1.0 INTRODUCTION

As prescribed in Sequoyah Nuclear Plant (SQN) Unit 1 Technical Specification 4.6.1.2, the leakage of air from the boundary forming the reactor building primary containment is limited to 0.25 percent by weight of the containment air mass per day at a pressure of Pa (i.e. 12.0 psig). In conformance with Title 10, Code of Federal Regulations (CFR), Part 50, Appendix J, SQN Technical Specifications require that a reactor building containment integrated leak rate test (CILRT) be performed as part of the surveillance program to demonstrate the continuing leak-tight integrity of the reactor building primary containment.

The fourth inservice reactor building CILRT was successfully completed on SQN Unit 1 by TVA personnel on December 17-20, 1993. This test was conducted in accordance with plant approved surveillance instructions 1-SI-SLT-088-156.0 and 1-PI-SLT-000-156.0, which are on file at the plant site. These SIs implement the requirements of SQN Unit 1 Technical Specifications and 10 CFR 50, Appendix J. The American National Standard for Containment Testing, ANSI 45.4-1972, the American Nuclear Society for Containment Testing, ANS 56.8, and the procedure outlined in Bechtel's topical report, "Testing Criteria for Integrated Leakage Rate Testing of Primary Containment Structures for Nuclear Power Plants" (BN-TOP-1, Revision 1) provided guidance for the procedures implemented by the SI and PI.

SQN Unit 1 is a 3,411 megawatt thermal, pressurized water reactor employing an ice condenser pressure suppression containment. The Final Safety Analysis Report defines the calculated peak accident pressure, Pa, to be 12.0 psig. The reactor building containment is divided into three major compartments for the CILRT analysis--the ice condenser houses the energy absorbing ice beds and supporting machinery for the ice condenser systems, the lower compartment which contains the reactor and main piping systems, and the upper compartment which provides for a large work area within containment and also can accommodate the displaced air mass from the other compartments in the unlikely event of a loss-of-coolant accident (LOCA). These three compartments are connected by means of blowout panels located between the ice condenser and the upper/lower compartments. In the event of a LOCA, steam flows from the lower compartment through the ice condenser compartment and into upper containment. The upper compartment is sealed from the lower compartment to ensure that any steam released in an accident will be forced through energy absorbing ice beds. For the performance of the CILRT, the lower compartment and upper compartments were not sealed from each other to promote the free flow of air in containment.

This report outlines the objectives, principal events, special equipment used, and analysis of the test results for the CILRT conducted on December 17-20, 1993, on SQN Unit 1. In addition, a summary of local leak rate tests conducted since the previous CILRT is included in Appendix L.

2.0 SUMMARY

The SQN Unit 1 inservice CILRT was conducted on December 17-20, 1993, in conjunction with the Cycle 6 refueling outage. The CILRT was successfully completed in 13 hours and 10 minutes and included 80 data points.

The calculated Total Time Leak Rate (TTLR) for the CILRT was 0.1333%/day. The associated reportable "as found" leak rate, which includes the upper confidence limit (UCL), the Type B and C leakage rates for systems in service during the CILRT, the leakage savings and leakage rate compensation for water level changes not accounted for by the CILRT computer system was 0.2416%/day. The "as left" leakage rate, including the UCL, leakage rates (Type B and C) of systems inservice during the CILRT, and leak rate compensation for water level change was 0.1742%/day.

The "as found" mass leak rate (MLR) for the CILRT was 0.1980%/day. The reportable "as left" leak rate was 0.1306%/day. These two values reflect the add on leakage adjustments described for the TTLR calculation.

The verification test agreement was -3.3590% for TTLR by Appendix J method and -2.2206% by BN-TOP-1 calculation. The MLR verification agreement by Appendix J method was 4.0515% and 2.5842% by BN-TOP-1 procedure. The allowable agreement is $\pm 25.0\%$.

Graphical and tabular data for the CILRT and verification test are included in Appendices A-F.

3.0 TEST PURPOSE AND RESULTS

3.1 Test Purpose

The objective of the inservice CILRT was to demonstrate the continuing leak tight integrity of the Unit 1 reactor building containment for return-to-power operation.

For SQN Unit 1, the leak-tight integrity is defined in Technical Specification 4.6.1.2 to be that the leakage of air from containment is not to exceed 0.1875%/day at peak accident pressure Pa (12.0 psig).

3.2 Test Results

NOTE: CILRT and verification test graphical and tabular data are included in Appendices A-F.

3.0 TEST PURPOSE AND RESULTS (continued)3.2 Test Results (continued)

Pressurization was started at 2238 on December 17, 1993. During pressurization, pressurizer level was reported to be dropping and at 2357 pressurization was stopped to evaluate this situation. Apparently an air void existed in the reactor coolant system. However, it was determined that compression of the air void would not affect test results since equilibrium with containment ambient pressure would exist. During the remainder of pressurization, make up to the reactor coolant system continued to maintain pressurizer level constant. Pressurization was completed at 0940 on December 18, 1993. The stabilization phase was started at 0956. During stabilization, a difference in control room containment pressure and CILRT data acquisition system containment pressure was noted. Investigation revealed the calibrated data for the atmospheric pressure gauge, which is part of the CILRT test system, had been entered incorrectly. After reentering the calibration data, the CILRT test system indicated a containment pressure of 13.32 psig. This pressure was greater than that specified by the test procedure but was below the ASME Section 8 Paragraph UG 100 limit of 13.5 psig. The decision was made to continue the test sequence at the current pressure since any possible effects or results would be in the conservative direction. The temperature stabilization phase was ended at sample 29 after four and one-half hours of data. Temperature stabilization was $0.0624^{\circ}\text{F}/\text{hour}$, which was only 12.5% of the allowable $0.5^{\circ}\text{F}/\text{hour}$.

The test phase was started at sample 30 at 1426 on December 18, 1993. At 1456, it was reported that a penetration used to supply ice during outages (X-79B) was leaking. The initial set of data was terminated at sample 60 at 1927 on December 18, 1993. The indicated calculated TTLR and MLR of sample 60 were 0.1825%/day and 0.187%/day, respectively. Inspection of the "O" ring seals on X-79B penetration revealed damage (breakage) which had apparently occurred when the penetration flange was replaced approximately two weeks prior to the conduct of the CILRT. This damage was not detected during the Type B LLRT performed after replacement due to an obstruction (foreign material) in the flange test port. The flange and surfaces were cleaned, the seals were replaced, and the flange retorqued. The possible presence of foreign material in the flange test port is being investigated. The seals were replaced and the flange retorqued. The test was resumed at sample 81 at 0221 on December 19, 1993.

3.0 TEST PURPOSE AND RESULTS (continued)

3.2 Test Results (continued)

The test continued until sample 160 when the TTLR UCL was 0.1742%/day and the MLR UCL was 0.1306%/day. The leak rate was increasing slightly at the conclusion of the test. However, the TTLR calculated value of 0.1338%/day, when extrapolated, as described in BN-TOP-1, was 0.1382%/day which is well within the required acceptance criteria of 0.1875%/day. The mean value of the measured total time leak rates over the last five hours of the test period was 0.1169%/day, which is significantly less than 0.75 La (0.1875%/day) as required by the termination criteria of BN-TOP-1.

A leak rate of approximately La was established and allowed to stabilize for one hour in accordance with BN-TOP-1 requirements for the verification test. The verification test started at sample 168 at 1651 on December 19, 1993 with an imposed leak rate of 104,884.4 standard cubic centimeters per minute (SCCM) or 98.6% of the allowable leak rate. The test was concluded satisfactorily at sample 210 at 2354 on December 19, 1993 after seven hours. The agreement was well within the limits of \pm 25%. The TTLR agreement per Appendix J and BN-TOP-1 was -3.3590% and -2.2206% respectively. The agreement for MLR was 4.0515% and 2.5842% for the Appendix J and BN-TOP-1 analysis respectively.

The following table presents the tests results as well as the instrument selection guide (ISG) evaluation for post test conditions.

TABLE OF CILRT AND VERIFICATION TEST RESULTS

TTLR = Total Time Leak Rate

MLR = Mass Leak Rate

- (1) Reflects leakage savings of 0.0674 percent per day.
- (2) Reflects leakage of systems inservice during CILRT of 0.0000 percent per day. See Appendix G.
- (3) Reflects adjustment of 0.0000 percent per day due to sump level changes. See Appendix H for calculations. Sump level influence on leak rate is facilitated by manual collection and evaluation of data. Pressurizer level changes are automatically monitored by the CILRT computer system and included in computed test results.
- (4) See Appendix F for verification calculations.

4.0 CONDUCT OF TEST

The following is a summary of events from the test log and test procedure for the Unit 1 CILRT.

<u>Date</u>	<u>Time</u>	<u>Event</u>
12/17/93	1400	Completed inspection of Unit 1 containment in accordance with SI-254.
12/17/93	2238	Started pressurization.
12/17/93	2357	Stopped pressurization due to pressurizer level drop.
12/18/93	0021	Pressurizer level drop apparently due to compression of air void in the reactor coolant system. Pressurizer makeup will be concurrent with pressurization.
12/18/93	0940	Completed pressurization.
12/18/93	0956	Started stabilization phase.
12/18/93	1042	Pressurization spool piece removed. Compressor is now disconnected from containment.
12/18/93	1100	Began leak checks in annulus. There is a discrepancy of 0.55 psi in the Unit 1 control room ready for containment pressure and the CILRT data acquisition system.
12/18/93	1340	Investigation into pressure discrepancy revealed calibration for CILRT atmospheric pressure gauge had been entered incorrectly. After reentering the calibration data pressure was 13.32 psig. This is greater than that specified by the test procedure but is below containment design pressure and ASME Section 8 Paragraph UG 100 limit of 13.5 psig.
12/18/93	1426	Temperature stabilization criteria met. Started test phase on sample 30.
12/18/93	1456	X-79B reported leaking.
12/18/93	1927	Test stopped at sample 60 to repair X-79B. Leak rate 0-1825%/day TIR (calculated) 0.187%/day MLR (calculated).
12/19/93	0050	Exited containment after repairs to X-79B.

4.0 CONDUCT OF TEST (continued)

<u>Date</u>	<u>Time</u>	<u>Event</u>
12/19/93	0200	Restart test at sample 78.
12/19/93	0215	Problem with P3 gauge reading (spike) will restart test at sample 81.
12/19/93	0221	Restart test at sample 81.
12/19/93	0900	Noticed anomaly in P3 reading. Deleted P3 from test data base.
12/19/93	1313	R24 in ice compartment overranged. Failed R24 from test data base.
12/19/93	1531	Concluded CILRT test phase at sample 160.
12/19/93	1550	Established verification test imposed leak.
12/19/93	1651	Started verification test at sample 168.
12/19/93	1750	AD 10/10 error 21 RS 232 1A timeout to primary computer. Concurrently bad data warning for dew cell D45. Failed D45 from test data based. Continuing on one computer.
12/19/93	2354	Terminated verification test.
12/20/93	0142	Started depressurization.
12/20/93	0615	Containment pressure is zero psig.

5.0 MEASUREMENTS AND CALIBRATIONS5.1 Test Equipment

Appendix K lists the instrument specification used for the Unit 1 Cycle 6 CILRT. All instruments were calibrated within six months of the CILRT and the temperature and dew point instruments also received an additional "in place" loop calibration after installation in primary containment.

5.2 Sensor Location

Appendix J gives the final volumetric weighing factor for each temperature and dew point sensor based upon a three-compartment model. The associated figures indicate sensor locations. The pressure sensors were divided so that two sensors measured each of the three compartments through X-27, X-87A, and X-87D.

5.0 MEASUREMENTS AND CALIBRATIONS (continued)5.2 Sensor Location (continued)

Utilizing two pressure sensors per compartment allows the removal of any one malfunctioning pressure gauge during the test and continue to accurately monitor pressure. An additional pressure gauge measured barometric pressure at the test station.

5.3 Computer-Based Data Acquisition and Data Reduction

The raw test data measured by the special test instrumentation during the SQN Unit 1 CILRT was scanned and collected by a microprocessor based data acquisition system. The raw test data was automatically presented to a portable minicomputer system for correction to calibration curves and reduction to containment leak rate. The minicomputer produced immediate statistical and graphical results of the containment test parameters, including temperature, pressure, vapor pressure, mass, total time leak rate, and mass leak rate plots.

These calculated results were reported automatically to the test director as the data was collected. Appendix I depicts the functional relationship between the special test instrumentation and the data acquisition and analysis system.

All calculations performed by the minicomputer system were in conformance with the procedure outlined in ANS 56.8, ANSI 45.4, and Bechtel Topical Report (BN-TOP-1), Revision 1).

Source listings for all computer programs are on file with the Plant Operating Systems Section in Chattanooga, Tennessee.

5.4 Reactor Building Containment Model

An ice condenser pressure suppression containment presents special problems not normally encountered in the leak testing of dry containment structures. The pressure suppression design feature requires the reactor building containment to be divided into distinct compartments, where vastly different temperatures and vapor pressures may exist. While each compartment is vented to the containment atmosphere during the performance of the CILRT, the direct circulation of air is limited.

5.0 MEASUREMENTS AND CALIBRATIONS (continued)5.4 Reactor Building Containment Model (continued)

Since an ice condenser containment typically exhibits a 40°F temperature differential between the ice compartments and others, it is necessary to compensate by compartmentalization so the leak rate is accurately measured. For SQN Unit 1 CILRT, a three-compartment containment model was used to measure the leak rate. The free air mass is calculated individually for each compartment, and containment leak rate is calculated from the sum of the compartmental masses. Each sensor within a compartment is volume weighted for the calculation of compartment average temperature and vapor pressure.

6.0 ANALYSIS OF TEST DATA

The previous sections of this report have discussed the general test conduct, calibration methods, and test equipment. In this section, events and problems that influenced the test results are discussed and are used to formulate conclusions on the performance of the SQN Unit 1, Cycle 6 CILRT.

6.1 Instrument Check

The instrument complement for SQN Unit 1 was 49 RTDs, 13 Dewcells (measure vapor pressure), 1 flow meter (for verification test), and 9 Mensor quartz pressure gauges (6 containment pressure and one atmospheric pressure gauge).

During testing, 1 pressure gauge, 1 resistance temperature detector, and 1 dew cell instrument had to be failed from the data base due to malfunctioning (i.e. spiking and overranging). Regardless of these losses, the instrumentation analysis in accordance with the ISG of ANSI 56.8-1987 proved that the instrument system provided excellent performance in determining the leak rate. See Section 3.2 for test results.

6.2 Discussion of Graphical and Tabular Results for the CILRT

The trends exhibited during the SQN Unit 1 Cycle 6 CILRT were typical of that experienced during past tests on a containment system employing an ice condenser. The trends of measured parameters in the upper and lower compartments uniformly are decreasing. However, the temperature and vapor pressure in the ice condenser typically, and in the case of the Unit 1 Cycle 6 CILRT, trend upwardly. This phenomenon along with electronic

6.0 ANALYSIS OF TEST DATA (continued)

6.2 Discussion of Graphical and Tabular Results for the CILRT (continued)

fluctuation in the instrument system and naturally occurring air currents in containment tend to produce instability in some test results. These influences appear to be the precipitating cause in the slight increase in the leak rate trend, although the extrapolated leak rate (as required and described by BN-TOP-1) was well below 0.75 La. No operational causes could be discovered to explain the trend and the magnitude of the trend (+0.002 slope of the leak rate line) was so small that the trend in leak rate had reversed itself (i.e. slope of leak rate line was -0.014) during the verification test. Other potential sources of instability, such as pressurizer level, which is monitored by the data acquisition and volume corrections made on a real time basis, and the influence of sump level on leak rates are corrected for subsequent to CILRT were found to be too small and not concurrent with the trend in leak rate to have been an influencing factor. Other than the slightly increasing trend in the leak rate toward the end of the test, no significant or unusual observations were recorded for the duration of the CILRT.

6.3 Discussion of Agreement (Verification Test)

Since this test was conducted in accordance with BN-TOP-1, the verification flow was allowed to stabilize for approximately one hour prior to starting the verification phase of testing. The verification test was concluded in seven hours, which is slightly over the duration of one-half the CILRT test phase as required by BN-TOP-1. No significant problems in data trends were recorded during this phase. Test summary data for the verification test is included in Appendix D, E, and F. The verification results were within $\pm 5\%$, which is well within the acceptance limit of $\pm 25\%$.

7.0 CONCLUSION

The CILRT performed on SQN Unit 1 Cycle 6 recorded an "as left" leak rates determined by the procedure outlined in BN-TOP-1, of 0.1742%/Day which is below the limit of 0.1875%/Day for return to power operation. The "as found" leak rate was 0.2416%/Day and included leakage savings of Type B and C tests performed prior to the CILRT. There was close agreement of the TTLR and MLR results, especially when the upper confidence limit is not included which gives credence to the test results produced by each method.

PENETRATIONS INSERVICE DURING CILRT

APPENDIX G

TESTABLE PENETRATIONS REQUIRED TO BE
INSERVICE DURING TEST PERFORMANCE

<u>Penetration</u>	<u>Description</u>	<u>Justification</u>	<u>Leakage Rate Added To 95% UCL</u>
X-27(C)	Integrated Leak Rate System Pressure	Isolation Valves Required To Be Open To Monitor Containment Pressure	0.0000 SCFH
X-47A	Ice Condenser System	Glycol Cooling supply To Air Handling Units In Ice Condenser Required To Ensure Ice Condition Is Maintained	0.0000 SCFH
X-47B	Ice Condenser System	Same As X-47A	0.0000 SCFH
X-54	Thimble Renewal	Used As Pressurization Point For Air Compressors	0.0000 SCFH
X-114	Ice Condenser System	Glycol Return From Air Handling Units Required To Ensure Ice Condition Is Maintained	0.0000 SCFH
X-115	Ice Condenser System	Same As X-114	0.0000 SCFH
X-118	Hatch	Used As Source For Verification Flow And Post-Test Depressurization	0.0000 SCFH
X-46	Waste Disposal	Used To Provide Leak-Off For RCP Seals	0.0000 SCFH
X-87A	Integrated Leak Rate System Pressure	Same As X-27C	0.0000 SCFH
X-87D	Integrated Leak Rate System Pressure	Same As X-27C	0.0000 SCFH

APPENDIX H

LEAK RATE CALCULATIONS DUE TO SUMP LEVEL CHANGES

CORRECTING LEAK RATES TO COMPENSATE
FOR SUMP LEVEL CHANGES

DATA: There was a two and one-half gallons increase in the Auxiliary Reactor Building Floor and Equipment Drain Sump during the CILRT and Verification Test.

CALCULATION: There are 7.48 gallons/ft³
 2½ Divided By 7.48 Yields 0.3342 ft³
 Decrease in Containment Volume

This corresponds to:

$$\frac{0.3342 \text{ ft}^3}{53.357 \frac{\text{lbf}}{\text{lb}_m} \frac{\text{ft}}{\text{in}^2}} = 0.0486 \text{ lb}_m$$

$$520.07 \text{ }^\circ\text{R}$$

Total containment mass is:

$$\frac{1,192,220.0 \text{ ft}^3}{53.357 \frac{\text{lbf}}{\text{lb}_m} \frac{\text{ft}}{\text{in}^2}} = 173,329.2341 \text{ lb}_m$$

$$520.07 \text{ }^\circ\text{R}$$

The leak rate impact due to increase in sump level is:

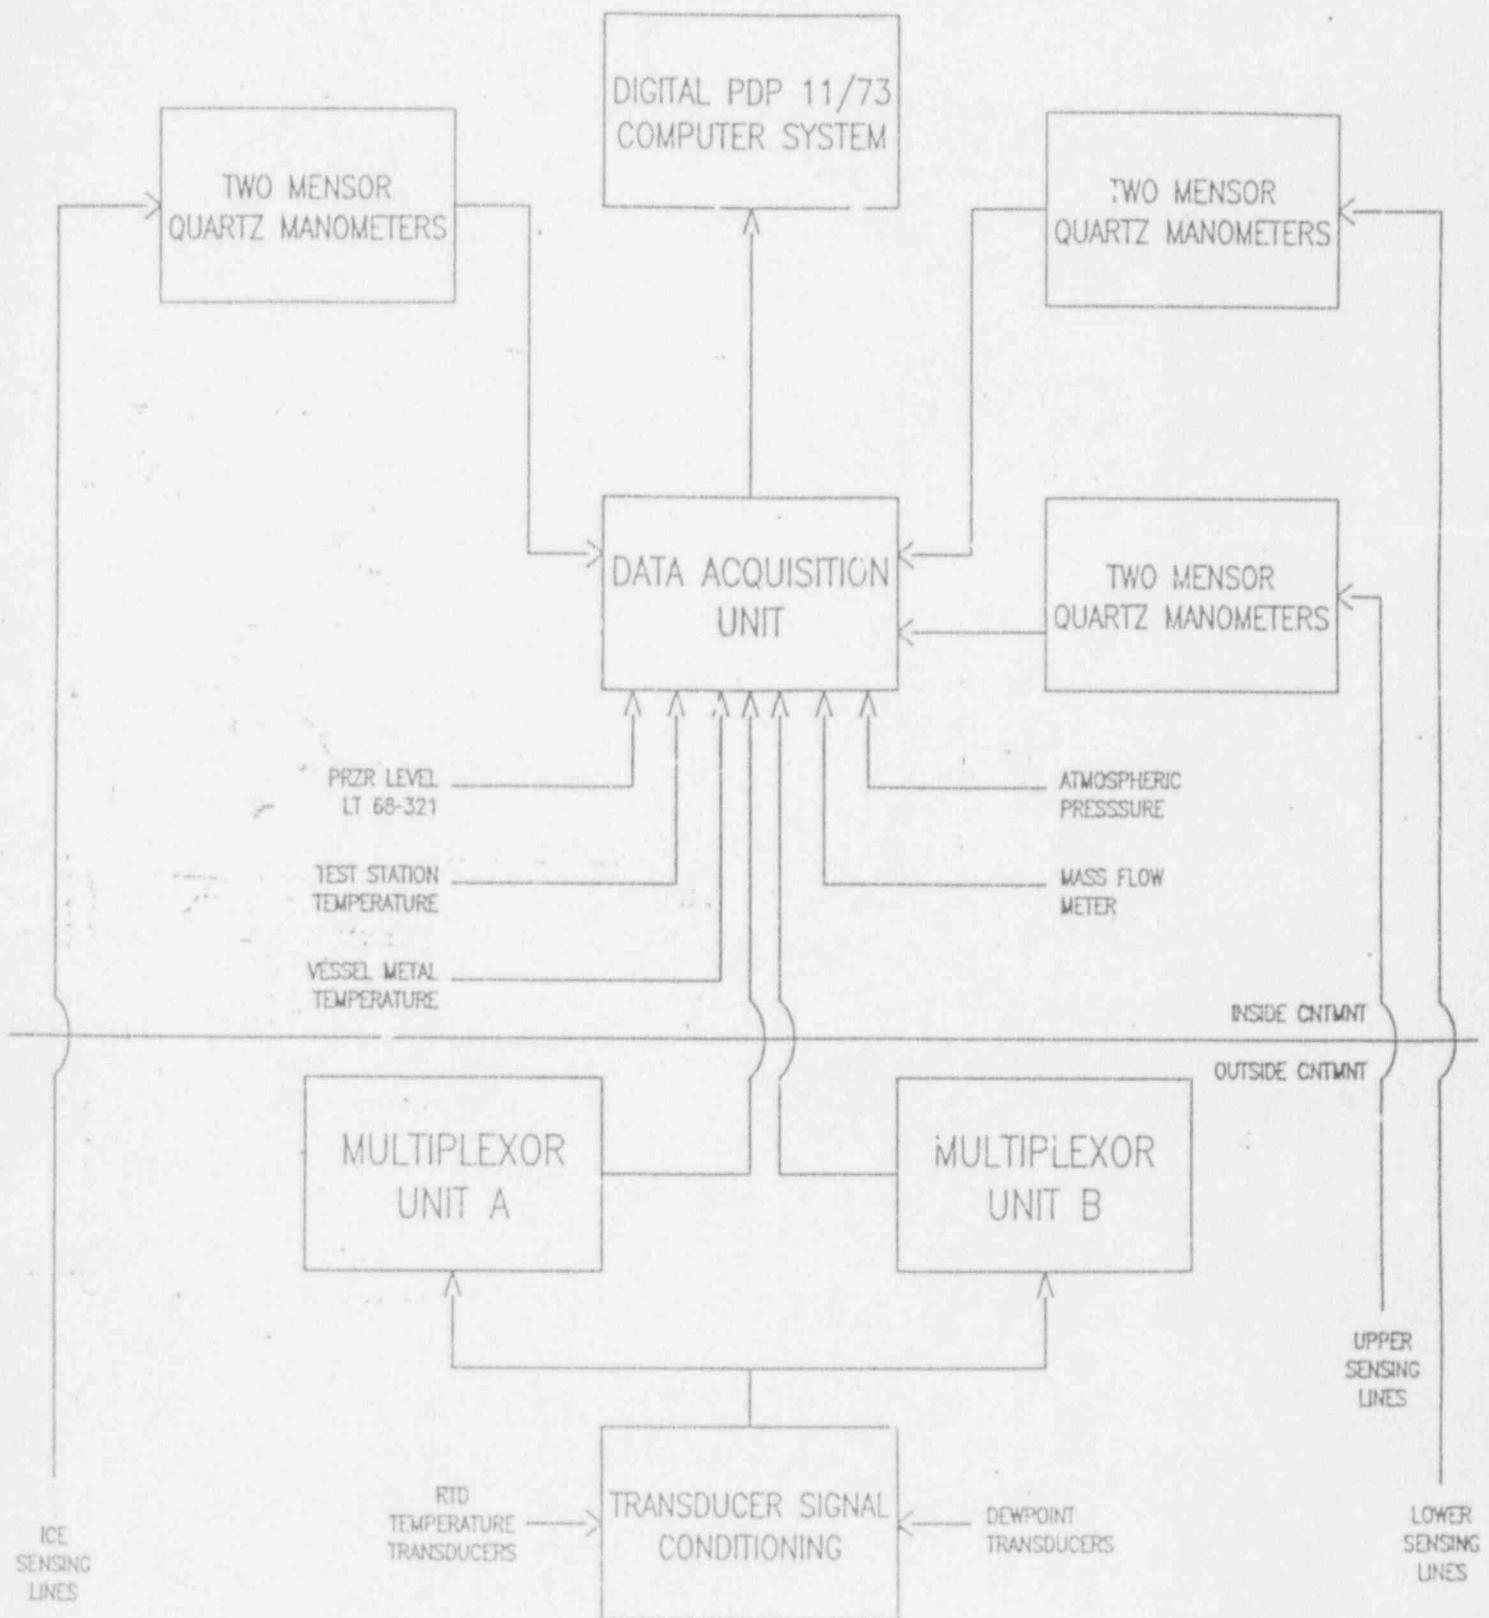

$$\frac{0.0486 \text{ lb}_m}{173,329.2341 \text{ lb}_m} \times 100 = 0.000028\%/\text{Day}$$

Since calculations for leak rate are reliable only to four decimal places, no addition to the CILRT or verification leak rates were required.
