INTRODUCTION AND SUMMARY

1. INTRODUCTION AND SUMMARY

Vermont Yankee Nuclear Power Corporation's generating station operated at an average capacity factor of 77.7% in 1979. Power production was interrupted for two weeks in March to replace some faulty fuel rods and six weeks in late September to early November for annual refueling. Power was generated during 7195 hours of the year (82.1%) on 307 days. The open cycle mode of condenser cooling was used during 177 days of operation; cooling towers were used in closed cycle cooling on 130 days of operation. The average power level during these 307 days of operation was 94.6%. Figure 1.1 is a graph of the plant's record of power production in 1979.

In 1978, Vermont Yankee's NPDES permit, issued by the Vermont State Agency of Environmental Conservation, the State of New Hampshire's discharge permit, and the Technical Specifications of Vermont Yankee's operating license were all amended to permit open cycle operation, with certain thermal limitations, in the period October 15 through May 15. Vermont Yankee operated in 1979 for the first full year under these amended conditions. This is the ninth report in a series (Webster-Martin 1971, Aquatec 1973, 1974, 1975, 1976, 1977a, 1978, 1979a) that have reported the environmental studies conducted under the conditions of Vermont Yankee's discharge permits and the non-radiological Technical Specifications.

Eight sampling stations in the Connecticut River near Vernon, Vermont were used in earlier studies. The approximate locations of these stations are shown in Figure 1.2. Collections were made at only six of these stations in the 1979 studies. The locations of these six in river miles north and south of Vernon Dam are shown below.

8	8.70 miles north

SUMMARY OF RESULTS

Water Quality Studies

In 1979, the annual peak river flows of spring run-off occurred in March, earlier than is usually the case. Mean Connecticut River discharge in March was more than double the March mean discharge observed in the years 1965-1978. River flow rates diminished rapidly after the March maximum. Mean flow rates for all subsequent months of the year were below monthly averages of the period October 1964 through 1978.

The relatively low river flows of the last eight months of the year resulted in some monthly temperature records that exceeded those observed in earlier years of temperature monitoring. The May mean temperature at the upstream monitoring site was greater than the previous maximum in 1975. Because of this unusually rapid warming of the river, Vermont Yankee reverted to closed cycle cooling at 0145 on 13 May, two days before the date required by discharge permits and the operating license.

Record maximum hourly temperatures occurred both upstream and downstream of Vermont Yankee in August, at the downstream monitor location in January, and at Monitor 7, upstream, in December.

Vermont Yankee's operation in 1979 in the open cycle mode of condenser cooling was within the three thermal criteria imposed upon such operation. These conditions require that Vermont Yankee's discharge not effect a temperature at Monitor 3 greater than 65°F; the maximum hourly mean temperature observed there during open cycle

operation was 63.0°F on May 12. The maximum allowable rate of temperature change between successive hourly average temperatures at Monitor 3 is 5°F per hour; the maximum observed was 2.7°F per hour in February and December. The maximum allowable increase in river temperature effected by Vermont Yankee's discharge is 13.4°F; the maximum difference observed between downstream Monitor 3 temperature and upstream Monitor 7 temperature was 10.2°F on January 1.

Some new record monthly maximum, mean, or minimum values for dissolved oxygen, conductivity, turbidity, and pH were observed also in 1979, but all exceeded those previously observed by small absolute amounts.

Grab samples, collected once each quarter in 1979 at the two monitor stations and from Vermont Yankee's cooling water discharge, were analyzed for sixteen water quality parameters. The concentrations of all parameters were found to be within previously observed ranges except two. The chloride ion concentrations at Station 3 in February and at both river locations in August were higher than in prior years of study. The total phosphate ion concentration in the May sample at Monitor 3, downstream of Vermont Yankee, was much higher than had been found in river samples since studies were begun in 1967. High solids concentrations and turbidity, relative to either the plant discharge or the Monitor 7 samples, were found also. The high concentrations of these parameters were undoubtedly caused by the work on construction of a fish ladder at Vernon Dam that was begun in early May.

Biological Studies

Diatoms were again predominant, as in all prior years of study, in the phytoplankton samples of 1979. Also, as in former years, the more commonly observed species of diatoms were Asterionella formosa, Fragilaria spp., Melosira italica, and Tabellaria fenestrata; of flagellates were Dinobryon spp.; of green algae were Pediastrum spp.; and of blue-greens were Oscillatoria spp. Small numbers of three species that had not been found in earlier Vermont Yankee studies were observed in 1979.

Concentrations of phytoplankters in the late summer and early fall samples at both the upstream and downstream monitor stations were low relative to mean counts observed in the years 1970-1974. At the downstream station, Monitor 3, phytoplankton counts were above the 1970-1974 means of January through April, June, July and December. For all these months, though, the counts were within two standard deviations of those means. The July count at Monitor 3 was greater, however, than that predicted by application of a statistical analysis of 1970-1974 data to the July upstream count.

One downstream zooplankton concentration observed in 1979 was also greater than that predicted by a statistical analysis of 1970-1974 zooplankton monitor data. This was the Monitor 3 zooplankton count of the March sample, collected during Vermont Yankee's shutdown for replacement of faulty fuel. Higher counts than the means of 1970-1974 were also found in May at Monitor 7, in February at Monitor 3, and at both stations in March and October. Zooplankton concentrations in summer months were low relative to former years.

Rotifers constituted at least fifty percent of the majority of the zooplankton samples collected in 1979. Those most commonly observed were Polyarthra sp., Synchaeta sp., Keratella cochlearis, and Philodina sp. Protozoa, particularly Vorticella sp., were present commonly in the samples of winter and fall months. Copepods were present in samples of all months of the year.

Seventy-one genera of macroinvertebrates were found in the thirty-eight benthic fauna samples collected in 1979, twenty-eight collected by Ekman dredge and ten by Henson trap. The number of genera found in Ekman dredge collections at three of the four sample stations used was greater than in earlier years when a similar number of samples had been collected there. Caddis fly and chironomid larvae were predominant in most of the spring and summer samples; planarians were the more commonly observed organisms in some fall samples. These three forms have been observed to constitute the major portion of samples in past years.

All fish impinged during open cycle operation in 1979 on Vermont Yankee's traveling screens at the intake structure were collected, identified, weighed, and measured. Over 50% of the fish impinged in 1979 were of three species – pumpkinseed, spottail shiner, and rock bass. No species were impinged that had not been observed in earlier Vermont Yankee studies. The daily mean numbers and weight of fish impinged in each month of open cycle operation in 1979 were all within two standard deviations of the daily means observed for those months in the five phases of special open cycle testing in 1974-1978.

In 1979, 2461 fish were taken in 66 collections made by trap net, gill net, and seine haul. Seventeen fish species were collected, of which sixteen were found in collections north of Vernon Dam and twelve were found in samples taken south of the dam.

The collection of over a thousand juvenile white suckers in seine hauls in 1979 increased the percentage by number of this species in the 1979 catch to a much larger percent than had been observed in surveys of prior years. A concomitant decrease in number percentages of other species resulted in record lows for smallmouth bass and rock bass. However, all species compositions by weight in the 1979 collections were within percentage ranges of earlier surveys.

The age-growth data of 1979 for yellow perch, white perch, and smallmouth bass show rates of growth for these species similar to those observed in 1969-1973, before Vermont Yankee began operation. For walleye, however, the 1979 data indicate, as did the data of 1977 and 1978, an enhanced growth rate relative to the 1969-1973 data. But this indication is tenuous, for the sample size in 1979 was small, as it also was in 1977 and 1978.

In conclusion, the 1979 studies have not developed any evidence that Vermont Yankee's discharge of heated condenser cooling water into the Connecticut River has effected any adverse impacts on either the water quality or the aquatic biota of the river.

SECTION 2

CONNECTICUT RIVER DISCHARGE

2. CONNECTICUT RIVER DISCHARGE

Connecticut River discharge in 1979 at Vernon, Vermont, computed from the records of the Vernon Hydroelectric Station at Vernon Dam, is summarized in Figure 2.1. The mean flow rate, the maximum daily average flow rate, and the minimum daily average flow rate are shown for each month.

Annual maximum discharge at Vernon usually occurs in April. In 1979, however, maximum spring run-off flow rates occurred in March. Mean discharge in that month was 33,590 cfs, more than two times the March mean observed in the years 1965-1978. The maximum daily mean discharge in 1979 was 69,060 cfs on 26 March; the maximum hourly discharge of 70,840 cfs occurred on 25 and 26 March.

River flow rates decreased rapidly after the peak flows of March. Mean discharges for all months after March were smaller than the monthly means for the period October 1964 through 1978 – the period for which river flow data have been given in previous reports of this series. In July and August, the mean flow rates of 1979 were 52% and 48% smaller than the means for those months in 1965-1978. The only month, other than March, in which the 1979 mean flow was greater than the mean of 1965-1978 was January.

The extremes of monthly flow rates observed in 1979 were not as great as have been observed in the years 1964-1978. The maximum daily average flow of each month of 1979 was smaller than a previously observed maximum for that month, and the minimum daily average flow was larger than a minimum observed previously in 1964-1978.

FIGURE 2.1

When river flow rates are less than 10,000 cfs the Vernon Hydroeletric Station is operated as a peak load facility. Often at such times, only one hydroeletric unit is utilized during off-peak hours. Operation of this one unit meets a condition of the operating licenses of the Vernon Station and of Vermont Yankee – that a sustained minimum discharge of at least 1200 cfs be provided.

Periods of minimum flow occurred in all months of 1979 except April and on all days of the months February, July, and August. On 80 days of the first six months of the year, 85 periods of minimum flow occurred in a total of 788 hours, 18.1% of the time. The duration of the minimum flow periods in these months ranged between 1 hour and 34 hours; the mean duration was 9.3 hours.

In the latter half of 1979, minimum flows were recorded during 2061 hours, 46.7% of the time, of 155 days. Minimum flow periods occurred 167 times with durations ranging from 1 to 65 hours about a mean of 12.3 hours.

SECTION 3

RIVER TEMPERATURE

3. RIVER TEMPERATURE

Temperatures of Connecticut River water are measured continuously by two automatic water quality monitoring systems, installed in buildings on the Vermont shore of the river at Sample Station 7, upstream of Vermont Yankee, and at Station 3, downstream of the plant. The temperature data of 1979, reduced to hourly, daily, and monthly means, are shown in Tables 3.1, for Station No. 3, and 3.2, for Station No. 7, at the end of this section of the report. These data are summarized graphically in Figures 3.1 and 3.2. The maxima and minima in those figures are hourly means.

Monthly mean temperatures observed in 1979 at the downstream location, Station 3, were all within the extremes that had been previously recorded since monitoring began there in 1968. At the upstream location, Station 7, the mean May temperature, 57.5°F, was higher than any mean observed in that month since temperature data collection began there in 1970. The previous high for May at Station 7 was 57.2°F in 1975.

Record maximum hourly temperatures were observed at both sample stations. At Station 3, the January maximum of 42.2°F was greater than the previous January maximum of 41.7°F observed in 1977 and the August maximum of 84.9°F exceeded the previous August high of 81.5°F in 1973. The August maximum at Station 7, 81.7°F, was also higher than the previously observed August maximum there —79.7°F in 1975. A new high, 41.7°F, occurred also in December at Station 7. The previous December Station 7 high was 41.0°F in 1975.

FIGURE 3.2

In 1979, Vermont Yankee operated in the open cycle mode of condenser cooling in the periods January 1 through May 13 and November 2 through December 31. Such operation is permitted in the period October 15 through May 15 under thermal effluent limitations set forth in Vermont Yankee's amended NPDES permit and the amended Technical Specifications of its operating license. These criteria, which define the maximum allowable thermal impact on the Connecticut River, are as follow:

A. The temperature at Monitor 3 during open cycle operation shall not exceed 65°F;

B. The rate of change of temperature at Monitor 3 shall not exceed 5°F per hour; and

C. The increase in temperature above ambient at Monitor 3 shall not exceed 13.4°F.

The temperature records at Stations 7 and 3 showed that these thermal limitations were not exceeded during open cycle operation in 1979. The maximum hourly average temperature observed at Monitor 3 was 63.0°F on May 12. The maximum rate of change of temperature at Monitor 3, the difference between successive hourly average temperatures there, was 2.7°F/hour. A -2.7°F/hour was recorded in February; a +2.7°F/hour in December. Tabulations of the hourly rates of change in Monitor 3 temperatures during the months of open cycle operation are given in Table 3.3. These data are summarized, for the dates of open cycle operation, as a frequency distribution in Table 3.4. The modal, median, and mean rate of temperature change during open cycle operation in 1979 was 0.0°F.

The hourly mean Monitor 3 temperatures (Table 3.1) minus the corresponding Monitor 7 temperatures (Table 3.2) are shown for the months of 1979 open cycle operation in Table 3.5. These data are reduced to a frequency distribution of the temperature differences, for the dates of open cycle operation, in Table 3.6. The greatest difference observed during 1979 open cycle operation was +10.2°F on January 1 from 1700 through 2000. The modal and median range of differences during open cycle operation was +1.6

– +2.0°F and the mean difference was in the +2.1 – +2.5°F range.

The mitigatory effect of high river flows on the impact of Vermont Yankee's discharge on Connecticut River temperature is evident in the statistics of both frequency distribution tables. The ranges of rate of temperature change (Table 3.4) and of the ΔT effected in the river (Table 3.6) by Vermont Yankee's discharge are much smaller during the months of spring run-off than in the months of lower river flows.

SECTION 4

WATER QUALITY STUDIES

4. WATER QUALITY STUDIES

Four water quality parameters, in addition to temperature, are monitored continuously by the Honeywell W-20 Water Quality Data Collection Systems located on the Vermont shore at Station 7, upstream of Vermont Yankee, and at Station 3, downstream of the plant. Summaries of the data collected in 1979 for the four parameters – dissolved oxygen, conductivity, turbidity, and pH – are shown in Tables 4.1 through 4.4 at the end of this section of the report. The dissolved oxygen data, reduced to daily means and daily maxima and minima with times of occurrence, and the conductivity data, as daily means are presented in Table 4.1 for Monitor 3 and Table 4.2 for Monitor 7 Turbidity data, as daily means and pH data, as daily maxima, minima and range, are shown in Tables 4.3 and 4.4 for Monitors 3 and 7, respectively. Those tabulated data are summarized in the graphs of Figures 4.1 through 4.8.

The monthly maximum dissolved oxygen concentrations observed in 1979 at Monitor 3 in March and at Monitor 7 in April were each 0.1 mg/l greater than maxima observed in those months in prior years. The monthly mean at Monitor 7 (13.9 mg/l) was 0.2 mg/l greater than the previous high observed in 1975. The only record monthly minimum D.O. observed was that of 11.1 mg/l at Station 3 in December, 0.1 mg/l less than the minimum of December 1971.

Low river flows in July and August resulted in slightly greater ($\sim$5 µmhos) mean conductivity records at both locations. Maximum conductivity observed at Station 3 was also greater in those months than in prior years. The Station 3 maximum in May and the minimum in January were new records also.

All turbidity values – maxima, means, and minima – observed in 1979 were within one turbidity unit of those found in earlier years.

No record pH minima were established in 1979 but maxima greater by 0.1-0.2 pH units than found in earlier years were observed at Monitor 3 in February, March, April, and September and at Monitor 7 in February and August.

Grab samples for water quality analysis were collected once each quarter in 1979 at the two monitor stations and from Vermont Yankee's cooling water discharge to the river. These samples were analyzed for sixteen parameters by the procedures of Standard Methods for the Examination of Water and Wastewater, 14th edition (APHA et al. 1976). The analytical results are shown in Table 4.5.

Construction of a fish ladder at Vernon Dam was begun in May 1979. The effects of this work on river water quality are evident in the data of the May sample at Monitor 3. The high solids concentrations and turbidity, relative to the upstream samples, were accompanied by the highest total phosphate concentration observed in the river since studies were begun in 1967. The only parameter, other than phosphate, for which higher concentrations were found in 1979 than had been observed in former years was chloride. The chloride ion concentrations at Station 3 in February and at both stations in August were higher in 1979 than in previous years of study.

On occasion Vermont Yankee adds the following chemicals to its cooling water discharge to the Connecticut River: sodium sulfate, as demineralizer regenerant; sodium hypochlorite, to control biological fouling of the condenser cooling system; and sulfuric acid, for pH control. The amounts of these chemicals discharged to the river are relatively small and not likely to significantly alter the river's water quality. However, to provide a quantitative basis for assessing the impact of Vermont Yankee's operation on Connecticut River water quality, data on

the concentrations of sodium ion, chloride ion, sulfate ion, and alkalinity concentrations were subjected to statistical analysis.

The statistical methods used with these four parameters have been detailed in Reports IV and V of this series (Aquatec 1975, 1976). Data collected on these four parameters at Stations 3 and 7 before Vermont Yankee began operation and during the times of closed cycle operation through 1974 were combined and subjected to linear regression analysis. These analyses, using Station 7 concentrations as the independent variable, resulted in the statistics summarized in Table 4.6.

TABLE 4.6

SUMMARY OF STATISTICS FROM
LINEAR REGRESSION ANALYSIS OF
PREOPERATIONAL AND CLOSED CYCLE DATA
AT STATIONS 7 AND 3 FOR FOUR PARAMETERS

	PARAMETER			
	Sodium	Sulfate	Chloride	Alkalinity
Sample size	70	72	79	80
Intercept	0.23	0.96	1.1	4.9
Regression coefficient	0.925	0.927	0.795	0.844
Standard error of regression coefficient	0.041	0.054	0.053	0.049
Correlation coefficient	0.941	0.899	0.861	0.890
Standard error of estimate	0.348	0.987	0.841	2.95

The regression lines generated by these analyses are plotted as solid lines in Figure 4.9 for sodium ion, Figure 4.10 for sulfate ion, Figure 4.11 for chloride ion, and Figure 4.12 for alkalinity. Each figure also show, as dashed lines, the 95% confidence limits for Station 3 concentrations predicted by the regression equation from new observations at Station 7. These confidence limits were drawn from limits calculated for the minimum, mean, and maximum Station 7 concentrations used for each parameter in the regression analyses. The applicable range of Station 7

concentrations for each regression equation is indicated on the figure by the vertical dashed lines at the minimum and maximum value of Station 7 concentrations used to develop the equation.

On each of the figures, the data collected in May and August, when Vermont Yankee was operating in the closed cycle mode of condenser cooling, are plotted as filled circles. The data of February and November were collected while Vermont Yankee was operating in the open cycle mode. Data of these dates are plotted in the figures as open circles.

The twelve plotted points on the sodium ion, sulfate ion, and alkalinity figures are all within the range of Station 7 concentrations used to calculate the regression equations and within the 95% confidence limits associated with the regression lines. The Station 7 chloride ion concentration in August (10.8 mg/l) is greater than the maximum concentration (10.2 mg/l) used in the regression analysis, but the plotted print for the August data would fall within the 95% confidence limits of an extrapolated regression line. However, the plotted point for the February chloride concentrations indicates that the observed Monitor 3 concentration is clearly greater than the 95% confidence limit for a Station 3 concentration predicted from that observed at Station 7.

SECTION 5

PLANKTON STUDIES

5. PLANKTON STUDIES

Plankton samples were collected by pump once each month in 1979 at the downstream and upstream water quality monitors, Stations 3 and 7 (Figure 5.1). In addition, samples of river plankton were collected on twenty dates in the 1979 entrainment studies. These latter collections were made by bucket from the river at Vermont Yankee's condenser cooling water intake structure.

Samples were collected with a No. 20 mesh Wisconsin plankton net and preserved in 5% formalin. Subsequently an aliquot of the sample was examined in a Sedgewick-Rafter counting cell. Plankton were identified to the lowest feasible taxonomic level and were counted as their normally occurring unit, i.e., phytoplankters as cells, colonies, or filaments and zooplankters as individuals or colonies. The results of these analyses are presented below.

5.1 Phytoplankton Studies

A summary of the counting results of the analysis of the 1979 phytoplankton samples is given in Table 5.1. This table shows for each sample the dominant species observed, when one taxon was found in greater numbers than any other one, the concentration in units per liter of that dominant organism, and the total count in units per liter of all algae in the sample.

The concentrations of phytoplankters found in the 1979 monitor samples are also shown graphically in Figures 5.2 and 5.3. To permit ready comparison of the 1979 monitor sample data with that of earlier years, Figures 5.2 and 5.3 also carry plots of the monthly mean phytoplankton counts observed in the years 1970-1974, excluding data collected in 1974 during Vermont Yankee's open cycle testing. Variability of algal concentrations about these means is indicated on the graphs by points which are two standard deviations greater than each monthly mean.

FIGURE 5.1

Algal concentrations observed in the Monitor 7 samples of January, February, and May were greater than the 1970-1974 means; that of February was more than two standard deviations greater. At Monitor 3, phytoplankton counts greater than the 1970-1974 means there were found in the samples of January through April, in June and July, and in December. All Monitor 3 counts, however, were within two standard deviations of the 1970-1974 means. Concentrations of phytoplankters in the late summer and early fall samples at both monitor stations were low relative to the mean counts observed in 1970-1974.

An exceptionally high concentration of algal units was found in the entrainment intake sample of 12 July 1979. This sample had a total count of 94,492 units per liter. Eighty-five percent of the organisms present were two diatom species – Asterionella formosa and Tabellaria fenestrata.

In earlier reports of this series (Aquatec 1975, 1976), a statistical analysis of the phytoplankton data collected prior to Vermont Yankee's operation and during closed cycle operation at the two monitor stations was presented. This analysis developed linear regression equations which predicted Monitor 3 counts from three ranges of observed Monitor 7 counts. All Monitor 7 counts observed in 1979, except the 1349 found in June, lie within the low range, 0-772 units per liter, for which the regression equation has an intercept of 29.3, a regression coefficient of 0.802, and a standard error of estimate of 193. A comparison of the phytoplankton counts observed at Monitor 3 in 1979 with counts predicted by this regression equation from counts observed at Monitor 7 is shown in Table 5.2.

The data of Table 5.2, except that of the July sample, are shown graphically in Figure 5.4, in which the regression equation is plotted as a solid line and the 95% confidence limits for Monitor 3 counts predicted by this equation are shown as dashed lines. These confidence limits were calculated for minimum, mean, and maximum Monitor 7 counts used in the regression analysis.

12/19/79	66	94	82	+12

Vermont Yankee was utilizing closed cycle cooling at the time of collection of the May through September samples and was not operating when the March and October samples were collected. The data for these dates are plotted in Figure 5.4 as filled circles; that of the other dates, when Vermont Yankee was operating in the open cycle cooling mode, are plotted as open circles.

All points in Figure 5.4 fall within the 95% confidence limits. The point for the data of 17 July was not plotted because it is so far above the upper 95% confidence limit that it is off the scale used in the figure. This sample was collected just 5 days after the intake entrainment sample that showed the very high concentrations of Asterionella formosa and Tabelleria fenestrata. These same two diatoms constituted 76% of the Monitor 3 sample.

The phytoplankton concentration observed at Monitor 7 in June fell within the middle range of counts used in the statistical analysis of preoperational and closed cycle data. The linear regression equation developed for this middle range, Monitor 7 counts of 772-7283, has an intercept of -483 and a regression

FIGURE 5.4

coefficient of 0.912. For the Monitor 7 count of 1349 observed on June 25, the Monitor 3 concentration calculated from this equation is 747; the observed concentration was 818. The difference between the predicted and observed concentrations is much less than the standard error of estimate (2443) for the regression equation.

Forty-six species of phytoplankton were identified in the samples collected in 1979 at the two monitor sampling stations. Thirty-one additional taxa were observed in small numbers in the samples of river water collected at Vermont Yankee's intake structure during entrainment studies. A checklist of these seventy-seven phytoplankters is shown in Table 5.3 at the end of this section. Following the name of each taxon in the list are three numbers in parenthesis. The first is the number of Monitor 3 samples in which the alga was observed; the second is the number of Monitor 7 samples in which it was found; the third is the number of entrainment sample dates on which the taxon was found in a river intake sample.

Three species listed in Table 5.3 have not been observed in prior years of Vermont Yankee studies. Single units of Gymnodinium sp. and Arthrodesmus sp. were found in entrainment intake samples. The green alga, Netrium digitus, was found in the Monitor 7 sample of 19 September.

The average number of species found in the twelve upstream monitor samples was 10.5. The minimum number, 6, was observed in the December sample; a maximum of 14 was found in the March and May samples. The minimum number observed in the Monitor 3 sample was also 6, in February and December; the maximum of 19 was found in the September sample. The mean number in the twelve samples at this downstream location was 11.1 species.

In all prior years of Vermont Yankee phytoplankton studies, diatoms have been found to be the predominant type of organisms. This was the case in 1979 also. The most commonly observed species were Tabellaria fenestrata, Fragilaria capucina, Asterionella

formosa, and Melosira italica. The latter two were present in all twenty entrainment intake samples. More than fifty percent of the algal counts in all 20 entrainment intake samples and in 11 of each of the 12 monitor samples were diatoms.

The most commonly observed flagellates were again Dinobryon spp., the most frequently observed green algae were Pediastrum spp., particularly P. simplex, and the most common blue-greens were Oscillatoria spp.

A summary of the percentages of diatoms, flagellates, green and blue-green algae found in the 1979 phytoplankton samples is given in Table 5.4.

5.2 Zooplankton Studies

The counting results of the analysis of zooplankton samples in 1979 are summarized in Table 5.5 and in Figures 5.5 and 5.6. Table 5.5 shows the concentration, in units per liter, of zooplankters observed in each sample and the name and concentration of the predominant taxon in the sample, when one taxon was observed in greater concentration than any other. In the figures, total zooplankton counts observed in 1979 at the two monitor stations are plotted, along with monthly mean counts observed at these stations in the years 1970-1974, excluding times of open cycle testing. To show variability about the means, the figures also carry plots of the means plus two standard deviations.

Zooplankton concentrations observed in the summer samples of 1979 were generally low relative to counts in that season in earlier years. Zooplankton counts greater than the corresponding 1970-1974 monthly means were observed, however, in March, May, and October at Monitor 7 and in February, March, and October at Monitor 3. The October concentrations at both locations were within two standard deviations of the 1970-1974 means, but the other four counts were more than two standard deviations greater than the 1970-1974 means. Only the March Monitor 3 count was greatly in excess of the 1970-1974 mean. The count there in 1979 was 283 organisms per liter; the mean count observed in the years 1970-1974 was 6.6 with a standard deviation of 1.7.

Statistical analysis of zooplankton data collected at the two monitor stations in the years 1970-1974, prior to Vermont Yankee's operation and during closed cycle operation, has provided a basis for comparison of zooplankton counts observed at Monitor 3, downstream of Vermont Yankee, with counts predicted from the zooplankton concentrations observed at Monitor 7 upstream. This analysis, analogous to that used for phytoplankton, resulted in a linear regression equation relating Monitor 3 count, as dependent variable, to the observed Monitor 7 count. For Monitor 7 counts ranging from 0.5 to 418.5, the equation has a regression coefficient of 0.918, an intercept of 15.7, and a standard error of

10/26/79	49.0	19.0	60.7	-41.7
11/21/79	8.5	4.5	23.5	-19.0
12/19/79	6.0	2.5	21.2	-18.7

This comparison is shown graphically in Figure 5.7, in which the regression equation is shown as a solid line and 95% confidence limits are shown as dashed lines. Zooplankton monitor data collected during open cycle operation of Vermont Yankee, in January, February, April, November and December, are plotted as open circles; that collected in other months are shown as filled circles. All plotted points fall within the 95% confidence limits except that of the 20 March samples, collected during a period of shutdown at Vermont Yankee.

A checklist of the zooplankton observed in 1979 is given in Table 5.7 at the end of this section of the report. Organisms observed in entrainment samples collected from the river at Vermont Yankee's intake structure are included in the list. The three numbers in parenthsis following the name of each taxon in

COMPARISON OF OBSERVED MONITOR 3 ZOOPLANKTON COUNT WITH MONITOR 3 COUNT PREDICTED FROM PREOPERATIONAL / CLOSED CYCLE MONITOR DATA OF 1970 - 74

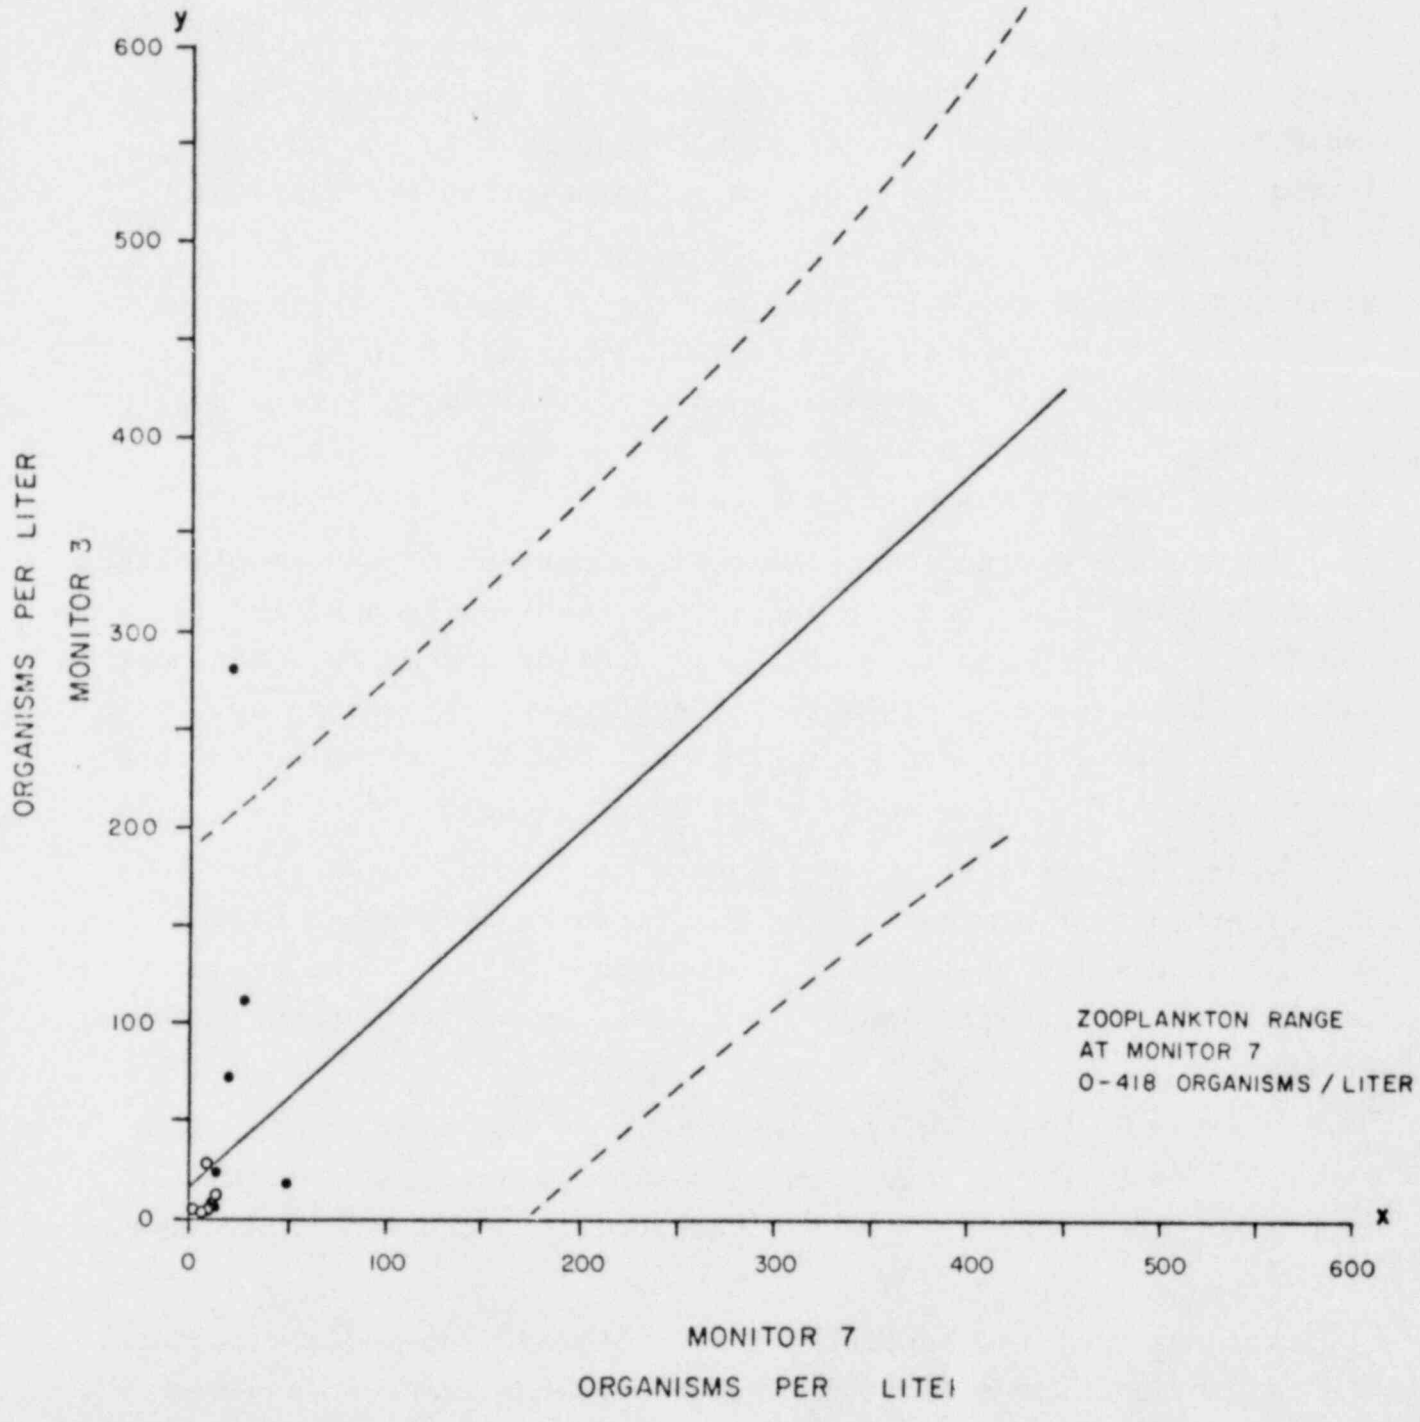

FIGURE 5.7

the list are: the number of Monitor 3 samples, of 12; the number of Monitor 7 samples, of 12; and the number of entrainment intake samples, of 20, in which the taxon was observed.

All taxa listed in Table 5.7 have been observed in earlier years except the cladoceran, Moina sp. A single organism was found in an entrainment intake sample in July. Of the 52 taxa in the list, 13 were found only in entrainment intake samples.

The number of taxa observed in a sample averaged 7.8 in the Monitor 7 samples and 7.3 in the Monitor 3 samples. The minimum number of taxa observed in a Monitor 7 sample was 2 in April, the maximum number of 14 was found in May. A minimum of 4 taxa per sample was found in the April, May, and December samples at Monitor 3; the maximum of 13 was observed in June and July.

Rotifers constituted at least fifty percent of the zooplankters found in 9 of the 20 entrainment intake samples, in 5 of the 12 Monitor 7 samples, and in 9 of the 12 Monitor 3 samples. The most commonly observed rotifers were Polyarthra sp., Synchaeta sp., Keratella cochlearis, and Philodina sp. The latter two were found in at least half of the samples collected at each location.

Protozoa, particularly Vorticella sp., constituted relatively large percentages of the samples collected in winter and fall months, especially the samples at Monitor 7. Protozoans predominated in the samples there in January and February and in October through December.

Copepod nauplii were present in 82% of the samples collected in 1979. They were observed in some samples all twelve months of the year. Adult copepods were found in all months except May and October.

A summary of the percentages of protozoa, copepoda, cladocera, and rotatoria observed in the 1979 zooplankton samples is given in Table 5.8.

SECTION 6

ENTRAINMENT STUDIES

6. ENTRAINMENT STUDIES

6.1 Phytoplankton and Zooplankton Entrainment

On 20 dates in 1979, samples of Connecticut River water at Vermont Yankee's cooling water intake structure and of the plant's cooling water discharge to the river were taken to assess the impact on phytoplankton and zooplankton due to entrainment. Duplicate samples were collected at approximately two week intervals during times when Vermont Yankee was operating.

For each sample, 40 liters of water, collected by bucket, were poured through a No. 20 mesh plankton net. A portion of the fresh sample concentrate was examined within the hour to determine the identity and relative numbers of living and dead organisms. Zooplankters were tabulated as living if they were observed to move or showed internal movement within one minute. Phytoplankters were listed as living if they had normal pigmentation and no signs of plasmolysis. The remaining portion of each sample was preserved with formalin for subsequent identification and enumeration of the organisms present.

The taxa of phytoplankton and zooplankton found in the entrainment intake samples are indicated in the two checklists, Tables 5.3 and 5.7, of the previous section of this report. In those lists, the third number in parenthesis after each taxon is the number of sample dates, of a total of 20, on which the taxon was observed in an intake sample. In general, the same taxa were observed in discharge samples as were found in river intake samples. However, five species of phytoplankton were found in 1979 discharge samples that were not observed in plankton samples or entrainment samples collected from the river. Four of these were green algae – Coelastrum mircroporum, Cosmarium sp., Crucigenia tetrapedia, and

Tetraedron sp.- that were observed in small numbers on one occasion each. The fifth, Calothrix sp. - a filamentous blue-green - was found in three samples of late summer. Lecane luna, a rotifer, was the only zooplankter found only in discharge samples in 1979. A single organism was found in a sample of 13 September.

The counting results of the analysis of the fresh and the preserved entrainment samples are summarized in Table 6.1. The data of Table 6.1 have been used to calculate the percent changes in live plankton concentrations between intake and discharge samples shown in Table 6.2. Greater concentrations of live organisms in discharge samples than in intake samples were observed for phytoplankton on 10 of the 20 sample dates; for zooplankton on 3 dates.

Increases in living and in total plankton concentrations in discharge samples over those in river intake samples have been observed in all years of entrainment studies at Vermont Yankee. They are greater, on a percentage basis, at times when the river temperature is low and ambient plankton concentrations are small. During open cycle operation when river temperature is below 50°F, Vermont Yankee often recirculates a portion of its cooling water to optimize the efficiency of electrical generation. The warmer recirculated water promotes algal growth on the walls of the cooling water system and this attached growth supports a community of microinvertebrates. This aufwuchs often sloughs off into the circulating water system and becomes planktonic.

The impact of Vermont Yankee's entrainment of plankton on the river's concentration of live plankton is dependent upon the proportion of river flow, Q_r, which is utilized as condenser cooling water. Calculations of the percent changes in river plankton concentrations due to entrainment on the 20 study dates of 1979 are shown in Table 6.3. These claculations assume uniform distribution of river plankton at the intake structure and complete mixing of plant discharge into the river.

During open cycle operation, plant discharge flow rate, Q_D, equals the rate of intake from the river, thus percent change of plankton concentration in the mixed river is the percent change through the plant, Table 6.2, multiplied by the ratio of Q_D to Q_R. During closed cycle operation, some water withdrawn from the river is lost by evaporation in the cooling towers. The closed cycle calculations in Table 6.3 have assumed a concentration factor of 2 due to evaporation, which would reduce river flow by an amount equal to plant blowdown discharge, estimated conservatively at 15 cfs. Percent change in river plankton concentration is calculated, then, by multiplying percent change through plant by the ratio of 15 cfs to (Q_R-15 cfs).

The largest calculated decrease in live plankton concentration in the river is -6.9% for phytoplankton and -8.9% for zooplankton, both based on the data of the 22 December samples. The river concentrations (the intake samples) on that date were low — 128 algal units per liter and 2.0 zooplankters per liter. The calculated percentage decreases would reduce river concentrations to 119 and 1.8 units per liter respectively. This is not a significant impact on river plankton concentrations.

In general, river plankton concentrations are so small in the colder months of the year, when Vermont Yankee is operating in open cycle, that the plant's impact on river biota is not significant, regardless of the effects of entrainment on viability of phytoplankton and zooplankton. In the warmer months, when plankton populations are greater, the impact of Vermont Yankee's closed cycle operation is minimal because such a small portion of total river flow is used as condenser cooling water.

6.2 Ichthyoplankton Entrainment

Studies on the entrainment of larval fishes conducted in 1977 and 1978 have been reported earlier (Aquatec 1977b, 1979b). Such studies were conducted in 1979 also. Samples were collected daily behind the trash racks in Vermont Yankee's intake bay from 3 April through the last date of open cycle operation, 12 May. Sampling was continued in the river near Vermont Yankee's intake structure through the end of June.

The samples were collected with a 0.5 meter diameter plankton net with a T.S.K. flowmeter positioned in the net's mouth. The net was mounted in an aluminum frame and lowered by ropes to collect intake bay samples; the net was towed by boat to collect the river samples.

The results of the studies in the intake bay are summarized in Table 6.4; those of the tows in the river are shown in Table 6.5. Intake bay data have been reduced to show the number of larvae entrained per hour and the intake flow expressed as a percentage of the river flow (measured as discharge at Vernon Dam).

Ichthyoplankters were first observed in the sample of 5 May and were found in all subsequent open cycle samples except that of 9 May. The first ichthyoplankter was observed on an earlier date, 2 May, in 1977, but more organisms were collected before 15 May in the samples of 1979. This is probably attributable to the more rapid warming of the river in 1979 than in 1977. Mean daily temperature observed at Monitor 7 on 15 May in 1977 was 54.8°F, in 1979 was 60.1°F. In the colder spring of 1978, the average temperature at Monitor 7 on 15 May was 51.6°F. No ichthyoplankters were collected until that date in 1978.

SECTION 7

BENTHIC FAUNA STUDIES

7. BENTHIC FAUNA STUDIES

Thirty-eight samples of Connecticut River benthos were collected at the four Vermont Yankee sample station locations shown in Figure 7.1. Twenty-eight samples, in seven sample sets, were collected with a 9" Ekman dredge and ten were collected by use of Henson traps, wire cages filled with 2 to 3 inch diameter rocks that were left on the river bottom for 6 to 10 weeks before retrieval. The Ekman dredge samples of the May set consisted of the organisms collected in 5 dredge hauls at each river quarter point. The remainder of the collections were made by 10 dredge hauls at each quarter point in the river. Henson traps set at Stations 2 and 5 in September were vandalized before the November retrieval date.

The material collected by either sample method was washed through a set of standard sieves and organisms retained by a No. 25 mesh sieve were preserved in 70% alcohol for subsequent analysis. Identification was made to the lowest practicable taxonomic level, usually to genus.

Seventy-eight taxa of bottom fauna were identified in the 1979 samples. A checklist of these macroinvertebrates, Table 7.1, appears at the end of this section of the report. The number of samples in which a listed taxon was found is shown in the table for each sampling technique at each sample station.

The number of genera observed in the 1979 samples was 71, of which 35 were found only in Ekman dredge samples, 11 were found only in Henson trap samples, and 25 were collected by both sample methods. The number of samples collected by Ekman dredge in 1979 was comparable to the numbers collected at Stations 2 through 5 in the years 1969, 1977, and 1978. A comparison of the numbers of genera collected by Ekman dredge at these stations in these years with the results of the 1979 collections is shown in Table 7.2

TABLE 7.2

COMPARISON OF NUMBER OF SAMPLES
AND NUMBER OF GENERA OF BENTHOS
COLLECTED BY EKMAN DREDGE

Station Number	Number of Samples/Number of Genera			
	1969	1977	1978	1979
2	6/33	8/20	8/22	7/27
3	6/24	8/25	8/13	7/26
4	7/16	8/19	8/17	7/26
5	8/18	8/20	6/14	7/28

More dredge hauls were used in the collection of most of the 1979 samples than were used in the previous years, but this increased sampling effort was not unproductive. More genera were found in 1979 at Stations 3, 4, and 5 than in earlier years, and the number observed at Station 3 was exceeded only by the number found in the 1969 collections.

The results of the analysis of the 1979 benthic fauna samples are summarized in Table 7.3. The summary shows for each sample the number of organisms and taxa observed and lists the predominant type of benthos in the sample and the percentage of that form in the sample. A diversity index is also tabulated for each sample. The index was calculated with the following equation:

$$\bar{d} = \frac{C}{N} \left(N \log_{10} N - \Sigma\, n_i \log_{10} n_i\right)$$

where C is a constant which converts logarithms from base 10 to base 2; N is the number of organisms: and n_i is the number of organisms in the $i^{\underline{th}}$ taxon.

Caddis fly and chironomid larvae were present in the largest numbers in most of the spring and summer samples; planarians were the dominant type of organisms in some fall samples. These three forms have been observed to constitute the major portion of samples in past years. Tubificids, which have been the predominant organisms in some samples of earlier years, were not observed, however, to be the major constituent of any 1979 sample.

SECTION 8

FISH STUDIES

8. FISH STUDIES

8.1 Fish Impingement Studies

During all five phases of the special open cycle testing conducted in the years 1974-1978, fish impinged on Vermont Yankee's traveling screens at the intake structure were collected each day and identified, counted, weighed, and measured. The results of these studies, summarized in the Phase V report (Aquatec 1979b), provided the basis for the schedule of impingement studies. set forth in Vermont Yankee's amended NPDES permit, to be conducted during open cycle operation. However, the Technical Specifications of the operating license, which require that all fish impinged be collected, have not been amended. Therefore, all fish impinged during open cycle operation in 1979 were collected.

A summary of the weight extremes and the extremes in total length of the fish species impinged in 1979 is given in Table 8.1. In Table 8.2, the numbers and total weight in grams of each impinged species are shown for each month of open cycle operation. The fish species are listed in order of the decreasing number of the species collected throughout open cycle operation in 1979.

The table also shows, for each month and for the year, the mean number and mean weight of fish impinged per day of open cycle operation in 1979. At the bottom of the table are listed the daily means and standard deviations, for both number and weight of fish impinged, that were observed for those months in the five phase open cycle test program.

All daily means, both number and weight, observed in each open cycle month of 1979 were within the two standard deviations of the Phases I-V daily means for the corresponding months. In fact, only the mean number of fish impinged in February, 3.1 per day, exceeded

the corresponding Phases I-V mean plus one standard deviation, 3.0 per day. Both the daily mean number and weight of fish impinged during 177 days of open cycle operation in 1979 were below the Phases I-V daily means for corresponding months.

8.2 Resident Finfish Studies

In 1979, 1232 fish were collected at Vermont Yankee Sample Stations 2 and 3, downstream of Vernon Dam, and 1229 fish were collected at Stations 4, 5, and 8, upstream of the dam. The locations of the sample stations are shown in Figure 8.1. The fish were taken in 66 collections by three capture methods – trap net, gill net, and seine haul. A summary by sample station and capture method of the fishing effort made and the numbers and weight of fish collected is shown in Table 8.3.

All fish collected were identified and their weight and total length were measured and recorded. Of the seventeen species observed in 1979 collections, eleven were collected both upstream and downstream of Vernon Dam. Five species – carp, spottail shiner, silvery minnow, American eel, and largemouth bass – were observed only in collections north of the dam; chain pickerel was found only in the collections downstream of Vernon Dam. No species were collected in 1979 that had not been captured in surveys of previous years.

The data of the 1979 fish collections are summarized by species in Tables 8.4, 8.5, and 8.6. Table 8.4 shows for all collections the number, the total weight, and the extremes in weight and total length observed for each species. Tables 8.5 and 8.6 summarize the number and total weights of the species captured north and south of Vernon Dam. In addition, frequency distributions by total length are shown in Table 8.7 for nine of the species.

The species compositions, by weight and by number, of the 1979 collections are graphed in Figures 8.2 and 8.3. These compositions are reduced to a percentage basis and shown in Figures 8.4 and 8.5, along with percentage compositions of earlier surveys to permit comparison with previous studies.

The percentages by weight in the 1979 study were all within the ranges that had been observed in earlier surveys, including the weight percentage of white sucker. But the number of white sucker taken in the 1979 collections represented a much greater percentage of the year's catch than in prior studies. This is attributable to the capture in seine hauls on 22 June 1979 of 1030 juvenile white suckers; 969 near Stebbin Island, south of Vernon Dam, and 61 along the New Hampshire shore of the river at Station 4. This great increase in the relative numbers of white sucker captured resulted in a smaller percentage by number for smallmouth bass and rock bass than had been found in earlier surveys.

Scale samples for age determination were taken from all white perch, yellow perch, walleye, and smallmouth bass collected in 1979 that had a total length more than 50 millimeters. The results of the reading of these scales, along with the age-growth data collected in years prior to Vermont Yankee's operation with open cycle cooling, are shown in Tables 8.8 through 8.11. The data on number of annuli and mean total length from these tables are shown graphically in Figures 8.6 through 8.9.

The points of difference that are found between the 1979 and the 1969-1973 age-growth curves for white perch, yellow perch, and smallmouth bass occur when few specimens in an annulus class were captured. For walleye, however, the age-growth data of 1979 again indicate, as did the data of 1977 and 1978, an enhanced growth rate compared to the statistics of the years 1969-1973. The number of walleye, though, in the sample of each of the three years has been small – 28 in 1977, 39 in 1978, and 23 in this year.
