Abstract

A series of 22 simultaneous releases of three gaseous tracers was conducted around the EOCR test reactor building at the Idaho National Engineering Laboratory in SE Idaho. Hourly averaged gaseous tracer concentrations were sampled on several concentric sampling arcs and at a limited number of elevated locations. Winds and temperatures were measured on a nearby 30m tower. Complete data appendices provide tracer concentration measurements, temperatures, winds and detailed wind statistics, derived diffusion statistics, and plots and analyses.

Building related effects upon diffusion near and downwind of the structure were grouped into 3 regions of characteristic behavior, a near building or cavity zone, a transition zone, and a far wake zone. Near the structure, vertical circulations altered the heights of tracer plume centers-of-mass and/or plume centerlines and produced a rapidly enhanced vertical diffusion. Elevated releases of tracer were conveyed downward with ground-level concentrations exceeding expectations from a Gaussian formulation for their physical release height; ground-level releases of tracer were substantially elevated so that ground-level concentrations were less than expected. Rapid vertical diffusion near the building yielded σ_z values 4-10 times greater than expected from Pasquill-Gifford curves. Within the transition zone rates of vertical diffusion were less than atmospheric; σ_z values returned to open-terrain expectations and continued near these open-terrain values within the far wake. Lateral plume spreading was well described by observed standard deviations of wind direction (σ_θ), except when σ_θ was less than 10 to 15°; with $\sigma\theta < 10^o$ a noticeable building induced plume broadening existed. The downwind extent of significant building alteration of rates of diffusion was from 100 to 400m (about 4 to 16 reference lengths); σ_y and σ_z values were nearly the open-terrain values by 400 to 800m (16 to 32 reference lengths). The building alterations of plume diffusion and maximum ground-level concentrations were minimal for stability category A and became largest for strongly stable categories (F and G). An initial volumetric plume dilution, the "cA term", did not properly correct the Gaussian plume equation. Changes in vertical distributions of plume mass still influenced maximum ground-level concentrations to 1600m (about 64 reference lengths) downwind. Because of this alteration of vertical plume mass distribution, the assumption of a Gaussian distribution was poor and calculations using the exponential term were inappropriate.

1.0 INTRODUCTION

Safety considerations, especially with respect to pollutant concentrations in the atmosphere, are playing a major role in the design and operation of nuclear power plants. Since pollutant concentrations are often greatest under low windspeed inversion conditions, a multi-part testing program has been undertaken to investigate the diffusion characteristics of the atmosphere under these conditions.

The first test series was conducted in 1974 at the Idaho National Engineering Laboratory (INEL) in the Eastern Idaho Desert (Sagendorf and Dickson, 1974), during conditions of low (less than 2.0 m/s) windspeed and temperature inversion over the flat terrain.

A second phase of testing was conducted during the summer of 1974 to contrast the effects of desert meteorological conditions with similar atmospheric conditions over a wooded, hilly terrain. The site of this second series was a proposed nuclear power station near Oak Ridge, Tennessee (Wilson, et al., 1976).

A need existed to examine the diffusive characteristics of the atmosphere under a variety of thermodynamic and hydrodynamic conditions in the vicinity of reactor complexes. A series of tests at the Rancho Seco Nuclear Power Station in 1975 have been previously described by Start, et al., 1977). Sagendorf et al, (1980) reported on the diffusion adjacent to both the Rancho Seco reactor complex and the EOCR complex in detail. The series of tests herein reported were conducted in 1975 and 1976 around the EOCR reactor building located on the INEL. Figure 1 is an aerial view of this reactor building.

The EOCR reactor complex is dominated by the large reactor building. This building has a square base with each side having a length of about 36.6 meters. The highest part of the roof has a height of 25 meters above ground level. The top of the stack is at a height of 30 meters. One small storage tank is located north of the buildings with additional tanks immediately northwest. The terrain over the sampling grid varies from a high point of 4960 feet MSL approximately 200 meters northeast of the building to a low point of 4920 feet MSL some 3200 meters to the northeast. Most of the grid is sagebrush covered.

When a building protrudes into the atmospheric flow, it produces distortions in the pressure and velocity fields. These distortions are loosely termed "building wake". "Cavity" refers to that portion of the wake immediately downwind of the structure. More complete discussion of aerodynamic flow around structures may be found in standard reference (e.g., Halitsky, 1968).

The EOCR experiment was conducted over a two-year period. It was designed to study atmospheric diffusion under a variety of stability and wind conditions and evaluate the building wake effects on dispersion.

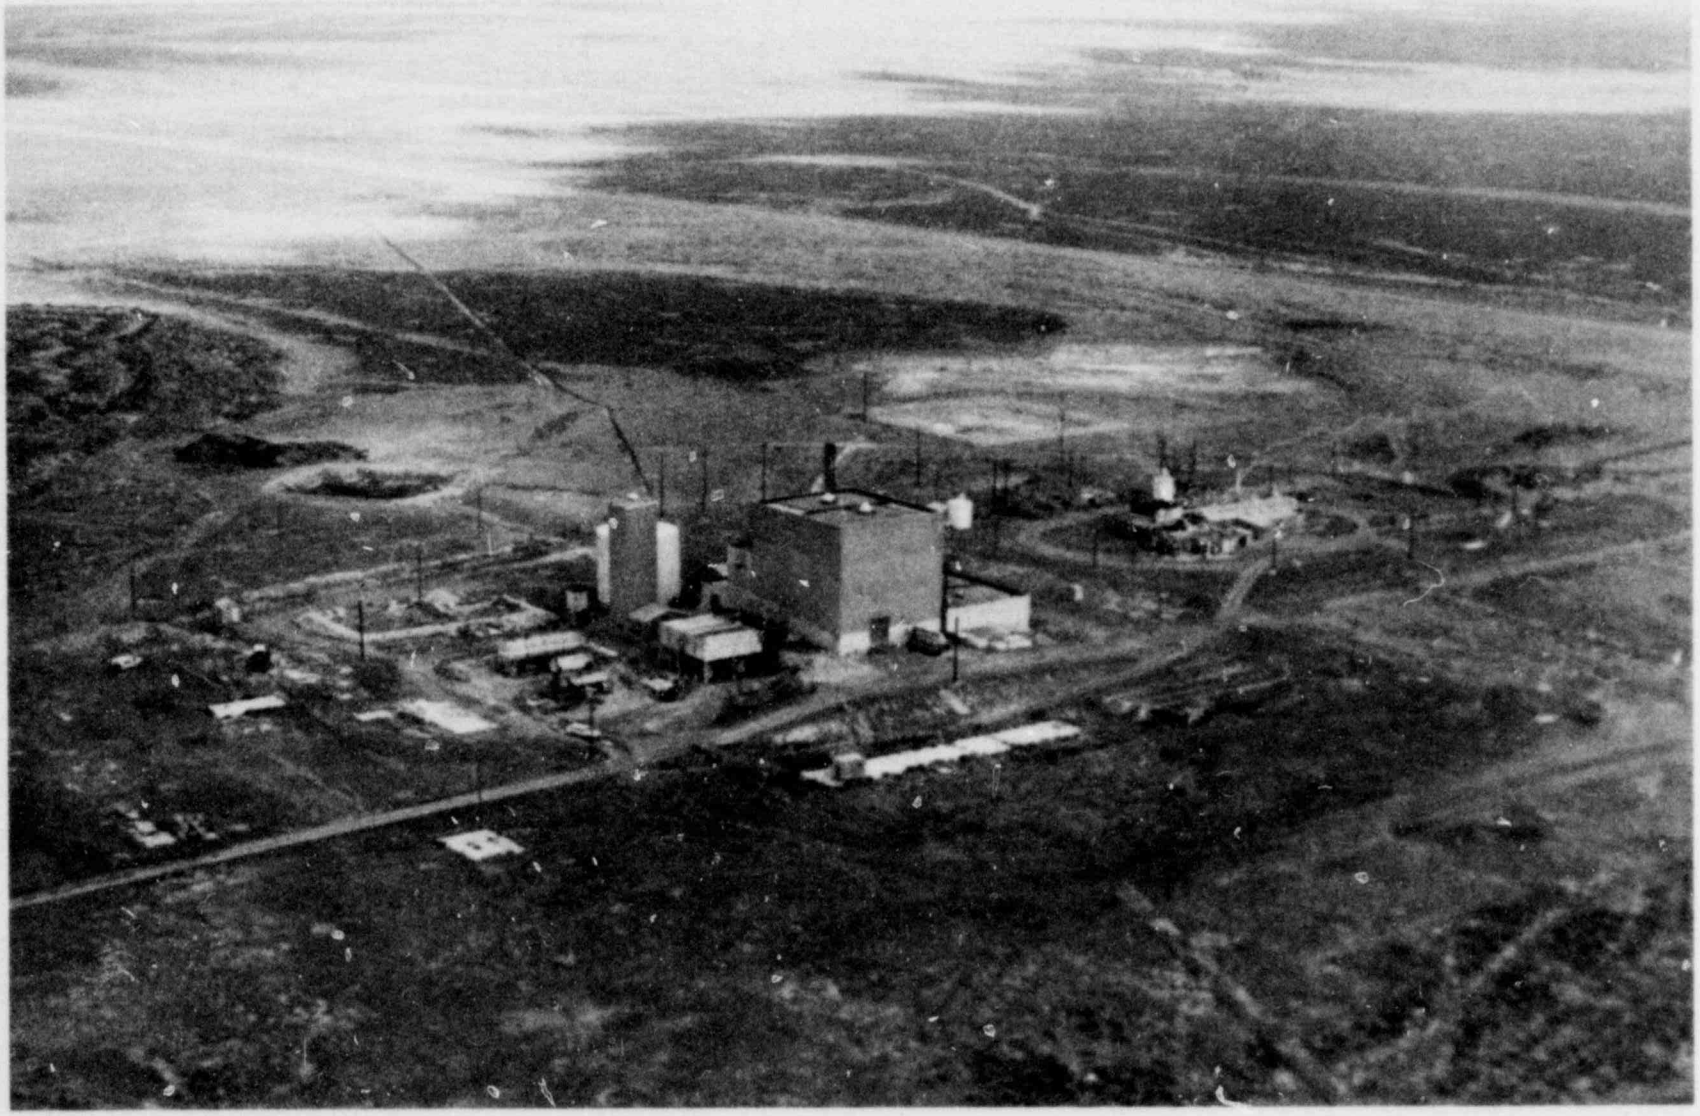

Figure 1. Aerial view of the EOCR reactor building looking east.

2.0 DIFFUSION THEORY

2.1 The Diffusion Equation

The windspeed-normalized relative concentrations are given in the form Cu/Q, where C is the concentration (in gm m^{-3}), u is the mean windspeed through the effluent-carrying layer (in m s^{-1}), and Q is the source strength (in gm s^{-1}). These concentration values may be related to the plume axis height above the ground (H) and to spatial Cartesian coordinates (x,y,z) through the Gaussian diffusion equation.

$$\frac{C(x,y,z;H)u}{Q} = \frac{1}{2\pi\sigma_y\sigma_z} \exp\left\{-\frac{1}{2}\left(\frac{y}{\sigma_y}\right)^2\right\}\left|\exp\left\{-\frac{1}{2}\left(\frac{z-H}{\sigma_z}\right)^2\right\} + \exp\left\{\frac{1}{2}\left(\frac{z+H}{\sigma_z}\right)^2\right\}\right| \quad (1)$$

Values for σ_y and σ_z, the standard deviations of effluent concentrations in the lateral and vertical coordinate directions (Pasquill, 1961 and Gifford, 1961 e.g.) have been determined for various stability categories. By direct measurements of some of the variables (x,u,Q) and by plume centerline sampling (y=0, z=0, H=0), the above equation simplifies so that comparisons may be made with σ_y and σ_z values commonly accepted for a given stability. If the receptors are at ground level, Equation (1) may be expressed as

$$\frac{C(x,y,o;H)u}{Q} = \frac{1}{\pi\sigma_y\sigma_z} \exp\left\{-\frac{1}{2}\left(\frac{y^2}{\sigma_y^2} + \frac{H^2}{\sigma_z^2}\right)\right\} \quad (2)$$

The factor of two accounting for ground reflection of the plume is included as is customary. Integration of Equation (2) with respect to y yields the familiar expression for the crosswind integrated concentration from a continuous, elevated-point source.

$$CIC(x;H) = \frac{2\,Q}{\pi\, u\sigma_z} \exp\left\{-\frac{1}{2}\left(\frac{H}{\sigma_z}\right)^2\right\} \quad (3)$$

Equations (1), (2), and (3) are widely known Gaussian plume formulas and may be examined in greater detail by referring to appropriate books and papers (e.g., Gifford, 1968 or Pasquill, 1974).

With cross-wind oriented samples of ground-level concentrations C(x,y,o), the second moment of the lateral effluent-concentration distribution for a fixed downwind-distance, x, is

$$\sigma_y^2 = \frac{N}{\Sigma}\left\{C(y).(y-y_o)^2\right\} \Big/ N.\frac{N}{\Sigma}\, C(y) \quad (4)$$

where the position of the center of mass of the mean plume, y_o, is

$$y_o = \sum^{N} \left| C(y).y \right| \Big/ \sum^{N} C(y) \tag{5}$$

If Equation (3) is solved for the effective σ_z (a virtual value of vertical spreading), the centerline Gaussian continuous point source equation for an elevated plume near a reflecting boundary is

$$\sigma_z(\text{effective}) = \sigma_z \exp\left\{\frac{1}{2}\left(\frac{H}{\sigma_z}\right)^2\right\} = \frac{2\,Q}{\pi\,u\,CIC(x;H)} \tag{6}$$

where H is the mean plume-axis height at downwind distance x, and σ_z is the Gaussian parameter for the plume with centerline at height H instead of the virtual value effective at ground-level (σ_z (effective)).

2.2 Building Wake Modifications of the Diffusion Equation

A simplified method to allow additional plume spreading behind the building structure is expressed as

$$\frac{C(x,o,z;H)u}{Q} = \frac{1}{2\pi(\sigma_y\sigma_z+cA)}\left[\exp\left\{-\frac{1}{2}\left(\frac{z-H}{\sigma_z}\right)^2\right\}+\exp\left\{-\frac{1}{2}\left(\frac{z+H}{\sigma_z}\right)^2\right\}\right] \tag{7}$$

Where A represents the area of the structure in the Y-Z (cross-wind oriented) plane and c is an appropriate constant. c is usually assigned the value 0.5, which Gifford (1961) chose by intuition as a plausible lower estimate of the fraction of the structural area producing an initial plume spreading. For Z and H both equal to zero, Equation (7) reduces to

$$\frac{C(x,o,o;o)u}{Q} = \frac{1}{\pi(\sigma_y\sigma_z+cA)} \tag{8}$$

In subsequent sections, Equation (7) will be evaluated with Pasquill-Gifford values of σ_y and σ_z, an area A equal to 1090 m^2, and c valued at 0.5.

3.0 MEASUREMENT AND ANALYSIS

3.1 Sampling grid

The sampling grid, as laid out for the 1975 series, consisted of five circular areas centered on the reactor building. Arc radii were 37, 68, 187, 386 and 794 meters. The 187 meter arc contained no ground samplers during any of the tests. The remaining arcs had sampler positions every six degrees. Additional arcs at 1200 and 1600 meters were used during the year 1976. These arcs had sampler positions every three degrees.

Positions were numbered clockwise beginning at north on the inner-most arc. Each arc was divided into six sectors which could be independently activated from the test control position. In addition four samplers were positioned on the auxilary wing roof of the EOCR building.

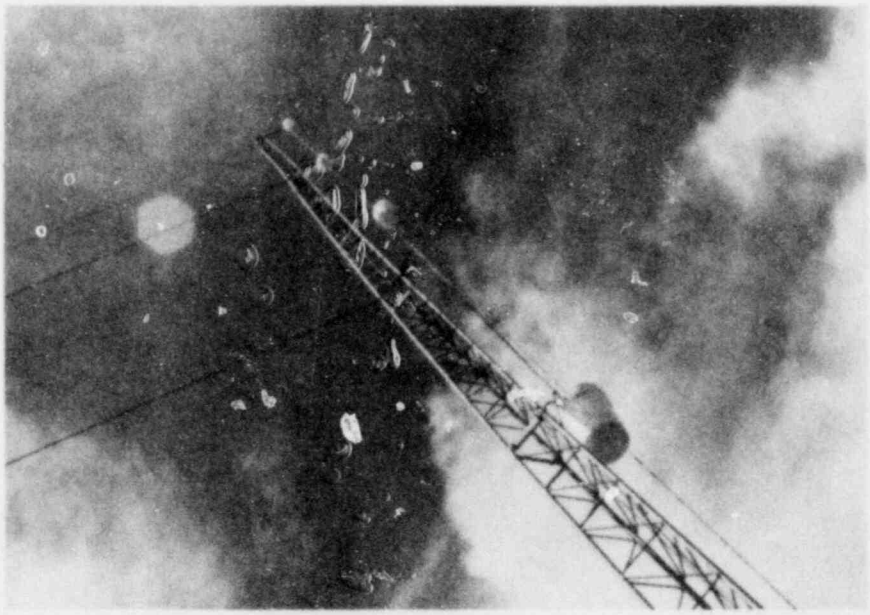

Figure 2. Vertical sampling tower with four suspended samplers at 7.5, 15, 22.5, and 30m above ground.

Vertical samples were taken at ground-level sampling positions 90, 93, 150, 153, 210, and 213 using one hundred foot towers. The sampling interval was twenty-five feet on all towers (fig. 2). A photograph of one of the sampler boxes was given by Start, et al, (1977). A plot plan of the EOCR grid was shown in figure 3. Arc distances have been rounded off to the nearest fifty meters for discussion purposes during the remainder of this report.

3.2 Photographic Description of Test Site

Each of the previously mentioned subparts of the field study, together with the relative magnitudes of the terrain features, may be related to the aerial photograph in figure 4. The EOCR complex is visible in the center of the photograph. The outer-most arc shown is the 800 meter arc. Features in the photograph may be correlated with the terrain map (fig. 5), the plot plan (fig. 3), and with the details of the concentration isopleth analyses found in Appendicies E, F, and G.

3.3 Meteorological Instrumentation

Meteorological data for both series of tests came from an instrumented tower located 150 meters northwest of the grid center. Since

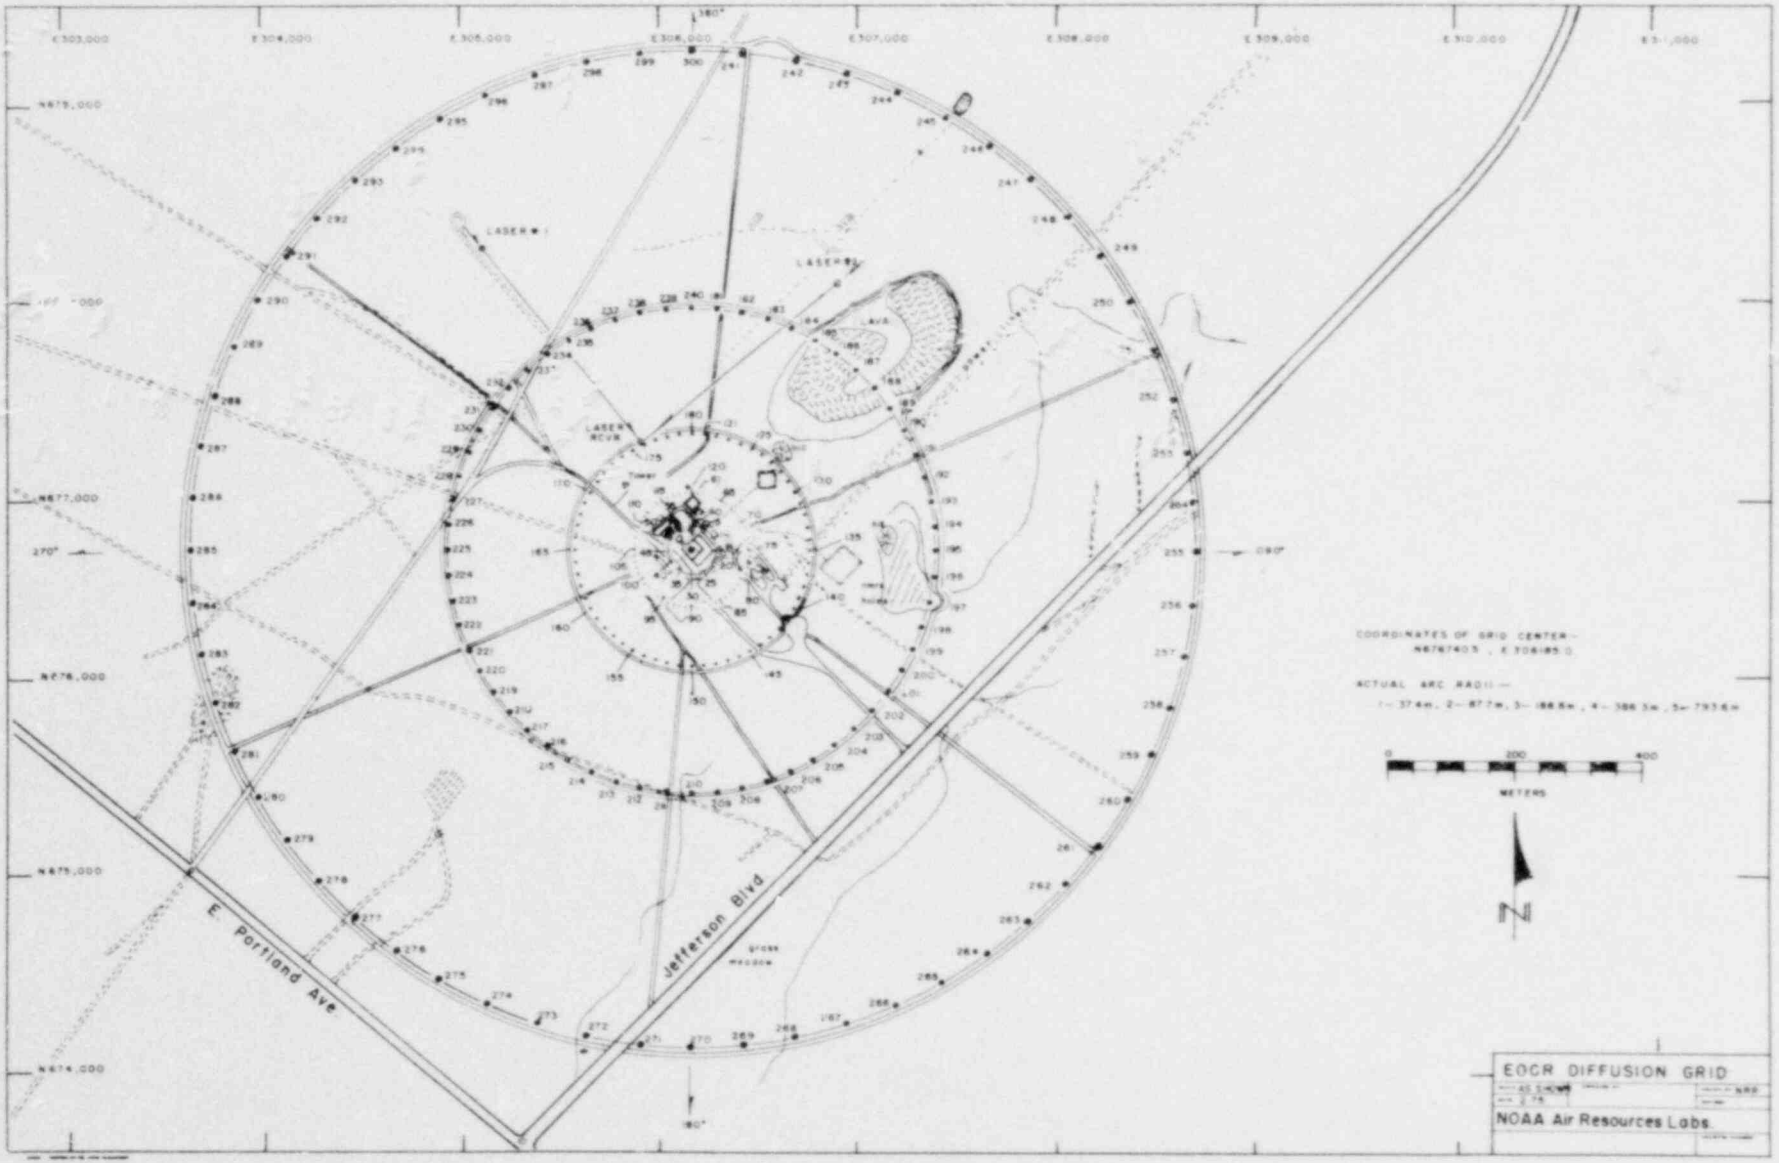

Figure 3. Plot plan of the innermost arcs of the EOCR grid. The outermost grid is at 800 m.

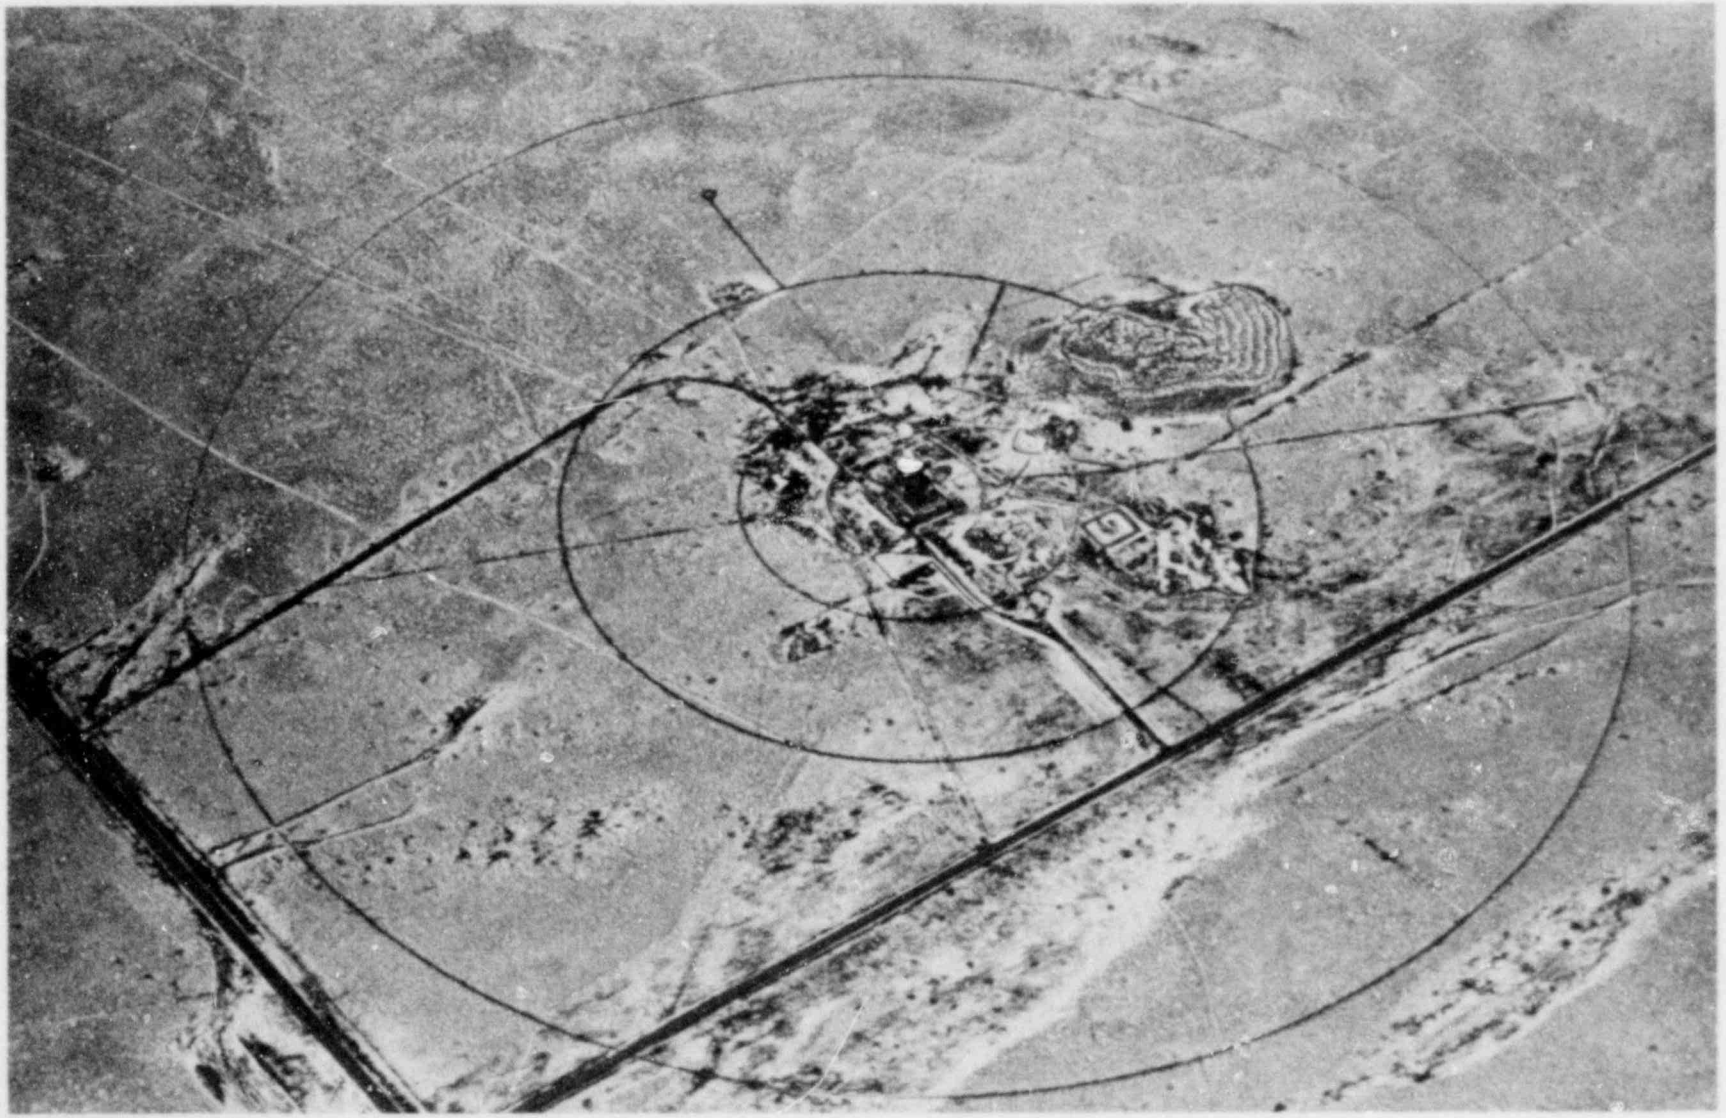

Figure 4. Aerial view of the innermost arcs of the EOCR grid. Photograph may be compared to the plot plan shown in figure 3. The outer circle corresponds to t 300 m arc of fig. 3. North is at the top of the picture.

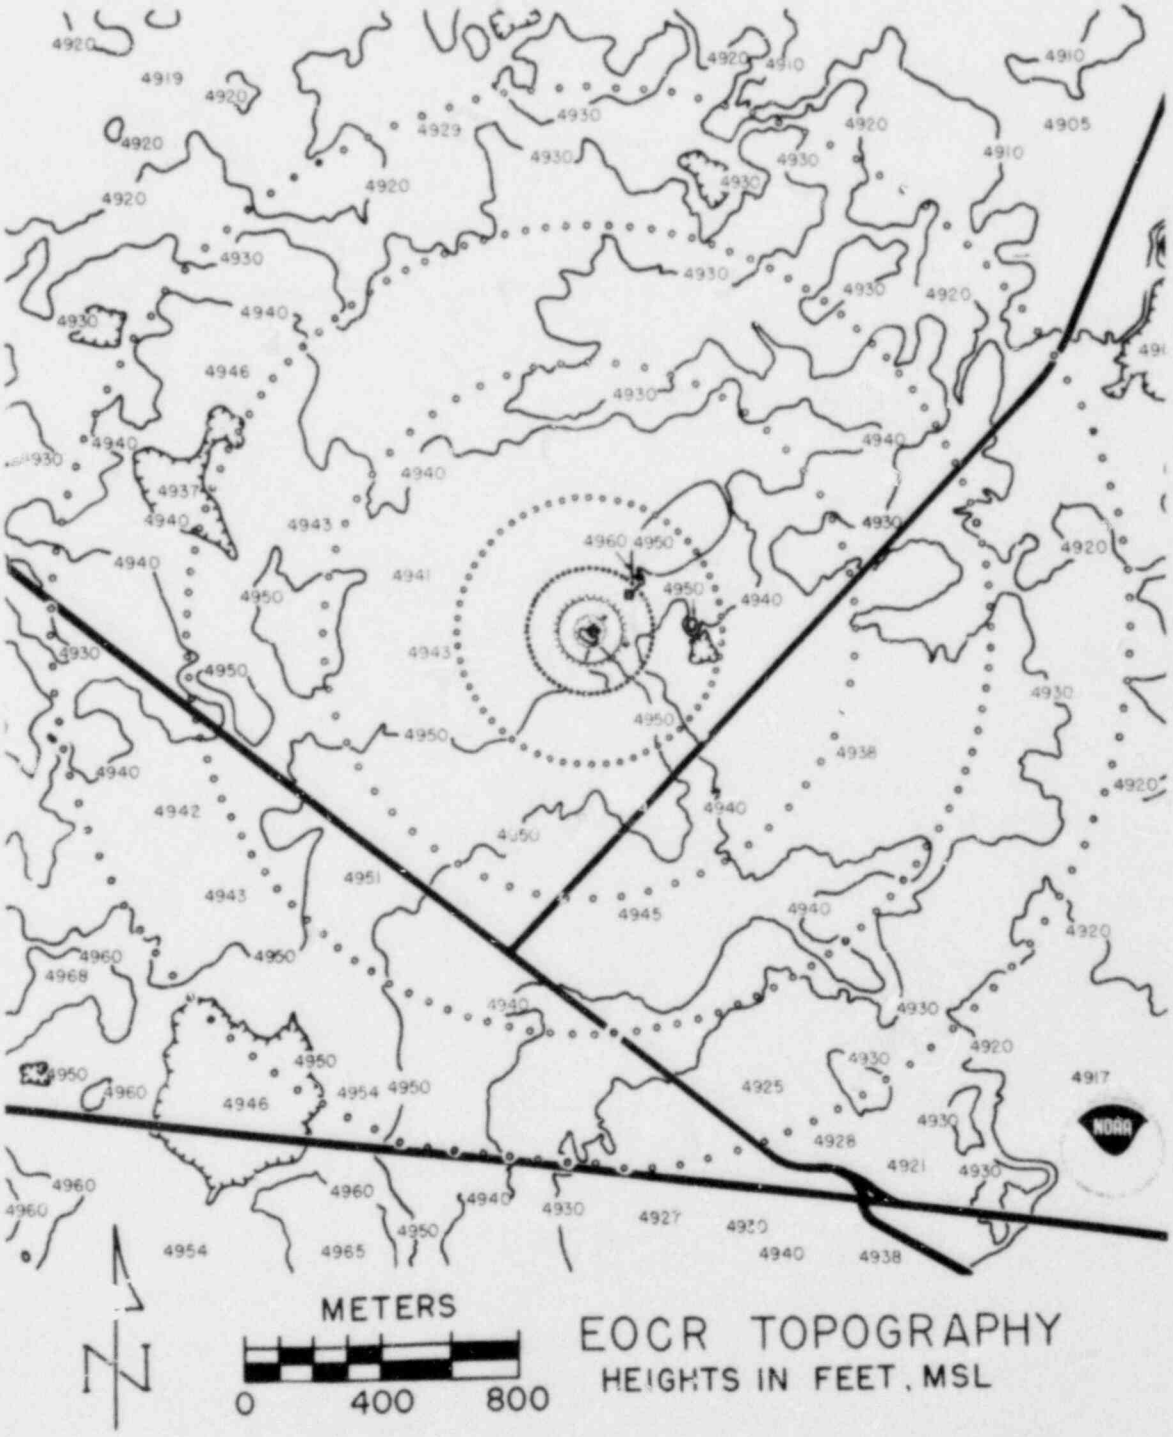

Figure 5. Terrain map of the entire EOCR grid. The outermost arc was at 1600 m. Contour lines were drawn for 10 foot height intervals.

southeast winds were a rare occurrence at the INEL, this location kept the tower out of the effects of the building wake. Temperature and wind sensors were located at the 4, 10, and 30 meter levels.

Temperature data were obtained from thermocouples mounted in Climet model 016-1 motor aspirated temperature shields. Horizontal wind speeds were obtained from Weather Measure model W103A cup anemometers with tri-cup stainless steel cup assemblies. Bivanes measured the horizontal and vertical wind angles. Photographs of the cup anemometer and bivane assemblies appeared in Start, et al, (1977).

During 1975, output signals from the sensors were input to a digital recording system housed in a small trailer. During 1976, this system was located in the instrumented bus described by Start, et al, (1977). This bus or trailer also served as a control center for test operations.

Additional meteorological data were gathered during the 1976 series of experiments. Weather Measure "103A" cup anemometers and Weather Measure light weight W104-2 direction vanes were mounted at the 70-ft level of nine 100-ft towers. They were located at grid tracer sampling positions 85, 88, 90, 92, 94, 96, 98, 100, and 103 in order to collect wind effect data within the wake of the building. This data was also digitally recorded, along with the same type of meteorological data collected in 1975 experiments.

3.4 Tracers

Sulfurhexafluoride (SF6), dichlorodifluoromethane (F12), and dibromodifluoromethane (12B2) were used as tracers in this test series. All three of these gases were inert, non-toxic in the concentrations used, and were of relatively small concentration in the free atmosphere. The tracers were released simultaneously with start-up and termination times being coordinated by radio. No grid samplers were activated until the tracer cloud had extended to the outermost sampling arc. Then samplers were actuated for the duration of the desired test. All samplers were shut down as the tracer releases were terminated. In this way, average concentrations were obtained instead of total integrated concentrations.

Figure 6 shows the various tracer release sites used during the tests. One tracer was released through the stack above the reactor building. A second release position was on the highest EOCR reactor building roof. The third tracer was released at ground-level (1m) on either the windward or lee side of the building. Table 1 lists the locations and heights of tracer releases by test number for the entire test series.

To provide visual plume references and allow for photographic documentation, oil fog was used as a visual tracer. Tracer gas samples were analyzed with an electron capture gas chromatograph system (Lovelock, et al, 1971). Additional details and photographs of the system were given by Start, et al, (1977).

4. RESULTS

A total of 24 gaseous tracer tests were conducted in and around the EOCR building complex. The first two tests were discarded due to various failings of meteorological data logging, the performance of the gas chromatographs, and loss of suitable weather conditions during the actual field measurements. Table 2 summarized the tests by NRC stability category during their conduct.

Additional details of the wind speeds and directions, standard deviations of wind direction, date and times of conduct of the tests, tower-measured temperature profiles, and NRC stability categories determined from tower temperature profiles are provided in appendix A.

Table 2. Stability Categories for Field Tracer Tests

STABILITY	TEST NUMBER	TOTAL
A	5,10,11,13	4
B	-	0
C	-	0
D	6,15,16	3
E	4,12,14,22,23	5
F	3,8,18,24	4
G	7,9,17,19,20,21	6

More detailed descriptions of the wind speeds and directions versus time are provided in appendices B and C. For each test, the total period of observation was subdivided into consecutive 2-min intervals; for each interval the average wind speed, direction, and the variance and standard deviation of wind direction and speed were provided for bivanes and/or cup anemometers at the 4, 10, and 30m heights on the EOCR meteorological tower. These data are listed in appendix B. A summary of total test information is given in appendix C. The total test summary provides average speeds and directions for the full period. For wind directions, the total variance during the test is listed along with the mean value of the 2-minute interval variances and the variance of the 2-minute average wind directions. The average 2-min variances may be viewed as a descriptor for the high frequency or turbulence diffusive process. Then, the variances of the 2-minute average directions are descriptive of the meandering or transport portion of the total dispersion of plume mass. The sum of the variance related to diffusion and variance due to meandering closely approximates the total variance for the entire period.

Table 3 lists the various sampling arcs, towers with samplers, and EOCR building roof-located samplers operated during each test. During part 1, tests 1-13, sampling arcs did not exist for 1200 and 1600m. For part 2, tests 14-24, these longer distance sampling arcs were established to investigate possible building influences at extended distances in a "far-wake" setting.

4.1 Measured Tracer Concentrations

Gaseous tracer concentrations were sampled at the various ground-level, tower heights, and roof locations described in figure 6 and table 3. A complete listing of all sampled concentrations (normalized by U/Q, where U was the average windspeed at the tracer release height and Q was the source strength) is given in appendix D. To better describe the contents of appendix D, the following illustrative plots are provided. Figure 7a,b,c depicts sampled concentration versus crosswind arc location (grid location number or

GLN) for successive downwind distances. Test 3 is shown in fig. 7a,b,c. Three lines are plotted in each figure to show the measurements for ground-level, roof, and stack released gaseous tracer. Figures 8a,b,c,d,e, and f depict tower sampled concentrations for test No. 16. Again, three separate lines identify the measurements for each of the gaseous tracers. In addition to these two types of regular array samplings of concentration, four samplers were operated on the lowest roof level of EOCR (fig. 6) and are listed under the heading of miscellaneous samples for each test during which they were operated.

Horizontal isopleths of gaseous tracer concentrations are provided in appendices E, F, and G. All isopleths for ground-level released tracer are in appendix E; appendix F contains isopleths for roof-level released tracer and appendix G contains isopleths for stack released tracer.

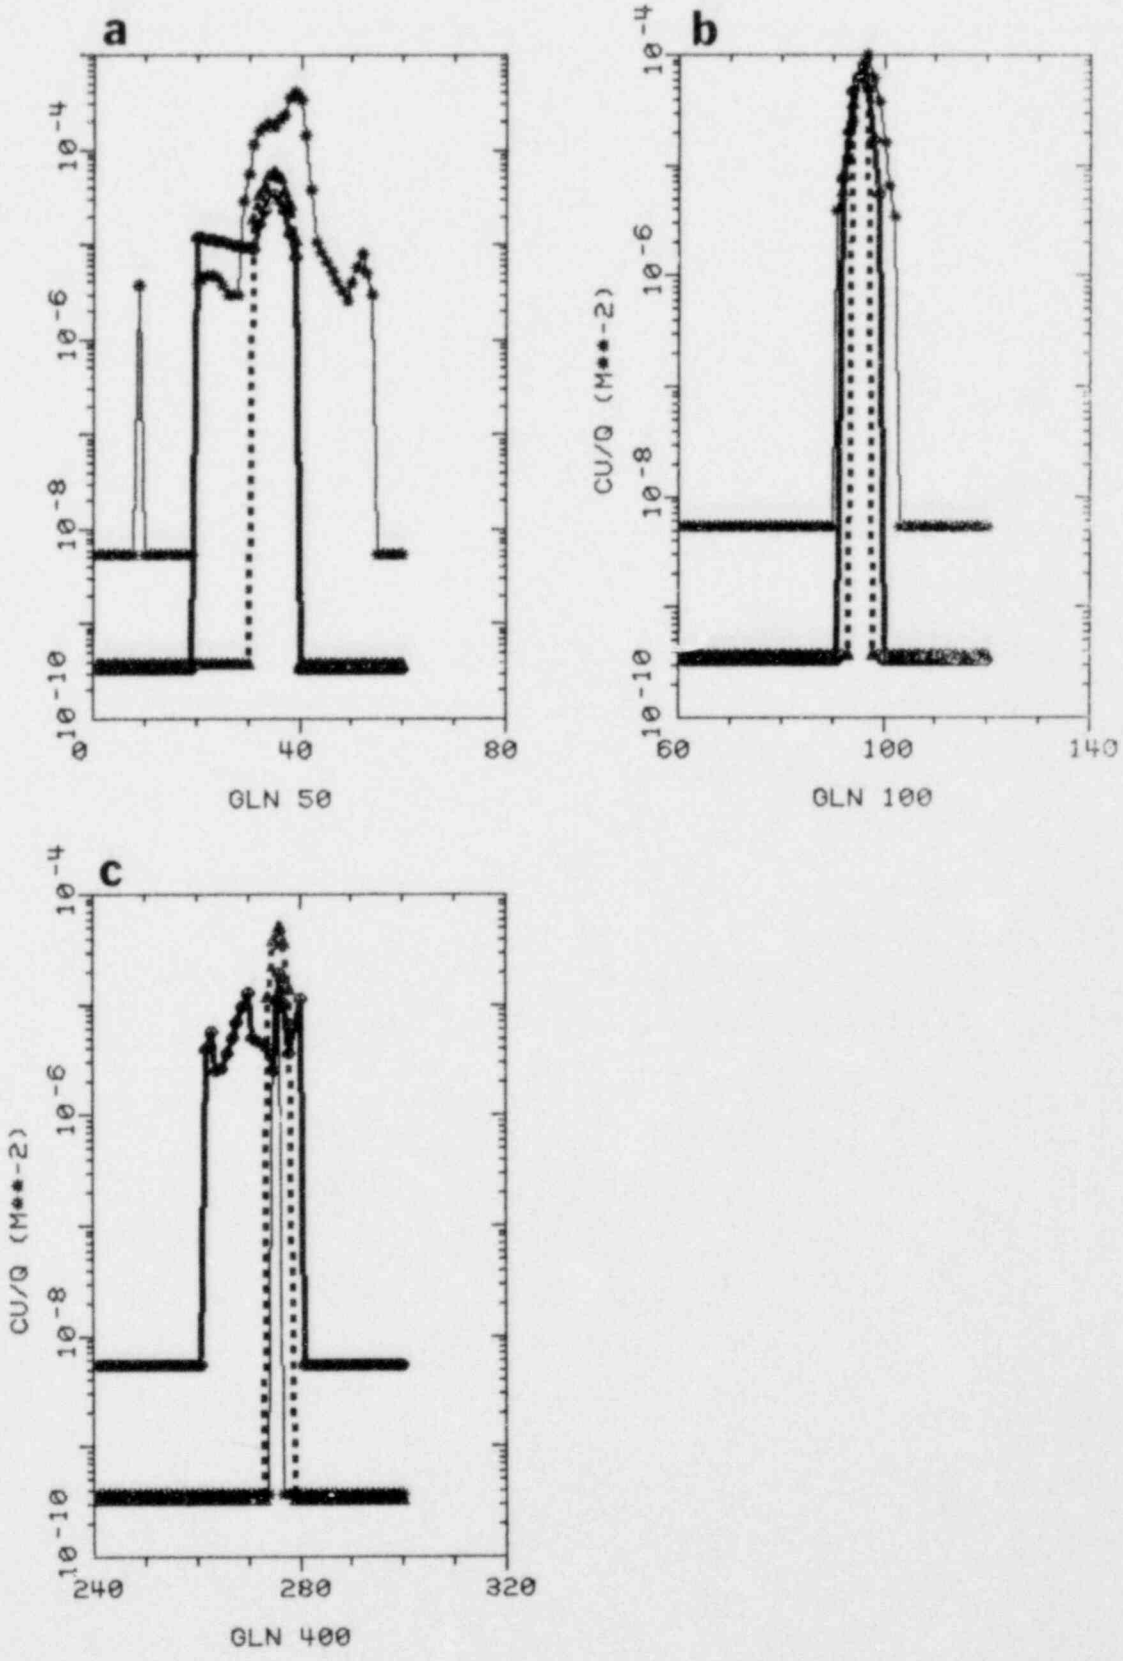

Figure 7. Sampled concentrations by grid location number for test 3 at the 50m, 100m, and 400m arcs. The thin solid line represents ground-level released tracer measurements, the dotted line represents roof-released tracer measurements, and the thick solid line represents stack-released tracer measurements.

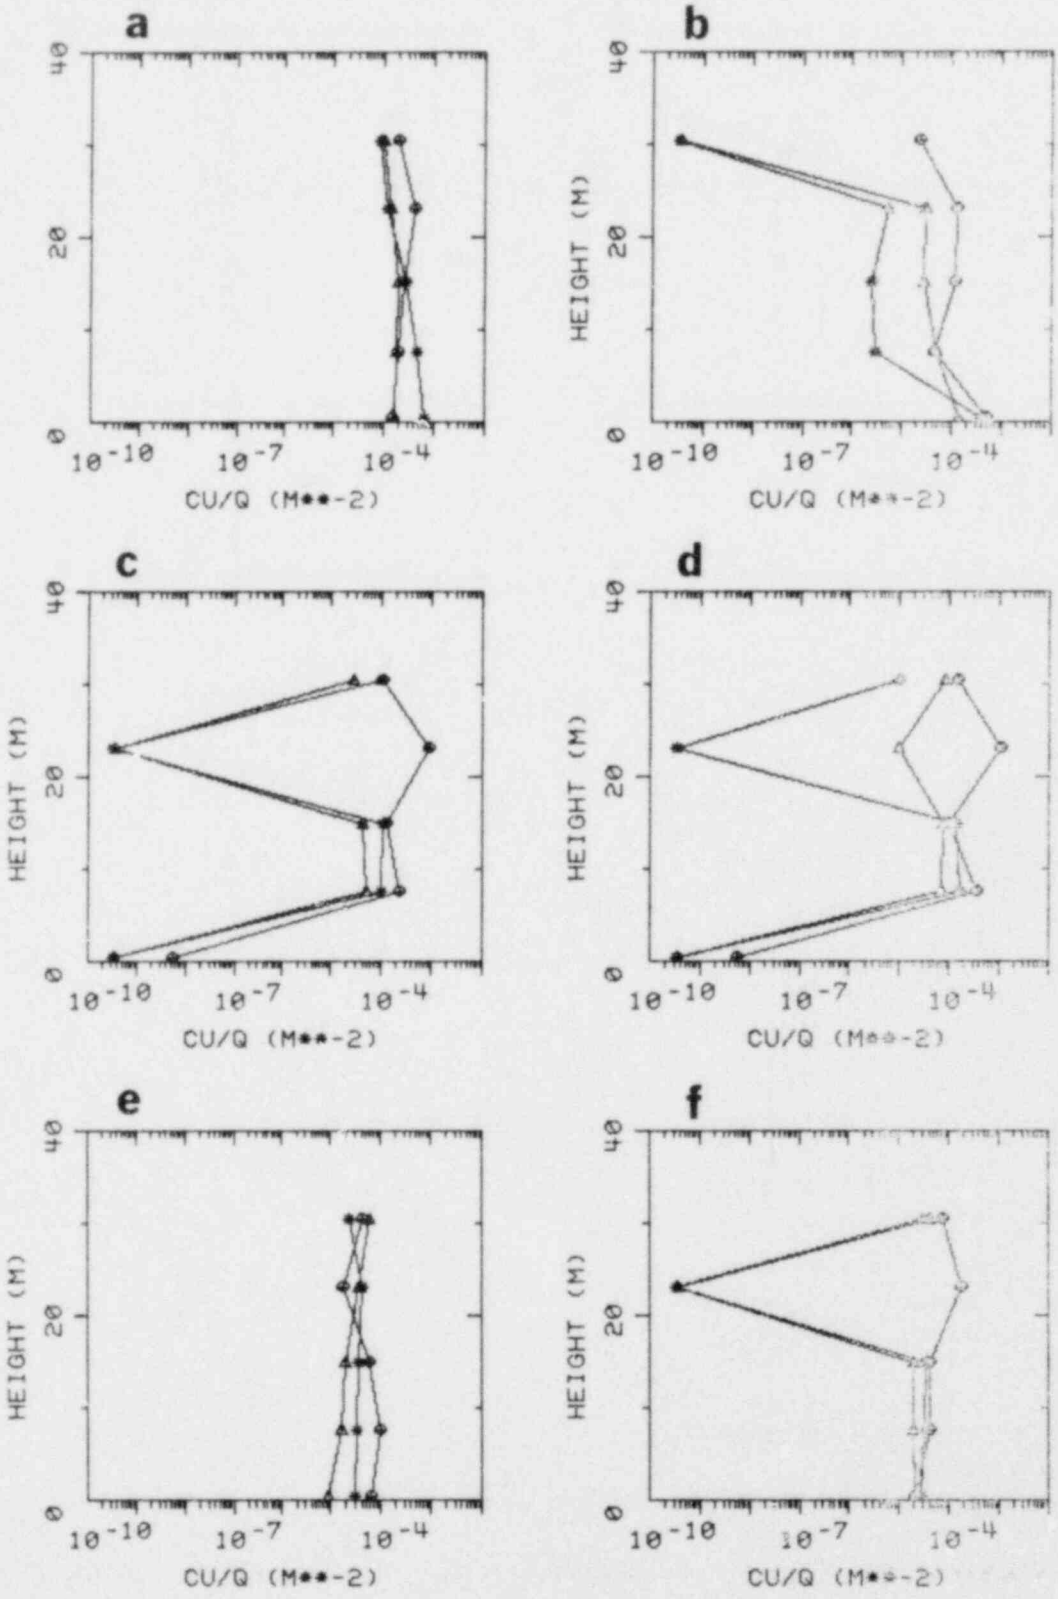

Figure 8. Tower sampled concentrations by height for test 16. Symbols used: * = ground-level released tracer, Δ = roof released tracer, ⊕ = stack released tracer. Figures 8a and b are for 100 m downwind; figures 8c and d are for 200 m and 8e and f are for 400 m downwind.

4.2 Visual Tracer Observations and Measurements

Before describing and discussing the behaviors of the sampled gaseous tracers it may be of benefit to examine a few selected pictures and descriptive diagrams based upon visual tracer observations and measurements. During each test, smoke was released to aid the visualizing and understanding of the airflows and effluent diffusion around and downwind of the EOCR structure.

Figure 9 shows the release of smoke tracer at ground-level in the lee of EOCR (SW face). A large amount of plume mass appeared to be drawn upward and streamed away at approximately roof height. The plume was mostly aloft at larger distances downwind. Figure 10 shows the plume in greater detail near the structure. A portion of the plume was mixed within a volume confined to the near-building wake; much plume streamed away aloft in a manner similar to the plume in figure 9.

In order to more clearly illustrate the systematic effects of the structure which both elevate the plume and produce an initial volumetric dilution, two simultaneous visual tracer plumes were developed. One plume was released at a location which should be influenced by turbulence and airflow streamlines which were altered by the presence of the building. The second plume was released crosswind from the building at a distance (150 to 200m NW) for which no building disruption occurred. Both plume photographs and lidar scans of these plumes were made. Figure 11 shows two visible plumes being observed.

One tracer was being released in the lee of EOCR. Return flows in the cavity zone drew the tracer toward the structure and lifted it. In the background (seen against the mountain slopes) the second tracer was streaming away from its release point with a normal amount of vertical spreading and remained relatively close to the ground. The plume behind EOCR was being mixed and lifted vertically, much more than the plume far from the building.

Lidar observations were performed by Stanford Research International in a manner depicted in figure 12. Approximate crosswind/vertical scannings of the plume were made along several direction rays to obtain plume particle concentrations at several different downwind distances. At present, quantitative descriptions of these plume sections are unavailable; computer processing of these data were never completed by SRI. A schematic illustration of qualitative preliminary LIDAR observations is given in figure 13. Initially the building-affected plume was larger and elevated compared to the open-terrain plume. The open-terrain plume dispersed more rapidly, in some cases, while the building affected plume was smaller, relatively. Eventually, the two plumes were of comparable size at the longer distances.

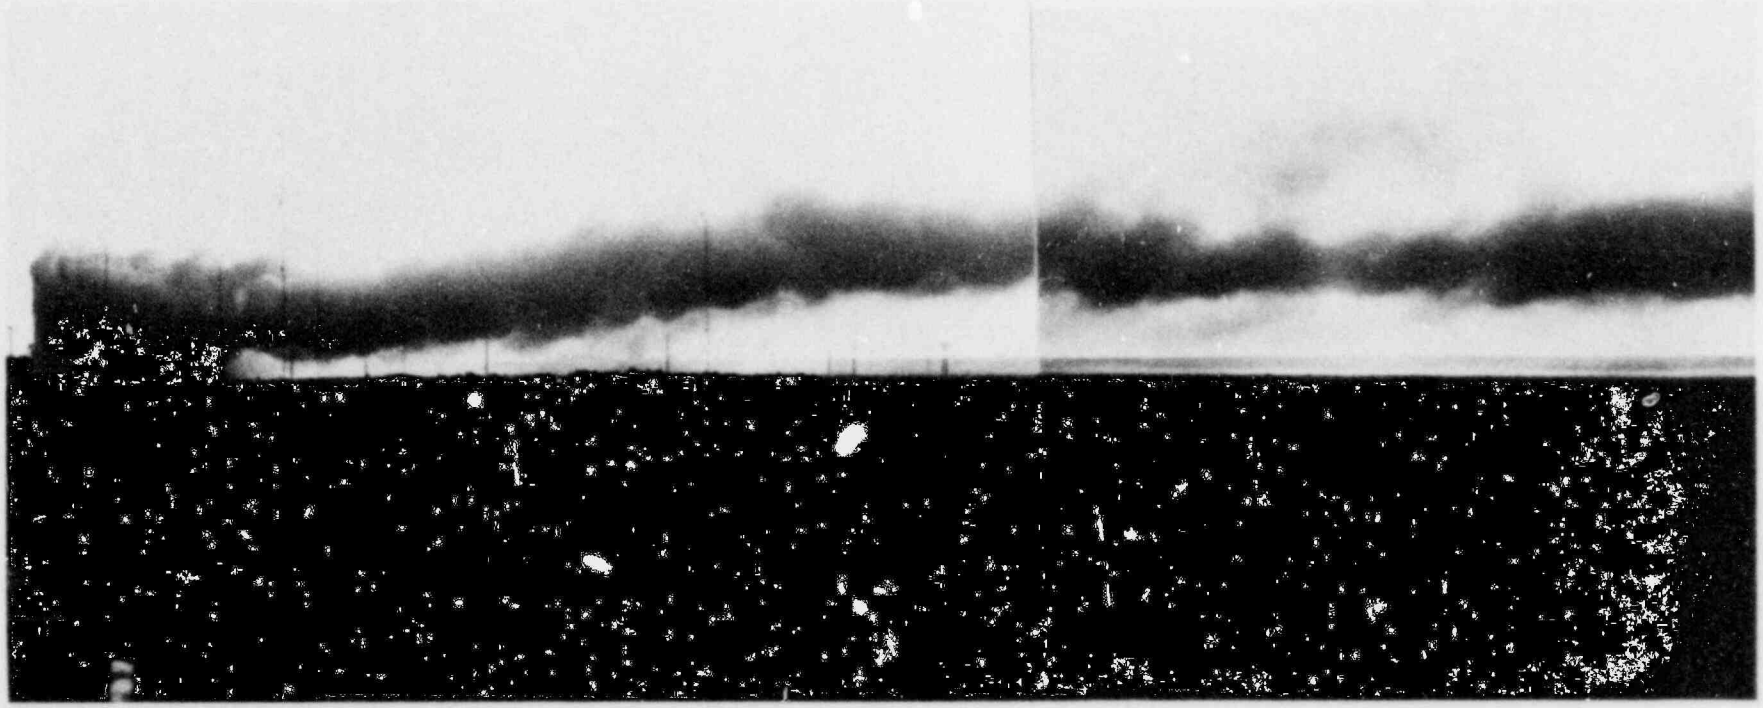

Figure 9. Ground-level smoke tracer release in the lee of the EOCR reactor building. Much of the plume is drawn upward and streams away at roof height. Further downwind a large portion of the plume remained aloft at about roof height. A more diffuse portion of the plume was near the ground beneath the elevated and most concentrated part of the plume.

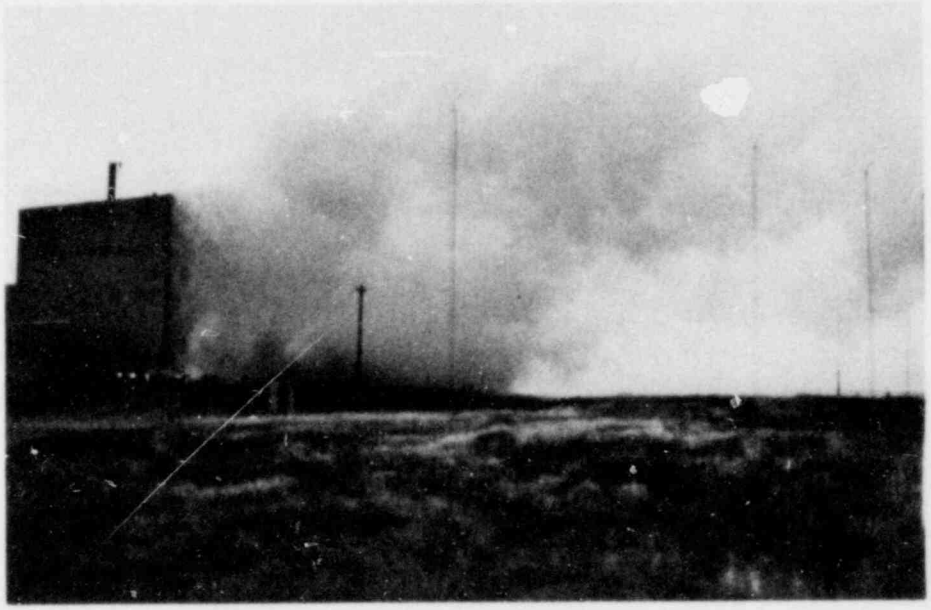

Figure 10. To compliment the smoke depiction of figure 9, a more detailed view is snown of ground-level smoke tracer release near the building. Some of the plume was mixed within the near-building wake; the remainder streamed away at about roof level.

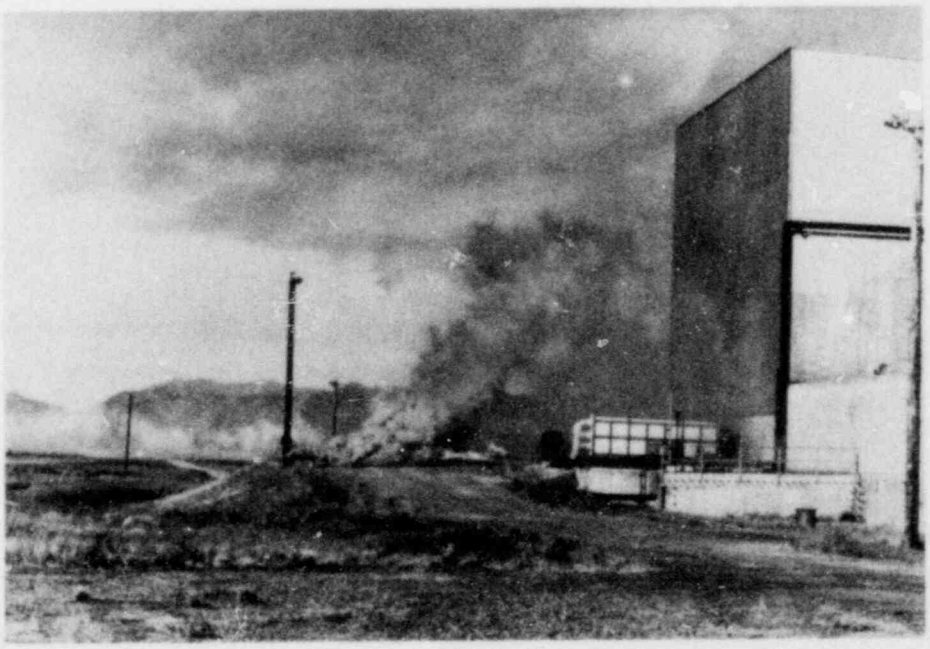

Figure 11. Simultaneous visual tracer releases were made. The first tracer was released in the lee of the building; second tracer was released crosswind far from the building where building disruption had no effect. The tracer which was released near the building was drawn toward the building and lifted. The second tracer plume streamed downwind normally and was mixed and lifted vertically much less than the tracer plume which was released near the building.

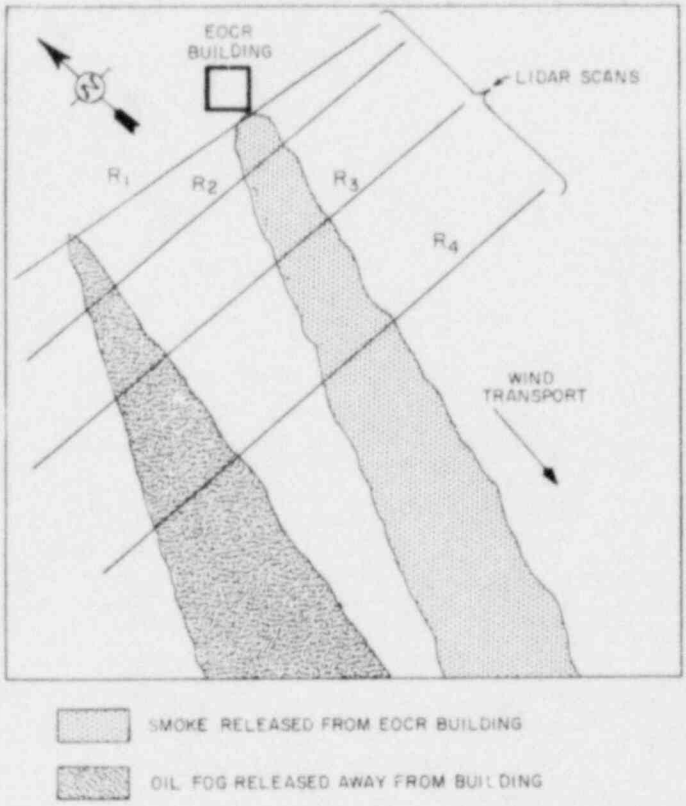

Figure 12. LIDAR observations of simultaneous visual plumes (shown in fig. 11) were performed by SRI, according to a plan shown by this schematic. Lateral/vertical cross-section scans were performed at several different direction rays (R_j) to observe both the smoke and oil fog plumes. The closest LIDAR scans were through the near building plume; the more distant scans were about 800m downwind.

4.3 Maximum Ground-level Tracer Concentrations, Sigma-y, and Effective Sigma-z Values.

To better understand the significance of the full collection of sampled tracer concentrations which were listed in appendix D and shown by the horizontal concentration isopleths depicted in appendix E, F, and G, selected parameters have been calculated or tabulated. Three parameters or statistics used were the normalized maximum (peak) tracer concentration observed on a particular ground-level (1m) sampling arc, the second moment of the tracer lateral mass distribution (σ_y), and the σ_z value. These σ_y and σ_z values were determined with eqns. 4 and 6, respectively. Figure 14 shows measured peak tracer concentrations plotted versus downwind distance for ground-level released tracer and stability category D. Also shown in fig. 14 are curves of predicted normalized peak concentrations calculated from eqn. 2 with customary values of σ_y and σ_z (Pasquill (1961) and Gifford (1961)). Curves were calculated for plume centerline heights above the ground equal to 1, 10, 25, and 30m. Separate symbol types were used to plot measured values for a particular test, in order to distinguish between values from tests within the same stability category. If the Gaussian equation were

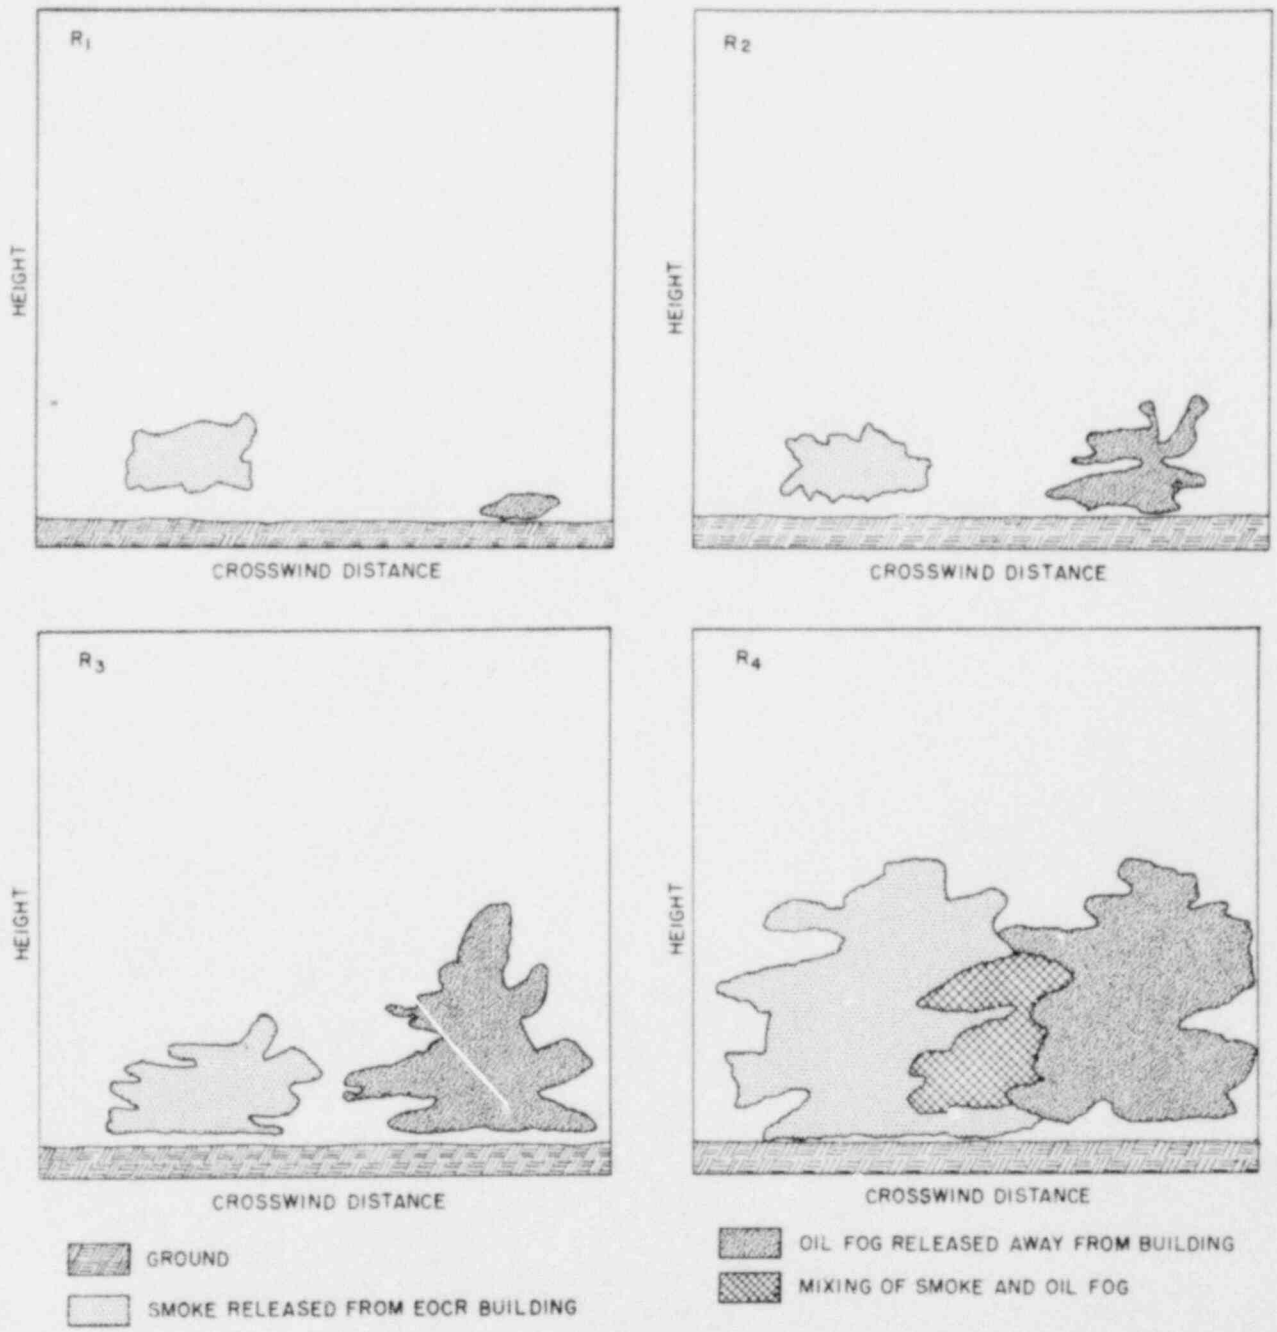

Figure 13. Schematic cross-sections of plumes from preliminary LIDAR observations are presented for increasing downwind distances. The plume on the left was the smoke released at the EOCR building while the plume on the right was oil fog released away from the building.

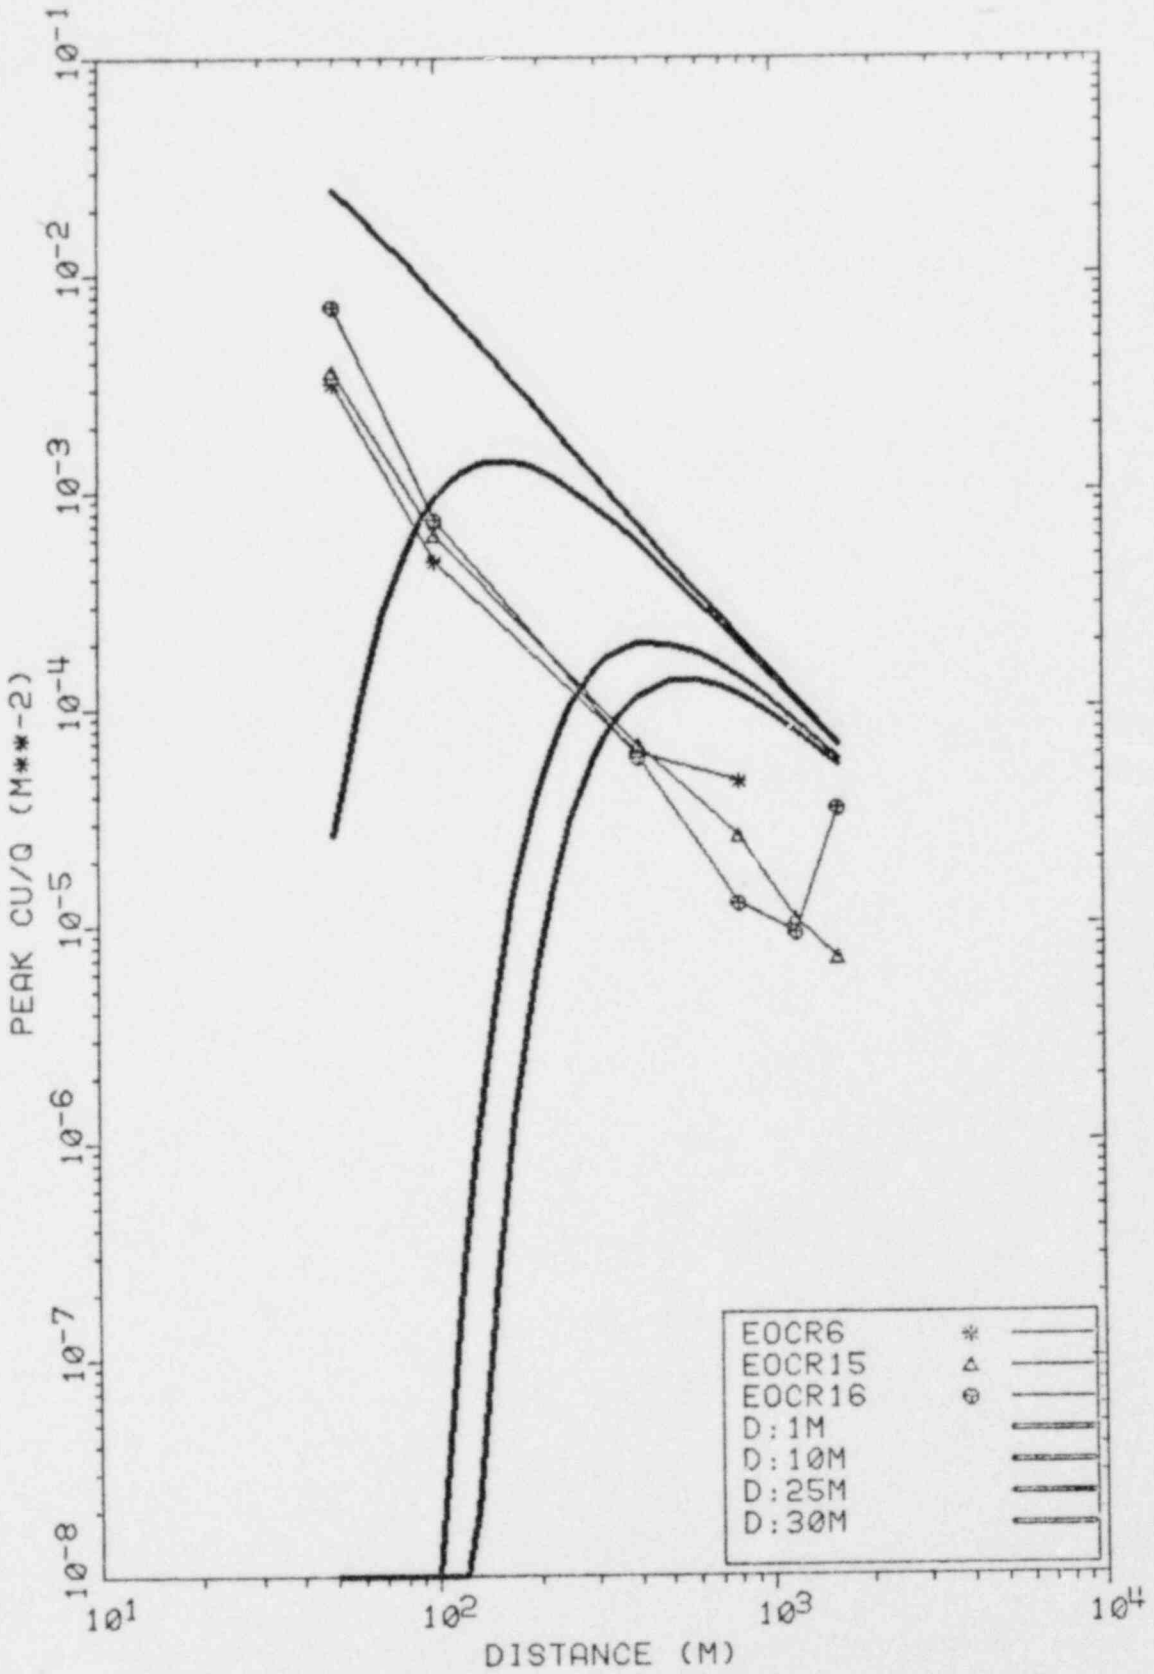

Figure 14. Measured peak normalized concentrations are plotted versus downwind distance for ground-level released tracer and stability category D. Also included are Pasquill-Gifford predictions of peak normalized concentrations for plume centerline heights of 1, 10, 25, and 30m with stability class D.

suitable and the Pasquill-Gifford values of σ_y and σ_z were appropriate, the observations for each test would match the upper curve for the 1m plume height. At times there was agreement between observations and calculation, but most often substantial differences were evident. Plots for other stability categories and tracer release heights were developed and the complete set is contained in appendix H.

In similar manner, tracer determined σ_y values (for all tracer release heights) were compared to Pasquill-Gifford (op. cit.) expected values (the heavy line) for stability D in figure 15. A regression line was drawn through the set of tracer derived σ_y values. A corresponding (parallel) but different behavior was evident. The complete set of σ_y comparisons with Pasquill-Gifford values are also contained in appendix H.

Figure 16 provides a scatter diagram of σ_z effective (eqn. 6) versus downwind distance. Data from all stability categories were included in the figure. Curves for stability categories A, B, C, D, E, and F (Pasquill- Gifford op. cit.) were included to place these effective σ_z values in perspective. One obvious discrepancy was shown by the very large values of σ_z effective at the smaller distances; values of many hundreds of meters were not credible. These virtual σ_z values were calculated using the ground-level sampled concentrations and no adjustment was made for elevated plume centerline heights. Additional discussion and reanalyses has been provided in a following section to better describe vertical diffusion and plume centerline heights.

4.4 Recalculated Sigma-z Values

Many σ_z effective values shown in fig. 16 were unrealistically large and were neither credible nor consistent with visual tracer observations at Rancho Seco (Start, et al., 1977) and during this study. Observations of oil fog visual tracer suggested that most ground-level and roof-top released effluents streamed away from the structure at roof-top height (essentially at the height of the flow separation zone). It seemed appropriate to calculate σ_z for ground-level and roof-top tracer release from σ_z (effective) values with effective plume height, H, equal to roof height (25m). Sigma-z values for stack released tracer were calculated using the physical stack height of 30m. Equation 6 was solved for σ_z solutions by iteration. Additional details of the numerical method for σ_z calculation are given in appendix I. Two roots of equation 6 were possible. One root (the smaller) represented the value of σ_z for an elevated plume with a Gaussian mass distribution; the second root (larger) provided σ_z for the well-mixed plume (non-Gaussian). The Gaussian plume values of σ_z (smaller or lower root) were adopted for the additional comparisons to follow; the implications of using the smaller root and the applicability of the well-mixed plume root will be discussed later. Comparison of σ_z from ground-level tracer

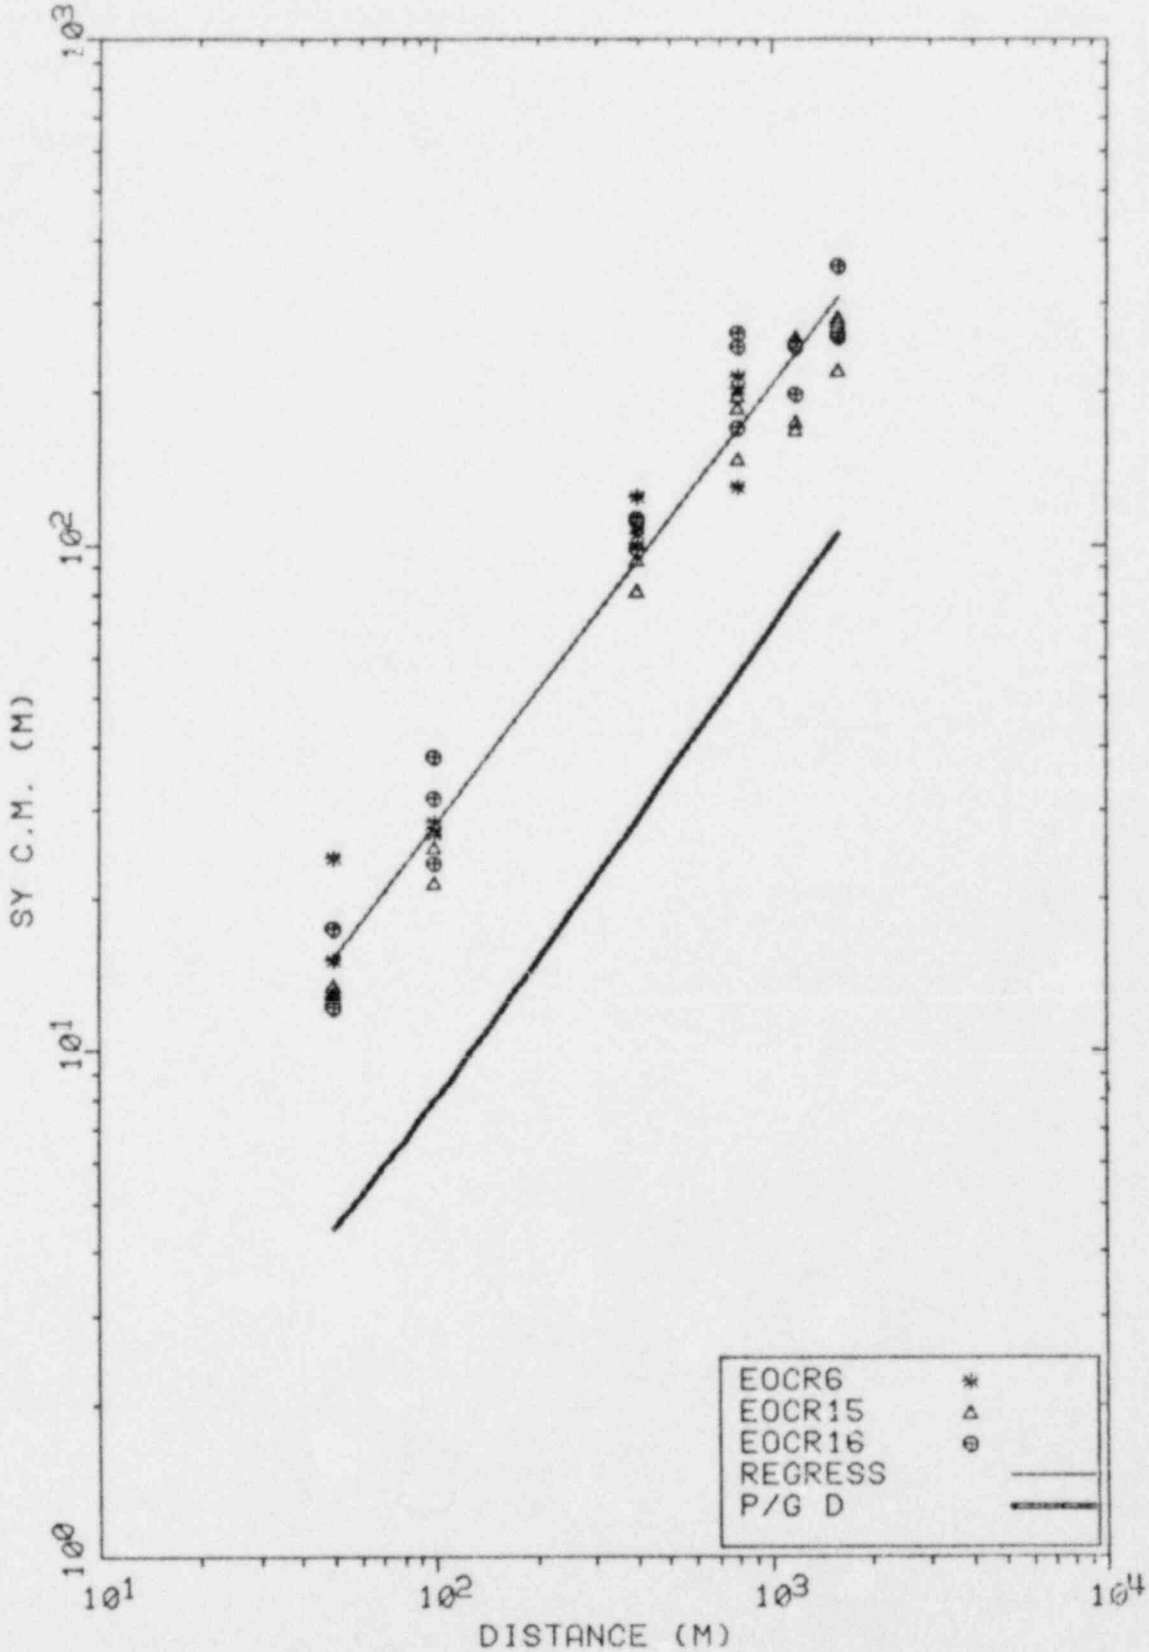

Figure 15. Tracer determined sigma-y values for stability class D were plotted versus downwind distance for all release heights with regression line for this set of values. Also included were Pasquill-Gifford expected values of sigma-y for stability class D.

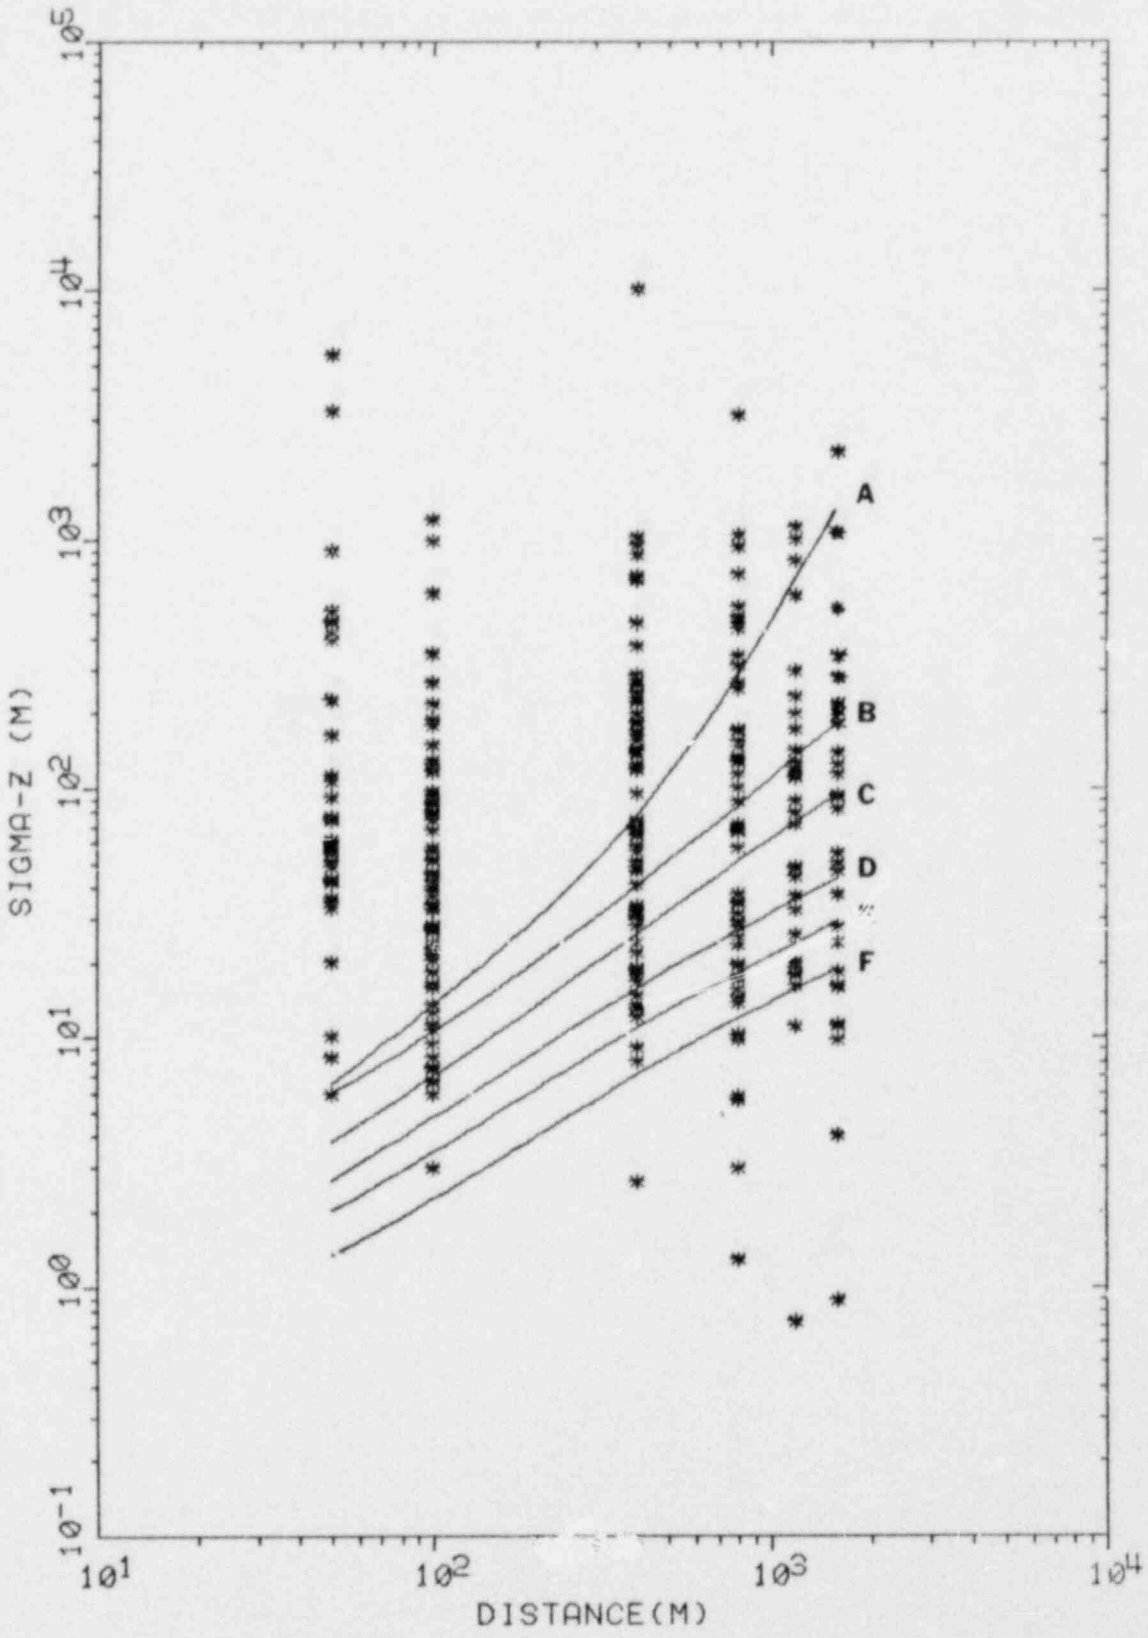

Figure 16. Tracer determined sigma-z effective values were plotted versus downwind distance for all stability classes. Data for all tracer release heights were included. Also included were curves of Pasquill-Gifford expected values of sigma-z for categories A, B, C, D, E, and F.

releases (for H = 25m) with σ_z for the roof and stack height discharged tracer showed good agreement; virtual σ_z for ground-level released tracer (with H = 1m) showed very poor agreement with σ_z for roof and stack releases. Figure 17 shows σ_z values for ground-level released tracer versus σ_z values for roof and stack discharged tracer. Figure 17a shows calculations of σ_z for ground-level tracer releases using plume centerline heights of 25m versus σ_z calculations using 25m plume height for roof releases and 30m heights for stack tracer plumes. Figure 17b is similar except a 1m plume height (the height of tracer release) has been used for the ground-level tracer.

Therefore, when making calculations of σ_z values, 25m (the approximate flow separation height for the structure) was a far better choice for the approximate plume height of ground-level release tracer than was the actual height (1m) of its release. Visual observations confirmed this conclusion; intuition suggested that vertical diffusion at a few meters above the ground surface should resemble the diffusion at 25 to 30m above the ground surface. This similarity should have been greatest during strongly unstable (temperature lapse) conditions and less similar during strongly stable (temperature inversion) conditions. However, with the additional turbulence developed by the structure, building induced circulations off-set or nullified the tendency for stable layering effects during the more stable conditions - especially within the first few tens of meters (a few building heights) downwind of the structure. Therefore, σ_z calculated for all three tracers should have been similar in value, regardless of the heights of these tracer releases, because they developed within approximately similar turbulence regimes. The large differences between σ_z calculated with H = 1m and calculations of σ_z for simultaneous releases of tracer at roof and stack heights were rejected. Therefore, discussions and comparisons to follow have utilized the knowledge that σ_z determined from eqn. 6 for ground level released tracer with H = 25m was reasonably appropriate and closely approximated the correct quantitative magnitudes.

4.5 Tracer Diffusion Statistics Ratios and Comparisons

In order to identify important physical phenomena and departures from expected plume behaviors without the presence of the structures, the parameters of normalized axial concentrations, σ_y, and σ_z were ratioed with the "expected" flat, open-terrain values presented by Pasquill (1961) and Gifford (1961) (hereafter simply refered to as Pasquill-Gifford or P/G values). Three important ratios were formed; a concentration ratio was calculated by dividing the P/G "expected" axial value by the observed peak value of tracer concentration. If more dilution (a smaller observed peak concentration) occurred, the ratio was greater than unity; if a larger than expected value was obtained the ratio was between unity and zero.

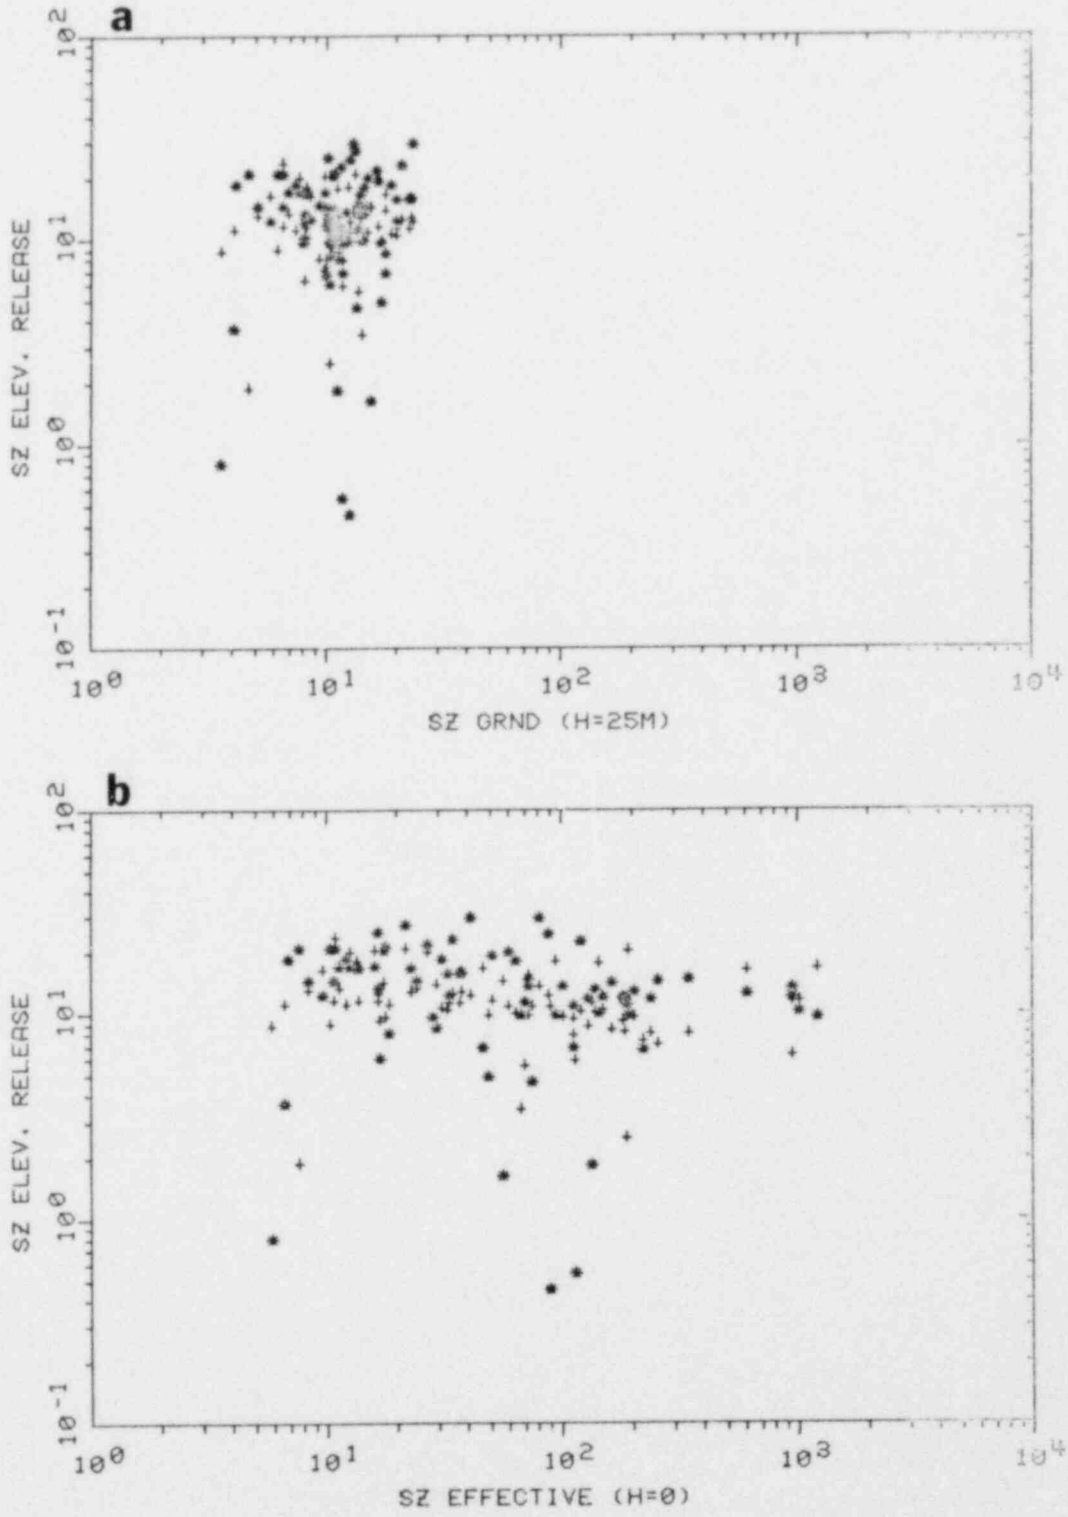

Figure 17. Calculated sigma-z values for ground-level tracer releases were plotted versus corresponding calculations for roof and stack height releases of tracer. Sigma-z values for ground-level tracer were calculated for plume height of 25m (upper figure) and ground-level or 1 m (lower figure). Comparisons with stack (roof) tracer are shown by *(+).

In similar fashion, ratios of σ_y and σ_z were formed. However, sigma ratios were formed by dividing observed values by the corresponding P/G values. This ratio convention was consistent with the concentration ratios. Larger than expected sigma values yielded ratios greater than unity; larger sigmas implied greater dilution of the tracer plume and a smaller peak concentration. As noted above, smaller observed peak concentrations yielded ratios greater than unity. Therefore, when consistency existed between concentration variabilty and differences in the lateral and vertical diffusive spreads (σ_y and σ_z), these ratios exhibited similar characteristics and behaviors.

Tables 4, 5, and 6 list ratios of concentration, σ_y, and σ_z. Table 4 contains ratios for only ground-level releases of tracer; table 5 contains ratios for the roof-level tracer release and table 6 contains ratios for stack released tracer. Within each table an average parameter ratio was listed for each stability category at each downwind sampling distance. The complete data set of all individual ratios is given in appendix J. The significance of all of these data points (ratios) could have been examined by use of scatter diagrams, each of which would contain a large number of points. The study and interpretations of these scatter diagrams have suggested the same conclusions and results. But for simplicity and ease of understanding, selectively pooled (averaged) ratios more directly illustrated the important phenomena and behaviors and were utilized for most of the remainder of this manuscript.

For ground-level tracer releases measured concentrations were generally less than P/G values determined for a 1m source height. Roof-level and stack discharged tracers had ground-level concentrations much greater than determined by the Gaussian plume model (eqn. 2) within the first several hundred meters downwind of the structure. In instances where equation 2 calculations produced very small values (near the building and stable conditions) the calculated values were replaced by the threshold tracer concentrations. Without this replacement RC values approached with 10^{-40}. With replacement, these RC values had magnitudes greater than 10^{-10}. The utility of this replacement was for graphical depictions. The physical interpretation of this alteration was that the downwash of elevated plumes really was greater than the RC ratios showed following the substitution. The meaning of the large RC values was that the Gaussian distribution was not applicable in stable conditions with building downwash.

The RY values were essentially the same, regardless of tracer release height. A definite increase in RY was shown as stability category progressed from A to G. A modest decrease in RY with distance may have occurred at distances beyond 800m, but it was not conclusive.

RZ values averaged slightly greater than unity; the largest departures from unity were for the most elevated tracer release and were greatest at shorter distances. At greatest downwind distances the RZ ratios were slightly less than unity.

Tables 7 through 12 list averaged ratios of normalized concentration, σ_y, and σ_z for ground-level, roof, and stack released tracer. These ratios were pooled averages for either specific arc distances (using all stability category data) or specific stability categories (using all arc distances). An overall or all-data ratio was listed for RC, RY, and RZ. These ratios were plotted in fig. 18a, b, c, d, e, and f. Three curves were plotted in each figure; a separate curve was plotted for data from ground-level, roof, and stack release heights. Figures 18a and b depict RC versus downwind distance and stability category, figures 18c and d depict RY vs distance and stability, and fig. 18e and f depict RZ versus distance and stability.

The lateral (indicated by RY) and vertical (shown by RZ) plume spreading ratios were very consistent regardless of the tracer release height. This consistency was expected since the tracers were experiencing the same fundamental atmospheric (and building wake) conditions which produced diffusion. The departures (ratios with Pasquill-Gifford values) from expected σ_y and σ_z were trivial for strongly unstable (A = 1) and largest for strongly stable (G = 7) stability categories (figs. 18d and f). A systematic behavior of these ratios with distance (figs. 18c and e) were also evident. RZ ratios (fig. 18e) clearly showed a large initial dilution process which was followed by a rapid (exponential-like) decrease in the relative contribution of this initial dilution. These RZ values approached unity between 400 and 800m downwind and remained in essential agreement with expected Pasquill-Gifford values of σ_z at the longer distances.

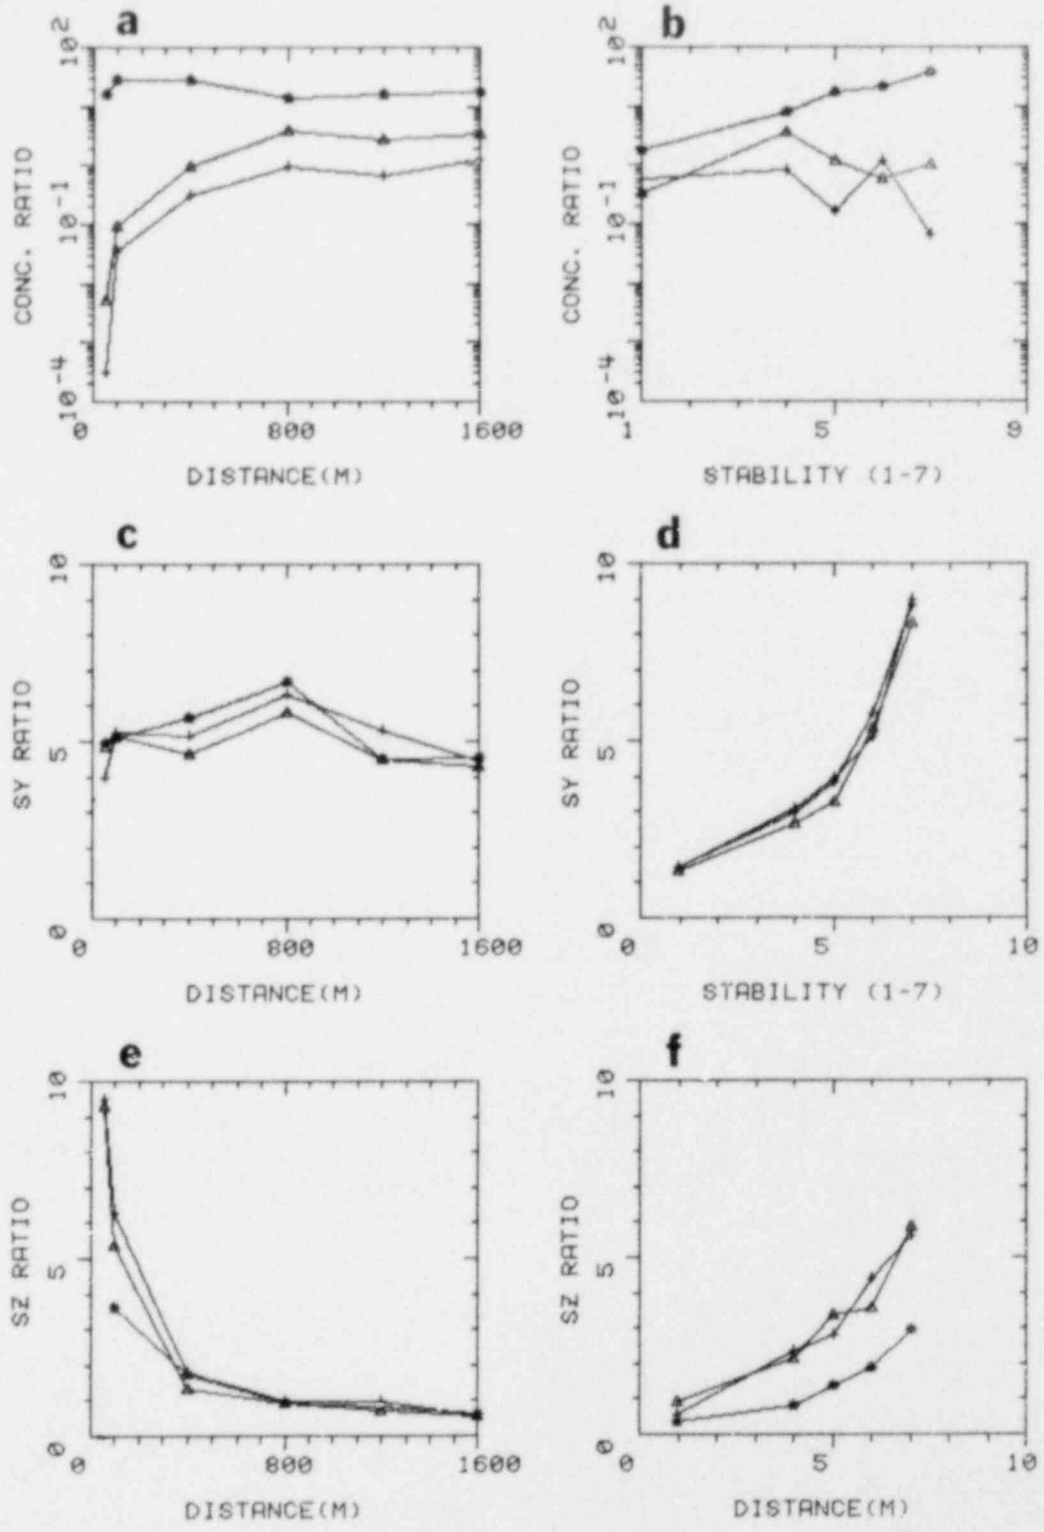

Figure 18. Averaged ratios of normalized concentration, sigma-y, and sigma-z for ground-level, roof, and stack released tracers. The first column of plots contain pooled averages for all stability categories for specific arc distances. The second column of plots contain pooled averages for all arc distances for specific stability classes. Symbols used: * = ground-level released tracer; Δ = roof released tracer, + = stack released tracer.

RY ratios (fig. 18c) depict an initial magnitude which increased more slowly to about 800m downwind. Beyond 800m, RY values slowly decreased; RY values from the Rancho Seco study (table 13), (Start, et al., 1977) agreed well with these EOCR findings. Rancho Seco values of RY ranged from 6.4 at 100m downwind to 4.8 at 800m downwind.

Concentration ratios are depicted in figs. 18a and b. RC values greater than unity resulted when the observed peak concentrations were less than values calculated by the Gaussian diffusion formula (eqn. 2). The calculated concentration values were obtained by substitution of expected (P/G) values of σ_y and σ_z and plume heights of 30m for stack, 25m for roof, and 1m for ground-level tracer releases into eqn. 2. Since values of RC were much greater than unity, measured ground-level peak tracer concentrations were substantially less than calculated from the Gaussian formula with H = 1m. Likewise, the corresponding measured peak concentrations from roof-level and stack discharged tracers were much greater than calculated at ground-level by the Gaussian formula.

In general, the RC ratios for stack and roof height tracer releases were similar; they were small in magnitude due to downdraught increases in ground-level measured concentrations near the structure. At longer distances the concentrations approached expectations (RC approaches unity). RC values for the ground-level tracer releases were large at all distances due to a substantial upward-mixing of plume mass behind the structure. RC for ground-level tracer releases varied from about 2 for stability A to almost 40 for stability G. No obvious systematic behavior was evident for roof and stack height tracer releases.

At any particular distance, RY values were approximately 4 to 6. Measured σ_y values were larger than the corresponding P/G values. RY values increased in magnitude from about 1-1/2 to 9 as stability changed from A to G, with great consistency for all tracer release heights.

The variations of RZ with distance and stability were more erratic than for either RC or RY. RZ increased with greater stability; CIC was less representative of the value which should be observed at plume axis height with more stable conditions. RZ decreased with greater distance.

4.6 Wind Direction Meandering, Building Induced Lateral Spreading, and Tracer Sigma-y

The RY ratios in tables 7 through 12 which were plotted in fig. 18c and d were developed from second moments of tracer mass distributions divided by the appropriate value of σ_y from the Pasquill-Gifford curves. These summarized ratios illustrated the differences during this test series from values expected with adaption of the Pasquill-Gifford curves without alterations.

The causes of these systematic differences from Pasquill-Gifford values will now be examined. Some physical basis for these differences may be postulated, such as building wake plume broadening, greater than expected wind direction meandering for the associated stability category, or perhaps incorrect specification of stability category. There was no known bias in stability category specification. However, there was a significant influence of wind direction meandering. Table 13 summarizes the average standard deviations of wind direction for EOCR by stability category and lists the corresponding values from Gifford (1968). For σ_y estimates, (Pasquill, 1976) derived using $\sigma_y = f(x).\sigma_\theta.X$, an adjusted standard deviation of direction, $\sigma_\theta.f(x)$, was appropriate. Example adjusted values for X = 800m are given in table 13. If the EOCR average σ_θ

Table 13. Observed and expected Values of Wind direction Standard Deviation by Stability Categories.

	Stability Category				
	A	D	E	F	G
Gifford (1968)	25.	10.	5.0	2.5	(1.25)[4]
EOCR avg.	25.7	23.0	9.5	20.6	15.6
Pasquill (1976)[1]	15.5	6.2	3.1	1.6	0.8
σ_θ ratio[2]	1.7	3.7	3.1	12.9	19.5
RY avg. (approx)[3]	1.5	3	3	5	9

σ_θ is standard deviation of horizontal wind direction

1 Pasquill (1976) σ_θ(effective) = f(x) * σ_θ (Gifford, 1968) where f(x)=0.61 at x=800m

2 σ_θ ratio is (EOCR avg.)/(Pasquill, 1976)

3 Tracer determined σ_y divided by expected Pasquill-Gifford sigma-y value

4 σ_θ for "G" is assigned 1/2 of value for "F" stability of Gifford (1968).

values were divided by these Pasquill adjusted values, the resulting ratios approximated the RY ratios presented in tables 4 through 12 and in figures 18c and d within a factor of about two or less. Therefore, there may be only minor effects of the building wake upon lateral plume spreading. A building induced spreading effect should have been most evident near the structure and diminish in importance at longer distances. To examine this behavior, measured tracer σ_y values were divided by σ_y values calculated from σ_θ measured at the 30m height

on the EOCR meteorological tower; the Pasquill (1976) formula was used. These ratios represented the reciprocal of the fraction of plume spreading described by σ_θ. The resulting ratios were plotted versus the σ_θ values in figures 19a,b, and c. Since a distance related behavior was postulated for this fraction versus σ_θ, regression lines with distance held constant (i.e., 100m, 400m, ...etc.) were calculated. They are plotted for ground-level (fig. 19a) roof-level (fig. 19b), and stack released (fig. 19c) tracer. There was a striking similarity for all tracers and distances. For measured values of σ_θ less than 10 to 20° σ_y values estimated from σ_θ are 2 to 4 times too small (the effect of the structure is noticeably important). For larger values of σ_θ, the atmospheric effect of wind direction meandering dominated the lateral dispersion process downwind of the structure.

The average values of RY shown in table 13 were similar to the average ratios of σ_θ for stabilities A, D, and E and were about 1/2 of the magnitude of ratio values for stabilities F and G. Examination of NRTS curves of σ_y values for 15-60 min tracer release times (Yanskey, et al, 1966) and Pasquill-Gifford σ_y values for approximately 3-5 min tracer release times (Turner, 1970) revealed that NRTS values of σ_y (for 60 min tracer releases) were about 2 to 4 times larger than the corresponding Pasquill-Gifford values at 800 to 1000m downwind during stabilities E, F (and G). These differences were expected due to longer averaging times for the NRTS observations of tracer spreading; likewise, σ_θ values for EOCR should have been larger than the short term values referenced by Gifford (1968). Based upon NRTS field data and EOCR findings (e.g., σ_y divided by σ_y(P/G) and RY(EOCR) it appeared that more reasonably expected values of σ_θ for stabilities E, F, and G should be about 15, and 20-25° for the 60 min EOCR tracer releases. If these values were used to recalculate σ_y according to Pasquill (1976), the observed tracer spreadings would have been well accounted for by observed standard deviations of horizontal wind direction. Therefore, much of the departure of RY values from unity resulted from comparisons with previous observations (diffusion climatology) which possessed a substantially smaller amount of wind direction meandering.

Apparently, these calculated enhancements of lateral tracer spreading downwind of the structure were not due particularly (on the average) to the effects of the structure; they resulted from the use of a reasonably correct method, Pasquill (1976) with the wrong σ_θ expectations (they were appropriate for too short of a tracer release/sampling time). The shortness (smallness of σ_θ) was most evident during the more stable atmospheric conditions of categories E, F, and G. However, as shown in figure 19, for small values of σ_θ (<15°), there was a substantial underprediction of plume spreading. When the meandering of the wind direction was sufficiently small (e.g. <10°), only 1/4 to 1/2 of the observed tracer spreading was accounted for by a σ_y calculated from σ_θ. Likewise, for large wind direction meanderings (e.g. $\sigma\theta$>25 to 30°) the effect of the EOCR structure on lateral plume spreading became indistinguishable from the expected plume spreading in the atmosphere without the structure present.

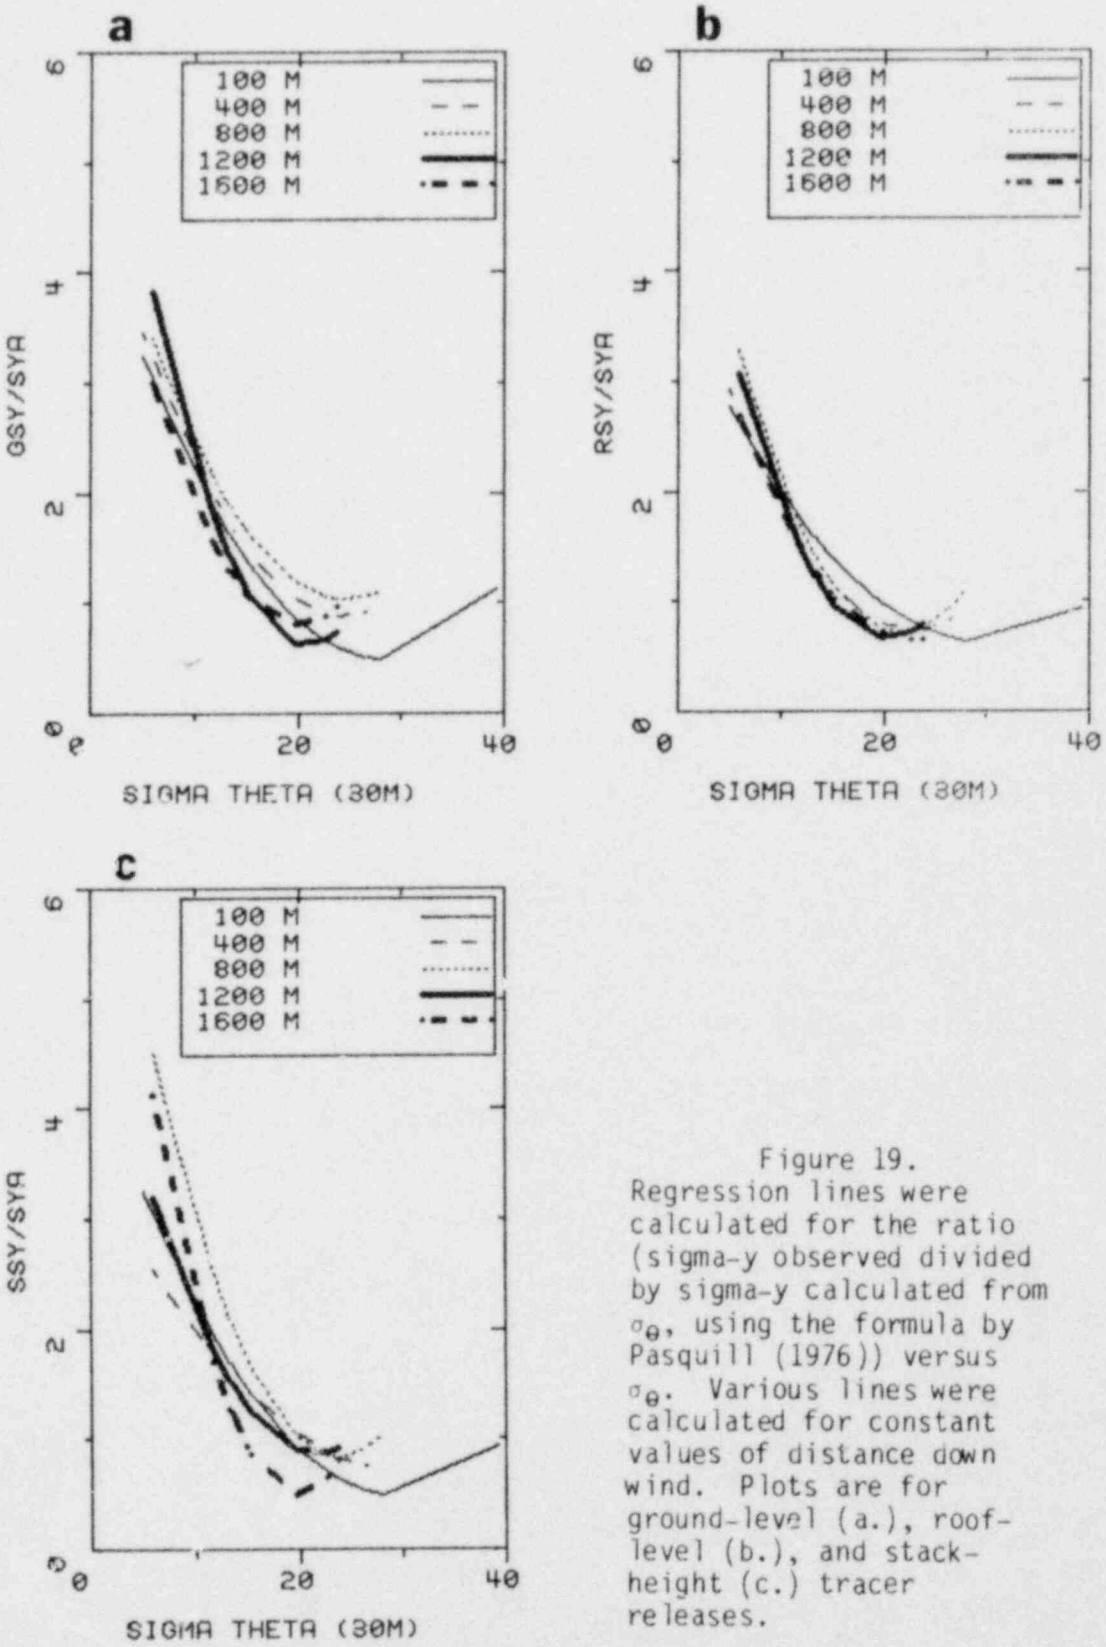

Figure 19. Regression lines were calculated for the ratio (sigma-y observed divided by sigma-y calculated from σ_θ, using the formula by Pasquill (1976)) versus σ_θ. Various lines were calculated for constant values of distance down wind. Plots are for ground-level (a.), roof-level (b.), and stack-height (c.) tracer releases.

4.7 Wake Dilution Estimates Using the "cA" Term.

To account for effects which alter effluent plume dimensions within airfows near and downwind of structures, a simple modification of the Gaussian plume model was presented by Gifford (1961). Equations 7 and 8 are example incorporations of this simple conceptual modification. These equations were used to examine the suitability of the add-on cA term to better account for observed ground-level tracer concentrations. This modification of the diffusion equation is envisioned to be most applicable to ground-level released effluent plumes, but roof and stack released tracer were also examined for completeness.

On the basis of diffusion statistic ratios presented in fig. 18c and 18e the following procedures were adopted for calculation of expected maximum concentrations for comparisons with observed maximum concentrations. After consideration of ratios in figure 18e, it was deemed appropriate to use the expected Pasquill-Gifford (P/G) values of σ_z, since the ratios converged to near unity at and beyond 400m downwind. Significant deviations from expected P/G values were confined to relatively near-building distances. These deviations were ascribed to near-building modifications of expected atmospheric rates of diffusion and to downwash and might be expected to be treated by the near-building modifications of the Gaussian diffusion equation, e.g. the cA term. Since the ratios shown for σ_y in figure 18c did not converge to unity, the actual test-by-test determined values were used in calculations of maximum tracer concentrations. (These values of σ_y and the associated σ_θ values were consistently larger than values usually related to the P/G stability categories.) The observed wind speeds at 30m, essentially at stack-top height, were selected since visible plume observations have shown that considerable plume mass streams away from the building at roof-level or a little higher. In summary, these calculations of maximum ground-level concentrations were made using the Gaussian diffusion equation with 1) observed values of σ_y and wind speeds (measured at 30m), 2) P/G values of σ_z appropriate to the stability category (determined by vertical temperature gradient), 3) plume axis height of 25 or 30m with and without the usual Gaussian exponential off-centerline reduction of concentration, and 4) with and without an add-on cA term in which c = 0.5 and A = 1090m^2.

Figure 20 relates calculated versus observed maximum concentrations. Data from all tests, release heights, stabilities were used, except that data from the 50m arc are not included. The term "CHI PEAK" denotes maximum measured normalized ground-level concentration. Two variations of calculations were used. In fig. 20a and c the add-on term, (+cA), was used as given in eqn. (8). In fig. 20a and b the exponential term (EXP), shown in eqn. (7) was used with z = o. In fig. 20d neither the (EXP) nor the (+cA) were used in calculation of normalized concentrations. It is very obvious from fig. 20 that significant large calculational errors result from use of

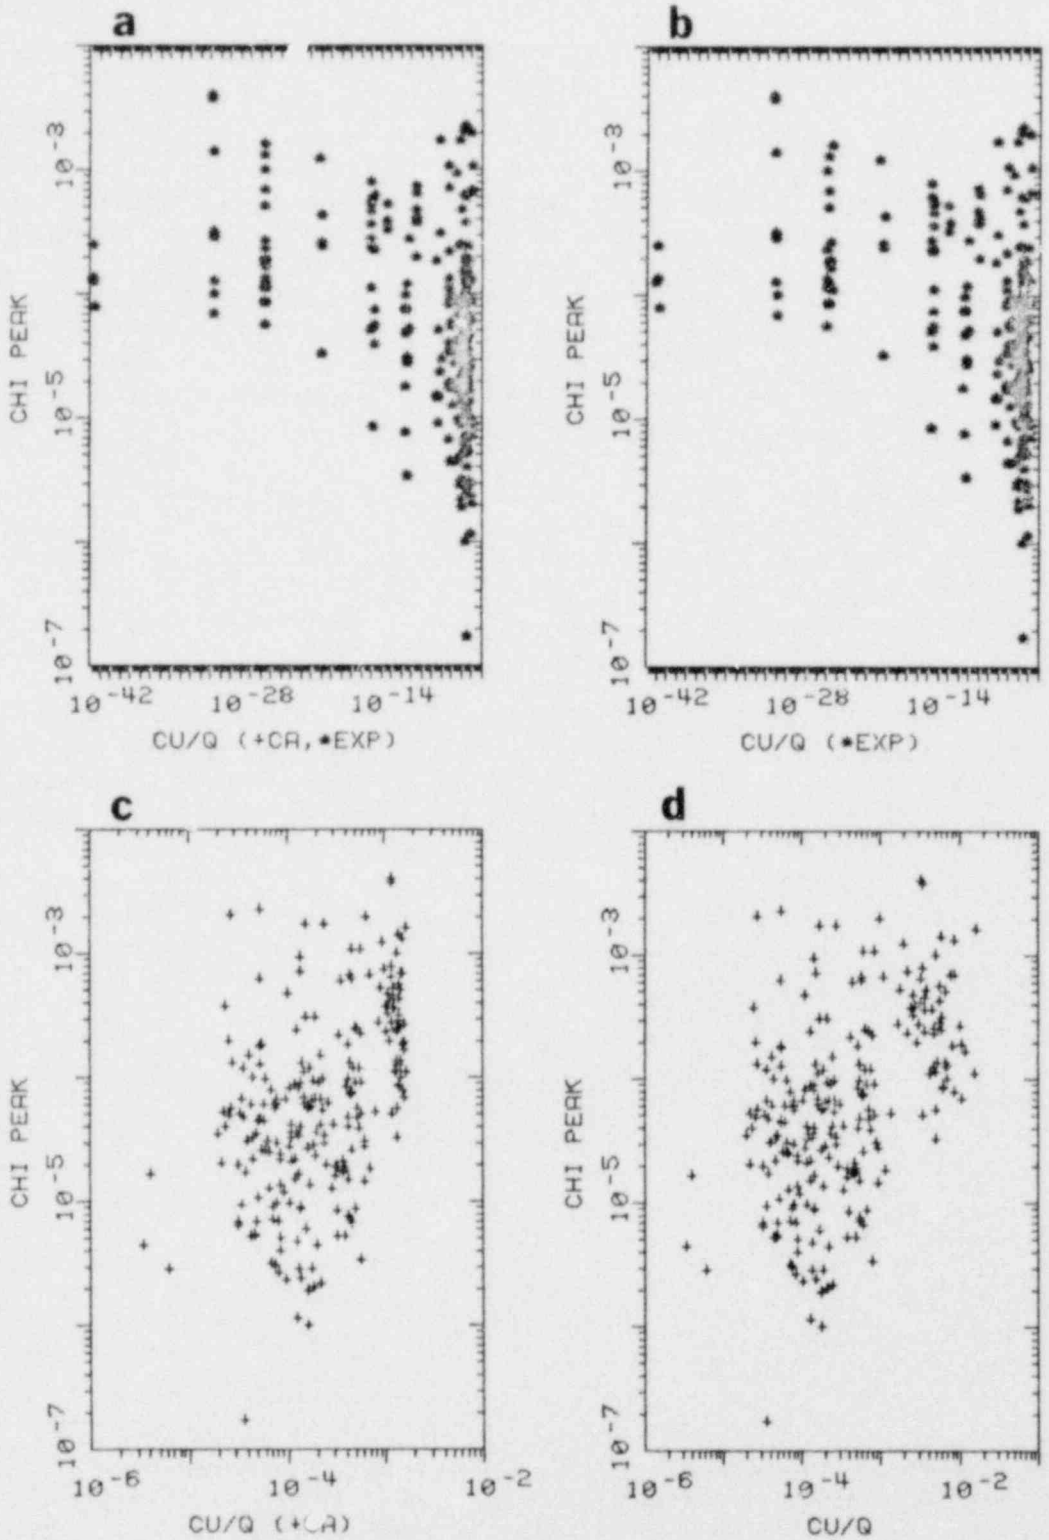

Figure 20. Calculated ground-level normalized concentrations were plotted versus observed normalized maximum concentrations (CHI PEAK). All stability categories, release heights, and all but 50m arc data were plotted. Calculations were made using eqns (7) and (8) with z=o. In figures 20c and 20d H=o was used; in figures 20b and 20d cA=o was used.

the Gaussian equation with EXP. Calculations without use of the EXP term yielded far better comparisons, as shown in fig. 20c and d. Use of the (+cA) term did little to remove the significant over estimation of concentrations. The use of the cA term had the largest relative effect on the largest concentrations (at the far right side). Some concentrations were under-calculated but the large majority (about 85 percent) of the values were over estimated. During the remainder of discussions and comparisons of concentration data, calculated concentrations will NOT include the Gaussian exponential term, EXP, to vertically adjust for off-axis concentration calculations. Instead, calculated axial concentrations will be compared with observed ground-level tracer concentrations. If a calculation or comparison includes the use of the EXP term, it will be explicitedly identified as included in the calculated value.

The relative contribution of the add-on cA term was more easily recognized from the scatter diagram in fig. 21. Calculated values (with and without the cA term) were divided by the observed maximum concentrations and plotted against one another. Differences due to the use of the cA term yielded less than a factor of ten modification of concentration relative to calculations without use of the add-on cA term. Variations of ratio value (whether or not the ratio was formed using concentrations calculated with the cA term) were much greater than the variability of concentrations attributable to use of the cA

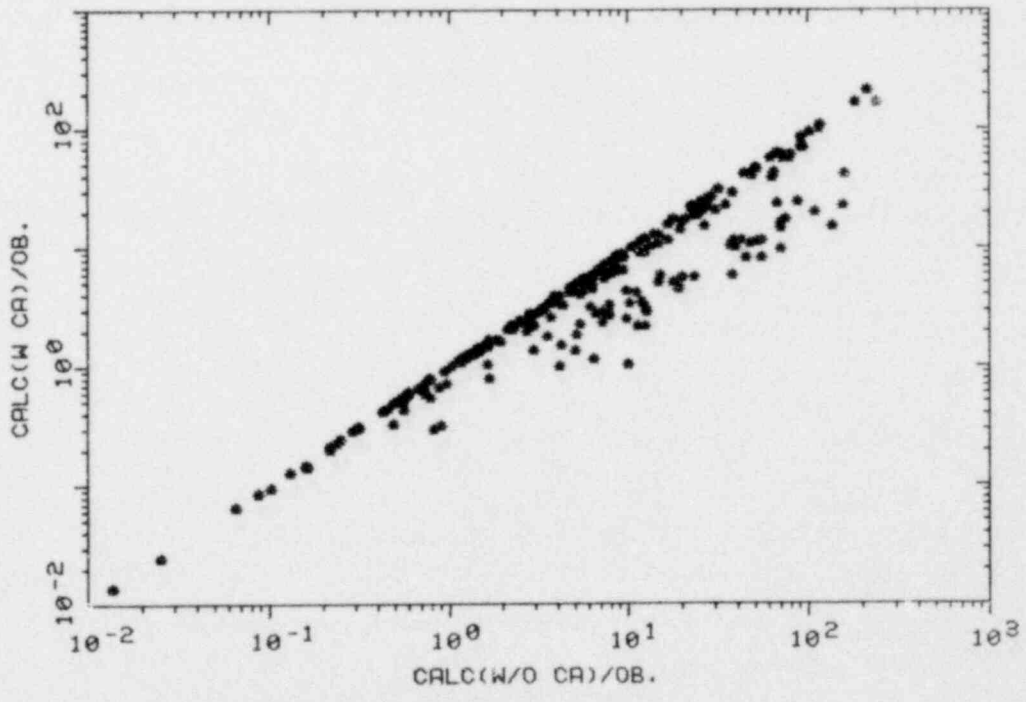

Figure 21. Relative contributions of the add-on cA term are shown by ratios of calculated axial (without the cA term) concentrations divided by observed maximum concentrations (abscissa) versus the corresponding ratios (ordinate) calculated with inclusion of the cA term.

term in the calculations. If 50m arc data were used, these differences would be larger. However, the presence of the structure resulted in tracer travel paths substantially different than 50m, due to non-symmetrical positioning of the tracer release points and trajectory length alterations due to flow around the structure. Therefore, the 50m arc values were given specialized analysis and were reported by Sagendorf et al, (1980) in a specific treatment of near-building diffusion.

Figure 22 presents data for only ground-level tracer releases. In Fig. 22a calculated (with cA term) maximum concentrations versus measured values are presented. The same over-calculation bias existed for ground-level releases as shown in fig. 20 (for all tracer release heights.) Figure 22b shows the ratio of calculated divided by observed concentrations (the same data points used in fig. 22a) versus downwind distance. Ten points were under-calculated and only 4 values (of 82 total points) were under-calculated by more than a factor of two. The largest under-calculation factor was about five. The calculation bias did not appear to be a function of distance.

The behaviors of calculated divided by observed concentration ratios are presented in figures 23, 24, and 25. Ratios were plotted versus distance, as in fig. 22b, but separate figures were provided for each stability class as well as for the entire data set. Figure 23 shows these depictions for ground-level released tracer with calculated values which included the cA term. Figure 24 presents the similar plots for roof-level tracer releases and figure 25 relates to stack discharged tracer; these calculations did not include the add-on cA term for the roof and stack released tracers. Stability category did not seem to be an uncompensated factor in errors (deviations) for calculation of tracer maximum ground-level concentrations. More under-calculations occurred for stack releases (less occurred for ground-level and roof-level releases); the maximum factor of under-calculation was least for ground-level tracer releases. This factor was more for roof-level and was most for stack releases. Under-calculation seemed largest at longer distances for stack-height tracer releases, relative to the other tracers at longer distances.

Ratios of calculated divided by observed concentrations versus wind speed at release height are shown in fig. 26. Figure 26a presents stack release data and fig. 26b depicts results for roof-level released tracer. Figures 26c and d present data for ground-level released tracer. Calculated concentrations included the cA term only in fig. 26c. For stack releases (fig. 26a) there were no under-estimations of concentrations for windspeeds less than 2 m/s, but there were many over-estimations by greater than an order of magnitude. A threshold windspeed for downwash of stack emitted tracer seemed to occur; no similar threshold for ground-level released tracer seemed to occur. Roof-level releases of tracer may have had a lower threshold for downwash (about 1.5 m/s) but it was less certain whether or not roof-level releases behaved substantially different than ground-level releases in this regard.

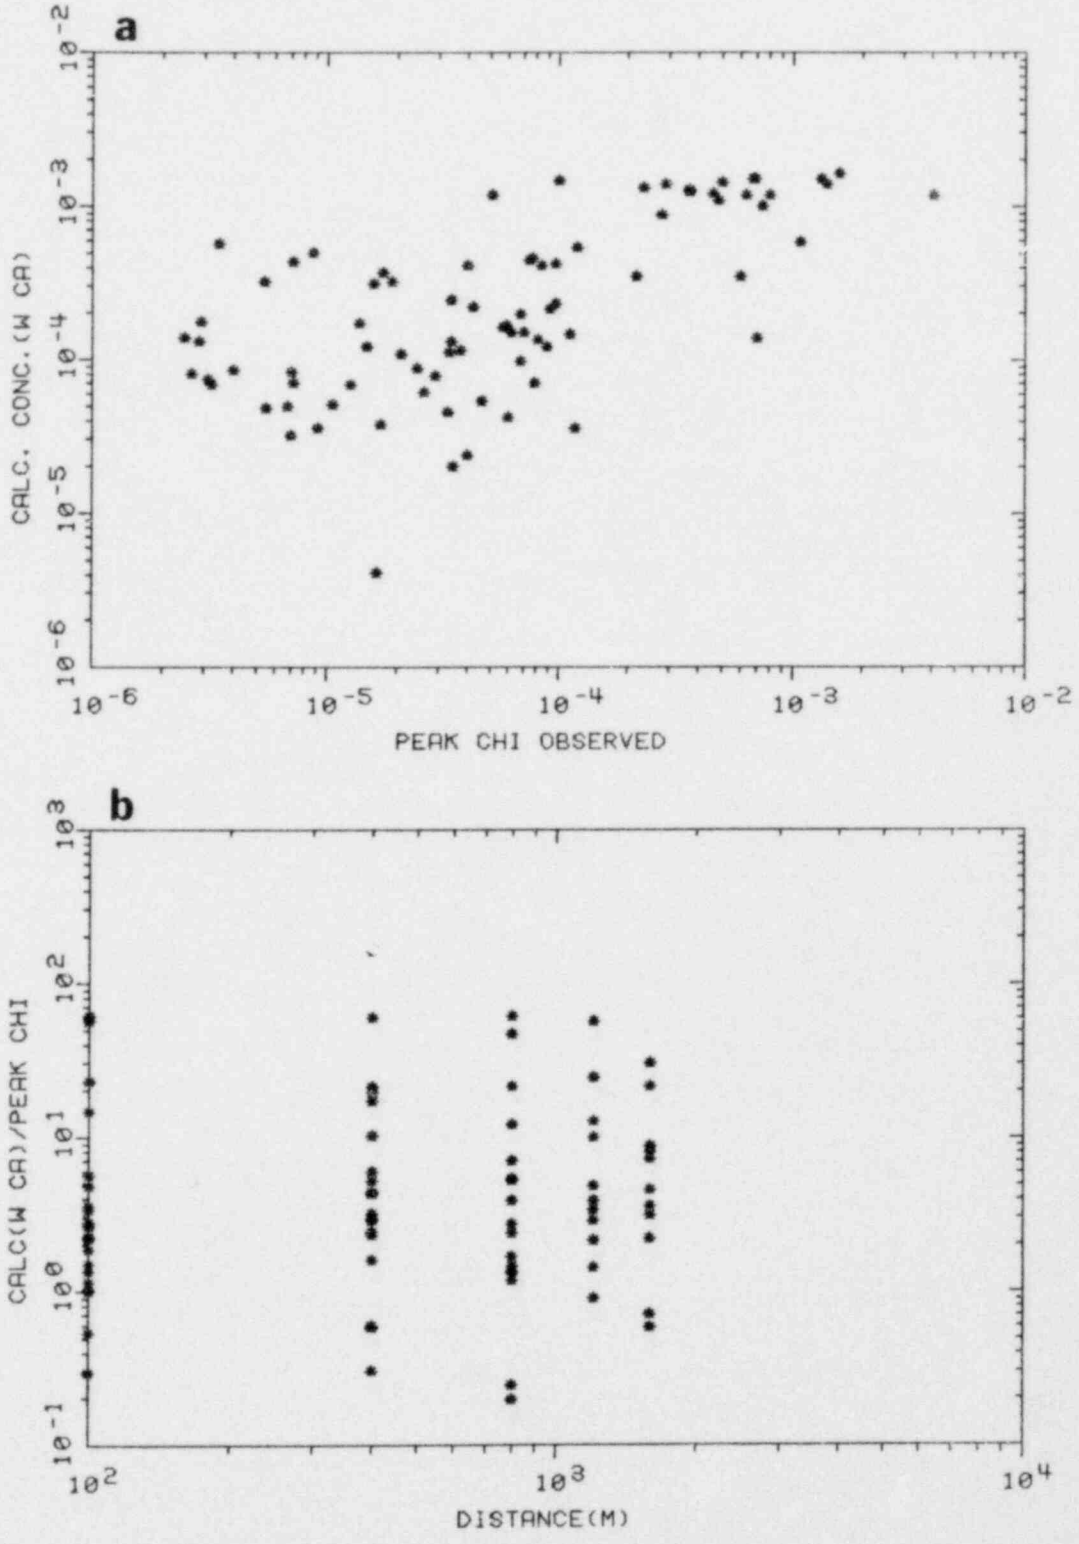

Figure 22. Comparisons of calculated (including the cA term) versus observed maximum concentrations are plotted for only ground-level tracer releases. Calculated values were plotted versus observed values in fig. 22a; most values were calculated too large. Ratios of calculated divided by observed concentration were plotted versus distance in fig. 22b; no significant effect versus distance was apparent.

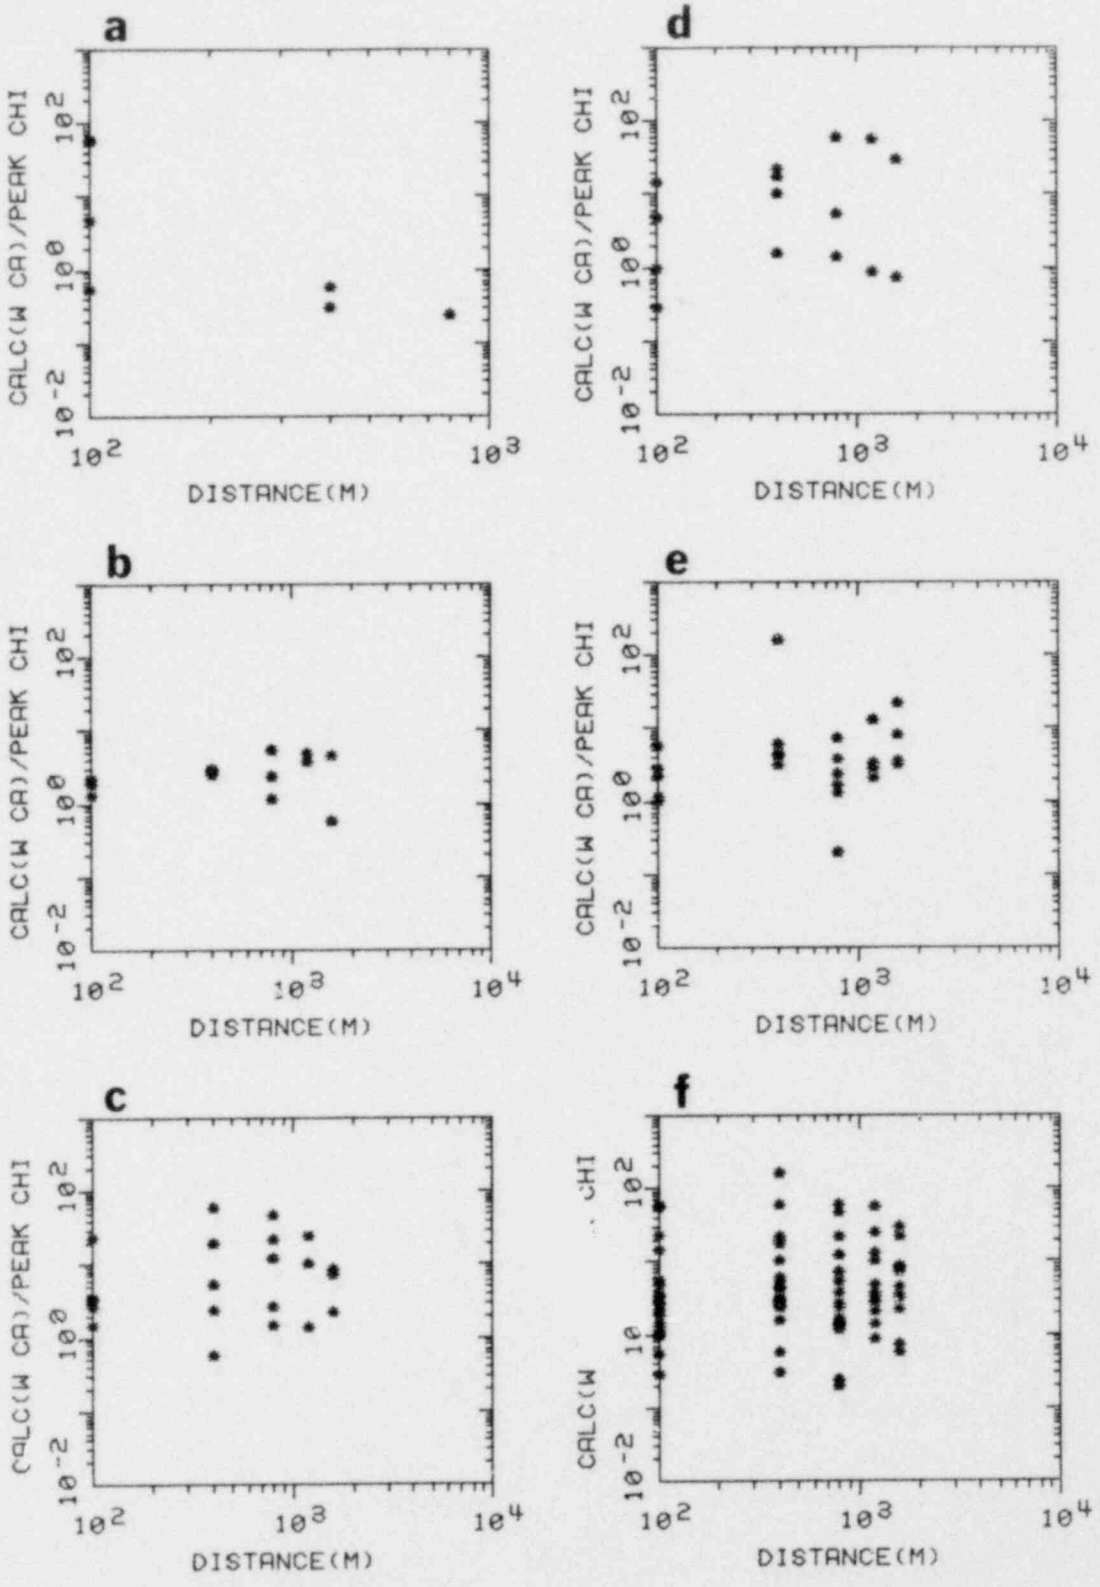

Figure 23. Ratios (of calculated divided by observed concentrations) versus distance are plotted for ground-level tracer releases. Plots were made for particular stability categories (fig. 23a for stability A, fig. 23b for D, fig. 23c for E, fig. 23d for F, fig. 23e for G) and for all stabilities in figure 23f.

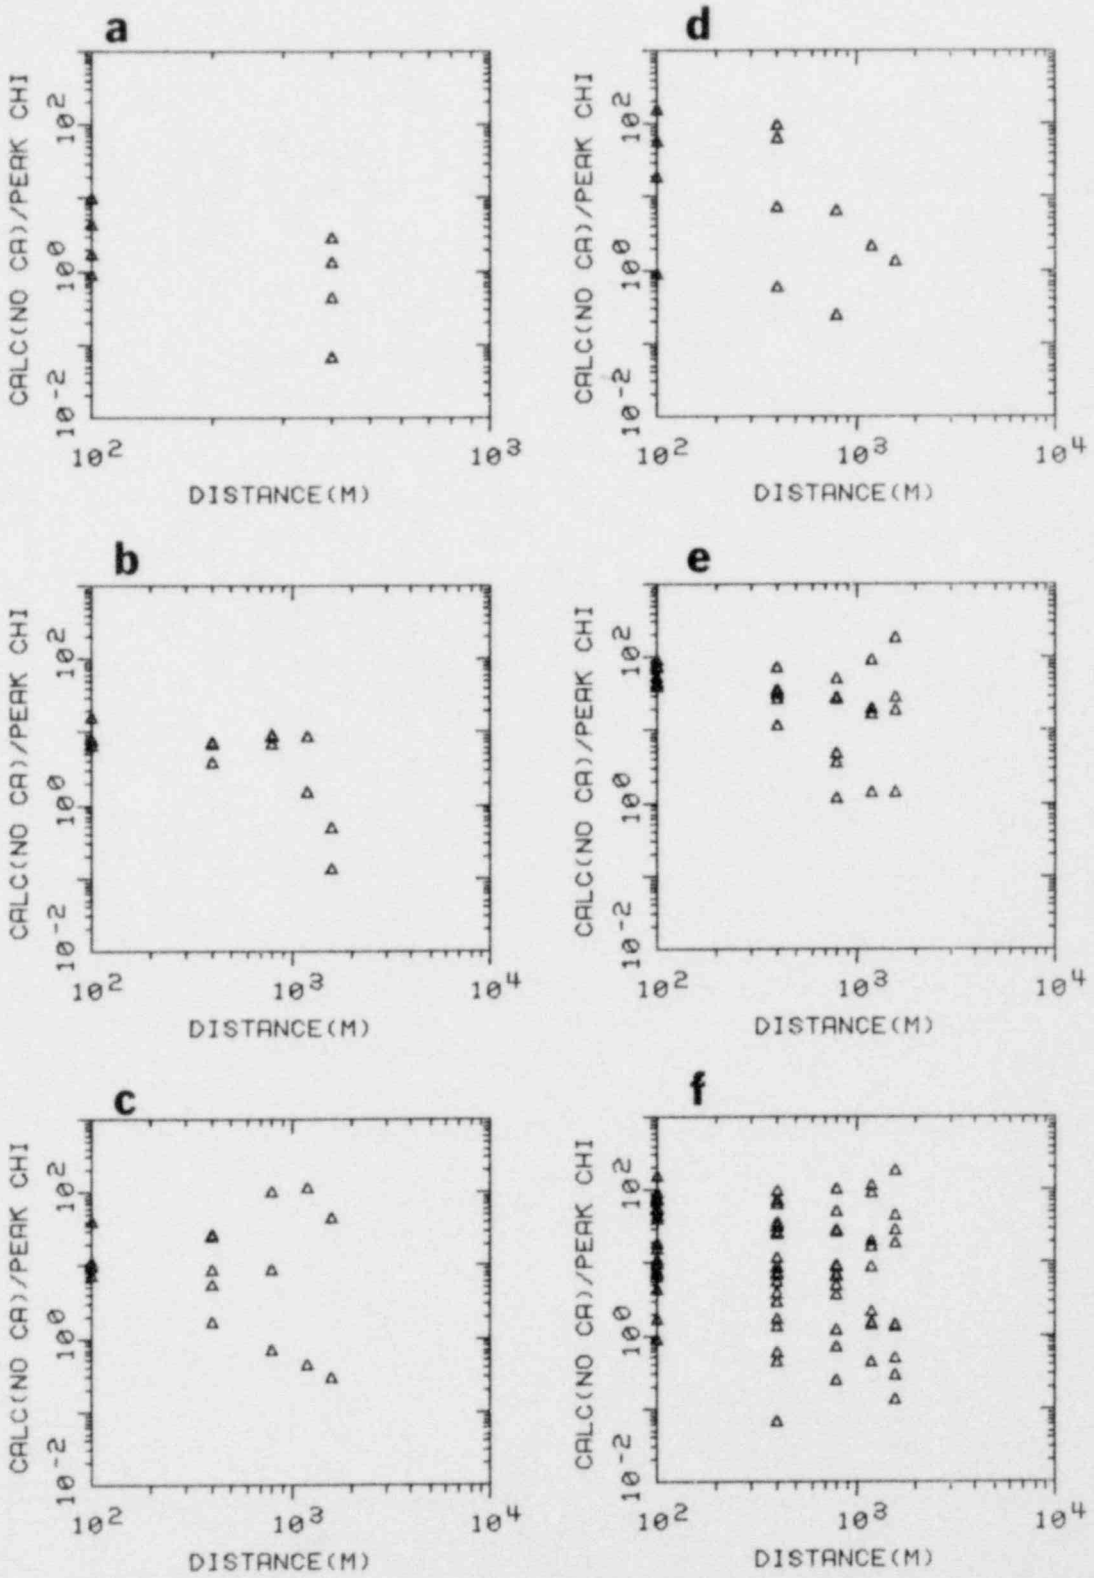

Figure 24. Ratios (of calculated divided by observed concentration) versus distance plotted for roof-level tracer releases. Plots were made for particular stability categories (fig. 24a for stability A, fig. 24b for D, fig. 24c for E, fig. 24d for F, fig. 24e for G) and for all stabilities in fig. 24f.

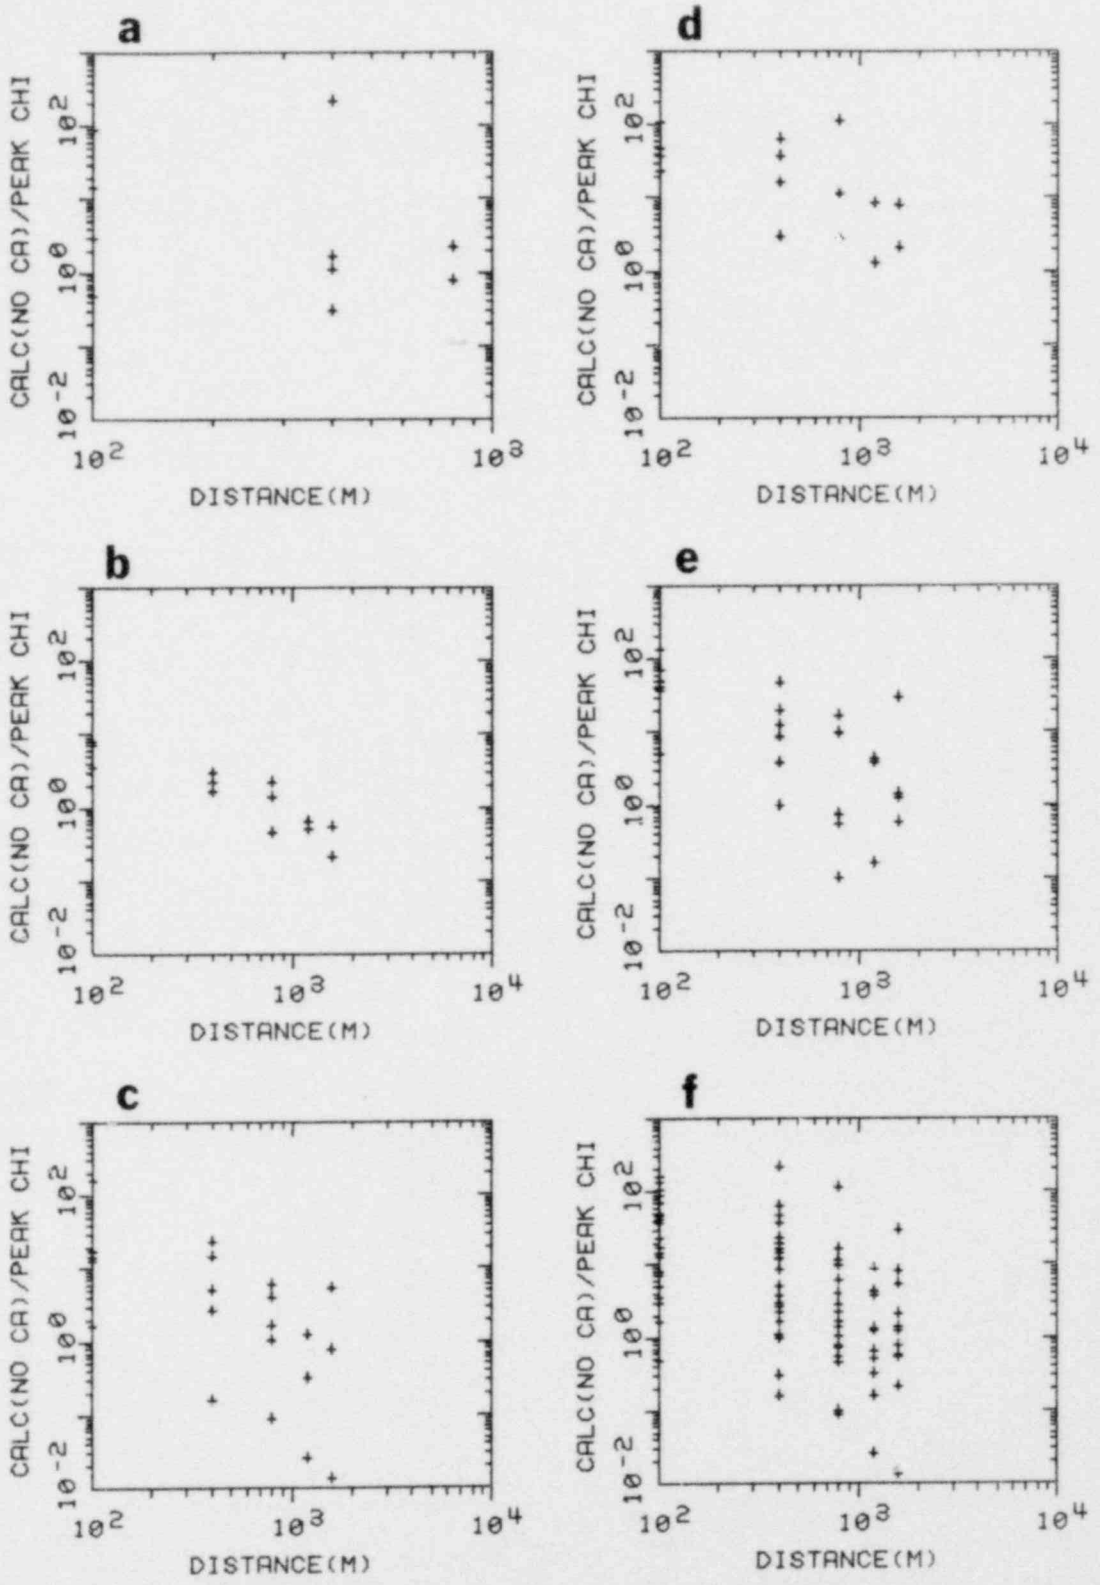

Figure 25. Ratios (of calculated divided by observed concentration) versus distance are plotted for stack tracer releases. Plots were made for particular stability categories (fig. 25a for stability A, fig. 25b for D, fig. 25c for E, fig. 25d for F, fig. 25e for G) and for all stabilities in fig. 25f.

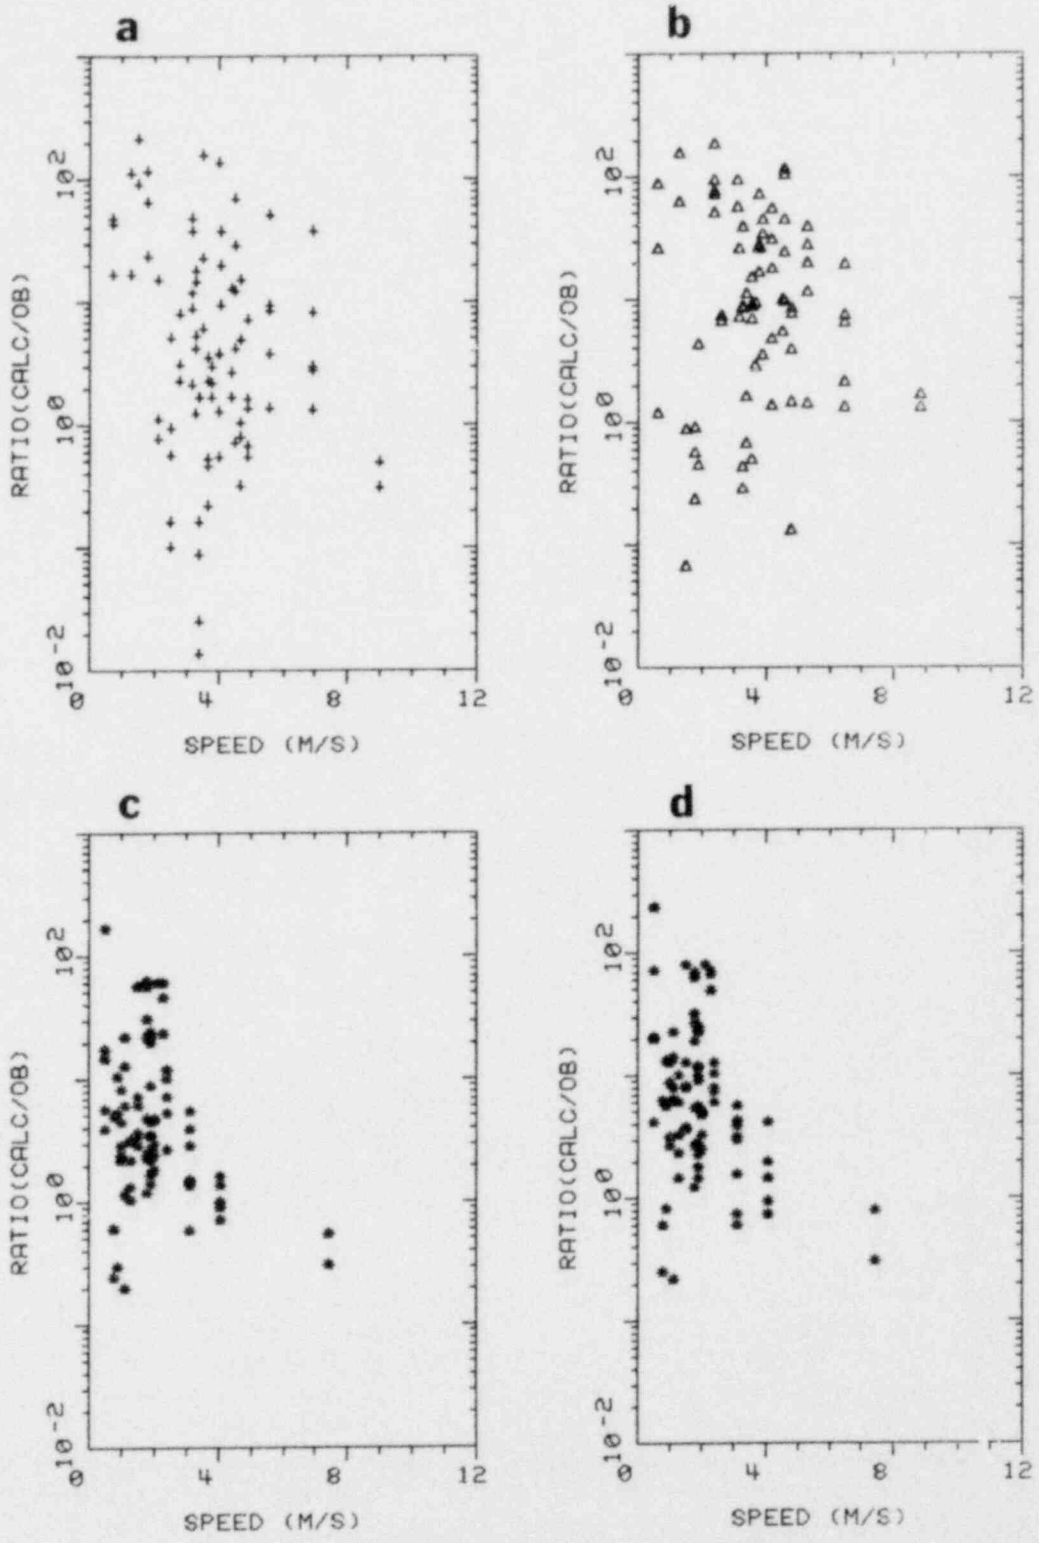

Figure 26. Ratios (of calculated divided by observed maximum concentrations) versus windspeed at 30m. Stack released tracer ratios are shown in fig. 26a and roof released tracer ratios are in fig. 26b. Ground-level tracer ratios are in figures 26c and 26d. Ratios in fig. 26c were based upon calculated concentrations which included the add-on cA term.

5.0 SUMMARY

A series of 22 simultaneous gaseous tracer releases were conducted around the EOCR reactor at the Department of Energy's Idaho National Engineering Laboratory. Sulfurhexafluoride (SF6), dichlorodifluoromethane (Freon 12), and dibromodifluoromethane (12B2) were released for approximately 1-hr intervals and collected by samplers placed on a surveyed grid about the EOCR facility. Average windspeeds for tests within the series varied from less than 1 to almost 10 mps. Atmospheric stabilities included Pasquill-Gifford A, D, E, F, and G (as determined by 10 to 30m temperature difference and NRC guidelines).

A detailed description of normalized relative concentrations near buildings, including EOCR, has been provided by Sagendorf, et al (1980) and was not treated in-depth in this study. In this report, complete data appendices provided lists of meteorological variables, wind direction statistics, sampled plume concentrations, derived diffusion statistics and their ratios with expected open-terrain values, and numerous analyses and plots of these values and statistics. Examples of statistics were described in the body of the report and summarized groupings were used to more clearly describe the main important findings.

Determinations of σ_z were made using numerical techniques to solve the non-linear equation relating crosswind integrated concentration, height of plume axis, and σ_z. The smaller (Gaussian) root was used throughout in this study for calculation of ratios. For stability category A (and some of category D) conditions, it was likely that the non-Gaussian root (vertically well-mixed plume) value of σ_z should have been adopted. For these situations the amount of building enhanced vertical diffusion was underestimated and the downwind extent of this enhanced diffusion was underestimated. For stabilities E, F, and G the use of a Gaussian (smaller) root seemed appropriate since the plumes were not yet well mixed in the vertical. Most test data were collected during these stable categories.

To summarize many of the findings regarding atmospheric diffusion near and downwind of the EOCR structure, Table 14 is presented. Three characteristic zones - a near structure or cavity zone, a transition zone, and a far wake zone - were identified. Relative diffusion and concentration effects were summarized versus distance downwind of the structure. Data from all stability categories were pooled at their common downwind distances. A distinction was made for varied heights of tracer release. Relative differences in tracer behavior were referenced 1) to the expectations of Pasquill-Gifford curves of σ_y, σ_z, and normalized concentration, 2) to substantial alterations of plume centerline height and/or 3) to departures from Pasquill-Gifford rates of growth of σ_y and σ_z. Ground-level releases of tracer were circulated aloft so that ground-level measured concentrations were 10 to 30 times less than expected. Elevated releases of tracer experienced downdraught effects so that their near ground-level measured concentrations exceed expectations from a Gaussian model by factors

exceeding 200-3000 to as much as tens of orders of magnitude. A Gaussian off center-line adjustment of concentration was very poor in the presence of downwash effects.

Table 14. Summary of atmospheric diffusion characteristics versus distance downwind from the EOCR structure. Behaviors within three characteristic zones are summarized. All stability categories were pooled and findings related to figures 18a, c, and e for stack, roof, and ground-level tracer releases.

Ground Level Tracer	Roof and Stack Level Tracer
Cavity Zone	**Cavity Zone**
1. Upward flux of considerable plume mass.	1. Downwash of plume into cavity region.
2. Initial plume broadening laterally and vertically	2. Initial plume broadening laterally and vertically
3. $\sigma_y \simeq 5*(\sigma_y(P/G))$	3. $\sigma_y \simeq (5)*(\sigma_y(P/G))$
4. $\sigma_z \simeq 5*(\sigma_z(P/G))$	4. $\sigma_z \simeq (5 \text{ to } 10)*(\sigma_z(P/G))$
5. $C_g \simeq (0.1 \text{ to } .04)*(C_p(P/G))$	5. $C_g \geq (200 \text{ to } 3000)*(C_p(P/G))$
Transition Zone	**Transition Zone**
1. $\frac{\partial}{\partial x}\sigma_y \simeq$ rate for P/G growth	1. $\frac{\partial}{\partial x}\sigma_y \simeq$ rate for P/G growth
2. $\frac{\partial}{\partial x}\sigma_z <$ rate for P/G growth	2. $\frac{\partial}{\partial x}\sigma_z <$ rate for P/G growth
3. $\sigma_y \simeq (5.5)*(\sigma_y(P/G))$	3. $\sigma_y \simeq (5.5)*(\sigma_y(P/G))$
4. $\sigma_z \simeq (3.5 \text{ to } 1.5)*(\sigma_z(P/G))$	4. $\sigma_z \simeq (5.5 \text{ to } 1.5)*\sigma_z(P/G))$
5. $C_g \simeq (0.04)*(C_p(P/G))$	5. $C_g \simeq (30. \text{to } 1.)*(C_p(P/G))$
Far Wake Zone	**Far Wake Zone**
1. $\frac{\partial}{\partial x}\sigma_y \leq$ rate for P/G growth	1. $\frac{\partial}{\partial x}\sigma_y \leq$ rate for P/G growth
2. $\frac{\partial}{\partial_x}\sigma_z \simeq$ rate for P/G growth	2. $\frac{\partial}{\partial_x}\sigma_z \simeq$ rate for P/G growth
3. $\sigma_y \simeq (6. \text{ to } 4.5)*(\sigma_y(P/G))$	3. $\sigma_y \simeq (6. \text{ to } 4.5)*(\sigma_y(P/G))$
4. $\sigma_z \simeq (1.5 \text{ to } 0.6)*(\sigma_z(P/G))$	4. $\sigma_z \simeq (1.5 \text{ to } 0.5)*(\sigma_z(P/G))$
5. $C_g \simeq (.04 \text{ to } 0.7)*(C_p(P/G))$	5. $C_g \simeq (3. \text{ to } 0.3)*(C_p(P/G))$

Where

C_g is ground-level concentration
x is distance in the along wind direction

Vertical diffusion differences ascribed to the structure developed very rapidly near the building; they rapidly diminished for all tracers and σ_z values approached the expected values by approximately 400m downwind (about the downwind extent of the transition zone). Thus, the overall effect upon vertical behavior of tracer was an initial alteration of plume center of mass and/or centerline, especially for near ground-level effluent releases. An initial vertical dispersion rapidly developed throughout a zone near the building with depth approximating the height of the structure. Within the transition zone vertical diffusion in the wake appeared inhibited and developed at a rate less than expected wtihout the presence of the structure and its wake turbulence effects. It was important to note that while the rate of diffusion appeared to be less than ambient rates, the vertical diffusion statistic (σ_z) remained greater than or about equal to the expected P/G value (RZ>1). In the far wake zone, vertical diffusion appeared to proceed as expected over open terrain and σ_z values were as expected without the presence of the building. Lidar observations (unpublished measurements by SRI) of simultaneous smoke plumes qualitatively supported these gaseous tracer findings.

Lateral plume spreading was observed to be larger than expected for open-terrain values relative to Pasquill-Gifford estimates of σ_y. This departure from expected σ_y values was not related to downwind distance. The enhanced lateral spreading at the EOCR site in SE Idaho was well explained by larger-than-expected variance in horizontal wind direction. When the observed standard deviation of horizontal wind direction was below a certain value (about 10 to 15^o for EOCR) an enhanced lateral plume spreading (not explained by use of σ_θ in calculations) within the turbulent wake became evident; calculated tracer σ_y values were significantly larger (2 to 4 times) than predicted by σ_θ measurements. Apparently, during the course of usual wind direction meandering in the atmosphere, minimal building induced plume broadening effect was evident for average one-hour plume concentration distributions. Obviously, for nearly instantaneous samplings of effluent plume, the quasi-instantaneous plume must have had initial plume broadening (easily seen from visual tracer plumes near the structure); this initial broadening usually was small compared to the plume broadening due to wind direction meandering. Physical modeling results should contain a noticeable effect of the structure and provide guidance on lateral plume spreading behavior for relatively short (a few minutes) sampling times, but physical modeling would not describe broadening due to meandering, without some adjustment.

The downwind extent of structure altered σ_z values (shown by RZ ratios) appeared to be 400m to 800m (about 16 to 32 reference lengths, where a reference length is distance divided by structure height (=25m). Differences in σ_y (shown by RY ratios) were mostly related to the amount of wind direction meandering and appeared to be independent of downwind distance. Maximum (peak) ground-level tracer concentrations for ground-level tracer releases were 3 to 4 times less

than expected at 800 to 1600m downwind (about 32 to 64 reference lengths) when the average concentration ratio (RC) was divided by the average σ_y (RY) ratio. Thus, these tracer plumes still appeared to be more elevated than the 1m physical height of release (the value used to calculate the expected concentration from the Gaussian formula) or the vertical gradients of concentration were less than expected for a Gaussian distribution. Concentrations for roof-level tracer release were essentially as expected from the Gaussian formula at 800m and farther downwind when they were divided by the average RY value. In the same manner, ground-level concentrations of stack discharged tracer were about five to ten times greater than expected from the Gaussian formula, i.e., when adjusted for greater lateral spreading than predicted from P/G curves of σ_y. Apparently the effects of downwash had not yet been compensated by vertical diffusion processes to the extent that calculations made with the Gaussian equation were free of a substantial bias for under-calculation.

Estimates of ground-level concentrations within the downwind wake of the EOCR structure were not well calculated if the off-axis plume concentrations were determined by inclusion of the customary Gaussian exponentail function of σ_z and H. A downwash of elevated plumes and an uplifting of ground-level plume occurred. In the presence of systematic, non-random vertical motions within the wake of the structure (especially within the cavity or near-building zone) use of the exponentail Gaussian-distribution adjustment is not recommended. Better estimated concentrations (even though biased toward over-calculation) were obtained if plume centerlines were assumed to occur near ground-level (e.g. figure 20d). Inclusion of an add-on term (+cA) in the denominator of the Gaussian diffusion equation (eqn.8) did relatively little to improve accuracy of calculations. It seemed that a downwash factor (adjusting both ground-level and elevated effluent releases) would be more appropriate. This mixed mode of release appeared to be a better concept for revision of ground-level tracer concentrations derived from the Gaussian equation. Ground-level concentration estimates might better be determined by a partitioning of the source into a fraction transported vertically and a fraction remaining near release height. The source term for elevated tracer releases would have a fraction of the effluent transported to near ground-level through downwash effects and a fraction remaining elevated.

6.0 RECOMMENDATIONS

A number of additional features of building wake effects should be examined from this data set. The fractions of source effluent which appeared to be displaced from the height of release should be evaluated to examine quantitatively the mixed mode of release behavior.

Specialized wind fluctation data exist for the 100m arc and these data should be related to physical modeling information such as described by Peterka and Cermak (1975).

Several alternate schemes for calculation of plume concentrations, dimensions, etc., (some semi-empirical), have been proposed for application to the cavity and wake zones of structures. These data might be used to evaluate the performance of these schemes.

Calculation of additional meteorological wind fluctuation statistics should be performed (Hunt, 1980) to examine the reasons for large σ_θ and σ_y, and to explore a theoretical method for calculation of σ_z.

Additional quantative measurements of vertical diffusion effects in the transition zone are desirable. These data would more clearly describe the apparent slower-than-ambient rate of diffusion operative on plumes within wakes compared to plumes outside structural turbulent wakes. SRI collected LIDAR data touched upon this behavior but the quantitative data were not available to complete this investigation.

Acknowledgments

Computer codes for special file handling and statistical processing were developed by G. R. Ackermann. The output data listings and graphical depictions of data were performed by generalized utility computer codes also developed by G. R. Ackermann.

Tower instrumentation and samplers for the test series were installed and operated by Mr. F. E. White.

Mrs. Lydia Thorngren typed and proof-read the manuscript.

1 Average wind direction in degrees from true north

2 Standard deviation of horizontal wind direction in degrees.

3 Average wind speed in m/sec

APPENDIX B: Two Minute Interval Wind Data for Each Test

This appendix gives the values of wind statistics averaged over two minute intervals during each test. Data given are given for the heights of 4m, 10m, and 30m.

Definitions of labels used.

TEST Number of test

DATE Date of test composed of six digits in the form YYMMDD. YY is the last two digits of the year, MM is the number of the month, and DD is the day of the month.

TIME Time (MST) of end of two minute interval composed of six digits in the form hhmmss where hh is the hour, mm is the minute, and ss is the second.

NUM PTS Number of wind observations taken during the two minute interval at each height

4M DIR Two minute average wind direction in degrees at 4m.

10M DIR Two minute average wind direction in degrees at 10m.

30M DIR Two minute average wind direction in degrees at 30m.

4M DSD Standard deviation of the wind direction in degrees during the two minute interval at 4m.

10M DSD Standard deviation of the wind direction in degrees during the two minute interval at 10m.

30M DSD Standard deviation of the wind direction in degrees during the two minute interval at 30m.

4M DVAR Variance of the wind direction in deg^2 during the two minute interval at 4m.

10M DVAR Variance of the wind direction in deg^2 during the two minute interval at 10m.

30M DVAR Variance of the wind direction in deg^2 during the two minute interval at 30m.

4M SPD Two minute average wind speed in m/sec at 4m.

10M SPD Two minute average wind speed in m/sec at 10m.

30M SPD Two minute average wind speed in m/sec at 30m.

4M SSD Standard deviation of the wind speed in m/sec during the two minute interval at 4m.

10M SSD Standard deviation of the wind speed in m/sec during the two minute inverval at 10m.

30M SSD Standard deviation of the wind speed in m/sec during the two minute interval at 30m.

APPENDIX C: Total Wind Statistics for Each Test.

This appendix contains wind statistics for the entire duration of each test. The next eight values for variables following the variable labeled "level" apply for that given height. Some of the statistics were calculated using the information in Appendix B.

Definitions of Variables Used.

TEST Number of Test.

DATE Date of test composed of six digits in the form YYMMDD where YY is the last two digits of the year, MM is the number of the month, and DD is the day of the month.

START Time of beginning of the test in Mountain Standard Time in the form hhmmss where hh is the hour, mm is the minute, and ss is the second.

END Time of end of the test in Mountain Standard Time in the form hhmmss where hh is the hour, mm is the minute, and ss is the second.

NUM PTS Number of wind observations recorded during the entire test at the specified height.

LEVEL Height in meters.

DIR Average wind direction in degrees for the entire test at the previously specified height.

SPD Average wind speed in m/sec for the entire test at the previously specified height.

TOT VAR Variance of the wind direction in deg^2 for the entire test at the previously specified height.

DIFF VAR Average of the two minute interval wind direction variances in deg^2 for the entire test at the previously specified height.

TRNSPT V Variance of the two minute interval wind direction averages in deg^2 for the entire test at the previously specified height.

TOT SIG Square root of the variance of the wind direction in degrees for the entire test at the previously specified height.

DIFF SIG Square root of the average of the two minute wind direction variances in degrees for the entire test at the previously specified height.

TRNSPT S Square root of the variance of the two minute interval wind direction averages in degrees for the entire test at the previously specified height.

APPENDIX D: Normalized Concentrations

This appendix contains a listing by test, arc, and gas of the normalized concentration values. Ground sampler positions are numbered 1-520 inclusive and tower data 6x0-6x4 where x is the tower number 1-6. Miscellaneous sampler positions are numbered 701-704 inclusive. These samplers were located on the lowest level roof on the reactor building. No ground samples were taken at the 200 meter arc during any of the tests nor at the 50 meter arc during tests 9 and 10. No miscellaneous samples were taken during tests 3-10 inclusive.

APPENDIX E: Ground Release Concentration Isopleths for Each Test.

Units are m^{-2}. Appendix D lists the individual values of concentration that form the basis for these isopleths. Figure 5 of the text depicts the site topography, which was considered during the isopleth analyses. Appendix A lists the temperature measurements that formed the basis for designating a stability category. Each sampler position in the 400 m, 800 m, 1200 m, and 1600 m arcs is shown. Isopleth analyses are ordered in the sequence shown in table E-1. Stability class A figures are given first and plots are ranked by windspeed; the lowest windspeed is first.

APPENDIX F: Roof Release Concentration Isopleths for Each Test.

Units are m^{-2}. Appendix D lists the individual values of concentration that form the basis for these isopleths. Figure 5 of the text depicts the site topography, which was considered during the isopleth analyses. Appendix A lists the temperature measurements that formed the basis for designating a stability category. Each sampler position in the 400 m, 800 m, 1200 m, and 1600 m arcs is shown. Isopleth analyses are ordered in the sequence shown in table F-1. Stability class A figures are given first and plots are ranked by windspeed; the lowest windspeed is first.

APPENDIX H: Plots of Peak Ground-level Concentrations, Sigma-y, and Sigma-z.

This appendix contains plots of three different diffusion parameters or statistics vs distance with separate plots for each stability category. The first three sets of plots contain measured peak concentrations and curves of Pasquill-Gifford predictions of peak concentrations at 1m, 10m, 25m, and 30m. Curves of predicted concentration with values less than 10^{-8} were truncated to 10^{-8} for plotting convenience and consistency of resolution of data within the autoscaled plots. There is a set of plots for each release height.

The next set of plots contain measured σ_y values, a first order regression line for these values, and a curve of Pasquill-Gifford predictions of σ_y. All release heights are combined on each plot.

The last set of plots contain all the measured values of peak concentrations, σ_y, and σ_z with all stability classes included on each plot. Curves of Pasquill-Gifford predictions for these statistics are also included on these plots.

APPENDIX I: Numerical Methods for Calculation of Sigma-z Roots

From the eqn. 6 σ_z is seen to be related to σ_z (effective) through the following non-linear expression

$$\sigma_z(\text{effective}) = \sigma_z \exp\left\{\frac{1}{2}\left(\frac{H}{\sigma_z}\right)^2\right\} = \frac{2Q}{\pi u\, CIC(x;H)} \qquad (I\text{-}1)$$

If σ_z (effective) is determined from measurements of tracer concentration, windspeed, and source strength, and if an approximate plume axis height H is chosen, initial estimates of σ_z may be determined numerically. Although plume geometry departures from Gaussian are probable, and particularly near the structure, useful estimates of σ_z may be obtained for use in the Gaussian equation. Two roots of eqn (I-1) are possible; one root (lower or smaller) occurs when $H \gg \sigma_z$ and the plume mass distribution is not uniform (assumed to be quasi-Gaussian). The second (upper or larger) root occurs when $H \approx \sigma_z$ and $\sigma_z \approx 0.6\sigma_z$ effective; in this situation the plume is well-mixed (at least below a "plume axis of sorts" which may even be a capping stable layer).

Equation (I-1) is solved by two separate numerical techniques. The Newton-Raphson iteration (Dorn and McCracken, 1972) is used on the lower (Gaussian solution) root which occurs where the solution curve attains a large negative slope. The method of false position (Conte, 1965) is used for the upper root (quasi uniformly mixed plume) which occurs along the solution curve with small positive to near-zero slope.

APPENDIX J: Complete Listing of Meteorological and Diffusion Parameters

This array is the basis for the statistical plots and summaries presented in the results section. Data are provided for each tracer gas (1=SF6, 2=F12, 3=12B2) and each sampling arc (1=50m, 2=100m, 3=400m, 5=1200m, 6=1600m) by each test. Ground tracer release data are not included for the 50m arc. The identification code IDENT allows unique description of each subset of information within the listed array.

Definitions of Meteorological and Diffusion Parameters.

IDENT Identification of data segment composed of four digits in the form TTAG where TT is the test number, A the arc number, and G the gas number.

STAB 1-7 NRC stability categories in 1=A, 2=B, etc.

CHI PEAK Chi u/Q maximum in m^{-2}.

SY C.M. Sigma-y in meters as calculated from equation 4 in text.

C.M. Position of center of mass in meters as calculated from equation 5 in text.

SZ EFF Sigma-z (effective in meters as calculated from the crosswind integrated concentration. Eq. 6 in text.

CIC NORM Normalized drosswind integrated concentration g/m^2.

SY Sigma-y in meters.

RLSE HT Release height of tracer in meters.

DWD(M) Downwind distance of arc in meters.

LOWER Lower root calculation for σ_z in meters. Assumed plume axis heights for ground and roof releases - 25m, stack release - 30m.

UPPER Upper root calculation for σ_z in meters. Assumed plume axis heights for ground and roof releases - 25M, stack release - 30m.

SY PG Pasquill-Gifford estimate of σ_y (meters).

RATIO SY Ratio of σ_y measured/P-G value.

SZ PG Pasquill-Gifford estimate of σ_z (meters).

RATIO SZ Ratio of σ_z (lower root calculation). /P-G value.

CHI PG Pasquill-Gifford estimate of maximum Chi u/Q (m^{-2}) at ground-level.[1]

RATIO C Ratio of P-G value of maximum Chi u/Q divided by the observed value.[2]

1 Estimated ground-level normalized concentration values were calculated using eqn. (2) with y=o. When calculated values were less than the minimum detectable or background value, the background normalized concentrations were substituted. At 100m downwind typical background values for stability class F were about $5x10^{-12}m^{-2}$. Equation (2) values were about $4x10^{-29}$ when a Gaussian distribution was applied to a roof height plume.

2 At short distances during stable conditions much smaller values could have been utilized were Gaussian distribution assumptions used instead of substitution of background concentrations, as described in footnote 1.
