

Effluent and Waste Disposal

Semi-Annual Report

3rd & 4th Quarter, 1978

Facility

Indian Point Station

Licensee

Consolidated Edison Company of New York, Inc.

This information is provided in accordance with the requirements of Regulatory Guide 1.21. The numbered sections of this report reference corresponding sections of the subject Regulatory Guide, pages 1.21-10 to 12. The Power Authority of the State of New York has chosen to issue a separate semi-annual report. This report covers discharges for the third and fourth quarters of 1978. The liquid discharges have been proportioned to Units 1 and 2 based on the total volume of site waste processed at Con Edison. The airborne releases are for Units 1 and 2 only.

A. Supplemental Information

1. Regulatory Limits

Indian Point Units 1, 2 and 3 are presently subject to specifications on radioactive waste releases that are set forth in sections 2.4 and 3.4 of Appendix B to Docket's 50-3, 50-247 or 50-286 entitled "Environmental Technical Specification Requirements for Once-Through Cooling". The percent of technical specification limit reported in Table 1A and the percent of applicable limit reported in Table 2A are the percent of the quarterly limit specified in the ETSR.

2. Maximum Permissible Concentrations

a. Fission and Activation Gases

The quarterly limits for those specifications stated in the ETSR have been used to calculate the percent of technical specification limit. The K, L, M, N values for Unit 2 vent release points are based on the isotopic concentrations reported in Table 1C and on the individual isotopic K, L, M, N values in Table 2.4-5 of the ETSR. The isotopic analysis in Table 1B and the values in Table 2.4-5 were used to determine the K, L, M, N values for Unit 1 stack releases.

7904130233 R

b&c      Iodines & Particulates

The quarterly limits for iodine-131 and particulates with half-lives greater than 8 days in section 2.4.2.b.3 of the ETSR have been used as the maximum permissible concentration for the purpose of calculating the percent of technical specification limit.

d.      Liquid Effluents

All liquid discharges from Indian Point are made through a common discharge canal with a minimum of 100,000 gpm dilution water. The isotopic content, excluding tritium and dissolved noble gas, of continuous and batch mode discharges for each calendar quarter have been added and a weighted average fraction of MPC has been calculated for this isotopic mixture as described in 10 CFR 20. The percent of applicable limit reported is the percent of MPC concentration of the time averaged diluted concentration for each calendar quarter.

The third and fourth quarter continuous releases are for Units 1 and 2 only. The batch releases discharged through the common site processing facility have been apportioned according to the volume transferred from the respective units to the processing facility.

The tritium limit has been established in the same manner as the other isotopes in liquid effluents.

Since there is no limit stated for dissolved noble gases in 10 CFR 20, we have established a limit of  $2.55 \times 10^{-3}$  uCi/cc.

3.      Average Energy

The average energy ( $\bar{E}$ ) of the radionuclide mixture in releases of fission and activation gases for the third quarter was  $\bar{E}$  of 3.83E-2 Mev/Dis, and  $\bar{E}$  of 1.51E-1 Mev/Dis. The corresponding values for the fourth quarter were  $\bar{E}$  of 3.97E-2 Mev/Dis and  $\bar{E}$  of 1.52E-1 Mev/Dis.

4.      Measurements and Approximations of Total Radioactivity

a.      Fission and Activation Gases

Analysis of effluent gases has been performed in

compliance with the requirements of Table 2.4-2 of the ETSR. In the case of isolated tanks (batch releases) the total activity discharged is based on an isotopic analysis of each batch and the volume of gas in that batch corrected to standard temperature and pressure.

Vapor containment ventilation discharges have been generally treated as batch releases. At least one complete isotopic concentration analysis of containment air is performed per month and this is applied to a gross analysis of the ventilation air performed prior to each discharge. This information is combined with the volume of air in each discharge to calculate the radionuclide composition of these discharges.

The continuous discharges are based on the isotopic content determined from weekly samples of ventilation air. This information is combined with total air volume discharged by this route. The accumulation of batch and containment ventilation releases are then used to determine total discharges.

For this reporting period, the plant vent was the major source of gaseous discharges.

b&c      Iodines and Particulates

Iodine-131 and particulate releases are quantified by collecting a continuous sample of ventilation air on a potassium-iodide impregnated activated charcoal cartridge and a glass-fiber filter paper. These samples are changed weekly as required in Table 2.4-2 of the ETSR and the concentration of isotopes found by analysis of these samples is combined with the volume of air discharged during the sampling period to calculate the amount of activity discharged.

For other iodine isotopes the ratio of each isotope to iodine-131 is determined for a monthly 24 hour sample. These ratios are then used, along with the total monthly discharge of iodine-131, to calculate the amount of these isotopes discharged in this monthly period.

d. Liquid Effluents

A proportional composite sample of each batch discharge is taken and an isotopic analysis is performed in compliance with requirements specified in Table 2.4-1 of the ETSR. This isotopic concentration data is combined with information of volume discharged to determine the amount of each isotope discharged in the period.

Samples of continuous discharges have been taken and analyzed in compliance with Table 2.4-1 of the ETSR. This concentration data is combined with the volume discharged to calculate the total activity discharged.

5.	<u>Batch Releases</u>	<u>1978</u>	
		<u>3rd Qtr.</u>	<u>4th Qtr.</u>
a)	<u>Liquid (1)</u>		
	Number of Batch Releases	366	360
	Total Time Period Batch Release (Min.)	43359	42996
	Maximum Time Period Batch Release (Min.)	180	857
	Average Time Period Batch Releases (Min.)	118	119
	Minimum Time Period Batch Releases (Min.)	25	15
	Average Stream Flow (cfs)	6670	10480
b)	<u>Gaseous (2)</u>		
	Number of Batch Releases	109	116
	Total Time Period Batch Releases (Min.)	36589	27278
	Maximum Time Period Batch Releases (Min.)	1632	1440
	Average Time Period Batch Releases (Min.)	336	235

EFFLUENT AND WASTE DISPOSAL  
SEMI-ANNUAL REPORT  
E. RADIOLOGICAL IMPACT ON MAN  
SECOND HALF, 1978

## RADIOLOGICAL IMPACT EVALUATION

Doses from noble gas immersion, inhalation, ground deposition, and vegetation ingestion were evaluated for the residence located 1525 meters SSW of Indian Point Unit No. 3, which is the point of maximum offsite radiation dose (all pathways considered) likely to be occupied. Doses were evaluated for an individual ingesting milk and meat from a cow located about 7.5 miles to the NNE. In all cases, these evaluations were performed using the models presented in Regulatory Guide 1.109. Noble gas releases were considered to be either batch or continuous, while all iodine and particulate release were considered to be continuous. Noble gas release from containment pressure reliefs and purges were treated as a continuous release, because of the large number of such releases. Other releases (e.g. gas decay tank releases) were considered as batch and were evaluated using actual meteorological conditions existing during the release period. Continuous releases were evaluated using average meteorological conditions based on the six month release period. Estimates of relative deposition per unit area were obtained from the numerical approximation presented in the NRC computer program X0QDOQ for ground releases. Values of atmospheric dispersion factors ( $X/Q$ ) were computed using the Sagendorf straight line air flow model, assuming a ground level release, and the subroutine POLYN (from X0QDOQ) for computing standard deviations in the horizontal direction ( $\sigma_x$ ) and vertical direction ( $\sigma_z$ ).

Integrated doses for the population within 50 miles of Indian Point from gaseous effluents were computed based on linear interpolation of 1970 - 2010 population data contained in the Indian Point Unit No. 3 FSAR.

NUREG-0017, "Calculation of Release of Radioactive Materials in Gaseous and Liquid effluents from Pressurized Water Reactors", assumes an annual release of 8.0 Ci/yr of Carbon-14. Therefore, to be consistent with NUREG-0017, a release of 4.0 Curies of Carbon-14 was assumed for the six month period in addition to the radioactive materials measured in Indian Point gaseous effluents.
