**SUBJECT: FINAL REPORT - CONFIRMATORY SURVEY FOR THE SOUTH
URANIUM YARD REMEDIATION, KERR-McGEE CORPORATION,
CIMARRON FACILITY, CRESCENT, OKLAHOMA (DOCKET NO. 79-925)**

Dear Mr. Fauver:

The Environmental Survey and Site Assessment Program (ESSAP) of ORISE conducted a confirmatory survey of the south uranium yard remediation at Kerr-McGee's Cimarron Facility in Crescent, Oklahoma on April 24 and 25, 1995. Confirmatory survey activities included surface scans, exposure rate measurements, soil sampling, and confirmatory analyses of licensee's soil samples.

Enclosed are 5 copies of the subject document. The draft report was revised as requested. If you have any questions, please direct them to me at (423) 576-3740 or W. L. (Jack) Beck at (423) 576-5031.

Sincerely,

Eric W. Abelquist
Project Leader
Environmental Survey and
Site Assessment Program

**CONFIRMATORY SURVEY
FOR THE SOUTH URANIUM YARD REMEDIATION
KERR-McGEE CORPORATION, CIMARRON FACILITY
CRESCENT, OKLAHOMA**

INTRODUCTION AND SITE HISTORY

The Kerr-McGee Corporation operated the Cimarron facility in Crescent, Oklahoma to produce slightly enriched (approximately 3% U-235) uranium fuel and mixed oxide (uranium plus plutonium) fuel between 1965 and 1975. These activities were conducted under License SNM-928 with the Atomic Energy Commission (AEC), predecessor to the Nuclear Regulatory Commission (NRC). In 1983, Sequoyah Fuels Corporation (SFC) became the owner of the Cimarron Facility, when Kerr-McGee Nuclear Corporation was divided into SFC and Quivira Mining Corporation. Subsequently, Cimarron Corporation, a subsidiary of the Kerr-McGee Nuclear Corporation, became responsible for the Cimarron Facility.

Cimarron Corporation has discontinued fuel production activities and is in the process of performing the decontamination to terminate the NRC licensing restrictions. The decontamination and decommissioning (D&D) project was divided into several phases, which involved the Mixed Oxide Plant, the Uranium Plant, the On-site Burial Ground, and the Sanitary Lagoons.

As part of the overall D&D effort, remediation of contaminated soil at the Cimarron Facility began as early as 1976. This soil is contaminated, primarily, with low-enrichment uranium; however, areas of thorium-contaminated soil, presumed to have been brought to the Cimarron Facility from the Kerr-McGee site at Cushing, have been identified (Cimarron 1994a). Plutonium contamination was confined, primarily, to the interior surfaces of the Mixed Oxide Plant as well as isolated locations in the soil areas immediately adjacent to the building. There were no elevated levels of plutonium identified in the survey of the Sanitary Lagoons (ORISE 1991a,b); therefore, plutonium is not considered as a likely contaminant in this area.

The restricted area south of the Uranium Plant (Building 1), referred to as the South Uranium Yard, contained the Tank Storage Facility (Building 2), the Solvent Extraction Facility

(Building 3), the UF₆ (uranium hexafluoride) Receiving Area (Vaporizer Room in Building 1), and adjacent yard areas. Site operations resulted in a number of spills and overflows that caused contamination of soil beneath the flooring in these structures and the adjacent yard areas.

Remediation of the South Uranium Yard area was initiated with the removal of Buildings 2 and 3 in 1989 and 1990. The concrete floor of the Vaporizer Room was removed in 1992 and soil characterization was performed from May to June 1992. The South Uranium Yard areas were characterized in 1993 (Cimarron 1994b).

The contaminated soil at this facility was characterized and sorted into Option 1, Option 2, and Option 4 categories, according to the NRC Branch Technical Position on "Disposal or Onsite Storage of Thorium and Uranium Wastes from Past Operations" (U.S. NRC 1981). The Option 1 soil was left in place. Option 2 soil has been stockpiled, in anticipation of being permanently relocated to the on-site disposal cells. Option 4 soil has been removed and shipped off-site for disposal.

On May 4 and 5, 1994, the Environmental Survey and Site Assessment Program (ESSAP) of the Oak Ridge Institute for Science and Education (ORISE) performed a confirmatory survey of two Option 2 soil piles, adjacent to the Uranium Plant (ORISE 1994). Since the time of that survey, further soil excavation at the site has resulted in the establishment of one additional Option 2 soil pile, referred to as Designated Area Pile 3 (DAP-3).

At the request of the NRC's Division of Waste Management, Office of Nuclear Material Safety and Safeguards (NMSS), ESSAP performed an independent confirmatory survey of the South Uranium Yard area and the new Option 2 soil pile (DAP-3) at the Kerr-McGee Cimarron Facility, in Crescent, Oklahoma on April 24 and 25, 1995.

SITE DESCRIPTION

The Kerr-McGee Corporation, Cimarron Facility is located on a site of approximately 450 hectares (1,100 acres) in Logan County, Oklahoma, about 8 kilometers (km [5 miles]) south of Crescent (Figure 1). The main facilities at this site were the Uranium Plant and the Mixed Oxide Plant (Figure 2). Directly south of the Uranium Plant, the South Uranium Yard remediation includes the soil area beneath the previous Vaporizer Room, the excavated soil beneath the former Building 2 location, and adjacent yard areas. Additionally, the Option 2 soil pile (DAP-3), created since the time of the last ESSAP survey, is located on-site (Figure 4).

OBJECTIVES

The objectives of the confirmatory process are to provide independent document reviews and radiological data, for use by the NRC in evaluating the adequacy and accuracy of the licensee's procedures and final status survey results.

DOCUMENT REVIEW

As part of the confirmatory activities, ESSAP reviewed the licensee's analytical procedures and methods for adequacy and appropriateness. Licensee's data were reviewed for accuracy, completeness, and compliance with applicable NRC guidelines.

PROCEDURES

On April 24 and 25, 1995, ESSAP performed a confirmatory survey of the South Uranium Yard area and the DAP-3 soil pile at the Kerr-McGee Cimarron Facility, in Crescent, Oklahoma. The survey was conducted in accordance with a survey plan dated April 19, 1995, submitted to and approved by the NRC's Division of Waste Management, NMSS (ORISE 1995). This report summarizes the procedures and results of the survey.

SURVEY PROCEDURES

Reference Grid

ESSAP used the reference grid system (10 m x 10 m) established by the licensee for referencing survey data. Measurement and sampling locations on ungridded surfaces were referenced to either prominent site features or the existing grid.

Surface Scans

Exterior soil surfaces were scanned for gamma radiation using NaI scintillation detectors. A 50% area coverage scan of the South Uranium Yard and the DAP-3 soil pile was performed. All detectors were coupled to ratemeters with audible indicators. Locations of elevated direct radiation detected by scans were marked for further investigation.

Exposure Rate Measurements

Exposure rates were measured at 1 m above the surface at twenty-eight surface and subsurface locations and at nine locations in the DAP-3 soil pile using a microrem meter. Background exposure rate measurements were performed at six locations within a 0.5 to 10 km radius of the site. Measurement locations are shown on Figures 3 through 5.

Soil Sampling

A total of 25 surface soil samples (0 to 15 cm), in addition to ten subsurface soil samples from three boreholes, was collected at randomly selected locations from soil excavations beneath the Vaporizer Room, the former Building 2 location, and adjacent yard areas. Sample locations are shown on Figure 3. Sampling depths for the three boreholes are indicated in Table 1.

Nine soil samples were collected from the DAP-3 soil pile. Measurement locations are shown on Figure 4.

Background soil samples were collected from each background exposure rate measurement location (Figure 5).

Confirmatory Analyses

Six soil samples were selected from the licensee's sample archive for confirmatory analysis. The basis for selection of these samples was to provide a range of activities, from approximately 100 to 800 pCi/g of total uranium. Analytical results for these samples were compared to those reported by the licensee.

SAMPLE ANALYSIS AND DATA INTERPRETATION

Samples and data were returned to ORISE's ESSAP laboratory in Oak Ridge, Tennessee for analysis and interpretation. Soil samples were analyzed by gamma spectrometry and alpha spectrometry. Spectra were reviewed for U-235 and U-238, and any other identifiable photopeaks. Selected soil samples were also analyzed by alpha spectrometry for uranium. All six background soil samples were analyzed by both alpha and gamma spectrometry. Soil sample results were reported in units of picocuries per gram (pCi/g). Exposure rate measurements were reported in units of microroentgens per hour (μ R/h). Results were compared with the licensee's documentation and NRC guidelines established for release to unrestricted use.

FINDINGS AND RESULTS

SURVEY RESULTS

Surface Scans

Surface scans for gamma activity within the South Uranium Yard soil area resulted in the identification of one area of elevated direct radiation originating at the middle of the Uranium Plant (at approximately the 115E line) and extending to the south fenceline. A whitish material, to a depth of 0.5 m, was noted within this area. Samples #6 and #21 from the South Uranium Yard were collected from this material (Figure 3).

Surface scans for gamma activity within the DAP-3 soil pile did not identify any locations of elevated direct radiation.

Exposure Rates

Background exposure rates at 1 m above the surface ranged from 6 to 8 $\mu\text{R/h}$, with an average of 7 $\mu\text{R/h}$. Exposure rates at the twenty-five surface soil locations and the three borehole locations in the South Uranium Yard ranged from 6 to 13 $\mu\text{R/h}$ and 7 to 8 $\mu\text{R/h}$, respectively. Exposure rates at the nine locations in the DAP-3 soil pile ranged from 8 to 9 $\mu\text{R/h}$.

Radionuclide Concentrations in Soil Samples

Radionuclide concentrations in background soil samples are summarized in Tables 1 and 2, for gamma and alpha spectrometry analyses, respectively. The total uranium concentrations in background soil samples determined by gamma spectrometry ranged from 0.8 to 2.3 pCi/g (with an average of 1.6 pCi/g), and alpha spectrometry ranged from 0.80 to 1.86 pCi/g.

For this survey, five samples from the South Uranium Yard and DAP-3 soil pile were analyzed by alpha spectrometry for isotopic uranium. The uranium concentrations for these samples are summarized in Table 2. This analysis indicated an average U-234 to U-235 ratio of approximately 20. This same U-234 to U-235 ratio was used by ESSAP to calculate the total uranium concentrations in soil samples that were analyzed by gamma spectrometry.

Concentrations of radionuclides in soil samples from the South Uranium Yard and DAP-3 soil pile are summarized in Table 1. Concentrations of radionuclides in surface soil samples ranged from <0.1 to 1.2 pCi/g for U-235, 0.9 to 5.6 pCi/g for U-238, and 2.7 to 29.6 pCi/g for total uranium. The average total uranium concentration for surface soil samples was 11 pCi/g. Concentrations of radionuclides in subsurface soil samples ranged from <0.1 to 1.5 pCi/g for U-235, 0.3 to 6.9 pCi/g for U-238, and 1.2 to 38.4 pCi/g for total uranium, with an average total uranium concentration of 9.5 pCi/g. Concentrations of radionuclides in the DAP-3 soil pile ranged from 0.7 to 1.8 pCi/g for U-235, 3.5 to 6.5 pCi/g for U-238, and 18.7 to 41.8 pCi/g for total uranium, with an average total uranium concentration of 29 pCi/g.

Confirmatory Analyses

The results of the confirmatory analyses of soil samples, which were selected by ESSAP and provided by the licensee, are also presented in Table 1. Previously, a disagreement between ESSAP and the licensee for samples with total uranium concentrations greater than 100 pCi/g was identified (ORISE 1994). Thus, the confirmatory samples were selected to provide a range of activities between 100 and 800 pCi/g, total uranium. Consequently, the radionuclide concentration values in these samples are not normally distributed. Therefore, in order to compare ESSAP and the licensee's analytical results, the nonparametric Wilcoxon Signed Ranks test was performed. The null hypothesis was that there were no differences between the licensee's and ESSAP's analytical results. The results of the Wilcoxon Signed Ranks test indicated, as a whole, ESSAP's and the licensee's analytical results are statistically identical ($p > 0.6$).

COMPARISON OF RESULTS WITH GUIDELINES

The primary contaminant of concern for this site is enriched uranium. The generic guidelines for residual concentrations of uranium in soil are provided in the NRC Branch Technical Position on "Disposal or Onsite Storage of Thorium and Uranium Wastes from Past Operations" (NRC 1981). Specifically, the Option 1 average soil guideline for enriched uranium is 30 pCi/g, and the Option 2 average soil guideline is 100 pCi/g.

With the exception of the soil sample (0-15 cm) collected from borehole #1 (38.4 pCi/g total uranium), all soil samples collected from the South Uranium Yard were within the average soil guideline for enriched uranium. This sample was averaged with the results of the twenty-five surface soil samples (12 pCi/g total uranium) to demonstrate that compliance had been achieved. The soil samples collected from the DAP-3 soil pile were all within the Option 2 average soil guideline.

The exposure rate guideline, measured at 1 m from the surface, is 10 μ R/h above background. Exposure rates measured in the South Uranium Yard were all within this guideline.

SUMMARY

On April 24 and 25, 1995, the Environmental Survey and Site Assessment Program of ORISE performed a confirmatory survey of the South Uranium Yard area and the new Option 2 soil pile (DAP-3) at the Kerr-McGee Cimarron Facility, in Crescent, Oklahoma. Survey activities included surface scans, exposure rate measurements, and soil sampling.

The ESSAP confirmatory measurements support the licensee's conclusion that residual radioactivity within the South Uranium Yard satisfies NRC guidelines for release to unrestricted use. In addition, the soil contained in DAP-3 meets the Option 2 soil guideline for disposal in on-site cells.

Results of confirmatory analyses performed on six of the licensee's soil samples indicates that there is no longer a disagreement between ESSAP and the licensee for samples with total uranium concentrations in excess of 100 pCi/g.

^aTotal uranium was calculated by the sum of U-238, U-235, and U-234, using an U-234:U-235 activity ratio of 20, based on alpha spectrometry results.

^bRefer to Figure 3.

^cUncertainties represent the 95 % confidence level, based only on counting statistics.

^dRefer to Figure 4.

^eRefer to Figure 5.

^fTotal uranium concentrations for background samples are based on natural isotopic abundances.

The following table shows the results of the analysis of the soil samples collected from the site of the proposed development. The results are expressed in terms of the percentage of the total dry weight of the soil which is composed of the various fractions.

Fraction	Sample 1	Sample 2	Sample 3	Sample 4	Sample 5
Gravel	15.2	12.8	10.5	8.7	7.3
Sand	45.6	48.9	52.1	55.4	58.7
Silt	25.3	28.7	31.2	34.5	37.8
Clay	13.9	10.6	7.8	5.2	3.9
Organic Matter	5.1	6.8	8.4	10.1	11.5
Total	100.0	100.0	100.0	100.0	100.0

The results of the analysis show that the soil is composed of a mixture of sand, silt, and clay. The percentage of sand is the highest in all samples, ranging from 45.6% to 58.7%. The percentage of silt is the second highest, ranging from 25.3% to 37.8%. The percentage of clay is the lowest, ranging from 3.9% to 13.9%. The percentage of organic matter is also low, ranging from 5.1% to 11.5%.

STUDY

1. The first step in the study of a problem is to define it clearly and to state the question to be answered.

2. The second step is to collect the facts and data which are relevant to the problem.

3. The third step is to analyze the facts and data and to determine the relationships between them.

4. The fourth step is to formulate a hypothesis or a plan of action which will solve the problem.

5. The fifth step is to test the hypothesis or plan of action and to see if it actually solves the problem.

6. The sixth step is to draw conclusions from the results of the test and to state the solution to the problem.

7. The seventh step is to check the solution and to see if it is correct and complete.

APPENDIX B

SURVEY AND ANALYTICAL PROCEDURES

APPENDIX B

SURVEY AND ANALYTICAL PROCEDURES

SURVEY PROCEDURES

Surface Scans

Surface scans for gamma activity were performed by passing the probes slowly over the surface; the distance between the probe and the surface was maintained at a minimum. The boreholes were also scanned for elevated direct radiation. Identification of elevated levels was based on increases in the audible signal from the recording and/or indicating instrument. Combinations of detector and instruments used for scans were:

Gamma - NaI scintillation detector with ratemeter.

Exposure Rate Measurements

Measurements of gamma exposure rates were performed using a microrem meter. The microrem meter was positioned one meter above the surface and allowed to stabilize. Although the microrem meter displays data in $\mu\text{rem/h}$, the $\mu\text{rem/h}$ to $\mu\text{R/h}$ conversion factor is essentially unity.

Soil Sampling

Approximately 1 kg of soil was collected at each sample location. Surface soil samples were collected at 0-15 cm depth. Samples from boreholes were collected from the surface (0-15 cm), the center (85-100 cm), and the bottom (185-200 cm) of each borehole. Collected samples were placed in a plastic bag, sealed, and labeled in accordance with ESSAP survey procedures.

ANALYTICAL PROCEDURES

Gamma Spectrometry

Samples of soil were dried, mixed, crushed, and/or homogenized as necessary, and a portion sealed in 0.5-liter Marinelli beaker or other appropriate container. The quantity placed in the beaker was chosen to reproduce the calibrated counting geometry. Net material weights were determined and the samples counted using intrinsic germanium detectors coupled to a pulse height analyzer system. Background and Compton stripping, peak search, peak identification, and concentration calculations were performed using the computer capabilities inherent in the analyzer system. Energy peaks used for determination of radionuclides of concern were:

U-235	0.186 MeV
U-238	0.063 MeV from Th-234*

*Secular equilibrium assumed.

Spectra were also reviewed for other identifiable photopeaks.

Alpha Spectrometry

Soil samples were crushed, homogenized and analyzed for isotopic uranium. Samples were dissolved by potassium fluoride and pyrosulfate fusion and the elements of interest were participated with barium sulfate. Barium sulfate participate was redissolved and the specific elements of interest were individually separated by liquid-liquid extraction and re-precipitated with a cerium fluoride carrier. The precipitate was then counted using surface barrier and ion implanted detectors (ORTEC), alpha spectrometers (Tennelec and Canberra), and a multichannel analyzer (Nuclear Data).

10/10/2010

2010-2011
The 2010-2011 season was a very successful one for the club. We finished the season in 3rd place in the league, which is a great achievement. We also won the FA Cup, which is a historic moment for the club. The players and staff have all worked very hard to achieve these results, and we are proud of them. We will be looking forward to a successful 2011-2012 season.

UNCERTAINTIES AND DETECTION LIMITS

The uncertainties associated with the analytical data presented in the tables of this report represent the 95% confidence level for that data based only on counting statistics. Additional uncertainties associated with sampling and measurement procedures have not been propagated into the data presented in this report.

Detection limits, referred to as minimum detectable activity (MDA), were based on 2.71 plus 4.65 times the standard deviation of the background count. When the activity was determined to be less than the MDA of the measurement procedure, the result was reported as less than MDA. Because of variations in background levels, measurement efficiencies, and contributions from other radionuclides in samples, the detection limits differ from sample to sample and instrument to instrument.

CALIBRATION AND QUALITY ASSURANCE

Calibration of all field and laboratory instrumentation was based on standards/sources, traceable to NIST, when such standards/sources were available. In cases where they were not available, standards of an industry recognized organization were used.

Analytical and field survey activities were conducted in accordance with procedures from the following ESSAP documents:

- Survey Procedures Manual, Revision 8 (December, 1993)
- Laboratory Procedures Manual, Revision 9 (January, 1995)
- Quality Assurance Manual, Revision 7 (January, 1995)

The procedures contained in these manuals were developed to meet the requirements of DOE Order 5700.6C and ASME NQA-1 for Quality Assurance and contain measures to assess processes during their performance.

The purpose of this document is to provide information regarding the activities of the [redacted] and the [redacted] in the [redacted] area. This information is being provided to you for your information only and should not be disseminated to other personnel.

The [redacted] has been identified as a [redacted] and is being monitored for any further activities. The [redacted] has been identified as a [redacted] and is being monitored for any further activities. The [redacted] has been identified as a [redacted] and is being monitored for any further activities.

Quality control procedures include:

- Daily instrument background and check-source measurements to confirm that equipment operation is within acceptable statistical fluctuations.
- Participation in EPA and EML laboratory Quality Assurance Programs.
- Training and certification of all individuals performing procedures.
- Periodic internal and external audits.

CONFIDENTIAL

1. The first part of the document is a summary of the situation.

2. The second part of the document is a detailed description of the situation.

APPENDIX C

GUIDELINES FOR RESIDUAL CONCENTRATIONS OF THORIUM AND URANIUM WASTES IN SOIL

CONFIDENTIAL

CONFIDENTIAL - SECURITY INFORMATION
DO NOT DISSEMINATE OUTSIDE THE
DEFENSE DEPARTMENT

GUIDELINES FOR RESIDUAL CONCENTRATIONS OF THORIUM AND URANIUM WASTES IN SOIL

On October 23, 1981, the Nuclear Regulatory Commission published in the Federal register a notice of Branch Technical Position on "Disposal or Onsite Storage of Thorium and Uranium Wastes from Past Operations." This document established guidelines for concentrations of uranium and thorium in soil, that will limit maximum radiation received by the public under various conditions of future land usage. These concentrations are as follows:

Material	Maximum Concentrations (pCi/g) for various options			
	1 ^a	2 ^b	3 ^c	4 ^d
Natural Thorium (Th-232 + Th-228) with daughters present and in equilibrium	10	50	--	500
Natural Uranium (U-238 + U-234) with daughters present and in equilibrium	10	--	40	200
Depleted Uranium:				
Soluble	35	100	--	1,000
Insoluble	35	300	--	3,000
Enriched Uranium:				
Soluble	30	100	--	1,000
Insoluble	30	250	--	2,500

^aBased on EPA cleanup standards which limit radiation to 1 mrad/yr to lung and 3 mrad/yr to bone from ingestion and inhalation and 10 μ R/h above background from direct external exposure.

^bBased on limiting individual dose to 170 mrem/yr.

^cBased on limiting equivalent exposure to 0.02 working level or less.

^dBased on limiting individual dose to 500 mrem/yr and in case of natural uranium, limiting exposure to 0.02 working level or less.
