1.0 Bioassays

1.1 Urinalysis

License Condition 38, Part D requires that bioassays exceeding 15 ug/l be investigated. Attachment 1 shows the results of 11 bioassay reports in which none exceeded the 150 ug/l reporting level.

2.0 Stack Sampling

Attachment 2 shows the results of stack sampling for the first and second quarters of 1989. The mill operated at or near tonnage capacity both quarters. No trends are apparent. Second quarter grizzly stack sampling data has been delayed from the laboratory and will be forwarded under separate cover.

3.0 Environmental, Radiological, and Effluent Monitoring Data

3.1 Environmental Radon

Environmental Radon concentrations are determined by Trak Etch detectors furnished by Terradex Corporation. There is one detector at each of the five environmental monitoring stations with a duplicate at BHV-2, the nearest residence. Figure 1 shows the locations of the environmental stations in and around the mill.

Table 1 and Graphs 1 through 5 show the results. Table 2 and Graph 6 are used for quality control purposes. Table 2 is the linear regression results comparing BHV-2 to BHV-6 (duplicate at BHV-2). The calculated r^2 is 0.06, a value little different from one generated by random selection. Graph 6 shows BHV-2 versus BHV-6 with the expected curve shown.

A significant trend has appeared at BHV-5. The corrected value at this location is below 25% MPC for an unrestricted area. However, it appears that this limit could be exceeded in the near future with no action on Umetco's part. Umetco has evaluated the condition and taken actions that should reverse this trend.

Radon at BHV-5 could be coming from the ore pad area, from ore carried onto the access road during muddy periods, from yellowcake stored on the property, or from the tailings area. The ore pad has been eliminated from consideration because the quantity of ore and the contained pounds stored there are less than during previous years.

It was possible though not likely, in Umetco's judgement, that the radon was coming from mud carried onto the access road (near BHV-5) from the ore pad by truck wheels during muddy periods. Umetco personnel performed a gamma scan and although the contamination was minimal, actions were taken to reduce the contamination to background levels.

3.2 Environmental Gamma

Gamma levels at the five environmental locations are determined by the Thermal Luminescent Dosimeters (TLDs) furnished by Eberline Instruments. The badges are exchanged quarterly and the data is presented in Tables 3 through 7 and Graph 7. There are no apparent trends in the data, with measured values in the range of previous values.

3.3 Vegetation Samples

Tables 8 through 10 and Graphs 8 through 10 show the results of the vegetation samples. No apparent trends appear in the data.

3.4 Environmental Air Monitoring

Air monitoring at the White Mesa Mill is accomplished by five high volume stations located around the periphery of the mill. See Figure 1. In all parameters with the exception of lead 210, BHV-5 registers the highest values. It is felt that this is the result of mud carried onto the mill access road by the ore haul trucks as they exit the mill yard. No other trends are apparent.

3.5 Groundwater Monitoring

The results of groundwater monitoring are shown in Tables 18 and 19 and Graphs 15 through 36. Table 20 can be used to evaluate the quality of analyses from the analytical laboratory. Three types of quality control samples have been submitted to the vendor laboratory: blanks, spikes, and duplicates,

all of which are "blind". No trends are apparent in the data.

3.6 Surface Water Monitoring

The results of surface water monitoring is presented in Table 21. Note that a request for License amendment has been submitted to drop Westwater Creek from monitoring requirements due to its being dry 15 out of the last 24 quarters. No apparent trends are visible.

4.0 Meteorological Data

The Semi-Annual Air Quality and Meteorology Monitoring Report provided by EnecoTech is attached as Appendix A.

Investigation of Elevated Bioassay

January 5, 1989

A sample collected from a yellowcake precipitation operator on January 5, 1989 exceeded the 15 ug/l u-nat resample level at 24 ug/l uranium. An additional sample was collected on 1/19/89 prior to going on long change which showed bioassay levels at 45 ug/l u-nat. The operator was removed from yellowcake until bioassay levels returned to normal levels. A sample collected on 1/24/89 showed bioassay levels had returned to near normal levels at 8 ug/l uranium. The investigation of this incident is based on information gathered from discussions with the operator.

1. Airborne results from breathing zone and area airborne samplers were showing low concentrations both inside and outside the enclosures.
2. Samples collected from yellowcake operators during this same time period were all at normal levels. This suggests this incident was an isolated occurrence and not a condition prevalent throughout yellowcake.
3. Discussion held with the operator indicate the elevated reading was a result of ingestion of material at the centrifuge area. During some cleanup around the centrifuge the operator got splashed with material from the hose attached to the pots that feed the centrifuge.

With the frequency at which this operator's samples exceed the 15 ug/l u-nat level it is recommended that he be removed from yellowcake permanently.

S. L. Schierman
Radiation Protection Officer

SLS/gp

Investigation of Elevated Bioassay

January 12, 1989

On 1/12/89 a sample collected from a yellowcake packaging operator exceeded the 15 ug/l resample level at 24 ug/l uranium. An additional sample collected on 1/21/89 shows bioassay levels had returned to normal levels. In discussions with the operator it appears the material was ingested during the cleanout of the yellowcake scrubber tank.

1. The yellowcake packaging and precipitation operator were assigned to cleanout the build-up in the yellowcake scrubber tank.
2. Build-up from the tank was transferred by bucket to 55 gallon drums to be reprocessed at a later date.
3. The remainder of the material is then washed back to a sump pump for reprocessing.

The operator removed his full-face respirator due to fogging to see how much build-up remained in the tank and was splashed causing the ingestion of some material.

4. Bioassay results from the other operator working on this job were at 2 ug/l or normal levels.

Nose cups are supplied to help prevent the fogging of full-face respirators which should prevent this from occurring in future jobs.

S. L. Schierman

S. L. Schierman
Radiation Protection Officer

SLS/gp

Investigation of Elevated Bioassay

January 20, 1989

A bioassay sample collected on 1/20/89 exceeded the 15 ug/l resample level at 17 ug/l uranium. Additional samples collected on 2/2/89 show bioassay levels had returned to normal at 2 ug/l uranium. The sample appears to have been contaminated as it was submitted one (1) day late. Discussions with the operator could not account for any explanation of elevated bioassay results.

The sample is considered to be contaminated prior to analysis due to being submitted late.

Discussions were held with the shifter and the operators about submitting samples in a timely manner. Any further problems of this nature could result in disciplinary action.

S. L. Schierman

S. L. Schierman
Radiation Protection Officer

SLS/gp

Investigation of Elevated Bioassay

January 20, 1989

A bioassay sample collected on 1/20/89 exceeded the 15 ug/l u-nat action level at 38 ug/l uranium. An additional sample from 2/1/89 showed bioassay levels at normal levels of 5 ug/l uranium. The Maintenance Foreman was notified of the results and his mechanic was restricted from work at yellowcake until bioassay levels returned to normal.

The investigation of this incident comes to the following conclusions:

1. Samples submitted by the maintenance workers for RWP 558 were turned in after break at 9:00 A.M. Both employees had been at work since 7:00 A.M.
2. Bioassay levels from other people working on this job were below the 15 ug/l u-nat level.
3. Discussions with the employee indicate there were no unusual circumstances this was verified with the Radiation Tech. present during the job.

It is felt that this sample exceeded the 15 ug/l uranium level because of contamination of the sample due to being submitted late.

S. L. Schierman

S. L. Schierman
Radiation Protection Officer

SLS/gp

Investigation of Elevated Bioassay

January 24, 1989

On 1/24/89 a sample collected from a yellowcake precipitation operator exceeded the 15 ug/l resample level at 29 ug/l uranium. An additional sample collected on 1/31/89 showed bioassay levels normal. Discussions with the operator have indicated this sample was contaminated due to late submittal. The following information was used to make this determination:

- 1) A sample collected on 1/21/89 was at normal levels of < 5 ug/l uranium.
- 2) The operator had no recollection of any circumstances that would have caused an elevated reading.
- 3) The sample was collected during the middle part of this operator's shift. The bioassay cup was put out for swing shift coming back from their long change. The sheet was read wrong and a cup put out for the wrong packaging operator.
- 4) The operator had been at work for approximately 2 hours before giving the sample. During this time he had barreled 2 drums of yellowcake.

Because the operator was not scheduled for a sample bottle he did not check prior to going to work. With the amount of time spent at the work location and the sample on 1/31/89 at normal levels, the sample is considered to be contaminated prior to analysis.

S. L. Schierman
S. L. Schierman

SLS/gp

Investigation of Elevated Bioassay

January 31, 1989

On 1/31/89 a bioassay sample was collected from a vanadium operator that exceeded the 15 ug/l resample level at 30 ug/l uranium. An additional sample was collected on 2/7/89 which shows bioassay levels at 12 ug/l uranium. Discussions with the operator have little explanation as to why or how his bioassays would have exceeded 15 ug/l uranium.

The operator works at vanadium and has spent little or no time at yellowcake.

No explanation as to why the sample exceeded the 15 ug/l uranium is available. The only likely circumstances would be that the sample was contaminated. This, however, would have had to have been prior to analysis as both laboratory surfaces were scanned prior to analysis and little to no contamination was found. Samples being assayed around this sample were not spiked or known to have any elevated readings so splatter during evaporation is not likely.

SLS/d

S. L. Schierman
Radiation Protection Officer

SLS/gp

Investigation of Elevated Bioassay

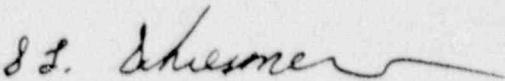

February 2, 1989

On 2/2/89 a sample was collected from a vanadium packaging operator which exceeded the 15 ug/l action level at 16 ug/l uranium. The sample was from a yellowcake operator that had been removed since 1/19/89 and assigned to vanadium. Samples collected on 2/17/89 show bioassay levels are at normal levels.

My evaluation of this incident is based on the following:

- 1) Monthly sampling at vanadium shows little airborne uranium.
- 2) Samples were submitted in a timely manner which minimizes contamination potential.
- 3) This operator had a frequent elevated bioassay history at yellowcake and was removed and it has been recommended that removal be permanent.
- 4) Discussions with the operator identified no potential explanation of why the sample exceeded 15 ug/l u-nat.
- 5) Laboratory analysis on the sample had good reproducibility and wipe tests for alpha contamination were negative.

Upon review of the data, how the sample was collected and submitted in a timely manner, no explanation as to why the sample is above 15 ug/l uranium can be given.

S. L. Schierman
Radiation Protection Officer

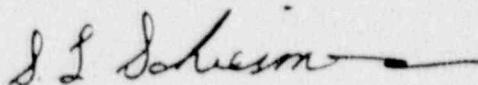

Investigation of Elevated Bioassay

February 16, 1989

A bioassay sample collected on 2/16/89 from an instrument man exceeded the 15 ug/l resample level at 59 ug/l uranium. Follow-up samples collected on 2/19/89 show bioassay levels were at < 5 ug/l or at normal levels. Interviews with the employee lead to the following conclusions:

- 1) The employee had worked on burners in the YC dryer enclosure for one (1) hour on 2/14/89. Additional time was spent working on burners on 2/15/89 about five (5) hours.
- 2) The job on the 15th shows the highest airborne concentrations but wearing a respirator would provide adequate protection.
- 3) Prior to submitting the sample on the 16th the employee had reported to work and filled the cup prior to changing into his work clothing. During discussions with the employee an accumulation of dust was observed on the hard hat with fingerprints on the bill. While submitting the sample the employee was wearing his hard hat. The hard hat was scanned later that day and the dust determined to be yellowcake.

Because the follow-up sample collected three (3) days after the initial sample of 59 ug/l shows no uranium content present. It is believed the sample was contaminated during collection by yellowcake from the hard hat. This is further evident by the fingerprints on the hat which would greatly increase the chance of contamination of the sample.

S. L. Schierman
Radiation Protection Officer

SLS/gp

BIOASSAY INVESTIGATION

March 24, 1989

A sample collected on 3/24/89 was in the 15 ug/l resample level. The sample was collected from a contractor doing refractory work to the Skinner dryer at yellowcake. A follow-up sample collected on 4/7/89 showed bioassay levels had returned to normal levels of 3 ug/l uranium.

Discussions with the employee and the following information indicate the material was ingested.

1. Airborne levels were not above protection levels for the type of respiratory protection used. Listed below are the airborne concentrations:

A. 3/21/89 2.5×10^{-10} or 250% MPC
B. 3/22/89 3.9×10^{-11} or 39% MPC
C. 3/23/89 1.1×10^{-10} or 110% MPC
D. 3/24/89 1.8×10^{-9} or 1800% MPC

Airline respirators were used for the duration of this job by the contractor.

2. After work each day the coveralls were laundered and showers were taken by the contractors.
3. Bioassay samples were collected on 3/20/89 as baseline samples all were below 5 ug/l uranium. Additional samples were taken mid-shift on 3/23/89 and all these samples were below 5 ug/l uranium.
4. Personal observations made during the construction were that respirators were removed frequently as only short durations of time could be spent in the Skinner dryer. It is my opinion that this is when the ingestion of material occurred. Discussion with the contractor could not identify an incident which would have lead to any elevated readings.

Investigation of Elevated Bioassay

May 2, 1989

A bioassay sample collected on 5/25/89 exceeded the 15 ug/l resample level at 22 ug/l uranium content. Follow-up samples collected on 5/31/89 show uranium levels had returned to normal at 2 ug/l.

The cause of the initial elevated bioassay is based on information gathered from the employee and personal observations. My evaluation of this incident is listed below:

- 1) Area airborne and breathing zone samples show uranium airborne concentrations are low during the period prior to submitting the bioassay sample.
- 2) The employee has no recollection of an incident which would have caused an elevated bioassay reading.
- 3) Other operators during the same time period show no elevated bioassay results.
- 4) The sample submitted on 5/25/89 was turned in about two (2) hours late. With no recall of an incident by the employee and follow-up levels showing normal values it appears the sample was contaminated prior to analysis.
- 5) Both the sample prep. and fluorometric room alpha wipe tests show levels were below 25 dpm/100 cm².

It is felt the sample was contaminated by the employee during collection due to being submitted late and not indicating a true value of 22 ug/l uranium content.

Discussions have been held with the shifter and the employee about submitting samples prior to reporting to the work location.

S. L. Schierman
S. L. Schierman
Radiation Protection Officer

SLS/gp

INVESTIGATION OF ELEVATED BIOASSAY SAMPLE

July 5, 1989

A bioassay sample collected on 6/21/89 exceeded the 15 ug/l action level. Follow-up samples collected on 6/28/89 show uranium levels had returned to normal levels. Discussions held with the operator suggest the sample was contaminated during collection. This is based on the following information supplied by the operator:

The sample was collected prior to reporting to his work location.

Because of the small amount submitted prior to work the operator filled the remainder of the specimen bottle at the end of his shift. This person was working as the yellowcake precipitation operator and submitted the sample prior to showering. Because of the above information, along with no recall of an incident by the operator, the sample is considered to be contaminated.

1.0 INTRODUCTION

In 1977, a meteorological, air quality, and radiological monitoring program was started at the Blanding Uranium Mill. The purpose of this monitoring program was to document the regional atmospheric baseline and to provide adequate data to assess the potential air quality impacts resulting from the mill. The monitoring program is ongoing to provide compliance monitoring for the mill operations. This report summarizes the data collected from this monitoring program for the period January through June, 1989.

2.0 MONITORING PROGRAM DESCRIPTION

This section presents the site location and describes the daily activities at the site. Data reduction and analysis procedures are also discussed.

2.1 Site Description

The region encompassing the UMETCO Blanding Uranium Mill is shown in Figure 1. The mill is located in an area known as the White Mesa and is approximately five miles south of the town of Blanding, Utah, just west of State Highway 47. The air monitoring station, located on the northern property boundary of the mill, is situated in the southwest corner of Section 22, T37S, R22E at an elevation of 5660 feet MSL. The site was located for the purpose of compliance monitoring for operations at the mill. Pertinent meteorological parameters are measured at this monitoring site.

2.2 Monitoring Instrumentation

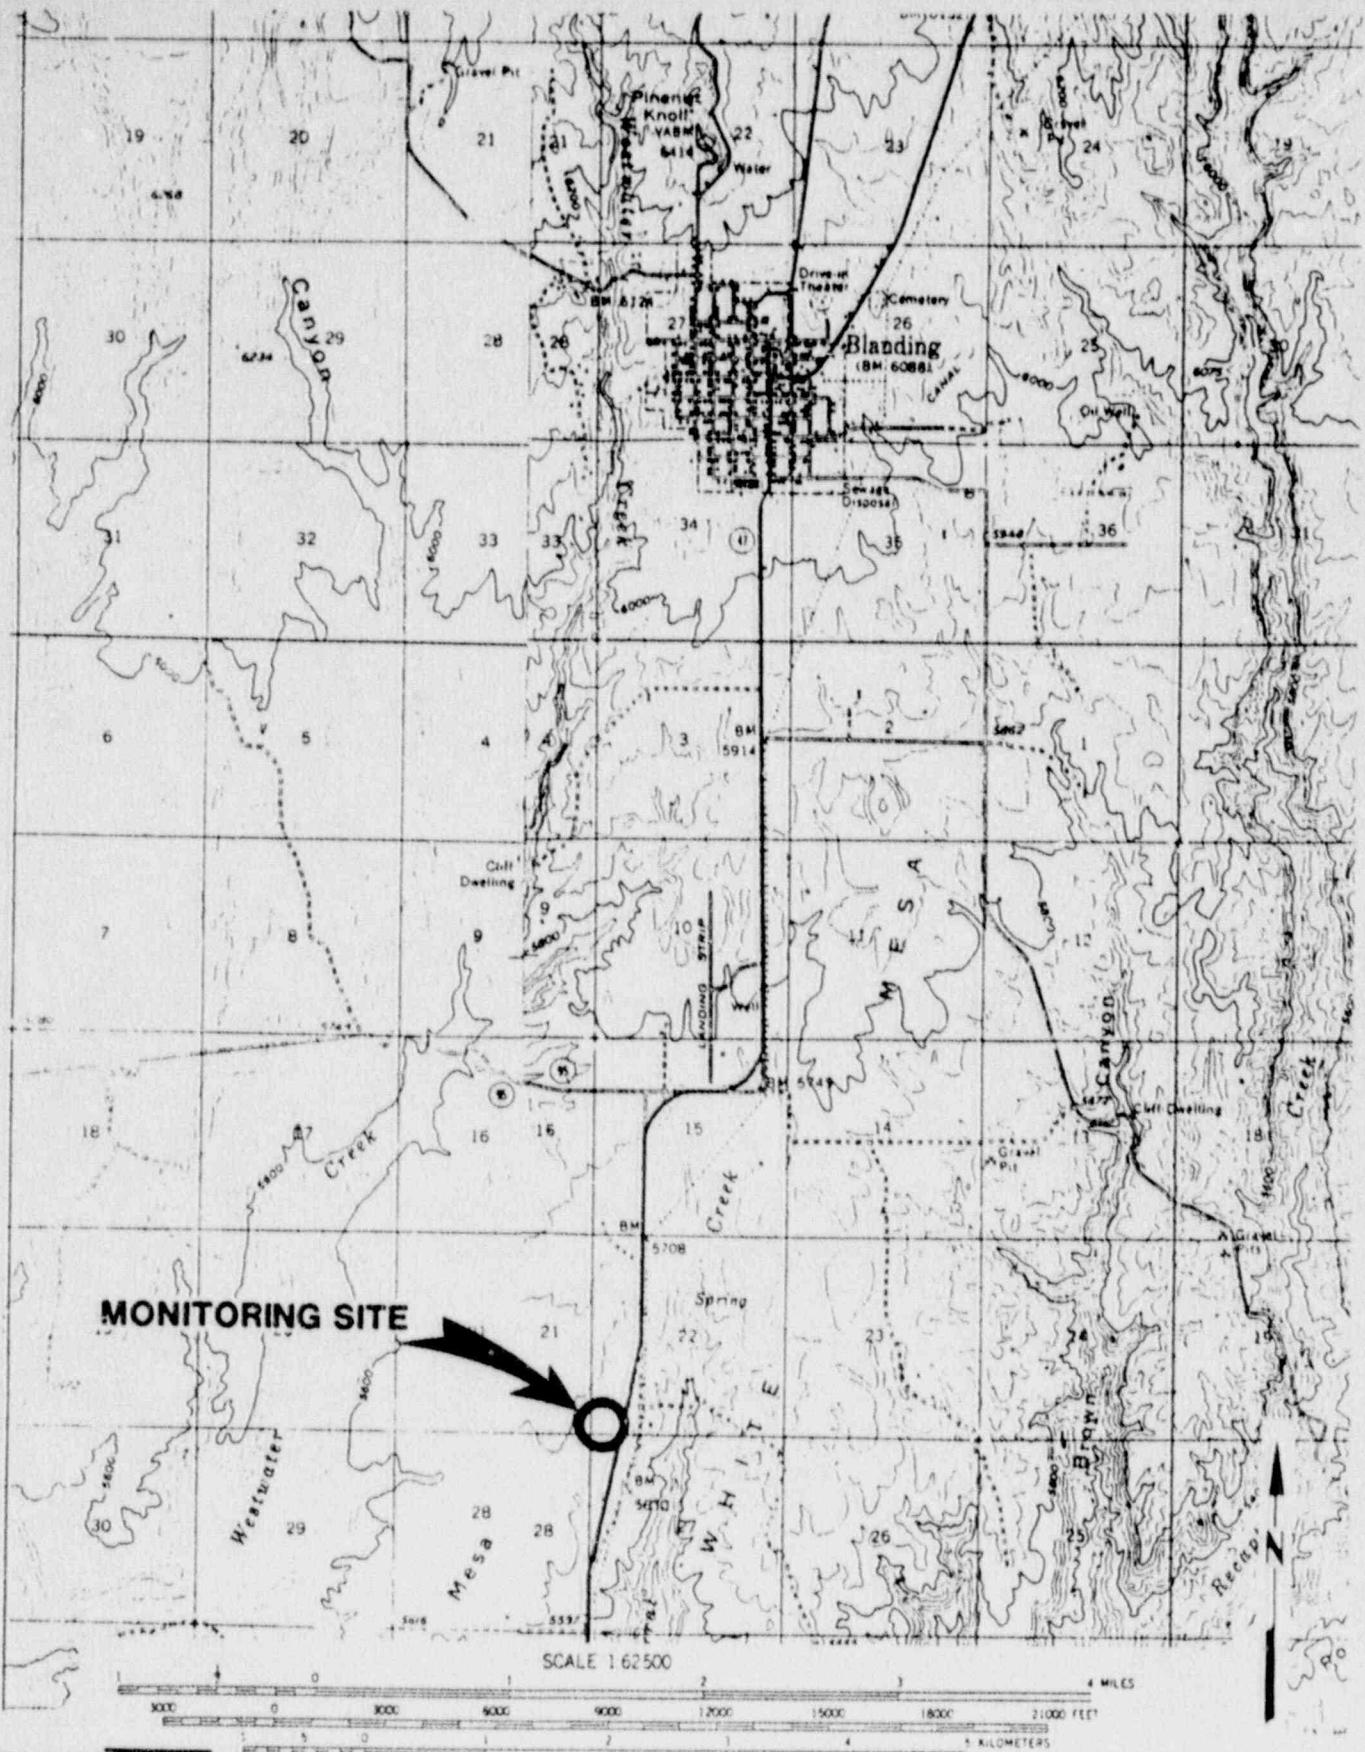

The instruments, sensor accuracies and sampling heights used in the monitoring program are shown in Table 2.1. Weathertronics wind speed and wind direction instrumentation, coupled with a Campbell Scientific CR-10 Data Logger, continuously record wind speed, wind direction and sigma theta (the standard deviation of wind direction) at the standard ten meter height. All meteorological data is stored in the data logger storage module and dumped to cassette tapes once a week. It should be noted that from January through approximately February of 1989, the original CR-5 system, which printed on paper charts, was utilized. It was replaced in March with the updated CR-10. Both systems give an hourly average reading for all parameters.

2.3 Data Reduction

From January through February, paper charts from the CR-5 were received at EnecoTech approximately once a month. The data was transferred to key-punch sheets and entered into the computer. From March on, cassette data tapes from the CR-10 were received at EnecoTech's Denver office also once a week and were subsequently downloaded onto a computer. Computer programs then process the newly created data file into the proper format for subsequent data analysis.

2.4 Quality Assurance

After the meteorological data is downloaded it is checked for any apparent anomalies. If any are discovered, the project manager is notified and the reasons for the erroneous data along with possible solutions to the problem are discussed. The site technician is then contacted and given instructions for any necessary repairs. If required, and the repairs cannot be implemented by the site technician, an EnecoTech scientist is dispatched to the site. Once the problem is discovered and fixed, the invalid data is corrected, if possible. If the erroneous data cannot be rectified it is left invalid in the data files.

Data Logger (March-June)	-	-	Campbell Scientific CR-10

3.0 RESULTS

This section describes the programming results and statistical analysis of the meteorological data collected during the period of January 1 through June 30, 1989.

3.1 Meteorological Data

3.1.1 Hourly Data Presentation

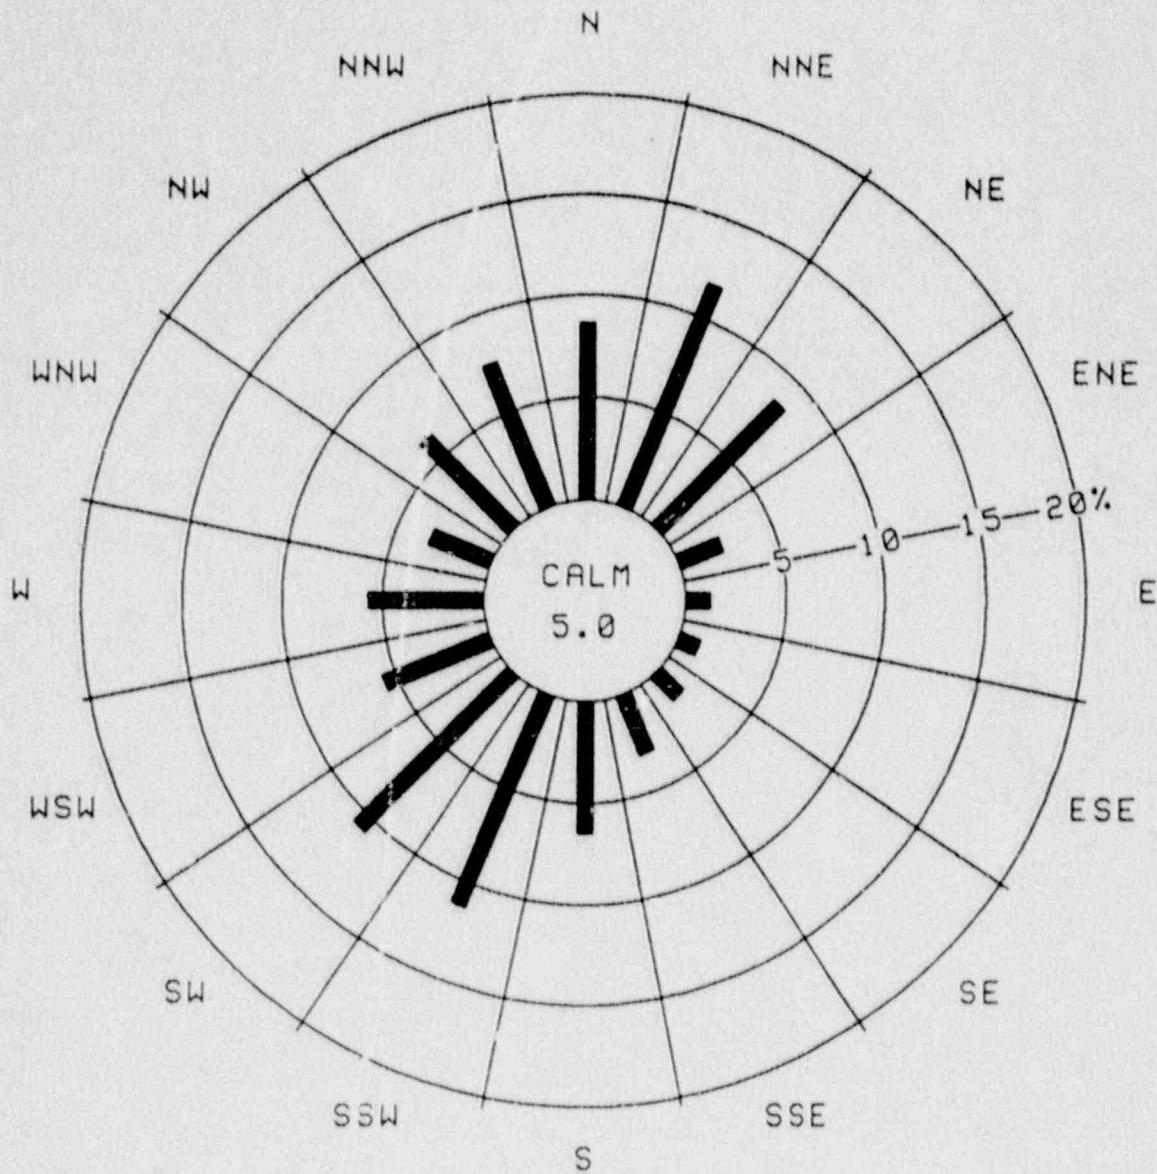

Hourly values of wind speed, wind direction, and sigma theta are presented in Appendix A in the Storage and Retrieval of Aerometric Data (SAROAD) format. This format is approved by the EPA as the standard method of presenting air quality/meteorological data. The SAROAD format also includes average monthly values for each hour, daily averages and monthly averages.

3.1.2 Wind Analysis

The standard wind rose (for all hours) from the reporting period is presented in Figure 2. To show the discussed wind patterns, semi-annual wind distributions in graphical form were developed for 4-hour segments throughout the day (midnight to 4:00 a.m., 4:00 a.m. to 8:00 a.m., etc.) and are presented in Figure 3. A distribution of wind direction by wind speed classes (joint frequency distribution) was also developed from the data collected at the site over the reporting period. This frequency distribution is presented in Table 3.1. The tabular joint frequency distributions for the Figure 3 wind roses are presented in Appendix B, Tables B-1 through B-6.

Figures 2 and 3 demonstrate that two dominant wind patterns exist at the site. One is the persistent local down-slope (drainage) flow from the higher elevations to the north to the lower elevations to the south-southeast through southwest. The other is an upslope wind (return flow) that blows towards the higher terrain. Figure 3 shows that the drainage flow develops just before sunset as shown by the 20-24 MST wind rose, and is most pronounced throughout the nighttime hours. In fact, Figure 3 shows that the winds were from the north-northwest through northeast sectors greater than 50 percent of the time between the hours 2000 through 0800 MST. During these hours, wind speeds of 2.6 to 4.2 m/sec (5.8 - 9.4 mph) were typical from these directions.

Figure 3 also shows, as daytime heating begins, that surface winds reversed from a predominate northeast drainage flow to a south-southwesterly upslope flow. As daytime heating progressed, over 51 percent of the winds were from the south through southwest during the hours of 0800-1600 MST. The speeds from these directions during this period typically ranged from 3.3 to 5.4 m/s (7.4 to 12.1 mph). The wind rose for the 1600 to 2000 MST time frame shows veering (changing in a clockwise direction) winds with over 48 percent of the flow from the southwest through west. Wind speeds ranged from 5.0 to 6.0 m/s (11.2 to 13.4 mph) during this four-hour block. However, for the entire reporting period, 64 percent of the wind speeds were between 1.5 and 5.0 m/s (3.4 and 11.2 mph) with the overall average at 3.8 m/s (8.5 mph). The strongest winds were out of the west-southwest while the weakest were out of the east. Calm winds occurred 5.0 percent of the time.

3.1.3 Atmospheric Stability

Atmospheric dispersion stability classifications in the standard Pasquill scheme have been estimated for the Blanding site using the Mitchell-Timbre sigma theta technique. In this technique, Pasquill stability classes are derived from the hourly sigma theta (standard deviation of wind direction), average wind speed and solar angle algorithm to differentiate daytime from nighttime conditions. The Pasquill stability classification scheme involves delineating stability into six classes, A through F. Classes A through C reflect unstable conditions with Class A being more unstable than Class B, which is more unstable than Class C. Stable conditions are represented by Classes E through F, with Class F being more stable than Class E. Neutral conditions are denoted by a D classification.

Typically, unstable conditions occur when there is good solar heating (clear days) and low wind speeds. Neutral conditions occur with cloudy skies and/or high wind speeds. Stable conditions typically occur when there is radiational cooling (clear nights) and low wind speeds. Usually, stable conditions result in the worst dispersion of atmospheric released pollutants.

Table 3.2 presents the frequency distribution of stability classes observed at the Blanding site throughout the reporting period. Neutral (D) conditions had the highest frequency of occurrence at 50.0 percent. Slightly stable (E) conditions were the next highest category at 14.5 percent, followed by extremely unstable (A) at 10.7 percent. Moderately unstable (B), slightly unstable (C), and moderately stable (F) all had an occurrence of approximately 8.0 percent. The extremely unstable category had a slightly higher frequency of occurrence than expected due to the higher data recovery in May and June relative to the other months for the period (see Appendix A and Section 3.2 for more information). This caused the May and June (the period of greatest solar heating) data to unfairly weigh the stability statistics of the period.

Figure 4 presents the individual wind distribution for each stability class. This figure shows that the atmospheric stability conditions track well with the local drainage/upslope pattern of the area. Unstable conditions (Classes A through C) are associated with winds from the south through southwest (upslope flow) since these winds typically occurring during the daylight hours. Also seen in Figure 3.3 stable conditions primarily occur with the nocturnal drainage (north through northeast) winds while the neutral category (D) contains both drainage as well as upslope type winds.

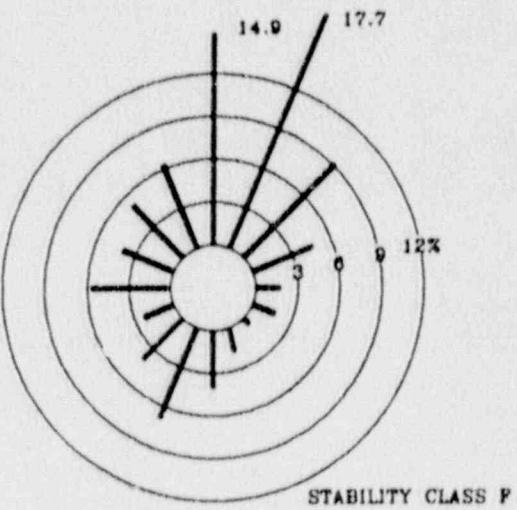

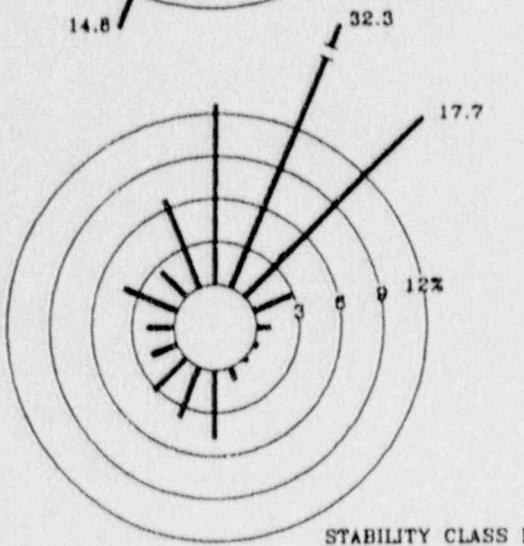

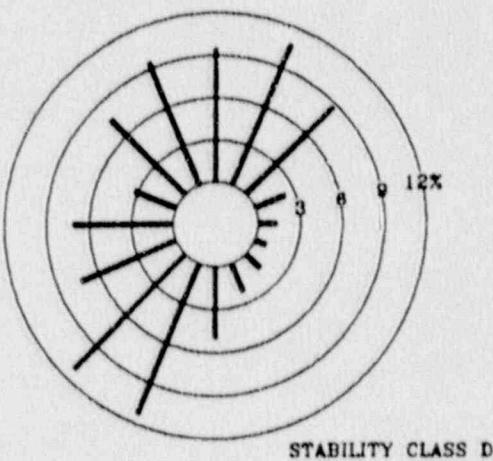

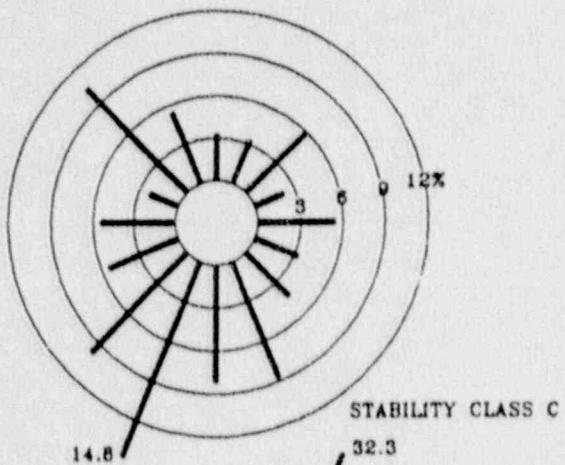

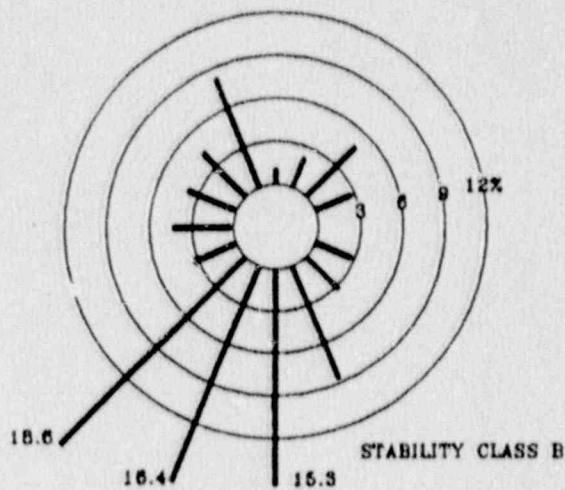

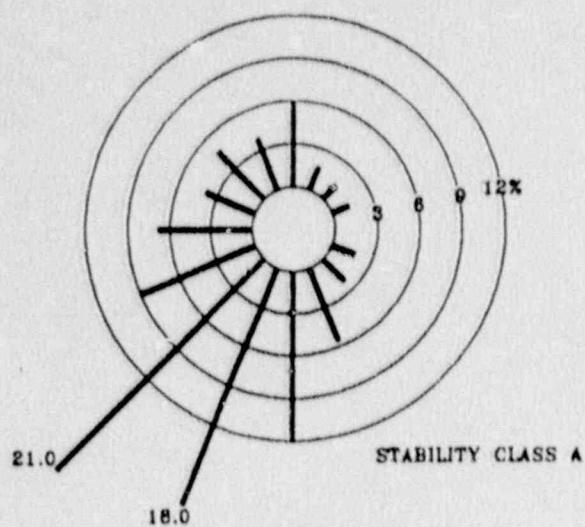

Table 3.3 presents a normalized distribution of Figure 4 along with the total percentage of calm winds so that the actual percentage of each stability class by wind direction may be observed. The highest frequency of occurrence was 5.4 percent and occurred with a north-northeast wind under D stability conditions.

The joint frequency distributions (JFD) of wind direction by wind speed class for each stability category are presented in Appendix C. Tables C-1 through C-7. These JFDs are presented in the Standard National Weather Service format with wind speed classes presented in knots. Thus, they are directly usable for any standard dispersion model requiring a JFD input. For reference, one knot equals 1.15 miles per hour.

3.2 Data Recovery

Table 3.4 summarizes the data recovery for this semi-annual reporting period. Data recoveries for wind direction, wind speed, and sigma theta were 52, 51, and 51, respectively. Data losses were due to chart jams, chart paper running out, and problems with the digital system. Due to equipment problems, the original CR-5 data logger, which prints on paper, was replaced in late March by a CR-10, which stores the data in digital format. However, the installed CR-10 did not operate properly and was sent back to Campbell for repair. In the interim, a substitute CR-10 was installed. The original repaired CR-10 was set up starting May 9, and since this time, recovery rates have been 100 percent.

TABLE 3.4

PERCENT DATA RECOVERY
JANUARY THROUGH JUNE 1989
UMETCO MINERALS - BLANDING

PARAMETER	PERCENTAGE
WIND SPEED	52.0
WIND DIRECTION	51.0
SIGMA	51.0
STABILITY	51.0

4.0 SUMMARY

Meteorological data was collected from January 1 through June 30, 1989 at the Blanding site with an overall recovery rate of 51 percent. Data losses were due to the CR-5 paper jams and system failure along with the CR-10 (the replacement system) initial set up problems. However, once the CR-10 was on-line commencing May 9, 1989, the data capture rate has been 100 percent.

The results of the meteorological data collected during this reporting period are representative of the monitoring location. The dominant feature in the wind data observed in the reporting period is a local nocturnal drainage flow from the higher elevations to the north and northeast along with a daytime upslope, return flow from the south through southwest. Stable, neutral and unstable atmospheric conditions occurred 22.5 percent, 50.0 percent, and 27.5 percent of the time, respectively. The relatively high occurrence of unstable conditions is probably due to the proportionally higher reliance of the May and June data, when solar heating was at a maximum for the period.

APPENDIX B
DIURNAL WIND SUMMARIES - TABULAR

LIST OF TABLES

<u>Table</u>	<u>Description</u>
B-1	Frequency of Winds by Direction and Speed for 0000-0400 MST
B-2	Frequency of Winds by Direction and Speed for 0400-0800 MST
B-3	Frequency of Winds by Direction and Speed for 0800-1200 MST
B-4	Frequency of Winds by Direction and Speed for 1200-1600 MST
B-5	Frequency of Winds by Direction and Speed for 1600-2000 MST
B-6	Frequency of Winds by Direction and Speed for 2000-2400 MST
