6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Sheet No: EEB 74-00021

Revision:

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.3 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: O

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Sheet No: EEB-74-0005

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: 0

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

Sheet No: EEB-74-0005

Revision No: 0

ATTACHMENT C (Continued)

C.5 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-3 DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.1 Integrated dose - 10 years plus accident

Beta Dose

References:

1. W. W. Parkinson, O. Sisman, October 1970, The Use of Plastics and Elastomers in Nuclear Radiation.

2. R. B. Blodgett, R. G. Fisher, June 1968, Insulations and Jackets for Control and Power Cables.

3. M. Asaka, S. Yamamoto, 1973, Radiation Resistance of Plastic Insulating Materials for Cable.

4. Anaconda-Continental Test Report No. 79117 dated April 1979.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

ATTACHMENT C (con'd)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 TVA Engineering Report No. 1946

Cable types: CP, CPJ, CPJJ, PXJ

Rooms: 0-18

The CP family of cables consists of cross-linked polyethylene insulation and polyvinyl chloride jacketing, and the PX family of cables consists of cross-linked polyethylene or ethylene propylene rubber, and the jacket is chlorosulfonated polyethylene or chloronated polyethylene. The following LOCA/SLB test apply:

CP types - Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

PX types - Franklin Institute Test Report F-C4113 dated May 1975.

- Rockbestos Company Test Report dated July 1977, amended 1979.

- Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment. Because of the conservatism of these tests including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

C.3 NUREG-0588 Material List

C.4 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.3 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: O

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

1C

Sheet No: EEB- 74-0028

Revision No: 0

ATTACHMENT C (Continued)

C.5 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chatt[illegible]ga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Sheet No: 74-0040

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.3 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: O

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

Sheet No: EEB- 74-0040

vision No: 0

ATTACHMENT C (Continued)

C.5 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation not even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation not even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 Integrated Dose - 10 years plus accident

Beta Dose

References:

1. W. W. Parkinson, O. Sisman, October 1970, The Use of Plastics and Elastomers in Nuclear Radiation.

2. R. B. Blodgett, R. G. Fisher, June 1968, Insulations and Jackets for Control and Power Cables.

3. M. Asaka, S. Yamamoto, 1973, Radiation Resistance of Plastic Insulating Materials for Cable.

4. Anaconda-Continental Test Report No. 79117 dated April 1979.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

1C

Sheet No: EEB-74-5046

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.3 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: 0

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

Sheet No: EEB- 74-0046

Revision No: 0

ATTACHMENT C (Continued)

C.5 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 Integrated Dose - 10 years plus accident

Beta Dose

References:

1. W. W. Parkinson, O. Sisman, October 1970, The Use of Plastics and Elastomers in Nuclear Radiation.

2. R. B. Blodgett, R. G. Fisher, June 1968, Insulations and Jackets for Control and Power Cables.

3. M. Asaka, S. Yamamoto, 1973, Radiation Resistance of Plastic Insulating Materials for Cable.

4. Anaconda-Continental Test Report No. 79117 dated April 1979.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Sheet No: EEB 74-0054

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.3 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: O

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

Sheet No: EEB-74-0054

Revision No: 0

ATTACHMENT C (Continued)

C.5 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

(2) Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943.

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

2. R. B. Blodgett, R. G. Fisher, June 1968, Insulations and Jackets for Control and Power Cables.

3. M. Asaka, S. Yamamoto, 1973, Radiation Resistance of Plastic Insulating Materials for Cable.

4. Anaconda-Continental Test Report No. 79117 dated April 1979.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Sheet No: EEB 74-0073

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.3 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Room: O

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperature. The in-containment SLB temperature and duration exceeds the cable ratings and the insulation and jacket distortion temperatures.

However, the service which these cable have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene insulated cable has demonstrated and is capable of withstanding the LOCA/ SLB and the post-LOCA environment of 1 year. Thus, continued operation is justified.

TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

C.4 Temperature Qualification Method

C.4.1 Standard material long-term overload temperature rating

C.4.2 Engineering analysis

Sheet No: EEB-74-0073

Revision No: 0

ATTACHMENT C (Continued)

C.5 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1343.

C.3 Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

C.1 Integrated dose - 10 years plus accident

Beta Dose

References:

1. W. W. Parkinson, O. Sisman, October 1970, The Use of Plastics and Elastomers in Nuclear Radiation.

2. R. B. Blodgett, R. G. Fisher, June 1968, Insulations and Jackets for Control and Power Cables.

3. M. Asaka, S. Yamamoto, 1973, Radiation Resistance of Plastic Insulating Materials for Cable.

4. Anaconda-Continental Test Report No. 79117 dated April 1979.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of 4×10^9 rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 5 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.8 \times 10^7$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^7 rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^7 rads which added directly gives a total dose of 7.3×10^7 rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.1 Wyle Laboratory Report No. 43854-3.

C.2 NUREG-0588 Material List.

C.3 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

ATTACHMENT C

C.1 TVA Engineering Report No. 1944

Cable types: CP, CPJ, CPJJ, PXJ

Rooms: 0-18

The CP family of cables consists of cross-linked polyethylene insulation and polyvinyl chloride jacketing, and the PX family of cables consists of cross-linked polyethylene or ethylene propylene rubber, and the jacket is chlorosulfonated polyethylene or chloronated polyethylene. The following LOCA/SLB test apply:

CP types Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

PX types Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment. Because of the conservatism of these tests including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

C.1 TVA Engineering Report No. 1942

Coax, Triax, and Signal Cable

Coaxial and triaxial cable installed at Browns Ferry were purchased in accordance with General Electric Company Specification 22A1181, and the appropriate MIL-C-17 specification. Signal cables, both twisted pair and multiconductor, were purchased in accordance with TVA specifications. Some cable were of cross-linked polyethylene and chloronated polyethylene construction while the same kind of cable furnished under other contracts were of high molecular weight, high density polyethylene/polyvinyl chloride construction and some even polyethylene/polyvinyl chloride construction. It is not possible to make a complete identification by contract as to which circuit and function they serve. Recent reclassification of some functions to 1E status has made it almost a certainty that some cables now in a safety category are of polyethylene/polyvinyl construction.

Accordingly, we have examined the 20 HELB temperature profiles and find that only compartments 1, 3, 6, and 9 show profiles which more than briefly surpass the softening temperature of the linear polyethylene. However. owing to the thermal time lag in the cable material and the cable installation including the heat sink of conduit, tray, and shield material, the insulation will not experience the HELB temperature profile until some time has elapsed and the temperature is lower. Further, no load heat rise need be taken into account for these signal cables.

TVA has conducted tests (Chattanooga Central Laboratories Report No. L81-81-6821 dated October 1980, of PE, PVC cables under a temperature profile which envelops all the HELB profiles. Following this exposure, these cables sustained a dielectric test while immersed in water of 660 volts for 5 minutes, 960 volts for 5 minutes, and 220 volts ac for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April, or replaced at the next refueling outage.

For those cables located in compartment 0 (the containment), the service which these cables have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene cable has demonstrated and is capable of withstanding the LOCA/SLB and the post-LOCA environment for a year.

Sheet No: EEB- 74-0092

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Continued operation is justified, and TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

One cable RG-114A/U has the possibility of being sensitive to pressure changes owing to its partial air dielectric; however, an analysis of this effect has indicated that the change in dielectric constant can be tolerated. Consequently for this cable too, there is justification for continued operation. The compression effect on the dielectric will be likewise tested at Wyle Laboratories along with the other cable tests and results are expected to be available by April 1981.

C.2 Standard Material Long-Term Overload Temperature Rating

C.3 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

C.1 TVA Engineering Report No. 1945

Cable types: Coax, Triax, and Signal Cables of Cross-Linked Polyethylene Construction

Rooms: 0-18

For signal cables which utilize cross-linked polyethylene insulation, and the jacket is chlorosulfonated polyethylene or neoprene. The following LOCA/SLB tests apply:

Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cables are qualified by the above for all HELB areas and the LOCA/SLB of the containment.

C.2 NUREG-0588 Material List

C.3 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

C.1 TVA Engineering Report No. 1947

Cable types: Coax, Triax, and Signal Cables of Cross-Linked Polyethylene Construction

Rooms: 0-18

For signal cables which utilize cross-linked polyethylene insulation, and the jacket is chlorosulfonated polyethylene or neoprene. The following LOCA/SLB tests apply:

Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment.

C.2 NUREG-0588 Material List

C.3 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

ATTACHMENT C

C.1 TVA Engineering Report No. 1942

Coax, Triax, and Signal Cable

Coaxial and Triaxial cable installed at Browns Ferry were purchased in accordance with General Electric Company Specification 22A1181, and the appropriate MIL-C-17 specification. Signal cables, both twisted pair and multiconductor, were purchased in accordance with TVA specifications. Some cable were of cross-linked polyethylene and chloronated polyethylene construction while the same kind of cable furnished under other contracts were of high molecular weight, high density polyethylene/polyvinyl chloride construction and some even polyethylene/polyvinyl chloride construction. It is not possible to make a complete identification by contract as to which circuit and function they serve. Recent reclassification of some functions to 1E status has made it almost a certainty that some cables now in a safety category are of polyethylene/polyvinyl construction.

Accordingly, we have examined the 20 HELB temperature profiles and find that only compartments 1, 3, 6, and 9 show profiles which more than briefly surpass the softening temperature of the linear polyethylene. However, owing to the thermal time lag in the cable material and the cable installation including the heat sink of conduit, tray, and shield material, the insulation will not experience the HELB temperature profile until some time has elapsed and the temperature is lower. Further, no load heat rise need be taken into account for these signal cables.

TVA has conducted tests (Chattanooga Central Laboratories Report No. L81-81-6821 dated October 1980, of PE, PVC cables under a temperature profile which envelops all the HELB profiles. Following this exposure, these cables sustained a dielectric test while immersed in water of 660 volts for 5 minutes, 960 volts for 5 minutes, and 220 volts ac for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April, or replaced at the next refueling outage.

For those cables located in compartment 0 (the containment), the service which these cables have seen thus far has exposed them to a gamma radiation dose of 6.25×10^5 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene cable has demonstrated and is capable of withstanding the LOCA/SLB and the post-LOCA environment for a year.

Sheet No: EEB- 74-0101

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Continued operation is justified, and TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

One cable RG-114A/U has the possibility of being sensitive to pressure changes owing to its partial air dielectric; however, an analysis of this effect has indicated that the change in dielectric constant can be tolerated. Consequently for this cable too, there is justification for continued operation. The compression effect on the dielectric will be likewise tested at Wyle Laboratories along with the other cable tests and results are expected to be available by April 1981.

C.2 Standard Material Long-Term Overload Temperature Rating

C.3 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

C.1 TVA Engineering Report No. 1947

Cable types: Coax, Triax, and Signal Cables of Cross-Linked Polyethylene Construction

Rooms: 0-18

For signal cables which utilize cross-linked polyethylene insulation, and the jacket is chlorosulfonated polyethylene or neoprene. The following LOCA/SLB tests apply:

Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment.

C.2 NUREG-0588 Material List

C.3 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

C.1 TVA Engineering Report No. 1942

Coax, Triax, and Signal Cable

Coaxial and Triaxial cable installed at Browns Ferry were purchased in accordance with General Electric Company Specification 22A1181, and the appropriate MIL-C-17 specification. Signal cables, both twisted pair and multiconductor, were purchased in accordance with TVA specifications. Some cable were of cross-linked polyethylene and chloronated polyethylene construction while the same kind of cable furnished under other contracts were of high molecular weight, high density polyethylene/polyvinyl chloride construction and some even polyethylene/polyvinyl chloride construction. It is not possible to make a complete identification by contract as to which circuit and function they serve. Recent reclassification of some functions to 1E status has made it almost a certainty that some cables now in a safety category are of polyethylene/polyvinyl construction.

Accordingly, we have examined the 20 HELB temperature profiles and find that only compartments 1, 3, 6, and 9 show profiles which more than briefly surpass the softening temperature of the linear polyethylene. However, owing to the thermal time lag in the cable material and the cable installation including the heat sink of conduit, tray, and shield material, the insulation will not experience the HELB temperature profile until some time has elapsed and the temperature is lower. Further, no load heat rise need be taken into account for these signal cables.

TVA has conducted tests (Chattanooga Central Laboratories Report No. L81-81-6821 dated October 1980, of PE, PVC cables under a temperature profile which envelops all the HELB profiles. Following this exposure, these cables sustained a dielectric test while immersed in water of 660 volts for 5 minutes, 960 volts for 5 minutes, and 220 volts ac for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April, or replaced at the next refueling outage.

For those cables located in compartment 0 (the containment), the service which these cables have seen thus far has exposed them to a gamma radiation dose of 6.25×10^6 rads or more. This is sufficient to have cross-linked the polyethylene and PVC as well. Consequently, the insulation is now in fact a thermoset material and is capable of the same temperature that TVA's cross-linked polyethylene cable has demonstrated and is capable of withstanding the LOCA/SLB and the post-LOCA environment for a year.

Sheet No: EEB-74-0109

Revision: 0

ATTACHMENT C (Continued)

C.1 (Continued)

Continued operation is justified, and TVA has prepared a LOCA/SLB, thermal aging, and radiation test procedure to be performed by Wyle Laboratories on samples of this cable to demonstrate the validity of this conclusion. Results of this testing program are expected to be available in April 1981.

One cable RG-114A/U has the possibility of being sensitive to pressure changes owing to its partial air dielectric; however, an analysis of this effect has indicated that the change in dielectric constant can be tolerated. Consequently for this cable too, there is justification for continued operation. The compression effect on the dielectric will be likewise tested at Wyle Laboratories along with the other cable tests and results are expected to be available by April 1981.

C.2 Standard Material Long-Term Overload Temperature Rating

C.3 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

C.1 TVA Engineering Report No. 1947

Cable types: Coax, Triax, and Signal Cables of Cross-Linked Polyethylene Construction

Rooms: 0-18

For signal cables which utilize cross-linked polyethylene insulation, and the jacket is chlorosulfonated polyethylene or neoprene. The following LOCA/SLB tests apply:

Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment.

C.2 NUREG-0588 Material List

C.3 Because of the conservatism of the tests for XLPE and for silicone insulation, including the severity of the mandrel bend and dielectric test in water after the combined LOCA/SLB profile, it is our engineering judgment that there is sufficient margin to give reasonable assurance of continued operability more than a year in the post-LOCA environment.

ATTACHMENT C

TVA Engineering Report EEB 1921

This report is to update the documentation of the qualification of the General Electric canister type electrical penetration assemblies used at Browns Ferry Unit 3 for Class 1E low voltage power and control service into the drywell. TVA designations for these units are EA, EB, EC, ED, EE, and EF.

The penetration assemblies inside the drywell consist of four pertinent features; the penetration conductor seals, the conductor pigtails, the connectors affixed to the ends of the pigtails, and the junction box which is bolted to the header plate and encloses the foregoing items.

The junction boxes are fabricated from 0.104-inch-thick steel. This thickness is sufficient to essentially completely shield the box contents from beta radiation and to reduce the total gamma dose by about 25 percent. Therefore, the integrated 40-year normal operation plus one LOCA dose seen by the box contents will be approximately 1.05×10^8 rads gamma and the 10-year plus LOCA dose would be about 4.9×10^7 rads gamma. GE report EPAQ-046 indicates this level should cause no change in the epoxy sealant. The GE Vulkene cable (cross-linked polyethylene) is also known to be little affected by 1×10^8 rads gamma (see the NRC 0588 materials list for acknowledgement of this). The connectors have been qualified for 6.9×10^7 rads (see Wyle report 43854-2) which exceeds the 10-year plus LOCA dose they would receive by about 40 percent.

Regarding thermal aging, GE report "Prototype Test Data, Epoxy Life Tests," indicates the epoxy is suitable for 40 years service and the Vulkene cable is known to also be suitable for 40 years service. Since the Browns Ferry containment is inerted a large portion of the time, thermal aging effects should be greatly reduced from what it would be in a normal air environment. The connectors have been qualified for 10 years (see Wyle report 43854-2).

The combined LOCA-HELB profile for Browns Ferry causes thermal aging equivalent to less than 30 days normal operation, as calculated by the 10^0 C rule. Therefore, the thermal aging effects of a LOCA-HELB can be neglected. Aging due to any one LOCA or HELB would be considerably less.

The long-term humidity resistance of the epoxy is satisfactory (see GE report EPAQ-037, Epoxy Insulation Resistance Tests) and that of the cable is well documented. Therefore, they will remain fully functional for a year after a LOCA or HELB since neither the radiation, thermal, or humidity effects of an accident have any significant effect on the materials. The connectors show adequate insulation resistance at the end of a combined LOCA-HELB event (see Wyle report 43854-2) to indicate the ability to function for a year after an accident. Note also the Wyle test was for a combined LOCA-HELB which is thermally more severe than any one event would be, and the pressures were 25 psi higher than is expected to actually occur.

ATTACHMENT C (Continued)

In conclusion, the penetration and cable are qualified for 39 years service plus a year of post-accident operation. The connectors are qualified for 10 years service plus a year of post-accident operation, and they should be replaced with qualified heat shrink splices at the end of 10 years operation.

ATTACHMENT C (Con'd) Revision: 0

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

.2 TVA Engineering Report No. 1943

Cable types: Coax, Triax, and Signal Cables of Cross-Linked Polyethylene Construction

Rooms: 0-18

For signal cables which utilize cross-linked polyethylene insulation, and the jacket is chlorosulfonated polyethylene or neoprene. The following LOCA/SLB tests apply:

Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment.

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

2. R. B. Blodgett, R. G. Fisher, June 1968, Insulations and Jackets for Control and Power Cables.

3. M. Asaka, S. Yamamoto, 1973, Radiation Resistance of Plastic Insulating Materials for Cable.

4. Anaconda-Continental Test Report No. 79117 dated April 1979.

5. Wyle Laboratory Test Report 43854-3.

6. Franklin Institute Test Reports E-C4113 and FC-5120.

7. Rockbestos Company Test Report dated July 1977 amended 1979.

The TVA value of $\times 10^{9}$ rads for the beta accident dose at the periphery of the containment is being reevaluated due to its high value. However, using this value and making reference to the 7901-B DOR guidelines section 4.2.1 and the depth dose penetration, which owing to the low penetrating power of beta particles gives a factor of 10 reduction for 40 mils of jacketing material, and a factor of 10 for an insulation thickness of 30 mils and which is conservative for TVA's 600-volt power and control cables and extremely conservative for TVA's triax and coax and signal cable due to their thickness and the presence of metallic shielding material, and assigning a factor of 3 for the installation shielding of metal trays, conduit, boxes, and flexible conduit, we arrive at a total effective dose of $.3 \times 10^{7}$ rads of beta.

Since the energy dissipation of gamma radiation occurs via ionizing processes, one can add the accident dose of 4×10^{7} rads of gamma directly. The accumulated integrated gamma 10-year dose (the time presently assigned to connectors and penetrations) amounts to 2.5×10^{7} rads which added directly gives a total dose of 7.3×10^{7} rads. In addition, since the containment is inerted in operation, the scission rate and deterioration of the insulation and jacketing materials through oxidation will be much less than for tests conducted in air.

Since the above value of 7.3×10^7 is less than the values for which we have in-air test data for SROAJ types (1.2×10^8) and for XLPE types (2×10^8), it is concluded that the beta dose in an accident will not disqualify the cables presently installed, and the cables will remain operable in the service environment.

C.2 TVA Engineering Report No. 1342

Cable types: Coax, Triax, and Signal Cables of Cross-Linked Polyethylene Construction

Rooms: 0-18

For signal cables which utilize cross-linked polyethylene insulation, and the jacket is chlorosulfonated polyethylene or neoprene. The following LOCA/SLB tests apply:

Wyle Laboratory Test Report 43854-3 dated April 26, 1978, LOCA and SLB Qualification Test of Cables and Cable Splices.

Franklin Institute Test Report F-C4113 dated May 1975.

Rockbestos Company Test Report dated July 1977, amended 1979.

Franklin Institute Test Report F-C5120 dated May 1980.

These cable are qualified by the above for all HELB areas and the LOCA/SLB of the containment.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.

ATTACHMENT C

C.1 IPCEA S-61-402 Paragraph 3.9 and Appendix D

C.2 TVA Engineering Report No. 1943

Cable types: PJ, PN, PNJ, PJJ, PSJ

Rooms 1-18

This class of cables was purchased under TVA Standard Specification No. 25.013, based on IPCEA S-61-402 (NEMA WC5). These standards provide a product with an operating rating of 75° C continuous, 95° C (203° F), 500-hour overload rating total in a normal lifetime. They are constructed of polyethylene insulation with Nylon and PVC jacketing.

The jacket material has a higher retention of strength at elevated temperatures, as the material was subjected to air oven aging of 121° C (250° F) for 7 days. Only compartments 1, 2, 3, 6, 9, 10, and 11 show HELB profiles which more than briefly surpass the softening temperature of the insulation. However, owing to the thermal time lags in the cable material and cable installation, the insulation nor even the jacket experience the temperature profile until some time has elapsed.

TVA has conducted tests (Chattanooga Central Laboratories Report No. 81L-81-6821 dated October 1980, of these cables under a temperature profile which envelopes all the HELB profiles. Following this exposure these samples sustained a dielectric test immersed in water of 660 volts ac for 6 minutes, 960 volts ac for 5 minutes, and 2200 volts for 5 minutes in succession.

It is therefore our engineering judgment that this test confirms the above and justifies interim operation until these types can be fully qualified by our Wyle Laboratory tests to be concluded next April or replaced at the next refueling outage.

C.3 Temperature Qualification Method

C.3.1 Standard material long-term overload temperature rating

C.3.2 Engineering Analysis

C.4 The post-HELB conditions are less than the normal cable rating and, in our judgment, the cables could operate satisfactorily for a post-accident of a year.
