Docket No. 40-2061

Board Notification 90-06

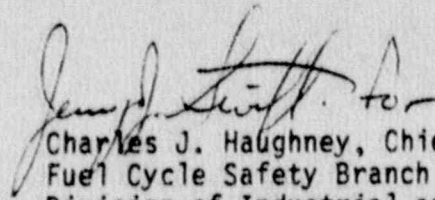

MEMORANDUM FOR: Atomic Safety and Licensing Appeal Board
and All Parties

FROM: Charles J. Haughney, Chief
Fuel Cycle Safety Branch
Division of Industrial and
Medical Nuclear Safety
Office of Nuclear Material Safety
and Safeguards

SUBJECT: NEW INFORMATION POTENTIALLY RELEVANT AND MATERIAL
TO BOARD PROCEEDING IN THE MATTER OF KERR-MCGEE
CHEMICAL CORPORATION, WEST CHICAGO RARE EARTHS FACILITY,
DOCKET 40-2061-ML

In conformance with the Commission's policy on notification of Licensing Boards, Appeal Boards, or Commission of new, relevant, and material information, this memorandum calls attention to the documents listed below.

The enclosed memorandum, dated August 1, 1990, provides a summary of the July 25, 1990, telephone conversation with Kerr McGee on erosion protection design of the West Chicago disposal cell (Enclosure 1). The enclosed letter, dated July 31, 1990 (Enclosure 2), provides information to supplement the report on erosion evaluation for the disposal cell that was forwarded by Board Notification 90-05. The additional information was requested by the July 25, 1990 telephone conversation. These documents are being brought to the attention of the Board as information which may be relevant and material to issues pending before the Board.

FROM: Jerry J. Swift, Section Leader
Advanced Fuel and Special
Facilities Section
Fuel Cycle Safety Branch

SUBJECT: CONFERENCE CALL OF JULY 25, 1990, WITH KERR-MCGEE
ON EROSION PROTECTION DESIGN OF THE WEST CHICAGO
DISPOSAL CELL

The following is a record of the July 25, 1990 conference call from the Nuclear Regulatory Commission (NRC) to James L. Grant & Associates, authors of the Kerr-McGee report entitled, "Erosion Evaluation West Chicago Disposal Cell," dated July 23, 1990. The Kerr-McGee report presents the results of analyses of potential erosion of the disposal cell proposed as a part of the closure of the Kerr-McGee Rare Earths Facility in West Chicago, Illinois. The purpose of the conference call was to request additional information needed to complete NRC's review of the report. A list of persons who participated in the conference call is enclosed.

During the discussions, Mr. Terry (Ted) L. Johnson of NRC's Division of Low-Level Waste Management and Decommissioning identified the specific areas of the report that require additional supporting documentation. These areas involve Sections 3, 4, 5, and 6 of the report and are outlined below.

Section 3 - Sizing of Erosion Barrier Materials

The stone size necessary to prevent erosion of the intrusion barrier was determined using flow rate estimates. Figure 5 of Section 3 shows a stone size (D-50 value) of 9.5 to 10.0 inches for a unit discharge rate of 9 cfs/ft at a 20% slope. It is unclear why a D-50 value of 9.0 inches was used for the stone size, as indicated on page 20 of the report.

Section 4 - Diversion Ditch and Toe of Slope Protection

Additional information regarding the diversion channel and toe is required for staff to base a conclusion on the adequate protection of these areas. Information including cross sections of critical areas, calculations and any basis for the decision on rock size should be included in the report.

~~008090333~~

3pp.

Section 5 - Offsite Flooding

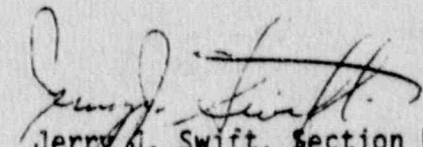

The report states that the flood flow rate value was derived by using Regulatory Guide 1.59 and was calculated to be about 61,000 cfs. The report should show how Regulatory Guide 1.59 was used in arriving at this value. If drainage area data presented in the guide was used to estimate the flood flow rate for an 18 square mile drainage area, then any extrapolation used should be presented in the report.

Slopes used to determine the flow velocities and depth in the channel should be shown in the report as well as calculations used in deriving the values.

Section 6 - Sedimentation Basin Failure

It is stated in this section that the berm that forms the side of the basin adjacent to the disposal cell will be protected from erosion by the same riprap protection provided in the drainage ditches around the disposal cell. This section lacks sufficient information to support this conclusion. Additional information is needed or a justification should be provided as to why this issue is not critical to the analysis.

Mr. Grant, of James L. Grant & Associates, responded in a positive way to each area discussed and stated that he will either provide the NRC with the additional information requested or will show adequate justification as to why the information is not needed. At the conclusion of the meeting it was agreed that Mr. Grant would "informally" send NRC the majority of the requested information that was readily available to him. A follow-up package addressing all the open items will formally be submitted to the NRC by Kerr-McGee as a supplement to the report. The purpose of an earlier informal submittal by Mr. Grant is to allow NRC staff to continue their review of the report. NRC should expect the early informal package by July 26, 1990 and the formal package by the week of July 30, 1990.

RE: Docket: 40-2061
 License: STA-583
 License Amendment Request for Authorization
 for On-Site Receipt and Disposal of Off-Site
Contaminated Soils - Supplemental Information

Dear Mr. Haughney:

During a conference call on July 25, 1990, NRC staff requested that Kerr-McGee Chemical Corporation ("Kerr-McGee") submit certain information to supplement the report filed on July 23, 1990, concerning the erosion evaluation of the West Chicago disposal cell. This letter is to provide the requested information on behalf of Kerr-McGee:

1. Staff requested information to justify the selection of rock with a D₅₀ of 9 inches for the intrusion barrier along the side slope of the disposal cell. Kerr-McGee's aim was to select a rock size that would be adequate to withstand the upper-bound estimate of the unit flow in a hypothetical gully along the side slope of the cell. As noted in the July 23 report (page 19), an upper bound estimate for this flow is about 8.8 cfs/ft. The relation set out in Figure 4.3 of Development of Design Criteria by Riprap Testing in Flumes, NUREG/CR-4651 (1987), shows that the median stone diameter to withstand a flow of this magnitude is nearly nine inches. A copy of Figure 4.3 is attached as Appendix 1.
2. Staff requested that Kerr-McGee submit the calculations underlying section 4 of Kerr-McGee's July 23 submittal. That section concerns the design of the riprap for the diversion ditches so that the cell can withstand storm flows that are significantly in excess of the probable maximum flood from the drainage areas upstream of the Kerr-McGee site. The calculations from the files of Kerr-McGee's consultants are attached as Appendix 2.

4008010053

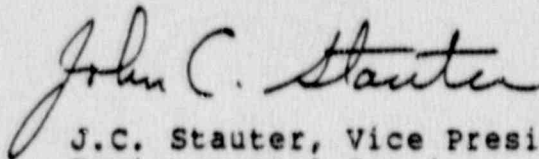

3. Staff requested that Kerr-McGee provide a cross-section showing the toe of the pile and its relationship to the diversion ditches. A conceptual design is attached as Appendix 3. The dimensions for the riprap depth shown in the sketch are appropriate for the diversion ditches along the western and northern sides of the cell; Kerr-McGee will install the riprap surrounding the cell so that the thickness of the riprap is at least twice the appropriate median stone diameter.
4. Staff requested that Kerr-McGee submit the calculations underlying section 5 of Kerr-McGee's July 23 submittal. That section concerns the adequacy of the cell design to withstand off-site flooding in Kress Creek that is significantly in excess of the probable maximum flood. The requested calculations are attached as Appendix 4.
5. Staff requested that Kerr-McGee submit information in support of the assertion in section 6 of the July 23 submittal that the riprap protection is adequate to prevent the release of radiological material in the event of failure of the sedimentation basin. The requested information is attached as Appendix 5. The riprap that protects the diversion ditch forms the side of the sedimentation basin adjacent to the disposal cell. As is shown in the appendix, that riprap is adequate to assure that a failure of the sedimentation basin will not threaten to erode the cell.

It is Kerr-McGee's understanding that the costs of construction of the cell are not substantially affected by the various commitments that Kerr-McGee has made in connection with its July 23 submittal. Indeed, the commitments do not alter the fundamental design of the cell in any material respect. These are the type of specifications that Kerr-McGee anticipated developing, subject to staff review, in the course of the detailed engineering work that will precede the commencement of cell construction.

Mr. Charles J. Haughney, Chief
July 31, 1990
Page 3

Because of the limited time available to respond to the staff's requests, formal narratives to describe the calculations have not been prepared. Rather, we have submitted relevant material from the files of Kerr-McGee's consultants. Although we believe this material is understandable, Kerr-McGee and its consultants stand ready to answer any further questions you may have concerning the erosion report or this submittal.

Very truly yours,

J.C. Stauter, Vice President
Environmental Services

Summary of Calculations I-1 through I-9

Several calculations contributed to the assembly of section 4: "Diversion Ditch and Toe of Slope Protection."

Planimeter measurement and calculation I-1 show the overall contributing drainage area to be 307 acres, 265 of which are offsite.

The contributing drainage areas for the westward and eastward drainage paths are produced in calculation I-6. As shown, about 94% of the drainage area yields westward flow around the disposal cell.

A copy of the upstream drainage map is included in calculation I-6, while the longest cross-basin flow path, 4800 feet, is generated in calculation I-3.

The slope of the off-site drainage basin is found to be .50% in calculation I-2, while the natural ground slope on-site is documented as 1% in calculation I-8.

Cross-sectional profiles of the drainage ditch were generated in calculation I-5. These cross-sections were then used to determine flows in channel and overbank ditch regions in calculation I-7. Flow data is included in the attachments to calculation I-7.

Calculation I-7 also gives depth vs. discharge and velocity vs. discharge curves, which can together be used to relate velocity and discharge to given depths.

The time of concentration for a 6500 cfs design discharge (recommended by NRC during a July 13 meeting) is shown to be about 41 minutes in calculation I-9, and the westward channel drainage time is an additional 3+ minutes.

For a previously analyzed design discharge of 920 cfs, total time of concentration of 1.7 hours is yielded in calculation I-3. This calculation also provides shear stress and median riprap size information.

The peak PMF flow rate for the Kress Creek drainage area (shown in calculation I-4) was estimated using NRC Reg. Guide 1.59.

JOB NO. 809307 SHEET 3 OF 10
JOB NAME West Chicago Erosion
BY DCS DATE 6-23-90
CHECKED BY KSR DATE 6-28-90

Determine potential erosion of toe of slope and determine ditch area around disposal cell.

Riprap requirements, if any, will be determined using the U.S. N.R.C. Staff Technical Circular (STC), May, 1990.

The design flow will be the PMF. Contributing areas, slopes, etc. to the ditches will be determined from USGS quadrangle maps and other available maps and plans.

Determine effective drainage area that may contribute runoff as in flow to the diversion ditches during a PMF.

The site is located in a developed area of West Chicago. As such, there are existing storm drainage systems, both surface and subsurface. However, the design criteria for these systems is the 100-year flood, not the PMF. Thus, no credit for these systems is taken in estimating the PMF flow into the diversion ditches. This is a conservative assumption.

The MCC Corp Earths Facility and its up gradient drainage area are included on USGS quadrangle maps (7.5 minute) for West Chicago and Naperville, Illinois. These maps provide topographic contours at 10-ft elevation intervals, with some information at 5-ft intervals.

Using these maps the contributing drainage area was delineated by drawing a line around the topographic high points up gradient of the site. The contributing up gradient drainage area is basically part of a divide that directs surface drainage either to Kress Creek (west and south of the site) or to the West Branch Village River (east of the site). The up gradient drainage area and the site itself slopes gently to the southwest towards Kress Creek.

The up gradient drainage area is bounded on the west by the Elgin, Joliet & Eastern Railroad bed, on the north by the Chicago and North Western Railroad bed, and on the east by Nelson Blvd. During a PMF this area will drain to the southwest across the site and around the disposal cell into the detention/sedimentation pond in the southwest corner of the site. The contributing drainage area, including the site, was determined using a planimeter (see Calculation No. I-1, 6/29/90).

A = 307,000 sq ft

The site area itself is comprised of 32.9 acres (the disposal cell and the south 300 ft of the intermediate site) and 9.5 acres (the Factory site and the northern portion of the intermediate site). Thus, site area is

$$A_s = 42.4 \text{ acres} \checkmark$$

Therefore, the off-site drainage area that may contribute runoff as a inflow to the diversion ditches during a RMP is

$$A_o = A_T - A_s$$

$$= 307 - 42.4$$

$$A_o = 265 \text{ acres} \checkmark$$

Determine the peak runoff rate from the total drainage area, including off-site area, as well as the site.

Use the Rational Method, since this is a small area and we are taking no credit for the existing storm drainage system.

$$Q = CIA$$

where

Q = Peak runoff rate (cfs)

C = Runoff coefficient

I = Average rainfall intensity (in/hr) lasting for a critical period of time, t_c

t_c = Time of concentration

A = Drainage area (acres)

Estimate time of concentration from the remotest point in the basin to the diversion ditch, t_c .

Assume that the runoff will be flowing across this small basin as shallow concentrated flow (since the length of travel is much greater than 300 ft, which is applicable to sheet flow). See Fig. 3 from NUS report (Attachment No. 1), which is taken from McEwen, 1992, Fig. 8 (p. 22).

From Calculation No. I-2 (6-24-90), the average basin slope is

$$S = 0.0055 \text{ ft/ft (or } 0.5\%) \checkmark$$

For paved area $V_1 = 1.40 \text{ ft/sec} \checkmark$ $A_1 = 20\%$

For grazed waterway $V_2 = 1.05 \text{ ft/sec} \checkmark$ $A_2 = 30\%$

For nearly bare $V_3 = 0.75 \text{ ft/sec} \checkmark$ $A_3 = 20\%$

For woodland $V_4 = 0.35 \text{ ft/sec} \checkmark$ $A_4 = 30\%$

Derive composite velocity based upon percentage of area of basin that is comprised of the four above listed uses.

$$V_1 \frac{A_1}{A} + V_2 \frac{A_2}{A} + V_3 \frac{A_3}{A} + V_4 \frac{A_4}{A} = V$$

$$1.4(0.2) + 1.05(0.3) + 0.71(0.2) + 0.35(0.3) = V$$

$$0.28 + 0.315 + 0.142 + 0.105 = V$$

$$V = 0.84 \text{ ft/s} \checkmark$$

From McEwen (Attachment No. 1), Eq. 11

$$t_{c1} = L/V$$

where

L is the longest flow path length from the USGS drainage basin divide, the length L from the most remote point to the diversion ditch is

$$L = 3300 = 1000 + 500$$

$$L = 4900 \text{ ft} \checkmark$$

where 3300 ft is length of line 1 (Catic No. 1-2, 6-29-90), 1000 ft is length beyond line 1 to basin edge, and 500 ft is length from diversion ditch to line 1

thus

$$t_{c1} = \frac{4900 \text{ ft}}{0.84 \text{ ft/s}} \left(\frac{3600 \text{ sec}}{1 \text{ hr}} \right)$$

$$t_{c1} = 1.6 \text{ hr} \checkmark$$

Estimate time of concentration through diversion ditch to outlet toward

Assume for conservatism that the velocity in the channel is the recommended maximum permissible velocity of (see NWS Report, p. 14)

$$V_d = 5.0 \text{ ft/sec} \checkmark$$

thus, the travel time through the ditch is

$$t_{c2} = L/V_d$$

$$= \frac{1900 \text{ ft}}{5.0 \text{ ft/sec}}$$

$$\left(\frac{3600 \text{ sec}}{1 \text{ hr}} \right)$$

$$t_{c2} = 0.1 \text{ hr} \checkmark$$

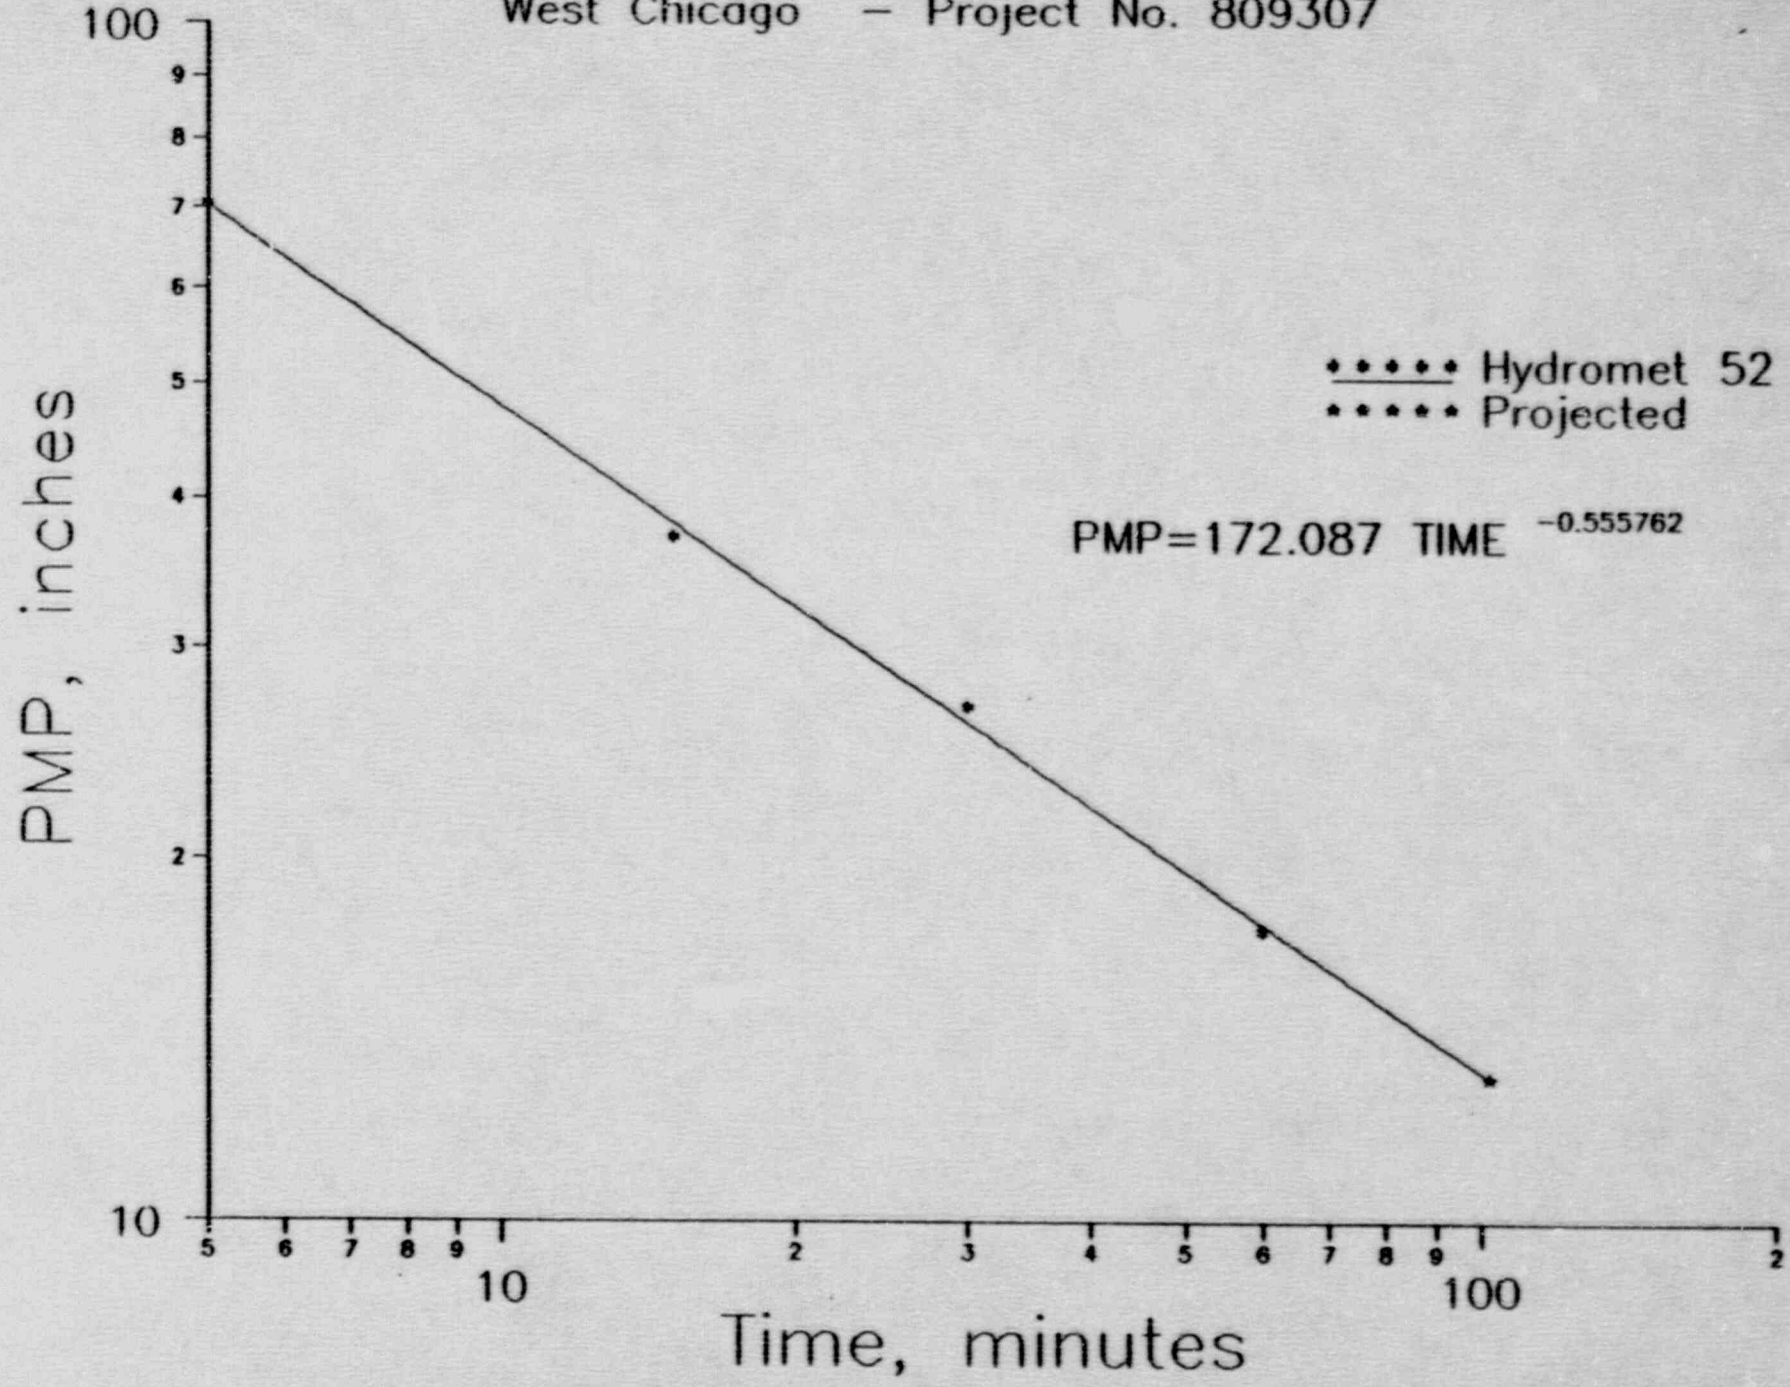

Therefore, the total time of concentration through the outlet all basin is

$$t_c = t_{c1} + t_{c2}$$

$$= 1.6 + 0.1$$

$$t_c = 1.7 \text{ hr} \checkmark$$

Determine peak flow Q from the 307-ac basin

$$Q = C I A$$

$$= 0.39 (2.7 \frac{in}{hr}) (307 \text{ ac})$$

$$Q = 920 \text{ cfs}$$

Determine the water depth y needed for this peak flow rate assuming uniform flow in diversion channels, thus Manning's Equation applies

$$Q = \frac{1.49}{n} A R^{2/3} S^{1/2}$$

where

- n = roughness coefficient
- A = wetted cross-sectional area
- R = hydraulic radius
- S = energy slope = bottom slope

From Chow, p. 21 (attachment No. 4), for a triangular channel

$$A = zy^2$$

$$R = \frac{zy^2}{2\sqrt{1+z^2}y}$$

where

- z = horizontal component of side slope = 5
- From Engineering Digest, Section 9.5.6.1
- y = water depth

thus,

$$920 = \frac{1.49}{n} (zy^2) \left[\frac{zy^2}{2\sqrt{1+z^2}y} \right]^{2/3} (0.01)^{1/2}$$

$$920n = \frac{1.49(5)(0.01)^{1/2}}{2\sqrt{1+5^2}} y^{2+2/3-1} = 0.49 y^{5/3}$$

$$1886. n = y^{5/3}$$

$$y = 17.35 \text{ ft}$$

Based upon USGS Water Supply Paper No. 1849, pp. 136-137 (Attachment No. 5), assume

$$n = 0.045$$

$$\text{then } y = 5.4 \text{ ft}$$

check on sensitivity of n . If $n = 0.03$ (pp. 29-33, USGS WSP 1849)

$$y = 4.6 \text{ ft}$$

JOB NO. 804307 SHEET 9 OF 10

JOB NAME West Chicago Erosion

BY DCS DATE 6-27-90

CHECKED BY KSP DATE 7-6-90

Compute the actual shear stress produced.
Using the safe by factor method (Final NRC
Staff Technical Position on Design of Erosion
Protection Covers, May, 1990), Appendix D, pp D-12
thru D-15 (Attachment No. 6)

$$\tau = \gamma_w y s$$

where

 τ = shear stress γ_w = unit weight of water y = normal depth s = bottom slope

use a water depth of 5.0 ft ✓

$$\tau = 62.4 \text{ lb/ft}^3 (5.0 \text{ ft}) (0.01)$$

$$\tau = 3.12 \text{ lb/ft}^2$$

Compute the required rock size.
From the NRC Staff Technical Position

$$D_{50} = \frac{\tau}{\alpha (W_s - W_w)}$$

where

 $\alpha = 0.04$ ✓ W_s = unit weight of stone, say 165 lb/ft³ W_w = unit weight of water D_{50} = stone size

thus,

$$D_{50} = \frac{3.12}{0.04 (165 - 62.4)}$$

$$D_{50} = 4.1 \text{ inches}$$

or

$$D_{50} = \frac{3.12}{4.1}$$

$$= 0.76 \text{ ft}$$

$$D_{50} = 0.76 \text{ ft, or say}$$

$$D_{50} = 9 \text{ inch stone}$$

This will protect the diversion channels from eroding
during the local P.M.F.

The Engineering Report, Section 9, sketch No. 269
indicates a stone size in the channel section of 4-inches.

Check the stone size required to filter sand erosion from a standard Street SPFF

An SPFF is generally considered to be about 40-60 percent the magnitude of a CIPFF that is, for 50%

$$Q_{SPFF} = 460 \text{ cfs}$$

Determine rip-rap size needed for the SPFF peak flow from pit of these calc's (uniform flow)

$$\frac{Q_{SPFF}}{1.49(1.5)(0.1)} = (0.49)^{2/3} y^{2/3}$$

$$\frac{460 \pi}{1.49(0.5)(0.62)} = y^{2/3}$$

$$994 \pi = y^{2/3}$$

$$y = 12.3 \text{ ft}$$

Since flow is less than SPFF, the rip-rap will be smaller in size. 12.3 ft

$$n = 0.03$$

then

$$y = 12.3(0.03)^{2/3}$$

$$y = 3.6 \text{ ft}$$

compute shear stress produced

$$\tau = W y S$$

$$= 62.4(3.6)(0.01)$$

$$\tau = 2.25 \text{ lb/ft}^2$$

compute rock size required

$$C = 2(W_s - W_w) D_{50}$$

$$C = 4.1 D_{50}$$

$$D_{50} = \frac{2.25}{4.1}$$

$$D_{50} = 0.55 \text{ ft}$$

$$D_{50} = 6.6 \text{ inches}$$

A GUIDE TO HYDROLOGIC ANALYSIS USING SCS METHODS

1982

The Upland Method

Essentially the same input is required for estimating t_c with the upland, or velocity, method as with the lag method. The velocity method has an intermediate step in which the velocity is estimated with the land use and the slope; Fig. 8 is used to estimate the velocity in feet per second (fps). The time-of-concentration equals the ratio of the hydraulic flow length to the velocity:

$$t_c = \frac{l}{V} \quad (11)$$

If l is measured in feet and V in fps, then the value resulting from Eq. 11 must be divided by 3600 in order to convert t_c from seconds to hours.

Adjustment for Urbanization

The curve number appears not to adequately reflect the effect of the soil cover complex in urban areas on the runoff potential. For composite land use areas where urban land uses provide a more efficient flow pattern than pervious land uses, Eq. 9 overestimates lag. TR-55 provides two figures that can be used to adjust the lag computed by Eq. 9 for the percentages of the hydraulic length that is modified (PHLM) and the impervious areas (PIMP); the lag adjustment factors are used independently, and therefore, both values can be applied on the same project. The lag factor (LF) for each adjustment can be computed using values from the following Equation:

$$LF = 1 - \text{PRCT}(-0.006789 + 0.000335 \text{ CN} - 0.0000004298 \text{ CN}^2 - 0.00000002185 \text{ CN}^3)$$

in which CN is the curve number for future land use conditions and PRCT is either the percent hydraulic length modified (PHLM) or the percent impervious area (PIMP). The lag computed from Eq. 9 is then multiplied by the lag factor from the above equation. If both adjustments are necessary, then the equations are used for both modifications and two lag factors are applied to the lag computed from Eq. 9.

TR-55 provides two important guidelines for use of these adjustment factors:

1. Since the lag factors are used only with future-condition curve numbers, the lag factors cannot be used to directly compute the decrease in lag from present conditions.
2. When only peak discharges are to be computed using the TR-55 methods, lag does not have to be computed; therefore, these lag factor adjustments are not necessary.

transposition limits. Comparison of this 18.3-in. value with the 1-hr 1-mi² MP on Figure 24 shows a difference of 0.6 in. We consider this a reasonable development of a moisture maximized transposed amount.

3.3 Depth-area ratios

Preparation of 1-hr MP values over the range of area sizes of interest required development of depth-area reduction ratios. A primary basis for such reduction ratios is the list in Table 19 of 12 extreme storms (those noted by asterisks) for which point or 1-mi² data are available at 1 hr. A problem with the data from these 12 storms is the limited area of most storms. Nearly 60 percent have an areal extent of less than 240 mi², while one fourth of them

and, therefore, of rainfall frequency. Higher values of runoff coefficient are applicable for higher values of rainfall intensity and return period. A typical C versus I curve is shown in Fig. 4-1 [5]. Alternate ways of expressing the variation of runoff coefficient with rainfall frequency are shown in Figs. 4-2 and 4-3 [6, 22].

With runoff coefficient, rainfall intensity, and catchment area determined, the peak discharge is calculated by Eq. 4-1. The apparent simplicity of the procedure, however, is misleading. For one thing, there is a range of possible runoff coefficients for each surface condition. Therefore, the chosen C value is usually based on additional field information or designer's experience. The effect of frequency and/or antecedent moisture condition needs to be evaluated carefully. Furthermore, there is no absolutely certainty that the calculated time of concentration (and therefore, the rainfall duration) is correct or even that it remains constant throughout the range of possi-

DRAFT

DRAFT

rainfall within a given storm event, the magnitude of historic flood events can provide some guidance in the selection of design parameters. For example, a flood with a magnitude of 2630 cfs occurred on a 200-acre drainage basin in southwestern Utah (Crippen and Bue, 1977, see Ref. D11). It can be seen that very high values of rainfall intensity and very low values of infiltration were necessary to produce such a flood.

Step 4. Calculate Riprap Size Required

- a. Assume a trial rock size D_{50} .
- b. Calculate Manning's 'n' value using either (1) the method discussed by Abt, et al. (1987, see Ref. D4), if the channel slope is steep and the depth of flow is small relative to the assumed D_{50} or (2) using the U. S. Army Corps of Engineers method (USCOE, 1970, Plate 4, see Ref. D5), if the slope is mild and the depth of flow is large, relative to the assumed D_{50} .
- c. Calculate normal depth using Manning's equation (Chow, 1959, see Ref. D6) if the channel cross-section and slope are uniform. Otherwise, a standard-step backwater model, such as HEC-2 (USCOE, see Ref. D7) should be used to determine flow depths and velocities.
- d. Compute the peak shear stress produced in the channel. The peak shear stress for a typical V-shaped or trapezoidal channel will be produced at the point where the depth of flow is the greatest. This depth should be used for design and should be used to compute shear stress.
- e. Compute the rock size necessary to resist the computed shear stress. Return to (a) if the computed D_{50} is significantly different from the assumed D_{50} .

DRAFT

3.3 Recommendations

Recommendations for each design area are discussed in the design procedures. As stated, the rock in the channels should be designed for the peak shear stress (rather than the average shear stress) produced. Manning's 'n' values should be determined based on the relative depth of flow in the channel.

In many cases where natural gullies discharge into diversion ditches, it may be necessary to assess the potential for possible clogging of the ditch due to sediment and debris. Particularly where the inflow slopes are greater than the ditch slopes, it is possible that the natural gully will be capable of moving material that the diversion ditch cannot flush out. If the larger material cannot be flushed by the ditch flows, the capacity of the ditch may be compromised, resulting in possible overtopping of the ditch. The following recommendations should be followed in such cases.

1. Diversion ditches should be designed to be self-cleaning.
2. If a ditch cannot be designed to be self-cleaning, it should be designed to contain the sediment/debris that will be deposited in the ditch during the design life. Justification may also be provided to show that there is little or no debris/sediment to be transported. It may also be possible to show that the configuration of the deposits in the ditch will have no adverse effects on either the flow capacity or the stability of the ditch.

3.4 Example of Procedure Application

A 15-foot wide trapezoidal channel with 1V on 5H side slopes will be constructed on a 5 percent slope and will carry a discharge of 1000 cfs. Determine the riprap requirements.

Step 1. Assume a trial D_{50} equal to 2.0 feet (24 inches).

DRAFT.

Step 2. Compute Manning's 'n' value.

Since the slope is relatively steep, the flow depth is likely to be small relative to the riprap size. Therefore, the 'n' value should be computed in accordance with the recommendations of Abt, et al. (1987, see Ref. D4).

Using the equation from Ref. D4:

$$n = 0.0456 (24 \times 0.05)^{.159}$$

$$n = 0.047$$

Step 3. Determine normal depth (y).

By trial and error for the trapezoidal channel, with

$$n = .047; Q = 1000 \text{ cfs; and } S = 0.05,$$

$$y = 3.0 \text{ feet}$$

Step 4. Compute the actual shear stress produced.

Using the Safety Factors Method or the simple equation, $t = \gamma y S$, which closely approximates the Safety Factors Equation for computing shear stress,

$$t = (62.4) (3.0) (0.05) = 9.36 \text{ lb/ft}^2$$

Step 5. Compute the required rock size.

Using an equation of the U. S. Army Corps of Engineers (USCOE, 1970, see Ref. D5),

DRAFT

$t = a(W_s - W_w) (D_{50})$ where:

$$a = 0.04$$

W_s = unit weight of rock, in lb/ft^3 , and

W_w = unit weight of water = $62.4 \text{ lb}/\text{ft}^3$

Based on an assumed stone weight of 165 pounds per cubic foot,

$$t = 4.1 D_{50}$$

The required size is calculated to be:

$$D_{50} = t / 4.1$$

$$D_{50} = 9.36 / 4.1 = 2.3 \text{ feet}$$

Since the required rock size (2.3 feet) is greater than the rock size assumed (2.0 feet), another iteration with a larger D_{50} will be necessary.

3.5 Limitations

The procedures just discussed may require several iterations before an agreement can be reached between the assumed and computed rock size. In some cases where the slope is very steep and discharges are very large, a balance may never be able to be reached, indicating that the slope or discharge is so great that riprap protection cannot be feasibly provided. For very steep slopes, use of the Stephenson Method, discussed previously, may be considered in sizing riprap.

JOB NO. 809307 SHEET 2 OF 5JOB NAME WEST CHICAGOBY KSR DATE 7-18-90CHECKED BY JHS DATE 7-18-90

OBJECTIVE: Determine drainage areas for east side and west side drainage ditches.

SITUATION:

The site was divided into three areas as shown on the attached site map.

The area of the east side was determined by planimetry of the area between the property line and the drainage divide (as shown on the attached map) plus the area east of the property line, shown on the USGS West Chicago Quadrangle (attached) (note, this area was approximated by an equivalent rectangle).

PLANIMETER:

3 readings 2727

2737

2744

Avg 2736, or 27.36 in²

Map Scale: 2 in = 300 ft or 1 in = 136.36 ft

$$\text{Area}_1 = 27.36 \text{ in}^2 \left(\frac{136.36 \text{ ft}}{1 \text{ in}} \right)^2 = 508,733 \text{ ft}^2 = 11.7 \text{ ac}$$

$$\text{Area}_2 = (0.125 \text{ in}) (0.375 \text{ in}) \times \frac{(2000 \text{ ft})^2}{1 \text{ in}^2} = 187,500 \text{ ft}^2 = 4.3 \text{ ac}$$

$$\text{East area} = 11.7 + 4.3 = \underline{16 \text{ acres}}$$

JOB NAME WEST CHICAGO

BY KSR DATE 7-8-90

CHECKED BY JHS DATE 7-18-90

The area in the southwest corner (including the pond) was determined by planimeter

3 readings

997

985

997

Aug. $\frac{993}{3}$ or 9.93 in^2

Map scale: $1" = 136.36'$

$$\text{S.W. Area} = 9.93 \text{ in}^2 \left(\frac{136.36 \text{ ft}}{1 \text{ in}} \right)^2 = 184,644 \text{ ft}^2 = 4.2 \text{ acres} \checkmark$$

The west side area was determined by subtracting the east and S.W. corner areas from the total basin area of 307 acres (from Calc. No. I-1).

$$\text{West Area} = 307 - 16 - 4 = \underline{\underline{287 \text{ acres}}} \checkmark$$

CALCULATION SUMMARY SHEET

PROJECT NO: 809307
TASK NO: 01
CALCULATION NUMBER: I-7
DATE: 7-18-90

DESCRIPTION OF CALCULATION:

GENERATION OF VELOCITY VS DISCHARGE AND
DEPTH VS. DISCHARGE CURVES FOR 3 CROSSSECTIONS
OF DRAINAGE DITCH AT WEST CHICAGO SITE.

REFERENCES USED:

809307 TASK I CALCULATION I-5

CALCULATION MADE BY: *David H. Schreiber* DATE: 7-18-90

CALCULATION CHECKED BY: *Kevin S. Lovel* DATE: 7-24-90

CALCULATION APPROVED BY: *David H. Schreiber* DATE: 7-18-90

OBJECTIVE : GENERATE FIGURES DEPICTING CHANNEL VELOCITY VS. TOTAL DISCHARGE AND NORMAL CHANNEL DEPTH VS. TOTAL DISCHARGE FOR 3 CROSSSECTIONS AT W. CHICAGO SITE: SE CORNER, SOUTH SIDE, AND WEST SIDE. (THESE LOCATIONS ARE INDICATED ON PAGE 6)

METHOD : USING DATA FROM CALCULATION I-5, A SPREADSHEET WAS DEVELOPED TO CALCULATE THE FOLLOWING QUANTITIES :

- 1) CROSSSECTIONAL PROFILE AREA FOR GENERAL DITCH/WATER DEPTHS (FOR CHANNEL AND OVERBANKS)
- 2) WETTED PERIMETER FOR CORRESPONDING DEPTHS
- 3) VELOCITY THROUGH THE DITCH AT CORRESPONDING DEPTHS
- 4) DISCHARGE THROUGH THE DITCH AT CORRESPONDING DEPTHS

GRAPHS COULD THEN BE GENERATED VIA LOTUS AND HARVARD GRAPHS

SOLUTION :

1) AREA CALCULATION

COORDINATES WERE TAKEN DIRECTLY FROM THE CROSSSECTION PROFILE PLOTS IN CALCULATION I-5. ADDITIONAL POINTS TO FILL OUT THE FINAL CURVES WERE LINEARLY INTERPOLATED FROM THESE PLOTS.

AS SHOWN IN THE FOLLOWING SPREADSHEET PAGES,
THE AREAS FOR SEVERAL DEPTHS WERE TABULATED
AND SUMMARIZED AT EACH CROSSSECTION.

THE DOUBLE AREA COORDINATE METHOD WORKS
LIKE THIS:

Y A

(0,20) (20,20)

A

(0,10) (20,10)

1) PICK COORDINATES
OFF OF PLOT

(we know the area should
turn out to be 100 sq. units
in this case.)

2) TABULATE, REPEATING THE
FIRST VALUE AT THE
LAST

3) CROSS-MULTIPLY IN BOTH DIRECTIONS
AND TABULATE.

+ AREA	- AREA
100	200
400	200
400	200
100	200
1000	800

$$\frac{200}{2} = 100$$

which
checks
out.

4) ADD AREA COLUMNS,
SUBTRACT - AREA FROM + AREA, AND DIVIDE BY 2.

2) WETTED PERIMETER CALCULATION

THE PYTHAGOREAN THEOREM FROM GEOMETRY WAS USED TO CALCULATE WETTED PERIMETER FOR EACH CASE.

EXAMPLE CALCULATION:

DASHED LINES ARE NOT WETTED PERIMETER LINES.

CHANNEL:

$$P = \sqrt{(0-4)^2 + (20-6)^2} + \sqrt{(4-6)^2 + (6-10)^2}$$

OVERBANK

$$P = \sqrt{(6-10)^2 + (10-0)^2} + \sqrt{(10-20)^2 + (0-20)^2}$$

3) VELOCITY CAN NOW BE CALCULATED USING MANNING'S FORMULA.

$$V = \frac{1.49}{n} R^{2/3} S^{1/2}$$

WHERE $R = \text{HYDRAULIC RADIUS} = \frac{\text{AREA}}{\text{WETTED PERIMETER}} = \frac{A}{P}$

$S = \text{SLOPE} = 10\% \text{ ON-SITE}^*$

AND $n = .045 \text{ FOR CHANNEL ROCK}, n = .02 \text{ FOR OVERBANK GRASS}$

4) DISCHARGE (Q) FOLLOWS FROM VELOCITY AND AREA

$$Q = VA$$

OBJECTIVE : DOCUMENT THE 1% NOMINAL SLOPE VALUE USED IN PREVIOUS WILCHUGO SITE CALCULATIONS

- METHOD :
- 1) LAY OUT 3 LINES \perp TO CONTOURS ON EAST SIDE OF SITE (NEAR RAILROAD TRACK) ON THE WSSGLP MAP (ATTACHED)
 - 2) LAY OUT A LINE \perp TO CONTOURS ACROSS THE SITE ON THE USGS N.C. QUAD MAP
 - 3) MEASURE "RISE" AS DIFFERENCE IN CONTOUR ELEVATIONS
 - 4) MEASURE "RUN" AS SCALED LINE LENGTH
 - 5) $SLOPE = \frac{RISE}{RUN}$ FOR EACH OF THE 4 LINES
 - 6) AVERAGE THE 4 VALUES
 - 7) CHECK THIS AGAINST "1% NOMINAL GRADE" GIVEN ON PAGE 9-14 OF LINDL REPORT

While 10 CFR 40 and 40 CFR 192 are not specific in defining a design flood event that would satisfy longevity requirements, (i.e. = 1000 years) the use of a Probable Maximum Flood event (PMF) is a generally accepted approach. The PMF is defined as the largest flood that can reasonably be expected to occur at a given area, based on the simultaneous occurrence of critical meteorological and hydrologic conditions. A reduction of the PMF is commonly utilized when failure of the structure would present a low hazard. In this case, the structures under consideration are the drainage swales and retention ponds. Failure of these structures would cause only loss of the structures with little additional damage to property and with no loss of life envisioned.

9.5.6.1 Drainage Swale

The peak discharge in cubic feet per second (Q) to be handled by the drainage swale is determined by the Rational Method:

$$Q = CIA,$$

Where C = runoff coefficient, expressing the ratio of rate of runoff to rate of rainfall = 0.95

i = intensity of rainfall, in inches per hour, for the selected frequency (PMF-B) and for duration equal to the time of concentration (6 min) = 10.7 inches per hour

A = drainage area, in acres, tributary to the point under design (west swale at point it enters detention/sedimentation pond) = 20 acres

$$Q = (.95)(10.7)(20) = 203 \text{ CFS}$$

The drainage swale is designed as a V-ditch with 5 to 1 side slopes, on a nominal grade of 1% from a high point near the northeast corner of the disposal cell to the detention/sedimentation pond at the southwest corner of the Disposal Site. The velocity in feet per second (V) and the required cross-sectional area in feet² (A) are computed by Manning's Equation:

$$Q = \frac{1.486}{n} AR^{2/3} S^{1/2},$$

Where n = coefficient of roughness of channel = .025

R = hydraulic radius, in feet (area/wetted perimeter)

S = slope of channel, in percent

$\frac{Q \text{ (cfs)}}{203}$	$\frac{V \text{ (fps)}}{6.8}$	$\frac{A \text{ (ft}^2\text{)}}{31.3}$	$\frac{\text{Depth of flow (ft)}}{2.5}$
-------------------------------	-------------------------------	--	---

Channel protection (riprap) is designed for the swale by Riprap Design with Safety Factors Method, developed by Colorado State University for the Wyoming Highway Department:

OBJECTIVE ESTIMATE TIME OF CONCENTRATION t_c
OF RAINFALL TO DRAINAGE CHANNEL
AND ADD t_c TO TIME IN CHANNEL

METHOD

- 1) USE KIRPICH'S FORMULA AND DATA FROM PREVIOUS CALCULATIONS TO ESTIMATE t_c
- 2) ESTIMATE TIME IN CHANNEL BY FINDING CHANNEL VELOCITY AT 6500 CFS DISCHARGE AND USING DISTANCE AROUND WEST SIDE CHANNEL
- 3) ADD RESULTS FROM 1) AND 2)

SOLUTION

1) KIRPICH'S FORMULA:

$$t_c = .00013 \frac{L^{0.77}}{S^{0.385}} \quad \checkmark$$

where: L = length of basin in ft.

S = upgradient avg. slope of basin

t_c = time of concentration in hrs

for this calculation,

$L = 4800$ ft (see pg 5 of calculation I-3)

$S = .5\%$ (see justification in calculation I-2)

$$t_c = .00013 \frac{4800^{.77}}{.005^{.385}} = .683 \text{ hrs} = 40.97 \text{ min} \quad \checkmark$$

2) ESTIMATE TIME IN CHANNEL

FROM WS/CLCP MAP (INCLUDED IN CALCULATION I-8)

DISTANCE FROM ^(HIGH POINT) NE CORNER OF CHANNEL WESTWARD

AND THEN SOUTHWARD TO SW CORNER IS

15.25"

15.10"

5.25"

15.10"

RECALL THAT $\frac{287}{307} = 93\%$

OF SITE AREA DRAINS

WESTWARD. (calculation I-6)

$$\sqrt[4]{60.7''} = \text{AVG} = 15.2'$$

∴ IGNORE EASTWARD DRAINAGE SITUATION

SCALE 1" = 136'

$$\text{DISTANCE} = 2060'$$

OBTAIN VELOCITY FROM CALCULATION I-7 PAGE 9

AT DISCHARGE = 6500 cfs,

$$V = 10 \text{ fps} \checkmark$$

$$\text{NOW TIME} = \frac{\text{distance}}{\text{velocity}} = \frac{2060 \text{ ft}}{10 \frac{\text{ft}}{\text{sec}}} \cdot \frac{60 \text{ sec}}{\text{min}} = 3.13 \text{ min} \checkmark$$

$$3) t_{\text{TOTAL}} = t_c + t_{\text{ch}} = t_1 + t_2$$

$$= 40.97 \text{ min} + 3.43 \text{ min}$$

$$t_{\text{TOTAL}} = 44.40 \text{ min} = 44 \text{ min}, 24 \text{ sec}$$

that a conservative value of C be applied for PMF estimation since infiltration and storage comprise a low percentage of the runoff. Furthermore, the C values presented were derived for storms of 5-100 year frequencies. Therefore, less frequent, higher intensity storms will require the use of a higher C value (Chow, 1964). It is recommended that a runoff coefficient of 1.0 be used for PMF applications in very small watersheds since the effects of localized storage and infiltration will be small.

Table 4.5. Values of C for Use in Rational Formula.

Soil Type	Watershed Cover		
	Cultivated	Pasture	Woodlands
With above-average infiltration rates; usually sandy or gravelly	0.20	0.15	0.10
With average infiltration rates; no clay pans; loams and similar soils	0.40	0.35	0.30
With below-average infiltration rates; heavy clay soils or soils with a clay pan near the surface; shallow soils above impervious rock	0.50	0.45	0.40

Source: Chow, 1964.

4.8.2 Rainfall Intensity

In order to determine the rainfall intensity, i , the time of concentration, t_c , must be estimated. The time of concentration can be approximated by:

(a) Applying one of the many accepted empirical formulae such as

$$t_c = 0.00013 \frac{L^{0.77}}{S^{0.385}} \quad (4.44)$$

where L is the length of the basin in feet measured along the watercourse from the upper end of the watercourse to the drainage basin outlet and S is the average slope of the basin. Time of concentration is expressed in hours. This procedure is not applicable to rock covered slopes. This expression was

Calculating Riprap Size for
6,500 CFS in western Diversion
channel

1 - Depth of flow is about 10' (see
Attached rating curve)

2 - Shear stress, $\tau = \gamma d S = 6.24$

3 - $d_{50} = \frac{6.24}{.04(\gamma_s - \gamma_w)}$
 $\gamma_s = 165 \text{ lb/ft}^3$

$d_{50} = 1.5 \text{ feet} = 18''$

OBJECTIVE: Determine the PMF flow for the Kress Creek drainage using Figures B.2 through B.7 of NRC Regulatory Guide 1.59.

SOLUTION:

From the USGS West Chicago Quadrangle, the site location is approximately

Latitude 41° 52' 30" N

Longitude 88° 12' 30" W

From Figures B.2 through B.7 of Ref 1 (see Attachment F) for the location above, the PMF flows for the given areas below are:

Area (mi. ²)	PMF (cfs)
100	100,000 ✓
500	215,000 ✓
1,000	310,000 ✓
5,000	600,000 ✓
10,000	770,000 ✓
20,000	940,000 ✓

The above data are shown plotted on a logarithmic scale on the next two pages.

Two procedures were used to extrapolate the data to estimate the DMF Flow for the 18 mi² Kress Creek drainage.

First, a power curve was fit to the data, since they plot along a relatively straight line, as shown on page 4. The equation of the power curve is

$$DMF = 9,096 \text{ Area}^{0.401}$$

Using this equation results in the following DMF Flow

Area (mi ²)	DMF (cfs)
18	60,850 ✓

This curve is considered to be a high estimate.

The second estimate involved plotting an "eyeball" curve through the points and extrapolating a line that increased in slope as area decreased, as shown on page 5. This was considered to be a low estimate of the DMF Flow. The corresponding DMF value

Area (mi ²)	DMF (cfs)
18	42,000 ✓

NUCLEAR POWER PLANTS

Attachment I

USNRC REGULATORY GUIDES

Regulatory Guides are issued to describe and make available to the public methods accessible to the NRC staff of implementing specific parts of the Commission's regulations, to delineate techniques used by the staff in evaluating specific problems or particular conditions, or to provide guidance to applicants. Regulatory Guides are not substituted for regulations, and compliance with them is not required. Methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the issuance or continuation of a permit or license by the Commission.

Comments and suggestions for improvements in these guides are encouraged at all times, and guides will be revised, as appropriate, to accommodate comments and to reflect new information or experience. This guide was revised as a result of substantiated comments received from the public and additional staff review.

Comments should be sent to the Secretary of the Commission, U.S. Nuclear Regulatory Commission, Washington, D.C. 20555, Attention: Drafting and Service Branch.

The guides are issued in the following ten broad divisions:

- | | |
|-----------------------------------|------------------------|
| 1. Power Reactors | 6. Products |
| 2. Research and Test Reactors | 7. Transportation |
| 3. Fuel and Materials Facilities | 8. Occupational Health |
| 4. Environmental and Siting | 9. Antitrust Review |
| 5. Materials and Plant Protection | 10. General |

Requests for single copies of issued guides (which may be reproduced) or for placement on an automatic distribution list for single copies of future guides in specific divisions should be made in writing to the U.S. Nuclear Regulatory Commission, Washington, D.C. 20555, Attention: Director, Division of Document Control.

Kerr-McGee West Chicago Facility

Evaluation of Potential Erosion

Influence of Retention Pond

Riprap for the western diversion ditch was sized based upon a critical channel section immediately upstream of the sedimentation basin. The same riprap will be continued around the side of the disposal cell that forms the northeastern side of the retention pond.

Most water enters the retention pond from the western diversion ditch. A lesser amount will flow into the pond from the southern diversion ditch (estimated to be about 400 cfs in section 5 of the report), and a small amount will flow directly from the surface of the disposal cell into the pond.

The retention pond discharges through a ten-inch discharge pipe. Flood flows discharge from the retention pond through an overflow spillway formed in the western berm of the pond. This spillway is approximately 75 feet wide, and the crest is one foot below the top of the berm. The spillway was sized to pass a reduced PMF without failure. Flows larger than the reduced PMF will overtop the berm forming the basin. The berm may erode if overtopped.

The position of the retention pond in relation to site topography and the disposal cell is shown in Figure 1 of the July 23 report. The pond is located at the southwest corner of the disposal cell, in a natural swale that extends to the south. The pond is located in a wide spot in the swale as is shown by the attached figure, which is a larger-scale drawing of the part of the site topographic map depicting existing ground surface around and within the area where the detention pond will be constructed. The approximate outline of the detention pond has been sketched to provide a reference on this figure. This sketch is only a rough outline of the proposed pond.

The swale widens at the retention pond because the disposal cell, which will form one side of the drainage channel, ends. Water flowing down the western side of the channel will spread upon entering the retention pond, and the velocity and depth of the water will decrease. Downstream of the proposed pond, the natural swale is constricted. This constriction will restrict flow, and will reduce velocities above the constriction.

The presence of the retention pond will have relatively little effect on flow conditions during large floods. The conservatively estimated depth of flow in the western diversion channel is ten feet. This depth is almost twice the depth of the retention pond, and represents a water surface that is about four feet above the berm forming the pond. The pond is constructed mostly above ground. The riprap in the diversion channel was sized based upon normal flow depths and velocities in the diversion ditch. Water entering the pond will spread into the wider channel that exists at the pond. The velocity will decrease. The riprap on the edge of the disposal cell will protect the cell from possible erosion by eddies in this flow.

Likewise, the failure of the retention pond berm will have little effect on the flow. The berm will be overtopped long before the peak flow (6500 cfs) used to size the riprap is reached. The flow still will spread and slow down as it enters the pond area because of the natural widening of the drainage swale and the fact that the disposal cell ends.

In summary, neither the presence of the retention pond nor its washing out will have much affect on flow conditions in the diversion ditches. The pond is located in a wide area of a natural drainage swale. The total depth of the pond is only slightly more than one-half of the depth of flow in the diversion ditch during the design flow, and the pond is constructed mostly above ground. The riprap was sized based upon normal flow depths and velocities in the diversion ditch. Because the swale downstream of the pond is wider than the design section of the diversion ditch, failure of the pond berm would merely remove a restriction in the swale, and would not lead to flow conditions more critical than those used to size the riprap for the channel.
