ABSTRACT

This document presents the results of a 1/4-Scale Safety/Relief Valve (SRV) discharge T-quencher test program performed June through October 1978.

The primary objective of this test program was to investigate the effect of varying SRV discharge line and plant operating parameters on the air clearing performance of a Mark I Containment T-quencher. The results of this test are to support the verification of an analytical model that calculates T-quencher air clearing design loads for Mark I plants.

1324 011

I. INTRODUCTION

This report documents the results of a series of scaled safety/relief valve (SRV) discharge tests conducted by the NUS Corporation (NUS) for the General Electric Company (GE).

Safety/relief valves are installed on Boiling Water Reactor (BWR) main steam lines to protect against over-pressurization and to provide a means of depressurizing primary coolant system. After the SRV is opened, steam enters the SRV discharge line (SRVDL), compressing the air in the line and causing a pressure buildup. This increased pressure accelerates the water slug initially occupying the submerged portion of the discharge line and water is expelled into the pressure suppression pool. The air initially contained in the discharge line follows the water into the pool. Expelled air forms oscillatory bubbles in the suppression pool. Pool hydrodynamics and inertia effects cause the bubbles to expand and contract as they rise to the pool surface, imposing oscillatory loads on the torus and associated structures.

The T-quencher allows the injection of the compressed air into the suppression pool and minimizes pressure pulses or forces on pool boundaries.

The objective of this test program was to determine the effects of varying operating and discharge line parameters on the air clearing performance of a reduced scale model of the Mark I T-quencher. Table 1-1 presents the test parameters and the test matrix is shown in Table 5-1.

Twenty-four test conditions were investigated and each test was repeated a minimum of four (4) times. Testing was conducted at 1/4 scale. Scaling was performed by GE in accordance with Reference 1. Two scaled versions of the Mark I T-quencher were tested: a choked flow and a geometrically scaled quencher. Three of the twenty-four tests were conducted with the choked flow device. The balance of testing was performed with the geometrically scaled quencher; for justification see Reference 2. Both T-quencher reduced scale models are described in detail in section 3.5 of this report. Motion photography at approximately 500 frames/second was used to document the effects of key parameters on air clearing performance.

1324 012

This report contains detailed descriptions of the test equipment, the instrumentation and the test procedures. The raw test data are only partly shown here as examples. The reduced data are presented and results discussed relative to trends for the parameters studied.

1324 015

2. SUMMARY OF PRINCIPAL OBSERVATIONS

- Highest measured test tank wall pressures were +2.47 and -2.41 psid resulting from Test 8 which represented the longest discharge pipe air leg length (108 ft) and the greatest initial tank and discharge pipe gas space pressure (11.25 psia). The corresponding peak air bubble pressures measured for Test 8 were +3.4 psid and 3.1 psid.
- Frequency of measured tank wall and air bubble pressures ranged from 12.8 Hz (for Test 7 in which a 108-ft long discharge pipe was initially pressurized to 3.7 psia) to 31.2 Hz for Test 6 (in which a 26-ft long discharge pipe was initially pressurized to 11.25 psia.)
- Maximum/minimum discharge line pressures downstream of the flow nozzle and at the location of the initial air/water interface were 131.7/56.6 and 91.4/38.2 psia, respectively.
- Air bubbles formed by the T-quencher were approximately in phase during all tests. In general, the bubbles that formed on the discharge pipe side of the T-quencher (for the inclined water leg tests) were significantly higher in pressure than those formed on the other side of the quencher arms. For the vertically oriented water leg, no significant difference in air bubble pressures was observed.
- Discharge line, air bubble and tank wall pressures increased with increasing steam flow rate.
- Tank wall pressures were not significantly affected by changing the vertical distance of the T-quencher to the bottom of the tank.

These observations and the underlying phenomena are discussed in Reference 2.

1324 016

3. FACILITY DESCRIPTION

The test facility simulated a typical BWP Mark I SRV piping system from the safety/relief valve to the torus. The facility included a steam supply, a steam flow control system, and a discharge line terminating with a T-quencher in a pressure suppression tank. A schematic of the test facility was shown in Figure 1-1. Figure 3-1 is a detailed system schematic layout in which all valves and instrumentation are represented, and Figures 3-2 shows the general piping layout. Figure 3-3 is a photograph of the overall test facility. Major valves and hardware are listed in Table 3-1.

3.1 STEAM SUPPLY SYSTEM

As shown schematically, the steam supply system consisted of power plant steam, a pressure-reducing system, and a surge tank. The power plant supplied 1800 psig saturated steam. This pressure was reduced to that required for the tests (approximately 300 psia) by pressure-reducing valve V-1. The steam entered the bottom of the surge tank and bubbled upward through saturated water. The 135.5 ft³, ASME Section VIII, 450 psia surge tank contained about 500 gallons of water (approximately half full) to ensure a constant pressure source of saturated steam. A photograph of the surge tank is shown by Figure 3-4. This vessel had a 3 gpm makeup pump, a sightglass for observing the water level and a 450 psia rupture disc for protection. A circular chart recorder (R-1) was used to document the tank pressure. This steam system was capable of delivering 4 lb/sec of saturated steam for a minimum of 20 seconds without the surge vessel pressure dropping below 300 ±10 psia.

Because of the slow response of pressure-reducing valve V-1, and in order to assist in maintaining a constant-pressure steam supply, a downstream pacing valve (V-7) was also used to obtain the required steam flow prior to test initiation.

The pacing valve was closed just before actuation of the fast-acting valve. By starting each test with an established steam flow through the pressure-reducing valve, this valve was not required to respond to the quick action of the SRV mockup.

3.2 STEAM FLOW CONTROL SYSTEM

The steam flow control system, which simulated an SRV, consisted of the fast-acting valve (V-9) and rupture disc combination in series with a flow control nozzle.

Fast-acting valve V-9 is a four-in. Fisher Type 657-ET (flow coefficient of 245) with a Type 657 (Size 40) actuator. A 3-in. rupture disc assembly was located downstream of this valve. The disc was designed to rupture at approximately 200 psig (at 70°F); it was pre-scored, reverse-buckling, non-fragmenting and made of nickel. The space between the rupture disc and the quick-opening valve was purged and pressurized to 100-150 psig with saturated steam before each test. The rupture disc assembly resulted in a pressurization pulse rise time upstream of the flow nozzle of 25 milliseconds. Also, the rupture disc ensured zero steam leakage into the discharge pipe.

The steam flow was metered using a venturi (choking-type) nozzle sized for each of the three required flows (0.8, 1.55 and 2.5 lbs/sec), based on a steam supply pressure of 300 psia. Fox Development Company, 1-1/2-in., slug insert, venturi nozzles were used. The flow of saturated steam at critical conditions through the nozzle was calculated from the following equation(2)

$$W = 0.3044 C_d A \left(\frac{P_1}{\bar{V}_1} \right)^{1/2}$$

where

W = Steam flow rate, lb/sec

P₁ = Inlet pressure, psia

\bar{V}_1 = Specific volume of steam, ft³/lb

A = Throat area, in²

C_d = Coefficient of discharge

= 0.97

The nozzle throat areas for the three required flows were 0.195, 0.376 and 0.605 in². The upstream pressure was measured using a pressure transducer (see PT-1 of Table 4-1 in Section 4.0) and recorded on Visicorder, VR-1. The accuracy of the flow measurement is discussed in Section 8.3.

3.3. DISCHARGE PIPING

All discharge piping was Series 300 stainless steel. There were two sizes of discharge pipe: 1-1/2 in. Schedule 40 and 2-1/2 in. Schedule 80. Figures 3-4 and 3-5 are photographs of two of eleven piping arrangements. The various piping arrangements used are illustrated in Figure 3-6. The discharge piping was insulated with 1-1/2-in. thick magnesia and/or fiberglass.

Electrical heating tape was installed on the initially air-filled portion of the discharge pipe to maintain the piping at 325°F for each test. A 1/8-in. thick Teflon gasket was used between the discharge pipe flanges near the water surface to reduce heat losses to the water. The heat tape (1 in. wide by 15 ft long, 470 watts) sections were spiral wound at three turns per foot and each tape was controlled manually with a Powerstat,

The discharge pipe was purged with dry air prior to each test. The purge system consisted of an oilless compressor, a Drierite bed and a 5-ft³ storage vessel. Valve V-11 is a full-port gate valve used to hold the suppression tank at subatmospheric pressure while purging the discharge line and to prevent moisture from diffusing from the suppression tank into the line.

The bends in the piping air lengths had radii of 16 in. for the 1-1/2 in. pipe and 24 in. for the 2-1/2-in. pipe to minimize unrecovered pressure losses. Because of space limitations inside the suppression tank, standard long-radius elbows were used at this location. The discharge piping was fabricated with a minimum continuous downward slope of 0.125 in. per foot to avoid condensation pockets.

3.4 SUPPRESSION TANK

The 82-13/16 in. (inside diameter) by 10-ft long suppression tank is shown in Figure 3-7. The shell was designed for an internal pressure range of 3.5-30 psia. External concrete and steel was used to achieve a tank wall natural frequency of 200 Hz. Figure 3-8 shows the tank in the concrete. Tank ports for venting and photography were sealed by 1-1/4 in.-thick Lexguard plates. The interior of the tank was painted blue-white to facilitate lighting for photographic purposes. The suppression tank water was periodically filtered to maintain clarity. City water was used in the tank, with ice added as needed for temperature adjustment. A manually-controlled vacuum pump, capable of removing 5.60 scfm, was used to establish the tank pressure.

3.5 T-QUENCHER

The T-quencher consisted of two perforated pipe "arms" welded to two short-radius elbows, which were in turn welded back-to-back to form a ramshead, as shown in Figure 3-9. Each arm contained 794 holes centered about the horizontal plane. Two scaled versions of the Mark I T-quencher were tested: a "choked-flow" scaled device and a geometrically scaled device. Figure 3-10 presents the details of the geometrically scaled T-quencher. The differences between the two quencher are shown in Table 3-2. As shown in the table, the SRVDL water leg pipe size was 2-1/2-in. Schedule 80 when the geometrically scaled quencher was used. For this case the SRVDL pipe diameter was increased from 1-1/2-in. Schedule 40 to 2-1/2-in. Schedule 80 just upstream of the discharge pipe initial water level. For the choked flow quencher the SRVDL was 1-1/2-inch Schedule 40 down to the quencher inlet. Figures 3-11 and 3-12 are photographs of the geometrically scaled T-quencher as installed in the tank. Figure 3-13 shows the T-quencher as supported in a test position. The T-quencher support system was designed to have a base natural frequency greater than 100 Hz. This rigid support minimized interferences with the hydrodynamic performance of the T-quencher and measurement of the pressure pulses caused by the quencher discharge.

--	---

4. INSTRUMENTATION

The primary measurements required in these tests were the pressure transients on the submerged portion of the suppression tank wall, in the suppression pool near the quencher discharge, and in the discharge pipe. These are the dependent variables whose measurements determined the effects of varying discharge pipe and simulated SRV operating parameters.

Additionally, to control test conditions, it was necessary to measure discharge line and suppression tank temperatures and pressures, pool water level, steam flow rate, discharge pipe pressurization rate, and the dew-point temperature of the air in the discharge pipe.

The locations and recording details of some of the instrumentation are shown schematically in Figure 3-1. A photograph of recorders is given in Figure 4-1. Table 4-1 lists the manufacturers' specifications for the various instruments. Figure 4-2 shows the thermocouple locations for a typical piping arrangement. Figure 4-3 shows locations of the pressure transducers. Additional instrumentation details are given below. Sensor characteristics are tabulated in Table 4-1. The camera arrangement for high speed photography of the simulated SRV discharge is shown in Figure 4-4. All sensors, sensor leads, signal conditioner channels and data acquisition channels were marked, logged and recorded during calibration to maintain identifications throughout the tests. All pressure sensors were calibrated using the procedure described in Appendix A. Sensor calibrations were performed before testing started and within every 30 days thereafter. Signal conditioner and Visicorder calibrations were performed at the start and end of each test day. Traceable standards (National Bureau of Standards) were used.

4.1 SENSOR TYPES AND LOCATIONS

1324 043

4.1.1 Discharge Piping and Suppression Tank Temperature Sensors

The discharge pipe temperature was measured with thermocouples mounted on the outside diameter of the piping at a maximum of ten-ft intervals extending

from just downstream of the rupture disc to one in. above the water surface in the suppression tank. See Figure 4-1 for locations and mounting details. TE-22, located one in. above the suppression tank water surface, was monitored to ensure that the temperature did not exceed 130°F prior to the initiation of a test run. This low temperature indicated that water vapor did not diffuse into the discharge pipe airspace.

For the portion of the discharge pipe initially filled with air, thermocouples were positioned under each section of the spiral wound heat tape used to maintain a uniform temperature over this section of piping.

The initial air temperature in the discharge pipe was monitored at five locations approximately evenly spaced over the pipe air length. These temperatures were measured by thermocouple TE-13, TE-14, TE-15, TE-16, and TE-17 as shown in Figures 3-1 and 4-2. These thermocouples were mounted to the discharge pipe using standard swage-type fittings.

The temperature of the suppression tank pool was monitored at three (3) locations: near the water surface, at an intermediate location, and near the bottom of the pool. These temperatures were measured by thermocouples TE-18, TE-19, and TE-20, respectively, as shown in Figures 3-1 and 4-2.

4.1.2 Discharge Piping and T-quencher Pressure Sensors

Discharge piping and T-quencher pressure sensors are represented in Figures 3-1 and 4-3 as PT-1 through PT-6. PT-1 is located upstream of the flow control nozzle and was used for measurement of the steam flow rate. (See Section 3.2). PT-2 and PT-3 are located in the air length of discharge pipe just downstream of the flow control nozzle and just upstream of where the pipe enters the suppression tank, respectively. PT-3 is used to measure the discharge pipe air/water interface pressure during the simulated SRV transient. PT-5 and PT-6, mounted on one arm of the T-quencher, are located just upstream of the first row of holes and just downstream of the last row of holes, respectively.

The discharge piping and T-quencher pressure sensors required thermal isolation. To accomplish this, the sensors were mounted vertically upwards and the discharge piping sensor cavities were filled with vacuum grease and the T-quencher sensor cavities were filled with water.

4.1.3 Discharge Pipe Humidity Sensor

The humidity of the air in the discharge pipe was determined just before start of a test by measuring the air dew-point temperature. To measure the dew-point temperature, air just downstream of the rupture disc was drawn through valve V-20, (see Figure 3-1) by the vacuum pump P-2. The air was cooled to approximately 85°F to be within the operating range of the dew-point condensation hygrometer. The humidity measurement sample was then returned to the discharge pipe through valve, V-13, just upstream of the pipe isolation valve, V-11. A minimum of 5% of the volume of the discharge piping air was sampled. It was not necessary to reheat the humidity measurement sample prior to returning it to the discharge line because of its relatively small heat capacity relative to that of the discharge pipe metal and the balance of the contained air.

4.1.4 Suppression Tank Wall and Pool Pressure Sensors

The suppression tank wall pressure was measured at twelve (12) locations. See Figure 4-3 for details. The sensors mounted on the tank wall, designated PT-7 through PT-18, were flush-mounted differential pressure transducers. The reference sides of these transducers were connected to the air space of the suppression tank. PT-7, PT-8, PT-9, PT-12, PT-15 and PT-18 were located in a line below the T-quencher with PT-15 being at the center of the T-quencher and PT-7 and PT-8 extending beyond the quencher arm. PT-10 through PT-14 were located in a line perpendicular to the quencher arms at a lateral position near the expected center of air clearing from one arm of the T-quencher. PT-16 and PT-17 were located in a line perpendicular to the center of discharge of the other quencher arm. Thus, the wall pressure attenuation was measured both parallel and perpendicular to the T-quencher arms.

1324 045

The T-quencher discharge air bubble pressures on each side of one quencher arm were measured using transducers PT-19 and PT-20, located near the center of the quencher arm. The bubble pressure sensors were the flush-mounted type mounted vertically downward with the transducer face level with the center of the quencher. These sensors are shown schematically in Figure 4-3.

4.1.5 Suppression Tank Gas Space Pressure and Water Level Sensors

The static pressure in the suppression tank gas space was measured prior to each test-run using sensor PT-4. The initial pool water level was measured visually by use of a sightglass. The initial discharge pipe water level was determined using a differential pressure manometer connected between the suppression tank and the air-filled portion of discharge pipe (See Figure 3-1).

4.1.6 Steam Supply Pressure and Temperature Sensors

The temperature and pressure of the steam/water in the steam supply surge tank was monitored before each test. The tank steam pressure was measured by pressure sensor PE-1 and the supply tank temperature was measured by thermocouples TE-1 and TE-2. The steam supply pressure and temperature for test results were taken from PT-1 and TE-13 because of the greater accuracy of these measurements.

4.1.7 Quick-Opening Valve Timing Sensor

Since rupture discs were used to effect a rapid pressurization of the discharge line, valve opening time was not of primary importance. However, a LVDT (linear variable differential transformer) was used to monitor opening (plug position) of the fast-acting valve, V-9. The output of the LVDT was recorded on visicorder chart, VR-1.

4.2 DATA RECORDING

1324 046

Two Honeywell 1858 visicorders (VR-1 and VR-2) were used to record pressure sensor outputs and the position of the quick-opening valve plug, see Table 4-2

and Figures 4-5 and 4-6. The recorders operated at 28 in./sec (716 mm/sec) for the first half second of a run, then at 7.5 in./sec for the remainder of the run. Vertical timing lines were automatically printed in the chart by the recorder at 10-msec intervals. The charts were microfilmed for permanent record.

Five thermocouple outputs from the discharge pipe and one from the suppression tank were recorded on a brush 260, 6-channel, strip-chart recorder at one in./sec (25 mm/sec). All other thermocouple outputs were recorded on an Esterline-Angus 24-point, strip chart recorder.

The visicorders and the Brush recorder added event marks to the charts; the event marker relay also started the time marker generator on the movie cameras when photography was used. All recorders were kept in a controlled temperature environment to reduce instrument drift (see Figure 4-1).

4.3 MOTION PICTURES

Two Milliken Model DBM5B cameras (500 frames per second) were used to record the air clearing phenomena under several test conditions. Sixteen millimeter color movies were taken. Event marks were placed at 0.010 second intervals on the film to allow for synchronization of the motion pictures with the sensor measurements recorded on visicorders and brush recorders. The cameras were positioned to photograph the quencher discharge from an end view of the quencher arm and from the top view approximately centered over the same quencher arm.

1324 047

4.4 FAILED OR MODIFIED SENSORS

Only one pressure transducer failed. This was PT-10 located on the suppression tank wall. PT-10 was determined to be inoperable after the completion of Test C and before Test 1. It is believed that the transducer was damaged during a facility modification. Starting with Test 5 and continuing through the rest of the test program, this transducer was replaced by a 0-15 psia, flush-mounted type made by Senso-Metrics, Inc., (Model SP-65B). See Table 4-1.

The only other failure was a humidity meter sensor. This was caused by a premature burst of a rupture disc, allowing steam to reach the sensor. The humidity monitor was out of service for Test 2 through 8.

Transducers PT-3 and -6 were relocated during some latter tests to determine if the 1-1/2-in. reducer and valve affected the pressure reading. Transducer PT-3 was relocated to approximately 6 in. upstream of valve V-11 for Tests 16 through 20. The prior location of PT-3 was approximately 6 in. downstream of Valve V-11. Transducer PT-6 was relocated for Tests 16 through 19 from the end of the T-quencher arm to just upstream of the location of the initial air/water interface in the discharge pipe. This relocation of transducers showed that the reducer and valve had no effect on the PT-3 pressure readings.

5. PROCEDURES

The test matrix is shown in Table 5-1. There were twenty-four (24) tests, each of which was performed a minimum of four (4) times. Thirteen piping configurations were tested as shown in Figure 3-6. The tests were performed in the sequence given in Table 5-1 to minimize piping changes. The tests were performed in accordance with a detailed GE-approved test plan, operating procedure and quality assurance plan.

5.1 TEST PROCEDURE

Before initiating a test, the surge tank steam pressure was brought up to the test value of 300 psia. The discharge pipe thermocouples and their associated heaters were continuously monitored to maintain the required pipe temperature of 325°F. The discharge pipe was purged with dry air and the pipe air humidity was checked. Pressurized dry air was pulsed into the suppression tank through the discharge pipe to loosen any attached bubbles from the tank wall, the T-quencher, or other submerged structures. Visual examinations for leaks and air bubbles were then made.

Final adjustments were made to ensure that the suppression tank airspace pressure was at the test value (usually 3.7 psia) and the water columns inside and outside the submerged discharge pipe were at the correct levels (usually equal).

The required steam flow rate was started through the pacing valve, V-7; just prior to test initiation, the equalization valve, V-13, located between the suppression tank and the discharge pipe was closed. (Note: valve, V-13, was kept closed for Tests 15, 18 and 19 for which an initial pressure differential between the suppression tank and the discharge pipe was required.) Just before test initiation the discharge pipe isolation valve, V-11, was fully opened.

For Test 16, 2.87 ft of discharge piping was wetted just prior to testing. This was accomplished by pressurizing the test tank, thus pushing the water

surface up into the discharge pipe. Just before valve actuation, the tank pressure was reduced to the discharge line pressure of 3.7 psia.

The detail pretest procedure is presented in the "Pre-Test Checklist" contained in Appendix B. Initial conditions for each test are contained in Appendix C.

The test was initiated by actuating a six-drum cam timer, which controlled the entire test sequence. The sequence of operations was:

<u>Event</u>	<u>Time, seconds</u>
• Start cameras (when used)	-1.63
• Start visicorders at 28 inch/second	-0.26
• Initiate event marker	0.00
• Actuate quick-opening valve, V-9	0.13
• Reduce visicorder speed to 7.5 inch/second	0.61
• Deactuate valve, V-9	5.00
• Stop event marker	7.40
• Stop visicorders	8.50

Post-test data were recorded at the conclusion of each test. The pressure and temperature traces were checked for legibility and consistency with previous runs of the same test. Each test was performed a minimum of four (4) times to ensure that the results were repeatable.

5.2 DATA ACCEPTANCE CRITERIA

After each test was performed four (4) times, a check on the data repeatability was made. The criterion, used as a guideline to determine if additional testing at a given condition was required, was that the standard deviation of the suppression tank wall pressure, as measured by PT-18, could not exceed 20% of its mean measured value. If this criterion was not met, additional runs were made and the data further evaluated. Standard deviations for each test are presented in Table 7-1.

1324 058

5.3 DATA REDUCTION

The pressures, recorded on visicorder charts, were read and tabulated for input to a computer program, which applied the appropriate calibration correction factors. Typical visicorder records for each test condition are presented in Figures 5-1 through 5-46. (Records for Test A are shown in Figures 4-5 and 4-6.) These figures present only the more pertinent time interval (the first 200-400 milliseconds after actuation of the quick-opening valve) on the charts for a typical run from each test. Data reduction sheets are presented in Appendix D.

The Visicorder deflections were multiplied by the appropriate calibration coefficients to obtain pressure values. The calibration coefficients were obtained by application of a linear least squares regression analysis to the monthly calibration data adjusted for daily shifts in the recording and signal conditioning equipment. These adjustments were made by multiplying the calibration coefficients obtained from the monthly system calibrations by the ratio of the monthly to daily signal conditioners and recorder calibrations.

The calibration coefficients for the monthly calibrations and the method used to perform the monthly calibration and daily electronic calibration checks are presented in Appendix A.

The computer printout of the reduced data for all tests is presented in Appendix D.

6. QUALITY ASSURANCE

The NUS-Clearwater Operations Quality Assurance staff performed several quality-related functions to ensure reliability and credibility of the test data. These functions are listed below:

Prior to Testing

- Evaluation, qualification and certification of the surge tank fabricator.
- Inspection and acceptance of the suppression tank at the supplier's plant prior to shipment to NUS
- Verification of T-quencher location in the suppression tank
- Verification of T-quencher configuration, including hole size and spacing
- Inspection and acceptance by checklist of the piping configuration and thermocouple locations
- Inspection of stiffeners on the bottom of the suppression tank near the pressure transducer locations.
- Calibration of all instrumentation prior to testing
- Verification of water level

During Testing

- Witness and signoff on at least one run of each test
- Dimensional checks of all changes to piping and thermocouple locations

- Dimensional checks of each change in heating tapes
- Witness the performance of each instruments calibration and recalibration
- Verification of sample data reduction input and output

After Testing

- Accumulation and management of quality assurance records
- Audit of project record files
- Internal QA audit of project performance.

1324 108

7. TEST RESULTS

A total of twenty four (24) test series were performed (see Table 5-1). A minimum of four (4) runs were made for each test condition to demonstrate data repeatability. In addition, two high speed color movies were made of Tests 1, 3, 7 and 11. Three test series were performed using the "choked flow" scaled T-quencher. These tests were designated, Tests A, B and C. The remaining twenty one (21) tests were performed with the geometrically scaled quencher. Typical visicorder data traces for one (1) run of each of the test series are presented in Figures 5-1 through 5-46. Representative sequential still pictures obtained from the high speed movies for Test 7 are presented in Figures 7-1 and 7-2. Test results are summarized in Table 7-1.

7.1 DESCRIPTION OF TEST PHENOMENA

Tests were initiated by releasing steam via the quick-opening valve, V-9, from the steam supply surge tank. The 300 psia steam burst the 200 psig (design pressure) rupture disc, thus affecting a rapid pressurization of the discharge pipe. The high pressure steam compressed the air initially contained in the discharge pipe. The increased pressure accelerated the water mass initially occupying the submerged portion of the discharge pipe and T-quencher and expelled the water into the suppression pool. As the water completely cleared the first row of T-quencher arm holes, air clearing was initiated. See Frame 1 of Figures 7-1 and 7-2 taken at 142 milliseconds after the rupture disc was burst. Air was sequentially cleared from the consecutive rows of quencher arm holes as the air/water interface moved toward the end of the quencher arms. Sequential air clearing is depicted in frame three of Figure 7-1 taken at 180 milliseconds. The compressed air expanded as it was expelled into the pool and coalesced into large bubbles (see frames 4 and 5 of Figures 7-1 and 7-2 taken at 264-670 milliseconds). As the air bubbles rose to the surface, they expanded and contracted, thereby exerting oscillatory pressures on the suppression tank wall. The wall pressure distribution was measured by pressure sensors PT-7 through PT-18. The air bubble pressures near one quencher arm were measured by PT-19 and PT-20. For Test 7, the air bubbles finally broke through the pool water surface at 286 milliseconds. This is depicted in Frame 6 of Figure 7-1.

7.2 TEST DATA

A complete set of data for each test run is presented in Appendix D. Tabulated in Appendix D are the following:

- Pressure Pulse Rise Time - Discharge pipe inlet pressurization rate as measured by PT-1
- Steam Flow Rate - Final steam flow rate through the discharge pipe as measured by PT-1 and calculated by the flow equation in Section 3.2.
- Steam Inlet Pressure - Pressure measured by PT-1 and used in steam flow calculation
- Peak Pipe Pressure - Peak discharge pipe pressure downstream of flow control nozzle and at air/water interface as measured by PT-2 and PT-3, respectively
- Inlet Steam Temperature - Steam supply temperature as measured by TE-13 in the discharge pipe upstream of the flow nozzle.
- Pipe Pressure at 5 Seconds - Discharge pipe pressures five seconds after initial pressurization of discharge pipe as measured by PT-2 and PT-3
- Peak Pressure - Peak transient pressures in the suppression tank gas space, the T-quencher upstream and downstream of the hole pattern as measured by PT-4, PT-5 and PT-6, respectively.
- Pressure at Five Seconds - T-quencher pipe pressures, five seconds after initial pressurization of discharge pipe, as measured by PT-5 and PT-6.
- Peak Positive Pressure - Peak positive suppression pool pressure during the air clearing phase of T-quencher discharge as measured by PT-19 and PT-20.

1324 110

- Peak Negative Pressure - Peak negative suppression pool pressure during the air clearing phase of T-quencher discharge as measured by PT-19 and PT-20.
- Average Positive Pressure - The average of the peak positive pressure measured by PT-19 and PT-20.
- Average Negative Pressure - The average of the peak negative pressures measured by PT-19 and PT-20.
- Frequency - Air bubble oscillation frequency as measured by suppression tank wall pressure sensor, PT-18.
- Peak Over Pressure - Peak positive pressure on suppression tank wall during air clearing phase of T-quencher discharge as measured by each of the wall pressure sensors, Pt-7 through PT-18.
- Peak Under Pressure - Peak negative pressure on suppression tank wall during air clearing phase of T-quencher discharge as measured by each of the wall pressure sensors, PT-7 through PT-18.

The results are summarized in Table 7-1, which presents the highest value, the mean value, the standard deviation and the ratio of the standard deviation to the mean for all test conditions.

In general, the pressures measured in the discharge pipe are similar from run to run. The ratios of standard deviation to the mean for these values are generally only a few percent. The same ratio for the wall and bubble pressure values are generally in the 20-40% range. The suppression tank wall pressure sensor readings demonstrate better repeatability than the bubble pressure sensors and are considered, therefore, to give a better indication of sensitivity of air bubble pressures to variations between the test conditions.

1324 111

Sample suppression tank wall pressure distribution, both longitudinal and circumferential, are presented in Figures 7-3 and 7-4. Presented in these figures are distributions for tests resulting in the greatest measured pressures (Test 8), the smallest measured pressures (Test 11), and average pressures measured for the remainder of the tests. The variability of test data is indicated on the average wall pressure distribution curve. The bars represent plus and minus one standard deviation. Both positive and negative pressures are represented. As shown in the figures, the peak longitudinal wall pressure occurred directly under the center of the T-quencher. However, the circumferential wall pressure distribution indicates pressure peaks to each side of the T-quencher arm. This observation is consistent with expectations because the T-quencher holes are centered about the horizontal plane on each side of the arm.

For principal observations of the test refer to Section 2.0 of this report.

8. DATA ACCURACY EVALUATION

The principal contributors to error and uncertainty in the final test data could arise in errors from sensors, signal processing instrumentation, recorders, and reading of the chart records. Each of these potential sources of errors is discussed in the following subsections.

8.1 TEMPERATURE MEASUREMENTS

Estimates of error band for temperature sensors are based on calibration checks using a stirred oil bath with a certified thermometer ($\pm 0.05^{\circ}\text{F}$) as a standard for the bath temperature. As indicated in Table 4-1, all sensors were purchased to a manufacturer's specification of $\pm 2^{\circ}\text{F}$ accuracy. As shown by the calibration procedure in Appendix A, the thermocouples were calibrated over the expected range of use.

All thermocouples were calibrated using the proper leads, amplifiers and recorders. Therefore, the error determined by calibration includes all sources of errors except drifts between calibrations. The temperature instrumentation was calibrated completely only once. To check for instrument drifts, two sensors were checked after five months showing no evidence of any change. An estimate of the possible error for the discharge pipe outside temperature measurements is $\pm 4^{\circ}\text{F}$. The possible errors in the temperature measurement for the internal air/steam temperatures is $\pm 1^{\circ}\text{F}$, and for temperature measurement of the tank water is $\pm 2^{\circ}\text{F}$.

8.2 PRESSURE MEASUREMENTS

Sources of errors in the pressure measurements are non-linearity, hysteresis, chart reading errors and shifts from thermal efforts and aging effects. The inherent errors such as non-linearity, hysteresis, thermal shifts, etc. were accounted for by calibration. The pressure sensors were calibrated over the ranges of use with the procedure in Appendix A. Examination of these calibration data show that, in general, the error in the recorded value is much less than 1% of the actual value.

1324 120

A reading error is a function of how precisely data can be extracted from the visicorder charts. The potential reading error was determined experimentally by operating the sensor at a known pressure in its normally-used range and adding a known small increment of pressure until a readable difference was seen on the visicorder chart. The same standards were used for this experiment as were used for calibration (see Appendix A); i.e., a dead-weight tester for the discharge line pressures, and a water column for the other sensors. Table 8-1 presents the results of this experiment.

Another source of error for the pressure data could be from drifts between calibrations, due to aging, etc. in the sensors. Daily calibration checks of the electronics accounted for drifts in amplifiers and recorders. An examination of the monthly calibrations for both pressures and electronics show that the monthly shifts in calibration results are probably due to changes in the electronics and were, therefore, corrected on a daily basis.

8.3 FLOW MEASUREMENTS

The error in the steam flow was based on the following equation⁽³⁾

$$\sigma_F = \left[\left(\frac{\partial W}{\partial A} \sigma_A \right)^2 + \left(\frac{\partial W}{\partial P} \sigma_P \right)^2 \right]^{1/2}$$

where

W = Flow nozzle equation in Section 2.3

$\sigma_A = 0.002 \text{ in.}^2$ (error in measurement of nozzle area)

$\sigma_P = 0.5 \text{ psi}$ (from Table 8-1)

The probable error in steam flow rates was $\pm 0.02 \text{ lb/sec}$ for the 0.8 lb/sec nozzle, $\pm 0.03 \text{ lb/sec}$ for the 1.55 lb/sec nozzle, and $\pm 0.04 \text{ lb/sec}$ for the 2.5 lb/sec nozzle.

1324 121

8.4 DATA VALIDITY

Several test situations or conditions were identified that could affect the test data. Although each equipment-procedure combination was engineered to preclude a contribution to error, each is discussed below to enable the reader to assess such possibilities.

One concern is that of condensation of steam on the discharge piping walls. The pipe was heated to 325°F for each test. To determine if steam condensation occurred in the discharge pipe, the saturation pressure corresponding to the wall temperature must be compared to the discharge pipe steam inlet pressure as measured by transducer PT-2. Thus, for tests where PT-2 measured greater than 95 psia, condensation may have occurred. From Table 7-1, it can be seen that PT-2 marginally exceeded 95 psia for several tests.

Air bubbles on suppression tank walls or internal structures could alter the pressure waves by modifying the boundary impedance represented by the structures. Therefore, before the first run of each test series, pressurized dry air was rapidly admitted through the discharge pipe into the suppression tank to remove bubbles from submerged surfaces. Also, a visual check was made to ensure that no clinging air bubbles remained.

An unknown relative humidity in the discharge pipe air could have resulted in an undefinable air mass. Therefore, before tests during which the air humidity meter was working, not only was the humidity monitored, but the piping was purged a minimum of four times (20 volume changes) with pre-dried air as well. For the tests during which the humidity monitor was not working, the piping was purged eight to ten times (40 volume changes). Also, after purging but only within 60 seconds of a test run, the block valve just above the water was opened. The short open time (before testing) was used to prevent water vapor from diffusing into the piping.

The T-quencher supports, the T-quencher and the suppression tank itself were calculated to have frequencies high enough to avoid local wave interference or generation. Also, the pressure transducer signal chart paper was examined

for spurious signals and none was noted that could have affected that data. Waves in the 300 Hz range were seen but these caused only minor perturbations in the traces (see Figures 5-1 through 5-46).

Any temperature stratification in the suppression water would have been seen by thermocouple records before a test and the differences seen were always much less than the change from run to run (about 2°F). Therefore, no unseen temperature effect on bubble or wave behavior was believed to have occurred.

1324 123

Table 8-1
EXPERIMENTAL ERROR DETERMINATION FOR PRESSURE DATA

<u>Function</u>	<u>Pressure Transducer*</u>	<u>Pressure Tested (psia)</u>	<u>Readable Difference (psia)</u>

APPENDIX A
SENSOR CALIBRATION PROCEDURES AND RESULTS

1324 126

CALIBRATION RESULTS

The calibrations for pressure and temperature sensors were done in accordance with the procedure which follows. The results for the monthly calibrations are presented in Table A-1. The slope values in psia/minor division of Visicorder deflection were obtained by a linear least squares regression analysis of the calibration data. The correlation coefficients for these values are generally greater than 0.999. The slope values in volts/division of Visicorder deflection were an average value since the relation of volts to deflections was essentially linear.

1324 127

Table A-1

1324 131

1.0 OBJECTIVE

- 1.1 To assure the calibrations are carried out in a uniform and approved manner.
- 1.2 To avoid operator error and to assure documenting calibration results in a uniform manner.

2.0 DEFINITIONS

NONE

3.0 WORKING STANDARDS

- 3.1 Ashcroft Type 1305 Dual Range Dead Weight Tester
 - Serial Number: 2BH-40I9I
 - Range: 5 to 10,000 psi
 - High Range Interval: 25 psi
 - Low Range Interval: 5 psi
 - Accuracy: 0.1% of value
 - Calibrated: May 4, 1978
 - Recalibration Required: May 4, 1979
 - Certification of Accuracy: in Instrument QA File

- 3.2 Taylor Certified Precision Thermometer
 - Scales: 70-400°F.
 - Subdivision: 0.2°F.

Report of Calibrations: attached to cases

- 3.3 Column of water at known temperature and height, measured with calibrated tape (record in 1884 file)
The tube is a 1/2" ID sight glass.

- 3.4 Transmation, Inc. Model 1040 PPS Digital Calibrator
 - Serial Number: 1040.2232
 - Accuracy: 0-11 volts, $\pm 0.04\%$ of range $\pm 0.03\%$ of reading max.
0-110 millivolts, $\pm 0.6\%$ of range, $\pm 0.6\%$ of reading, max.

Calibration: April 28, 1978 (in QA File)

1324 132

4.0 CALIBRATION METHODS

4.1 Pressure Transducers Calibrations

4.1.1 PT-1, 2, 3, 5 and 6 will be calibrated using the dead weight tester and pages 3-4 through 3-8 of the Honeywell Technical Manual (HTM) for Model 1885-SGC, Strain Gage Control Unit *with 12.5KHz low pass filter.* The same cables will be used during calibrations that will be used for testing. The Model 1885 is set up for 10 vdc excitation according to the same manual.

CTS
5/25/78

The procedure is:

- 1) Complete top portion of Calibration Form (001)
- 2) Assure correct cable, signal conditioner, sensor and visicorder channel.
- 3) Set calibration signal on the 1885 as follows (HTM, pp. 3-7h):

PT-1 - 18.02 mv = 300 psia = 5 in. deflection

PT-2 - 15.03 mv = 150 psia = 5 in. deflection

PT-3 - 15.02 mv = 150 psia = 5 in. deflection

PT-5 - 14.985 mv = 100 psia = 5 in. deflection

PT-6 - 14.988 mv = 100 psia = 5 in. deflection

The 1885 signal conditioner and Visicorder will be checked with a standard voltage source (Working standard 3.4) at the following points:

PT-1 - 0, 6, 12, 18, 24 mv.

PT-2, ~~through~~ ^{3 sensors} 6 - 0, 5, 10, 15, 20 mv

CTS
5/23/78

Daily electronic calibration checks will be made before and after testing with the standard voltage source at 0 and 18 mv for PT-1 and 0 and 15 mv for PT-2, PT-3, PT-5, and PT-6.

1324 133

4.1.1 (cont'd)

- 4) Adjust balance and zero (HTM, pp.3-7i) with vacuum of 0.1 micron (0.0001 mmHg) on the transducer by the vacuum pump and record on Visicorder chart.
- 5) Check and record on Calibration Form deflection at atmospheric pressure.
- 6) Check and record on Calibration Form the deflection at 25 psi intervals using the dead weight tester up to the following:
 - PT-1.....350 psig
 - PT-2.....175 psig
 - PT-3.....175 psig
 - PT-5.....125 psig
 - PT-6.....125 psig

Also, three or four points will be checked with pressure decreasing.

4.1.2 PT-4, 19 and 20 will be calibrated using a vacuum pump and a column of water at known temperature.

CF
5/25/78 PT-4 uses the 1885-SGC while PT-19 and 20 use a 1883 preamplifier ^{no filter} for the Visicorder.

4.1.2.1 The procedure for PT-4 is the same as 4.1.1 except the following:

- 3) Set the calibration signal on the 1885 to 30.05 mv = 15 psia = 6 in. deflection.

Check and record the deflection with 0, 7.5, 15, 22.5 and 30 mv input to the 1885 with the voltage standard. The daily electronic calibration check will be at 0 and 30 mv.

1324 134

4.1.2.1 (cont'd)

6) Check and record on the Calibration

Form the deflection at:

- 14.7 psia
- 10.0 psia
- 7.5 psia
- 5.0 psia
- 2.5 psia
- 0.0 psia

Also, 3 or 4 points will be checked with the pressure increasing.

4.1.2.2 The procedure for PT-19 and 20 is:

- 1) Complete top portion of Calibration Form 001.
- 2) Assure correct cable, signal conditioner, sensor, and visicorder channel.
- 3) Apply power and allow unit to warm up 30 minutes.
- 4) With vacuum of 0.1 micron on the transducer, adjust zero and record on visicorder chart.
- 5) With atmospheric pressure, adjust gain for 5" deflection on the Visicorder chart.
- 6) Check and record on the Calibration Form the deflection at:
 - 14.7 psia
 - 10.0 psia
 - 7.5 psia
 - 5.0 psia
 - 2.5 psia
 - 0.0 psia
- 7) Check and record with the standard voltage source input to the signal conditioner the deflection at the following points: 0, ^{0.4}0.8, 1.6 mv.

CTS
5/23/78

The daily electronic calibration check will be at 0 and ^{0.8}1.6 mv.

CTS
5/25/78

1324 135

4.1.3 PT-7 through 18 will be calibrated using a column of known temperature water.

The 1883 Honeywell preamplifier ^{with no filter} is used with these transducers. The procedure is:

CF
5/23/78

- 1) Complete the top portion of the Calibration Form 001.
- 2) Assure correct cable, signal conditioner, sensor, and visicorder channel.
- 3) With no load adjust zero and record on visicorder chart.
- 4) Check and record on the Calibration Form the deflection at 0, +1, ^{1.5}+2, ^{2.5}+3, +~~4~~, and +~~4~~ psi (increasing pressures) and at +~~4~~, ^{3.5}+3, ^{2.5}and +2 psi (decreasing pressures).

CTS
6/2/78

The standard voltage source will be used to check the deflection by 0, 5, 1.0, 1.5, 2.0, 2.5 and 3 volts input to the 1883 and recording the results on the Visicorder. Daily electronic calibrations will be at 0 and ~~1.5~~ ^{1.5} volts.

CTS
5/23/78

4.2 Thermocouple Calibrations

The thermocouples will be calibrated using a stirred oil bath with the proper range of Taylor Certified Precision Thermometer as a standard.

4.2.1 Thermocouples TE-1-12, 21 and 22 read directly in °F. on the Leeds and Northrup recorder with a 0-500°F. range.

The following ranges and calibration checkpoints are applicable:

- TE-1 and 2 - Range 375-400°F. - check:
- 375
 - 400
 - 425
 - 450

1324 136

4.2.1 (cont'd)

TE-3-12, 21 - Range 200-400°F. - check: 200
 300
 325
 350
 400

TE 22 - Range 100-150°F. - check: 100
 130
 150

The procedure is:

- 1) Complete top portion of Calibration Form 002
- 2) Assure correct cable, signal conditioner, sensor, and recorder channel.
- 3) Allow proper warmup for recorder.
- 4) Apply calibration standard and record results on Calibration Form 002.

4.2.2 Thermocouples TE-13 through 20 are connected through thermocouple amplifiers (Gould Md1.13-4615-40) to the Brush 220 and 260 which read in °F./division of deflection. The following ranges and calibration points are applicable:

TE-13 - Range 375-450°F. - check: 375
 400
 425
 450

TE-14 through 17 - Range 250-400°F. - check: 250
 300
 350
 400

TE-18 through 20 - Range 70-150°F. - check: 70
 80
 100
 150

1324 137

4.2.2 (cont'd)

The procedure is:

- 1) Complete top portion of Calibration Form 002.
- 2) Assure correct cable, signal conditioner, sensor and recorder channel.
- 3) Allow proper warmup (15 minutes) for recorder and thermocouple amplifiers.
- 4) Set recorder sensitivity to OFF position.
- 5) Adjust recorder position control to position pen at exact chart center and lock knob.
- 6) Check that recorder vernier Sensitivity XI control is in the detent position, and lock knob.
- 7) Set recorder sensitivity to 100 MV/DIV.
- 8) Connect thermocouple amplifier outputs to recorder in such a way that turning the pre-amplifier position control clockwise will move the pen to the right. The recorder ground strap may have to be disconnected, depending on the output polarity of the thermocouple amplifier.
- 9) On thermocouple amplifiers set degrees full scale switch to range or span of temperature to be monitored.
10. Adjust thermocouple preamplifiers' ZERO SUPPRESSION controls to allow the reference point on the recorder to be set at some temperature other than zero desired for each channel.
11. Apply calibration standard and record results on Form 002.

		GOVERNMENT CLASS
REPRODUCIBLE COPY FILED AT TECHNICAL SUPPORT SERVICES, R&UO, SAN JOSE, CALIFORNIA 95125 (Mail Code 211)		NUMBER OF PAGES 378
SUMMARY <p>This document presents the results of a 1/4-Scale Safety/Relief Valve (SRV) discharge T-quencher test program performed June through October 1978.</p> <p>The primary objective of this test program was to investigate the effect of varying SRV discharge line and plant operating parameters on the air clearing performance of a Mark I Containment T-quencher. The results of this test are to support the verification of an analytical model that calculates T-quencher air clearing design loads for Mark I plants.</p>
