

January 27, 1994

Mr. Thomas E. Tipton  
Nuclear Management and Resources Council  
1776 Eye Street, NW  
Suite 300  
Washington D.C.

Dear Mr. Tipton:

The United States Nuclear Regulatory Commission (NRC) will conduct a public workshop on March 31, 1994 to discuss a draft maintenance inspection procedure developed for use by NRC inspectors to verify the implementation of the Maintenance Rule requirements. The effective implementation date of the Maintenance Rule is July 10, 1996. The workshop will be held on March 31, 1994, at the Holiday Inn Crown Plaza, Rockville, Maryland.

I am enclosing a copy of the NRC press release announcing this workshop and a copy of the "Draft Maintenance Inspection Procedure XXXX" for your information. Please disseminate these to your members to ensure proper notification. Notification of this workshop will also be published in the Federal Register of February 1994, Nuclear News magazine, and The Nuclear Plant Maintenance Newsletter.

Should you have any questions regarding this workshop, please call Richard Correia at (301) 504-1009.

FOR IMMEDIATE RELEASE  
(Thursday, January 26, 1994)

NRC STAFF PLANS WORKSHOP ON  
MAINTENANCE RULE INSPECTION PROCEDURE

The Nuclear Regulatory Commission staff has scheduled a workshop for Thursday, March 31, to discuss a draft maintenance procedure which is being developed for use by NRC inspectors to verify implementation of NRC requirements governing maintenance at NRC-licensed nuclear power plants. The NRC's maintenance requirements are contained in Part 50 of the Commission's regulations and are to become effective on July 10, 1996.

The workshop will be held at the Holiday Inn Crowne Plaza, 1750 Rockville Pike in Rockville, Maryland 20852. It is scheduled to begin at 9 a.m. and run through 5 p.m.

Prior to finalizing the inspection procedure, the staff believes that it would be beneficial to obtain public comment on the document from all interested parties and the March 31 workshop is planned for that purpose. Participants will be encouraged to ask questions and provide written comments on the procedure during the workshop. In addition, other written comments from parties unable to attend the workshop will be accepted through April 14. The workshop will conclude with a summary of the major issues identified at the session as well as a discussion of the planned use of the procedure during pilot inspections.

In order to assure that adequate seating is available, persons planning to attend the workshop are requested to either to call or complete a registration form and forward it, by March 25, to Thomas Foley, Office of Nuclear Reactor Regulation, Nuclear Regulatory Commission, Washington, D.C. 20555; telephone: 301.504-1036.

A group of rooms has been reserved at the Holiday Inn Crowne Plaza (1-800/638-5963) for the convenience of meeting attendees. These rooms will be available at a reduced group rate until March 9 and, when requesting rooms, attendees should mention the workshop and the number 4093 to assure the group rate. The hotel will collect a ten dollar fee at registration or the morning of the workshop to cover the costs of morning and afternoon refreshments.

A copy of a memorandum from Gary E. Zech to Elizabeth S. Yeates dated January 25, 1994, with the draft inspection procedure "Maintenance Inspection Procedure XXXXX" attached has been placed in the NRC's Public Document Room located on the lower level of the Gelman Building at 2120 L Street, N.W. in Washington, D.C. The telephone number is 202/634-3273.

4  
5 MAINTENANCE INSPECTION PROCEDURE XXXXX

6  
7  
8 PROGRAM APPLICABILITY: 2515

9  
10  
11 XXXXX-01 INSPECTION OBJECTIVES:

12  
13 01-01 To verify the implementation of 10 CFR 50.65, "Monitoring the  
14 Effectiveness of Maintenance at Nuclear Power Plants" (the maintenance rule or  
15 the rule), which will take effect on July 10, 1996.

16  
17 01-02 To verify the effectiveness of emergency diesel generator (EDG)  
18 maintenance activities associated with commitments made in response to 10 CFR  
19 50.63, "Loss of All Alternating Current Power" (the station blackout (SBO)  
20 rule).

21  
22  
23 XXXXX-02 INSPECTION REQUIREMENTS<sup>1</sup>:

24  
25 There are three steps in the inspection requirements section. The inspector  
26 should perform steps 02.01 and 02.03 at each nuclear power site, and has the  
27 option of performing step 02.02 depending on the results of step 02.01. The  
28 inspector should perform step 02.02 if the results of the reviews and  
29 inspections performed in step 02.01 indicate that licensee maintenance  
30 activities may not be effective. If these reviews and inspections indicate  
31 that maintenance activities are effective, then step 02.02 need not be  
32 performed at that site. (However, step 02.02 will be performed at all plants  
33 inspected during the pilot inspection program).

34  
35 02.01 Evaluate Maintenance Effectiveness. Perform onsite inspection of the  
36 condition of plant SSCs and review equipment history records and other  
37 available documentation in order to determine if the licensee's maintenance  
38 program is effectively controlling the performance and condition of SSCs at  
39 that plant.

40  
41 02.02 Verify Implementation of the Maintenance Rule. Perform the following  
42 reviews to verify the licensee's implementation of the maintenance rule.

- 43  
44 a. Goal Setting and Monitoring, 50.65(a)(1). Verify that the licensee has  
45 implemented goal setting and monitoring as required by paragraph (a)(1) of

---

46 <sup>1</sup>The items listed in this section are not necessarily regulatory  
47 requirements unless explicitly stated. They are also not necessarily  
48 inspection requirements; the inspector may select some or all of the items  
49 listed for review, depending on the intended scope of the inspection and the  
50 resources the region has allotted for the inspection.

DRAFT

(inspection requirement 02.02 cont.)

1 the maintenance rule. The licensee is required by the rule to perform the  
2 following:

- 3
- 4 1. Monitor the performance or condition of SSCs against licensee  
5 established goals in a manner sufficient to provide reasonable  
6 assurance that such SSCs, as defined in 10 CFR 50.65(b), are capable of  
7 fulfilling their intended functions.
- 8
- 9 2. Establish goals commensurate with safety and, where practical, take  
10 into account industrywide operating experience.
- 11
- 12 3. Take appropriate corrective action when the performance or  
13 condition of an SSC does not meet established goals.
- 14

15 b. Preventive Maintenance, 50.65(a)(2). For those SSCs that are within  
16 the scope of the rule (see step 02.02.d below) but are not monitored under  
17 paragraph (a)(1) of the rule, verify that the licensee has demonstrated the  
18 following:

- 19
- 20 1. Performance or condition of an SSC is being effectively controlled  
21 through the performance of appropriate preventive maintenance so that  
22 the SSC remains capable of performing its intended function; or,
- 23
- 24 2. The SSC is inherently reliable or of low risk significance and,  
25 therefore, preventive maintenance is not required.
- 26

27 c. Periodic Evaluation, 50.65(a)(3). Verify that the licensee is  
28 performing the evaluations and assessments required by paragraph (a)(3) of  
29 the maintenance rule. The licensee is required by the rule to perform the  
30 following:

- 31
- 32 1. Evaluate performance and condition monitoring activities and  
33 associated goals and preventive maintenance activities at least every  
34 refueling cycle, provided the interval between evaluations does not  
35 exceed 24 months. The evaluations shall take into account, where  
36 practical, industrywide operating experience.
- 37
- 38 2. Make adjustments where necessary to ensure that the objective of  
39 preventing failures of SSCs through maintenance is appropriately  
40 balanced against the objective of minimizing unavailability of SSCs  
41 because of monitoring or preventive maintenance activities.
- 42
- 43 3. Assess the total plant equipment that is out of service and  
44 determine the overall effect on the performance of safety functions of  
45 performing monitoring and preventive maintenance activities.
- 46

47 d. Scope of the Rule, 50.65(b). Verify that the licensee has identified  
48 those SSCs that are required to be within the scope of the maintenance rule  
49 as defined in paragraph 50.65(b) of the rule.

50

51 02.03 Effectiveness of Emergency Diesel Generator Maintenance Activities.  
52 Verify that the licensee, as part of its maintenance program, has evaluated  
53 the reliability of emergency diesel generators and that this maintenance  
54 program satisfies the commitments made by licensees in response to 10 CFR  
55 50.63, the station blackout rule. In some instances, depending on the

XXXXX

# DRAFT

1 commitments made by the licensee, the NRC may perform the inspections  
2 described under this section of the inspection procedure (02.03) before the  
3 implementation date (July 10, 1996) of the maintenance rule.  
4

5  
6 XXXXX-03 INSPECTION GUIDANCE

7  
8 General Guidance

9  
10 Implementation Guidance: Except when the licensee proposes an alternate  
11 method for complying with specified portions of the maintenance rule, the  
12 methods described in Regulatory Guide 1.160, "Monitoring the Effectiveness of  
13 Maintenance at Nuclear Power Plants," May 1993 (Ref. 1), will be used to  
14 evaluate the effectiveness of maintenance activities of licensees who are  
15 required to comply with the maintenance rule. The regulatory guide will also  
16 be used to evaluate the effectiveness of emergency diesel generator  
17 maintenance activities associated with compliance with 10 CFR 50.63 (more  
18 information on emergency diesel generator testing is contained in Generic  
19 Letter [GL number to come later]. This regulatory guide endorses NUMARC  
20 93-01, "Industry Guideline for Monitoring the Effectiveness of Maintenance at  
21 Nuclear Power Plants," May 1993 (Ref. 2), and provides methods acceptable to  
22 the NRC for complying with the maintenance rule. The inspector should become  
23 familiar with Regulatory Guide 1.160 and NUMARC 93-01 before initiating this  
24 inspection. The inspector should also be aware that licensees may use methods  
25 other than those described in NUMARC 93-01 to satisfy the requirements of the  
26 maintenance rule.  
27

28 Differences Between Plants: Differences in plant design (i.e., system  
29 boundaries), even among plants that have the same nuclear steam supply system  
30 (NSSS), can result in significant differences in the number and types of SSCs  
31 included under the scope of the rule. The types of goals and monitoring  
32 established at different plants may also differ significantly between similar  
33 plants. Therefore the inspector should not put too much emphasis on comparing  
34 one plant to another when evaluating maintenance activities under the rule.  
35 The inspector should verify that licensees are evaluating maintenance and  
36 equipment problems at plants with similar NSSS designs to identify possible  
37 generic problems.  
38

39 Requirements vs. Acceptable Methods: The specific guidance that follows was  
40 derived from information contained in the maintenance rule (10 CFR 50.65), the  
41 statements of consideration (SOC) for the rule, the regulatory guide, and the  
42 industry guideline (NUMARC 93-01 (Ref. 2)). Reference was made to the source  
43 document, where possible, in order to help the inspector differentiate between  
44 the guidance that represents regulatory requirements and guidance that is  
45 optional. In general, anything that is stated in the rule itself is a  
46 requirement. The SOC contains information that could be used to clarify the  
47 intent of the rule. Information derived from the regulatory guide and the  
48 referenced industry guideline provides optional, acceptable methods for  
49 complying with the rule and is not to be considered a regulatory requirement.  
50 If the licensee chooses not to implement the maintenance rule in accordance  
51 with the regulatory guide and the industry guideline, then the licensee must  
52 demonstrate that the alternate methods satisfy the requirements of the rule.  
53

54 Assignment of SSCs to (a)(1) or (a)(2): Paragraph (a)(1) of the maintenance  
55 rule requires that goal setting and monitoring be established for all SSCs  
56 within the scope of the rule except for those SSCs whose performance or  
57 condition is adequately controlled through the performance of appropriate

(general guidance cont.)

1 preventive maintenance as described is paragraph (a)(2) of the rule. The  
2 industry guideline for implementing the rule, NUMARC 93-01, has taken the  
3 approach that all SSCs are initially placed under paragraph (a)(2) and are  
4 only moved under paragraph (a)(1) if experience indicates that the performance  
5 or condition is not adequately controlled through preventive maintenance.  
6 However the rule does not require this approach. Licensees could also take  
7 the approach that all (or most) SSCs would be handled under paragraph (a)(1)  
8 of the rule and none (or very few) would be handled under paragraph (a)(2) of  
9 the rule. Licensees have the option of taking either approach.

10  
11 Appendix B Not Applicable to Non-Safety-Related SSCs: The scope of the  
12 maintenance rule (10 CFR 50.65(b)), includes both safety-related SSCs and non-  
13 safety-related or balance-of-plant (BOP) SSCs. As stated in Regulatory Guide  
14 1.160 (Ref. 1), it is understood that BOP SSCs may have been designed and  
15 built with normal industrial practices that may not have met the criteria in  
16 Appendix B to 10 CFR Part 50. The inspector should understand that it is not  
17 the intent of the maintenance rule to require licensees to generate paper work  
18 to document the basis for the design, fabrication, and construction of BOP  
19 equipment. However, all requirements of Appendix B remain in effect for  
20 safety-related SSCs that are within the scope of the rule.

## 21 Specific Guidance<sup>2</sup>

22  
23  
24 03.01 Evaluate Maintenance Effectiveness. Sources of information that could  
25 provide insight on the effectiveness of a licensee's maintenance program  
26 include: SALP reports, licensee event reports, NRC inspection reports,  
27 equipment maintenance history records, plant performance reviews, reliability  
28 and unavailability data, equipment performance or condition trending data, and  
29 performance indicator data collected by licensees to meet the requirements for  
30 goal setting and monitoring contained in the maintenance rule.

31  
32 The inspector shall review a sample of available documented information that  
33 could provide insight on the effectiveness of the licensee's maintenance  
34 activities. The inspector should select a balanced sample which includes:  
35 active and passive systems; mechanical, electrical, instrumentation and  
36 controls systems and components; and structures. The inspector shall also  
37 tour the plant and perform a walkdown inspection of the condition of SSCs at  
38 the licensee's facility. During these inspections the inspector should look  
39 for signs of leakage, corrosion, excess vibration, loose fasteners or other  
40 conditions that could indicate inadequate maintenance. The inspector should  
41 also discuss the plant operating history with licensee personnel responsible  
42 for operation and maintenance of the plant. If, based on these initial  
43 reviews, it appears there may be a need to perform further reviews of a  
44 licensee's implementation of the maintenance rule, the inspector should  
45 proceed by performing the inspection requirements in Section 02.02 of this  
46 procedure.  
47

48 <sup>2</sup>The specific guidance adds information intended to clarify the  
49 inspection requirements listed in the Inspection Requirements section (XXXXX-  
50 02). To correlate the guidance with its associated requirement, the numbered  
51 designations used in the Specific Guidance section correspond to the numbers  
52 used in the Inspection Requirements section. For example, Section 03.01.a.1  
53 provides specific inspection guidance for Inspection Requirement 02.01.a.1.

1 03.02.a. Goal Setting and Monitoring 10 CFR 50.65(a)(1). The licensee is  
2 required to set goals and monitor the performance or condition for all SSCs  
3 selected or required to fall under paragraph (a)(1) of the rule.  
4

5 1. Monitoring: The rule requires that licensees monitor performance or  
6 condition of SSCs in a manner sufficient to provide reasonable assurance  
7 that SSCs are capable of fulfilling their intended functions. This wording  
8 is intentionally non-prescriptive and is intended to allow licensees  
9 considerable flexibility in the methods used to monitor SSC performance or  
10 condition.  
11

12 (a) Risk Consideration in Monitoring: The statements of consideration  
13 (Ref. 4) and the regulatory guide (Ref. 1) state that the extent of  
14 monitoring may vary from system to system depending on the system's  
15 importance to risk (or safety). This determination may be quantitative  
16 or qualitative. Section 9.0 of NUMARC 93-01 (Ref. 2) provides guidance  
17 on various methods for establishing which SSCs are risk significant.  
18 These methods include the use of individual plant examination (IPE)  
19 results, plant-specific probabilistic risk assessment (PRA), preventive  
20 maintenance program results, and others. Guidance is also provided on  
21 the use of risk importance measures such as risk reduction worth, core  
22 damage frequency contribution, and risk achievement worth. The  
23 licensee may use other methods to determine the risk-significance of  
24 SSCs.  
25

26 The inspector should verify that the licensee has considered risk when  
27 determining the extent of monitoring required. To accomplish this, the  
28 inspector should select a sample of SSCs that are within the scope of  
29 the maintenance rule and, using the licensee's own criteria, determine  
30 if the licensee has identified those SSCs that are risk-significant.  
31 The inspector should verify that the monitoring for these risk  
32 significant SSCs is commensurate with their importance to plant risk.  
33

34 (b) Monitoring at the Plant, System, or Train Level: It is expected  
35 that most monitoring should be done at the plant, system, or train  
36 level, although some monitoring at the component level may be  
37 necessary. The three examples listed below are taken from the  
38 regulatory guide (Ref. 1):  
39

40 (1) For less-risk-significant systems, indicators of system  
41 reliability (where sufficient performance data exist) and  
42 availability may be all the monitoring that is necessary (i.e.,  
43 monitoring the reliability and availability of the overall system  
44 provides adequate indication of the performance of the individual  
45 components).  
46

47 (2) For more-risk-significant systems, some parameter trending may  
48 also be required for critical components whose unavailability or  
49 failure could cause a system train to be unavailable, or whose  
50 failure is otherwise unacceptable.  
51

52 (3) For other SSCs, rather than monitoring the many SSCs that  
53 could cause plant scrams, the licensee may choose to monitor  
54 unplanned scrams as an indirect means of monitoring performance.  
55

56 Additional guidance on acceptable methods of performing monitoring is  
57 described in Section 9.4.2. of NUMARC 93-01 (Ref. 2).

(specific guidance 03.02.a. cont.)

1 Having reviewed records and spoken with personnel, the inspector should  
2 verify that the licensee has established and implemented adequate  
3 performance or conditioning monitoring for all SSCs within the scope of  
4 the rule.  
5

6 (c) Use of Existing Programs for Monitoring: The regulatory guide  
7 (Ref. 1) states that it is intended that most activities currently  
8 being conducted by licensees, such as technical specifications  
9 surveillance testing, can be used to satisfy many of the monitoring  
10 requirements; and, consistent with the rule, the inspector should allow  
11 licensees maximum flexibility in establishing and modifying their  
12 monitoring activities. Additional guidance on the use of existing  
13 programs for monitoring is described in Section 9.4.2 of NUMARC 93-01  
14 (Ref. 2). Although licensees are free to initiate any new activities  
15 they believe necessary to ensure that SSCs are adequately monitored,  
16 the inspector is cautioned not to expect licensees to establish many  
17 new activities to satisfy the requirements of the maintenance rule.  
18

19 2. Goal Setting: Paragraph (a)(1) of the rule requires licensees to  
20 establish goals commensurate with safety and, where practical, to take into  
21 account industrywide operating experience. Licensees have a great deal of  
22 flexibility in choosing goals and may elect to choose component-, train-,  
23 system-, or plant-level goals. These goals may be performance oriented  
24 (reliability, availability) or condition oriented (such parameters as pump  
25 flow, pressure, vibration, valve stroke time, current, electrical  
26 resistance). Licensees should document the bases for the goals and any  
27 subsequent changes made to those goals. Guidance on documentation is  
28 provided in section 13.2.1 of NUMARC 93-01 (Ref. 2). The rule specifically  
29 states that the goals are to be "licensee established." Therefore, the  
30 inspector should allow licensees maximum flexibility in establishing and  
31 modifying their goals. However, the goals must represent reasonable  
32 attempts to establish targets for monitoring SSCs within the scope of the  
33 rule. Licensees should consider the following when setting goals:  
34

35 (a) Risk Consideration for Goal Setting: The rule specifically  
36 requires licensees to establish goals commensurate with safety (or  
37 risk). Information on an SSC's contribution to plant safety can be  
38 obtained from various sources including the Individual Plant  
39 examination (IPE) or probabilistic risk assessment (PRA) results (if  
40 available). Section 9.0 of NUMARC 93-01 (Ref.2) provides guidance on  
41 acceptable methods for establishing risk-significant criteria. These  
42 methods include the use of risk reduction worth, core-damage frequency  
43 contribution, and risk achievement worth. Licensees may use these or  
44 other methods to determine risk significance.  
45

46 The inspector should select a sample of SSCs for which the licensee has  
47 established goals and verify, by reviewing licensee records and  
48 speaking with responsible personnel, that risk or safety was taken into  
49 account when establishing goals.  
50

51 (b) Operating Experience for Goal Setting: The licensee should also,  
52 where practical, take into account industrywide operating experience  
53 when establishing goals. Sources of industrywide operating experience  
54 include, but are not limited to, NRC bulletins and information notices,  
55 the Institute of Nuclear Power Operations (INPO) Nuclear plant

(specific guidance 03.02.a. cont.)

1 reliability data system (NPRDS), vendor technical information letters  
2 (TILs), and vendor service information letters (SILs). Although a  
3 great deal of failure information is available in the industry in  
4 various forms, the availability, accessibility, and usefulness may be  
5 limited. In view of these limitations, the inspector should not expect  
6 the licensee to be able to identify all failures of similar SSCs in the  
7 industry when reviewing industry operating experience.  
8

9 The inspector should verify that the licensee has established and  
10 implemented a documented method or process for considering industry  
11 operating experience, where practical, when establishing goals.  
12

13 3. Corrective Action: Licensees are required to monitor the performance  
14 or condition of SSCs against the established goals and take appropriate  
15 corrective action where the goals are not met or where a clearly declining  
16 trend in SSC performance or condition indicates the goals would not be met  
17 before the end of the next surveillance cycle. Where analysis determines  
18 that the performance or condition of the SSC is acceptable, the licensee  
19 may elect to modify the original goals and continue monitoring.  
20

21 The inspector should select a sample of maintenance monitoring records and  
22 compare them to the established goals. Where goals were not met, or where  
23 a clearly declining trend in SSC performance or condition is indicated, the  
24 inspector should examine the licensee's corrective actions to determine if  
25 the root cause was identified, if reasonable corrective action was taken,  
26 and if an evaluation of the effectiveness of the corrective action was  
27 performed. Licensee activities such as root cause analysis and corrective  
28 actions must be documented by the licensee.  
29  
30

31 03.02.b. Preventive Maintenance, 50.65(a)(2). The maintenance rule states  
32 that monitoring as specified in paragraph (a)(1) is not required if it has  
33 been demonstrated that the performance or condition of an SSC is being  
34 effectively controlled through the performance of appropriate preventive  
35 maintenance so that the SSC remains capable of performing its intended  
36 function. The statements of consideration (SOC) (Ref. 4) clarify that  
37 licensees are not required to monitor under paragraph (a)(1) of the rule  
38 if they have demonstrated that preventive maintenance has been effective or  
39 if an SSC has inherently high reliability and availability as discussed below.  
40

41 1. Demonstrated Effective Maintenance: As stated in the SOC, under the  
42 terms of paragraph (a)(2), preventive maintenance must be demonstrated to  
43 be effective in controlling the performance or condition of an SSC so that  
44 the SSC remains capable of performing its intended function. In order to  
45 assure that preventive maintenance is effective, some evaluation or  
46 monitoring process needs to be established under paragraph (a)(2).  
47

48 (a) Performance Criteria: NUMARC 93-01 (Ref. 2) introduced the use of  
49 performance criteria as a method of demonstrating satisfactory  
50 performance or condition under paragraph (a)(2) of the rule. Where the  
51 performance or condition is not adequately controlled, the SSC would  
52 generally be dispositioned to paragraph (a)(1). Section 9.3.2 of  
53 NUMARC 93-01 recommends that performance criteria should be  
54 availability, reliability, or condition. It also recommends that  
55 specific performance criteria be established for all risk-significant

(specific guidance 03.02.b. cont.)

1 SSCs and for non-risk-significant SSCs that are in a standby (not  
2 normally operating) mode. Plant-level performance criteria would be  
3 established for all remaining non-risk-significant, normally operating  
4 SSCs. Performance criteria would not be required for SSCs determined  
5 to be inherently reliable<sup>3</sup> or for those SSCs that contribute little or  
6 nothing to safety function and that could be allowed to run to failure  
7 (i.e., perform corrective maintenance rather than preventive  
8 maintenance).  
9

10 (b) Maintenance-Preventable (Functional) Failure: Section 9.4.5 of  
11 NUMARC 93-01 (Ref. 2) recommends the use of the term "maintenance  
12 preventable functional failures (MPFFs)" rather than "maintenance  
13 preventable failures (MPFs)" as described in the SOC, in order to  
14 differentiate between failures that cause an SSC to be incapable of  
15 performing its intended function and failures that do not affect an  
16 SSC's function. There are many possible failures of some SSCs that  
17 would not affect the intended safety function of the system.  
18

19 (c) Dispositioning from paragraph (a)(2) to paragraph (a)(1): The SOC  
20 (Ref. 4) states that it is expected that where one or more maintenance  
21 preventable failures (or MPFFs) occur on SSCs treated under paragraph  
22 (a)(2), the effectiveness of preventive maintenance is no longer  
23 demonstrated. As a result, the SSC would be required to be treated  
24 under the requirements of paragraph (a)(1) until such time as a  
25 performance history is established to demonstrate that performance or  
26 condition are once again effectively controlled by an established  
27 preventive maintenance regimen. Section 9.4.4 of NUMARC 93-01 (REF. 2)  
28 provides additional guidance on determining when dispositioning SSCs  
29 from paragraph (a)(2) to paragraph (a)(1) would be required. This  
30 would generally be required if a performance criterion were not met or  
31 if a repetitive MPFF occurs. The inspector should note that an SSC  
32 could continue to be treated under paragraph (a)(2) after experiencing  
33 a single MPFF if the root cause evaluation determined the cause of the  
34 failure and if the corrective action that was taken prevented  
35 recurrence. However if a second, repetitive, MPFF occurred, then the  
36 SSCs would have to be dispositioned to paragraph (a)(1). Once an SSC's  
37 preventive maintenance has been demonstrated effective again, it would  
38 be acceptable to return to treating the SSC under paragraph (a)(2).  
39 Section 9.4.3 of NUMARC 93-01 (Ref. 2) provides guidance for  
40 dispositioning SSCs from paragraph (a)(1) to paragraph (a)(2).  
41

---

42 <sup>3</sup>The statements of consideration (Ref. 4) describe the purpose of (a)(2)  
43 of the maintenance rule as to provide an alternate approach for those SSCs  
44 where it is not necessary to establish the monitoring regime required by  
45 paragraph (a)(1). This provision might be used where an SSC, without  
46 preventive maintenance, has inherent reliability and availability (e.g.,  
47 electrical cabling) or where the preventive maintenance necessary to achieve  
48 high reliability does not itself contribute significantly to unavailability  
49 (e.g., moisture drainage from an air system accumulator). NUMARC 93-01,  
50 sections 9.3.3 and 10.2 (Ref.2), describe an inherently reliable SSC as one  
51 that, without preventive maintenance, has high reliability (e.g., jet shields,  
52 raceways).

(specific guidance 03.02.b. cont.)

1 The inspector should verify that the licensee has established and  
2 implemented some monitoring or assessment process for determining if the  
3 preventive maintenance program is effectively maintaining the reliability  
4 of those SSCs (except for inherently reliable SSCs described below) that  
5 are maintained exclusively under paragraph (a)(2) of the maintenance rule.  
6 The inspector should review the maintenance history for a sample of SSCs  
7 maintained under paragraph (a)(2) to verify that the monitoring or  
8 assessment process ensures that acceptable performance or condition of the  
9 SSCs is maintained and, where that performance or condition degrades to an  
10 unacceptable level or experiences a second maintenance preventable failure,  
11 the SSC is treated under paragraph (a)(1) until such time as the  
12 performance or condition improves to an acceptable level. The inspector  
13 should select a sample of SSCs that experienced maintenance preventable  
14 functional failures and review the licensee's actions to determine if they  
15 were dispositioned properly.  
16

17 2. Preventive Maintenance Not Required: As indicated in the SOC (Ref. 4),  
18 the purpose of paragraph (a)(2) of the rule is to provide an alternate  
19 approach for those SSCs where it is not necessary to establish the  
20 monitoring regimen required by paragraph (a)(1). This includes those SSCs  
21 that are adequately controlled by preventive maintenance (described above)  
22 and those SSCs that are inherently reliable without maintenance (described  
23 below), or those SSCs that are of low risk significance (described below):  
24

25 (a) Inherently Reliable: This provision might be used where an SSC,  
26 without preventive maintenance, has inherent reliability and  
27 availability (e.g., electrical cabling) or where the preventive  
28 maintenance necessary to achieve high reliability does not itself  
29 contribute significantly to unavailability (e.g., moisture drainage  
30 from an air system accumulator). It is expected that many structures,  
31 such as cable raceways, water storage tanks, and buildings, could be  
32 considered inherently reliable. However, it should be noted that such  
33 activities as inspections, surveys, and walkdowns could be considered  
34 maintenance activities and, therefore, most SSCs would be subject to  
35 some maintenance. Therefore, the concept of identifying inherently  
36 reliable SSCs as those that require no maintenance may be of limited  
37 usefulness. Licensees should document their reasons for concluding  
38 that certain SSCs are inherently reliable.  
39

40 The inspector should review the documentation for a sample of SSCs that  
41 have been determined to be inherently reliable, verify that the  
42 licensee's determination appears reasonable, and that the SSC's  
43 condition or performance is acceptable without maintenance.  
44

45 (b) Low Risk Significance: Methods for determining risk (or safety)  
46 significance are described in NUMARC 93-01, section 9.0 (Ref. 2). As  
47 described in NUMARC 93-01, section 9.3.3 (Ref. 2), SSCs that contribute  
48 little or nothing to system safety function could be allowed to run to  
49 failure (i.e., perform corrective maintenance rather than preventive  
50 maintenance). To accomplish this, the licensee should establish  
51 appropriate criteria for determining if SSCs have low risk significance  
52 and should use these criteria to identify SSCs that could be allowed to  
53 run to failure. Licensees should document these criteria and their  
54 reasons for deciding that individual SSCs could be allowed to run to  
55 failure.

(specific guidance 03.02.b. cont.)

The inspector should select a sample of these SSCs and evaluate them to verify that the licensee has followed its own criteria for determining low risk significance and that these evaluations are reasonable.

03.02.c. Periodic Evaluations, 50.65 (a)(3). The licensee is required by paragraph (a)(3) of the maintenance rule to perform the following periodic assessments and evaluations:

1. Refueling Cycle Evaluation: The rule requires that licensees evaluate performance and condition monitoring activities and associated goals and preventive maintenance activities at least every refueling cycle, provided the interval between evaluations does not exceed 24 months. The SOC (Ref.4) states that these activities are to be evaluated in light of SSC reliabilities and availabilities as well as the following:

(a) Goals and Monitoring: For SSCs under paragraph (a)(1), adjustments are to be made to goals, monitoring, or preventive maintenance activities when equipment or performance has not met established goals. Conversely, the licensee may, at any time, eliminate the monitoring activities initiated in response to problematic equipment performance or industry experience once the root cause of the problem has been corrected and the adequacy of the equipment performance has been confirmed.

On the basis of a review of records and discussions with responsible personnel, the inspector should verify that the licensee has reviewed goals, monitoring, and preventive maintenance activities and made adjustments, where necessary.

(b) Preventive Maintenance: For SSCs under paragraph (a)(2), adjustment of preventive maintenance activities may be warranted where SSC availability is judged to be unacceptable. SSCs treated under paragraph (a)(2) which experience repetitive maintenance- preventable functional failures (MPFFs), become subject to the requirements of paragraph (a)(1) or, where this is not feasible, may require other remedial action, such as modification or replacement.

On the basis of a review of records and discussions with responsible personnel, the inspector should verify that the licensee has adjusted preventive maintenance activities where necessary and dispositioned SSCs that experienced repetitive MPFFs to the requirements of paragraph (a)(1).

(c) Operating Experience: The maintenance rule also requires that the evaluations shall take into account, where practical, industrywide operating experience. Sources of industrywide operating experience include, but are not limited to, NRC bulletins and information notices, the INPO NPRDS, vendor technical information letters (TILs), and vendor service information letters (SILs).

The inspector should verify that the licensee has established and implemented a documented method or process for considering industry operating experience when performing evaluations.

(specific guidance 03.02.c. cont.)

1       2. Balancing Unavailability and Reliability: The maintenance rule  
 2 requires that licensees make adjustments where necessary to ensure that the  
 3 objective of preventing failures of SSCs through maintenance is  
 4 appropriately balanced against the objective of minimizing unavailability  
 5 of SSCs due to monitoring or preventive maintenance activities. The intent  
 6 of this requirement is to ensure that monitoring or preventive maintenance  
 7 activities do not result in excessive unavailability that would negate any  
 8 improvement in reliability achieved as a result of the monitoring or  
 9 maintenance activity. This process can be qualitative, but it should be  
 10 documented. Additional guidance is provided in section 12.2.4 of NUMARC  
 11 93-01 (Ref. 2).

12  
 13       The inspector should ask licensees to explain their processes and to  
 14 provide examples of evaluations that resulted in adjustments to achieve  
 15 this balance. The inspector should verify that the licensee has  
 16 implemented a method or process for evaluating the improvements in  
 17 reliability and balancing them against the unavailability that results from  
 18 maintenance.

19  
 20       3. Assessment of Equipment Out of Service: In performing monitoring and  
 21 preventive maintenance activities, an assessment of the total plant  
 22 equipment that is out of service should be taken into account by the  
 23 licensee to determine the overall effect on the performance of safety  
 24 functions. This assessment is to be performed on an ongoing basis, not  
 25 just during the periodic assessment performed at the end of every refueling  
 26 cycle. As stated in the SOC (Ref. 4), assessing the cumulative impact of  
 27 out-of-service equipment on the performance of safety functions is intended  
 28 to ensure that the plant is not placed in risk-significant configurations.  
 29 These assessments do not necessarily require that a quantitative assessment  
 30 of probabilistic risk be performed. However the PRA or IPE may provide  
 31 useful information on risk significance of various SSCs. The level of  
 32 sophistication with which such assessments are performed is expected to  
 33 vary, according to the assessments performed. These assessments may range  
 34 anywhere from simple deterministic judgments to the use of an on-line  
 35 living PRA. It is expected that, over time, assessments of this type will  
 36 be refined as the technology improves and experience is gained. In order  
 37 to accomplish these assessments licensees must keep track of the status (in  
 38 or out of service) of plant equipment. This status may be kept as a manual  
 39 list or on a database but must be easily accessible and kept up to date.  
 40 In order to be useful and accessible the information should be kept in one  
 41 location and not scattered among several documents (shift logs, status  
 42 boards, tag out status boards) in various locations. Additional guidance  
 43 is provided in section 11.0 of NUMARC 93-01 (Ref.2 ).

44  
 45       The inspector should verify, based on a review of licensee records and  
 46 discussions with appropriate personnel, that the licensee has established  
 47 and implemented an ongoing, documented process for assessing the overall  
 48 effect on the performance of safety functions before SSCs are taken out of  
 49 service for monitoring or preventive maintenance. The inspector should  
 50 verify that the licensee maintains a list of all SSCs within the scope of  
 51 the maintenance rule and that the licensee updates this list to indicate  
 52 when SSCs are in or out of service. The inspector should select a sample  
 53 of SSCs from the licensee's list of SSCs that have been taken out of  
 54 service and review the adequacy of the evaluations made by the licensee  
 55 before taking the SSCs out of service. The inspector should also verify

(specific guidance 03.02.c. cont.)

1 that the licensee reviews the results of this process during the periodic  
2 assessment performed each refueling cycle.  
3

4 03.02.d. Scope of the Rule, 50.65(b). The scope of SSCs that are required to  
5 be included within the rule is defined in 10 CFR 50.65(b). Section 8.0 of  
6 NUMARC 93-01 (Ref. 2) provides additional guidance on methods for selecting  
7 SSCs to be included in the scope of the maintenance rule. In order to verify  
8 that the licensee has correctly identified and documented SSCs at its facility  
9 the inspector should perform the following reviews.  
10

11 1. Safety-Related SSCs per 50.65(b)(1): Identifying safety-related SSCs  
12 should be uncomplicated since all licensees should have a well-defined list  
13 of safety-related SSCs in their final safety analysis report, (FSARs),  
14 Q-lists or master equipment lists (MELs).  
15

16 The inspector should independently review the FSAR, Q-list, or MEL to  
17 select a sample of SSCs and then verify that the licensee has included  
18 these safety-related SSCs within the scope of the maintenance rule.  
19

20 2. Non-Safety-Related SSCs That are Relied Upon to Mitigate Accidents or  
21 Transients per 50.65(b)(2)(i): The FSAR describes non-safety-related SSCs  
22 needed to mitigate accidents and transients. Examples of non-safety-  
23 related SSCs that are used in the FSAR analysis to mitigate accidents  
24 include: the condensate storage tank (supply to auxiliary feedwater), the  
25 fire-suppression system, and the boric acid transfer system used for  
26 emergency boration and makeup water to the refueling water storage tank.  
27

28 The inspector should independently review the plant safety analysis report  
29 and attempt to identify a sample of non-safety-related SSCs relied upon to  
30 mitigate accidents or transients. If it is not feasible to select an  
31 independent sample in this manner, the inspector should perform a review of  
32 non-safety related SSCs that were identified by the licensee as necessary  
33 to mitigate accidents and transients. This sample may include a very small  
34 number of SSCs. The inspector should review the licensee's determinations  
35 and verify that they appear to be reasonable.  
36

37 3. Non-Safety-Related SSCs That Are Used in Emergency Operating Procedures  
38 (EOPs) per 50.65(b)(2)(i): Paragraph (b)(2)(i) of the maintenance rule  
39 states that all SSCs in EOPs are required to be included within the scope  
40 of the rule. However, many utilities have included more SSCs in their EOPs  
41 than are required by the Emergency Procedure Guidelines. Some of these  
42 SSCs were included because they could possibly assist in the event of an  
43 emergency, not because they are relied upon in the licensee's accident  
44 analysis to protect other equipment from being damaged or contaminated.  
45 Subsequently, the NRC staff endorsed the guidance contained in section  
46 8.2.1.3 of NUMARC 93-01 (Ref. 2) which allows the exclusion from the rule  
47 of those non-safety-related SSCs that are not considered important because  
48 they do not add significant value to the mitigation function of an EOP by  
49 providing a significant fraction of the total functional ability required  
50 to mitigate core damage or radioactive release. Some examples of SSCs that  
51 might be excluded on this basis are instrumentation that provides redundant  
52 local information and does not provide a control function, fire-protection  
53 system capacity capable of supplying only a small fraction of what is  
54 required to mitigate the accident, and portable emergency equipment that is  
55 available from offsite sources and is not under utility control.

(specific guidance 03.02.d. cont.)

1 Conversely, if a fire-protection system provides a large fraction of what  
2 is required to mitigate the accident, it should be under the scope of the  
3 rule. The inspector should keep these exceptions in mind when reviewing  
4 the scope of SSCs included in the rule.  
5

6 The inspector should independently review the EOPs to identify a sample of  
7 non-safety-related SSCs and verify that they are included within the scope  
8 of the rule or were excluded based on the criteria described above. The  
9 inspector should select a sample of SSCs from the EOPs that were excluded  
10 from the rule and verify that the licensee's documented reasons for  
11 excluding the SSC from the rule appear to be reasonable.  
12

13 4. Non-Safety-Related SSCs Whose Failure Could Prevent Safety-Related SSCs  
14 From Fulfilling Their Intended Function as per 50.65(b)(2)(ii): To  
15 identify failure modes of non-safety-related SSCs that will directly affect  
16 safety-related functions, the licensee should investigate the systems and  
17 their interdependencies. A utility should rely on actual plant-specific  
18 and industrywide operating experience<sup>4</sup>, prior engineering evaluations such  
19 as PRA, IPE, environmental qualification (EQ), and 10 CFR Part 50 (Appendix  
20 R) analyses. Industrywide operating experience should be used to the  
21 extent practical to preclude unacceptable performance experienced at a  
22 similar plant from being repeated. Examples of such non-safety-related  
23 SSCs could include instrument air system that opens containment isolation  
24 valves for purge and vent, a fire damper in the standby gas treatment  
25 system whose failure would impair air flow, or a condensate storage water  
26 tank that is a source of water for ECCS. However, it is not intended that  
27 licensees attempt to determine hypothetical failures that could result from  
28 system interdependencies that have not previously been experienced or  
29 analyzed. NUMARC 93-01, section 8.2.1.4 (Ref. 2) provides additional  
30 guidance. See paragraph 03.02.d step 6 below for exceptions.  
31

32 The inspector should review records of failures of non-safety-related  
33 systems and attempt to identify a sample of SSCs that could have prevented  
34 a safety-related SSC from fulfilling its intended function. The inspector  
35 should verify that the licensee has included these SSCs within the scope of  
36 the maintenance rule. If it is not feasible to select an independent  
37 sample in this manner, the inspector should perform a review of the non-  
38 safety related SSCs that were identified by the licensee as likely to  
39 prevent safety related SSCs from fulfilling their intended function. The  
40 inspector should review the licensees determinations and verify that they  
41 appear to be reasonable.  
42

43 5. Non-Safety-Related SSCs Whose Failure Could Cause a Scram or Actuation  
44 of a Safety System as per 50.65(b)(2)(iii): Licensees are required to  
45 identify, on the basis of utility-specific and industrywide operating

---

46 <sup>4</sup>Industrywide operating experience includes information from NRC,  
47 industry, and vendor sources that is generally available to the nuclear  
48 industry. Sources of this type of information could include: NRC bulletins,  
49 information notices, generic letters, 10 CFR Part 21 reports; the INPO NPRDS  
50 system, vendor service, and technical information letters and reports. It is  
51 intended that licensees will obtain this operating experience information from  
52 existing programs; it is not intended that licensees will establish new  
53 programs to satisfy the needs of the maintenance rule.

(specific guidance 03.02.d. cont.)

1 experience, those non-safety-related SSCs whose failure could cause a  
2 reactor scram or safety system actuation. The licensee should consider  
3 other engineering evaluations, such as PRA, IPE, environmental  
4 qualification (EQ), and 10 CFR Part 50 (Appendix R) analyses. The licensee  
5 should also consider industrywide operating experience and any event that  
6 has occurred at a similarly configured plant. However, the licensee is not  
7 required to determine hypothetical failures that could result from system  
8 interdependencies that have not previously been experienced or analyzed.  
9 Examples of transient initiators from the FSAR include turbine trips, loss  
10 of feedwater, and loss of instrument air. Examples of non-safety-related  
11 SSCs whose failure could cause a plant trip are the turbine generator, non-  
12 ESF buses that power reactor coolant pumps, and rod control system failure  
13 that allows multiple rods to drop into the core. One example of a non-  
14 safety-related system whose failure could cause a safety system actuation  
15 is a radiation monitor which could isolate control room ventilation.  
16 NUMARC 93-01, section 8.2.1.5 (Ref. 2), provides additional guidance.  
17

18 The inspector should review licensee event reports or other available  
19 operating history information to identify SSCs that have actually caused a  
20 scram or safety system actuation and should verify that those SSCs had been  
21 included in the licensee's maintenance program.  
22

23 6. SSCs Outside the Scope of the Maintenance Rule: Unless they meet the  
24 criteria described above, the following categories of SSCs are generally  
25 outside the scope of the maintenance rule: fire protection systems; seismic  
26 class II SSCs installed in proximity to seismic class I SSCs; security  
27 systems; and, emergency facilities described in the emergency plan.  
28 Further guidance is provided in section 8.2.1.6 of NUMARC 93-01 (Ref. 2).  
29

30 The inspector should not expect that these SSCs would be included within  
31 the scope of the maintenance rule because maintenance requirements already  
32 exist for these categories of SSCs.  
33

34 7. Switchyard Activities: The regulatory guide (Ref. 1) states that the  
35 scope of monitoring efforts under the maintenance rule, as defined in 10  
36 CFR 50.65(b), encompasses those SSCs that directly and significantly affect  
37 plant operations, regardless of which organization actually performs the  
38 maintenance activities. Maintenance activities performed by plant  
39 maintenance personnel, as well as by corporate maintenance or contractor  
40 personnel, come under the scope of the rule. Since maintenance activities  
41 that are performed in the switchyard can directly affect plant operations,  
42 electrical distribution equipment out to the first intertie with the off-  
43 site distribution system (i.e., equipment in the switchyard) should be  
44 considered for inclusion under the scope of the maintenance rule. Plant  
45 managers should be aware of, and should have the ability to control, these  
46 activities even if the switchyard is not onsite.  
47

48 The inspector should verify that the appropriate SSCs in the switchyard are  
49 included within the scope of the maintenance rule.  
50

51 8. Safety Systems with Non-safety Functions: Examples provided in section  
52 8.2.1 of NUMARC 93-01 (Ref. 2) illustrate that some safety-related systems  
53 may perform safety-related as well as non-safety-related functions. In  
54 such cases, the components that perform only a non-safety-related function  
55 may not necessarily come under the scope of the rule. For example, the

(specific guidance 03.02.d. cont.)

1 non-safety-related function of an ECCS could be to fill the safety  
2 injection accumulators.

3  
4 The inspector should not expect that these SSCs with non-safety-related  
5 functions necessarily come within the scope of the maintenance rule.  
6

7 9. Documentation. The licensee's process for reviewing and selecting SSCs  
8 shall be documented. The licensee shall also develop a list of all those  
9 SSCs selected for inclusion within the scope of the rule. This list could  
10 take the form of either a manual list or an electronic database. In either  
11 case, licensees must have a process to periodically revise the list as  
12 modifications or other changes are made to the plant that result in SSCs  
13 being added or deleted from the scope of the rule. NUMARC 93-01, section  
14 13.2 (Ref. 2) provides additional guidance on documenting the SSC selection  
15 process.  
16

17 The inspector should verify that the licensee has established adequate  
18 documentation which includes a listing of all SSCs that are within the  
19 scope of the maintenance rule and made provisions for updating the list.  
20

21 Summary for 03.02.d., Scope of the Rule 50.65(b), steps 1 through 9: If the  
22 inspector identifies one or more significant examples, or several minor  
23 examples, of failures to identify SSCs required to be within the scope of the  
24 rule, the inspector should examine the licensee's process and procedures to  
25 determine why they were not included.  
26

27 03.03. Effectiveness of Emergency Diesel Generator Maintenance Activities.  
28 The inspection requirements and guidance given in other sections of this  
29 inspection procedure apply to all SSCs within the scope of the maintenance  
30 rule, including the emergency diesel generators. In addition, the following  
31 requirements derived from Regulatory Guide 1.160 apply to emergency diesel  
32 generators only.  
33

34 03.03.a. Early Implementation for Emergency Diesel Generators: In order to  
35 remove certain EDG requirements from the technical specifications and still  
36 satisfy certain commitments made in response to the station blackout rule (10  
37 CFR 50.63), licensees may elect to implement the requirements of the  
38 maintenance rule for the emergency diesel generators earlier than the  
39 effective date of the maintenance rule, July 10, 1996. If the licensee has  
40 made the decision to remove the SBO commitments from the technical  
41 specifications, then the maintenance of the emergency diesel generators would  
42 be subject to inspection under the requirements of the maintenance rule before  
43 July 10, 1996.  
44

45 03.03.b. Target Reliability Values as Goals or Performance Criteria: The  
46 station blackout rule (10 CFR 50.63) requires each licensee to perform plant-  
47 specific coping analyses to ensure that a plant can withstand a total loss of  
48 ac power for a specified duration and to determine appropriate actions to  
49 mitigate the effects of a total loss of ac power. Most licensees endorsed the  
50 program embodied in NUMARC 87-00 (ref. 3) and subsequently docketed  
51 commitments to maintain a target EDG reliability value of either 0.95 or  
52 0.975. These target values could be used as the basis for goals or as  
53 performance criteria for EDG reliability under the maintenance rule (10 CFR  
54 50.65). As part of their plant-specific coping analyses, licensees were  
55 allowed to use plant-specific data concerning unavailability due to

(specific guidance 03.03.b. cont.)

1 maintenance. This unavailability due to maintenance, assumed in a plant-  
2 specific individual plant examination (IPE) analysis, could also be used as  
3 the basis for goals or performance criteria for EDG reliability under the  
4 maintenance rule.

5  
6 The inspector should verify that the licensee has either (1) incorporated  
7 these commitments into its maintenance program as goals or performance  
8 criteria or (2) established an alternate method of meeting licensee  
9 commitments to the station blackout rule and the requirements of the  
10 maintenance rule.

11  
12 03.03.c. Balancing Unavailability and Reliability: Paragraph (a)(3) of the  
13 maintenance rule requires that adjustments be made where necessary to ensure  
14 that the objective of preventing failures of SSCs through maintenance is  
15 appropriately balanced against the objective of minimizing unavailability of  
16 SSCs due to monitoring or preventive maintenance. Therefore, both plant-  
17 specific EDG reliability and plant-specific EDG availability should be  
18 monitored as goals under paragraph (a)(1) or should be established as  
19 performance criteria under the plant's preventive maintenance program under  
20 paragraph (a)(2), to satisfy the objectives of paragraph (a)(3). The  
21 regulatory guide endorses the example in NUMARC 93-01, section 12.2.4 (Ref.  
22 2), which refers to optimizing EDG reliability and availability.

23  
24 The inspector should verify that the licensee is monitoring both plant-  
25 specific EDG reliability and plant-specific EDG availability as goals under  
26 paragraph (a)(1) or performance criteria under paragraph (a)(2), or that the  
27 licensee has established an alternate method of meeting its commitments to the  
28 station blackout rule and paragraph (a)(3) of the maintenance rule for  
29 emergency diesel generators.

30  
31 03.03.d. Dispositioning From Paragraph (a)(2) to Paragraph (a)(1): Licensees  
32 who decide to establish performance criteria under paragraph (a)(2) of the  
33 maintenance rule would establish performance criteria for EDG reliability and  
34 EDG unavailability. The performance criteria for reliability could be, for  
35 example, no maintenance-preventable failures, or a maximum of one maintenance-  
36 preventable failure if it is followed by appropriate root-cause determination,  
37 corrective action, and subsequent EDG performance monitoring to assure the  
38 problem was resolved. Likewise, the performance criteria for unavailability  
39 could be set as a specific maximum number of unavailable hours, on a rotating  
40 1-year basis. If either of the performance criteria is exceeded, then the  
41 licensee would be required to set goals and to monitor under paragraph (a)(1)  
42 of the maintenance rule. The regulatory guide (Ref. 1) endorses the example  
43 in NUMARC 93-01, section 12.2.4 (Ref. 2), which describes an acceptable method  
44 to establish EDG performance criteria and/or goals and subsequently monitor  
45 EDG performance.

46  
47 The inspector should review the performance criteria established by the  
48 licensee and the performance history of the EDG to verify that the performance  
49 criteria were not exceeded, or, if they were exceeded, that goals were set and  
50 monitoring was performed in accordance with paragraph (a)(1) of the  
51 maintenance rule.

52  
53 03.03.e. Implementing the Station Blackout Rule: The EDG reliability  
54 performance criteria or goals selected for implementing the intent of the  
55 station blackout rule (10 CFR 50.63) for coping with station blackout could be

XXXXX

# DRAFT

(specific guidance 03.03.e. cont.)

1 monitored through the use of the triggers and monitoring methods described in  
2 Appendix D of NUMARC 87-00 (except for triggers and testing for "problem  
3 diesels" as described in section D.2.4.4) (Ref. 3). An acceptable  
4 unavailability goal could be to have fewer hours of unavailability (on a  
5 rotating 1-year basis) than the number of hours established as acceptable by  
6 the licensee.

7  
8 The inspector should review the EDG reliability and availability commitments  
9 made by the licensee in response to the station blackout rule and verify that  
10 these commitments have been addressed by the licensee's implementation of the  
11 maintenance rule or that the licensee has established an alternate method of  
12 meeting its commitments to the station blackout rule and the requirements of  
13 the maintenance rule.
