### 1.0 INTROOUCTION

At 1300 hours on November 24, 1981 Zion Unit 2 achieved initial criticality for Cycle 6. As part of the Zero Power Physics Program the "Rod Swap Technique" was utilized to measure rod worths. This was the second time at Zion that this technique was used, solely by itself, in determining rod worths.

The results of the rod swap technique were satisfactory. All acceptance and design criteria were met. The total rod worth was measured to be $94 \%$ of the total predicted value. This is well within the acceptance criterion that the total rod worth as determined by rod swap be greater than or equal to $90 \%$ of the predicted total rod worth.

The detailed results of the rod swap technique are summarized in the following sections.

### 2.0 ROO SWAP TECHNIQUE

Before the Rod Swap Technique, rod worths were measured utilizing a reactivity computer. This reactivity computer measured the worth of the control rods during a change in the boron concentration of the reactor coolant system. This is a relatively slow process and results in large amounts of water being letdown from the RCS which needs to be processed.

The rod swap technique is simply a method to determine the worth of a bank relative to a "reference" bank. The reference bank is the bank with the highest predicted worth. The method is used in the following manner:

1. The worth of the reference bank is measured using conventional methods (i.e. reactivity computer and boron changes).
2. The worth of the remaining banks is then measured, individually and at a constant boron concentration, by an exchange with the reference bank.

The data from the exchange with the reference bank allows the worth of the remaining banks to be inferred from the measured worth of the reference bank. The inferred worths are calculated using the following formula:

Westinghouse supplied Zion with predicted worths for each rod bank (Ref 1). These predictions are shown in Table 1.

The acceptance criterion for the Rod Exchange Technique was that the total rod worth as determined by rod exchange must be greater than or equal to $90 \%$ of the predicted total rod worth.

The design (review) acceptance criteria was
A. The absolute value of the percent difference between measured and predicted integral worth for the reference bank is $\leq 10 \%$.
B. The absolute value of the percent difference between inferred and predicted integral worths for all other banks is $\leq 15 \%$. For banks having a predicted integral worth equal to or less than 600 pcm , the absolute difference between the inferred and predicted worth is $\leq 100 \mathrm{pcm}$.
C. The absolute value of the percent difference between the sum of the measured/ inferred bank worths and the sum of the predicted worths is $\leq 10 \%$.

### 3.0 RESULTS

Since Control Bank D was predicted to be the highest worth bank, it was used as the reference bank. The worth of CBD was measured using the reactivity computer and the conventional boron dilution method. The results of this measurement are shown in Table 2. The integral and differential worths for CBD are plotted in Figure 1.

With CBD near the fully inserted position, each bank was then swapped individually with this reference bank. Critical configura ${ }^{+1}$ ion data was recorded for each bank before and after the swap. This data is shown in Table 3.

Using this critical configuration data, the inferred worth (W又) for each bank was then calculated. A plot of the integral worth of CBD from 0 to 30 steps is shown in Figure 2. Using this plot, each bank was then calculated. These values are snown in Table ${ }^{-} \mathbf{4}^{-1}$

The values of $\quad]^{+a, c}$ 5. Thes or each bank are shown in Table 5. These values were calculated USing the integral and oifferential rod
worths of Table 2 and Figure 1 . With the values of calculated, the inferred worth of each bank was then computed. These inferred worths are shown in Table 6.

Table 7 shows the comparison of the rod worths as measured by the rod swap technique with the predicted values. All acceptance and design criteria were met.

The total rod worth was measured to be 9a\% of the total predicted value. This meets the acceptance criterion that the total rod worth as determined by rod swap be greater than or equal to $90 \%$ of the predicted total rod worth.

The difference between the measured worth of the reference bank CBO and its predicted worth was $\mathbf{- 4 . 2 2 \text { . This is well within the design acceptance }}$ criterion that the absolute value of the percent difference between measured and predicted integral worth for the reference bank must be $\leq 10 \%$.

The second design acceptance criterion was that the absolute value of the percent difference between inferred and predicted integral worths for all other banks is $\leq 15 \%$. For banks having a predicted integral worth equal to or less than $60 \overline{0} \mathrm{pcm}$, the absolute difference between the inferred and predicted worth is $\leq 100 \mathrm{pcm}$.

As seen in Table 7 the largest percent difference for those banks with a predicted worth of > 600 pcm was $\mathbf{- 7 . 5 8 \%}$ for Shutdown Bank B. For banks having a predicted worth $\leq 600 \mathrm{pcm}$ the largest difference was 36.0 pcm for Shutdown Bank C.

The last design acceptance criterion was that the absolute value of the percent difference between the sum of the measured/ inferred bank worths and the sum of the predicted worths is $\leq 10 \%$ The total rod worth as measured by rod swap was 4730.6 pcm. This value is $\mathbf{- 5 . 9 9 \%}$ from the predicted value.

Following the completion of the rod swap the worth of CBO was remeasured while borating it out to the nearly withdrawn position. The integral worth of CBO from this remeasurement was 957.9 pcm. This is a $+0.01 \%$ difference from the integral worth measured during dilution.

### 4.0 SUMMARY

The Rod Swap Technique for measuring rod worths was utilized for the second time at Zion Station during the Unit 2 Cycle 6 startup testing program. The results of the technique were very satisfactory with good agreement between measured/ inferred worths and the predicted worths. All acceptance and design acceptance criteria were met.
