

Donald J. Broeni - Assistant Vice President

December 13, 1979

Mr. R. H. Engelken, Director
U. S. Nuclear Regulatory Commission
Region V
Suite 202, Walnut Creek Plaza
1990 N. California Blvd.
Walnut Creek, CA 94596

Dear Sir:

Enclosed are responses to the five questions posed at the exit meeting on December 6, 1979 in Bethesda, Maryland regarding LER 79-15 and supplements thereto.

Sincerely,

Donald Ball

c: Mr. A. Schwencer, Chief
Operating Reactors Branch #1
Division of Operating Reactors
U. S. Nuclear Regulatory Commission

Mr. Lynn Frank, Director State of Oregon Department of Energy

NRC Question (12/6/79)

Question 1 Page 1 of 2

Describe the state of stress at the interface of the masonry block and the mortar, for mortared double-wythe masonry walls, and at the interface of the masonry and core concrete for composite walls considering the following:

- a. In-plane seismic loads
- b. Out-of-plane seismic loads including pipe restraint reactions
- c. Interstory displacements

Provide the above information for three representative walls of each type (mortared, double-wythe and composite wall types) which have the highest loading conditions per a, b, and c above. Show each interface load (stress) separately.

Answer:

The predicted interface shear stresses between masonry block and mortar for three highly stressed double wythe masonry walls and between masonry block and core concrete for three highly stressed composite walls, as well as the vertical reinforcing steel stresses for these walls, are shown in Tables 1 through 6.

Walls at el. 5 ft are selected for investigation because they resist large pipe support reactions. Walls at el. 61 ft and 72 ft are selected because they resist large seismic in-plane and out-of-plane forces. These forces include the global building shear forces, the forces produced by interstory displacement and the wall inertial loads.

Question 1 Page 2 of 2

This analysis is performed for the Safe Shutdown Earthquake condition using the criteria— iffied in Supplement 1 to LER 79-15. The effects of wall dead load and vertical seismic load were neglected to provide conservatism in the analyses of the vertical reinforcing steel stresses. The results indicate that for the walls analyzed, the interface shear stresses are substantially lower than the allowables (18 psi for double wythe masonry walls and 40 psi for composite walls) specified in Supplements 1 and 2 to LER 79-15. The stresses in the reinforcing steel are also within the limits specified in those supplements.

TABLE 1 STRESSES IN 30 INCH COMPOSITE WALL AT EL. 5'-0" ON COLUMN LINE 54 BETWEEN COLUMN LINES D AND E

V = Shear force on wall in the in-plane or out-of-plane direction.

v = Concrete shear stress.

f_c = Vertical reinforcing steel stress.

NRC Question (12/6/79)

Question 2 Page 1 of 2

Provide the basis for the stress distribution considered at the interface between the masonry block and concrete core due to pipe restraint anchor bolt loads.

Answer:

The resistance to tension developed in an expansion anchor bolt occurs in the flared section at the end of the anchor bolt. If a tensile force is placed on the bolt, shear and compression stresses develop in the zone adjacent to and above the flared portion. The load is thereby distributed horizontally to the surface of the wall. The load spreading may be considered as a 450 shear cone which projects to the surface (see Figure 2-1). To estimate the tension at the interface between the masonry block and concrete core, the vertical component of the stress on the shear cone is assumed to be uniformly distributed over the circular area formed by the intersection of the cone and the block surface. The tension on the masonry block-concrete core interface due to the surface stresses can be estimated using theories developed by Boussiness for determination of stress distributions in an elastic media(1). The normal stress at the block-core interface as derived from this theory is shown on Figure 2-1. The maximum stress was calculated from the Boussiness equation for a circular area with a uniform load, and the stress distribution was obtained from stress curves(2). Also shown is an average normal stress for a cone with 2:1 slope (Cone 1). It can be seen that this cone gives a good approximation of the stress calculated from the Boussinesa equation at the interface.

The tension on the masonry block-concrete core interface due to the surface stresses can also be calculated using theories developed by Westergaard for calculation of soil stresses under circular foundations. The stress coefficients are shown in Table 2-1 along with a comparison

Question 2 Page 2 of 2

of the stress if cone 1 (2:1 slope) and cone 2 (1:1 slope) shown in Figure 2-1 are used. This table gives the ratio of the maximum stress at depth Z with the applied uniform stress at the surface for the four methods indicated. For expansion anchor bolts ranging in size from 1/2 in. to 7/8 in. in diameter, the ratio Z/2R ranges from 1.7 to 1.0 where R is the radius of the shear cone at the surface. For this range, cone 2 underestimates the stress and cone 1 provides an overestimate. For the urper range of Z/2R, the overestimate is by a factor of 2 to 3. Therefore, cone 1 is considered to provide a reasonable representation of the stress distribution and was used for calculating distribution for the tension stress at the concrete core-block interface.

NRC Question (12/6/79)

Question 3 Page 1 of 2

Provide documentation which will substantiate the extent of inspection performed on masonry construction to support your claim that the masonry construction at Trojan qualifies under the category of "special inspection" per the UBC. Also provide additional verification of the completeness of mortar between masonry wythes based on field testing and inspection (1" ± diameter core drills).

Answer:

Installation of the concrete unit masonry was performed by L. C. Pardue, a subcontractor to Hoffman Construction Company. This subcontractor implemented a QA Program in conformance with applicable sections of Appendix B to 10 CFR 50, which contained inspection responsibilities that were performed on a daily basis. Hoffman Construction Company's QA procedures assured the quality of L. C. Pardue's effort. In addition, both the Construction Manager (CM) and the Licensee implemented QA programs which contained inspection and monitoring requirements. The CM performed daily inspection of the masonry work to assure conformance with drawing and specification requirements. The implementation of such programs and procedures is evidenced by QA audit reports, nonconformance reports, and inspection reports. Attachment 3-1 provides a sampling of such reports.

To assure that the specified requirements were met during the construction period, the Licensee contracted with Northwest Testing Laboratory (an independent testing laboratory) to provide on-site inspection and testing services for masonry and concrete. One of the services they provided was furnishing qualified inspectors to perform daily inspection of masonry wall construction and testing of materials used therein. This laboratory implemented a QA program approved by the CM. Attachment 3-2 is a letter from Northwest Testing Laboratory which documents the fact that their inspection of the masonry construction at Trojan qualifies the work under the UBC classification of "Special Inspection".

Question 3 Page 2 of 2

The inspection of walls identified in Attachment 5, Supplement 2 to LER 79-15 disclosed some void areas in the inter-wythe mortar. As voids were found, they were filled with Five Star Grout in accordance with manufacturer's instructions. In addition to those walls, the N-line wall at elevation 65, the 46-line wall at elevations 61 and 77, and the east wall of the Control Building Mechanical Room at elevations 61 and 77 have been field checked for the presence of inter-wythe mortar by random sampling with a 1-1/2" core drill of 10 locations at different elevations in each wall. Based on this sampling, greater than 90% mortar was determined to be present in each wall, which is substantially greater than that required to develop the 18 psi shear capacity allowed by 1.5 UBC.

Re: Portland General Electric Audit of L. C. Pardue Inc.

Gentlemen:

In regards to the recent audit preformed by PGE of our QA records I would like to make the following attacements regarding corrective action.

- 1) QA Manual: An Rochtel approved copy of the L. C. Pardue QA manual is now available in the L. C. Pardue site office as of October 6, 1972.
- 2) MRR #10263: MRR#10263 stated that all records and material were received on 7/19/72. On close examination of the test results accompanying the certification a discrepancy was found by L.C. Pardue QA personal. The material in question was put on hold at that time untill a typographical error could be corrected by Northwest Testing on 7/21/72 at which time the material was released for use. A note has been added to MRR#10263 stating the reason for the date discrepancy.
- 3) Prawings: A complete andit of all drawings was initiated upon completion of the PGE audit. Upon completion of our sudit all noncurrent drawings were throught to a current status with Hoffmans drawing log.
- 4) Audits: Three audits of Empire Building Material were present in the L.C. Pardue files at the time of the PGE audit. Unfortunately one of the audit reports was filed with the field inspection reports. This brings the amount of audits of Ampire to three which is in accordance with the L.C. Pardue CA manual. An audit check list has been initiated for L.C. Pardue inhouse audits.
- 5) Storage Report: A material storage and protection report has been incorporated in the Parise field impostion report file and will to maintained.
- 6) NCR Log: L.C. Pardue MCR/3 han been elered out in the MCR 14-.

Pour Cards: The use of one pour card for more than one lift or pour will not be permitted in the future. The invoice number of all grout invoices will be listed on each rour card and the pour card wall numbers listed on each invoice for cross reference and material control. All pour cards and grout invoices in the L.C. Pardue file now contain this information.

Yours truly,

L. C. Pardue Jr.

> Re: Masonry Inspection Trojan Nuclear Plant Rainier, Oregon

Gentlemen:

We would like to confirm our telephone conversation of the last few days regarding the masonry inspection at the Trojan Nuclear Plant at Rainier, Oregon.

We did as a course of our work (inspection and testing) provide special inspection of the masonry work during its construction at the Trojan Nuclear Plant.

The full time inspection of the masonry work at Trojan was performed by qualified personnel and thus would qualify for the classification in the U.B.C. as masonry work performed under special inspection.

If we can be of further service please call on us.

Very truly yours,

NORTHWEST TESTING LABORATORIES, INC.

Charles R. Lane, P.E.

NRC Question (12/6/79)

Question 4 Page 1 of 2

Provide documentation which supports the use of an allowable value of 18 psi (ie 12 psi \times 1.5) for shear transfer at the interface between masonry block and mortar for the mortared double wythe walls.

Answer:

The following information substantiates the design criteria given in Supplements 1 and 2 to LER 79-15 relative to shear values at block-mortar interfaces.

The most relevant tests to establish shear values for vertical mortar joints in masonry construction are shear tests to demonstrate adhesion between masonry veneer and masonry backing. Albyn MackIntosh* has reviewed these test reports and has characterized them as consistently showing a value for shear stress exceeding 50 psi and ranging as high as 200 psi. The test laboratory where these tests were performed (Smith-Emery Test Laboratory, Los Angeles, California) will not release these test results since they are considered to be proprietary reports by the organizations requesting the tests. However, Bechtel was informed by the test laboratory that such consistently high shear values formed the basis for the 50 psi allowable shear stress at the veneer mortar interface in UBC Chapter 29, 1967 edition.

The most relevant available test data concerns transverse bending of multiple wythe unreinforced masonry. Failure consistently occurred in tension between mortar and masonry units at the wall surface. At this failure load, the shear stress present in the inter-wythe space can be computed even though failure has not occurred at this location. Transverse bending tests have been performed on 8 in. double wythe

^{*} Chairman of ACI Committee 531 which is specifically charged with providing requirements for design and construction of concrete masonry and composite elements.

brick walls (Attachment 1) and 10 in. brick-hollow block "composite" walls (Reference 1). The tests performed on the 8 in. brick with metal truss wall ties (Attachment 1) provide useful information in evaluating the performance of the inter-wythe joint of the double wythe masonry wall construction at Trojan. As expected, these walls failed in tension at the horizontal brick-mortar interface when subjected to lateral bending. It is important to note that the 8 in. brick walls demonstrated an average transverse strength of over four times the average strength of similarly tested 4 in. brick walls, thus demonstrating composite action of the two wythes. At the load level at which the tensile bond failed, the inter-wythe shear can be computed to be from 9.0 psi to 14.5 psi for these brick walls (Test: TS-1 thru TS-5, Table 5-1). Because of the tension failure mode, inter-wythe shear was sever fully developed. Comsidering the fact that the Trojan masonry walls are reinforced concrete masonry with equivalent ties and type M rather than the type S mortar used in these tests, we believe that these tests demonstrate that composite action will occur and the 12 psi allowable stress in UBC (multipled by 1.5) is reasonable for masonry block walls. Similar results were derived from the 10 in. composite #11s, tests 4C2, 4C9 through 4C11 in Reference 1.

The lateral load tests of unreinforced masonry cavity walls referred to by Mr. Mackintosh at the December 5, 1979 meeting in Bethesda, Maryland as demonstrating composite action using masonry ties only are identified in Reference 2.
