Re: Annual Review, Groundwater Corrective Action Plan

Ambrosia Lake Facility

License SUA-1473, Docket No. 40-8905

Dear Mr. Konwinski:

The attached is the annual review of Quivira Mining Company's Corrective Action Plan (CAP) for its Ambrosia Lake facility. This review is being submitted in accordance with license condition #34 of the above referenced license. This plan reviews the hydrologic effects on the different geologic units resulting from the approved corrective measures implemented on each unit.

If you have any questions or need further information please contact me at (405) 842-1773.

Sincerely,

Bill Ferdinand, Manager Radiation Safety, Licensing & Regulatory Compliance

ANNUAL CORRECTIVE ACTION PLAN REVIEW

In accordance with Ambrosia Lake's NRC source material SUA-1473, condition #34, paragraph d, the licensee is to review and submit on or before August 1 of each year, the Corrective Action Plans (CAP) effect on the different aquifers. This reports reviews the those effects and the progress of Ambrosia Lake's CAP.

I. REVIEW OF CORRECTIVE ACTION PROGRAM

The Corrective Action Plan (CAP) at the Ambrosia Lake facility was formally approved by NRC as amendment #15 on May 14, 1990. This program requires the operation of Quivira's Section 30 and Section 30 West mine dewate ing and maintenance programs and the alluvium interceptor trench. These programs allow for the interception, collection and removal of contaminated fluids from the affected geologic units. These corrective programs are in place and operating.

For the year through June 30, the Section 30 and 30 West mines have pumped a total of 86.1 and 99.1 million gallons of water respectively. It is estimated using the 1989 ventilation hole survey information as a basis of contamination interception and collection that approximately 0.49 million gallons of water was collected from the Tres Hermanos B formation and with 3.2 million gallons collected from the Dakota formation. During this same time period, the interceptor trench has recovered approximately 13.0 million gallons attributable from tailings impoundment #1 seepage and 13.0 million gallons collected from water being sweep back towards the interceptor trench from the NPDES discharge creek.

The CAP also requires samiannial monitoring of specified alluvial, Tres Hermanos A and . and Dakota wells with an annual progress report on or before August 1 of each year. . complete set of monitoring and analytical results for the

1st half of 1990 has been collected in accordance with license condition #34, paragraphs A and B. These results are attached in Appendix A.

As expected, due to the short time interval between the last submittals to NRC on December 22, 1989 and March 30, 1990, negligible changes in water quality have occurred. Therefore, it is felt that the ground water information submitted within these reports including contamination delineation are still applicable.

Although not lired by the CAP, Quivira is continuing to pump water from its dewatering trench located on the west side of tailings impoundment #2. Built in May 1989, the trench has eliminated all standing water in tailings impoundment #2 and is providing some dewatering of the tailings. Since pumping begin in late May 1989, a total of 27.96 million gallons of fluids have been pumped from the trench. For the year through June 30, a total 6.57 million gallons have been pumped from the dewatering trench and subsequently disposed at the Section 4 lined evaporation ponds.

II. REVIEW OF CHLORIDE CONCENTRATIONS - MONITOR WELLS MW-20\MW-29

As requested within the May 14, 1990, amendment #15 corrective active plan approval letter, Quivira has reviewed past chloride values from the Section 4 evaporation ponds monitor wells including monitor wells MW-20 and MW-29.

The area in which the Section 4 evaporation ponds are located, was once the drainage for discharges from Berious mines and heap leach operations. The drainage flowed diagonally from the northeast to the southwest section corners of Section 4. Attached in Appendix B is Figure 1 which shows the typical drainage on the U.S.G.S map prior to the construction of the

lined evaporation ponds. Figure 2 shows the same map with the "as built" location of the evaporation ponds.

The area in which monitor well MW-29 is situated is upstream of the Section 4 evaporation ponds. This is shown on Figure 3 and is also included in Appendix B. This well was installed to determine upstream water quality flowing down dip into the Section 4 area. The chloride values being seen within this well are due in part to previous mine discharges and chlorides naturally associated with the shales and clays in the area. The chlorides are not from the Section 4 lined vaporation ponds.

Although the chloride values are elevated as compared to other wells within the area, the chloride values are not uncommon for alluvial wells. The high occurrence of intermixing lenses of shales and clays throughout the alluvium probably cause the elevated chloride concentrations as the shales were originally deep sea deposits that contain elevated concentrations of salts, including sodium chloride. Although a majority of the salts have been washed from the material, residues still remain within the shales and clays.

Monitor well sinitially completed in August 1980 with the first monitoring data collected the next month. The initial chloride concentration was 324 mg/l. The most recent concentrat. India value of 243 mg/l. As shown on the attached graphs are also slightly decreasing with one. These historical graphs are attached in Appendix C.

As can be seen, the high chloride values within this well are not associated with Quivira's evaporation ponds but rather

TOTAL WANTED SALE OF FIRST

from previous mine discharges and natural geochemical actions associated with the shales\clays.

Quivira has examined the historical analytical data along with the geology of the area and concludes that the elevated chloride levels in monitor well MW-20 are probably caused by geochemical process associated with the shales and clays of the area. The elevated levels are not caused by a leak within a pond liner.

Located on the barm between evaporation ponds 19 and 20, if a pond liner look had occurred, the chloride values within monitor well would be much higher than their current two year average of 164 mg/l. Historically, the average chloride concentrations within ponds 19 and 20 respectively are approximately 37,000 and 34,600 mg/l.

In conjunction with any pond liner leak, other parameters such as sulfates and TDS would also be greatly elevated because of the high concentrations of these parameters within the ponds. The sulfates concentrations within evaporation ponds 19 and 20 are 144,000 mg/l and 165,000 mg/l respectively while TDS are 280,000 mg/l and 270,000 mg/l. Monitor well MW-20 sulfates and TDS concentrations on the other hand have remained relatively constant with a historical average of 2,600 and 4,400 mg/l. Because of the high sulfates and TDS concentration within evaporation ponds 19 and 20, a leak would clearly be identified by high sulfates and TDS in monitor well MW-20. This is clearly not the case. Attached in Appendix D are graphs of the historical chloride, sulfate, TDS, and pH values for monitor well MW-20 and the lined evaporation ponds.

In addition to much higher chlorides, sulfates, and TDS concentrations, a drastic lowering of the pH and increase in the depth to water would be expected. However, such is not

the case as the historical pH values for evaporation ponds 19 and 20 are 1.0 and 0.9 respectively while monitor well MW-20 has been constantly neutral or around 7. The depth to water has remained relatively constant for monitor well MW-20. The historical graphs of MW-20 for pH and depth to water are included in Appendix D. Also included are the historical pH values of solutions within the lined evaporation ponds.

Since the elevated chloride concentrations cannot be attributed to pond liner leaks, Quivira has previously performed various test to try and explain the sometimes fluctuating and elevated chloride concentrations that have historically occurred.

The first test that was performed was a stratification test. It was suspected that perhaps the wells contained stratified zones of concentrations. Using a special bailer to obtain water samples at various depths, two wells were selected and sampled. The results of the sampling are presented below.

Stratification Sampling (mg/1)

Well	Comments	Chlorides
MW-27	Normal Bail	140
	3 Foot Depth	140
	6 Foot Depth	130
	9 Foot Depth	130
MW-29	Normal Bail	320
	3 Foot Depth	320
	6 Foot Depth	320
	9 Foot Depth	320

As shown, the results indicate that the wells are not stratified nor do the sampling procedures employed bias the analytical results.

Because most Section 4 wells have less than 10 feet of water with little recharge capacity, a second test was performed to find whether the fluctuating and elevated chloride concentrations resulted from collection of samples from static well water versus "formation" water being rawn into the well. Another set of two wells were selected and bailed dry several times before collecting a sample. These results were compared to samples collected from the same wells from static well water. The comparison results are presented below.

Formation Water Sampling (mg/l)

Well	Comments	Chlorides
MW-10	Bailed Dry 2 Times Normal Bail	84 76
MW-19	Bailed Dry 3 Times	26
	Normal Bail	33

As indicated, the analytical results compared very favorably indicating that due to the limited recharge capacity of the alluvium, the chloride elevations and periodic fluctuations were not the result of sampling technique.

Finally, to assure that cross-contamination was not occurring resulting from the leaching of chlorides from the bailer, 200 ml of deionized water was poured into the bailer and agitated. The deionized water was analyzed for chlorides and the results indicated that less than 0.5 mg/l was leached from the bailer.

In conclusion, the only plausible explanation for the elevated chloride concentrations for this well seems to be the naturally occurring geochemical reactions occurring within the shales and clays. Since evaporation ponds 19 and 20 abut and partially overlay the outcropping of Mancos shale and Tres Hermanos B sandstone as shown on a photocopy of Tres Hermanos B outcroppings as attached in Appendix D, it would seem that the elevated chloride levels are in fact probably due to shale contact in this region.

APPENDIX A
