6 SUBCOMMITTEE ON ADVANCE REACTORS  
7

8 Rodeway Inn  
9 Room 215  
10 Chicago, Illinois

11 Wednesday, July 15, 1981

12 The Subcommittee met, pursuant to notice,  
13 at 8:30 a.m.

14 BEFORE:

15 M. CARBON, Subcommittee Chairman  
16 J. MARK  
17 M. BENDER

18 ACRS CONSULTANTS:

19 R. Avery  
20 G. Golden  
21 J. Hartung  
22 W. Lipinski  
23 S. Siegel  
24

LS:1 1 MR. CARBON: No statements are required,  
2 Frank. We will move right on.

3 MR. GAVIGAN: Our first speaker will be  
4 Lou Baker from the NCR, who will describe what we  
5 do in 3.2 and why we do it.

6 MR. BAKER: My name is Louis Baker, and  
7 I will be discussing our LOA 3.2 activities, debris  
8 accommodation.

9 The overall objective is to demonstrate  
10 a low probability of containment failure from core  
11 debris-related threats.

12 Our work breakdown structure considers  
13 this in three categories: accommodation within the  
14 primary system boundary or within the reactor vessel;  
15 within the inner cells, the reactor cavity; and within  
16 the containment as a whole.

17 Our major program task -- let me first  
18 say, our discussion will be divided into three parts.  
19 I will talk about the results of a task force which  
20 we have recently concluded on core debris program  
21 planning.

22 Then Dean Pedersen from Argonne will  
23 discuss the ANL work on particulate debris bed cool-  
24 ability, and molten debris interactions.

Then Louis Muhlestein from HEDL will talk

2  
1 about the sodium-concrete interactions work at HEDL.

2           The other key activities are debris  
3 retention design options or engineering analysis at  
4 GE; hydrogen detection and control at HEDL; gas  
5 release from concrete at HEDL.

6           And we have three code activities which  
7 I will mention in a minute.

8           The overall strategy in the debris  
9 accommodation area is to demonstrate inherent debris  
10 accommodation capabilities, and in addition to that,  
11 provide a wide range of design options to enhance  
12 debris accommodation capabilities.

13           And our approach, as I mentioned, one  
14 was to convene a task force this year on debris  
15 accommodation.

16           In general, to develop understanding of  
17 inherent in-vessel retention processes, and evaluate  
18 the potential for engineer's in-vessel retention features.

19           The task force determined that a very  
20 important aspect of debris accommodation is what we  
21 call debris carryover. This is the debris which might  
22 be carried out of the reactor vessel into the piping.  
23 So this is an important aspect of our work.

24           We are also investigating the inherent  
limitations of the sodium-concrete interaction. We are

3  
1 evaluating design options to enhance ex-vessel debris  
2 accommodation. Our major code development efforts are  
3 the containment analysis code system CONACS development  
4 at HEDL.

5 This is a code system which is designed  
6 to be a comprehensive method for containment analysis.

7 A complementary effort is a development  
8 of concrete structural road at Argonne, to establish the  
9 combined thermal and thermal stress behavior of  
10 concrete structures which might become overheated in  
11 the core debris process.

12 Also, Don Ferguson mentioned yesterday  
13 our spray fire code work at AI.

14 MR. MARK: The concrete structural code,  
15 is there nothing covering that same point in the  
16 light water reactor business?

17 MR. BAKER: I don't know.

18 MR. MARK: The concrete structure and the  
19 temperature is not really a new phenomenon.

20 MR. BAKER: No. But there is really not  
21 an adequate treatment which includes the effects of  
22 cracking and the gradual heating of concrete.

23 Most of the work I think have been  
24 directed toward response to explosions or very rapid  
pressure rises.

4  
1 But the question of whether, when or  
2 how the concrete structures will respond to gradual  
3 heating in a post-accident situation is not well  
4 established.

5 MR. MARK: Well, then I would guess if they  
6 don't have such a thing, when you get yours, it would  
7 be of as much interest there as here.

8 MR. BAKER: Right.

9 MR. MARK: In fact, for some time there  
10 will be more such reactors.

11 MR. BAKER: I would think there would be.

12 I would like to say a little bit then  
13 about the results of our core debris accommodation  
14 task force.

15 We essentially did three things. First  
16 of all, we examined the potential design options, the  
17 inherent retention capability, but what could we do  
18 to enhance this.

19 Secondly, we looked at each of these  
20 situations to establish what potential safety issues  
21 there are; that is, what parts of each analysis  
22 might become a matter of discussion at regulatory  
23 hearings.

24 And thirdly, from that, from the issues,  
what tasks, what R and D task do we need to do?

5  
1 First of all, then, the design options.  
2 We considered in-vessel debris retention to be of high  
3 priority. And in addition to that, we considered a  
4 core retention plate, or without defining it in any  
5 detail, the general concept of adding a steel structure  
6 within the vessel to assist in retaining the debris.

7 As I mentioned, the retention of debris  
8 carryover, what is the fate of debris which may be  
9 carried through the piping into components.

10 And then in ex-vessel retention, we  
11 considered the three options to be extremely important.

12 First of all, the separation of released  
13 water, water which might be released from the concrete,  
14 separating that from sodium.

15 None of these, except with the possible  
16 exception of the actively cooled ex-vessel core catcher,  
17 these were not intended to be complete solutions to the  
18 core debris problem.

19 MR. CARBON: Excuse me. What does high priority  
20 mean? Promises, or that it needs urgent work? What is  
21 priority and what is high?

22 MR. BAKER: It means that it would be most  
23 likely to be used by a designer. Our goal was to provide  
24 the maximum flexibility for the designer without trying  
to tell him what he should do, but rather investigate

6  
1 the possibilities.

2 But at the same time, we didn't want  
3 to base a research program on very unlikely methods.

4 MR. CARBON: Okay.

5 MR. BAKER: The concept of a delay bed,  
6 this is the addition of high melting ceramic material  
7 to the reactor cavity. This will delay the release  
8 of water and gases from the concrete, and eventually  
9 delay the penetration, the penetration of the core  
10 debris in the concrete.

11 Cavity pool cooling by boil-off is  
12 looking at the advantages of letting the sodium in the  
13 cavity boil off, thereby delaying penetration into the  
14 cavity.

15 Less promising, but nevertheless worthy  
16 of looking at, was cavity cooling by the DRACS. In  
17 this the direct reactor auxiliary cooling system is  
18 in the reactor vessel.

19 It is conceivable one could make the  
20 cavity small enough that the DRACS would still be  
21 submerged, even after reactor vessel failure, and  
22 achieve cooling that way.

23 Of course, actively cooled ex-vessel  
24 core catchers were considered, and a range of alternative  
options were discussed.

7 1 MR. LIPINSKI: How does that ex-vessel core  
2 catcher differ from the engineer's retention, core  
3 retention plate?

4 MR. BAKER: This is within the reactor. This  
5 is outside.

6 MR. LIPINSKI: One is definitely cooled.  
7 On the other there is no word cooled, so is there any  
8 effort to engineer any type -- is this just a big  
9 steel plate, or is it ceramic?

10 MR. BAKER: It would not be ceramic because  
11 we felt we would not want to put foreign materials  
12 into the reactor vessel for fear of causing an  
13 accident.

14 MR. LIPINSKI: What is it, a big steel plate?

15 MR. BAKER: It would be -- it is not defined.  
16 It would be a set of trays. Just in general, putting  
17 something near the bottom of the vessel to increase  
18 the area for core debris.

19 MR. BENDER: When you are talking about delay,  
20 or time, what objectives do you have in mind? How  
21 much delay?

22 MR. BAKER: Well, again, we are not specifying  
23 a particular situation. It would be rather, than, just  
24 to, again, this would depend on an overall design, and  
we did not create an overall design.

8  
1 We are saying we are interested in the  
2 principle of putting non water-releasing material in  
3 the cavity to delay the water release from concrete,  
4 and also the penetration into the concrete.

5 MR. BENDER: I am trying to get some feeling  
6 for the importance of this capability. And I would  
7 assume for it to be of value it has to be associated  
8 with either time to get the fission products out of  
9 the way, or to provide arrangements for some future  
10 cooling capability to be brought into place.

11 And it would have an influence on how  
12 useful such devices might be. When you make a judgment  
13 something has a high value, you have to say why.

14 MR. BAKER: I think the intent of it is to  
15 delay the generation of pressures within the containment  
16 or hydrogen in the containment, which would require you  
17 to vent at an early time, or in the absence of venting,  
18 expect building failure of some kind.

19 MR. GAVIGAN: Also allows evacuation within a  
20 reasonable length of time, if you want to put it right  
21 here.

22 MR. BENDER: That is one way of dealing with  
23 it. I wasn't really sure what you were driving for.

24 MR. GAVIGAN: These are R & D options we make  
available to design. We make them available, and now

9  
1 they are going to approach the safety problems.

2 MR. BAKER: The next step was to develop  
3 potential safety issues from the considerations of  
4 the design options.

5 We have divided these into in-vessel  
6 debris carryover and ex-vessel.

7 I won't go through all these in  
8 detail, but an example, debris ejection is associated  
9 with how does the core debris leave the core region.

10 We concluded here that in general we  
11 will have to consider that core debris may be  
12 ejected upward or downward, or both, so that there  
13 is no R & D there.

14 We have to consider all possible  
15 options.

16 In-place coolability is particularly  
17 associated with the blanket coolability.

18 In other words, we don't necessarily  
19 have to assume that all of the fuel melts out of  
20 the core region, or is ejected from the core region  
21 at time zero. There may be a considerable quantity  
22 which remains in place permanently or for a considerable  
23 period of time.

24 The next question is: Is the fragmenta-  
tion of the material ejected from the core region

10  
1 complete? Can we consider particulate beds only, or  
2 do we have to be concerned with dense masses of fuel  
3 or molten pieces?

4 And is the process of fragmentation  
5 of the fuel cooled interaction source sufficient to  
6 damage important structures.

7 An important consideration is the  
8 particulate form from fragmentation distributed  
9 uniformly over the cross-section, or is there concern  
10 over piling up?

11 Of course, the question of coolability  
12 of the debris, debris which is ejected downward, or  
13 we have to establish whether it flows through the  
14 core support structure or whether it freezes in the  
15 plugs of the core support structure, and if so,  
16 how does it remelt?

17 The structural integrity of the core  
18 support structure, as well as any in-vessel retention  
19 plate, both from the thermal effects of debris  
20 penetration, as well as the structural, the pressure  
21 force effect of the ACDA itself.

22 We may wish to evaluate the coolability  
23 of dense masses of debris, that is molten layers or  
24 solid frozen layers.

We have to establish that the sodium

11 1 natural convection and flow is able to carry the heat  
2 away from these debris concentration areas to the  
3 cooling system as a whole.

4 It showed that there is an available  
5 heat sink. This is to establish in-vessel retention.

6 We need to know where the decay heat  
7 is distributed. Does it remain with the fuel, partly  
8 dissolved in the sodium and partly in the steel.

9 We have to be concerned with the  
10 question of possible recriticality during motion  
11 within the vessel; penetration by hot jets of any  
12 retention structure.

13 And we have to be concerned with falling  
14 masses.

15 I won't go through all of these, but  
16 I think it is important to mention the debris carryover.

17 The accident initiators, we have to  
18 look at the range of accidents which leads to the  
19 post-accident situation, particularly to establish  
20 what sodium flow rates we might have to determine the  
21 conditions under which the debris is ejected, in order  
22 to be able to calculate then the debris carryover.

23 If we assume that particulate forms  
24 in the upper plenum, we establish other limiting flow  
rate .

12 1 We need methods of predicting the  
2 fate of the debris; how much is carried over, where  
3 does it settle out in the primary system.

4 Debris coolability within the primary  
5 circuit is very similar to particulate coolability  
6 in the vessel, but here we are in a more constrained  
7 situation in piping or parts of components.

8 Should the debris become uncoolable in  
9 the primary system, we would then have to consider  
10 failure of the primary system and debris coming into  
11 the primary heat transferer system. We would examine  
12 then the liner integrity, possibly the penetration of  
13 core debris into concrete.

14 In general, our feeling is that debris  
15 carryover is limited, because in the loss of flow  
16 accident, the flow rate is well down before ejection  
17 from the core region would be expected.

18 And in the transient overpower accident  
19 there is relatively small amounts ejected upward  
20 before the nuclear reaction is turned off by the loss  
21 of fuel, such that we are optimistic about this.

22 But nevertheless, we have to look at  
23 all these steps, and even the possibilities of a small  
24 amount coming out into the PHTS cells may not be an  
unacceptable result.

13

1 Ex-vessel, of course, I think these  
2 are pretty well known. We have to establish the  
3 behavior of the cavity material, coolability in the  
4 cavity, possible penetrations of part or all of the  
5 cavity material, the structural integrity.

6 This refers to the sidewalls, the  
7 sidewalls should be up here.

8 Falling masses protection for the  
9 cavity system, heat transport, heat sink availability,  
10 sodium concrete reactions, gas release from concrete,  
11 and an important aspect is hydrogen monitoring and  
12 control.

13 These issues then were coalesced to  
14 a series of R & D tasks.

15 I have indicated here which tasks are  
16 in progress.

17 The first three are rather general.  
18 Containment response analysis, we haven't done a  
19 great deal of this this year. We have instead  
20 concentrated on the development of methods.

21 The CONACS program at HEDL is being  
22 supported actively by ANL, GE and AI.

23 The models, specific models to be used  
24 in the overall CONACS problem are being recommended  
and developed at ANL, GE, ANL and HEDL.

14  
1 HEDL will then put it together to  
2 the overall code.

3 In-vessel analysis is going on at  
4 GE. They are looking particularly at core debris  
5 distribution, the structural integrity of the core  
6 support structure. And they are looking at possible  
7 in-vessel retention devices.

8 The remainder of these, except for  
9 physical properties, our last one, are more or  
10 less in order of priority as we developed them in  
11 the task force.

12 In other words, the most important,  
13 other than the general analysis methods, development,  
14 is distribution and carryover.

15 We don't have anything going right  
16 now, but we expect to initiate work next year, which  
17 will use the available mockups of FFTF or CRBR, to  
18 inject simulated core debris into a water loop,  
19 examine it, where it goes and where it tends to  
20 concentrate, and how it would tend to spread across  
21 the reactor vessel.

22 Later on we may, we may have to do  
23 some real material experiments, probably with thermal  
24 generated core debris.

MR. BENDER: To what degree are these studies

1 related to specific configurations?

2 Are they all general?

3 MR. BAKER: I think they are pretty well  
4 general.

5 MR. PETERS: The distribution and carryover --

6 MR. CARBON: Would you identify yourself?

7 MR. PLTERS: Dean Peters.

8 The distribution and carryover is going  
9 to be very design dependent. so you would have to --  
10 they will have to take and consider in the performance  
11 of that task, the various design concepts.

12 There is a significant difference in  
13 design between FFTF and CRBR, and CEF, in terms of  
14 their -- in terms of the effect that it will have on  
15 the design and on distribution and carryover.

16 MR. BENDER: That would be a volume in  
17 geometry.

18 MR. PETERS: Excuse me?

19 MR. BENDER: They are a volume in geometry.

20 MR. BAKER: Our main effort is to establish  
21 the general, the generic behavior.

22 And when we do have a new reactor  
23 design, presumably either the project or the base  
24 program would investigate that more specifically.

For example, in FFTF, you leave the

16  
1 reactor vessel and you immediately go to upflowing  
2 pipe. And this helps to avoid excessive carryover.

3 Only the finest particles can make  
4 it up the riser.

5 But in general we would like to  
6 know how things might behave in a variety of cases.  
7 For example, in cavity performance, we would investigate  
8 the general behavior of core debris, and as it interacts  
9 with either concrete or cavity material that might be  
10 used.

11 Eventually, if a cavity is designed  
12 that we feel needs to be looked at, we would use  
13 that specific design.

14 I think that has been done. Dr.  
15 Muhlestein's group has looked at specific liner  
16 features and contact with sodium in the past for  
17 CRBR. I think it is a combination.

18 Now, we have identified in the area  
19 of, the need in the area of cavity performance for  
20 a larger core melt facility.

21 One of our tasks next fiscal year will  
22 be to examine the methods used at ANL and at AI with  
23 relatively small scale electrically heated facilities  
24 which Pedersen will mention, and to see if they are  
amenable to scale up. And also to study in more

17

1 detail just what we do need.

2 We will also be looking at the CND core  
3 melt facility for the potential to meet this need.

4 MR. BENDER: I am still not clear on the  
5 parameters that have to be investigated.

6 I understand temperatures being  
7 a parameter, but the heat removal and distribution  
8 is a function of the way in which the material lays  
9 in the cavity.

10 And I am not sure that I understand  
11 how you do the experiments without having some specific  
12 arrangement in mind.

13 It seems to me it might be important  
14 to know that.

15 MR. BAKER: I think we have general arrange-  
16 ments in mind. In other words, one would -- the most  
17 promising cavity material other than pure concrete  
18 would be generally considered to be magnesia bricks.  
19 So we tend to study these, this system.

20 On the other hand, a designer might  
21 choose to choose an alumina liner, or some other  
22 combination.

23 When that selection is made, then we  
24 will tend to study that system.

I mentioned a concrete core development

1 at Argonne, and eventually we feel in a few years  
2 we will need some large scale thermal structural  
3 experiments on concrete in order to verify the codes.

4 We will be hearing about sodium  
5 concrete, core debris and dense mass coolability.

6 These, I might mention, are natural  
7 convections and heat transfer needs in the core  
8 debris area. We expect to be met by, as part of the  
9 LOA-2 programs mentioned yesterday by Emil Gluckler  
10 and Joe Mills, that both the tests in the water and  
11 in sodium would be extended to include typical core  
12 debris configurations where there is a distributed  
13 heat source corresponding to debris locations within  
14 the vessel.

15 I think I will, in the interest of time,  
16 leave it here. These are relatively lower priority  
17 needs which would be addressed later in the program.

18 We would not expect to start anything  
19 for a few years in these areas.

20 MR. FERGUSON: I would like to just add  
21 something. Don Ferguson from Argonne.

22 With regard to this core debris,  
23 what you are viewing here is the safety program,  
24 the base program trying to take the offensive in this  
area, in the following sense:

1 Always in the past, and in the past  
2 at least in my time, FFTF and later on in Clinch River,  
3 at some point in the project they realized that they  
4 had a problem with respect to core debris accommoda-  
5 tion following severe accidents.

6 The safety-based program was always  
7 told, "Okay. Here is our design. Solve our problem."

8 And a series of stories were put  
9 together to try to justify whatever was required to  
10 meet their needs.

11 In the case of FFRF, showing successful  
12 in-vessel retention so that one did not have to worry  
13 about special containment features for core debris  
14 accommodation.

15 In the case of CRBR, essentially  
16 showing that by adding a vent filter system you would  
17 meet at least this twenty-four hour requirement for  
18 no venting and filtering that NCR placed on Clinch  
19 River in the case of the May 6th letter, May 6, 1976,  
20 letter.

21 During the FFTF days, the great bulk  
22 of the effort within the base program was aimed at  
23 providing the requisite technology for supporting  
24 this in-vessel storing.

Along Clinch River, given the same

20  
1 twenty-foot diameter vessel, much larger core, it  
2 was noticed at a glance that in-vessel storage would  
3 never be successful.

4 So suddenly all the attention in  
5 the base program was focused on supporting this  
6 core in the floor concept that evolved at Clinch  
7 River.

8 CDS has essentially punted by saying  
9 we don't know what requirements NCR might place on  
10 us; and secondly, given a set of requirements, we  
11 really don't know what we can do to meet those in  
12 terms of well-defined demonstrated technology.

13 So at the present time the CDS  
14 project is taking a very much wait-and-see attitude  
15 in this area.

16 The words are that leaving imbedments  
17 in the reactor cavity, for example, to be able to  
18 support the cavity liner material, for example.

19 What we in the base program are trying  
20 to do is to look across the whole broad picture and  
21 say what, what the totality of the range of options  
22 that a designer could possibly choose, and in each  
23 case, what technology would be require to determine  
24 whether or not that option could be -- it is viable  
or not viable.

1                   And so what we would add up here is  
2 the full range of options we considered to attempt  
3 to prioritize those in terms of giving consideration  
4 to things like both cost and probability of success  
5 of the technology development efforts.

6                   And then we are embarking upon a  
7 program to investigate these areas, so hopefully a  
8 few years down the road we would be in the position  
9 to tell a designer, "The following design option  
10 will give you twenty-four hours, or thirty-six  
11 hours, or forty-eight hours, or in the case of  
12 some actively cooled concept, perhaps indefinite  
13 delay before you would have to worry about containment  
14 failure."

15                   So that is the attitude. That is  
16 the perspective that we have in terms of this program  
17 that we are embarking on at the present time.

18                   It is an attempt to take the offensive  
19 and put the base program in a position to tell the  
20 designers what range of options they could possibly  
21 choose, as opposed to the other way around, which  
22 is taking whatever the designers have evolved and  
23 trying to construct a story to meet their needs.

24                   MR. BENDER: I like that idea, but just  
to pursue a thought that came to me earlier, it

22 1 seems to me you would have to be presenting something  
2 like the heat transfer rate per unit of area, or  
3 per unit of volume has to the sum amount in order for  
4 the designer to know whether you have something that  
5 he can apply, is that coming out of these experiments?

6 MR. FERGUSON: Yes. For example, in the case  
7 of in-vessel retention with a flat plate, a core much  
8 like what the British are talking about for CDFR,  
9 or concepts of a phrase, like the French are talking  
10 about for Superphoenix, we would hope to be able to  
11 be able to establish what kind of thickness of bed  
12 as a function of time could be cooled without fuel  
13 melting and bed dryout. So that then the designer  
14 could say, "Okay. I have a given fuel loading in  
15 my core. I have a given diameter vessel. Will this  
16 concept be a viable one strictly from the standpoint  
17 of ability to cool a debris bed of a certain thickness?"

18 Of course, one also has to address  
19 the question, would the debris bed level to the point  
20 where I can concern myself with a uniform thickness  
21 and so on.

22 Going beyond that, if you wanted to  
23 have a thicker bed, are there concepts that would  
24 work, such as where the British are talking about where  
they have pipes that carry the sodium from below the

23

1 pipe to above the pipe to enhance the natural circula-  
2 tion flow around the plate.

3 So yes, the idea would be to develop  
4 for the designer some design guidelines that tell  
5 him how far he can go with a given concept.

6 MR. BENDER: Now, the other aspect is a  
7 question of what the age of the melt is.

8 MR. FERGUSON: Excuse me?

9 MR. BENDER: The age of the melt is the  
10 other parameter that has to be taken into account.

11 At what time in the life of the core  
12 does the melt reach this bed, because that would,  
13 that to some degree determines how much heat is being  
14 evolved.

15 MR. FERGUSON: We certainly would be trying  
16 to deal with the worst case situation, which is an  
17 end-of-life core with a maximum decay heat loading.

18 MR. BENDER: I am thinking about how many  
19 hours or days it takes for the melt to reach the  
20 melt.

21 MR. FERGUSON: I think in the case of an  
22 LMFBR, liquid metal fast-breeder reactor, the debris  
23 retention plate in the matter of at most a few  
24 minutes, and it reached the cavity, and it didn't stop  
it there, at most ten minutes to fifteen minutes,

24  
1 something like that, it is effectively instantaneous.

2 You are still in the area of two to  
3 three percent full power in terms of total decay  
4 heat loading.

5 MR. BENDER: There is no heat capacity  
6 system?

7 MR. FERGUSON: That's right, for that purpose.

8 MR. LIPINSKI: I have a question. What kind  
9 of specifics is put on this in terms of the retention  
10 for what period of time, one year, ten years, fifty  
11 years, because I am just wondering if this is kind of  
12 like TMI-2 happens now in R & D programs, and try to  
13 solve the problem, because here we have the retention  
14 device that is being put into place, the material  
15 being collected, and then what happens into the  
16 future.

17 MR. BAKER: There is a designer option. It  
18 depends on his strategy.

19 We have not assumed any particular  
20 one here. We have considered the whole range.

21 He may wish to retain containment  
22 integrity only for twenty-four hours, as was suggested  
23 in the CRBR case, and then allow overpressuring and  
24 release it by venting.

MR. LIPINSKI: That is --

25 1 MR. BAKER: Or he may wish to choose a  
2 permanent containment situation where there is  
3 never any relief.

4 MR. LIPINSKI: Can I rely on that for  
5 fifty years?

6 MR. FERGUSON: There is absolutely no work  
7 going on in the safety program in the area of accident  
8 recovery.

9 NCR in the past hasn't concerned them-  
10 selves with accident recovery. They may well concern  
11 themselves now.

12 Our program is not concerned with  
13 that. It says in the requirement thirty-six hours.  
14 We will meet thirty-six hours.

15 Beyond that we will try to tell you  
16 what kind of releases come from containment as a  
17 consequence of the vent filter or overpressurization  
18 or cracking of the containment or whatever.

19 MR. LIPINSKI: It is not accident recovery,  
20 it is accident continuation, because this accident  
21 continues indefinitely into the future.

22 MR. GAVIGAN: What we did, I mentioned  
23 earlier, we are guided by two criteria.

24 One is the dose that occurs from the  
accident, or the normal risk curve that you are trying

26 1 to achieve. Given that, if you are able to allocate  
2 that down the system, we developed the R & D strategy  
3 that allows the designer to meet these criteria in a  
4 number of ways.

5 And from what we have seen so far,  
6 you meet those criteria.

7 Then considerations beyond that, that  
8 is out to fifty years or so, are not health criteria  
9 any more. They are psychological, and they are  
10 property damage.

11 So from our viewpoint we can't set  
12 a psychological criterion, because it is difficult  
13 to do research. And we don't do property damage  
14 research.

15 So we are left with either dose or  
16 risk.

17 Based on dose or risk, how far into  
18 time do you carry on to meet the criterion?

19 MR. GAVIGAN: That depends on the project  
20 approach. If the project decides where this particular  
21 site, where they have this reactor, and as such  
22 evacuate the population in blankety-blank time,  
23 one could keep the containment for twenty-four hours  
24 or forty-eight hours, and that there sets a requirement  
on what kind of R & D he selects, what has already been

27  
1 done, and what design features he puts in the building.

2 So he puts the time requirement on,  
3 and we try to provide all the information so he has  
4 the option of meeting the time.

5 MR. LIPINSKI: Are evacuation and containment  
6 figures of twenty-four hours satisfactory, even though  
7 the containment fails and the entire area is contaminated?

8 MR. GAVIGAN: I think that is true.

9 MR. BENDER: It is not the kind of thing which  
10 we could present in regulatory context.

11 There has to be a walkaway position  
12 which says the reactor system can be left in a state  
13 of permanence, if I can call five years or ten years  
14 permanence.

15 I don't know how long it is going to  
16 be, until something can be done to correct the  
17 situation.

18 And it is a matter of how the public is  
19 convinced that given an accident, it can be, the  
20 system can be put into some kind of passive condition  
21 that is acceptable, like TMI-2.

22 I think Walters is right. You would  
23 have to be able to show that when the accident is  
24 over and the people have evacuated, that there is a  
subsequent set of actions that can be done to make the

28  
1 situation, at least that status quo, stay where it is  
2 without jeopardizing the area any further.

3 MR. GAVIGAN: The particular plant, certainly  
4 they are all valid considerations. The plant we are  
5 designing for or thinking, is a government plant on  
6 a government site.

7 We are talking about a site in Idaho  
8 or Hansard or some place. Even though we have to  
9 consider those things in the long run, they may not  
10 be specific considerations for this reactor.

11 Of course, you can't say, therefore,  
12 we will melt down the plant and walk away.

13 You have to consider how you are  
14 going to recover. But recovery is by mandate, not  
15 part of our program. We have to be told that before.

16 MR. BENDER: I am not thinking about recovery  
17 in the sense of trying to reclaim the reactor system,  
18 but the ability to leave it in a passive condition.  
19 That is the thing that I think needs to be dealt with.

20 And I am not sure that you can afford  
21 to say that once you evacuated and got on all the  
22 people out of there, that that is a sufficient answer.

23 MR. GAVIGAN: I agree. That is one of the  
24 options.

The project has a number of options,

29 1 different kinds of containment approaches, different  
2 kinds of auxiliary cooling systems you can bring off.

3 People talk about bringing sodium  
4 tank cars in and pumping it in and cooling the system.  
5 There is a lot of things you can think of.

6 What bothers me about thinking these  
7 things, we sit here, we started on LOA-1 and LOA-2  
8 presented yesterday.

9 We try and get the message across that  
10 we could have designed such that these accidents  
11 shouldn't have to be considered.

12 When we get out into this R & D program  
13 out in LOA-4, we now treat them as real things. In  
14 fact, we try to generate real criteria one would have  
15 to meet, because we act as if the accident is really  
16 going to happen.

17 It is a dichotomy in the thinking we  
18 have.

19 MR. BENDER: You are misinterpreting what  
20 I am saying. I am not trying to provide a solution.  
21 I am trying to argue that the philosophy associated  
22 with how to deal with the situation has at least been  
23 thought along further than the first few days, and  
24 I don't get that feeling right now.

MR. GAVIGAN: It has --

30  
1 MR. BENDER: I don't think it -- feel it  
2 really would.

3 MR. GAVIGAN: We are not talking about the  
4 project. We are talking about the R & D program where  
5 some of those other options I haven't mentioned are  
6 relaly project decisions.

7 For the R & D program we developed a  
8 capability for some of those options, not all of  
9 them. For example, the evacuation thing doesn't impact  
10 our R & D program much. It is something someone else  
11 may choose.

12 MR. LIPINSKI: In the debris accommodation,  
13 ex-vessel, is there a specific that that thing has  
14 a function for a certain period of time; days, months,  
15 years.

16 MR. GAVIGAN: No.

17 MR. LIPINSKI: That seems to be missing.

18 MR. GAVIGAN: That's right.

19 MR. LIPINSKI: Because in twenty-four hours  
20 you will guarantee it will work. Tell me what  
21 happens after twenty-four with respect to debris  
22 retention.

23 MR. GAVIGAN: One of the reasons, one of  
24 the charters the subcommittee has or will have is  
development of R & D criteria.

1           If you look at the existing criteria,  
2 there is nothing there on whether one would involve  
3 a core catch, how long it should operate.

4           You don't have it, we don't have it.  
5 And it is because you will have the uncertainty of  
6 this business that you try to understand what the  
7 problems are.

8           MR. LIPINSKI: Getting back to your earlier  
9 comment for looking at the government site, on one of  
10 your drafts you have associated with commercialization,  
11 meeting safety criteria.

12           MR. GAVIGAN: Right.

13           MR. LIPINSKI: Your task on the government  
14 site could be a lot easier by bypassing a question  
15 that you could not bypass if you were going to  
16 commercialize.

17           MR. GOLDEN: The counter argument to that is  
18 that you might learn enough to the operation, the  
19 building and operation of that plant on the government  
20 site so that you would have an easier time in the  
21 licensing, and not have to put in as many levels of  
22 descents.

23           MR. LIPINSKI: I only agree with that if you  
24 are going to guarantee a core meltdown and give the  
experimental data.

32

1 MR. CARBON: Let me suggest we better move  
2 on.

3 MR. MARK: Could I ask one question about  
4 what is here?

5 The debris that is accumulated and  
6 which you are studying, where it is in the tray or  
7 can be cooled, is hot.

8 I don't notice here a program to find  
9 out what fraction of the fission fragments actually  
10 stay with the hot broken-up core material.

11 All the volatiles will migrate at  
12 some rate or another. It is alleged they will take  
13 some of the source material with them.

14 MR. BAKER: Yes. We are concerned with  
15 that. We called in the KE distribution, task 17.

16 MR. MARK: I see. That includes the fact  
17 that the iodines will have left in one minute and  
18 so forth?

19 MR. BAKER: Right.

20 MR. GOLDEN: With the ions in the sodium.

21 MR. MARK: Where will they be?

22 MR. GOLDEN: In the sodium.

23 MR. GAVIGAN: The next presenter is Dean  
24 Pedersen from Argonne National Laboratory.

MR. PEDERSEN: I want to talk about two

33

1 technology areas. One is the coolability of particulate  
2 debris beds, which is work being performed at Argonne.

3 And the second area is the penetration  
4 of molten core debris into substrates, substrates being  
5 steel, concrete, MgO, anything of that.

6 And this work on molten penetration  
7 is being performed out at AI and at Argonne.

8 In the area of debris bed coolability,  
9 the debris is going to settle out in the ex-vessel  
10 cavity. It is going to settle on structure in-vessel,  
11 and there is going to be significant quantities of  
12 sodium overlying it.

13 Our program has been considering cases  
14 where the only mode of heat transfer or removal that  
15 the generation is upwards into the sodium pool that  
16 is above.

17 In this case, the heat removal is  
18 by liquid down below into the bed, and vapor flow  
19 back out of the bed.

20 Once you get into a boiling condition,  
21 it is possible to have a bed that is cooled by  
22 conduction, but with reasonable size bed depth that  
23 you expect in the ex-vessel cavity, and reasonable  
24 times, fairly early times of entry, you will be  
boiling in the debris bed relatively soon.

1 In the cooling of debris there is  
2 basically two regions here. A deep bed regime is  
3 when the bed becomes fairly thick, greater than  
4 approximately ten centimeters.

5 And a shallow bed regime where the  
6 bed is a lot shallower. The vapor channels here  
7 penetrate all the way to the bottom of the bed, and  
8 you get a significant increase in coolability.

9 If you look at the coolability versus  
10 height, this is  $Q$  versus  $H$ ,  $H$  meaning the depth of  
11 the bed, you will find that in a deep bed regime out  
12 here, that the heat flux that you can remove, the  
13 most heat flux you can remove without exceeding  
14 the saturation temperature of sodium is almost  
15 independent of bed depth.

16 Where we get down into the shallow  
17 bed regime, where the vapor channels are penetrating  
18 to the bottom, then the heat flux that you can remove  
19 is a strong function of the bed depth.

20 And most of the time the bed depth  
21 you are talking about in the ex-vessel cavity will  
22 be in the shallow bed regime.

23 To give you some perspective as to  
24 what has been done in this field, Argonne, to support  
FFTF, performed experiments which direct joule heating

35  
1 of debris beds, and where they were heating, they  
2 wound up heating the sodium instead of the fuel,  
3 but measured the coolability limits of debris bed  
4 as a function of depth to support FFTF.

5 And this work was done in 1974.

6 They did experiment not only with  
7 sodium and  $UO_2$ , but they looked at the effect, the  
8 addition of stainless steel.

9 The major results of that work was  
10 that they did identify the deep and shallow bed regimes.

11 They only know the effect of subcooling  
12 of the overlying sodium. That is a point I will get  
13 back to a little bit later.

14 And they also observed, if you have  
15 this stainless steel lying on top of the bed, that  
16 you get some reduction in the overlying coolability  
17 of the bed.

18 In 1976 UCLA proposed a method  
19 of induction heating of particulate beds. You can't  
20 do this induction heating with simulate fluids.

21 We directly heat two beds itself.  
22 If you have a bed of steel particles you can in-  
23 ductively heat the bed and wind up with fairly  
24 uniform heat generation in the bed, and perform  
volume heated experiments on debris bed coolability

36  
1 with simulate materials.

2 And this work has been used a lot  
3 at Argonne. It has been used in Germany also as  
4 methods of studying some of the details of debris bed  
5 coolability.

6 Sandia in 1980, - have got 1978 to  
7 '80, has been performing some in pile experiments  
8 on debris bed coolability in their D series experiments.

9 And these in pile allow direct heating  
10 of the  $UO_2$  particulate in sodium. Their results are  
11 in basic agreement with the Argonne data of 1974.

12 However, there is a couple inconsistencies.  
13 One is they observed a coolability reduction. You have  
14 large subcooling of the overlying sodium.

15 I am going to get back to that issue  
16 later. But we disagree as to the cause of that reduc-  
17 tion.

18 They also indicated the significant  
19 margin beyond dryout, and dryout here is where the  
20 sodium boiling removes the sodium, the liquid sodium  
21 from a section of the bed, and the temperatures rise  
22 above the saturation temperature.

23 So you can have a portion of the  
24 bottom of the bed here that could be devoid of  
liquid sodium, and yet you could be in a coolable

37 1 state, because now, these thicknesses aren't terribly  
2 great, but the upward heat transfer by conduction  
3 into this region can be removed in a steady state  
4 situation.

5 Since that time, we have also been  
6 performing in the last couple three years, we have  
7 been looking at debris bed coolability, trying to  
8 develop a set of data base, an experimental data base  
9 with simulate fluids and uniform size particles so  
10 that we can develop models in the future to handle  
11 the many cases that we are going to run into.

12 In the same sense here, in historical  
13 perspective on some of the modeling work, Gabor and  
14 ANL, actually Lubaker, took the data that was  
15 performed, the experiments that were performed on  
16 direct electric heating, and just correlated that  
17 data with us where the least squares fit.

18 But that was just in FFTF, that  
19 correlation, those maximum heat loads were used in  
20 FFTF.

21 DHIR and Catton at UCLA performed  
22 the first debris bed modeling in which we assumed  
23 that the dominant resistance to coolability of the  
24 bed was the liquid flow. Where you are getting the  
liquid back in performed a dominant resistance.

38 1 This here has proven to be wrong in  
2 the sense that the dominant resistance is really in  
3 the vapor phase instead of in the liquid phase.

4 Hardee and Nilson at Sandia treated,  
5 used a model like this where they treated the downward  
6 liquid flow covering many particles, with a corresponding  
7 upward vapor flow covering many particles.

8 And they again, they were able to  
9 successfully develop a coolability model.

10 Jones and Epstein, using a similar  
11 type model, but instead of assuming that the liquid  
12 flow is covering many particles, they assumed that  
13 the liquid flow is on the surface of the particles,  
14 and the vapor flow is up between them.

15 This in essence, and the limit here,  
16 in both of these models, is when the upward vapor  
17 flow is preventing the downward liquid flow. You  
18 reach a flooding limit. The upward vapor prevents  
19 any more liquid from coming in.

20 Lipinski at Sandia has also developed  
21 a flooding model. And also John Gabor at Argonne  
22 has developed a bubble model where he assumes that  
23 the vapor is rising as bubbles in the liquid.

24 So we have a lot of models.

Now, a lot of models isn't our problem.

39 1 Our problem is none of the models agree very well.

2 Most of these models can be non-  
3 dimensionalized in terms of dimensional heat flux,  
4 which is a function of this property group here, which  
5 is the property group being  $Q$ , meaning the maximum  
6 heat flux, the vapor viscosity, one minus the void  
7 fraction in the bed.

8 The  $FG$ , or  $H$  of  $VL$ , the latent heat  
9 of vaporization, density difference and diameter  
10 squared, again, vapor factor, and again, porosity.

11 As a function of the Kinematic  
12 viscosity ratio of the liquid to the vapor.

13 You can see here Hardee-Nilson predicts  
14 the highest heat flux. The Jones-Epstein model,  
15 which is this liquid film contiguous flow model,  
16 predicts the lowest heat flux.

17 Lipinski tends to fall pretty much  
18 in the center.

19 I should say, for what you see on  
20 here, the experimental data from water, methanol,  
21 acetone, isopropanol or freon, for bottom heated  
22 experiments.

23 And for the bottom heated experiments,  
24 they seem to agree best with the Jones-Epstein model.

When we go to volume heated experiments,

40 1 it does -- we seem to see a factor of two increase in  
2 the coolability limits.

3 So in that sense, Lipinski's model  
4 seems to be one agreeing fairly well with lots of  
5 the data. His probably is the dominant model at  
6 this time.

7 In the area of debris bed coolability,  
8 the outstanding questions are, we do have a large  
9 number of models, and all these models have been  
10 developed for uniform sized particles. There is  
11 very little work on particle size distribution.

12 So we don't have a real good --  
13 in terms of, in terms of uniform sized particles,  
14 I think we do have a good data base, and we can  
15 compare the various models with that. And the  
16 Lipinski model probably agrees best.

17 But again, they tend to agree to  
18 be developed for the deep bed zone instead of for  
19 the shallow bed zone.

20 The deep bed is the zone where the  
21 coolability limit becomes independent of depth, and  
22 in most of our situations we are going to be worried  
23 about, or are in the shallow bed region where the  
24 heat flux is a function of depth.

The other thing that they really

41 1 can't handle, for nonuniform particle distribution  
2 is one of their limitations.

3 The other limitation is stratification.

4 MR. BENDER: Excuse me. The point about  
5 shallow bed depth and its applicability to these models  
6 didn't come out very clearly to me.

7 Are you saying we don't have a model  
8 that is suitable for shallow beds?

9 MR. PEDERSEN: Yes, I am.

10 MR. BENDER: Can you say something about,  
11 or maybe you are coming to it, let me ask, are you  
12 going to discuss how you get at shallow beds?

13 MR. PEDERSEN: How we get a shallow bed  
14 model?

15 MR. BENDER: Yes.

16 MR. PEDERSEN: No, I wasn't going to discuss  
17 that issue.

18 MR. BENDER: Is what you are telling me  
19 academic?

20 MR. PEDERSEN: I think it is possible to  
21 develop a shallow bed model. It is just at this time  
22 one of the problems we don't have a significant,  
23 sufficient data base with uniform sized particles to  
24 develop a shallow bed model.

42  
1 I think we are developing that right  
2 now. And that will be in place in the near future,  
3 that data base. Once you have the data base then  
4 you can start looking at models.

5 MR. BENDER: So you need more experiments?

6 MR. PEDERSEN: We need more experiments.  
7 There was already some theoretical work which was  
8 performed at Argonne that we think will be the basis  
9 for a shallow bed model, in that we are now able to  
10 predict the depth of these channels.

11 And we think we know how, or have  
12 some idea as to how to predict the lumber density  
13 of the channels.

14 With those two facts, then we feel  
15 it is possible to develop a shallow bed model. But  
16 that work is yet to be done.

17 MR. HARTUNG: Could I ask this question:  
18 On the shallow bed is it necessary to have a shallow  
19 bed model?

20 What I am wondering is the heat  
21 flux is greater.

22 MR. PEDERSEN: That's right.

23 MR. HARTUNG: Is the region in which we  
24 will be able to cool the deep bed, so that by  
inference, you cool a deep bed you can always cool

43  
1 a shallow bed?

2 MR. PEDERSEN: We are almost always in  
3 the shallow bed, and we would like the benefit  
4 associated with the shallow bed.

5 MR. BENDER: I didn't understand that term.  
6 Let me try it again.

7 The benefit associated with the  
8 shallow bed is what? Why do you need the benefit?  
9 That is what I am trying to get at.

10 MR. PEDERSEN: What I was proposing was that  
11 if this heat flux here, the deep bed heat flux is  
12 sufficient to remove any potential generation, or  
13 any potential, in any accident you could run into,  
14 if this is greater, it is sufficient, the deep bed  
15 heat flux, for any sort of accident that you could  
16 run into, then why worry about developing a shallow  
17 bed model.

18 But the answer is, what we need to  
19 take benefit of this additional heat removal associated  
20 with being in the shallow bed region.

21 MR. BENDER: Because if we don't, what  
22 happens?

23 MR. PEDERSEN: Because if we don't we are  
24 going to dry the bed out and move into the next

44 1 region of coolability of the debris.

2 MR. BENDER: And you don't know how much  
3 enhancement you need, I take it, at this stage of  
4 the game?

5 MR. PEDERSEN: We do know how much enhancement  
6 we need.

7 Are you going to answer that question?

8 MEMBER OF THE AUDIENCE: I was going to  
9 just add, we need to do that because that is going to  
10 be very important for our in-vessel change in strategy,  
11 because the state we are at, you are saying, the  
12 confidence saying, the whole core vessel, because  
13 you are saying it is going to dry out and it is  
14 based on a conservative limit.

15 If we can demonstrate with models,  
16 I think we are going to make some progress.

17 MR. PEDERSEN: It is one of those things  
18 where you want everything you can get.

19 MR. CARBON: Move along.

20 MR. PEDERSEN: Another area which we intend,  
21 we are going to need to look at, is the area of debris  
22 bed level in the ex-vessel cavity, or in the in-vessel.

23 We have, at this time, no assurance  
24 that we can have in essence a uniform bed depth  
throughout, as the material enters the ex-vessel

45

1 cavity, whether it will settle into a uniform bed  
2 depth or whether it will pile up in a corner.

3 So what you want to be able to show  
4 is that that bed will level with time, and it will  
5 level before you dry out any portions of the bed.

6 There is, we do know the beds will  
7 level. What we don't know is the rate of leveling.  
8 So work will be done in that area.

9 In addition, another area where  
10 there is questions is that of bed fixation. If  
11 you just wait until the next viewgraph I will talk  
12 about that fixation a little bit.

13 The final area, in the final area  
14 of debris bed coolability, this has to do with  
15 post dryout behavior, is the post dryout region  
16 a stable region?

17 What happens to the steel that is  
18 in the debris bed when it melts? How is it going  
19 to move around?

20 And how do you in essence wind up  
21 making the transition in a debris bed which has  
22 exceeded the dryout limit, into the next state of  
23 actually a molten pool.

24 On the area of bed fixation, Sandia  
observed in their experiments a reduction in the

46 1 coolability of the debris bed when the overlying  
2 sodium was subcooled.

3 Now, this is countered to the previous  
4 experiments at Argonne which were performed with  
5 joule heat.

6 They, Sandia explains this, and I  
7 agree with the explanation. We just don't agree  
8 with the cause.

9 What happens with overlying sodium  
10 subcooled, you wind up with a conjunction zone here  
11 at the top of the bed.

12 Now, what they -- the way they feel  
13 what happens is you have a subcooled zone at the  
14 top, you have a boiling zone down here.

15 Now, they say that all the vapor  
16 that is generated in this region comes up and  
17 condenses on this surface, and must be transferred  
18 by conduction through this surface. So you wind up  
19 with series heat removal.

20 Now, we feel that if this is the  
21 way bed fixation can cause a reduction in the heat  
22 transfer, if however you could show even with a  
23 subcooled layer up here that a vapor channel would  
24 penetrate that subcooled zone, then the energy  
which is simulated down here in the bottom, in the

1 boiling zone, can go up through the vapor channel,  
2 and you in essence wind up with parallel heat transfer.

3 So the question is, is it possible in  
4 the area of bed fixation, is it possible to develop  
5 a layer -- the top that is sufficiently strong to  
6 prevent the vapor channels from penetrating.

7 Now, Sandia feels in their experiments  
8 that subcooling of the bed was the only -- was a  
9 sufficient requirement to do that.

10 We have, the Argonne experiments,  
11 we have performed experiments with simulative fluids,  
12 with water, and saw no reduction in coolability with  
13 subcooling.

14 With real materials, though, there  
15 is a couple of other effects that can potentially  
16 come in.

17 One is, we feel the  $UO_2$  that was  
18 used in the Sandia experiments was  $UO_2$  plus X. It  
19 had been sieved and ground, or ground and sieved --  
20 I guess you have to grind it before you sieve --  
21 a couple years previous to the experiment, and stored  
22 in plastic bottles.

23 Now,  $UO_2$  will oxidize to  $UO_2$  plus X.  
24 We don't believe that the X is very high in these  
experiments. We believe it is probably not more

1 than O1 to O4.

2 But that, when you have  $UO_2$  plus X,  
3 and sodium, you could have a chemical reaction  
4 between the  $UO_2$  plus X and sodium, which produces  
5 a sodium urinate, if the temperatures are high  
6 enough, or a sodium oxide for low temperatures.

7 And what we are feeling is that if  
8 this with two particles here, that this, the  
9 chemical reaction products are sufficient to provide  
10 the cohesive force to hold the bed together.

11 MR. CARBON: Excuse me, Dr. Pedersen. We  
12 are running way over time on this, and we  
13 really would like to stay fairly close to our  
14 schedule.

15 MR. PEDERSEN: I will move faster.

16 MR. CARBON: Maybe we could just skip some  
17 of the details and hit the high points

18 MR. PEDERSEN: The other potential problem  
19 is that  $UO_2$  plus X can cause a reduction in the  
20 wettability.

21 And if you can't get the sodium to  
22 wet, to get into the bed, you can't cool it either.

23 What we at Argonne, we intend to  
24 look at these effects with a facility here which is

1 -- we are going to do real material coolability  
2 experiments with sodium,  $UO_2$  and bottom heat.

3 I won't go any farther into that  
4 other than that is a facility that we have.

5 Here is a little viewgraph of the  
6 actual design of that facility. We are going to  
7 be heating it from the bottom.

8 You have a debris bed here that we  
9 are going to heat in sodium. We can have either  
10 subcooled sodium or we can have saturated sodium.

11 We can also look at the effect of  
12 concrete reaction products.

13 We want to be assured that concrete  
14 reaction products coming into the bed or settling  
15 into the bed from the top will not cause bed fixation.

16 In addition to the area of debris  
17 bed coolability at Argonne, we are also looking at  
18 the area of debris penetration in the substrates,  
19 particularly molten debris penetration.

20 And what we are interested in is  
21 penetration rates of molten debris into the substrate,  
22 whether it is  $UO_2$  or  $MgO$ , you are interested in the  
23 gas release rates as it penetrates.

24 The various substrates you are  
interested in can be characterized as basically three

50 1 different types; miscible, non-gas releasing, which  
2 would be MgO, Al<sub>2</sub>O<sub>3</sub>, or alumina, et cetera;

3 Miscible gas-releasing, which is  
4 concrete;

5 And immiscible non gas-releasing,  
6 which is steel.

7 And one of the experimental requirements  
8 for these is you have got to have continued decay  
9 heating because are interested in long-term penetration.

10 You can't just perform bump experiments  
11 to address long-term penetration.

12 This next viewgraph, which I won't  
13 cover other than to say is real material experiments  
14 are very difficult to interpret. And so you need to  
15 have, to back it up with a set of simulate material  
16 experiments we can visualize what is going on.

17 And so that is what this slide dis-  
18 cusses, is the various experiment that are going  
19 on in the area of simulate fluids to look at, to help  
20 develop models for molten debris penetration.

21 In the area of UO<sub>2</sub>-concrete, some of  
22 the outstanding areas are still the gas release during  
23 penetration, long-term penetration rates, possibility  
24 of stress levels in concrete.

We want to be sure that as this

51 1 material penetrates, we are not cracking the concrete,  
2 and in essence activating the penetration.

3 Present data only for limestone  
4 concrete, which is of the CRBR type.

5 MR. BENDER: Let me interrupt for just a  
6 minute to get it in context.

7 What we are interested in, I think,  
8 is how long it takes to get through this delay  
9 bed, or whatever it is.

10 MR. PEDERSEN: Right.

11 MR. BENDER: Right.

12 I mean, I am interested in the matter  
13 of the order of difference we are talking about.  
14 Are there variations in penetration of time, a  
15 factor of two, ten or a hundred? What is it we are  
16 dealing with here?

17 MR. PEDERSEN: Penetration of  $UO_2$  into --

18 MR. BENDER: Into the delay bed or whatever  
19 it is you have got there, the  $MgO$  mixture.

20 MR. PEDERSEN: There have been no experiments  
21 performed up until just a couple weeks ago which  
22 addressed the question of long-term penetration of  
23  $UO_2$  into  $MgO$ .

24 MR. BENDER: That still leaves me, there has  
been some analysis.

52  
1 MR. PEDERSEN: There have been analyses,  
2 yes.

3 MR. BENDER: In doing experiments, normally  
4 you do it because the analysis had a spread that  
5 was so big that you couldn't give -- live with it.  
6 and so I am asking now --

7 MR. PEDERSEN: -- what is that spread?

8 MR. BENDER: What is the time span we are  
9 seeing? Are they trying to condense the time or  
10 increase the time by doing experiments that show  
11 it is longer than we have to assume?

12 MR. PEDERSEN: Some of the questions are  
13 really with respect to what is going on in the bed.

14 We didn't, with respect to the MgO,  
15 one of the questions you want to ask, will the  
16 MgO, being lighter than UO<sub>2</sub>, you want to ask will  
17 bricks float out?

18 And that is where you need fairly  
19 big experiments to address that question because if  
20 your bricks can float out of the delay bed, you  
21 can in essence enhance the penetration considerably.

22 The actual mechanism of penetration  
23 is also a little bit uncertain, in that UO<sub>2</sub> and MgO  
24 forms a utectic, and there have been very little  
experiments or analysis directed at actual penetration

55  
1 of one material into another with that form of  
2 eutectic mixture.

3 And the analysis in essence ignores  
4 those issues so far. So I don't really know if I  
5 can answer your question as to what is the uncertainty  
6 in terms of the penetration. That is a good question.

7 This shows the results of the experi-  
8 ment performed at Argonne a couple -- about a year  
9 ago, which looked at the penetration of  $UO_2$  into  
10 concrete that was direct electrically heated on a  
11 continuous basis.

12 The apparatus here basically consists  
13 of, as we all see is half of it, Brass "U's" that are  
14 insulated from one another. So the two sides are  
15 in essence high resistance path.

16 We have an electrode here, which in  
17 this case is graphite.

18 Another electrode here on the other  
19 face of this apparatus, and we are able then, by  
20 direct electrically heating of the  $UO_2$  to generate  
21 molten  $UO_2$  that can interact with concrete.

22 With this experiment, it was carried  
23 on for approximately one hour, we saw a penetration  
24 in that time of about five centimeters.

Now, what w characteristic is we

54

1 generated this, this layer down here which is a  
2 mixture of  $UO_2$  and concrete.  $UO_2$  and concrete are  
3 miscible in one another and generate a low melting  
4 point eutectic almost at the concrete melting point.

5 We saw loss of gas release of the  
6 top surface, and we saw some throwing of that, of  
7 the material off of this surface, up, and actually  
8 generated a mound of molten material off the top.

9 Now, these experiments have only  
10 been done on limestone concrete, and they have  
11 only been done for limited times, limited being  
12 an hour or so.

13 But these experiments done will form  
14 the basis for developing of an adequate penetration  
15 code, being  $Q$ , you can calculate the penetration of  
16 materials, molten core materials into concrete.

17 We have performed an experiment just  
18 a couple weeks ago which in essence repeated this  
19 in a slightly different apparatus.

20 Both Argonne and AI have been looking  
21 at the penetration of molten  $UO_2$  into  $MgO$ .

22 The penetration, you might say, "Well,  
23 you guys penetrated into concrete. You ought to be  
24 able to do it into  $MgO$ ."

Well, the problem is, the  $MgO$  has a

55  
1 much higher melting point, utectic temperature is  
2 like 2200 degrees C as opposed to concrete, which  
3 has a utectic melting point with  $UO_2$  of around 1300  
4 degrees C.

5                   So you are talking about almost  
6 another 900 degrees C.

7                   So both Argonne and AI have been  
8 looking at programs to develop methods to experimentally  
9 assess both  $UO_2$  presentation into  $MgO$ .

10                   Argonne has been using in essentially  
11 the same apparatus that was used for the concrete,  
12 with the only real -- this was an experiment which  
13 was a preliminary experiment performed approximately  
14 a year ago with a ten by ten centimeter cell, with  
15 thirty-three centimeters of Harklase brick. Harklase  
16 is a manufacturer of  $MgO$  brick, very high density,  
17 about ninety-nine percent dense.

18                   In the experiment we generated a  
19 molten  $UO_2$  pool, but we were only able to penetrate  
20 approximately a half-centimeter into the  $MgO$ .

21                   At that time, the radial heat loss  
22 to these bases, which are insulated, was matching  
23 the generation that they were putting into the molten  
24  $UO_2$ .

                  We have just last week repeated this

56

1 experiment with a twenty by twenty centimeter cell, and  
2 we were able to achieve penetrations in the order of  
3 three or four, three centimeters.

4 So we believe that now we are capable  
5 of looking at longer term penetrations.

6 In this experiment, the  $UO_2$  is direct  
7 electrically heated by dual resistance heating from  
8 one electrode to the other electrode.

9 AI has been attempting to develop an  
10 induction heating method. What they have is a low  
11 frequency induction thermos, a hundred kilowatts,  
12 about 3600 hertz, in which they would like to direct,  
13 directly inductively heat the  $UO_2$ .

14  $UO_2$  at room temperature has a very  
15 low resistance, but as your temperature gets up  
16 near the melting point, above, actually somewhere  
17 above 1500 to 2000 C, its resistance drops fairly  
18 fast.

19 And the goal is in essence to transfer  
20 and directly inductively heat the  $UO_2$  itself.

21 Now, they have run two experiments  
22 with stainless steel. They used stainless steel  
23 layers.

24 The goal of the experiments is to  
hear the stainless steel hot enough to transfer the

57  
1 temperature to the  $UO_2$ . When the  $UO_2$  gets hot enough,  
2 you should be able to transfer from heating the  
3 stainless to inductively heating the  $UO_2$ .

4 Now those, the first two experiments  
5 were not successful. They are going to now take and  
6 put a tungsten layer here.

7 What happens with the stainless, it  
8 melts and runs away. So you now have no way of heating  
9 the  $UO_2$  at all.

10 By switching to a tungsten layer, the  
11 tungsten is not going to melt until actually above  
12 the  $UO_2$  melting point. And hopefully you can generate  
13 an open  $UO_2$  tool and directly heat that.

14 Their go for their experiment is  
15 sometime in the next month to perform that experiment.

16 That was all I had to say. Any  
17 questions?

18 MR. GAVIGAN: The next speaker is Lou  
19 Muhlestein from HEDL.

20 MR. MUHLESTEIN: What I am going to try  
21 to do is summarize some tests and some results which  
22 have been completed in terms of sodium-concrete  
23 reaction. I want to take a few minutes and realize,  
24 I guess we all do, in the postulated core meltdown  
incident we have core debris that we talked about,

1 you have sodium. They are separated from the concrete  
2 by a steel liner.

3 But you try to break the problem up  
4 into small enough pieces that you can analyze,  
5 and this is the thing we are trying to do.

6 But we have to be careful not to  
7 research the problem to death for its own sake, but  
8 put it in total perspective.

9 So let me remind us that the issue  
10 of LOA-3 is to demonstrate even if we have a core  
11 meltdown we can maintain the containment integrity.

12 And there are two things that may  
13 violate containment integrity; overpressurization  
14 or hydrogen buildup.

15 And as you break this total big problem  
16 into smaller problems and look at them, the fact is  
17 that sodium-concrete reactions do provide a source  
18 term for both energy and hydrogen generation.

19 And so what we are attempting to do is  
20 provide a basic understanding of these reactions,  
21 and developing also the analytical tools that we can  
22 predict the rate and quantity of hydrogen and energy  
23 which is released under these accident scenarios.

24 I want to show you a matrix of a  
series of tests that have been performed at the

59  
1 Hanford Engineering laboratory. And what I want to  
2 do is break them down and talk about specifics.

3 So there is a matrix, you can look  
4 at it.

5 What I have done on the nex' slide is  
6 to break this up in terms of the variations of para-  
7 meters that have been performed in these tests.

8 First of all, in terms of sodium,  
9 the cool temperature has ranged from five hundred  
10 to eight hundred sixty degrees Centigrade in that  
11 test; the amount of sodium, from one kilogram to  
12 approximately four hundred fifty kilograms; contact  
13 time, three to five hours.

14 The concrete, from very small to nearly  
15 three square meters of concrete; thickness, a couple  
16 of inches to two feet.

17 Type: Basalt, limestone and magnetite.

18 And the water content, normal water  
19 content or that which the water has been carefully  
20 griffined from the concrete prior to the test.

21 And then because of additives, we have  
22 looked at sodium hydroxide, pre or post-sodium spill.

23 I would like to in somewhat of a  
24 summary fashion treat each one of those issues.

First, let me talk about sodium pool

50  
1 temperature. The water released from heated concrete  
2 is dependent upon the driving temperature and the  
3 time. So the amount of sodium-water reaction you  
4 would expect to be dependent upon the sodium pool  
5 temperature and the time that that sodium pool  
6 temperature was being applied to the concrete.

7 We know the mechanical properties of  
8 concrete are also temperature dependent.

9 There is data that exists both on  
10 differential thermal analysis and large scale, which  
11 show a temperature threshold exists, below which  
12 sodium-concrete reactions will not occur at a very  
13 substantial rate.

14 Put that together, however experience  
15 is that the total chemical reactions do not appear  
16 to be strongly dependent upon the sodium pool  
17 temperature as long as you are about the threshold  
18 temperature. That is in that range from five hundred  
19 to eight hundred sixty, the reactions have been  
20 quite similar.

21 What I want to show you is just a  
22 table of some differential thermal analyses performed  
23 early in this program.

24 The thing of essence here is the  
fact that in the basalt concrete there appears to be

61 1 an exothermic temperature around twenty-five hundred  
2 degrees Centigrade, with something like one hundred  
3 ninety-five calories per gram of energy released,  
4 or magnetite around five hundred again, and for --  
5 or this is magnetite, and limestone is here.

6 But the point is it is around that  
7 temperature regime, and we realize the differential  
8 thermal analysis may be somewhat insensitive, but  
9 the point is that there is some temperature has to be  
10 reached before these reactions can occur at a very  
11 substantial rate.

12 In terms of the amount of sodium,  
13 shallow sodium pools tend to totally react until all  
14 the sodium is consumed.

15 However, there have been tests where  
16 deeper sodium pools have not totally reacted. So  
17 sodium pools may or may not react until the sodium  
18 is consumed.

19 The total sodium-concrete reaction  
20 penetration does not strongly depend on the sodium  
21 pool depth. This, I think, this counts an earlier  
22 sodium hypothesis that the sodium pool had to be  
23 saturated by sodium hydroxide before a reaction  
24 could occur.

And let me point out some data that

62 1 illustrates that issue. And I want to look at these  
2 two sets of curves.

3 Here we have the hydrogen accumulation  
4 is a function of time. The reaction penetration is a  
5 function of time. And the remaining sodium left is a  
6 function of time.

7 First of all, let's look at the hydrogen  
8 generation.

9 The depth of the sodium pool was 6.3  
10 centimeters to about four and a half kilograms; 15.2  
11 centimeters, about 10 kilograms; fifty pounds and a  
12 hundred pounds. Those conversions!

13 The point is that for the shallower  
14 pool the amount of hydrogen given off is certainly  
15 less. It increases as you go to the deeper pool.

16 Let's look at this maximum reaction  
17 penetration, which is the dotted curve here.

18 For the four and a half kilogram,  
19 all of the sodium reacted. It penetrated somewhere  
20 in the order of five centimeters total.

21 We increase it to about 10 kilograms.  
22 The reaction penetration, about five or six centimeters,  
23 but in fact while you start to see that there is some  
24 sodium remaining.

And the numbers here are the times at

1 which the reaction, certainly when the sodium is  
2 consumed the reaction terminates.

3                   As you go on, we go into longer times.  
4 For example, you get down here to a hundred pounds of  
5 sodium, forty-five kilograms, you had nearly twenty  
6 percent of the sodium remaining. And you notice  
7 that the reaction penetration tends to level off.  
8 It does not continue at the same rate for an indefinite  
9 period of time.

10                   Let me turn to sodium contact time.  
11 Again, the water release from heated concrete is  
12 dependent on the driving temperature and duration of  
13 that heat flux.

14                   However, in tests which we performed  
15 independently, most of the free water is evolved in  
16 the early time frame. Therefore, the amount of sodium  
17 water reaction you would expect to be dependent upon  
18 time and temperature, with a majority of that reaction  
19 occurring early in time.

20                   And what we have in fact observed is  
21 that most of the sodium-concrete reactions occurred  
22 in the early time frame, zero to two-hour time frame,  
23 with little noticeable reactions beyond that.

24                   And let me illustrate that point by  
two pieces of data.

64

1  
2  
3  
4  
5  
6  
7  
8  
9  
10  
11  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24

The first is a large basalt test, about a meter square, four hundred fifty kilograms of sodium.

And what we have plotted here is first of all the pool temperature is a function of time. And then the thermal couples in successive depth to the concrete.

What you see is within three hours, down to even fifteen centimeters, as you look at this test in the long-term, that is after a hundred hours, the reaction had not penetrated more beyond this temperature, or this point here.

So you see the reaction occurred in a very short time frame. And even though there was sodium left over to some forty, fifty hours, the penetration was fairly slow. So it occurred fairly rapidly.

MR. BENDER: Before you take that off, my recollection isn't very good, nor is my understanding, but it would seem to me that the Sandia tests had suggested that there wasn't any point at which the sodium stopped penetrating.

Did I misinterpret what they said?

MR. MUHLESTEIN: No. You have to be careful. The Sandia tests, many of them were sodium-limited, so

65  
1 so there is a fixed amount of sodium. And the  
2 conclusion was it reacted until all the sodium was  
3 consumed.

4 The conclusion was therefore it  
5 would react indefinitely. And I will show you  
6 some results on large-scale tests.

7 All their tests, the majority of  
8 their reactions and reaction rates were in a very  
9 short time frame. But I don't believe personally  
10 one can conclude therefore that in longer times it  
11 would continue at that same rate.

12 They were sodium-limited and you have  
13 to be careful in drawing that conclusion.

14 Let me show you the results of the  
15 other test which was not sodium-limited.

16 This is a large limestone reaction  
17 test, which at test conclusion was over fifty per cent  
18 of the sodium left over. So there was a large amount  
19 of sodium.

20 Again, you see down to even a depth  
21 of 7.6 centimeters, a reaction occurred in the early  
22 time frame, down to that point of time.

23 But on disassembly, the total reaction  
24 was not beyond 7.6 centimeters, and there was plenty  
of sodium left over.

66  
1 MR. BENDER: The explanation for this  
2 limit is what?

3 MR. MUHLESTEIN: I will get to that.

4 MR. HARTUNG: Let me ask a question before  
5 you leave this.

6 Is the reason, as you go deeper, the  
7 temperature doesn't go up very greatly? Is that  
8 possibly because it was cooled at the bottom in some  
9 way?

10 MR. MUHLESTEIN: The situation is where  
11 you have the hot sodium applied to the top, that is  
12 by thermal conduction heating the concrete below,  
13 it takes a while for thermal conduction to heat the  
14 sodium.

15 There is a surface reaction occurring,  
16 but water is driven deep from within the concrete.

17 We find that typically eighty percent  
18 of the water is going in the total test duration.

19 But you see these thermal couplings,  
20 and I didn't show you the curve, even at long terms,  
21 in this test, fifteen to twenty hours, they were not  
22 very hot.

23 MR. HARTUNG: So the delay is just a matter  
24 of conductivity? There is no cooling on the outside.

MR. MUHLESTEIN: There is no forced cooling

67  
1 on the other side, no forced cooling.

2 MR. HARTUNG: Well, I guess that is the  
3 point I was getting at. Even if you have just ambient  
4 temperature on the other side, I will think about it  
5 on my own, but it could be there is a substantial  
6 cooling effect occurring unless you have done something  
7 to mock up what, if you had, let's say, a very deep  
8 bed in a reactor, you would have no capability for  
9 cooling the other side, even ambient.

10 MR. MUHLESTEIN: But I still could expect,  
11 the heat has to be from the top down, and you start  
12 at ambient temperature.

13 And our thermal analysis model says  
14 it takes some time for that concrete to get hot to  
15 drive off this water. So I don't anticipate this  
16 to be atypical.

17 MR. MARK: The fact that the bottom thermal  
18 couplings don't get off the ground at all means there  
19 isn't much heat flow.

20 MR. MUHLESTEIN: It takes a while for the  
21 heat to conduct itself down to the concrete, and  
22 it would in a real situation, too.

23 Let me talk about concrete pipe and  
24 size.

It seems that the limestone test

1 results were more consistent as we looked at the  
2 data, between the small and large scale tests. And  
3 in all of our limestone tests, even I will show you  
4 some data earlier where we had some deeper penetrations  
5 early, but the end result is that the chemical reactions  
6 were self-limiting.

7 For basalt, however, most of the  
8 small scale tests had limited reaction penetration,  
9 but it didn't continue forever.

10 But the reaction for larger scale  
11 tests were more extensive. There is more uncertainty  
12 in the sodium-concrete reaction with basalt than with  
13 either limestone or magnetite.

14 Let's look at water content. We have  
15 done a series of tests with dehydrated concrete, and  
16 dehydrated basalt concrete reacts extensively with  
17 sodium.

18 But as you would expect, the amount  
19 of energy and hydrogen is considerably reduced. The  
20 water is gone, the hydrogen is gone, and the energy  
21 is reduced.

22 Dehydrated magnetite concrete, on  
23 the other hand, does not react extensively with sodium.  
24 And although we have not completed the test, there is  
data to suggest that the limestone concrete, dehydrated

1 concrete also does not react extensively with sodium.  
2 And that has to feed in our understanding of formulas  
3 and what is going on in the total problem.

4 And let me, to illustrate, go back  
5 to this curve, which now I want to concentrate on  
6 these two.

7 We have the hydrogen accumulation is  
8 a function of time, and the hydrogen accumulation and  
9 the reaction penetration function of times.

10 The first test, one and six were  
11 dehydrated with nearly eighty percent of the total  
12 water used in the concrete driven off before the test  
13 was started.

14 Where the four, SET four had the  
15 normal water content.

16 As I said earlier, the amount of  
17 hydrogen generated is greatly reduced because the  
18 water is gone.

19 If you look at the hydrogen generation  
20 here as a function of penetration, this is the dash  
21 line here is the dehydrated basalt concrete. Very  
22 little hydrogen, this curve. But the penetration was  
23 rapid and extensive. Merely a foot of concrete in a  
24 very short time frame reacted right through it.

Whereas the amount of hydrogen given

70  
1 off in the concrete which had the full water content  
2 had relatively little penetration.

3 That is a surprising result for us.  
4 We were looking at the effect of water on the reaction  
5 period, we have had to revise our thinking just a little  
6 bit. And I will try to wrap that up as we continue.

7 There have been a number of tests  
8 looking at additives.

9 The question is what about sodium  
10 hydroxide. Sodium hydroxide alone does not react  
11 extensively with basalt or limestone concrete. There  
12 is a little erosion, but nothing extensive.

13 Sodium hydroxide has been added  
14 before or after or during a sodium spill, and it  
15 does not drastically alter the reaction in terms of  
16 how much reaction occurs.

17 However, sodium hydroxide, which is  
18 formed from the sodium water reaction, is an important  
19 mechanism in the total concrete reaction.

20 You see, we tried to look at it a  
21 piece at a time. It didn't give us the results we  
22 anticipated.

23 But it is important in the total  
24 understanding of what we think is happening.

Let me talk about some observations

1 that we have seen from a large number of tests.  
2 It has been very striking that in those situations  
3 where you have deep, rapid reaction penetrations,  
4 they are characterized by a very voluminous friable  
5 type of reaction product.

6 On the other hand, for those situations  
7 where they were characterized by a limited reaction,  
8 the reaction products were very glasslike and hard.

9 Now, that has to be fed back into  
10 our understanding.

11 The extent of the chemical reaction  
12 penetration is reflected by the hydrogen generation.  
13 And I will illustrate that by some data.

14 The point is we don't know which is  
15 the cause and which is the effect; hydrogen released  
16 because of rapid penetration, or rapid penetration  
17 occurring because of hydrogen release. That is a  
18 fact we have got to contend with.

19 We do note, I believe, that the sodium-  
20 water reaction is dominant. Water deep within the  
21 concrete is thermally released. In the test up to  
22 eighty percent of the content of the water is released.  
23 Water migration is to the hot surface by pressure-  
24 driven flow, so there is not much going off the cold  
surface. And it dominates the hydrogen and energy

1 release.

2 I will just point out, there have  
3 been a number of tests, a question, what happens  
4 if you have a liner but the liner is faulted, will  
5 the sodium proceed through the fault.

6 The first thing is the fact that  
7 the insulated material does thermally insulate the  
8 concrete in the early time frame. That is important  
9 from the amount of water griffined off. And hence  
10 the energy and the hydrogen generated, there is a  
11 reduced rate of water released and hydrogen released.

12 Obviously if you thermally insulate  
13 the concrete, depending on the material, it has,  
14 it may inhibit the sodium migration to the surface.

15 If it is salicious kinds of material  
16 like basalt, it will probably, the tests seem to  
17 indicate it does react much like that basalt concrete.  
18 But in that early time frame, which is important,  
19 they will tend to insulate the concrete, reducing the  
20 water content and energy.

21 And I have to remind us that is the  
22 thing we are concerned about.

23 Let me show you some examples. This  
24 is one of our large scale basalt tests. What we have  
plotted here is the hydrogen generation, generation

73  
1 rate, the penetration and penetration rate, and as  
2 functions of time.

3 First of all, the red curve is the  
4 measured hydrogen generation rate as a function of  
5 time. That measured, we integrated that to find the  
6 hydrogen generation, and that is this curve right  
7 here. That is an experiment. That is a determined  
8 parameter.

9 They then measured the reaction  
10 penetration into the concrete, the circled data here.  
11 And we integrated that to get a penetration rate.

12 And the thing that is important, again,  
13 is that the penetration rate envelops the hydrogen  
14 release rate. And it occurs in the early time frame,  
15 and with a little given off beyond that.

16 Again, I said I don't know which is  
17 the cause and which is the effect of that, but it  
18 is important to realize that on those time frames  
19 we are having large quantities of hydrogen evolve  
20 from the sodium-water reactions is the same period  
21 of time you are getting the rapid penetration into  
22 the concrete.

23 MR. BENDER: I don't know if I understand  
24 what you are telling us, so I am just trying to ask a  
couple of questions.

74 1 MR. MUHLESTEIN: I am not sure I have the  
2 answer, but I know what the data says.

3 MR. BENDER: You are measuring the reaction  
4 of sodium with free water primarily.

5 MR. MUHLESTEIN: With free water which is  
6 driven from the concrete, so it is actually sodium  
7 onto the concrete. But there is water given off,  
8 and that is what is giving the hydrogen.

9 MR. BENDER: Is the combined water also  
10 reacting?

11 There is cement.

12 MR. MUHLESTEIN: That's right. You have  
13 what is of all evaporable water, which is maybe  
14 fifty percent of the water, that is certainly being  
15 driven off quickly.

16 But also because of the heat load  
17 to the concrete, we also get some of the bound water  
18 given off. That is nearly eighty percent of the  
19 total, the evaporable water, plus the bound water.

20 MR. BENDER: What is dominating the hydrogen  
21 generation?

22 MR. MUHLESTEIN: Total water.

23 MR. BENDER: Obviously the total water. Is  
24 most of it doing something?

MR. MUHLESTEIN: Again, the free water comes

75  
1 off at a lower temperature. The bound water comes  
2 off as a function of temperature and time.

3 In concrete particularly, in the order  
4 of fifty percent is what we call evaporable, and the  
5 other fifty percent is what we call bound water.

6 MR. BENDER: You are trying to show a curve  
7 which has a time element, and I can see most of the  
8 reaction is free water in that two hours, and the  
9 rest of the water tied up in the concrete isn't going  
10 to react for a while. And I don't know what you are  
11 telling me, so I am asking.

12 MR. MUHLESTEIN: The dominant early time is  
13 evaporable water because that comes off quickly and  
14 faster.

15 However, as part of this is also  
16 bound water in the distances not very deep within  
17 the concrete.

18 Now, if you remember the temperature  
19 curve, deep within the concrete it doesn't get very  
20 hot. Therefore, we don't have the bound water. We  
21 have the evaporable water. But in the top surface  
22 we have got the evaporable and the bound water, so  
23 I can't say which is more dominant, but obviously  
24 the evaporable water comes off at lower temperatures,  
faster.

76  
1 So in the early time frame it has to  
2 be a dominant factor. Eventually you get it all.

3 You have to consider the heat load to  
4 the concrete and the total water content. I can't  
5 isolate it to just the evaporable versus the bond.

6 MR. BENDER: Go ahead.

7 MR. MUHLESTEIN: They both contribute.

8 What I want to point out is another  
9 large limestone test.

10 MR. BENDER: I think you have to understand  
11 that to some degree, in order to make some argument  
12 about what the hydrogen influence is.

13 MR. MUHLESTEIN: I guess I should point out,  
14 we do have a model, and basically the first water to  
15 come off is the evaporable water. But later in time  
16 the bound water comes off as well.

17 And you have to look at that as a  
18 function of the heat load to the concrete, because  
19 some places both is coming off, and other places  
20 just evaporable water.

21 What I have here is another large  
22 limestone test in which we have the hydrogen generation  
23 as a function of time. And the hydrogen generation  
24 rate, it is very low, not very much, eighty gram  
moles per hour.

BOTTOM CONTENT

77  
1 But again it peaked in the early  
2 time frame.

3 I am going to contrast that with  
4 another large-scale limestone test very similar to  
5 the first, in which we had the early time frame,  
6 a very rapid hydrogen generation rate, the order  
7 of maybe three hundred fifty gram moles per hour,  
8 again, in a very short time frame.

9 But those two tests at different  
10 looked very much the same. This had a more rapid  
11 penetration rate than the other one, as again evidenced  
12 by the hydrogen generation. But the total results  
13 are very similar.

14 And I need to point out, too, that  
15 the total hydrogen generation, also are very similar  
16 for the two tests. How they came out were different,  
17 but the total end results were very identical.

18 I want to spend just a moment on  
19 current understanding. Certainly sodium-water  
20 reaction produces the sodium hydroxide and hydrogen.

21 Both small and large tests indicated  
22 a reaction threshold around five hundred degrees  
23 Centigrade.

24 Most of the sodium-concrete reaction  
tests do not continue. Like I say, because of some

78 1 sodium-limited tests, that assumption has been drawn.  
2 But we have tests in which both all reactants have  
3 been available after, we can feel that the sodium-  
4 concrete reactions consider almost a protective  
5 reaction product layer is formed, reaction product,  
6 sodium hydroxide, sodium carbonate, which are more  
7 effective in forming a reaction product layer than  
8 solid reaction products.

9 And this is typical, when we get  
10 that glasslike, very hard reaction product layer,  
11 that is typical of a viscous liquid product layer,  
12 which then prohibited further sodium from coming in  
13 contact with further solid materials.

14 Obviously the water vapor continues  
15 to migrate through it and react with the sodium.  
16 And that is why the sodium-water reaction, I think,  
17 is dominant.

18 So from this we conclude that most  
19 sodium-concrete reaction tests have shown that the  
20 chemical reactions are self-limiting. Most of them  
21 occur in the early time frame.

22 I think I can generalize that to all  
23 of the tests we have seen. The large reaction rate  
24 has occurred in the early time frame. We have to  
be careful and not extrapolate for those tests which

79  
1 were sodium-limited.

2 But under many conditions we have  
3 seen tests in which a protective reaction product  
4 layer has formed which separates the sodium from  
5 unreacted concrete and terminates the reaction.

6 Some tests have been sodium-limited.  
7 Some may have been water-rate limited. But when we  
8 overcome those two things, in the long time frame,  
9 lots of water, lots of sodium, we find things happen  
10 in the early time frame. But they do not continue at  
11 that same rate. I think that is important point.

12 Also, limestone concrete is more  
13 resistant to reaction with sodium than is basalt.

14 I want to show you just one other  
15 slide which is not part of your handout. As I said,  
16 sort of the committee, we are trying to find the  
17 hydrogen and energy generated. This is one test in  
18 which we had enough data that we could actually  
19 calculate the energy release as a function of time  
20 for basalt.

21 We have to make the assumption, first  
22 of all, we can calculate the hydrogen, the energy  
23 release from sodium-water reaction. That is somewhat  
24 easy to do, based on the hydrogen generation rate  
that considers all the water.

1                   One has to assume that the silicious  
2 reaction is mostly coming from the silicate.

3                   Now, the concrete is very complicated  
4 mixtures of minerals. But as you look at those  
5 minerals, the majority is silicate, though it is  
6 not in free silicate. It is tied up in a number of  
7 compounds.

8                   But if you consider that as energy  
9 from the solid reactions is dominant, you get this  
10 curve. You add the two together, you get curve one.

11                   What we attempted, take the differential  
12 thermal analysis which looks at reaction products,  
13 and we multiply. That is far too many joules per  
14 amount of material.

15                   And we knew at the N state how much  
16 material had been reacted, and so we calculate at  
17 an energy, and that is the value there at the long  
18 time at forty hours it was this number.

19                   We know how much water was driven  
20 from the concrete. Therefore we know how much water  
21 reacted, and that gives us an energy number there.  
22 You add the two together.

23                   And I think the agreement is fortuitous.  
24 But what it tells us in terms of these calculations,  
taking the energy from the hydrogen reaction and the

81

1 energy from the differential thermal analysis and  
2 the amount of material consumed gives us a fairly  
3 good pound of total energy which is produced.

4 It is the kind of thing, yes, we are  
5 in the ball park, and yes, we can calculate. And  
6 with that I will end.

7 MR. MARK: When you refer to limestone  
8 concrete, is it the same this week as it was last  
9 year in its detailed chemical analysis?

10 MR. MUHLESTEIN: Let me refer specifically  
11 to the Clinch River limestone mix. That is the  
12 thing we know more about.

13 Over the last several years the mix  
14 specifications have changed, but they have changed  
15 slightly.

16 MR. MARK: I am wondering about the chemical  
17 composition.

18 MR. MUHLESTEIN: Long-term chemical composi-  
19 tion?

20 MR. MARK: One of them had a certain amount  
21 of silicates. Does the next batch have the same  
22 number, or is it dug from a different corner of the  
23 gravel pit?

24 MR. MUHLESTEIN: Again, the silicates would  
be the basalt. For the limestone it is more dolemite,

1 and there is a number of other aggregates and  
2 combinations.

3 I think in the long term the chemical  
4 nature of the concrete is not changing.

5 There is some change in chemistry  
6 as the aging time progression in terms of aging,  
7 water changes, but I don't think that is a major  
8 effect. At least we have, for example, in the test  
9 series we looked at these reactions with concrete  
10 cured just twenty-eight days, and some cured over  
11 three years. And we don't see any major difference.  
12 The chemistry analysis we have don't show large  
13 differences.

14 But I have to point out in Petrographic  
15 analyses by very skilled people in concrete, it is  
16 more than a guess as to what is really there.

17 MR. BENDER: When you say limestone concrete,  
18 are you saying that the mortar mixture is ground  
19 limestone?

20 MR. MUHLESTEIN: I am saying that's the  
21 fine aggregate and coarse aggregate is dolemite or  
22 limestone rather than a basaltic kind of mixture.

23 The cement paste is very much the  
24 same. Earlier we thought because the cement paste  
was dominant in the water --

83 1 MR. BENDER: When you say basalt concrete,  
2 fine aggregate and coarse aggregate is all a form of  
3 rock broken up to some degree?

4 MR. MUHLESTEIN: That's correct.

5 MR. CARBON: Thank you.

6 (Short break in the proceedings.)

7 MR. GAVIGAN: The next speaker is Lou  
8 to talk about LOA-4.

9 MR. BAKER: I would like to introduce the  
10 LOA-4 program. LOA-4 refers to attenuate  
11 radiological consequences.

12 Our top level objective is to  
13 demonstrate a high probability of obtaining a large  
14 attenuation of consequences from a radioactive  
15 release inside containment by inherent mechanisms  
16 and by engineered systems.

17 Our second level divides this into  
18 engineered attenuation and inherent attenuation.

19 Louis Muhlestein will be back in a  
20 minute to describe our program on air cleaning  
21 systems, which is our total engineered attenuation  
22 program.

23 Then Ravnesh Amar will be up to  
24 describe our inherent attenuation program, which  
includes aerosol behavior program at HEDL, high

1 density studies at AI.

2 Our studies of leak plugging by  
3 aerosols, sparging source term development at  
4 GE, and our review of environmental attenuation  
5 models at Oak Ridge.

6 Our strategy in this area is one to  
7 develop efficient, reliable vent/filter systems such  
8 that they are available.

9 The technology base is available if  
10 designers wish to use this approach.

11 And also to demonstrate dose reduction  
12 by natural processes.

13 The approach to this is to, as I  
14 mentioned, support the containment air cleaning  
15 program at HEDL; to look at aerosol behavior  
16 experiments to demonstrate the rapid agglomeration/  
17 fallout of sodium and fuel aerosols.

18 We have initiated a program called  
19 ABCOVE, of aerosol code comparisons and experiments,  
20 large scale experiments in the containment systems  
21 test facility at HEDL.

22 The analysis program will predict the  
23 results of planned experiments as the key feature of  
24 the program.

We have also developed a -- we also

85

1 wish to establish a sparging source term, that is  
2 the availability of radiological species from the  
3 reactor cavity by bubbling, either by sodium boiling  
4 or by the bubbling of gases releases through concrete  
5 through the fuel-sodium mixture in the cavity.

6 And also, to demonstrate the self-  
7 plugging tendency of containment penetrations, and  
8 to establish improved environmental attenuation  
9 models.

10 With that I will turn it over to  
11 Louis again.

12 MR. LIPINSKI: Question: What is the self-  
13 plugging material? Are you talking about sodium  
14 systems?

15 MR. BAKER: It has been shown that sodium  
16 aerosol has a marked tendency to plug small holes.  
17 And this appears to be worthwhile exploiting, with  
18 regard to showing that leaks and containments may  
19 very well be explained.

20 MR. MARK: How do you exploit it? Do you  
21 drill little holes in the containment?

22 MR. BAKER: It is said --

23 MR. MARK: Never mind.

24 MR. LIPINSKI: The words containment  
presentation are not the words, but if you -- lines,

1 but if you develop cracks, that is the way you are  
2 using the term containment penetration.

3 MR. BAKER: Yes. It is independent.

4 MR. LIPINSKI: If the pipes are open you  
5 will get the material through the pipe. Then it is  
6 a function of pipe size.

7 MR. GAVIGAN: And concentrate of sodium,  
8 that is they are very rapid, one-inch, two-inch,  
9 three-inch, four-inch, isn't that right, ram?

10 MR. AMAR: In fact, that is one of the  
11 concerns.

12 MR. MUHLESTEIN: Yes. With high aerosol  
13 concentrations, thirty to a hundred grams per cubic  
14 meter, we would get, if you have flow through four-  
15 inch duct it will plug very rapidly.

16 MR. BAKER: This should say leaks rather  
17 than penetration.

18 MR. CARBON: Thank you, Lou.

19 This is a good time for a break.

20 (Short break in the proceedings.)

21 MR. MUHLESTEIN: I have two boundary  
22 conditions. I am supposed to talk slower for this  
23 young lady, and I am supposed to speed up to keep on  
24 schedule.

MR. BENDER: How about skipping some?

87  
1 MR. MARK: Maybe if the transcript contained  
2 only every other word it would be almost as valuable.

3 MR. MUHLESTEIN: What we are going to do is  
4 talk about engineering attenuation.

5 As Lou pointed out, the issue here  
6 is to be able to attenuate the release of radioactive  
7 aerosols within engineered systems.

8 There are two phases: one, internal  
9 systems; the other, exhaust systems.

10 For internal systems, we call those  
11 that act within containment to reduce the source term.

12 They can be categorized in terms of  
13 direct acting features, that which will enhance the  
14 already natural phenomena of agglomeration, settling  
15 and played out of the radioactive aerosols so they  
16 do not become part of the source term; or recirculating  
17 systems, which internally would circulate the radio-  
18 active particles through internal filtration device,  
19 and feed them back into containment.

20 For exhaust systems, we are talking  
21 about the collection of radioactive aerosols as exhausted  
22 from containment from a controlled manner to environ-  
23 ment. That is the key issue, in a controlled manner.

24 Two things are necessary. One, if you  
choose to vent to prevent overpressurization of

88

1 containment, or if you choose to purge to control  
2 the hydrogen concentration in containment, and we  
3 will talk about both active and passive systems.

4 Our aerosol, or excuse me, our  
5 containment air-cleaning program, shown pictorially,  
6 is to develop and improve test containment systems.

7 You will hear Ravnesh Amar talk  
8 about the aerosol agglomeration program.

9 These tests are performed in the  
10 HEDL systems facility, which is in essence a large  
11 vessel, twenty-five feet in diameter, sixty-seven  
12 feet in a rural height, which is approaching on the  
13 right scale, the size of large containment as far  
14 as vertical height is concerned.

15 We have capability of handling either  
16 sodium sprays or sodium pool situations to create  
17 the containment systems.

18 I want to point out first that a  
19 path which has not been completed was to evaluate  
20 commercially available air-cleaning systems. That  
21 was first done for a postulated head reliance  
22 accident.

23 So we looked at the available air-  
24 cleaning devices and chose those which had most  
promise of being effective.

89

1 We then evaluated the same systems  
2 for a vent purge mode, following a melt-through  
3 accident, primarily in the Clinch River kind of  
4 an accident situation.

5 We then repeated that evaluation for  
6 the postulated SFTS conditions, and like I say,  
7 those have been completed.

8 The kinds of systems that we looked  
9 at I will divide in terms of active systems, prefilters  
10 along with HEPA combination, two or three stage aqueous  
11 scrubber.

12 For the passive systems, the sand and  
13 gravel bed, and a new system which I will talk about  
14 which we call our submerged gravel scrubber.

15 And I want you to realize never did  
16 we feel that the HEPA filters would adequately contain  
17 the amount of airfalls one would expect in a melt-  
18 through kind of accident, but things we had to look  
19 at in terms of smaller accident situations where  
20 HEPA systems may be used.

21 In that regard, HEPA filters, as you  
22 know, have a high removal efficiency. However, their  
23 mass loading capacity is variable, and it depends on  
24 the aerosol moisture content and the composition.

It is low in relation to the amount

90 1 of term that one anticipates would be available.

2 There is a reliability question with  
3 the corrosive sodium hydroxide aerosols in long-term,  
4 and it would require large filter bags, as I said,  
5 to achieve the mass loadings that are anticipated  
6 under accident conditions.

7 And so this was not a serious  
8 consideration. But it was something we wanted to  
9 look at for completeness.

10 Basically, due to suggestions made by  
11 ACRF in relation to FVTF, they continually ask about  
12 sand and gravel bed filters.

13 They have some attractive characteristics  
14 in that they are passive, high reliability. They  
15 withstand temperatures in a corrosive environment.

16 Their particle-removing efficiency  
17 is high for a broad range of air velocities.

18 But the fact is they operate at low  
19 velocity, meaning they have to be big in general.  
20 They have low mass loading capacity, again, requires  
21 a large surface area.

22 And because of this they tend to be  
23 costly.

24 Evaluation, the conclusions of our  
evaluations is that the loading capacity per unit

1 area is too small for the anticipated melt-through  
2 accidents, such that the relative size and cost  
3 would be prohibitive.

4 We did look at them, however, did  
5 some experimental work and we found that we could  
6 optimize the loading capacity by changing the  
7 aggregate distribution and the superficial gas  
8 velocity by a factor of about two.

9 Therefore, we say that they are not  
10 recommended for situations which require high mass  
11 loading cases.

12 MR. BENDER: Before you get off that subject,  
13 the term prohibitive is hard to deal with in this  
14 discussion.

15 Are we talking about the cost being  
16 some fraction of capital investment plan, or how do  
17 you decide prohibitiveness in this case?

18 MR. MUHLESTEIN: Let me just say for  
19 shortness of time that we costed out a system, for  
20 example, for FFTF for Clinch River, and it looks like  
21 for what we were going to get out of it, that was  
22 just too expensive to put on. There are better  
23 ways to go.

24 MR. BENDER: That is not, since we are  
dealing with an issue here that as a matter of fact

1 is about as important for water-cooled reactor  
2 stores as it is for LMFBR, it is important to know  
3 the absolute terms, what a system like that might  
4 cost.

5 MR. MUHLESTEIN: Okay.

6 MR. BENDER: How you cost them.

7 MR. MUHLESTEIN: I won't tell you what it  
8 is going to cost, but I will tell you how big it is  
9 going to be.

10 A large breeder reactor, for the  
11 sand and gravel bed, would have to be two football  
12 fields in size.

13 Now, people have taken those numbers  
14 and have run them through engineering analyses.  
15 I don't have the numbers, but that is the size.

16 MR. BENDER: And is that because of the  
17 existence of the sodium oxide particles?

18 MR. MUHLESTEIN: That is because of the  
19 large mass loadings, sodium hydroxide aerosols.

20 Now, with light water reactors  
21 there is another problem in terms of magnitude and  
22 rate.

23 MR. CARBON: That was for a thousand mego-  
24 watt size plant.

MR. MUHLESTEIN: I think that in essence, or

93 1 Clinch River.

2 MR. CARBON: When you said a couple football  
3 fields, what is the volume?

4 MR. MARK: The depth?

5 MR. MUHLESTEIN: I believe we are talking  
6 about something like 4.6 feet high and two football  
7 fields.

8 MR. MARK: And there is a football field  
9 at Madison. You can go look at it.

10 MR. MUHLESTEIN: The point is from super-  
11 ficial gas velocity you can back out and get the  
12 size, roughly, as the two football parks, four to  
13 six feet high.

14 MR. BENDER: There is a question of gas  
15 distribution.

16 MR. MUHLESTEIN: That's right. And how  
17 do you feed that to get uniform distribution.

18 As I said, there are more viable  
19 alternatives. Three-stage aqueous scrubler systems,  
20 shown in the photograph, where we have a quench tank,  
21 the red chamber there, then followed by a Venturi  
22 scrubber, and a high efficiency fibrous scrubber to  
23 cool incoming gas to acceptable levels.

24 Most of the material was collected in  
a Venturi scrubber, but you have a wide range of

1 particle size, and the high efficiency fiber scrubber  
2 is intended to take out the small particle size of  
3 that distribution.

4 Shown here we injected sodium iodide,  
5 we missed in to look at the materials.

6 The other system we looked at was  
7 a two-stage system depicted here, in which we removed,  
8 now, the quench tank, and just used a Venturi  
9 scrubber followed by the high efficiency fibrous  
10 scrubber.

11 And I will show you some results.

12 MR. LIPINSKI: Relative to the two  
13 football fields, how many millions of gallons does  
14 that system need?

15 MR. MUHLESTEIN: Small. These units you saw  
16 are now CFM units, and the tanks are what, about four  
17 or five feet in diameter.

18 For FTF system, which is being  
19 installed, I don't remember the capacity. It is  
20 the order, or not very much more than this area,  
21 much smaller.

22 MR. LIPINSKI: The total volume of water,  
23 because you are showing draining that system on a  
24 continuous basis.

MR. MUHLESTEIN: We have it on a drain

1 because we want to collect the material so we  
2 absolutely know what went in and what went out.

3 The FFTF concept is one total  
4 system. I don't remember the volume, but it is  
5 not that big. It is acceptable.

6 MR. BENDER: It is a recirculating system.  
7 You just pump the water out.

8 MR. MUHLESTEIN: You have a big tank and  
9 pump it. You are circulating. You have to worry  
10 about the concentrated sodium hydroxide that is in  
11 that, and from that we can calculate how big it  
12 has to be.

13 Let me show you some tests. Tests  
14 1 through 4 were with a three-component system.  
15 5 through 6 were two-component system.

16 We looked at dry sodium peroxide,  
17 we had sodium oxide, sodium carbonates. Again,  
18 added water to the sodium hydroxide. We tried to  
19 vary the aerosol composition through a wide range  
20 of anticipated numbers.

21 The aerosol concentration, this is  
22 in grams of sodium per standard cubic meter, and so  
23 normally speaking, that is the order of fifty  
24 grams per cubic meter in total airfall concentration.

We try to be specific, and particle

96 1 sizes and the amount of actual material which is  
2 removed.

3 Let me then quickly show you, for  
4 removal of efficiencies for the three-stage system,  
5 loose, you collect some in the duct, the quench tank  
6 for the first fifty-one percent. The majority of the  
7 material is caught in the Venturi scrubber. As I  
8 said, the fibrous scrubber is for the small particle  
9 size material.

10 The point is, this unit, three scrubber  
11 system or two scrubber system, is over 99.9 percent.  
12 We started looking at ninety-five percent. We  
13 would be happy, in fact, it is over 99.9 percent  
14 efficient.

15 We also looked at the very small  
16 particles that would be formed from the sodium iodide.  
17 That is very much different than the big agglomerates  
18 of the sodium oxides and hydroxides. So we took  
19 sodium iodide. But again, the total system is ninety-  
20 nine percent efficient.

21 You see the high efficiency fibrous  
22 scrubber doing its job, picking up.

23 MR. BENDER: What is the nature of the  
24 fiber?

MR. MUHLESTEIN. It is a packed polypropylene

1 fiber.

2 It is a commercially available unit  
3 from Monsanto.

4 The conclusions are that the sodium  
5 removal average, as I said, larger than 99.9 percent.  
6 With the iodine it was again larger than 99 percent.

7 It is independent of the sodium  
8 aerosol composition.

9 The two systems, two or three-stage  
10 systems, are very comparable. However, the two  
11 component system is more sensitive to the flow  
12 conditions, the water flow conditions with the air,  
13 so you have to be a little bit more careful in  
14 the design of that one.

15 We looked at some ducts, too.

16 MR. MARK: If you had a lot of fission frag-  
17 ments in your aerosol, would that fiber scrubber get  
18 into trouble with a heat source there?

19 MR. MUHLESTEIN: We don't think so.

20 The reason I say we don't think so,  
21 we are looking at that. We have to separate effects  
22 tested to tell us, but we think the majority of  
23 material is going to be collected in that system in  
24 the Venturi scrubber anyway.

Obviously if you have large particles

98

1 in the small fiber, it would be very dangerous,  
2 plugs it up very rapidly.

3 But all of the things, most of the  
4 material, even the big stuff and the fission fragments  
5 we think would be caught in the Venturi scrubber,  
6 although we have a separate test.

7 MR. BENDER: That is such a loose term.  
8 If we were to try to define fission fragments, what  
9 would we be saying?

10 MR. MUHLESTEIN: The thing we are looking  
11 at is nonsoluble kinds of materials like plutonium  
12 oxide, uranium oxide. I think we are more interested  
13 in the nonsoluble materials.

14 Soluble materials I don't think we  
15 have any difficulty.

16 MR. BENDER: It is really broken-up fuel  
17 particles.

18 MR. MUHLESTEIN: Yes. Let me turn to the  
19 submerged gravel scrubber. I will show you a picture.

20 In essence, as passive system in the  
21 venting case, again, if you had to purge, there is  
22 no system that is passive there. It is a continuously  
23 washed gravel bed in that the density gradient of  
24 water flow or water slug flow provides a pumping  
mechanism so that you continuously wash the gravel bed.

99 1 And therefore you have large direction  
2 column. In essence, take the main features of an  
3 aqueous unit, the good features of a sand and gravel  
4 bed, merge them together and come up with a passive  
5 unit with a high-volume capacity, and that is what  
6 we did.

7 We add on to that a fiber demister pad,  
8 and the water then entrained from the pool continually  
9 washes that fiber demister pad, and you also have a  
10 positive pressure seal from the water pool.

11 Let me show you the engineering.

12 The engineering model of that system  
13 is shown in the figure here. In essence you have  
14 the gravel bed which is immersed in the pool of water,  
15 the incoming gas stream comes into the bottom, then  
16 back up through the gravel bed.

17 The density difference, I said,  
18 continually washes the gravel bed. The gas again  
19 goes out through the fibrous cylinder, and this  
20 entrained air is enough to keep that fiber bed moist.

21 So again, as far as a vent system  
22 is concerned, it is passive.

23 This shows one demister pad, and  
24 that shows pictorially, too.

Let me show you very quickly --

100

1 MR. BENDER: Does water carryover have an  
2 effect on the filter?

3 MR. MUHLESTEIN: The one up above?

4 MR. BENDER: The polymer.

5 MR. MUHLESTEIN: The packed polypropylene,  
6 it has to be continually washed. But there is no  
7 chemical reactions. We have looked at long-term  
8 chemical reactions.

9 MR. BENDER: Just a matter of whether the  
10 carryover, the mist itself.

11 MR. MUHLESTEIN: If it is too much mist,  
12 too much water entrained.

13 MR. BENDER: Yes.

14 MR. MUHLESTEIN: We have not seen any bad  
15 effects from this. We did several experiments trying  
16 to look at those kinds of things, and as I recall, we  
17 didn't get too much.

18 MR. GOLDEN: If you did, you could just put  
19 it in a cyclon stage and get rid of it.

20 MR. MUHLESTEIN: There are ways around it.  
21 We have looked at a variety of kinds of aerosol  
22 conditions, various sizes in the tests.

23 Again, there is the engineering model  
24 demonstrating feasibility, and one of the first  
questions we had to address, is there enough water

101

1 pumping as a function of the superficial gas velocity  
2 to continuously wash the bed.

3 This is the base case. We say yes,  
4 there is enough pumping. You can wash the bed.

5 What about the pressure drop, because  
6 obviously you want -- you have got the positive pressure  
7 seal, you don't want more than is necessary. So we  
8 look at the pressure drop as a function of the gas  
9 velocity. Actually it turns around and goes back  
10 up, so there is optimum value.

11 There is more data than this now,  
12 but it turns out the removal efficiency is not very  
13 dependent upon the superficial gas velocity. Within  
14 some bands it is all about the same number, and there  
15 is obviously a removal efficiency as a function of  
16 bed height, and we strive to maximize that.

17 Let me show you some test results for  
18 a number of parameters. Again, you notice for just  
19 the submerged gravel scrubber by itself, the removal  
20 efficiency is the order of ninety-nine percent.

21 For a variety of the things like  
22 aerosol type, bed height, packing size, so forth.

23 We add the fiber demister and we get  
24 up to larger than 99.9 percent.

This one was with just a demister pad,

102

1 not the packed polypropylene fibers, but a normal  
2 demister pad.

3 And it did not collect the small  
4 particle size. We really need to go back to packed  
5 polypropylene fiber.

6 In summary, we have done the develop-  
7 ment, eight aerosol tests, seventy-five hours of  
8 total operation. The aerosol removal efficiency  
9 was independent of the chemical form.

10 Aerosol, there was adequate gas cooling  
11 for the inlet gas temperatures up to one hundred  
12 twenty-five.

13 In the big test we have gone up to  
14 higher temperatures and shown there was adequate  
15 cooling in the gas stream.

16 Let me move really to the final thing.  
17 We have gone to a solvent CFM units, which is shown  
18 pictorially here as the large red tank.

19 The inlet gases coming right there,  
20 down through the bottom of the fiber, or through  
21 the gravel bed, bubbles up to the gravel be, out  
22 through two demister pads and out through this exit.

23 We left these two components out.  
24 We didn't want to tear them out until they were  
through with them. And we have tested this large

103 1 unit, and its removal efficiency is larger than  
2 99.9 percent effective with the demister pads being  
3 effective for the very small particle size.

4 MR. BENDER: Excuse me. I don't understand  
5 that system as well as I should. The gravel is submerged  
6 in water to some depth?

7 MR. MUHLESTEIN: That's right.

8 MR. BENDER: And the idea is that you  
9 minimize the pressure drop across the gravel, but  
10 keep enough water there so at least you have to bubble  
11 through some water.

12 MR. MUHLESTEIN: That's correct. We looked  
13 at the bed height, height of water above it, a  
14 variety of parameters to see how this thing operates.

15 It turns out there is a minimum bed  
16 height below which you certainly don't get the  
17 collection efficiency.

18 But the ideal, you see, the collection  
19 method is by the compaction through the voids in the  
20 gravel. So it is like a gravel bed.

21 But the nice thing, it is washed out.  
22 The size of this tank depends on the solubility of  
23 the aerosols in the water. So you can again size  
24 that tank.

For example, this tank here is about

104

1 six feet in diameter, and that is a thousand CFM  
2 unit.

3 You could either go ten times that  
4 for ten thousand CFM unit, or put ten of them in.

5 The point is we have drastically  
6 reduced it from our two football field size down  
7 to something that is manageable in a plant.

8 MR. LIPINSKI: What is the equilibrium  
9 operating temperature in terms of the gas in, gas out?

10 MR. MUHLESTEIN: I am going to have to say  
11 I don't remember.

12 MR. LIPINSKI: Do you have a design target  
13 for highest gas temperature of operating?

14 MR. MUHLESTEIN: One of the tests we are  
15 going to do is heat up the inlet gas by propane  
16 burner to the odor of about twelve hundred degrees  
17 Fahrenheit, and then we will measure the outcoming  
18 gas.

19 For the gas, we don't get very hot  
20 temperatures in large volume, sodium burning, you  
21 get ordinarily on the order of three hundred degrees  
22 Fahrenheit, and the gas coming out here is one  
23 hundred, one hundred degrees Fahrenheit.

24 But the point is I don't have a  
number. We think this is sufficient cooling. That

105 1 test is coming up in a couple weeks. We will  
2 actually heat the incoming gas, get it very hot and  
3 look at the cooling.

4 MR. LIPINSKI: You will have water  
5 evaporation, constant replenishment.

6 MR. MUHLESTEIN: Within some level you would  
7 have to have a makeup system, that's correct.

8 And that leads me to our conclusion  
9 that air cleaning system with high removal efficiency  
10 have been developed which can remove mass loading  
11 anticipated in postulated accident conditions.

12 We have systems that will work. The  
13 submerged gravel scrubber with the high efficiency  
14 fiber scrubber, we think is the best option for  
15 filter/vented containments because of its specificity  
16 and size.

17 MR. BENDER: What kind of gas velocities  
18 go with that submerged gravel filter?

19 MR. MUHLESTEIN: I wish I remembered all  
20 those things.

21 MR. BENDER: I don't want to know exactly.  
22 Roughly?

23 MR. MUHLESTEIN: What are we talking about?  
24 Something like four-tenths of a meter per second.

MR. BENDER: Thank you.

1 MR. MARK: Is that for your thousand CFM?

2 MR. MUHLESTEIN: That was for the smaller  
3 unit.

4 MR. MARK: But you said the thousand CFM  
5 thing had a diameter of approximately six feet.

6 MR. MUHLESTEIN: That is the tank is about  
7 six feet. The gravel bed is about four feet, as I  
8 recall.

9 MR. MARK: You can get the velocity.

10 MR. BENDER: I have to know the void fraction.

11 MR. MUHLESTEIN: I am sorry. I don't have  
12 that number. We have it in the data bank, but I  
13 don't have it upstairs.

14 As the magnitude, it is not supersonic.  
15 It is acceptable. It is not going to pose a problem  
16 to engineers to build that.

17 We are going to build a ten thousand  
18 CFM unit to use, and also demonstrate you don't  
19 need that.

20 MR. BENDER: I think gas distribution in that  
21 system will be an issue, and we need to know better.

22 MR. MUHLESTEIN: It is. Now, what we have  
23 done is we have taken a pie-shaped section of it on  
24 a rather large, we have numbers, about how big, how  
the diameter has to be before you get good distribution.

107 1 As I recall, we could go out to some-  
2 thing like four feet and still get good gas distribu-  
3 tion.

4 If you go much beyond that, what you  
5 would envision in this is a tank with several of these  
6 units in it, sized so you do have good gas distribu-  
7 tion.

8 MR. GAVIGAN: The next speaker is Ravnesh  
9 Amar from the TMC.

10 MR. AMAR: The overall objective in the  
11 inherent evaluation program is to demonstrate that  
12 natural processes substantially limit the radiological  
13 consequences.

14 As Lou indicated before, the significant  
15 activities in this program are the study of sparging  
16 phenomena, the aerosol behavior studies, plugging of  
17 leakage paths, and radiological consequence assessment  
18 studies.

19 In order to determine the radiological  
20 consequences, one needs to evaluate what the source  
21 term is, and the release of solid particles from  
22 boiling or bubbling sodium pools can be as significant  
23 as, say, the gaseous species. Very little work has  
24 been done to date on the release of solid particles.

And so, the objective is to provide

108

1 the data base for characterizing the transport of  
 2 release of solid particles from either the boiling  
 3 pools or the bubbling pool which simulates, which  
 4 can simulate the sodium-concrete reactions.

5 It is intended to achieve this, and  
 6 existing sodium loop at General Electric, and what  
 7 we intend to do is inject Argon gas at the bottom of  
 8 a sodium pool, and you could vary the size of these  
 9 holes to simulate either the boiling phenomena or  
 10 the boiling of gas.

11 The test parameters that have been  
 12 identified as being potentially important for this  
 13 phenomena, gas flow rate, that is as it can affect  
 14 the number of bubbles reaching the sodium pool  
 15 surface; the gas bubble size; the pool height. Pool  
 16 height can affect the length of time the bubbles are  
 17 in contact with the contaminated sodium.

18 Pool temperature; cover gas pressure;  
 19 sodium impurity level.

20 These can affect the dynamics.

21 Bubble as it breaks away from the  
 22 surface; particle size and the particle concentration.

23 Now, the proposed experiment shall be  
 24 designed to be capable of --

MR. BENDER: Could you clarify the source

MILLERS FALLS

FIELD HOUSE

109

1 of the bubbles that are being simulated?

2 MR. AMAR: We will inject Argon gas.

3 MR. BENDER: That is what you are using  
4 to simulate?

5 MR. AMAR: It could be the gas coming  
6 out of the sodium-concrete reactions.

7 MR. BENDER: So it might be hydrogen.  
8 What else?

9 MR. AMAR: Carbon dioxide.

10 MR. BENDER: Maybe some steam?

11 MR. AMAR: The proposed experiment shall be  
12 designed to be evaluating all of the parameters shown,  
13 unless it can be convincingly demonstrated by analysis  
14 or water simulation studies that are in progress  
15 that the particular parameter is not important.

16 There has been only one attempt, one  
17 analyzing attempt, to model the sparging phenomena,  
18 which is the expression for the decontamination  
19 factor, which is the ratio of the concentrations  
20 in the pool to that of in the atmosphere above it.

21 And the proposed experiment shall either  
22 validate this model or maybe indicate improvements  
23 are required.

24 The next item is the aerosol behavior  
studies. The nonvolatiles released in an ACDA soon

110 1 condense to form aerosols. And associated with  
2 these nonvolatiles can be a release of sodium that  
3 burns and adds to the aerosols.

4 Agglomeration and fallout of these  
5 aerosols can potentially result in reductions of  
6 several hours of magnitude in terms of release.

7 So this, the objective of these studies  
8 then is to demonstrate that natural phenomena such as  
9 agglomeration and settling significantly reduce  
10 aerosol concentration.

11 The accomplishments to date, this  
12 mitigation potential, led to significant activity  
13 in the model development and the code development  
14 in the last decade.

15 But in the last year or two, we have  
16 made some significant improvements in the model that  
17 basically has been used for FFTF and CRBR which is  
18 the HAA code.

19 And the basic improvement has been  
20 that we have incorporated a size dependent -- size  
21 dependence of the particle density, as to the  
22 various rate processes that have been shown to be  
23 important for the aerosol behavior studies.

24 And these have been incorporated into  
the HAA code.

111

1 In addition to that, the atmosphere has  
2 been generalized in the sense that now we can vary  
3 the volume and the atmospheric properties, pressure  
4 and temperature as a function of time.

5 Also, advanced computer technology  
6 has been utilized to revise the code structure.

7 Obviously, for these models to be  
8 acceptable, you need to validate these experiments.  
9 And experiments are in progress at containment  
10 systems; test facilities at HEDL and at facilities  
11 at AY.

12 MR. CARBON: Excuse me. The aerosols here  
13 are plutonium aerosols?

14 MR. AMAR: Well, we haven't done any experi-  
15 ments with plutonium.

16 MR. CARBON: What is your objective here?

17 MR. AMAR: The modeling has been mostly  
18 done with sodium aerosols or UO<sub>2</sub> aerosols.

19 MR. CARBON: But this work is aimed at your  
20 source term from fission products and plutonium  
21 products.

22 MR. AMAR: Right.

23 VOICE FROM THE AUDIENCE: In combination  
24 with the sodium oxide as well.

MR. BENDER: Are you covering the whole

12 1 spectrum of an accident, starting out with the  
2 premise that the initial evolution is a large  
3 volume of hydrogen or steam and hydrogen, and  
4 that it changes from one as time goes by to some  
5 different mixture of gases, in order to see all the  
6 ways in which the aerosols are moved out of the  
7 system?

8 MR. AMAR: I would, I am tempted to say  
9 yes, we would.

10 MR. BENDER: Would you postulate?

11 MR. AMAR: The scope of the modeling and  
12 the experimental efforts so far have been narrower  
13 than what you are saying.

14 MR. BENDER: It seems to me that all the  
15 conditions ought to be postulated, and in some  
16 way the experiment should bracket the conditions.

17 And presumably you could do them all  
18 in this kind of test. But I am not sure that we  
19 know what they are yet.

20 MR. MUHLESTEIN: May I answer a question?  
21 Lou Muhlestein from HEDL.

22 As far as verifying the models, we  
23 will in fact look at the full spectrum, including  
24 the sodium aerosols.

We look at the situation where you

13 1 have lots of oxygen in containment to where you go  
2 to a very low oxygen content.

3 We ran a test a couple weeks ago with  
4 one percent oxygen, with sodium vapor as an aerosol.

5 We try to bracket that in the experiments  
6 and see how well this will treat the cases.

7 MR. AMAR: Now, aerosols produced in an  
8 ACDA are typically assumed to leak from the contain-  
9 ment building, as would a gas as one-tenth of one  
10 percent volume per day.

11 Experiments on leakage of these  
12 aerosols, through capillaries, have indicated that  
13 these leak paths tend to plug up. So plugging of  
14 flow paths by deposits of aerosols can play a major  
15 role in reducing these radiological consequences.

16 So the purpose of activities in this  
17 program is to demonstrate that actual aerosol leakage  
18 will be significantly less than currently estimated.

19 Two efforts in this area in the recent  
20 past, a preliminary study was completed to characterize  
21 the leakage paths in a typical LMPR containment shell.  
22 About one hundred seventy different penetrations have  
23 been identified.

24 They have been categorized into several  
major categories; the failure modes identified; and

1 design modifications suggested.

2 The second effort is the modeling  
3 effort, and very modest modeling efforts have  
4 produced a very encouraging result, that the mass  
5 that is transported past a plug can be described  
6 by this expression, before the plug, before this  
7 growing plug plugs up and prevents any further  
8 leakage through the path.

9 MR. BENDER: You are investigating circular  
10 holes?

11 MR. AMAR: That's the assumption at this  
12 time, yes.

13 We are not only assuming -- we are  
14 assuming there is one single plug. That may be a  
15 gross assumption, but I think it does reflect that  
16 a growing plug has a tendency to intercept more  
17 of the aerosol that goes past it.

18 MR. BENDER: I guess I would have to say  
19 that that is unlikely that that is going to be the  
20 form of the leak, if you have one.

21 And I wonder whether that is a valid  
22 basis.

23 MR. AMAR: I said modest efforts have  
24 produced a fairly encouraging result.

MR. MUHLESTEIN: May I also make a comment,

1 that a straight through hole is the worst course.  
2 Where you have a tortuous path, turbulence is  
3 established around the corner. and that tends to  
4 plug up first anyway.

5 MR. BENDER: My only --

6 MR. MUHLESTEIN: The path is going to be  
7 very tortuous, and one can envisualize that is  
8 going to plug up quicker than a straight hole because  
9 of the turbulence around the corners.

10 MR. AMAR: That is going to be true in the  
11 case of concrete buildings where you have penetrations.  
12 Then your path may not be tortuous.

13 Well, just to indicate a success of this  
14 model, I would say, you know, it is encouraging. We  
15 have some data, and it correlates pretty well.

16 MR. MUHLESTEIN: May I add also, we have  
17 some six to ten-inch diameter ducts. We don't under-  
18 stand why it follows that same general, even the  
19 ten-inch diameter ducts seem to follow that curve  
20 as well.

21 MR. AMAR: True.

22 So the future plans in both aerosol  
23 and leakage studies are to continue updating the  
24 HAA code, continue comparison with experiments to  
verify the new models incorporated into this code,

1 perform high density aerosol experiments, determine  
 2 need for additional leakage and plugging tests,  
 3 and lastly, an important effort here called ABCOVE  
 4 means Aerosol Behavior Code Verification Program,  
 5 being coordinated at HEDL.

6 It is an additional effort to  
 7 investigate several aerosol codes, and specify the  
 8 range of validity of each code.

9 And the program would be conducted in  
 10 two phases. In Phase 1 we will have several bench  
 11 mark cases, and those would be run by the six  
 12 different aerosol codes being investigated.

13 And the purpose is to judge the  
 14 adequacy of different aerosol codes.

15 The last activity --

16 MR. MARK: Could you put a time scale on  
 17 that?

18 MR. AMAR: The ABCOVE program?

19 MR. MARK: Is it a year or two years?

20 MR. MUHLESTEIN: It is like a two and a  
 21 half to three-year effort.

22 MR. AMAR: Two and a half to three-year  
 23 effort. And NRC is expected to participate in  
 24 that effort.

In the consequence assessment area,

117

1 a new code called the Cracome code, which stands for  
2 Calculation of Reactor Accidents with effects of  
3 contamination and evacuation code was completed.

4 What this does is merges the more attractive elements  
5 of the NRC Cracome code and Comrade X code with the  
6 addition of some new features.

7           Some of the new features are the Kaselman  
8 boil-off. It gives you the flexibility of putting  
9 in the release of fission products, which is different  
10 from the practice that was in the pool. And most  
11 other codes don't do that.

12           And then it has an improved evacuation  
13 model in the sense that it allowed you evacuation  
14 in the crosswind direction, which other codes don't  
15 do. Plus it allows you to put in a delay time and  
16 a warning time for evacuation.

17           So the overall dose that it calculates  
18 is a function of the initial position, the evacuation  
19 of the velocity, and the angle of evacuation, which  
20 is a new feature.

21           MR. MARK: Do I understand from that that  
22 the new code allows people to move in directions other  
23 than --

24           MR. AMAR: Than the radiant direction.

          MR. MARK: Instead of staying right with

1 the cloud they can get away from it. Cracome is  
2 marvelous in that respect.

3 MR. AMAR: There is no concept, it is just  
4 radiant.

5 MR. MARK: It is in the direction the crowd  
6 goes, too.

7 MR. AMAR: But this gives you an additional  
8 flexibility, cross-ventilation.

9 MR. MARK: Does this code exist?

10 MR. AMAR: It is operational. It exists.

11 MR. MARK: Where?

12 MR. AMAR: HEDL.

13 MR. MARK: You are keeping it there. You  
14 have to go to HEDL to use it?

15 MR. AMAR: It is available.

16 MR. GAVIGAN: Is Cracome in the Argonne  
17 Center yet, but it may state that it may be sent  
18 there.

19 MR. MUHLESTEIN: I think the answer to that  
20 question is yes. I am not totally involved with it,  
21 but I remember, I think it is available. People  
22 are using it. And I don't know why it couldn't be.

23 MR. AMAR: That is my understanding. Very  
24 interesting.

Going back to some of the other things

1 we are looking at in the consequence assessment,  
2 a program to perform an in-depth evaluation of all  
3 the existing models and data base is underway at  
4 Oak Ridge. And one of the objectives of this program  
5 is to identify any additional needs relevant to  
6 breeder safety.

7 So far they have identified needs  
8 in five different areas. They are rather generic, but  
9 the hope is that eventually when the study is completed  
10 we will know the different and the consequent assessment  
11 area, the differences for calculating consequences  
12 with the breeder situation.

13 Another particle in cell model code  
14 is being developed at Oak Ridge. This would take  
15 care of the closing distances.

16 The closing distances also would be  
17 useful for the breeder situation in the sense that this  
18 code is capable of taking care of the chemical reaction  
19 that goes on when you have sodium vapor release and  
20 the reaction is there.

21 Part of the same project is they are  
22 trying to quantify the imprecision in the dose  
23 estimates for various situations.

24 I guess that finishes my talk.

MR. GAVIGAN: Don?

120

1 MR. FERGUSON: In the interest of moving  
2 the meeting along, I am going to use only two or  
3 three of the new graph I have here.

4 The last major part of our program  
5 to be discussed here today is the part we label R&D  
6 integration, and the focus of that effort is to see  
7 that the technology that is developed throughout  
8 the four LOA areas, LOA-1 through 4, is properly  
9 integrated and presented to plant designers in such  
10 a way that they can understand the totality of  
11 implications for their safety considerations in  
12 the plant design.

13 We have three second level products,  
14 the integrated analyses, project support, and  
15 research and development management, the role  
16 performed by the technology management center.

17 In the integrated analyses area,  
18 we do work on generally in three areas: methodology  
19 and data base development; integrated analysis  
20 analysis and risk assessment.

21 The major tasks that we presently  
22 have in lace include the maintenance and assistance  
23 of users of the large codes that have been developed  
24 at Argonne and Hanford and Los Alamos.

We have risk analysis methodology,

121  
1 risk allocation and risk analysis being performed by  
2 General Electric and Atomics International.

3 We have the physical property data  
4 base development work, the actual measurements going  
5 on at Argonne and HEDL and other places outside of  
6 DOE and Oak Ridge National Laboratory, and actually  
7 operating the data base, which is called SACRED.

8 The reliability data base, called  
9 CREDO, that Oak Ridge National Laboratories also  
10 maintains, and then sensitivity studies and methodology  
11 development going on at Argonne and Sanford.

12 Mark Tempe is going to be talking  
13 about the risk analysis methodology and risk allocation  
14 methodology development work following my brief  
15 introduction.

16 Project support then focuses on design  
17 and licensing support, and dissemination of the  
18 safety technology for support of licensing.

19 Several major program tasks here,  
20 actually all of the industrial contractors, are  
21 participating in this effort. It is being funded  
22 at Westinghouse.

23 This is the development of low-risk  
24 design guidelines in support of the standards under  
ANS 5411, to say the major industrial contractors are

1 working along with NRC people in the formulation of  
2 that standard, and analytical work in support of  
3 that has been going on at Westinghouse.

4 A number of contractors, Argonne,  
5 Hanford, General Electric, Westinghouse, Atomics  
6 International, Los Alamos, have done analyses in  
7 support of the large development plant project.

8 Clinch River tasks, the entire program  
9 is meant to be supportive of Clinch River.

10 There are particular tasks that are  
11 identified by Clinch River as being specifically  
12 important at Argonne and Hanford, going on.

13 And then at HEDL we are fabricating  
14 special high enrichment fuel pins for insertion in  
15 special vehicles in the fast flux test facility for  
16 radiation, and these fuel pins will then be available  
17 for testing in TREAT sometime in the post-TREAT  
18 upgrade era.

19 They are special pins in the sense  
20 that we have a variety of designs, and they are also  
21 high enrichment pins which enable us to get better  
22 coupling factors in test reactors, if you will,  
23 a larger difference between the fission density and  
24 the test fuel and the fission density in the reactor  
in the test reactor itself.

1 MR. MARK: Those things we are just referring  
2 to would have to wait for the TREAT upgrade?

3 MR. FERGUSON: They would not necessarily  
4 have to wait for TREAT upgrade, but it turns out that  
5 they will be available at about the same time the TREAT  
6 upgrade becomes operational.

7 MR. MARK: That was nearly three years from  
8 now, two and a half?

9 MR. FERGUSON: That's right. The first,  
10 we hope to have the first of the assemblies of the  
11 high enriched pins, there are a total of ninety-one  
12 pins in each subassembly, the fabrication completed  
13 by the end of fiscal '82.

14 And they, the first of those would be  
15 inserted in FFTF sometime in late '82, for several  
16 cycles of radiation.

17 In order to irradiate these, there is  
18 a special double ducted vehicle that was built, and  
19 between the two ducts are two rows of boron carbide-  
20 filled pins, and that pulls the flux down enough  
21 that you can keep the linear heat rating and these  
22 high enrichment pins within tolerable levels.

23 And there is also special facing to  
24 control the flow of sodium, so it is an expensive  
undertaking.

1 The enrichment level in these pins  
2 goes up to essentially about ninety percent fissile  
3 material in there, but using enriched uranium in  
4 place of the depleted uranium that would normally  
5 go along with the plutonium, so they are very high  
6 enriched pins.

7 MR. CARBON: What kind of safety experiments?

8 MR. FERGUSON: All of the tests that will  
9 be carried out in the advanced treatment, the  
10 large, for use in TREAT upgrading, will require  
11 these enriched pins in order to get adequate coupling  
12 factor in order to get a high enough fission in  
13 those pins in order to be prototypic of starting in  
14 steady state conditions and going from there and doing  
15 accident conditions.

16 With that, I am going to turn it over  
17 to Mark Temme, who is going to discuss then the work  
18 going on at General Electric in the area of risk  
19 allocation and risk assessment methodology development.

20 MR. MARK: You mentioned that some of the  
21 work is directly thought of as supporting licensing  
22 activities. Do you have an idea of when it would be  
23 possible, as you see it, to get a construction permit  
24 for CRBR?

MR. FERGUSON: You have made a rather large

1 jump there. There have been a variety of estimates  
2 made by various parties.

3 I think the Clinch River planning  
4 called for the granting of a limited work authoriza-  
5 tion, from fourteen months after the start of inter-  
6 action. And that allowed for a start-up time for  
7 NCR, et cetera.

8 That is probably at the extremely  
9 optimistic end. NRC estimates twenty-four months  
10 from the time they formally start.

11 MR. MARK: When is this mysterious starting  
12 date?

13 MR. GAVIGAN: It hasn't come. We haven't --  
14 the funding bill for CRBR presently is that the  
15 Senate has fully supported two hundred fifty-four  
16 million, and the House, I think, supported two  
17 hundred twenty-four million, \$30 million reduction.

18 After the conference committee meeting  
19 we will have the money for FY '82.

20 Meanwhile we are doing some preliminary  
21 interactions with regular trying to get them to line  
22 up the personnel on the regulatory side and trying to  
23 help them with R&D.

24 MR. MARK: If that bill stays somewhere  
in the rank you have described and doesn't just get

1 cut out altogether, then this start of the interaction  
2 would perhaps be --

3 MR. GAVIGAN: -- next month or so.

4 MR. MARK: Or the start of fiscal '82?

5 MR. GAVIGAN: Prior to that, as soon as  
6 possible. July, perhaps. We will write a letter  
7 that the NRC shall turn on the process.

8 Meanwhile we are working behind the  
9 scenes to line up the people.

10 MR. MARK: What do you think it is? This  
11 is the month of July.

12 MR. GAVIGAN: You are right. July or  
13 August.

14 MR. MARK: Okay. Thank you.

15 MR. TEMME: As Don mentioned, I am going  
16 to be talking about work both recent and ongoing  
17 work at GE in the area of risk analysis methods  
18 development and some of the applications thereof,  
19 and also risk allocation methods that have been  
20 developed both at Atomics International and GE, in  
21 somewhat separate programs.

22 The risk assessment methods program  
23 objective, the principal one have been to develop  
24 a technical basis for performing credible risk  
assessments of breeder reactors. That has been our

MI  
E  
COTTON CONTENT

127 1 objective since we first started this work in 1974.

2 Additional objectives have come along.  
3 We have not a very large level of effort right now  
4 applied to the establishment of line of assurance  
5 goals, but we are doing a little bit of work on it.

6 And we are doing work in support of  
7 the LVP project by doing risk assessment of the  
8 conceptual design as it evolves. And I am not going  
9 to go into that because we covered that in a previous  
10 presentation to this committee just a couple of  
11 months ago.

12 Since we are methods development  
13 program, one might ask what needs to be developed.

14 And out of our own experience, the  
15 attempts at applications of risk assessment techniques  
16 as well as the experience expressed in the Louis  
17 Committee Report, there are some needs to improve  
18 risk assessments in certain areas.

19 Scrutability is a popular term since  
20 Dr. Louis issued his report. That means principally  
21 to us, to define this in clear, straight-forward  
22 mathematical terms, how you get from the input to the  
23 output.

24 And it wasn't all that totally clear  
in some of the earlier applications. That probably

1 is the only one of these technical challenges which  
2 has something like a nice, neat closed mathematical  
3 solution.

4           The development of methodology to  
5 address these other issues, it appears to me, is  
6 primarily a matter of trying things, seeing what  
7 seems to work, and getting agreement and consensus  
8 among the users that yes, it works, and they want to  
9 use it. And ultimately getting the same kind of  
10 agreement and consensus between the users and the  
11 reviewers.

12           I would be talking more about what we  
13 are doing in this area.

14           Completeness, of course, is another  
15 issue that Dr. Louis and others have mentioned. The  
16 statement has been made, we are not so much worried  
17 about what you have in the risk assessment as what  
18 you have left out of it.

19           Within our framework of doing things,  
20 the completeness issue probably, the initiating event  
21 completeness and radiological release category  
22 completeness, questions are at least to me the most  
23 bothersome.

24           The way we do our risk calculations  
implies, at least, that we have collectively exhausted

129  
1 a set of accident initiating events, and collectively  
2 exhausted the set of radiological release categories.

3 I don't know of any formal proof of that.  
4 I think the things that we do, somewhat systematically  
5 to give ourselves assurance that we are achieving  
6 that objective, are things like the use of deductive  
7 logic; that is, to lay out what you want to see at  
8 the end of the problem and then try to ask yourself  
9 how many ways can I get there.

10 Specifically, this would start by  
11 dividing up the range of possible consequences into  
12 discreet intervals and work your way back.

13 That, of course, is a principal of  
14 Foulrey logic and it does help you achieve completeness,  
15 perhaps, a little better than the inductive logic,  
16 which is related to failure modes and effects analysis.

17 And I am not trying to say that that  
18 should not be used, by the way. But, on the other  
19 hand, one can get quite involved in looking at all  
20 the possible ways a given accident scenario can go  
21 without considering how many of those ways contribute  
22 significantly to the final result of the risk analysis.

23 So when we are looking for completeness,  
24 it seems to me that principally the use of deductive  
logic is your best bet for a solution.

130

1 At the same time, I want to add here  
2 that we don't -- we aren't attempting, at least in  
3 our approach to risk analysis, to quantify the  
4 things we have never thought of. It just doesn't  
5 make sense to us.

6 So whatever we do in the way of risk  
7 assessment, we will always have a constraint on it.  
8 It can only include those events and the consequences  
9 from those events that we are able to conceive of.

10 Lack of data is brought up as a  
11 problem with risk assessment. To me it is kind of  
12 a subordinate issue.

13 I think the real question is what is  
14 the right way to use the data that we have. One of  
15 the questions that we always have, if we are able to  
16 use the data that we have correctly, is do we need  
17 more of it.

18 But I think in principle, one of the  
19 major reasons for doing risk assessment is that that  
20 is a way of dealing with the lack of data.

21 We have uncertainty, and that leads us  
22 into doing risk assessment.

23 We also would like to find ways in  
24 which people can estimate probabilities in a  
consistent fashion. And that certainly is a difficulty

131

1 when we find people using the same information and  
2 producing probability estimates that are orders of  
3 magnitudes apart.

4           Again, I think there is a certain  
5 amount of systematic approach that we can take to  
6 this. But ultimately I think it is a matter of defining  
7 the rules in a way that is acceptable to both the  
8 performers of the risk assessment and the reviewers  
9 of the risk assessment.

10           Estimation of uncertainty really goes  
11 together with probability estimation in my view,  
12 because it has the same problems. And there I mean  
13 specifically rather than inputting to a risk model  
14 single point values of the risk probability, we should  
15 be working in distributions representing uncertainties  
16 on failure rates and so forth. So we approach both of  
17 these problems at the same time.

18           Then, in the risk models themselves,  
19 which are at least summarized normally in the form of  
20 event trees, we have to deal with uncertainties about  
21 accident progression. Do we have enough understanding  
22 of basic phenomena to get all the branches in the  
23 event tree. ~~STENT~~

24           People at least raise questions,  
particularly regarding the sequence of events following

1 a severe core damage accident or a core melt.

2 I don't really think the problem is  
3 as undual as some people suggest, but at the same  
4 time I think we need a significantly better structure  
5 for defining the possible courses of events and  
6 assigning probabilities to them.

7 And the only way to get it that I can  
8 conceive of is to get deeply involved in the problem  
9 and see how you can solve it. I don't know of a  
10 mathematical solution.

11 System interactions and common cause  
12 failures are somewhat related. The issue there is  
13 one of dependencies of failure probabilities. For  
14 example, the probability of shut-down system  
15 failure for the same system may be quite different  
16 depending on whether the initiating event is a small  
17 reactive accident or a one g earthquake.

18 And as you work your way through an event  
19 tree logic, all of the subsequent event possibilities  
20 really are in principle dependent upon what went  
21 before.

22 Modeling this system interaction, it  
23 is not so terribly hard to realize where they are,  
24 but it is a practical problem. It seems to me, because  
it can swamp you in enormous detail to get them all into

1 the risk model.

2 So the key here I think is to find a  
3 way of using practical judgment so that you model  
4 the ones that are important and you don't model  
5 the ones that aren't important.

6 And that comes principally with  
7 experience.

8 The quantification of common cause  
9 failure probabilities has been a very bothersome  
10 issue since Wash 1400, and still is to my knowledge.

11 In my last discussssion with the NRC,  
12 or at least some of the NRC people who work on them  
13 things, I ask them what are you doing about it now  
14 that the square root law is no longer in favor.

15 And they said, well, we don't really  
16 know what to do about it.

17 The only thing I think we can do about  
18 it is to try to use systematic approaches to identify  
19 dependencies, because that is what it is all about.  
20 And the assignment of the failure probabilities  
21 corresponding to those dependencies may turn out in  
22 a lot of cases to be fairly subjective, in which case  
23 the best thing to do, I think, is to evaluate the  
24 sensitivity of the conclusion to the subjective inputs.

Quantification of the effects of human

134 1 factors, I think, if we do this, we will be able to  
2 include both positive and negative impacts on risk,  
3 due to having operators present.

4 And some of the more simplistic  
5 studies that we have been doing, for example, we  
6 make an assumption that if decay heat removal is  
7 lost, it never can become restored, which is a  
8 very unreasonably conservative assumption.

9 If we were to try to factor into the  
10 picture the likelihood that operators will find  
11 some way to restore a heat sink at some time, we  
12 could improve the risk.

13 There are also, of course, negative  
14 effects on risk that one ought to take into account.  
15 We hope to get a little bit into this during our  
16 fiscal year '82 work.

17 We have done nothing specific about  
18 it in the program so far.

19 Now, we got into the risk allocation  
20 applications because we felt that if we are going  
21 to be calculating risk, that the calculation  
22 should be something more than just after-the-fact  
23 windowdressing; that in fact we should be finding  
24 some way of using that information to influence what  
we do in the design.

1 So, this structure describes the, at  
2 least in block diagram form, the logic that GE uses  
3 in its risk allocation.

4 And I will show you a summary of the  
5 AI approach, which is a little bit different.

6 Basically, we treat the risk allocation  
7 problem as a constrained optimization problem. We are  
8 searching for a design configuration within the  
9 choices that we have available, which meets a given  
10 risk constraint at minimum cost.

11 And one can argue at great length about  
12 what should be included in cost for this purpose.  
13 I will mention what we include, or have included in  
14 our application so far.

15 Cost model has to identify for each  
16 of the safety-related design options, an associated  
17 cost, and an associated reliability, because these  
18 are the reliabilities, particularly are the kind of  
19 numbers that go into the event tree model.

20 We have, in our only application of  
21 this technique so far, included in cost only two  
22 elements. First, a kind of development cost, and  
23 plant capital cost.

24 And the former of those would also  
include cost of reliability demonstration. The logic

1 that we have applied to limiting the cost to those  
2 two was simply we were focusing on CPS, which is  
3 a one-of-a-kind developmental plant. And it was  
4 our assumption that what we would want to minimize  
5 was not necessarily the overall cost of electrical  
6 generation from that plant, but the cost of getting  
7 it built and on-line.

8 Now, one can put different costs into  
9 this process, depending on what seems important at the  
10 time. Certainly, if we were trying to design a  
11 family of commercially -- plants we intended to make  
12 commercial, we would want to be optimizing the total  
13 cost of electrical generation.

14 The risk model that we use is an  
15 event tree model, and it is very similar to the one  
16 that we use in our risk assessment. We try to keep  
17 it a little simple and cut down on the number of  
18 events and event tree branches by sticking with those  
19 which are dominant.

20 But we find we are able to use a  
21 fairly large model, say, fifteen or so initiating  
22 events, without getting into any severe problems  
23 with respect to the calculation costs.

24 The risk criteria, which expresses the  
safety limit that we have been using for this, for

137  
1 these applications, is the Wash 1400 results for a  
2 single light water reactor plant, which expressed  
3 the risks of acute facilities, latent facilities and  
4 property damage.

5 And the rationale for that is simply  
6 that we are trying to achieve with this plant  
7 comparable risk to a typical LWR.

8 It is certainly not a presumption that  
9 the risk that is expressed by Wash 1400 has some  
10 formal acceptance, or that it should. It is just  
11 that we are trying to equal it with our design.

12 We have a computerized algorithm which  
13 takes all of these inputs, and since we are dealing  
14 with a discreet number of possibilities, we are  
15 able to use, rather than a continuous optimization  
16 scheme, a branch and bound technique, which assures  
17 us that we have not found a false optimum.

18 We are in principle, at least, we  
19 order from beginning, from highest cost to lowest  
20 cost, all of the design options which meet the risk  
21 constraint. And we take that with the lowest cost.

22 In practice, because of the nature of  
23 the relationship between cost and risk, we are using --  
24 we can save a lot of computer time. we don't really  
have to specifically calculate the costs and the risks

1 of all the options.

2 Now, this is one form in which we  
3 display the results of our allocation analysis. It  
4 is not as complicated as it looks at first glance.

5 For the problems we have been running,  
6 we have with each design option or each category of  
7 design option, we have put in only two alternatives.

8 It might be a high or low reliability,  
9 or to include or not include the particular design  
10 feature.

11 So the ones and twos represent low-cost  
12 options is number one, and two is high-cost option.

13 And we found this particular sensitivity  
14 analysis to be helpful to us in gaining insights on  
15 what is going to reduce risk.

16 All we have done here is simply reduce  
17 the risk limit criteria from its true value, which is  
18 the Wash 1400 curves, by different factors. So the  
19 particular answer that is the optimum configuration  
20 that just meets the Wash 1400 criteria for this case,  
21 happened to be one in which we were able to accept  
22 the low-cost option for all of these design questions,  
23 and the higher cost options for just these two.

24 Now, if we, due to a risk limit which  
is ninety percent of the original one, we find that

139

1 we don't use these two any more, but we introduce  
 2 this one, this one, the particular choice in this  
 3 column happened to be the choice between a reinforced  
 4 concrete containment building and a coolable steel  
 5 building.

6 The key there was that the second one  
 7 was coolable. And therefore, there is a way of preventing  
 8 containment failure if you have a core melt.

9 And the picture that this conveys is  
 10 that over a wide range of variations of the risk  
 11 limit itself, this comes up as having significant  
 12 potential to reduce risk.

13 MR. LIPINSKI: What is the difference between  
 14 option three and seven? There is no digits changing  
 15 in that table.

16 MR. TEMME: The differences between options  
 17 three through seven, what this says is if you go to a  
 18 risk limit that is ninety percent of the Wash 1400  
 19 curve, in fact, you can go clear down to one that  
 20 is fifty percent of it, and this design option will  
 21 suffice in meeting that risk constraint. And it is  
 22 still the cheapest way to do it.

23 MR. LIPINSKI: What do I interpret from  
 24 your table, because each horizontal line is the same  
 for three, four, five, six. And I see a reduction

140 1 taking place in the right column.

2 MR. TEMME: The reduction is not of the  
3 calculated risk, but of the risk limit. That is the  
4 criteria.

5 MR. GAVIGAN: That is the goal.

6 MR. TEMME: That is the goal.

7 MR. LIPINSKI: What does your table tell me?  
8 I only see one and two and three. I go to four and I  
9 see the same entries horizontally.

10 MR. TEMME: What that says is that you can  
11 reduce the risk limit, the criterion, by a factor of  
12 two, and still meet it with this particular design  
13 configuration at optimum cost.

14 So it tells you something about the  
15 robustness of the choice.

16 MR. LIPINSKI: I am with you. It is not  
17 until you get to eight that you have to pick another  
18 option.

19 MR. TEMME: Then you have to begin adding  
20 more. If you go down far enough you will have all  
21 of them in and you still won't be able to meet the risk  
22 in.

23 MR. LIPINSKI: I notice you didn't carry that  
24 to where everything was a two.

MR. TEMME: No, we didn't. There was no --

141 1 MR. LIPINSKI: You have only got a factor  
2 of ten from top to bottom, from 1 to .1.

3 MR. GAVIGAN. The next step then is zero.

4 MR. LIPINSKI: The question is do you pick  
5 up another ten?

6 MR. TEMME: Use the same increment.

7 There are other ways in which we have  
8 tried to display the results of this, because to  
9 really get information of this kind of analysis,  
10 obviously there is a lot of subjective inputs to  
11 this, and we felt that the useful thing is to try  
12 to see how sensitive the conclusions you get from it  
13 are to the things you are very uncertain to it.

14 We have done a lot of systemic sensitivity  
15 analyses. And there is one of them which seems informa-  
16 tive to me.

17 Now, I am going to go to risk allocation  
18 approach that Atomics International has developed  
19 and applied, and summarize that.

20 It is a little bit different from ours  
21 in some ways, although in general it is an optimization  
22 scheme with a constraint.

23 Candidate plants are selected via a  
24 screening procedure. A candidate plant here is one,  
one per mutation, or one combination of all of the

1 possible combinations of different safety design  
2 features that exist.

3 And I think they have typically had  
4 several hundred of these possible combinations, if  
5 I remember correctly.

6 They use some screening procedure, for  
7 example, if you have two choices, both of which  
8 produce the same risk, but one of them is less  
9 costly than the other, then you can throw out one of  
10 them and leave it out of the rest of the analysis.

11 They calculate risk and cost for all  
12 candidate plants, and their measure of the cost is  
13 energy generation costs rather than just the plant  
14 capital cost or development cost.

15 There is also a transformation of risk  
16 into a dollar unit which they are using, so they can  
17 actually calculate a cost benefit ratio, whereas we  
18 keep risk in units of consequence.

19 And then as we do, they perform  
20 sensitivity analysis to see how the conclusions from  
21 it stand up under the uncertainties.

22 There also is a formal alternative  
23 analysis in which we input probability distributions  
24 on cost and reliability and see how that affects the  
decisions.

1 And then they are choosing roughly the  
2 minimum generation cost within the safety objective.

3 The risk model, I won't try to go  
4 through all the details of this, but just to give you  
5 a concept of the level of detail and the way the risk  
6 model is used, this is essentially the risk model that  
7 is used in the AI allocation approach, although there  
8 is a lot of analysis behind arriving at these probability  
9 numbers.

10 Severe core damage can occur with a  
11 failure to shut down, or failure to remove decay  
12 heat. So these are the respective frequencies of  
13 these two events.

14 And then you have an accident that either  
15 progresses through generic failure of containment,  
16 or through the melt-through kinds of scenarios.

17 And this is the model that relates  
18 risk to a particular design configuration, since  
19 each design configuration has specific probabilities  
20 for these branches.

21 Now, the result of the AI risk alloca-  
22 tion, this kind of plot where there is energy genera-  
23 tion cost and it is actually a relative cost compared  
24 to a reference, differential cost from a reference,  
and this is risk expressed in relative dollar units,

1 actually, percent of reference energy costs.

2 The result looks like this. The  
3 result is actually a whole series of points, each  
4 one corresponding to a particular configuration.

5 The envelope of those, the lower  
6 envelope looks like this, and has the character: cics  
7 of going back up.

8 If you go far enough out on the risk  
9 scale, because one of the elements of cost is the  
10 cost of making repairs after the accident. So you  
11 find that if you are allowing enough accidents to  
12 happen, your risk is going up and your cost is going  
13 up as well.

14 So you can see, you can get different  
15 looking results here, depending on what you choose  
16 as an element of cost in the allocation process.

17 This line represents the strict risk  
18 limit. And another criterion used by AI is a cost  
19 benefit criterion. That is, hey want the slope of  
20 the cost-to-risk curve to be less than -- it is  
21 greater than ten. That is the point right here.

22 Now, these particular goals came  
23 from the AI risk allocation, and were input to  
24 the CDS conceptual design studies, just to give you a  
feeling for the kinds of numbers that derive from it.

1 And since the results of the GE risk allocation come  
2 at a slightly different level of detail, we wanted to  
3 compare our risk allocation results with AI risk  
4 allocation results at one point.

5 So we tried to summarize ours in the  
6 same framework. And this, this actually is the  
7 result of the GE risk allocation. They are not vastly  
8 different from those coming out of the AI one, with  
9 the exception of the probability of melt-through  
10 failure containment.

11 Again, this is not a calculation of the  
12 performance of the plant. This is a calculation that  
13 gives you an objective for the design of the plant.

14 If each of these is achieved, you would  
15 be able to meet the risk goal, and in principle, at  
16 a minimum cost.

17 I am going to shift gears at this  
18 point to talk about some of the risk analysis methods  
19 development work that we are involved in at CE, and  
20 particularly a thing we have called the single plant  
21 risk model.

22 This relates to the development need  
23 under the heading of scrutability that I mentioned  
24 earlier, or at least I view it in those terms.

The principal idea here is to try to

1 write down a mathematical statement which can allow  
2 someone to pick up a risk report and understand what  
3 you have done with the inputs to get the output.

4 At the same time, having to do that  
5 causes you to -- forces you to think about what  
6 assumption you have made in order to get the mathematical  
7 statement.

8 So we have found it somewhat enlighten-  
9 ing to try to do this because it makes us realize at  
10 least a couple of the important assumptions that  
11 have been made in doing risk analyses.

12 We got started on this principally  
13 because we found a need to derive a logical  
14 relationship between initiating event frequencies and  
15 probabilities, and that is simply because the informa-  
16 tion that we normally deal with about the occurrence  
17 of initiating events is information about their  
18 average rate of occurrence over some period of time.

19 But the thing that we want to calculate  
20 in a risk calculation is a probability, so one has  
21 to ask himself how do you transform from frequency  
22 to probability. And that turned out to be a less  
23 simple question than it might appear at first, although  
24 there is a variety of ways of making such a transforma-  
tion. Each of them implies a certain set of assumptions.

1 Also, we found it convenient, and  
2 not altogether unrealistic to make this assumption.  
3 This is the equivalent of the assumption that sometimes  
4 is made in reliability evaluations of no replacement.  
5 This simply says if an event occurs that has off-site  
6 consequences, that at least for the purpose of this  
7 risk model, operation of that plant is assumed to  
8 terminate.

9 Now, of course, we hope that that is  
10 not true in reality. And there are ways of dealing  
11 with it in a risk model to represent reality.

12 For example, one could view the  
13 restart of a badly damaged plant as a new decision  
14 requiring a new risk analysis. There are other  
15 ways to do it, too.

16 The model also allows you to consistently  
17 treat uncertainties in the input and propagate them  
18 clearl through the analysis so we can actually  
19 consider risk analysis in the risk curve, and in  
20 keeping with the fact that this is part of LOA integra-  
21 tion, I had to put up something that had integrals  
22 in it.

23 This is what we mean when we refer to the  
24 single plant risk model.

Specifically, the calculation that we

1 are trying to do is the probability that the  
2 consequence of operating the plant exceeds some  
3 value for a discreet set of values. If we plot  
4 all of these we get the complimentary cumulative  
5 distribution of consequence.

6 There is a conditional probability,  
7 conditioned on operation of the plant for a given  
8 time, and  $L$  represents that time.

9 Normally, the time that we use  
10 is one year, but it also could be the plant lifetime.  
11 for example, or some other period of time.

12 You have the formal equation is  
13 simply this. This term is the probability of  
14 exceeding a given level of consequence for a given  
15 period of operation, and for a given vector, which  
16 represents the long run relative frequency of  
17 consequences in each interval. And that has to be  
18 developed further.

19 I will go into that a little bit. The  
20 integration is an integration over all the uncertainties  
21 and all the inputs.

22 Well, what I can do is not go into  
23 all of the details of the rest of these equations.  
24 My principal reason for showing them in the first  
place was so that people would have a concept of

1 what we mean when we talk about a single plant model.

2 I want to point out that numerically  
3 it is not all that different from what you have seen  
4 before. In fact, this term right here is very close  
5 to a mathematical expression of the risk model that  
6 was used in Wash-1400.

7 If you expand this exponential in a  
8 Taylor series, and the exponent is small, which is  
9 turns it is, you get precisely what Wash-1400 did.

10 So we have a way of relating this nicely  
11 expressed mathematical model to the one we used in  
12 Wash-1400, and elsewhere.

13 Of course, we also have expanded it  
14 to specifically include the uncertainties.

15 And one thing I wanted to point out,  
16 that in order to get that point, we made an assumption  
17 which is implicit in Wash-1400; that is, initiating  
18 events for model, improbability of occurrence in  
19 initiating events is modeled by a Poisson probability  
20 method. That is what we are doing currently, although  
21 we have not investigated the appropriateness of that  
22 model, nor have we yet looked into what will  
23 if we change the model.

24 I will skip this one on uncertainty  
and go a little bit on results.

1 This is a typical input into this  
2 model. Instead of having a single number called  
3 probability of failure to remove decay heat, we  
4 have a distribution which represents our uncertainty  
5 about that number.

6 And this is also an initiating event,  
7 dependent probability, these two, this one would apply  
8 to initiating events which tend to not damage the  
9 decay heat removal function.

10 The other two have some potential for  
11 doing that. These are dominated largely by seismic  
12 events. In fact, this one by a very large seismic  
13 event.

14 And finally, there is a result. Now,  
15 the actual answer that is the result of that first  
16 integral equation is this curve labeled mean.

17 The other curves are percentiles in  
18 the uncertainty distribution, or more strictly, they  
19 are conditional probability distributions conditioned  
20 on the corresponding percentiles and the inputs.

21 Now, since we are a methods development  
22 program, and the kind of methodology that we are  
23 developing isn't one that you tie up all nice in a  
24 computer code, we always have this nagging question  
of how do we know when we are through, because the

131  
1 major part of the development is done by gaining the  
2 experience in trying to find out what works well.

3 That caused us at one point to focus  
4 on writing a procedural manual. We thought that if  
5 we are able to do that in a way that we think is  
6 intelligent, and people find a way to use it, then  
7 we ought to say we are through.

8 We took a stab at that a few years ago  
9 and got some review and comments on it. And we weren't  
10 totally satisfied with it for various reasons.

11 We have not gotten back to reissuing  
12 that as yet, or trying to do it again.

13 Meanwhile, there is a very large  
14 national effort to write something similar for  
15 application to light water reactors, specifically  
16 to the NREP studies. And so it seems logical to us  
17 to first interface with that effort in some way as  
18 a reviewer of their product, and a provider of  
19 suggestions and so forth.

20 And if at the end of that there  
21 still seems to be a need for us to do more in this  
22 area to tie up our effort, we will get back to our  
23 procedures manual.

24 Now, I also wanted to mention, this  
really, the point of these comments probably should

1 have been on a different viewgraph, not under the  
2 heading of finishing the development, but the main  
3 point I want to make here is we came to the conclusion  
4 fairly early that it was hard to know when our  
5 methodology was adequate without knowing what it is  
6 to be used for.

7 You can endlessly perfect the way you  
8 do a calculation, if you don't have in mind what kind  
9 of decision someone is going to make with the numbers.

10 We also conclude from that, then,  
11 that the need, the methods development needs are  
12 a little different in each of these major areas of  
13 application. Design safety management is essentially  
14 addressed by the risk allocation type of analysis.

15 And those are not results that you  
16 have to prove in a licensing environment. They are  
17 to guide the designer into a product that he then has  
18 to prove in a licensing environment.

19 He can assume a lot of approximations.  
20 R&D management is more or less the same.

21 So the point is we need to define the  
22 ultimate decisions that are to be made with the  
23 calculations in order to know when the calculations  
24 are good enough.

Now, at the same time, I find myself

153

1 recently telling people who are working on safety  
2 goals that you can't define a safety goal in the  
3 absence of a definition for how you do the calcula-  
4 tions.

5 So what I am trying to say is the  
6 two must go together very closely.

7 Now, I had two charts here at the end  
8 which make reference to the work that we have done  
9 on quantification of line of assurance goals. And  
10 we are doing, currently, a very small amount of work  
11 just to demonstrate how one might go back to that, to  
12 see if it is at all credible and worthwhile.

13 We will be discussing what we find  
14 from that with the TMC, and if they feel that some  
15 systemic way of quantifying the line of assurance  
16 goals is of value to them in making their decisions,  
17 we may do more work on it.

18 That is all I have.

19 MR. BENDER: One question. Excuse me.

20 MR. MARK: Go ahead.

21 MR. BENDER: I don't have any real problem  
22 with the approach you are suggesting. As a matter  
23 of fact, it looks to me like this kind of risk alloca-  
24 tion is about the only way to play the game.

But the information requirements to the

ZERASE

1 risk assessment still seem to be very vague. There  
2 is a lot of subjective judgment in the assignment of  
3 risk.

4 And I don't see very much of that in  
5 this discussion.

6 How do we decide what information is  
7 needed to do the risk analysis?

8 MR. TEMME: Probably one reason you don't  
9 see it in there is I don't think I have a real good  
10 answer to that.

11 I have directions, I think, we should  
12 explore. I think in general you have to carry the  
13 details of your system reliability models and your  
14 models for core disruptive accident progression and  
15 so forth, to a level which would allow you to input  
16 information from SASCOV results, or SIMER, or  
17 structural analysis results, and there will be  
18 subjective judgments made. I don't think that can be  
19 avoided.

20 The only thing that you can do is  
21 try to make them at a level at which it is feasible  
22 to get agreement on them.

23 But really I do think this is a  
24 process that will, if it works at all, will require  
agreement on subjective judgments at some level. I

155 1 don't think that can be avoided.

2           And if we really can't handle that,  
3 we aren't going to use PRLA, I believe. I think,  
4 I think we can become accustomed to dealing with that,  
5 and derive areas of agreement so that we don't have  
6 to argue endlessly about every single probability  
7 number and every risk assessment. It may take a  
8 while.

9           MR. BENDER: Let me take a couple areas  
10 and then I will stop.

11           One is the question of how much R&D  
12 is necessary in order to establish a risk basis,  
13 and where do you put the R&D at?

14           MR. TEMME: That we probably can treat a  
15 little bit more informally. And in fact, that is  
16 really essentially what we are trying to do with  
17 this whole angle quantification exercise.

18           MR. BENDER: The other question is who is  
19 authorized to make subjective judgments?

20           MR. TEMME: I think we all are.

21           MR. MARK: Who is excluded?

22           MR. BENDER: That is not a minor issue.

23           MR. TEMME: No, it is not.

24           MR. BENDER: The difficulty is nobody has  
been excluded up to now, and somehow or other you have

156 1 to have a hierarchy of authority in deciding what  
2 risks to take.

3 MR. TEMME: Yes. This is the kind of  
4 concern that has led some people to talk about such  
5 a thing as a science court or a risk verification  
6 panel. And both of those concepts bother me a great  
7 deal, but I do agree that it is an unresolved question.

8 MR. MARK: I am glad you asked your question  
first. You will be able to answer my two.

10 On the slide you didn't show, there is  
11 a nice acronym, WBS. I am not familiar with it.

12 MR. TEMME: Work Breakdown Structure, and  
13 that refers to level one, level two and level three,  
14 which you have seen earlier in a number of viewgraphs.

15 MR. MARK: And another question, I presume  
16 from what you said Bernaro and Rosem at NRC are  
17 familiar with the work you have described here.

18 MR. TEMME: They probably are not as familiar  
19 with it today as you are. They know, they have been  
20 in this business, and I know Frank has had numerous  
21 discussions with them over the years of what we are  
22 doing.

23 But we haven't had any sort of formal  
24 presentation like this.

MR. MARK: You know who they are.

OTTCIP CONTENT

157

1 MR. TEMME: Indeed. I know them both pretty  
2 well. And I talk to them. But we haven't gone through  
3 any presentation of this work.

4 MR. GAVIGAN: They know our work and they  
5 get our reports.

6 MR. TEMME: That is true.

7 MR. MARK: Maybe even I get the reports, but  
8 that doesn't close any loop, necessarily.

9 MR. BENDER: I have one on my desk, about this  
10 thick, from GE.

11 MR. CARBON: Any other questions of Dr. Temme?

12 I have a general question, Frank. Do  
13 you have anything in your program on the effects of  
14 different environments on instrumentation?

15 MR. GAVIGAN: No. We do have, of course,  
16 as I mentioned, a division that does components and  
17 instrumentation development for normal operation.

18 That group does a little bit of work  
19 on environment, but not on access environments. There  
20 is work now starting, I think the CRBR project office  
21 is letting a number of RFP's down throughout the  
22 country to develop performance data in environments  
23 for a number of their components.

24 MR. GOLDEN: Frank, tangentially you would  
get into this NNMI area if you get into censored

158  
1 allegation.

2 MR. GAVIGAN: Right. But we don't have  
3 any work of that type now.

4 MR. LIPINSKI: That doesn't fall into MMI.  
5 It falls in NUREG 197, which says you will have  
6 adequate instrumentation.

7 MR. GOLDEN: All I am saying is censor  
8 validationis well recognized prior to the MMIF that  
9 you people talk about, in the NMFBR, NMF plant.

10 MR. LIPINSKI: Not in the same sense, having  
11 an accident and then verify is the censor working.  
12 You are looking at it more from an operational  
13 standpoint, whereas the accident case is special.

14 MR. CARBON: A second, general question.  
15 I think we found in the LWR area earlier we treated  
16 things too much independently and didn't pay enough  
17 attention to systems integration, systems interaction  
18 and so on.

19 Is there anything in your program  
20 that is oriented in that aspect, that concept, that  
21 these are systems that function together and have to  
22 worry about how one system interacts with another?

23 MR. GAVIGAN: I think the risk study does  
24 that for us. It is a total system study, because  
it does consider systems' interactions and how one

159 1 failure affects the other, and for normal operation.

2           However, we have systems' performance  
3 codes, you have heard about those, all in demo  
4 code 4 CRBR, it talks about normal performance, and  
5 special codes developed for FFTF are YONIS, with  
6 some special in-core modifications to help give  
7 system performance, but not plant performance.

8           Overall the plant is considered in the  
9 risk analysis.

10           MR. CARBON: Any other questions anyone  
11 would like to raise?

12           MR. BENDER: Let me comment for a minute  
13 on what Frank just said.

14           In order to use this risk approach  
15 that has been described here, you have to have, for  
16 systems' interaction purpose, you have to have a lot  
17 of knowledge about explicit hardware.

18           As a matter of fact, you have to have  
19 the discreet system defined.

20           MR. GAVIGAN: Right.

21           MR. BENDER: So that means you have to start  
22 with equipment that exists. Is that being done or  
23 has it been done?

24           MR. GAVIGAN: Demo is a word that was  
coined for the Clinch River plant for those components,

1 and YONIS, and it is core modification of COBRA is  
2 developed specifically for FFTF, its geometries,  
3 its pressure drops, its flows, its dimensions in  
4 core.

5 MR. LIPINSKI: Frank, you are not talking  
6 about the same thing. Those codes do analyze the  
7 systems.

8 The interactions we are talking  
9 about take a balance of plant air system that is  
10 connected to the instruments, and somewhere there  
11 is a connection with a water system that uses that  
12 air in a mixing valve. And somebody shoved the  
13 water up the air line and knocks out all the instruments.

14 Now, that is two systems that are  
15 interacting because somebody put a common valve in  
16 that that lets the water into the air system.

17 MR. GAVIGAN: That has been changed.  
18 The ACDF study, by having the overall study performed  
19 by GE and AI, and Stone and Webster did a balance  
20 of risk study on interaction between balance of plant  
21 and reactor system itself, as well as effect of fires,  
22 flood and other items in the DOP.

23 And it is a special method F & W used  
24 for their light water reactor plants, also. So I can't  
say specifically that one issue you mentioned is done.

161

1 But we have looked at it.

2 MR. LIPINSKI: It is those type of inter-  
3 actions that are put into these plants, if anything  
4 works, everything is fine. But if they go sour and  
5 you see an interaction you are not expecting where a  
6 water line will knock out your whole instrument  
7 air system.

8 MR. BENDER: I am not so impractical as  
9 to assume that they found everything. But just the  
10 idea that they have gone through the process I think  
11 has some merit.

12 MR. GAVIGAN: It always has merit. It is  
13 interesting, when we first started, FME, with FTF  
14 Clinch River four years ago, sort of forced the  
15 contractor into doing it, when they started doing  
16 it, it is amazing the things they found in simple  
17 analysis weren't quantitative, but were qualitative.

18 When it was presented to the designer  
19 he made a change simply to make material in design.  
20 It is difficult to quantify, but we know the designer  
21 feels much better about the capability of that  
22 system to perform.

23 There were a lot of changes like  
24 that in Clinch River.

MR. CARBON: Well, let us thank you, Frank,

162  
1 and your colleagues. You have given us a wealth of  
2 very worthwhile material, and I think it is going to  
3 be very useful to us.

4 This will end the formal portion of  
5 the meeting. This afternoon the key members and  
6 consultants will continue to meet to have discussion  
7 with future plans.

8 This is open. No one needs to stay.

9 On the other hand, if anyone wishes to,  
10 they are certainly invited. We don't need to keep  
11 transcripts this afternoon.

12 Unless there is anything else to bring  
13 up, we will adjourn this portion of the meeting.

14

15 (WHICH WERE ALL THE PROCEEDINGS  
16 HELD THIS DAY.)

NUCLEAR REGULATORY COMMISSION

This is to certify that the attached proceedings before the

\_\_\_\_\_

in the matter of: ACRS-SUBCOMMITTEE ON ADVANCED REACTORS

Date of Proceeding: July 15, 1981

Docket Number: \_\_\_\_\_

Place of Proceeding: Chicago, Illinois

were held as herein appears, and that this is the original transcript thereof for the file of the Commission.

Leslie Sherman
