

SACRAMENTO MUNICIPAL UTILITY DISTRICT 🗆 6201 S Street, Box 15830, Sacramento, California 95813; (916) 452-3211

November 16, 1979

Mr. Robert W. Reid, Chief Operating Reactors Branch #4 Division of Operating Reactors U.S. Nuclear Regulatory Commission Washington, D. C. 20555

> Docket No. 50-312 Rancho Seco Nuclear Generating Station Unit No. 1

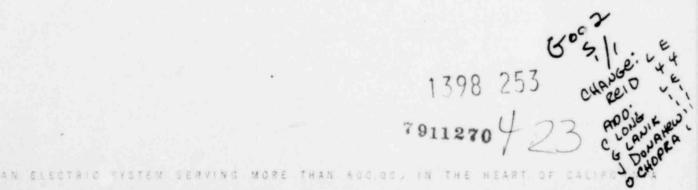

Dear Mr. Reid:

Your letter of September 28, 1979, requested information concerning PORV and safety valve lift frequency and mechanical reliability. This letter forwards the requested information.

Sincerely,

9 mattind

John J. Mattimoe Assistant General Manager and Chief Engineer

#### Request 1

1.3

. · · · ·

According to statements made by B&W, there are approximately 146 documented occasions where PORV actuation occurred at B&W facilities prior to the accident at Three Mile Island, Unit 2 (TMI-2). For each of these events which have occurred at your facility(ies), provide the following information:

- a. The cause of the event;
- b. the initial power level prior to the transient;
- c. Indicate which of these transients caused the reactor to trip on high RCS pressure and/or caused the safety valves to lift; and,
- d. If you assume that the present setpoints for high RCS pressure trip and PORV actuation were in effect at the time of each of these transients, estimate whether either of the following would have taken place:
  - (1) PORV actuation, and
  - lifting of the safety valves.

(For this item assume no credit for the anticipatory controlgrade reactor trip on loss of feedwater or turbine trip.)

#### Response

The requested information has been compiled in the following plant specific tables (Reactor trips with a PORV actuation).

In addition, there have been seven (7) instances when the PORV stuck open - three (3) when the plant was at power and four (4) when it was not producing power.

- a. At power:
  - Oconee-3, June 13, 1975 (Feedwater oscillations while shutting down)
  - (2) Davis-Besse 1, Sept. 24, 1977 (Loss of Feedwater)
  - (3) TMI-2, March 28, 1979 (Loss of Feedwater)

# ATTACHMENT I (Cont'd)

b. Not producing power:

- (1) Oconee-2, August 15, 1973 (Pre-op Testing)
- (2) Oconee-2, November 6, 1973 (RCS Heatup)
- (3) Davis-Besse 1, October 13, 1977 (Hot Standby)
- (4) TMI-2, March 29, 1978 (Zero Power Physics Testing)

# ATTACHMENT II (7 PAGES)

#### Request 2

Provide a complete listing of reactor trips for your facility(ies) which have occurred subsequent to the revised setpoints for PORV actuation and high RCS pressure trip. This listing should include the following items:

- a. The cause of each event;
- b. The initial power level prior to the transient;
- c. Indicate which of these transients caused the PORV and 'or safety valves to open; and,
- d. If the old (pre-TMI-2) setpoints for high RCS pressure and PORV actuation were in effect at the time of these transients, estimate whether any or all of the following would have taken place:
  - PORV actuation;
  - (2) Reactor trip on high RCS pressure, and
  - (3) Lifting of the safety valves.

# Response

This information has been compiled and is presented in the attached tables. ... a hypothetical actuation of the PORV and/or safety valves and high pressure trip assuming the old setpoints had been in effect is not based on any analytical technique. Rather, Engineering judgement, coupled with past operating history led to these results.

## ATTACHMENT III (3 PAGES)

# Request 3:

Provide an estimate of the increase in reactor trip frequency since lowering the high pressure trip setpoint and adding the anticipatory reactor trip. Include a review of the design criteria for the number of reactor trips over the plant life and evaluate the effect of the increase in trip frequency on these criteria. Also provide the basis for the acceptable number of reactor trips in terms of the limiting component(s).

### Response

- A. An increase in reactor trip frequency will result from a lowering of the high pressure trip setpoint and the addition of the anticipatory reactor trip. To estimate the effect of these changes, total reactor trips were divided into two (2) categories:
  - Category 1 Trips that should not be affected by the above changes (e.g., total loss of feedwater, since this led almost invariably to a reactor trip with the old setpoints; power to flow trips; test trips; etc.)
  - Category 2 Trips that are affected by the above changes (e.g., high pressure trips, feedwater upsets, and turbine trips).

Category 2 trips are listed in the following table (Table 1) in the "A" columns while total trips (Category 1 plus Category 2) are listed in the "B" columns. The number of trips and frequencies in Table 1 are based on commercial calendar time. The post-TMI-2 frequencies should be viewed with caution as they are based on only a short operating history following the setpoint changes.

Ideally (i.e., with a large enough data base), the Category 1 trip frequency ("B" column minus the "A" column) should be similar for the pre- and post-TMI-2 periods. The fact that this is not the case can be attributed to the difference in calendar time and also statistical variations of the pre- and post-TMI-2 samples.

However, on the average, it can be observed that the trip frequency in Category 2 (i.e., "A" column) has increased by approximately a factor of 3 (0.23 to 0.71); which would almost double the total trip frequency.

Thus, although the data indicate approximately a doubling of the average trip frequency, the following must be considered:

- There has been a relatively short period of operation since the changes.
- There have been many startups and shutdowns during the post-TMI-2 period.

# ATTACHMENT III (Cont'd)

- As operators become familiar with the revised setpoints and operating conditions, it is reasonable to assume the trip frequencies may decrease.
- B. The structural design criterion for the number of reactor trips over the life of the plant is to keep the fatigue usage factors of all RCS components below '.0 as supported by the component stress analysis. In general, this usage factor is made up of contributions due to all specified transients. Since the largest contribution to the fatigue usage factor is attributable to heatup and cooldown transients, with reactor trips producing only a small effect, the increase in trip frequency (indicated by the average data to date) should only have a small effect relative to plant life.

As a part of the total allowable transient picture, 400 reactor trips are specified. Assuming a 40-year life, this translates into 10 trips per year or .83 per month. With the pre-TMI-2 setpoints, only the most recent plants to come on line (Davis Besse-1, Crystal River-3, and TMI-2) exceed this figure. As these plants accumulate operating experience, their trip frequencies would be expected to decline under the pre-TMI-2 setpoints. With the new setpoints, three plants exceed 0.83; however, for the reasons discussed in A above, it is premature to draw any conclusions over the life of the plant based on the little data available with these setpoints.

C. To determine the acceptable number of reactor trips in terms of the limiting component(s), it is necessary to review the stress report for each component and plant and evaluate the fatigue usage factor.

If the number of trips were to exceed 400 on any plant, that plant would have to be reanalyzed based on actual transients and the limiting component would be a function of these actual transients plus those that would be expected throughout the remainder of the plant's life.

It is important to recognize that usage factors below 1.0 represent design margin in the plant design. Any change that increases the frequency of transients causes a decrease in this margin whether the actual limit is reached or not. Therefore, steps (such as raising the high pressure trip setpoint, etc.) should be considered to reduce the trip frequency thereby improving design and safety margins.
