection system shall be designed to permit periodic testing of its functioning when the reactor is in operation, including a capability to test channels independently to determine failures and losses of redundancy that may have occurred.”

Response:

The protection system is designed to conform with the requirements of IEEE Std. 603-1991 (Reference 6) and other standards, as noted in Subsection 7.1.2. No credible single failure will result in a loss of the protection function. The protection channels are independent with respect to wire routing, sensor mounting, and supply of power.

Each channel of the protection system, including the sensors up to the reactor trip switchgear system (RTSS) and ESFAS actuation devices, is capable of being checked during reactor operation. Process sensors of each channel in the protection systems are checked by comparison of the redundant process sensor values using the discrete indications and alarms in the MCR, as described in Subsection 7.7.1.2.

To minimize an inadvertent actuation of an ESF system or an inadvertent reactor trip, the protection systems use a coincidence of two-out-of-four logic to operate. The channel being testing is bypassed so the protection system converts to a two-out-of-three logic. This allows periodic testing and the operation of various protective functions without a loss of the protection function.

3.1.18 Criterion 22 – Protection System Independence

“The protection system shall be designed to assure that the effects of natural phenomena, and of normal operating, maintenance, testing, and postulated accident conditions on redundant channels do not result in loss of the protection function, or shall be demonstrated to be acceptable on some other defined basis. Design techniques, such as functional
diversity or diversity in component design and principles of operation, shall be used to the extent practical to prevent loss of the protection function.”

Response:

The protection systems conform with the independence requirements of IEEE Std. 603-1991. Four independent measurement channels, complete with sensors, sensor power supplies, signal conditioning units, and bistable trip functions, are provided for each protective parameter monitored by the protection systems, except for the CEA position sensors that are two-fold redundant. The measurement channels are provided with a high degree of independence by separate connection of the channel sensors to the process systems. Refer to Chapter 7 for a more detailed description of the protection systems.

Power to the protection system channels is provided by independent vital bus power supply systems. The power supply systems are described in Subsection 8.3.2.

Functional diversity is incorporated into the system design to prevent a loss of the protective function. When an RPS trip function is required, it is frequently backed up by other trip functions. The ESFAS actuation signals are used to actuate two or four independent ESF trains.

The diverse protection system augments reactor trip and auxiliary feedwater system (AFWS) actuation by using separate and diverse non-Class 1E trip logic from that used by the plant protection system.

The design goals are accomplished without excessive complexity by using only four channels for each parameter. This allows for testing and maintenance of a channel without reducing the system to a single channel for trip, which would make the system susceptible to spurious trip or actuation signals.

Environmental and seismic qualifications are also performed using type tests, specific equipment tests, appropriate analyses, or prior operating experience. Further information is provided in Sections 3.10 and 3.11.

3.1.19 Criterion 23 – Protection System Failure Modes

“The protection system shall be designed to fail into a safe state or into a state demonstrated to be acceptable on some other defined basis if conditions such as disconnection of the system, loss of energy (e.g., electric power, instrument air), or postulated adverse
environments (e.g., extreme heat or cold, fire, pressure, steam, water, radiation) are experienced.”

Response:

The plant protection system trip channels are designed to fail into a safe state or into a state established as acceptable in the event of loss of power supply. A failure is assumed to occur in only one channel (i.e., a single failure). This channel can be placed into bypass, which places the RPS/ESFAS local coincidence logic into a two-out-of-three configuration. Refer to Sections 7.2 and 7.3 for information on the failure modes and effects analysis.

A loss of power to CEDM coils would cause the CEAs to insert into the core. Redundancy, channel independence, and separation are incorporated into the protection system design to minimize the possibility of the loss of a protective function. The loss of offsite power would cause the standby diesel electric generators to start and energize the ESF trains with actuation signals present.

3.1.20 Criterion 24 – Separation of Protection and Control Systems

“The protection system shall be separated from control systems to the extent that failure of any single control system component or channel, or failure or removal from service of any single protection system component or channel which is common to the control and protection systems leaves intact a system satisfying all reliability, redundancy, and independence requirements of the protection system. Interconnection of the protection and control systems shall be limited so as to assure that safety is not significantly impaired.”

Response:

Protection system components and control system components are electrically and functionally isolated from each other. Further details are provided in Sections 7.2, 7.3, and 7.7.

Isolation devices provide reasonable assurance that when protection signals are used by non-safety systems and non-safety signals are used by safety systems, credible single failures in the non-safety system do not degrade the performance of the safety system. In addition to the electrical and physical isolation, functional isolation between non-safety systems and safety systems is provided. The functional isolation is provided by priority logic in the safety systems or by signal selector logic in the non-safety systems. The
priority logic provides reasonable assurance that safety actuation signals, both automatic and manual (system level and component level), override all control signals from the non-safety systems. Signal selection logic in the control system prevents erroneous control actions due to single sensor failures. Eliminating these erroneous control actions prevents challenges to the protection system while it is degraded due to the same sensor failure.

The adequacy of the system isolation capability has been verified by testing under conditions of postulated credible faults. The failure of any single control system component or channel, or the failure or removal from service of any single protection system component or channel, which is common to the control and protection system, leaves intact a system that satisfies the requirements of the protection system.

3.1.21 Criterion 25 – Protection System Requirements for Reactivity Control Malfunctions

“The protection system shall be designed to assure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control systems, such as accidental withdrawal (not ejection or dropout) of control rods.”

Response:

Shutdown of the reactor is accomplished by the opening of the reactor trip switchgear system (RTSS) circuit breakers, which interrupts power to the CEDM coils. Actuation of the circuit breakers is independent of any existing control signals.

The protection systems are designed such that SAFDLs are not exceeded for any single malfunction of the reactivity control systems, including the withdrawal of a single full- or part-strength CEA. Analyses of possible reactivity control system malfunctions are described in Chapter 15.

3.1.22 Criterion 26 – Reactivity Control System Redundancy and Capability

“Two independent reactivity control systems of different design principles shall be provided. One of the systems shall use control rods, preferably including a positive means for inserting the rods, and shall be capable of reliably controlling reactivity changes to assure that under conditions of normal operation, including anticipated operational occurrences, and with appropriate margin for malfunctions such as stuck rods, specified acceptable fuel design limits are not exceeded. The second reactivity control system shall be capable of
reliably controlling the rate of reactivity changes resulting from planned, normal power changes (including xenon burnout) to assure acceptable fuel design limits are not exceeded. One of the systems shall be capable of holding the reactor core subcritical under cold conditions.”

Response:

Two independent reactivity control systems of different design principles are provided. The first system, using CEAs, includes a passive means (gravity) for inserting CEAs and is capable of reliably controlling reactivity changes to provide reasonable assurance that under conditions of normal operation, including AOOs, SAFDLs are not exceeded. The CEAs can be mechanically driven into the core.

The appropriate margin for stuck rods is provided by assuming in the analyses of AOOs that the highest-worth CEA does not fall into the core.

The second system, using neutron-absorbing soluble boron, is capable of reliably compensating for the rate of reactivity changes resulting from planned normal power changes (including xenon burnup) such that SAFDLs are not exceeded. This system is capable of holding the reactor subcritical under cold conditions.

Either system is able to insert negative reactivity at a rate sufficient to prevent exceeding SAFDLs as the result of a power change (i.e., positive reactivity added by xenon burnup).

3.1.23 Criterion 27 – Combined Reactivity Control Systems Capability

“The reactivity control systems shall be designed to have a combined capability, in conjunction with poison addition by the emergency core cooling system, of reliably controlling reactivity changes to assure that under postulated accident conditions and with appropriate margin for stuck rods the capability to cool the core is maintained.”

Response:

Dissolved boron addition capability provided by the safety injection system (SIS) (Chapter 6) in conjunction with the CEAs is such that under postulated accident conditions (Chapter 15), even with the CEA of highest worth stuck out of the core, adequate reactivity control is available to maintain short- and long-term core cooling.
3.1.24 Criterion 28 – Reactivity Limits

“The reactivity control systems shall be designed with appropriate limits on the potential amount and rate of reactivity increase to assure that the effects of postulated reactivity accidents can neither (1) result in damage to the reactor coolant pressure boundary greater than limited local yielding nor (2) sufficiently disturb the core, its support structures or other reactor pressure vessel internals to impair significantly the capability to cool the core. These postulated reactivity accidents shall include consideration of rod ejection (unless prevented by positive means), rod dropout, steam line rupture, changes in reactor coolant temperature and pressure, and cold water addition.”

Response:

The bases for CEA design include providing reasonable assurance that the reactivity worth of any one CEA is not greater than a preselected maximum value. The CEAs are divided into two sets, a shutdown set and a regulating set, further subdivided into groups as necessary. Administrative procedures and interlocks provide reasonable assurance that only one group is withdrawn at a time, and that regulating groups are withdrawn only after shutdown groups are fully withdrawn. The regulating groups are programmed to move in sequence and within limits that prevent the rate of reactivity addition and the worth of individual CEAs from exceeding limiting values.

The maximum rate of reactivity addition that can be produced by the chemical and volume control system (CVCS) is too low to induce pressure forces significant enough to rupture the RCPB or disturb the reactor vessel internals.

The RCPB (Chapter 5) and reactor internals (Chapter 4) are designed to appropriate codes (e.g., the response to Criterion 14) and accommodate the static and dynamic loads associated with an inadvertent, sudden release of energy such as that resulting from a CEA ejection or steam line break (Chapter 15) without rupture and with limited deformation so that core cooling capability is not impaired.

3.1.25 Criterion 29 – Protection Against Anticipated Operational Occurrences

“The protection and reactivity control systems shall be designed to assure an extremely high probability of accomplishing their safety functions in the event of anticipated operational occurrences.”
Response:

Plant events, designated in ANSI/ANS 51.1, have been carefully considered in the design of the protection and reactivity control systems. Redundancy, independence, and testability have been considered in the design. These considerations, coupled with careful component selection, overall system testing, and adherence to detailed quality assurance requirements, provide reasonable assurance that protection and reactivity control systems will accomplish their safety functions in the event of AOOs.

Refer to Chapter 7 for detailed descriptions of the protection systems and Chapter 17 for description of design quality assurance. DBE analysis is addressed in Chapter 15.

3.1.26 Criterion 30 – Quality of Reactor Coolant Pressure Boundary

“Components which are part of the reactor coolant pressure boundary shall be designed, fabricated, erected, and tested to the highest quality standards practical. Means shall be provided for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage.”

Response:

RCPB components are designed, fabricated, erected, and tested in accordance with ASME Section III. All components are classified safety Class 1 or 2 in accordance with ANSI/ANS 51.1 and undergo all quality assurance measures that are appropriate for the respective classification.

Means are provided for identifying the source of reactor coolant leakage, which includes detection of leakage to systems connected to the RCPB as well as leakage from the boundary into the containment.

Instrumentation is provided to indicate and record makeup flow rates to the primary water system. This instrumentation permits detection of both suddenly occurring and gradually increasing leaks. Leakage detection methods are described in Subsection 5.2.5.1.

3.1.27 Criterion 31 – Fracture Prevention of Reactor Coolant Pressure Boundary

“The reactor coolant pressure boundary shall be designed with sufficient margin to assure that when stressed under operating, maintenance, testing, and postulated accident
conditions (1) the boundary behaves in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the boundary material under operating, maintenance, testing, and postulated accident conditions and the uncertainties in determining (1) material properties, (2) the effects of irradiation on material properties, (3) residual, steady state and transient stresses, and (4) size of flaws.”

Response:

All the RCPB components are designed and constructed in accordance with ASME Section III and conform with test and inspection requirements of these codes. The test and inspection requirements provide reasonable assurance that flaw sizes are limited so that the probability of failure by rapid propagation is extremely remote. Particular emphasis is placed on the quality control applied to the reactor vessel, on which tests and inspections exceeding ASME Code requirements are performed. The tests and inspections performed on the reactor vessel are described in Subsection 5.3.1.3.

Carbon and low-alloy steel materials that form part of the RCPB are tested in accordance with fracture toughness requirements for materials in ASME Section III. Nonductile failure prevention is reasonably assured by adhering to the relevant sections of the ASME Code.

Excessive embrittlement of the reactor vessel material due to neutron irradiation is prevented by providing an annulus of coolant water between the reactor core and the vessel. In addition, to minimize the effects of irradiation on material toughness properties of core beltline materials, restrictions on upper limits for residual elements that directly influence the reference temperature for nil-ductility transition (RTNDT) shift are required by design specification. Specifically, upper limits are placed on copper, nickel, phosphorous, sulfur, and vanadium.

The maximum integrated fast neutron exposure of the reactor vessel wall opposite the midplane of the core is less than $9.5 \times 10^{19}$ n/cm$^2$. This value assumes a 60-year design life and a 93 percent plant capacity factor. The maximum expected increase in transition temperature for vessel weld materials is approximately $31.4 \, ^\circ$C ($56.6 \, ^\circ$F) provided that weld metal is conservatively assumed to be exposed to the peak value of neutron fluence, $9.5 \times 10^{19}$ n/cm$^2$. Actual locations of welds are outside the active core region. The actual change in material toughness properties due to irradiation is verified periodically.
during plant lifetime by a material surveillance program. Based on the initial $RT_{NDT}$ of archive pressure vessel beltline material, which is $-23.3 \, ^\circ C \, (-10 \, ^\circ F)$ or less, operating restrictions are applied as necessary to limit vessel stresses.

The thermal stresses induced by the injection of cold water into the vessel following a LOCA have been examined. Analyses have shown that there is no gross yielding across the vessel wall when using the minimum specified yield strength in ASME Section III.

3.1.28 Criterion 32 – Inspection of Reactor Coolant Pressure Boundary

“Components which are part of the reactor coolant pressure boundary shall be designed to permit (1) periodic inspection and testing of important areas and features to assess their structural and leaktight integrity, and (2) an appropriate material surveillance program for the reactor pressure vessel.”

Response:

Provisions have been made in the design for inspection, testing, and surveillance of the RCS boundary as required by ASME Section XI. The system designer recommends a reactor vessel surveillance program to the owner. The reactor vessel surveillance program provided to the owner conforms with 10 CFR Part 50, Appendix H. Sample pieces taken from the same material used in fabrication of the reactor vessel are installed between the core and the vessel inside wall. These samples are removed and tested by the owner at intervals during vessel life to provide an indication of the extent of the neutron embrittlement of the vessel wall. Charpy tests are performed on the samples to develop a Charpy transition curve. By comparing this curve with the Charpy curve and drop weight test results for specimens taken at the beginning of the vessel life, the change of $RT_{NDT}$ is determined and operating procedures adjusted as required. Further details are provided in Chapter 5.

3.1.29 Criterion 33 – Reactor Coolant Makeup

“A system to supply reactor coolant makeup for protection against small breaks in the reactor coolant pressure boundary shall be provided. The system safety function shall be to assure that specified acceptable fuel design limits are not exceeded as a result of reactor coolant loss due to leakage from the reactor coolant pressure boundary and rupture of small piping or other small components which are part of the boundary. The system shall be designed to assure that for onsite electric power system operation (assuming offsite power
is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished using the piping, pumps, and valves used to maintain coolant inventory during normal reactor operation.”

Response:

Reactor coolant makeup during normal operation is provided by the CVCS. The two charging pumps can be powered from either onsite or offsite power sources. The system is described in Subsection 9.3.4. The CVCS has the capability of replacing the flow loss to the containment due to leaks in small reactor coolant lines such as instrument and sample lines. These lines have 5.56 mm (7/32 in.) diameter by 25.4 mm (1 in.) long flow-restricting devices to limit loss of RCS coolant due to postulated pipe breaks in RCS piping.

The CVCS is not required to perform any safety-related function, such as accident mitigation or safe shutdown. This does not, however, compromise the defense-in-depth provided by the system as the normal means of maintaining RCS inventory and primary water chemistry. The CVCS is essential to day-to-day plant operations and has been provided with a high degree of reliability and redundancy, and is designed in accordance with accepted industry standards and quality assurance commensurate with its importance to plant operation. Design criteria, including ASME Code classification assignments, are in accordance with ANSI/ANS 51.1, which requires that portions of the CVCS in the RCPB, all portions that provide reasonable assurance of containment isolation and reactor coolant normal makeup, have a rigorous safety classification in accordance with the functional performance requirements.

3.1.30 Criterion 34 – Residual Heat Removal

“A system to remove residual heat shall be provided. The system safety function shall be to transfer fission product decay heat and other residual heat from the reactor core at a rate such that specified acceptable fuel design limits and the design conditions of the reactor coolant pressure boundary are not exceeded.

Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.”
Response:

Residual heat removal capability is provided by the shutdown cooling system (SCS) for reactor coolant temperature and pressure less than 176.7 °C (350 °F) and 31.6 kg/cm²A (450 psia). For temperatures greater than 176.7 °C (350 °F), this function is provided by the SGs. The AFWS provides a dedicated, independent, safety-related means of supplying feedwater (FW) to the SGs for removal of heat and prevention of reactor core uncovery. The design incorporates sufficient redundancy, interconnections, leak detection, and isolation capability to provide reasonable assurance that the residual heat removal function can be accomplished, assuming a single active failure. Within appropriate design limits, either system can remove fission product decay heat at a rate that SAFDLs and the design conditions of the RCPB are not exceeded.

The SCS and SG auxiliaries are designed to operate from offsite or from onsite power sources.

Further description of the SCS is provided in Subsection 5.4.7, and further description of the steam and power conversion system is provided in Chapter 10.

3.1.31 Criterion 35 – Emergency Core Cooling

“A system to provide abundant emergency core cooling shall be provided. The system safety function shall be to transfer heat from the reactor core following any loss of reactor coolant at a rate such that (1) fuel and clad damage that could interfere with continued effective core cooling is prevented and (2) clad metal-water reaction is limited to negligible amounts.

Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.”

Response:

Emergency core cooling is provided by the SIS as described in Section 6.3. The system is designed to provide cooling water to limit peak clad temperature to less than 1,204 °C (2,200 °F), to remove heat at a rate sufficient to maintain the fuel in a coolable geometry
and to provide reasonable assurance that zirconium-water reaction is limited to a negligible amount (less than 1 percent) following a LOCA, including breaks in the pipe in the reactor coolant pressure boundary up to and including a break size equivalent to the double-ended rupture of the largest pipe in the RCS. Performance of the emergency core cooling system (ECCS) has been analyzed using the evaluation models complying with the requirements of 10 CFR 50.46(a)(1), and performance has been verified adequate to meet the criteria prescribed in 10 CFR 50.46(b).

The system design includes provisions to provide reasonable assurance that the required safety functions are accomplished with either onsite or offsite electrical power, assuming a single failure of any component which is qualified as described below.

The single failure considered may be limited to an active failure\(^1\) during the short-term cooling phase of safety injection or an active or limited-leakage passive failure\(^2\) during the long-term cooling phase of safety injection.

Although the SIS is designed to accommodate a limited leakage passive failure during the long-term cooling phase, it does not accommodate arbitrary large-leakage passive failures, such as the complete double-ended severance of piping, which are extremely low probability events.

3.1.32 Criterion 36 – Inspection of Emergency Core Cooling System

“The emergency core cooling system shall be designed to permit appropriate periodic inspection of important components, such as spray rings in the reactor pressure vessel, water injection nozzles, and piping, to assure the integrity and capability of the system.”

\(^1\) An active failure is a malfunction, excluding passive failure, of a component that relies on mechanical movement to complete its intended function upon demand. Examples of active failures include the failure of a valve to move to its correct position, or the failure of a pump, fan, or diesel generator to start. Spurious action of a powered component originating within the actuation system or its supporting systems shall be regarded as an active failure, unless specific design features or operating restrictions preclude such spurious action.

\(^2\) A passive failure is a failure of a component to maintain its structural integrity or the blockage of a process flow path. Blockage of a process flow path could occur, for example, due to separation of a valve disc from its stem. Refer to Subsection 6.3.2.5.4 for a description of a limited-leakage passive failure of the SIS.
Response:

The SIS is designed to facilitate access to all critical components. All pumps, heat exchangers, valves, and piping external to the containment structure are readily accessible for periodic inspection to provide reasonable assurance of system leak-tight integrity. Valves, piping, and tanks inside the containment may be inspected for leak-tightness during plant shutdowns for refueling and maintenance.

Reactor vessel internal structures, reactor coolant piping, and water injection nozzles are designed to permit visual inspection for wear due to erosion, corrosion, or vibration and nondestructive inspection techniques where applicable and desirable.

Descriptions of the inspection program are provided in Chapters 5, 6, and 16.

3.1.33 Criterion 37 – Testing of Emergency Core Cooling System

“The emergency core cooling system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system.”

Response:

The SIS is provided with testing capability to demonstrate system and component operability. Testing can be conducted during normal plant operation with the test facilities arranged not to interfere with the performance of the systems or with the initiation of control circuits, as described in Section 6.3 and Chapter 14. During in-service testing, testing is performed to confirm that the SI pump return line to the in-containment refueling water storage tank (IRWST) allows each SI pump to be operated at rated flow.

3.1.34 Criterion 38 – Containment Heat Removal

“A system to remove heat from the reactor containment shall be provided. The system safety function shall be to reduce rapidly, consistent with the functioning of other
associated systems, the containment pressure and temperature following any loss-of-coolant accident and maintain them at acceptably low levels.

Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.”

Response:

The containment spray system (CSS) consists of two independent divisions. Each division consists of a containment spray pump, a containment spray heat exchanger, a containment spray pump miniflow heat exchanger, a containment spray header, and associated piping and valves. The heat removal capacity of each division is sufficient to keep the containment pressure and temperature below design conditions for any break size in the RCS piping up to and including a double-ended break of the largest reactor coolant pipe, with an unobstructed discharge from both ends.

The CSS takes suction borated water from the IRWST, which is located in the containment. Borated water is sprayed downward by the CSS from the upper regions of the containment to cool the containment atmosphere. The removed heat is transferred by the component cooling water via the CSS heat exchangers to the ultimate heat sink (UHS).

Suitable redundancy in components and features is designed into the CSS to maintain the pressure and temperature conditions below containment design conditions even in the event of a single failure including the loss of onsite or offsite electrical power.

The CSS is supplied from separate Class 1E buses and receives electrical power from electrically independent and redundant emergency power supply systems as well as offsite power supplies.

The CSS is described further in Subsections 6.2.2 and 6.5.2. Electrical power supplies are described further in Subsections 8.2 and 8.3.
3.1.35  Criterion 39 – Inspection of Containment Heat Removal System

“The containment heat removal system shall be designed to permit appropriate periodic inspection of important components, such as the torus, sumps, spray nozzles, and piping to assure the integrity and capability of the system.”

Response:

Inspections of the CSS are conducted to confirm the integrity and capability and provide reasonable assurance of the system. All essential equipment of the CSS is located outside the containment, except for spray headers, nozzles, containment sump, IRWST, and associated piping. These components include two containment spray pumps, two containment spray pump miniflow heat exchangers, two containment spray heat exchangers, and independent containment spray headers.

The detailed arrangement and layout of system piping, pumps, heat exchangers, and valves provide the separation, availability, and accessibility required for periodic inspection. Nozzle inspection capability is provided as well.

The CSS is described further in Subsections 6.2.2 and 6.5.2.

3.1.36  Criterion 40 – Testing of Containment Heat Removal System

“The containment heat removal system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole, and under conditions as close to the design as practical the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system.”

Response:

The containment heat removal system is arranged so that components can be tested periodically for operability. The operational tests are performed to verify the proper operation of CSS and include the calibration of instrumentation, verification of adequate pump performance, verification of the operability of all associated valves, and verification that the spray headers and spray nozzles are free of obstructions. Testing can be
conducted during normal plant operation with the system configured to not interfere with the performance of the initiation of control circuits, as described in Subsection 6.2.2.

All components of the CSS are hydrostatically tested in the manufacturer’s shop. A hydrostatic test is performed in the field to verify the leaktightness of the system.

The performance testing of containment spray pumps is conducted at some time other than refueling. The pumps are aligned to take suction from and return flow to the IRWST. Flow and head are recorded by the installed instrumentation.

Actuator-operated valves can be tested from the control room and operation verified by observing control room indication.

The valves on the inlets and outlets of the containment spray pumps can be tested to provide reasonable assurance that the valves operate properly.

3.1.37 Criterion 41 – Containment Atmosphere Cleanup

“Systems to control fission products, hydrogen, oxygen, and other substances which may be released into the reactor containment shall be provided as necessary to reduce, consistent with the functioning of other associated systems, the concentration and quality of fission products released to the environment following postulated accidents, and to control the concentration of hydrogen or oxygen and other substances in the containment atmosphere following postulated accidents to assure that containment integrity is maintained.

Each system shall have suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) its safety function can be accomplished, assuming a single failure.”

Response:

The CSS and containment hydrogen control system are provided to control fission products, hydrogen, oxygen, and other substances that may be released into the containment. The CSS is an automatically actuated ESF system that provides heat removal and fission product removal following a LOCA. The fission products are removed to reduce activity at the site boundary by the CSS and the post-accident pH of the sprayed fluid is controlled by using trisodium phosphate (TSP). The CSS consists of two independent divisions that
are supplied power from separate Class 1E buses and has sufficient redundancy to perform its safety functions. The CSS is designed so that a single failure coincident with a loss of offsite power does not prevent performance of the safety function.

Passive autocatalytic recombiners (PARs), which have 200 percent of required capacity, are located in containment and preclude hydrogen concentration buildup to detonable levels.

The systems are described in detail in Subsections 6.2.5 and 6.5.2.

3.1.38 Criterion 42 – Inspection of Containment Atmosphere Cleanup Systems

“The containment atmosphere cleanup systems shall be designed to permit appropriate periodic inspection of important components, such as filter frames, ducts, and piping to assure the integrity and capability of the systems.”

Response:

The containment atmosphere cleanup systems are designed and located so that they can be inspected periodically as required. Inspection of the CSS function relative to iodine removal is treated as described in GDC 39.

All major active components of the containment atmosphere cleanup systems are located outside containment and are readily accessible for periodic inspection.

The inspection and surveillance program for the containment hydrogen control system is described further in Subsection 6.2.5.

3.1.39 Criterion 43 – Testing of Containment Atmosphere Cleanup Systems

“The containment atmosphere cleanup systems shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the systems such as fans, filters, dampers, pumps, and valves and (3) the operability of the systems as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the systems into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of associated systems.”
Response:

Testing of the CSS is conducted to provide reasonable assurance of structural and leaktight integrity and operability and performance in accordance with GDC 40. In addition, performance testing is conducted on CSS components. These tests are normally conducted while the plant is operating. System design includes provisions to prevent accidental containment spray during component testing. The test for the CSS is described further in Subsections 6.2.2 and 6.5.2.

The containment hydrogen control system is designed to permit periodic testing for confirming the continued operability. Testing may be conducted during normal plant operation or shutdown. The test for the containment hydrogen control system is described in Subsection 6.2.5 for details.

3.1.40  Criterion 44 – Cooling Water

“A system to transfer heat from structures, systems, and components important to safety, to an ultimate heat sink shall be provided. The system safety function shall be to transfer the combined heat load of these structures, systems, and components under normal operating and accident conditions.

Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure.”

Response:

The cooling water systems, which function to remove the combined heat load from safety-related systems and components under normal operating and accident conditions, are the component cooling water system (CCWS) and the essential service water system (ESWS). The CCWS is a closed-loop system that removes heat from nuclear safety-related and potentially radioactive systems. The ESWS removes heat from the CCWS and transfers it to the environment through the UHS.
Suitable redundancy, systems interconnection, leak detection, and isolation capabilities are incorporated into the design of these systems to provide reasonable assurance of the required safety function, assuming a single failure with available onsite or offsite power.

The CCWS and the ESWS are described in Subsections 9.2.2 and 9.2.1, respectively.

3.1.41 Criterion 45 – Inspection of Cooling Water System

“The cooling water system shall be designed to permit appropriate periodic inspection of important components, such as heat exchangers and piping, to assure the integrity and capability of the system.”

Response:

Components of these systems are located in accessible areas with the exception of any underground piping for the ESWS. These components have suitable manholes, handholes, inspection ports, or other appropriate design and layout features to allow periodic inspection. The integrity of any underground piping is demonstrated during normal power operation as well as by pressure and functional tests. The inspection and testing requirements for the CCWS and the ESWS are described in Subsections 9.2.2 and 9.2.1, respectively.

3.1.42 Criterion 46 – Testing of Cooling Water System

“The cooling water system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and the performance of the active components of the system, and (3) the operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation for reactor shutdown and for loss-of-coolant accidents, including operation of applicable portions of the protection system and the transfer between normal and emergency power sources.”

Response:

The design provides for periodic testing of the cooling water systems for operability and functional performance.
The manufacturer is required to conduct performance tests of the components. An initial system flow test demonstrates proper functioning of the system. Thereafter, periodic tests provide reasonable assurance that components are functioning properly.

Cooling water system valves can be connected to the preferred power source at any time during reactor operation to demonstrate operability. The system is operated normally, thereby demonstrating operability. Remotely operated valves are exercised and actuation circuits are tested. Automatic actuation circuitry, valves, and pump breakers can also be checked when integrated system tests are performed during a planned cooldown of the RCS. Provisions have been made to permit periodic leakage tests to verify the continued leak-tight integrity of the systems. The inspection and testing requirements for the CCWS and the ESWS are provided in Subsections 9.2.2 and 9.2.1, respectively.

3.1.43  Criterion 50 – Containment Design Basis

“The reactor containment structure, including access openings, penetrations, and the containment heat removal system shall be designed so that the containment structure and its internal compartments can accommodate, without exceeding the design leakage rate and with sufficient margin, the calculated pressure and temperature conditions resulting from any loss-of-coolant accident. This margin shall reflect consideration of (1) the effects of potential energy sources which have not been included in the determination of the peak conditions, such as energy in steam generators and as required by § 50.44 energy from metal-water and other chemical reactions that may result from degradation but not total failure of emergency core cooling functioning, (2) the limited experience and experimental data available for defining accident phenomena and containment responses, and (3) the conservatism of the calculational model and input parameters.”

Response:

The containment structure, including access openings and penetrations, is designed to accommodate, without exceeding the design leak rate, the transient peak pressure and temperature associated with a LOCA up to and including a double-ended rupture of the largest reactor coolant pipe.

The containment structure and ESF systems have been evaluated for various combinations of energy release. The analysis accounts for system thermal and chemical energy, and for nuclear decay heat. The SIS is designed such that no single active failure could result in significant metal-water reaction, as described in Subsection 6.2.1.
The containment heat removal system is described in Subsection 6.2.2. Further information is provided in Subsections 3.8.1 and 3.8.2.

3.1.44 Criterion 51 – Fracture Prevention of Containment Pressure Boundary

“The reactor containment boundary shall be designed with sufficient margin to assure that under operating, maintenance, testing, and postulated accident conditions (1) its ferritic materials behave in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the containment boundary material during operation, maintenance, testing, and postulated accident conditions, and the uncertainties in determining (1) material properties, (2) residual, steady state, and transient stresses, and (3) size of flaws.”

Response:

The containment’s ferrite materials are selected to provide reasonable assurance that their temperature under normal operating and testing conditions is at least 16.7 °C (30 °F) above the nil-ductility transition temperature (NDTT). Detailed stress analyses of the containment liner anchors are conducted under normal and postulated accident conditions.

Further details regarding ferrite materials used in the containment and associated design requirements are described in Subsections 3.8.1, 3.8.2, and 6.1.1.

3.1.45 Criterion 52 – Capability for Containment Leakage Rate Testing

“The reactor containment and other equipment which may be subjected to containment test conditions shall be designed so that periodic integrated leakage rate testing can be conducted at containment design pressure.”

Response:

Criterion 52 is complied with the plant design. The provision for testing in conformance with this criterion and the provisions for conformance with 10 CFR Part 50, Appendix J, are described in Subsection 6.2.6.1. Containment design relative to test pressure is described in Subsection 3.8.1.3.
3.1.46 Criterion 53 – Provisions for Containment Testing and Inspection

“The reactor containment shall be designed to permit (1) appropriate periodic inspection of all important areas, such as penetrations, (2) an appropriate surveillance program, and (3) periodic testing at containment design pressure of the leaktightness of penetrations which have resilient seals and expansion bellows.”

Response:

The containment design permits access to penetrations and other important areas for implementation of the surveillance program described in Chapter 16. Penetrations with resilient seals and bellows are visually inspected and pressure tested periodically for leaktightness according to the Technical Specifications. Leakage rate testing is described in Subsection 6.2.6.

3.1.47 Criterion 54 – Piping Systems Penetrating Containment

“Piping systems penetrating primary reactor containment shall be provided with leak detection, isolation, and containment capabilities having redundancy, reliability, and performance capabilities which reflect the importance to safety of isolating these piping systems. Such piping systems shall be designed with a capability to test periodically the operability of the isolation valves and associated apparatus and to determine if valve leakage is within acceptable limits.”

Response:

Piping systems that penetrate containment are designed to provide the required isolation and testing capabilities. These piping systems are provided with test connections to allow periodic leak detection tests to provide reasonable assurance that the leakage is within the acceptable limits of 10 CFR Part 50, Appendix J, and Chapter 16.

The ESFAS circuitry provides the means for testing isolation valve operability.

The fuel transfer tube is not classified as a fluid system penetration. The blind flange and the portion of the transfer tube inside the containment are an extension of the containment boundary. The blind flange isolates the transfer tube at all times, except when the reactor is shut down for refueling. This assembly is a penetration in the same sense as the equipment hatches and personnel locks.
Subsection 6.2.4 addresses penetration design. Additional information is given in the responses to GDC 55, 56, and 57 (Subsections 3.1.48 through 3.1.50).

3.1.48 Criterion 55 – Reactor Coolant Pressure Boundary Penetrating Containment

“Each line that is part of the reactor coolant pressure boundary and that penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

a. One locked closed isolation valve inside and one locked closed isolation valve outside containment.

b. One automatic isolation valve inside and one locked closed isolation valve outside containment.

c. One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

d. One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

Isolation valves outside containment shall be located as close to containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety.

Other appropriate requirements to minimize the probability or consequences of an accidental rupture of these lines or of lines connected to them shall be provided as necessary to assure adequate safety. Determination of the appropriateness of these requirements, such as higher quality in design, fabrication, and testing, additional provisions for inservice inspection, protection against more severe natural phenomena, and additional isolation valves and containment, shall include consideration of the population density, use characteristics, and physical characteristics of the site environs.”
Response:

All RCPB lines penetrating containment meet the isolation criteria of GDC 55 using the following basis for specific lines in addition to those noted above:

a. Safety injection lines, as shown in Figure 6.3.2-1, are used to mitigate the consequences of accidents and therefore do not receive an automatic closure signal and are not locked closed.

b. When in shutdown cooling mode, the shutdown cooling system is an extension of the RCPB and is isolated from the environment by two isolation valves in series.

c. The charging and seal injection lines shown in Figure 9.3.4-1 have automatic valves outside containment that do not receive a closure signal (CIAS) because it is desirable to maintain charging and seal injection flow as long as the charging pumps are in operation.

d. Special cases are described in Subsection 6.2.4.

3.1.49 Criterion 56 – Primary Containment Isolation

“Each line that connects directly to the containment atmosphere and penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

a. One locked closed isolation valve inside and one locked closed isolation valve outside containment.

b. One automatic isolation valve inside and one locked closed isolation valve outside containment.

c. One locked-closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

d. One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.
Isolation valves outside containment shall be located as close to the containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety.”

Response:

Fluid systems conform with the requirements of GDC 56 with the following exceptions:

a. Lines that connect directly to the containment atmosphere and are used for mitigating the effects of accidents are connected to a closed piping system outside containment, which is isolated from the environment in accordance with the requirements of GDC 55.

b. In addition, the capability for remote double isolation at the containment boundary is provided in accordance with GDC 56.

c. Special cases are described in Subsection 6.2.4.

3.1.50 Criterion 57 – Closed System Isolation Valves

“Each line that penetrates primary reactor containment and is neither part of the reactor coolant pressure boundary nor connected directly to the containment atmosphere shall have at least one containment isolation valve which shall be either automatic, or locked closed, or capable of remote manual operation. This valve shall be outside containment and located as close to the containment as practical. A simple check valve may not be used as the automatic isolation valve.”

Response:

The system conforms with the requirements of GDC 57 as described in Subsection 6.2.4.

3.1.51 Criterion 60 – Control of Releases of Radioactive Material to the Environment

“The nuclear power unit design shall include means to control suitably the release of radioactive materials in gaseous and liquid effluents and to handle radioactive solid wastes produced during normal reactor operation, including anticipated operational occurrences. Sufficient holdup capacity shall be provided for retention of gaseous and liquid effluents containing radioactive materials, particularly where unfavorable site environmental
conditions can be expected to impose unusual operational limitations upon the release of such effluents to the environment.”

Response:

The sources and expected quantities of radioactive materials produced during normal reactor operation, including AOOs, are presented in Chapter 11. The radioactive waste systems to suitably control the release of these materials in gaseous and liquid effluents and handle radioactive solid wastes are described in Sections 11.2 through 11.4.

3.1.52 Criterion 61 – Fuel Storage and Handling and Radioactivity Control

“The fuel storage and handling, radioactive waste, and other systems which may contain radioactivity shall be designed to assure adequate safety under normal and postulated accident conditions. These systems shall be designed (1) with a capability to permit appropriate periodic inspection and testing of components important to safety, (2) with suitable shielding for radiation protection, (3) with appropriate containment, confinement, and filtering systems, (4) with a residual heat removal capability having reliability and testability that reflects the importance to safety of decay heat and other residual heat removal, and (5) to prevent significant reduction in fuel storage coolant inventory under accident conditions.”

Response:

The spent fuel cooling and cleanup system, fuel handling system, building ventilation systems for radiation control areas, and radioactive waste management systems are designed to provide reasonable assurance of adequate safety under normal and postulated accident conditions.

Structures, systems, and components are designed and located so that appropriate periodic inspection and testing can be performed.

Information on shielding is provided in Section 12.3. Radiation monitoring is described in Section 11.5 and Subsection 12.3.4.

The individual components that contain radioactivity are located in confined areas and ventilated through appropriate filtering systems. Information on radioactive waste management systems is provided in Chapter 11.
The spent fuel pool cooling and cleanup system provides cooling to remove residual heat from the fuel stored in the spent fuel pool. The system is designed with redundant and testable features to provide reasonable assurance of continuous heat removal. The spent fuel pool cooling and cleanup system is described in Subsection 9.1.3.

The spent fuel pool is designed in accordance with seismic Category I requirements so that no postulated accident can cause excessive loss of coolant inventory.

3.1.53 **Criterion 62 – Prevention of Criticality in Fuel Storage and Handling**

“Criticality in the fuel storage and handling system shall be prevented by physical systems or processes, preferably by use of geometrically safe configurations.”

**Response:**

The restraints and interlocks provided for safe handling and storage of new and spent fuel are described in Section 9.1.

The fuel handling area is laid out to preclude the spent fuel shipping cask from traversing the spent fuel storage pool.

The design of fuel storage racks provides reasonable assurance of an effective multiplication factor ($K_{\text{eff}}$). For new fuel storage racks, $K_{\text{eff}}$ is less than 0.95 with full density unborated water and less than 0.98 with optimum moderating condition. For spent fuel storage racks, $K_{\text{eff}}$ is less than 0.95 with partial credit for soluble boron and less than 1.0 with full density unborated water.

Criticality in the fuel storage area is prevented by the physical separation of fuel assemblies, the fixed neutron absorber attached on the spent fuel rack wall, and the presence of borated water in the fuel storage pool.

3.1.54 **Criterion 63 – Monitoring Fuel and Waste Storage**

“Appropriate systems shall be provided in fuel storage and radioactive waste systems and associated handling areas (1) to detect conditions that may result in loss of residual heat removal capability and excessive radiation levels and (2) to initiate appropriate safety actions.”
Response:

Instrumentation is provided to monitor the spent fuel pool (SFP) water level and water temperature continuously, and their indications and annunciations are provided in the main control room (MCR). Two redundant safety-related fuel handling area radiation monitors are provided to monitor SFP area radioactivity continuously, and their indications and annunciations are provided in the MCR. In case of an inadvertent release of radioactivity, the area radiation monitor generates local and MCR alarms and an ESFAS fuel handling area emergency ventilation actuation signal as required for the appropriate safety actions. Information on the ESFAS is provided in Section 7.3 and information on the fuel storage area radiation monitoring system is provided in Subsection 9.4.2.

3.1.55 Criterion 64 – Monitoring Radioactivity Releases

“Means shall be provided for monitoring the reactor containment atmosphere, spaces containing components for recirculation of loss-of-coolant accident fluids, effluent discharge paths, and the plant environs for radioactivity that may be released from normal operations, including anticipated operational occurrences, and from postulated accidents.”

Response

The reactor containment atmosphere is continuously sampled and monitored for any radioactivity that is released from normal operations (including AOOs) by a continuous air monitoring system located outside the containment. A separate system is provided to enable collection and analysis of grab samples of the containment atmosphere during normal operations and accident conditions. Area monitors such as high-range ion chambers are located inside the containment to measure radiation levels from normal and accident conditions.

Gamma and beta scintillators are located outside the containment for containment air monitoring.

Spaces containing components for recirculation of LOCA fluids and areas contiguous to the containment structure are monitored for airborne radioactivity by systems that sample and monitor the air exhausted from the associated areas. The systems consist of continuous air monitors, duct radiation monitors, and air samplers to enable the collection of samples of exhaust air for laboratory analysis during normal and accident conditions.
Effluent discharge paths and plant environs from the facility are continuously monitored for radioactivity during normal operations with continuous air and liquid monitoring systems. Sampling provisions are included to allow sample collection for analysis during normal operations and accident conditions. Extended-range noble gas monitors are provided to allow for continuous monitoring during accident conditions. The systems provided for monitoring radioactive releases from the facility are described in Sections 11.5 and 12.3.

3.1.56 Combined License Information

No COL information is required with regard to Section 3.1.

3.1.57 References

3.2 Classification of Structures, Systems, and Components

The APR1400 structures, systems, and components (SSCs) are classified according to nuclear safety classification, quality groups, seismic category, 10 CFR Part 50, Appendix B, quality assurance program, and codes and standards.

Safety-related SSCs are defined in 10 CFR 50.2 as SSCs that are relied on to remain functional during and following design basis events to ensure the following:

a. The integrity of the reactor coolant pressure boundary

b. The capability to shut down the reactor and maintain it in a safe shutdown condition; or

c. The capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures comparable to the applicable guideline exposures in 10 CFR 50.34(a)(1) or 10 CFR 100.11

The APR1400 SSCs that perform the above safety functions are classified as safety-related. The safety-related SSCs meet the quality assurance requirements of Appendix B of 10 CFR Part 50. SSCs that do not perform the above safety functions are classified as non-safety-related, and the requirements of 10 CFR Part 50, Appendix B, are not applied to these SSCs.

However, APR1400 SSCs that are important to safety but are not safety-related are additionally classified so that they are designed to the appropriate quality standards. The augmented quality assurance requirements for these SSCs, which are described in Chapter 17, are commensurate with the importance of their safety functions. The areas where these augmented quality controls are applied to SSCs important to safety are anticipated transient without scram (ATWS), station blackout, fire protection, seismic Category II SSCs, and risk-significant non-safety-related SSCs determined by the design reliability assurance program, which is described in Section 17.4.

This section provides the methodology that is used to classify APR1400 SSCs. Seismic classifications are described in Subsection 3.2.1, and quality group classifications are described in Subsection 3.2.2. The safety classifications are described in Subsection 3.2.3.
3.2.1 Seismic Classification

General Design Criterion (GDC) 2 (Reference 1) requires, in part, that nuclear power plant SSCs important to safety be designed to withstand the effects of earthquakes without loss of capability to perform their safety function. Plant features, including foundations and supports, that are designed to remain functional in the event of a safe shutdown earthquake (SSE) or surface deformation are designed as seismic Category I. These plant features are the features that are necessary to provide reasonable assurance of (1) the integrity of the reactor coolant pressure boundary (RCPB), (2) the capability to shut down the reactor and maintain it in a safe shutdown condition, or (3) the capability to prevent or mitigate the consequences of accidents that could result in potential offsite exposures comparable to the guideline exposures of 10 CFR 50.34(a)(1) and 10 CFR 52.79 or 10 CFR 100.11 (Reference 2).

The earthquake for which these plant features are designed is defined as the SSE in 10 CFR Part 100, Appendix A (Reference 3), and 10 CFR Part 50, Appendix S (Reference 4). The SSE is based on an evaluation of the maximum earthquake potential and produces the maximum vibratory ground motion for which SSCs important to safety are designed to remain functional.

The seismic classification used in APR1400 complies with the seismic criteria stated in NRC RG 1.29 to meet the requirements of both GDC 2 and 10 CFR Part 50, Appendix S. Radioactive waste management SSCs comply with the seismic design criteria specified in NRC RG 1.143 (Reference 6). Radioactive waste management SSCs are designed to meet the design basis loads including natural phenomena and internal/external man-induced hazard design criteria in accordance with NRC RG 1.143. Designing and constructing radioactive waste management SSCs to meet the requirements of GDC 61 and the guidance on seismic design and classification in NRC RG 1.143 provide reasonable assurance that SSCs that contain radioactivity are properly classified and that radiation exposure as a result of a seismic event will be as low as is reasonably achievable (ALARA). The radwaste safety classification is described in Table 3.2-1.

Instrument sensing lines and their supports are designed in accordance with the seismic design criteria of NRC RG 1.151 (Reference 7). Compliance with Positions C.2 and C.3 of NRC RG 1.151 provides reasonable assurance that the instrument sensing lines used to
actuate or monitor safety-related systems are appropriately classified and will be capable of withstanding the effects of the SSE.

Fire protection systems are designed in accordance with the seismic design criteria of NRC RG 1.189 (Reference 8). Compliance with Positions 3.2.1, 6.1.1.2, and 7.1 of NRC RG 1.189 provides reasonable assurance that the SSCs important to safety that are required to function during an SSE are properly classified as seismic Category I, will function during such events, and will provide reasonable assurance that the safety functions can be performed.

Seismic categories are designated as seismic Category I, II, or III.

The seismic categories of SSCs are listed in Table 3.2-1. The COL applicant is to identify the seismic classification of site-specific SSCs that are to be designed to withstand the effects of the SSE (COL 3.2(1)).

The seismic category portions of SSCs are indicated by the class breaks shown on the flow diagrams for the appropriate systems described in this DCD. Seismic Category I requirements extend to the first seismic anchor beyond the interface of the classification change. Supports for piping and components have the same seismic classifications as the piping and components that are supported.

Seismic Category I, II, and III SSCs are defined as follows:

a. Seismic Category I

SSCs that are important to safety and designed to remain functional in the event of an SSE are designated as seismic Category I.

The selection of seismic Category I SSCs is in accordance with the definition above and the guidance provided by NRC RG 1.29 (Reference 5). Seismic Category I components have a designated safety class in accordance with ANSI/ANS 51.1 (Reference 9; see Subsection 3.2.3). All components in Safety Classes 1, 2, and 3 are seismic Category I. The portions of SSCs that form an interface between seismic Category I and seismic Category II/III features are designed to seismic Category I requirements in accordance with Regulatory Position C.3 of NRC RG 1.29 (Reference 5). Seismic Category I design
requirements extend to the first seismic anchor (restraint) beyond the defined boundaries.

Portions of some non-safety-related systems (e.g., fire protection system) are classified as seismic Category I to conform with NRC RG 1.189.

Seismic Category I SSCs are designed to remain functional and within the applicable stress and deformation limits (elastic range of material properties) when subjected to the effects of the vibratory motion of the operating basis earthquake (OBE) in combination with normal operation loads. This design is based on the design for SSE loads where an OBE is defined as one third of the SSE, as described in Subsection 3.7.1. Seismic Category I structures are protected from interaction with adjacent non-seismic structures, as described in Subsection 3.7.2.8. The seismic classifications of platforms and miscellaneous steel located in seismic Category I application are described in Subsection 3.8.3.

Seismic Category I SSCs meet the pertinent QA requirements of 10 CFR Part 50, Appendix B (Reference 10). The criteria used for the design of seismic Category I SSCs are described in Section 3.7.

b. Seismic Category II

Seismic Category II applies to SSCs which do not perform safety-related function, and whose continued function is not required, but whose structural failure could reduce the functioning of a seismic Category I SSC to an unacceptable safety level or could result in incapacitating injury to occupants of the control room.

Seismic Category II SSCs are designed to preclude a gross structural failure resulting from an SSE that could degrade the ability of an adjacent safety-related SSC to function to an unacceptable level or result in incapacitating injuries to personnel in the main control room (MCR).

Seismic Category II SSCs meet the augmented quality assurance requirements for non-safety-related SSCs as described in Section 17.5.

c. Seismic Category III
All SSCs not covered by seismic Category I or II are classified as seismic Category III and are designed in accordance with industry codes and standards as applicable for their design function.

3.2.2 System Quality Group Classification

GDC 1 of 10 CFR Part 50 Appendix A (Reference 1) requires that nuclear power plant systems and components important to safety be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety function to be performed. Fluid systems and pressure-retaining components are part of the RCPB and other fluid systems that are important to safety. Such systems (1) prevent or mitigate the consequences of accidents and malfunctions originating in the RCPB, (2) permit shutdown of the reactor and maintain it in a safe shutdown condition, and (3) retain radioactive material.

NRC RG 1.26 (Reference 11) is the principal document that is used to identify, on a functional basis, the components of systems that are important to safety and that are in Quality Groups A, B, C, and D, which are defined below. ASME Section III, or Safety Class 1, components that are part of the RCPB are identified in 10 CFR 50.55a (Reference 12).

Systems and components are assigned to quality groups in accordance with the quality group classification system (NRC Quality Groups A, B, C or D) defined in NRC RG 1.26 (Reference 11), which was established for water-steam-containing components important to safety. Two other quality groups, E and G, are defined, in addition to those designated in NRC RG 1.26, to indicate the governing design codes for the components that are not covered under NRC Quality Groups A, B, C, or D.

The quality group classifications and codes and standards for mechanical and fluid systems and components are listed in Table 3.2-1 and are shown on the applicable flow diagrams. The flow diagrams identify the classification boundaries of interconnecting piping and valves, as well as the interfaces between the safety-related and non-safety-related portions of each system. The COL applicant is to identify the quality group classification of site-specific systems and components and their applicable codes and standards (COL 3.2(2)).

Quality Groups A through E and G are defined below.
Quality Group A

Quality Group A applies to the components that are part of the reactor coolant pressure boundary (RCPB), except for the portions that are included in Quality Group B below. This exclusion applies to components whose failure would not prevent the reactor from being shut down and cooled down in an orderly fashion with normal makeup and components that are or can be isolated from the reactor coolant system by two valves in series (with automatic closure of open valves).

Quality Group A water-, steam-, and radioactive-waste-containing components are designed to meet the requirements for Class 1 components in ASME Section III, Division I, NB.

Quality Group B

Quality Group B applies to water- and steam-containing components that support the systems or portions of systems listed in the regulatory position C.1 of NRC RG 1.26.

These systems or portions of systems are as follows:

a. Portions of the RCPB that are excluded from Quality Group A

b. Systems or portions of systems important to safety that are designed for the (i) emergency core cooling, (ii) post-accident containment heat removal, or (iii) post-accident fission product removal

c. Systems or portions of systems important to safety that are designed for (i) reactor shutdown or (ii) residual heat removal

d. Portions of the steam and feedwater systems of pressurized-water reactors extending from and including the secondary side of steam generators up to and including the outermost containment isolation valves, and connected piping up to and including the first valve (including a safety or relief valve) that is either normally closed or capable of automatic closure during all modes of normal reactor operation

e. Systems or portions of systems that are connected to the reactor coolant pressure boundary and are not capable of being isolated from the boundary during all modes of normal reactor operation by two valves, each of which is either normally closed or capable of automatic closure
Quality Group B water- and steam-containing components are designed to meet the requirements for Class 2 components in ASME Section III, Division I, NC and NG.

**Quality Group C**

Quality Group C applies to water-, steam-, and radioactive-waste-containing components that are not part of the reactor coolant pressure boundary or included in Quality Group B but part of the following:

a. Cooling water and auxiliary feedwater systems or portions of those systems important to safety that are designed for emergency core cooling, post-accident containment heat removal, post-accident containment atmosphere cleanup, or residual heat removal from the reactor and from the spent fuel storage pool

b. Cooling water and seal water systems or portions of those systems important to safety that are designed for the functioning of components and systems important to safety

c. Systems or portions of systems that are connected to the reactor coolant pressure boundary and are capable of being isolated from that boundary during all modes of normal reactor operation by two valves, each of which is either normally closed or capable of automatic closure

d. Systems, other than radioactive waste management systems, not covered by the above item a. through item c. that contain or may contain radioactive material and whose postulated failure would result in conservatively calculated potential offsite doses that exceed 0.5 rem to the whole body or its equivalent to any part of the body; only single component failures need be assumed for those systems located in Seismic Category I structures, and no credit should be taken for automatic isolation from other components in the system or for treatment of released material, unless the isolation or treatment capability is designed to the appropriate seismic and quality group standards and can withstand loss of offsite power and a single failure of an active component.

Quality Group C pressure retaining components are designed to meet the requirements for Class 3 components in ASME Section III, Division I, ND.
Quality Group D

Quality Group D applies to non-safety-related systems and components that are not covered under Quality Group A, B, or C and that are designed to ASME B31.1 (Reference 13) code criteria or other codes and standards listed in Table 1 of NRC RG 1.26. Quality Group D may include parts or portions of systems that contain or may contain radioactive material.

The radwaste management system and steam generator blowdown system (SGBS), which contain or may contain radioactive materials, are designed in accordance with applicable codes and standards, QA requirements, and guidance provided in NRC RG 1.143.

Quality Group E

Quality Group E pertains to non-safety-related fluid systems and components that are designed to codes other than ASME B31.1 code criteria and codes and standards listed in NRC RG 1.26.

Quality Group G

Quality Group G pertains to safety-related fluid systems and components that are designed to codes and standards other than those listed for Quality Group A, B and C in Table 1 of NRC RG 1.26.

3.2.3 Safety Class

Fluid system components important to safety are classified in accordance with ANSI/ANS 51.1 (Reference 9). Safety Class 1, 2, 3, and non-nuclear safety (NNS) of ANSI/ANS 51.1 are equivalent, on a functional basis, to Quality Groups A, B, C, D of NRC RG 1.26. The criteria establish safety classes that are used as a guide to the selection of codes, standards, and quality assurance provisions for the design and construction of the components. The safety class designations are also used as a guide to the fluid system components that are classified as seismic Category I and II (see Subsection 3.2.1).

The safety classification in ANSI/ANS 51.1 is summarized as follows:

a. Safety Class 1

Safety Class 1 (SC-1) applies to pressure-retaining portions and supports of mechanical equipment that form part of the RCPB whose failure could cause a
loss of reactor coolant in excess of the reactor coolant normal makeup capability and whose requirements are within the scope of the ASME Section III.

b. Safety Class 2

Safety Class 2 (SC-2) applies to pressure-retaining portions and supports of primary containment and other mechanical equipment, whose requirements are within the scope of the ASME Section III, which are not assigned to SC-1 but are relied on to accomplish the following safety functions:

1) Provide fission product barriers or primary containment radioactive material holdup or isolation

2) Provide emergency heat removal for the primary containment atmosphere to an intermediate heat sink, or emergency removal of radioactive material from the primary containment atmosphere (e.g., containment spray)

3) Introduce emergency negative reactivity to make the reactor subcritical (e.g., boron injection system), or restrict the addition of positive reactivity via pressure boundary equipment

4) Provide reasonable assurance of emergency core cooling where the equipment provides coolant directly to the core (e.g., residual heat removal, emergency core cooling)

5) Provide or maintain sufficient reactor coolant inventory for emergency core cooling

c. Safety Class 3

Safety Class 3 (SC-3) applies to equipment not included in SC-1 or SC-2 that is designed and relied on to accomplish the following safety functions:

1) Provide the functions defined in SC-2 where equipment, or portions thereof, is not within the scope of ASME Section III

2) Except for the primary containment boundary extension function, provide reasonable assurance of hydrogen concentration control of the primary containment atmosphere to acceptable limits
3) Remove radioactive material from the atmosphere of confined space outside primary containment (e.g., MCR, fuel building) containing SC-1, SC-2, or SC-3 equipment

4) Introduce negative reactivity to achieve or maintain subcritical reactor conditions (e.g., boron makeup)

5) Provide or maintain sufficient reactor coolant inventory for core cooling (e.g., reactor coolant normal makeup system)

6) Maintain geometry within the reactor to provide reasonable assurance of core reactivity control or core cooling capability (e.g., core support structures)

7) Structurally load-bear or protect SC-1, SC-2, or SC-3 equipment

8) Provide radiation shielding for the MCR or offsite personnel

9) Provide reasonable assurance of required cooling for liquid-cooled stored fuel (e.g., SFP and cooling system)

10) Provide reasonable assurance of nuclear safety functions provided by SC-1, SC-2, or SC-3 equipment (e.g., provide heat removal for SC-1, SC-2, or SC-3 heat exchangers, provide lubrication of SC-1, SC-2, or SC-3 pumps, provide fuel oil to emergency diesel engine)

11) Provide actuation or motive power for SC-1, SC-2, or SC-3 equipment

12) Provide information or controls to provide reasonable assurance of capability for manual or automatic actuation of nuclear safety functions required of SC-1, SC-2, or SC-3 equipment

13) Supply or process signals or supply power required for SC-1, SC-2, or SC-3 equipment to perform its required nuclear safety functions

14) Provide a manual or automatic interlock function to provide reasonable assurance that the proper performance of nuclear safety functions required of SC-1, SC-2, and SC-3 equipment is maintained
15) Provide an acceptable environment for SC-1, SC-2, or SC-3 equipment and operating personnel

d. Non-nuclear safety

Non-nuclear safety (NNS) applies to equipment or structures that are not included in SC-1, SC-2, or SC-3. These items are not relied on to perform a nuclear safety function.

All pressure-containing components in SC-1, SC-2, and SC-3 are designed, manufactured, and tested in accordance with the requirements of ASME Section III Code Class 1, 2, and 3, respectively. Components designated as NNS are designed and constructed with appropriate consideration of the intended service using applicable industry codes and standards. Table 3.2-2 shows the interrelationship and/or correspondence between the classifications.

The electrical equipment in SC-3 is in accordance with IEEE Std. 308 (Reference 14), IEEE Std. 603 (Reference 15), and applicable IEEE standards. The structures in SC-2 and SC-3 are in accordance with ASME Section III, Division 1, MC (Reference 16); ASME Section III, Division 2, CC (Reference 17); ACI-349 (Reference 18); and ANSI/AISC N690 (Reference 19).

The safety classification system is also used to identify the components that fall under the requirements of 10 CFR Part 50, Appendix B (Reference 10). Components in safety Classes 1, 2, and 3 are designed and manufactured under a rigorous quality assurance program reflecting the requirements of 10 CFR Part 50, Appendix B, and are designated as such in Table 3.2-1 in the column labeled 10 CFR Part 50, Appendix B. Components that do not serve a safety-related function are not subject to the quality assurance requirements of 10 CFR Part 50, Appendix B, and are designated as such in Table 3.2-1 in the column labeled 10 CFR Part 50, Appendix B.

Supports for piping and components have the same classification as the component or piping supported. Supports for APR1400 Quality Group A, B, and C mechanical components and piping are constructed to ASME Section III, Subsection NF requirements. The principal construction code for supports for non-safety-related components and piping is the same as that for the supported component or piping.
The safety classification systems described above meet the intent of NRC RG 1.26 and the requirements of 10 CFR 50.55a.

3.2.4 Classification Listings

Table 3.2-1 provides component classifications as defined in Subsections 3.2.1 through 3.2.3. Table 3.2-1 also provides the quality assurance requirements of 10 CFR Part 50, Appendix B, and the applicable codes and standards.

3.2.5 Combined License Information

COL 3.2(1) The COL applicant is to identify the seismic classification of site-specific SSCs that should be designed to withstand the effects of the SSE.

COL 3.2(2) The COL applicant is to identify the quality group classification of site-specific systems and components and their applicable codes and standards.

COL 3.2(3) The COL applicant is to provide the classification of structures, systems, and components for turbine generator building drain system.

112. DT - Turbine Generator Building Drain
The COL applicant is to provide the classification of structures, systems, and components for turbine generator building drain system (COL 3.2(3)).

(1) As used in this document, the term safety-related area applies to those areas containing equipment or structures required for safe shutdown (including accident mitigation).

(2) Locations are defined below:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

(3) Legend:

- **Yes** – Compliance with the requirements of 10 CFR Part 50, Appendix B, is required.
- **A** – Augmented quality assurance requirements of Appendix B to 10 CFR Part 50, is applied. Augmented quality controls are applied to the following areas:
  - (a) ATWS (Anticipated Transient without Scram)
  - (b) Station Blackout
  - (c) Fire Protection
  - (d) Seismic Category II SSCs, external injection provision to cope with severe accident
  - (e) Risk significant non-safety-related SSCs determined by design RAP
- **N/A** – The requirements of 10 CFR Part 50, Appendix B, are not required.
Table 3.2-1 (85 of 86)

(4) Designed in accordance with NRC RG 1.143. The radwaste facilities, including the structures, systems, and components, are designed to meet the design basis loads, including the natural phenomena and internal and/or external man-induced hazards design criteria, in accordance with NRC RG 1.143.

- The radwaste safety classifications for the radioactive waste management systems: LWMS, GWMS, SWMS, and the SGBD systems and components, are presented in Sections 11.2, 11.3, 11.4, and 10.4.8, respectively.
- The radwaste safety classification for the compound building and the auxiliary building, in which the radioactive waste management systems (LWMS, GWMS, and SWMS) and the components for the SGBD system are housed respectively, is RW-IIa in accordance with the guidance in NRC RG 1.143.

(5) Designed based on guidance contained in NRC NUREG-0696 and NUREG-0737, Supplement 1.

(6) Security system requirements per 10 CFR Part 73.

(7) NRC RG 1.97 endorses IEEE Std. 497 as an acceptable method for providing instrumentation to monitor variables for accident conditions, subject to the 5 NRC positions. Instrumentation meets qualification and quality requirements of NRC RG 1.97 and IEEE Std. 497.

(8) Guidance per NUREG-0718 and NRC RG 1.47.

(9) Earthquake monitoring is per NRC RG 1.12.

(10) Design guidance per NRC RG 1.13.

(11) Design guidance per NRC RG 1.13, NUREG-0554, and NUREG-0612.

(12) Design guidance per NRC RG 1.189.

(13) The entire crane, including the bridge and trolley, is designed and constructed in accordance with NRC RG 1.29.

(14) Non-safety-related diverse protection system per 10 CFR 50.62 and GL 85-06.

(15) Non-safety-related ACUs and components, including fan/motor and associated isolation dampers, are designed and constructed per NRC RG 1.140.

(16) Design guidance per NRC RG 1.45.

(17) These codes and standards are applied to requirements of interface design.
NSSS Notes:

(N-1) Two safety classes are used for heat exchangers to distinguish primary and secondary sides where they are different.
(N-2) All of the reactor internals are classified as seismic Category I.
(N-3) The reactor coolant pump (RCP) auxiliaries are not required to be classified as seismic Category I because 1) continuous operation of the pumps is not required during or following an SSE and 2) sufficient time is available (i.e., >30 minutes) for the operator to stop the RCPs before loss of the RCP auxiliaries would cause any damage to the RCPs (see CENPD-201-A).
(N-4) Only those structural portions of the RCPs that comprise the RCPB and, therefore, support the safety function of the integrity of the RCPB must be categorized as Safety Class I.
(N-5) Safety classes of piping within the RCPB (as defined in 10 CFR 50) are selected in accordance with the ANSI/ANS 51.1 criteria. Safety Classes 1, 2, 3 and Non-Nuclear Safety of ANSI/ANS 51.1 are equivalent to Quality Groups A, B, C, and D of NRC RG 1.26, respectively.
(N-6) Flow-restricting orifices are provided in the nozzles for the RCS sampling lines, the pressurizer (PZR) level and pressure instruments, the RCP differential pressure instrument lines, the common SI header pressure instrument lines, the RCP seal pressure instrument lines, the charging line differential pressure instrument line, and the SI hot leg injection pressure instrument lines to limit flow in the event of a downstream break of a nozzle. The orifice size, 5.55 mm (7/32 in.) diameter x 25.4 mm (1 in.) long, precludes exceeding fuel design limits while using minimum makeup rates. This permits orderly shutdown in the event of a downstream break in accordance with 10 CFR Part 50, Appendix A, GDC 33. A reduction may therefore be made in the classification of downstream lines of the orifice.
(N-7) All containment isolation valves (and their operators) within NSSS scope of supply including manual valves, check valves, and relief valves, which also serve as isolation valves, are subject to the pertinent requirements of the Quality Assurance Program.
(N-8) The POSRVs are used for overpressure protection and rapid depressurization function.
(N-9) The “Associated Circuits” are defined, in accordance with IEEE Std. 384, as equipment, components, or systems the functions of which are Non-Nuclear Safety (NNS) and electrically Non-Class 1E, though their failures or abnormal states can affect the Class 1E equipment, components, or systems due to the effects of less than the minimum separation or the absence of electrical isolation from the Class 1E equipment, components, or systems. Consequently, the equipment, components, or systems, which are defined as “Associated Circuits” although they are functionally Non-Nuclear Safety, are subject to the qualification requirements placed on Class 1E equipment, components, or systems.
(N-10) Codes and standards are not specified because CEDM motor assembly and extension shaft assembly are neither pressure boundary components nor electric component. Safety function of those components is limited to scramability.

(1) Seismic Category I items that are not safety-related but are required by regulatory requirements to be designed for seismic loads are Quality Group D or E (e.g., portions of fire protection system).
3.3 Wind and Tornado Loadings

All seismic Category I and II structures, systems, and components (SSCs), except those not exposed to wind, are designed for wind and tornado/hurricane loadings.

3.3.1 Wind Loadings

The design wind loadings on the surfaces of seismic Category I and II SSCs subject to wind are determined in accordance with ASCE/SEI 7-05 (Reference 1).

Load combinations including wind loads are discussed in Section 3.8.

3.3.1.1 Design Wind Velocity and Recurrence Interval

The 50-year 3-second wind gust speed of 64.8 m/s (145 mph) corresponds to the wind speed at 10 m (33 ft) above ground for exposure Category C (open terrain), as defined in Section 6.5.6.3 of ASCE/SEI 7-05 (Reference 1). A recurrence interval of the design wind speed is 50 years with a 0.02 annual probability of being exceeded.

The design wind speed specified for the APR1400 standard plant covers most of the contiguous United States based on the basic wind speed map provided in Figure 6-1 of ASCE/SEI 7-05 (Reference 1).

The COL applicant is to demonstrate that the site-specific design wind speed is bounded by the design wind speed of 64.8 m/s (145 mph) (COL 3.3(1)).

3.3.1.2 Determination of Applied Forces

Wind pressure on the surfaces of the seismic Category I and II SSCs is determined in accordance with Equation (6-15) of ASCE/SEI 7-05 (Reference 1). The wind directionality factor ($K_d$), velocity pressure exposure coefficient ($K_z$), and topographic factor ($K_{zt}$) are defined in SRP 3.3.1 and conform with the provisions of SRP 3.3.1. For seismic Category I and II SSCs, an importance factor (I) of 1.15 is used in order to be compatible with the recurrence interval of 100 years. Exposure category D is applied in determining wind loads regardless of the site location.

Wind forces on the surfaces of seismic Category I and II structures, which are classified as enclosed or partially enclosed structures, are determined in accordance with the equation (6-17) of ASCE/SEI 7-05 (Reference 1).
All non-safety-related facilities subject to winds are designed using the same design wind speed and methodology applied to seismic Category I SSCs except the load combinations. A wind-loading-caused full or partial failure of seismic Category II SSCs adjacent to seismic Category I SSCs does not affect the ability of the seismic Category I SSCs to perform their intended safety functions. Otherwise, the seismic Category I SSCs are designed to maintain their integrity from the failure of seismic Category II SSCs.

The COL applicant is to demonstrate that the site-specific seismic Category II structures adjacent to the seismic Category I structures are designed to meet the provisions described above (COL 3.3(2)).

3.3.2 Tornado Loadings

The APR1400 standard and site-specific plant is designed to protect SSCs listed in the Appendix to NRC Regulatory Guide (RG) 1.117 (Reference 2) from tornadoes and hurricanes. All seismic Category I and II SSCs subject to tornado and hurricane winds are designed to meet the acceptance criteria described in Section 3.8.

3.3.2.1 Applicable Design Parameters

As provided in Table 2.0-1, the design basis tornado parameters are the same as those of Region I and categorized in NRC RG 1.76 (Reference 3). The annual probability of exceedance of the design basis tornado described above is $10^{-7}$, and the corresponding recurrence interval is approximately 10 million years.

The maximum wind speed of design basis hurricane is 116 m/s (260 mph) from the wind speed contour maps for hurricane-prone regions of the contiguous United States presented in NRC RG 1.221 (Reference 4). The annual probability of exceedance of the design basis hurricane is $10^{-7}$. The wind speed is nominal 3-second peak gust at a height of 10 m (33 ft) in flat open terrain.

The seismic Category I and II SSCs subject to extreme winds such as the design basis tornado or design basis hurricane are designed individually for the postulated extreme winds enveloping both the design basis tornado and design basis hurricane in terms of straight winds and wind-borne missiles. The pressure drop effects due only to the design basis tornado are combined with the design basis hurricane loadings, as described in Subsection 3.3.2.2.4.
The COL applicant is to perform an analysis if the site-specific wind and tornado/hurricane characteristics are not bounded by the site parameter postulated for the certified design (COL 3.3(3)).

3.3.2.2 Determination of Forces on Structures

The forces on seismic Category I and II SSCs due to the postulated extreme winds are obtained using methods outlined in Subsection 3.3.1.2. The missile barriers of the seismic Category I structures are designed based on the missiles listed in Table 3.5-2. The design method of missile barriers is presented in Subsection 3.5.3. The pressure drop effects due to the design basis tornado are determined using the guidance provided by Simiu and Scanlan (Reference 5). The loading combinations associated with the postulated extreme wind loadings are described in Tables 3.8-2, 3.8-7A, and 3.8-7B.

3.3.2.2.1 Hurricane Velocity Forces

Velocity forces due to the postulated extreme winds are determined using the approach described in Subsection 3.3.1.2 in conjunction with an importance factor (I) of 1.15 in accordance with SRP 3.3.2.

3.3.2.2.2 Hurricane Missile Effects

The missile barriers of seismic Category I structures are designed in accordance with the missile spectrum identified in Table 3.5-2. The missile barriers are designed to prevent the penetration, perforation, and withstand scabbing effects due to the hurricane missiles, as described in Subsection 3.5.3.

3.3.2.2.3 Tornado Pressure Drops

Pressure drop effects during the design basis tornado are evaluated based on the enclosure category of seismic Category I and II SSCs, as applicable. Vented or partially enclosed and enclosed buildings are designed to withstand the pressure drop while pressure drop effects are not considered in the interior of unvented structures.

3.3.2.2.4 Combined Extreme Wind Effects

The loading combinations of the individual extreme wind loading components are in accordance with SRP 3.3.2. The total extreme wind load W, used in the load combinations
described in Section 3.8 is determined for the combined effects using the following relationships:

\[
W_t = W_w \\
W_t = W_p \\
W_t = W_m \\
W_t = W_w + 0.5 W_p \\
W_t = W_w + W_m \\
W_t = W_w + 0.5 W_p + W_m 
\]

Where:

\[
W_t = \text{total extreme wind load} \\
W_w = \text{load from hurricane wind effect} \\
W_p = \text{load from tornado atmospheric pressure change effect} \\
W_m = \text{load from hurricane missile impact effect} 
\]

Pressure drop effects due only to the design basis tornado are combined with the design basis hurricane loadings.

3.3.2.3 Effect of Failure of Structures or Components Not Designed for Extreme Wind Loads

Failure of any SSCs not designed for postulated extreme wind loads does not affect the capability of safety-related SSCs to perform their intended safety functions.

The non-safety-related SSCs not designed for extreme wind loads are evaluated and designed using one of the following methods:

a. Designing the SSCs adjacent to seismic Category I SSCs to wind, and tornado/hurricane loadings
b. Investigating the effect of adjacent structural failure on seismic Category I SSCs to provide reasonable assurance that the ability of the seismic Category I SSCs to perform their intended safety functions is not impacted or affected

c. Designing and providing a structural barrier to protect seismic Category I SSCs from adjacent structural failure

The COL applicant is to provide reasonable assurance that site-specific structures and components not designed for the extreme wind loads do not impact either the function or integrity of adjacent seismic Category I SSCs (COL 3.3(4)).

3.3.3 Combined License Information

COL 3.3(1) The COL applicant is to demonstrate that the site-specific design wind speed is bounded by the design wind speed of 64.8 m/s (145 mph).

COL 3.3(2) The COL applicant is to demonstrate that the site-specific seismic Category II structures adjacent to the seismic Category I structures are designed to meet the provisions described in Subsection 3.3.1.2.

COL 3.3(3) The COL applicant is to perform an analysis if the site-specific wind and tornado/hurricane characteristics are not bounded by the site parameter postulated for the certified design.

COL 3.3(4) The COL applicant is to provide reasonable assurance that site-specific structures and components not designed for the extreme wind loads do not impact either the function or integrity of adjacent seismic Category I SSCs.

3.3.4 References

3.4 Water Level (Flood) Design

All seismic Category I structures, systems, and components (SSCs) are designed to withstand the effects of flooding due to natural phenomena or onsite equipment failures without loss of the capability to perform their safety-related functions.

The potential causes of external flooding include probable maximum precipitation, potential dam failures, and high groundwater and outdoor tank failures, and extreme sea waves such as storm surges, seiches, tsunamis, high tides, etc., as described in Section 2.4.

This analysis includes a site description and elevations of safety-related structures and equipment; evaluations of penetrations in seismic Category I structures; and the effects of flooding due to postulated pipe failures, inadvertent operation of fire protection systems, and failures of non-seismic and non-high-wind (including tornado and hurricane) protected tanks, vessels, and piping.

3.4.1 Flood Protection and Evaluation

3.4.1.1 Design Bases

The design basis flood level at the reactor site will be determined in accordance with NRC RG 1.59 (Reference 1) and ANSI/ANS 2.8 (Reference 2). Because the design basis flood level of the APR1400 standard design is at least 0.3 m (1 ft) below the plant grade as specified in Table 2.0-1, all safety-related SSCs located on the dry site as defined in NRC RG 1.102 (Reference 3) are protected from an external flood event.

The COL applicant is to provide the site-specific design of plant grading and drainage (COL 3.4(1)).

The COL applicant is to provide site-specific information on protection measures for the design basis flood, such levees, seawalls, flood walls, revetments or breakwaters or site bulkheads pursuant to NRC RG 1.102 as described in Subsection 2.4.10 (COL 3.4(2)).

All seismic Category I structures are designed to withstand the static and dynamic forces due to the maximum groundwater level, which is 0.61 m (2 ft) below the plant grade as provided in Table 2.0-1.
3.4.1.2 Flood Protection from External Sources

The flood protection measures for seismic Category I SSCs are designed in accordance with NRC RG 1.102 (Reference 3).

Seismic Category I structures identified in Table 3.2-1 are designed for flood protection. Seismic Category I structures are designed to protect safety-related equipment from flooding by incorporating the following safeguards into their construction:

a. No exterior access openings are lower than 0.41 m (1 ft 4 in.) above plant grade (yard grade) elevation.

b. The finished yard grade adjacent to the safety-related structures is maintained at least 0.41 m (1 ft 4 in.) below the ground floor elevation, except where ramps or steps are provided for access.

c. Waterstops are used in all horizontal and vertical construction joints in all exterior walls up to flood-level elevation.

d. Water seals are provided for all penetrations in exterior walls up to flood-level elevation. The water seals are designed for the static pressure of water at the flood elevation. Water seals in safety-related structures are designed to maintain integrity in the event of an SSE.

e. All below-grade exterior walls and basemats of seismic Category I structures are thickened by more than or equal to 0.6 m (2 ft) to protect against water seepage, as required in SRP 14.3.2.

Penetrations below the external flood level in the external walls of the auxiliary building include component cooling water, radwaste, and diesel fuel oil system piping and cable penetrations. Additional penetrations may be identified when layouts are finalized for systems such as sewage, demineralized water, station air, and security. All penetrations are sealed on the inside of the penetration to eliminate the potential of flooding through the penetration. The penetration seals are periodically inspected to ensure their functionality.
3.4.1.3 Flood Protection from Internal Sources

The APR1400 arrangement provides physical separation of redundant safety-related SSCs. The flood protection mechanisms related to minimizing the consequences of internal flooding include the following:

a. Structural enclosures or barrier walls

b. Drainage systems

c. Emergency sump

d. Internal curbs or ramps

e. Watertight doors

The APR1400 minimizes penetrations through enclosures or barrier walls below the flood level. Enclosures and barrier walls below the flood level are sealed to maintain watertightness. Barrier walls, floors, and penetrations are designed to withstand the maximum anticipated hydrodynamic loads associated with a pipe failure, as described in Section 3.6.

Divisional and quadrant separation by flood barriers with watertightness is provided for internal flood protection. Each quadrant is protected against propagation of internal flood event from one quadrant to any other.

The floor drainage systems are separated by quadrants with no common drain lines between the quadrants. Floors are gently sloped to allow for good drainage to the quadrant sumps. The functional capability of equipment and floor drainage system is maintained because the piping of the drainage system is designed as seismic Category II and embedded into the concrete of seismic Category I structures such as reactor containment building and auxiliary building.

The COL applicant is to establish procedures and programmatic controls to ensure the availability of the floor drainage (COL 3.4(3)).

The vertical and horizontal Emergency Overflow Lines (EOLs) are used to provide flow paths for the draining of flooded water, in addition to floor drains, as one of the flood mitigation measures. EOLs are the embedded pipes that connect rooms. EOLs are
seismically designed as seismic Category II. The sizes of the EOLs are determined based on the combination of available number of floor drains and required flow area needed to support drainage of the flooded water volume.

The lowest spaces of each building are designed as an emergency sump to keep flood water within the building where a flooding event could occur. The emergency sump is large enough to accommodate the volume of limiting flooding source.

Additionally, curbs or ramps and sealed penetrations function as flood barriers. Safety-related equipment and components are located at higher elevations so flooding events do not affect them.

Watertight doors are used for internal flood protection. Watertight doors are specified to withstand the static pressure from the maximum flood elevation as determined in the flooding analysis. Sensor signals of sensors to indicate the status of open and close of the watertight doors are provided to the main control room. The COL applicant is to periodically inspect watertight doors and the penetration seals to ensure their functionality (COL 3.4(4)).

The areas of concern in APR1400 are as follows:

a. Reactor containment building

The reactor containment building systems to be protected from flooding are the reactor coolant system (RCS), safety injection system (SIS), reactor coolant gas vent system (RCGVS), feedwater system (FWS), auxiliary feedwater system (AFWS), shutdown cooling system (SCS), component cooling water system (CCWS), and main steam system (MSS). The components to be protected from flooding are the valves and electric instrumentation of these systems.

b. Auxiliary building

The auxiliary building systems to be protected from flooding are the SIS, shutdown cooling system (SCS), chemical and volume control system (CVCS), containment spray system (CSS), auxiliary feedwater system (AFWS), and component cooling water system (CCWS). The components to be protected from flooding are the motor-driven pumps, valves, electrical equipment and instruments, Class 1E electric/instrumentation components, and cubicle coolers in the relevant system.
c. Emergency diesel generator building

The systems in the emergency diesel generator building to be protected from flooding are Class 1E emergency diesel generator system, and the emergency diesel generator fuel oil storage and transfer system. The components to be protected from flooding are diesel generator, diesel fuel oil transfer pump, and exhaust fan.

d. Site-specific safety structures

The COL applicant is to provide flooding analysis with flood protection and mitigation features from internal flooding for the CCW Heat Exchanger Building and ESW Building (COL 3.4(5)).

Tables 3.4-1 and 3.4-2 provide the locations of safety-related SSCs and a comparison of the maximum internal flood elevation in the vicinity of the components. Figures 3.4-1 through 3.4-7 provide the locations of watertight doors and flood barriers in the auxiliary building.

3.4.1.4 Evaluation of External Flooding

External flooding is evaluated based on flooding sources such as natural phenomena and the failure of onsite tanks or large buried pipes. The failure of non-safety-related onsite tanks such as condensate storage facilities (CSF) could result in a potential flood source. However, onsite tanks are located in the tank yard that is an adequate distance from safety-related structures, and watertight doors are installed at the exterior entrances located on the ground level of safety-related structures to prevent inflow of external flooding. Therefore, a non-safety-related tank failure does not result in adverse effects to safety-related SSCs. The maximum water level and flow velocity of an individual flood event are determined to estimate flood loads on seismic Category I structures and the watertightness of the structures during an external flood event. Seismic Category I structures are designed for the design basis flood level and the maximum groundwater level defined in Table 2.0-1.

The COL applicant is to provide the site-specific flooding hazards from engineered features, such as water tank collapsing, water piping breaking, etc. (COL 3.4(6)).
The COL applicant is to confirm that the potential site-specific external flooding events are bounded by design basis flood values or otherwise demonstrate that the design is acceptable (COL 3.4(7)).

No permanent dewatering systems are necessary to maintain safe and acceptable groundwater levels.

The COL applicant is to provide the site-specific dewatering system if the plant is built below the design basis flood level (COL 3.4(8)).

3.4.1.5 Evaluation of Internal Flooding

The internal flooding analysis demonstrates that plant nuclear safety functions are protected from the effects of internal flooding that are the result of a postulated failure or operation of the plant fire protection system. The safety-related SSCs included in Table 3.2-1 are protected against an internal flood. Potential flooding sources are as follows:

a. High- and moderate-energy piping failures

b. Full-circumferential ruptures in non-seismic moderate-energy piping

c. Postulated failures of non-seismic and non-tornado/hurricane-protected tanks and vessels

d. Pump mechanical seal failures

e. Operation of the fire protection system

Criteria and assumptions described in Subsection 3.6.2 are used for the internal flooding analysis. Subsection 3.6.2 provides the criteria used to define break and crack locations and configurations for high- and moderate-energy piping failures.

For flooding analysis, the single worst-case piping rupture for non-seismically analyzed piping is assumed for each analyzed area. Also, only one break at a time is postulated for non-seismic Category I or II piping as the result of a seismic event in the internal flooding analysis. All piping inside the reactor containment building and auxiliary building are seismically designed. Therefore, no breaks are postulated during a seismic event in these buildings. The discharge volume through the ruptured area is calculated in accordance with the formula given in ANSI/ANS 56.10, Section 3 (Reference 4). The released steam...
flow rate is conservatively assumed to be completely condensed to result in a higher flood level.

The discharge flow rate from a high-energy line break is obtained by one of the following critical flow correlations.

a. Moody model for two-phase mixture and saturated steam conditions

b. Henry-Fauske model for subcooled liquid

A LOCA that results in the largest discharge volume to the reactor containment is assumed as a flooding source in the flooding analysis of reactor containment building. The flood level of the reactor containment building is determined by dividing the accumulated volume by the total floodable area at El. 100 ft 0 in. For conservatism, the entire released volume is taken to accumulate at El. 100 ft of containment with no drainage to the HVT at a lower elevation before recirculation mode, although fluid flow to the lower elevation will actually be established when broken flow arrives at the openings to the lower elevation.

In the long term cooling period, during recirculation mode with containment spray from IRWST, the inflow of water onto El. 100 ft of containment consists of ECCS (SI and CS) injection flow from the IRWST with an outflow to the HVT and discharging back into the IRWST through spillways. The outflow to the IRWST through spillways is determined by using the general equation for pressure drop, Darcy’s formula.

Fire hose stations that could reach the area or zone where a fire occurs are contributed to internal flooding sources when a fire occurs. The discharge flow rate from fire hose stations is assumed to be 0.044 m$^3$/s (700 gpm).

The lowest level of the auxiliary building is designed to function as an emergency sump to collect flooding sources when a flood event occurs. The flood level of the emergency sump is determined by dividing the maximum volume of flooding sources by the floodable area of the emergency sump. The flood level, except for the lowest elevation, is determined based on the level established by the difference between the inflow rate of the postulated flooding source and the outflow rate through drains or openings in steady-state condition.

Fluid flow rates through stairwells, floor openings, and under door gaps are determined in accordance with the formulae given in ANSI 56.11 (Reference 5). The fluid flow rate through a stairwell or a floor opening is calculated using equation 5.2-1, and the flow rate
under a door is calculated using equation 5.2-3 in Reference 5. It is assumed that the total inventory of the IRWST and SI tanks are spilled out. The total water volume in the IRWST is considered as a limiting flood source in auxiliary building only as a result of a pipe rupture. No credit is taken for operation of sump pumps to mitigate the flooding consequences.

The internal flooding analysis is performed on a floor-by-floor and room-by-room basis.

Flooding analysis consists of the following steps:

a. Identification of safety-related SSCs
b. Identification of potential flooding sources
c. Determination of flow rates and flood levels
d. Risk assessment for components affected by a flood event
e. Determination of the need for protection and mitigation measures

3.4.1.5.1 Reactor Containment Building

The APR1400 is designed to accommodate the effects of, and to be compatible with, the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including LOCA's.

The reactor containment building is not designed to provide divisional separation but it allows flooding sources to flow to the lowest level of the building i.e., containment annulus area at El. 100 ft 0 in. through the floor openings and stairwells.

a. Water at El. 156 ft 0 in. flows to the lower elevation through four reactor containment fan cooler duct openings, two stairwells, and four safety injection tank openings.

b. Water at El. 136 ft 6 in. flows to the lower elevation through the grating on this floor. Water in the pressurizer cavity flows to the containment annulus area through the wire mesh door.
c. Water at El. 114 ft 0 in. flows to the lower elevation through the grating on this floor. Water in each valve room flows to the containment annulus area through the wire mesh door.

d. Water collected at El. 100 ft 0 in. flows to the holdup volume tank through the floor opening and then to the IRWST through the spillway. Water in the letdown heat exchanger room and reactor drain tank room flows to the containment annulus area through the wire mesh door.

The worst-case flooding event is a LOCA in reactor containment building because it results in maximum flood water volume to the reactor containment building as a flooding source. The water volume of bounding case is 109,197 ft³ which is summation of total discharged water volume from a LOCA (19,482 ft³) and the recirculation mode with IRWST water volume (89,715 ft³). There are flooding sources inside the reactor containment building such as reactor coolant system, main feedwater, auxiliary feedwater, component cooling water, fire protection and chemical and volume control systems.

The flooding source of an AF tank does not gravity discharge into the reactor containment building since the location of the piping is higher than the top level of the AF Tank.

The discharged water volume from the FW system during the isolation time by safety-related main feedwater isolation valve and the volume of AF makeup flow to steam generator are less than the volume of water from a LOCA in recirculation mode. For the FW line break evaluation, the transient water level is evaluated using a time history approach to determine the flood height and takes a credit of the flow path from the floor opening at El. 100 ft of RCB. Based on the sensitivity analysis, the flood level resulting from a postulated FW line break remains below El. 102 ft.

The water volume of FP system is isolated with flood protection measures including operator action. It has sufficient time for operators to identify and isolate the fire protection system in a flooding event. Non-seismically designed pipes are excluded as flood sources because all piping inside the reactor containment building is seismically designed. Operator action is credited for identification and isolation of flood sources that could result in larger volumes to containment than a worst case LOCA.

Discharged water first fills up the volume below elevation El. 100 ft 0 in. and then spreads the volume above the grade level of the reactor containment building. Water released by a
LOCA is collected in the IRWST through the spillways between HVT and IRWST. It then flows back to the reactor coolant system or is sprayed into the containment and recirculated.

The total discharged volume of a LOCA is 551.67 m$^3$ (19,482 ft$^3$) which consists of volume for reactor coolant system and four safety injection tanks described in Table 6.2.1-20 and Table 6.2.1-21. The net floodable volume under El. 100 ft 0 in., including volume of air space of IRWST 753 m$^3$ (26,592 ft$^3$), holdup volume tank 242.3 m$^3$ (8,557 ft$^3$), and normal sump 6.7 m$^3$ (237 ft$^3$) is 1,002 m$^3$ (35,385 ft$^3$). The total discharged water volume due to LOCA is smaller than the total floodable volume.

The flood level of the bottom area of the reactor containment building with total water volume of LOCA is determined to be 0.61 m (2 ft) from the El. 100 ft 0 in. The maximum containment flood level is determined by dividing total LOCA volume by floodable area 11,215 ft$^2$ of El. 100 ft. For LOCA evaluation, the analysis conservatively assumes that the break volume is discharged to containment with no loss of volume through the floor openings at El. 100 ft of the RCB prior to recirculation. The resulting containment flood level has been determined to be an additional 0.61 m (2 ft) to El. 102 ft. In the long term period with the containment water level at El. 102 ft, the outflow into the IRWST through two 24 inch spillways is greater than the inflow from SI and CS pumps into containment. The flood height decreases during the recirculation period, and, therefore, the flood water level remains less than the determined level of 0.61 m (2 ft) established before recirculation period. It envelops all flood levels throughout the entire containment area at El. 100 ft 0 in. The flood levels in the separately compartmentalized areas located above the bottom and annulus area are independently determined by taking account of flows in and out of these areas. The maximum flood level of containment does not affect safety-related equipment. There are no submerged SSCs required for safe shutdown. Table 3.4-1 provides a list and the locations of SSCs inside the reactor containment building that require flood protection. These SSCs are located above the maximum internal flood level.

**3.4.1.5.2 Auxiliary Building**

The auxiliary building is designed to provide physical separation to prevent spreading of fluids to the areas housing safety-related equipment and components.

**Elevation 55 ft 0 in**

The primary means of flood protection is the divisional or quadrant walls, which serve as flood barriers between redundant trains of safe shutdown systems and components. Flood
barriers provide separation between the quadrants, while maintaining equipment removal capability.

On the divisional wall, penetrations are sealed and no doors are provided up to El. 64 ft 0 in., which is the potential flood level from the bottom elevation. The heights of the divisional walls at El. 55 ft 0 in. are 13 ft (El. 68 ft 0 in.) as shown in Figures 1.2-11 and 1.2-12. The divisional walls are sufficiently high to contain total water volume in the affected quadrant. Watertight doors are provided between the quadrants to prevent potential flooding sources from spreading to adjacent quadrants.

The equipment to be protected at El. 55 ft 0 in. includes SI pumps, SC/CS pumps, heat exchangers, and CCW pumps. In each quadrant, the SI pump rooms, SC/CS pump rooms, and CCW pump rooms are separated by a flood barrier.

The following potential flooding sources are considered:

a. A postulated pipe failure is considered in only one area of the quadrant. During normal operation, a 0.25 m (10 in.) pipe crack in the SIS suction line from the IRWST is considered a potential flooding source.

b. There is no break in non-seismic moderate-energy piping because piping in the auxiliary building is designed as seismic Category I or II.

c. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate for firefighting equipment is assumed to be 0.044 m$^3$/s (700 gpm).

The worst case of flooding in the auxiliary building is the water source in the IRWST. The total water volume of the IRWST is 2,540 m$^3$ (89,715 ft$^3$) and the floodable area in the four quadrants (A, B, C, and D) is 1,168 m$^2$ (12,577 ft$^2$), 1,176 m$^2$ (12,664 ft$^2$), 1,232 m$^2$ (13,263 ft$^2$), and 1,232 m$^2$ (13,263 ft$^2$), respectively.

Based on these values, the maximum water level is 2.74 m (9 ft) with some margin. The released water volume is contained within the affected quadrant.

Elevation 78 ft 0 in

Flood water above El. 78 ft 0 in. drains to the lower elevation through the floor drain, stairwells, and openings. To avoid flooding adjacent quadrants, a curb or ramp is installed.
at each quadrant intersection. The emergency diesel generator is separated by distance and flood barriers. Radiation-control areas are also separated by flood barriers. A watertight door is provided to prevent spreading of flooding water through the potential flow path from the boric acid storage tank (BAST) tunnel to the auxiliary building.

The equipment to be protected from flooding at El. 78 ft 0 in. includes motor-driven AF pumps, turbine-driven AF pumps, Class 1E switchgear, essential chiller, and related electrical equipment. The turbine-driven AF pump and motor-driven AF pump are separated by a quadrant flood barrier.

The following potential flooding sources are considered:

a. A postulated pipe failure of a moderate-energy line is considered.

b. A high-energy line break event is not considered because there is no piping break in this area.

c. A break in non-seismic moderate-energy piping break is not considered because piping in the auxiliary building is designed as seismic Category I or II.

d. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate for firefighting equipment is assumed to be 0.044 m³/s (700 gpm).

The worst-case flooding scenario is a postulated pipe failure of a 0.10 m (4 in.) AF moderate-energy line in normal operation, during which flood water would drain to lower elevations through the drain system and openings. The potential flood level at this elevation is assumed as 0.15 m (6 in.).

AF pumps are located above the potential internal flood levels. Pressure door protection is provided for the turbine-driven auxiliary feedwater pump room to further protect these pumps and the adjacent motor-driven pumps from the impact of pipe ruptures. Electrical equipment is installed above the flood level so that flooding events do not affect this equipment. Therefore, AF pumps and electrical equipment are not flooded.

**Elevation 100 ft 0 in**

Flood water above El. 100 ft 0 in. drains to the lower elevation through floor drains, stairwells, and openings. To avoid flooding adjacent quadrants, a curb or ramp is installed
at each quadrant intersection. The emergency diesel generator is separated by distance and protected by flood barriers. The radiation control area is also separated by flood barriers. Watertight doors are installed to prevent spreading of flood water through the potential flow path from the compound building to the auxiliary building.

The equipment to be protected from flooding at El. 100 ft 0 in includes the 480V Class 1E motor control center, electrical equipment, and related cubicle coolers.

The following potential flooding sources are considered:

a. Postulated pipe failure of a moderate-energy line is considered.

b. A high-energy line break event is not considered because there is no piping break in this area.

c. There is no break of non-seismic moderate-energy piping because piping in auxiliary building is designed as seismic Category I or II.

d. The total water inventory of the volume control tank is considered a flooding source at quadrant A.

e. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate for firefighting equipment is assumed to be 0.044 m$^3$/s (700 gpm).

Based on flooding sources, the worst-case flooding scenario is postulated failure of a 0.36 m (14 in.) component cooling line in the general access area, during which flood water would drain to lower elevations through the drain system and openings. The potential flood level at this elevation is assumed as 0.15 m (6 in.).

The safety-related equipment and components are elevated above the flood level so that flooding events do not affect components. Therefore, the electrical equipment and related cubicle cooler are not flooded.

**Elevation 120 ft 0 in**

Flood water above El. 120 ft 0 in. drains to the lower elevation through floor drains, stairwells, and openings. To avoid flooding adjacent quadrants, a curb or ramp is installed at each quadrant intersection. The emergency diesel generator is separated by distance
and protected by flood barriers. The radiation control area is also separated by flood barriers.

The equipment to be protected from flooding at El. 120 ft 0 in includes the Class 1E motor control center, related cubicle coolers, safety injection containment isolation valves, and AF modulating valves.

The following potential flooding sources are considered:

a. A postulated pipe failure of a moderate-energy line is considered.

b. A high-energy line break is considered for the 0.10 m (4 in.) steam generator blowdown system line.

c. There is no break of non-seismic moderate-energy piping because piping in the auxiliary building is designed as seismic Category I or II.

d. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate for firefighting equipment is assumed to be 0.044 m³/s (700 gpm).

Based on flooding sources, the worst-case flooding scenario is the HELB of a 0.10 m (4 in.) steam generator blowdown system line. The floor drains are conservatively assumed to be clogged due to debris resulting from dynamic forces in the high-energy line break areas. The flood relief opening is installed toward the outside to remove flood water. A watertight door is installed to protect against spreading flood water to adjacent areas in the steam generator blowdown regenerator heat exchanger room.

In other areas except the SGBD regenerator heat exchanger room, the 0.10 m (4 in.) fire protection system line is considered a flooding source. The flood water is drained to lower elevations through the drain system and openings. The potential flood level at this elevation is assumed as 0.15 m (6 in.).

Safety-related equipment and components are elevated above flood level. Therefore, the Class 1E motor control center, cubicle coolers, and valves are not flooded.
Elevation 137 ft 6 in

Flood water above El. 137 ft 6 in. drains to the lower elevation through floor drains, stairwells, and openings. To avoid flooding adjacent quadrants, a curb or ramp is installed at each quadrant intersection. The remote shutdown room and reactor trip switchgear room are protected by flood barriers.

The equipment to be protected from flooding at El. 137 ft 6 in. includes Class 1E motor control center, switchgear, remote shutdown panel, main feedwater isolation valves, and main steam safety valves.

The following potential flooding sources are considered:

a. A postulated pipe failure of moderate-energy line is considered.

b. A high-energy line break is considered in the main steam enclosure and main steam valve room.

c. There is no break of non-seismic moderate-energy piping because piping in the auxiliary building is designed as seismic Category I or II.

d. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate for firefighting equipment is assumed to be 0.044 m³/s (700 gpm). The malfunction of sprinklers is also considered a potential flooding source.

A rupture of a feedwater system line is the worst case of flooding for the main steam valve room. The cross-section area of the break is based on 0.09 m² (1.0 ft²), as defined in Standard Review Plan, Branch Technical Position 3-3 (Reference 6). In addition, a main feedwater pump is assumed to operate at the maximum flow rate. The floor drains are conservatively assumed to be clogged due to debris resulting from dynamic forces in the high-energy line break areas. An emergency flood relief path is installed to drain out at each room. The potential flood level is 1.82 m (6 ft) above El. 137 ft 6 in. and the safety valves are located above the flood level, so these valves are not flooded.

In other areas except the main steam valve room, the fire suppression system is considered a flooding source. The flood water is drained to lower elevations through the drain system and openings. The potential flood level at this elevation is assumed as 0.15 m (6 in.).
The safety-related equipment and components are elevated above the flood level. Therefore, the Class 1E motor control center, switchgear, and remote shutdown panel are not flooded.

**Elevation 156 ft 0 in**

Flood water above El. 156 ft 0 in drains to the lower elevation through the floor drain and stairwells.

The equipment to be protected from flooding at El. 156 ft 0 in includes I&C equipment, cubicle coolers, and the console in main control room. The main control room area is protected from flooding in that no water lines are routed above or through the control room or computer room. Water lines routed to HVAC air handling units around the control room are contained in rooms with curbs that preclude the potential for water leakage from entering the control room or computer room. The MCR is also protected from the flooding sources outside the main control room with curbs and steel hole panel installed at the entrance of the MCR.

The following potential flooding sources are considered:

a. A postulated pipe failure of a moderate-energy line is considered.

b. A high-energy line break is not considered because there is no piping break in this area.

c. There is no break of non-seismic moderate-energy piping because piping in the auxiliary building is designed as seismic Category I or II.

d. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate is for firefighting equipment is assumed to be 0.044 m$^3$/s (700 gpm).

Based on flooding sources, the worst-case flooding scenario is rupture of a 0.10 m (4 in.) fire protection system line in a corridor. The flood water is drained to lower elevations through the drain system and openings. The potential flood level at this elevation is assumed as 0.61 m (2 ft) from the bottom El. 156 ft 0 in.

The safety-related equipment and components are elevated above El. 158 ft 0 in, so the I&C equipment, cubicle cooler, and consoles in the MCR are not flooded.
Elevation 174 ft 0 in

Flood water above El. 174 ft 0 in drains to the lower elevation through floor drains, stairwells, and openings. The EDG normal exhaust fan room is separated by distance and protected by flood barriers.

The equipment to be protected from flooding at El. 174 ft 0 in includes the control room supply air handling unit and EDG room normal supply air handling unit.

The following potential flooding sources are considered:

a. A postulated pipe failure of a moderate-energy line is considered.

b. A high-energy line break event is not considered because there is no piping break in this area.

c. There is no break of non-seismic moderate-energy piping because most of the piping in the auxiliary building is designed as seismic Category I or II.

d. Firefighting equipment represents internal flooding sources from at least the nearest two fire hose stations that could reach the fire zone. The discharge rate is for firefighting equipment is assumed to be 0.044 m$^3$/s (700 gpm).

Based on flooding sources, the worst-case flooding scenario is rupture of a 0.10 m (4 in.) fire protection system line in the general access area. The flood water is drained to lower elevations through the drain system and openings. The potential flood level at this elevation is assumed as 0.15 m (6 in.) from the bottom El. 174 ft 0 in.

The safety-related equipment and components are located above the flood level. Therefore, the control room supply AHUs, control room emergency makeup ACUs, and EDG room normal supply AHUs are not flooded.

3.4.1.5.3 Emergency Diesel Generator Building

The emergency diesel generator building is separated by distance from other buildings and divisionally separated by flood barriers. Emergency diesel generators (EDGs) are separated by distance and flood barriers so that an internal flooding event does not affect both EDGs simultaneously.
3.4.2 Analysis Procedures

Flood loads due to the design basis flood level and maximum groundwater level are estimated using the applicable codes and standards, as described in Section 3.8. Seismic Category I structures are designed to withstand flood loads and to remain watertight during the design basis flood event. The loads and load combinations provided in Section 3.8 take into consideration the static and dynamic loadings on seismic Category I structures including hydrostatic loading due to the design basis flood and/or the groundwater conditions specified in Table 2.0-1.

The COL applicant is to describe the basis for the Probable Maximum Flood (PMF) to determine the maximum site-specific ground water elevation above the grade that may occur from tsunami or hurricane sources (COL 3.4(9)).

The COL applicant is to identify any site-specific physical models that could be used to predict prototype performance of hydraulic structures and systems (COL 3.4(10)).

3.4.3 Combined License Information

COL 3.4(1) The COL applicant is to provide the site-specific design of plant grading and drainage.

COL 3.4(2) The COL applicant is to provide site-specific information on protection measures for the design basis flood, such levees, seawalls, flood walls, revetments or breakwaters or site bulkheads pursuant to NRC RG 1.102 as required in Subsection 2.4.10.

COL 3.4(3) The COL applicant is to establish procedures and programmatic controls to ensure the availability of the floor drainage.

COL 3.4(4) The COL applicant is to periodically inspect watertight doors and the penetration seals to ensure their functionality.

COL 3.4(5) The COL applicant is to provide flooding analysis with flood protection and mitigation features from internal flooding for the CCW Heat Exchanger Building and ESW Building.
COL 3.4(6) The COL applicant is to provide the site-specific flooding hazards from engineered features, such as water tank collapsing, water piping breaking, etc.

COL 3.4(7) The COL applicant is to confirm that the potential site-specific external flooding events are bounded by design basis flood values or otherwise demonstrate that the design is acceptable.

COL 3.4(8) The COL applicant is to provide the site-specific dewatering system if the plant is built below the design basis flood level.

COL 3.4(9) The COL applicant is to describe the basis for the Probable Maximum Flood (PMF) to determine the maximum site-specific ground water elevation above the grade that may occur from tsunami or hurricane sources.

COL 3.4(10) The COL applicant is to identify any site-specific physical models that could be used to predict prototype performance of hydraulic structures and systems.
