1. Introduction

This analysis has been performed per NRC staff request to evaluate bending stresses in the MTC wall.

2. Assumptions and input

MTC weight $P_{MTC} = 193,600$ lbs

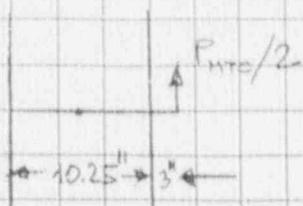

Dynamic increase factor $K = 1.1$

Roark, Edition IV, Table X, #5 was

used. Radius a has been assumed to be 36 in (as in the original analysis, WEP 109.002.) However, the calculations are not sensitive to changes in a .

Trunnion radius $r_0 = 5.4$ in

3. Calculations

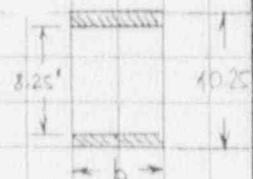

$$M = \left[\frac{P_{MTC}}{2} \right] \cdot 1.1 \cdot \left(3 + \frac{10.25}{2} \right) = 865,150 \text{ lbs}\cdot\text{in}$$

Since the MTC has a composite wall, the equivalent solid wall thickness must be found in order to use Roark. Only inside and outside shells are considered for moment resistance:

$$\frac{1}{6} b (10.25^2 - 8.25^2) = \frac{1}{6} b t^2$$

equivalent section modulus

where b = width (not important)

$$t = \sqrt{10.25^2 - 8.25^2} = 6.0 \text{ in} - \text{thickness}$$

of the wall with equivalent resistance to bending moment.

Roark, Table X, #5:

$$K = \frac{0.49 a^2}{(r_0 + 0.7a)^2} = 0.67$$

$$S_b = \frac{3 \cdot 865,150}{4\pi \cdot 6^2 \cdot 5.4} \left[1 + \frac{4.33}{3.33} \ln \frac{2(36 - 5.4)}{0.67 \cdot 36} \right] =$$

$$= 2,350 \text{ psi}$$

Sensitivity: if $a = 24'' \rightarrow K = 0.57 \quad S_r = 2,430 \text{ psi}$

The bending stress has to be added to the membrane stress which is

$$S_m = 6,840 \cdot \frac{1}{1.33} \cdot \frac{1}{2} = 2,570 \text{ psi},$$

where: 6,840 - value for membrane stress
calculated previously (WEP 109.002.)

1.33 - that value was calculated as
 $P_{int}/2 \left(1 + \frac{3}{9.25}\right)$ in order to resist the
bending moment.

2 - only the outer shell has been ana-
lyzed; now the membrane stress is
taken by both shells.

Thus, total stress is (outer shell)

$$S = S_m + S_b = 4,920 \text{ psi}$$

This is less than 6,840 psi previously calcu-
lated. Therefore, PSN's approach was
conservative.

$$K_w = 70/4.92 = 14.2 > 10 \text{ OK}$$

$$K_y = 46/4.92 = 9.3 > 6 \text{ OK}$$

The inner shell stress is

$$S = 2,570 - 2,250 = 320 \text{ psi} \text{ OK}$$

present and the operator lifted the MSB too much. For the short time this condition would exist, the dose rate would be acceptable. However, with the lid present it could be avoided. The situation would be quickly relieved by lowering the MSB into the dropped MTC. Thus, no fuel or safety related equipment would be impacted. This is another reason why this is not a critical lift. Also, under such a drop the MTC could not topple off of the VCC because the 18 ft long MSB held by the crane will still be inside the MTC preventing the tipover.

A lift of approximately 3 ft (see attached Figure) would be required before the MTC would be high enough to tip and get its cg over the edge such that it would fall off. This is clearly much higher than the cask could get with a failing lid. At crane speeds of 2 to 6 ft/min, 30 seconds or more would be required for the lid to hold and then fail. However, the operator is only going to "bump" the MSB weight off of the doors and, hence, the crane should only be on for less than a second. Even if the operator erred severely, the MTC would only be lifted an inch or less. Hence, even if the operator erred severely and the lid and/or bolts failed (two concurrent unlikely events), the MTC would only move a few inches or less, and (as considered in both NUREG 0612 and past Part 72 licensing conditions) a movement of 12 to 18 inches is not considered a drop. Therefore, even if everything that could go wrong went wrong the event would not be considered a heavy load drop and the MTC would not topple. The MTC is prevented from toppling by the potential height of the drop, the large area of the concrete cask and the MSB connected to the crane and still wholly or partially inside the MTC. See the attached figure for a sketch of the situation.

Lastly, even if the NRC staff still considered the potential accidental lift of the MTC by its lid as a critical lift, NUREG 0612 provides for a number of ways to meet its guidelines besides the increased factors of safety. One of these is to show by analysis that the results from off-site doses caused by the drop do not exceed 1/4 of the 10 CFR 100 limits. As shown by the attached figure (from NUREG 0612, pg 2-6), with no credit for auxiliary building filters, one would have to damage well over 5,000 five-year old assemblies to exceed 1/4 of the 10 CFR 100 limits. Hence, if the potential lift by the lid is to be considered a critical lift, PSN will meet NUREG 0612 by the following evaluation criteria (NUREG 0612, pg 5-1):

1. Doses less than 1/4 of 10 CFR 100 limits per attached figure.
2. $k_{\text{eff}} \leq 0.95$ because no moderator present.
3. No possibility of damage to reactor vessel or spent fuel pool.
4. No damage to redundant or dual safe shutdown equipment - damage will be to empty concrete cask and trailer.

In regard to the bolt diameter issue, PSN did use the gross section area for the bolt stress calculation. The actual bolt stress area is 0.696 in² (Marks' Handbook, 9th Edition, Table 8.2.2). Therefore, the bolt stress will be

$$\sigma = 38.3 (0.7854/0.606) = 49.6 \text{ ksi}$$

This is still less than S_u of 60 ksi for the A-307 bolt.

In summary, the lid and bolts are back-up safety devices, not special lifting devices. Therefore, they are not subject to the ANSI 14.6 increased factors of safety for special lift devices used in critical lifts. The AISC allowable stress of 20 ksi is also applicable to the normal operation loads (hold lid in place during transfer). PSN has selected and used the ultimate capacity of the lid and bolts as the design criteria for their performance in unexpected or accident conditions. This is in keeping with most all structural codes. Furthermore, failure of the lid and bolts would not result in any unallowable on-site or off-site safety consequence.

II. CALCULATIONS

Comment 1

This issue was discussed over the phone in September and we were of the understanding that it had been resolved. The discussion is presented below.

2.5°F is the Lowest Service Temperature (LST) as determined by PSN. PSN also calculated that in order to avoid brittle fracture, the materials Nil Ductility Transition (NDT) Temperature has to be 35°F below the LST, i.e., -32.5°. It is our understanding that the NRC staff agrees with this. Please see attached Figure 3 of Section 5.1.1 (NUREG/CR-1815).

However, Section 5.1.1 does not relate the NDT temperature of the material to the Charpy V-notch data. This is done by Figure 2 and Section 4.2 of NUREG/CR-1815 (attached). Note that this is stated in Section 5.1.1 (bottom of page 15).

Specifically, with Charpy test at -32.5°F resulting in a value of 12.6 lb•ft, one would calculate the K_{ID} of

$$K_{ID} = (5 \cdot 12.6 \cdot 28 \cdot 10^6)^{0.5} = 42,000 \text{ psi } \sqrt{\text{in}}$$

and find from Figure 2 that -32.5°F is the NDT temperature of the material. On the other hand, if one test the material at 2.5°F and the result is 25 lb•ft, the K_{ID} is

$$K_{ID} = (5 \cdot 25 \cdot 28 \cdot 10^6)^{0.5} = 59,000 \text{ psi } \sqrt{\text{in}}$$

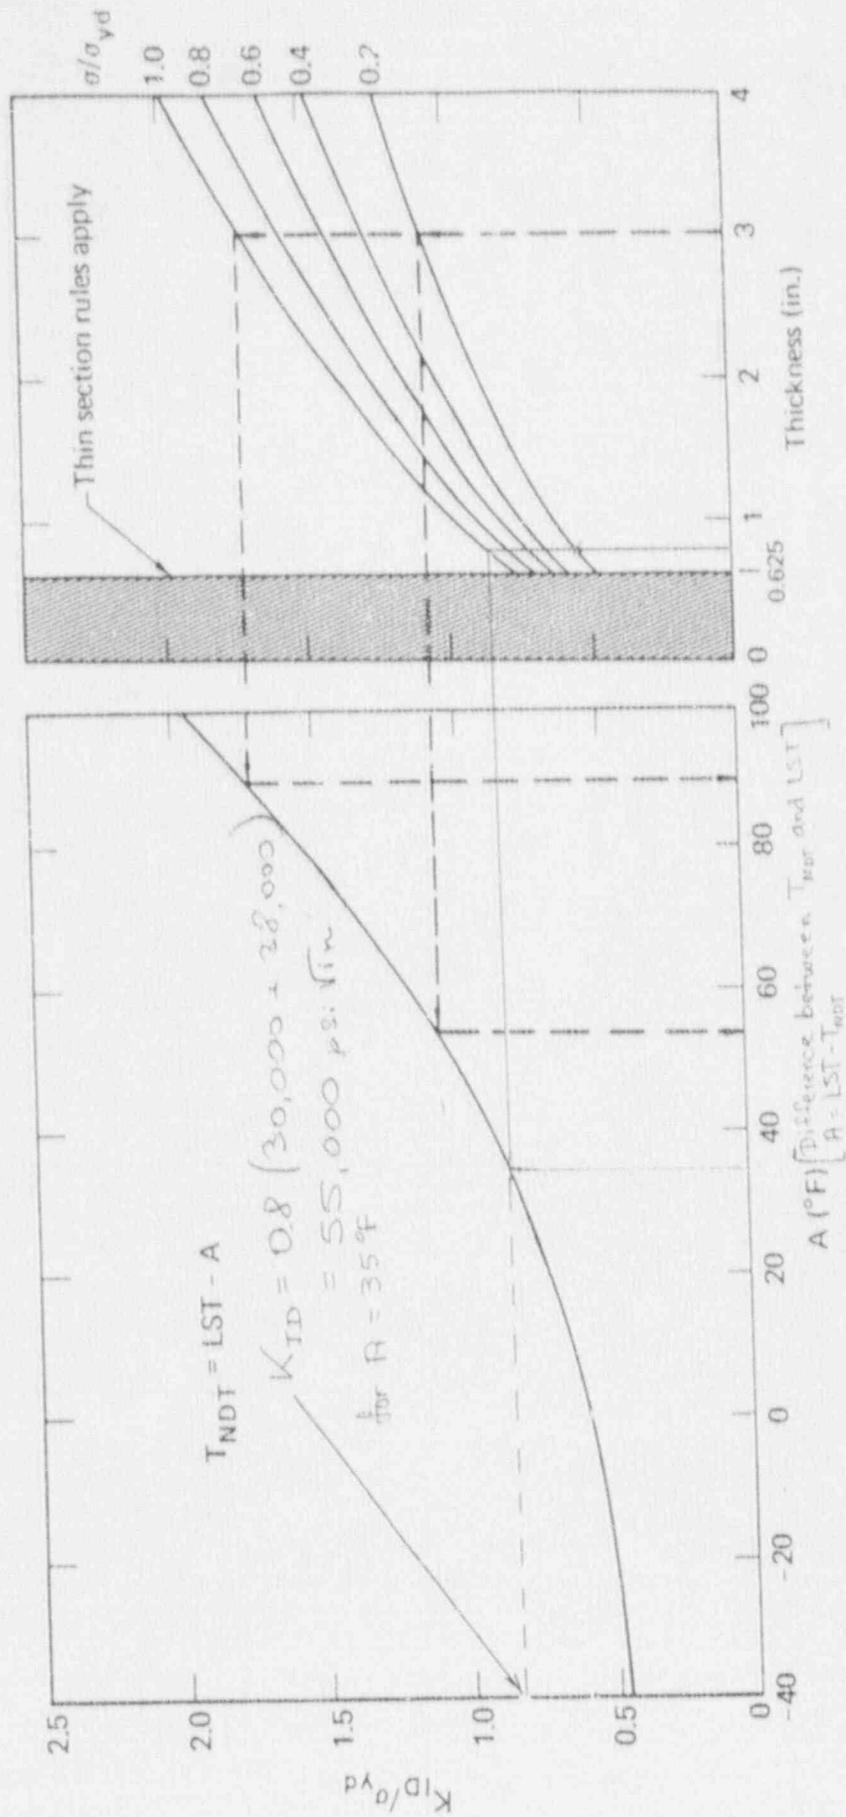

and (from Figure 2) the test temperature of 2.5°F is 35° above the NDT temperature of material (which is then -32.5°F).

Therefore, in both cases the results are the same: the NDT is -32.5°F. PSN specified 12.6 lb•ft at -30°; however, we would achieve the same purpose if we required 25 lb•ft at 2.5°. At the same time, the NRC suggested requirement of 25 lb•ft at -30° would require NDT of -30° - 35° = -65° which is not necessary.

If the NRC staff wishes, PSN can change the Charpy requirement to 25 lb•ft at 2°F.

Comment 2

PSN has responded to this comment by the FAX of September 14, 1996. Once again, based on the previous NRC licensing actions, we do not believe that the pressurization accident should be considered during the transfer operations due to the short-lasting temporary nature of the transfer. This load combination should not have been included in Table 2.2-4 of the TR. Nevertheless, as discussed in the referenced FAX, the increase of pressure by 14% has no impact on the MSB adequacy because the stresses are two times

NOTE: From above for our $LST = 2.5^\circ\text{F}$ we get $NDT = -32.5^\circ\text{F}$

FIG. 3. Design chart for Category I fracture critical components.

used for fabricating the structure. Welding procedures should be cited as part of the design and fabrication specifications.

All welds for Categories I and II should be inspected and repaired as necessary in accordance with the requirements of Sec. III, Class I and II respectively, of the ASME Pressure Vessel Code.

4.2 TESTING METHODS

The AAR guidelines procedures for fracture-safe design of steel structures are based on the Design Reference K_{ID} Curve (see Fig. 2), which is a lower bound curve relating fracture toughness to temperature relative to NDT. Our use of this curve will be limited to structural steels having minimum specified static yield strength no greater than 100 ksi. Using this curve, toughness requirements expressed in fracture mechanics terms can be converted to the reference temperature (or temperature relative to NDT) at which the steel has at least this required level of toughness. Conversely, if the NDT

temperature of a steel is known, the curve gives the minimum toughness of that steel as a function of temperature. Fracture toughness and NDT are therefore directly related by the curve, and the toughness-temperature relationship can be established by measuring or specifying the NDT. This indirect method is used because there are currently no standard methods for measuring dynamic fracture toughness K_{ID} . The AAR Guidelines³ and Manual⁸ also provide a procedure to develop a K_{ID} curve for a specific steel using Charpy V-notch data. The following relationship⁹ must be used if a K_{ID} curve is constructed from Charpy data:

$$K_{ID}^2 = 5(C_V)E$$

where

K_{ID} = dynamic fracture toughness in $ksi\sqrt{in}$.

E = modulus of the steel in psi

C_V = Charpy V-notch measurement in ft-lb.

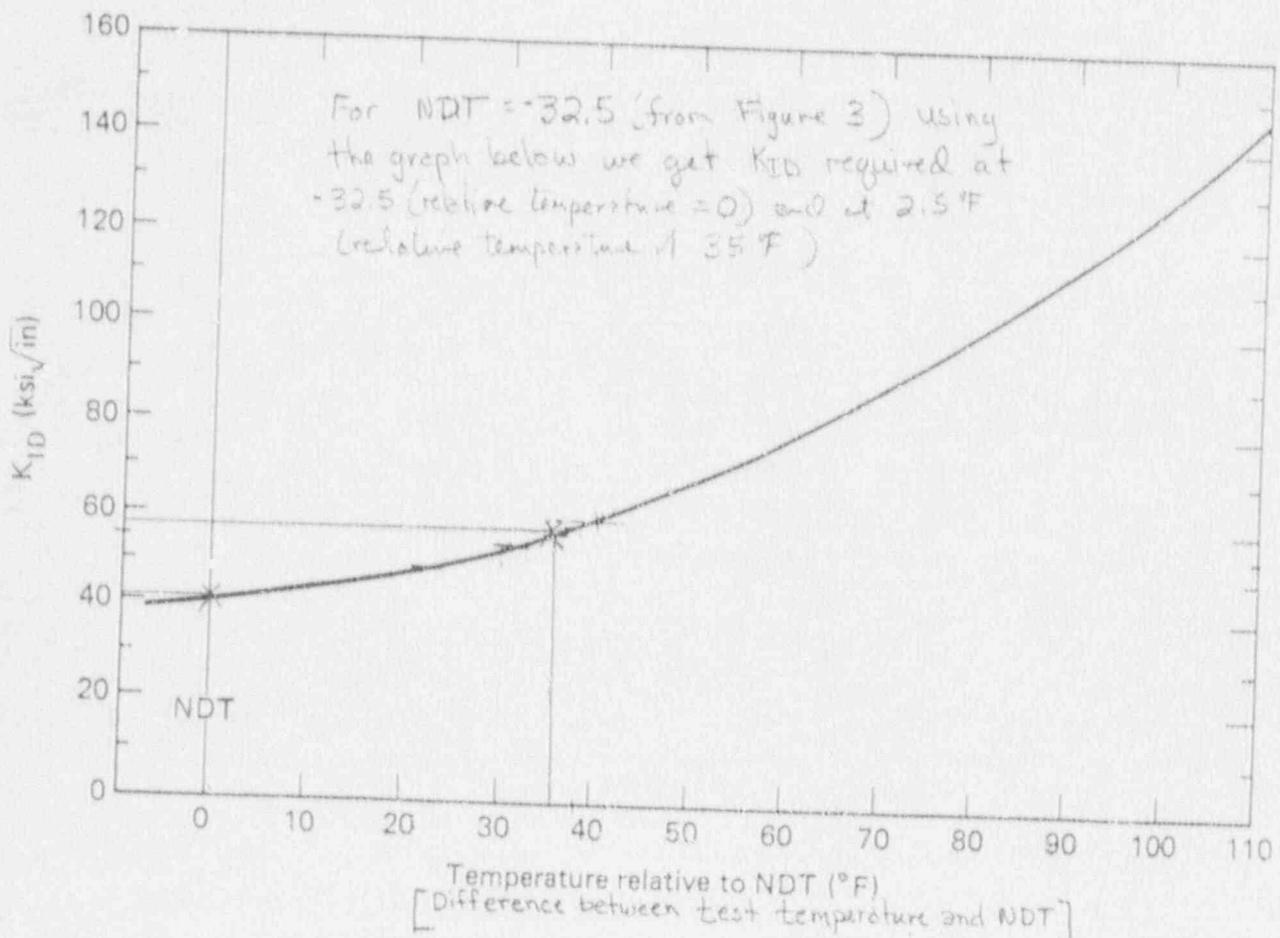

FIG. 2. Design-reference curve relating K_{ID} and the temperature relative to NDT (from Ref. 3).

below allowables. PSN will change Table 11.2-3 as directed: to remove this load combination or to include the maximum hypothetical accident pressure.

Comment 3

A ΔT of 310°F between nodes 81 and 83 is maintained due to the conductivity of the heated region of 2.4 BTU/hr/ft. The conductivity of the steel bottom is 26 BTU/hr/ft which is higher by the order of magnitude. Thus, the ΔT in the bottom plate will be lower accordingly.

Nevertheless, PSN has estimated the thermal stresses in the MSB bottom assuming the ΔT between the center and the edge to be 310°F. The analysis has been done using Edition IV of Roark, Chapter 15, Article 88, case 12. The obtained maximum stress intensity of 20.5 ksi is well within the allowable of 63.5 ksi even after adding all other loads. Please see Table 3.4-5 of the TR for the bottom plate margin.

Comment 4

Enclosed please find the requested printout. We have also included the membrane stresses so that the NRC staff could make sure that this is the output from the same run. Please note that essentially no bending is present in the sleeve walls. This is because each sleeve bends over its length without significant distortion of the section, thus, bending stresses are insignificant and membrane stresses are dominant.

Comment 5

PSN contacted American Drill Bushing Company. The hoist rings high alloy, Q&T 4140 steel has S_u of 180 ksi and S_y of 160 ksi. Thus, the ultimate strength is controlling. The safety factor for yield will be

$$K_y = 5 (160/180) = 4.4 > 3$$

Furthermore, in accordance with Figure 1 of the NUREG/CR-1815 (attached) the conservative NDT temperature for this steel is below -80°F.

Comment 6

The MTC is always operated inside the Auxiliary Building where the temperature is at least 50°F. The specification of this temperature will be added to Section 12.0 of the Topical Report. This is well above the temperature at which the brittle fracture could be a concern. The NDT temperature range for the ASTM 588 steel is -70°F to -10°F.

Comment 7

The toughness requirements for the MSB steel are based on the analysis for 20-year-old fuel and the ambient temperature of -20°F. Therefore, -20°F will be specified as a minimum temperature for MSB handling. This specification will be added to Section 12 of the TR.

Comments 8 & 9

PSN has previously submitted responses to comments 8 (FAX of October 12, 1990) and 9 (letter of October 31, 1990). As stated in Response #2 of Attachment 2 to the October 31, 1990 letter, PSN believes that the deceleration load of 22 gs has been calculated using an overly-conservative stiffness for the foundation [per EPRI methodology (EPRI NP-4830)]. This results in an overly conservative target hardness number to be used in the ensuing calculations. The drop load is a strong function of this target hardness number. Based on the design of the ISPSI foundations for Wisconsin Electric Power, Consumers Power, Toledo Edison, a survey of other near term potential sites, and PSN's generic pad, PSN concludes that using a conservative but bounding foundation target hardness would significantly decrease the design drop load on both the VCC and the MSB. Furthermore, in all plants we have analyzed the roadways and auxiliary buildings that the cask might be carried back into after 20 years of storage are not nearly as stiff as the pad. Hence, the storage pad represents the limiting operating condition in terms of hardness. Therefore, in order to resolve the NRC staff concerns outlined in comments 8 and 9, we suggest including in the TR the technical specification for hardness of the surfaces where the VSC is stored or carried over. These are easy to evaluate and can be performed quickly by any utility as part of site specific license applications or 50.59 safety reviews (along with the site heavy loads and radiological reviews).

The following presents a discussion of this issue. The calculation package "Alternative Analysis of the VCC-24 5 ft Drop" submitted with the October 31, 1990 letter is used as Reference 1.

The controlling parameter for the horizontal drop/tipover is a moment capacity of the concrete cask section. This capacity has been previously calculated as 1,325 kips•in (please see calculation package WEP-109.002.15, Rev. 2). From Ref. 1, page 4 the maximum dynamic moment shall be

$$M_{\max} = 1,325/1.06 = 1,250 \text{ kips}\cdot\text{in},$$

where 1.06 is the resistance/force ratio determined from dynamic loading curves (page 5 of Ref. 1).

Therefore, the maximum deceleration level that the cask can accommodate (to meet ANSI 57.9) is

$$a_{\max} = 1,250 (22g/2,123) = 13 \text{ gs},$$

where 2,123 kips•in is the moment produced by a 22g load (as calculated on page 14 of WEP-109.002.15, Rev. 2) and since the relationship is linear the resulting 13 gs deceleration is obtained.

For the deceleration of 13 gs, the shear force in the concrete section will be

$$V = 11.7 \text{ kips} (13/22) = 6.9 \text{ kips,}$$

where 11.7 kips is a shear force produced by 22gs (WEP-109.002.15, Rev. 2, p. 14).

Hence, the required capacity is

$$V = 6.9 \cdot 1.5 = 10.4 \text{ kips} < 39 \text{ kips,}$$

where 1.5 is the required resistance/force ratio for shear as determined in Ref. 1, p. 5, and 39 kips is the concrete section capacity as calculated in WEP-109.002.15, p. 15.

Therefore, the concrete cask can withstand a maximum horizontal deceleration load of 13 gs and meet the Load Combination #6 of ANSI 57.9. Other loads do not add to the moment or shear from the drop because of their axisymmetric nature (as discussed in our FAX of October 2, 1990).

For the MSB, the deceleration level decrease from 22 gs to 13 gs (44 gs to 26 gs statically) will cause a proportional reduction of the stresses. Therefore, the maximum bending stress in the shell (drop combined with other loads, as applicable) will be

$$P_L + P_t = 71.8 \cdot (13/22) + 1.2 = 43.6 \text{ ksi}$$

With a corrosion rate of 0.003 in/year (as calculated by PSN earlier and discussed again below), the stresses after 50 years of storage will be

$$P_L + P_t = 43.6 [0.75 / (0.75 - 50 \cdot 0.003)]^2 = 68.2 \text{ ksi}$$

which is less than the allowable of 73.5 ksi.

The corrosion rate of 0.003 in/year estimated by PSN previously is higher than the NRC staff's value of 0.002 in/year for moderate marine environments. There is no steam present in the VCC annulus since the concrete inside surface is steel lined and the maximum exiting air temperature is only 193°F. The water in the concrete can evaporate only from the outside surface. The severe marine environment rate is also not applicable to the VCC because the cask does not get splashed by the seawater. Thus, the moderate marine environment is adequately conservative for the MSB, and the value of 0.003 in/year is justified.

Thus, both the VCC and MSB will meet the applicable codes with a deceleration level of 13g. The load is fully determined by the hardness of the impacted surface. Using EPRI

Report NP-4830, page 2-39 (for the 5 ft. drop) we obtain that in order to restrict the load to below 13 gs, the target hardness number of the foundation should not be more than 8,000.

Therefore, PSN suggests to include a technical specification for the storage pad and transfer roads in the Topical Report. The specification would state that the surface hardness number calculated in accordance with EPRI NP-4830 methodology shall not exceed 8,000. Please note that the hardness number for a real foundation (selected to bound Consumer Power's and Wisconsin Electric's storage pads) has been calculated as only 3,560. This calculation is presented in Ref. 1. Thus, there is adequate margin to cover other pad designs.

Comment 10

- (1) The calculations for Figure 11.2-6 was done for the most reactive unburned, reactor fuel, CE 15 x 15.

The results shown in Figure 11.2-6 include all uncertainties discussed in Section 6.0 of the TR.

Assembly Location
Water Density
Fuel Homogenization
KENO-IV Bias
2 Sigma

The calculation estimated the 5.0% point using the KENO calculated point at 4.2 and the Δk /ppm calculated from all the KENO calculations.

- (2) It is our understanding that the discussion on the potential for boiling sent to the NRC on November 7, 1990 was acceptable. If this is not the case, please let us know at your earliest convenience.

Comment 11

In response to the differences between the MORSE and SKYSHINE calculated neutron dose rates we would like to point out that variations of 36 to 77 times are typical for neutron skyshine. Results are very dependent on calculational technique, source strength (was the peak or average surface dose rate used), geometry, detector location, meteorological conditions, etc. Such variations have been documented by the ANS committee on neutron skyshine. However, further work was not done because no one in the industry (NRC, EPRI and utilities) has determined from operating data that any excessive doses are coming from neutron skyshine. One can only assume that if such is the case then the lower calculated neutron dose rates must be closer to actuality than the

higher rates. PSN designed the VSC so that neutron doses are low enough such that even if such large variations were realized the doses would be within regulations.

We would also like to point out that the VSC has a lower neutron dose rate than any other metal dry storage cask and comparable to other concrete casks. The Table below shows this.

SURFACE NEUTRON DOSE RATE (mrem/hr)

	VSC	MC-10	GNSI* CASTOR 5	NUHOMS
SIDE	0.15	19.2	16	0.1 (top)
TOP	14.4	10	36	6.6 (front)
Area Weighted Average	2.2	17.2	21.6	2.9

* The CASTORs results are from measurement (EPRI NP-4887). The others are calculated.

The uncertainty in neutron dose rates is why PSN designed the concrete cask to yield such a low neutron dose rate.

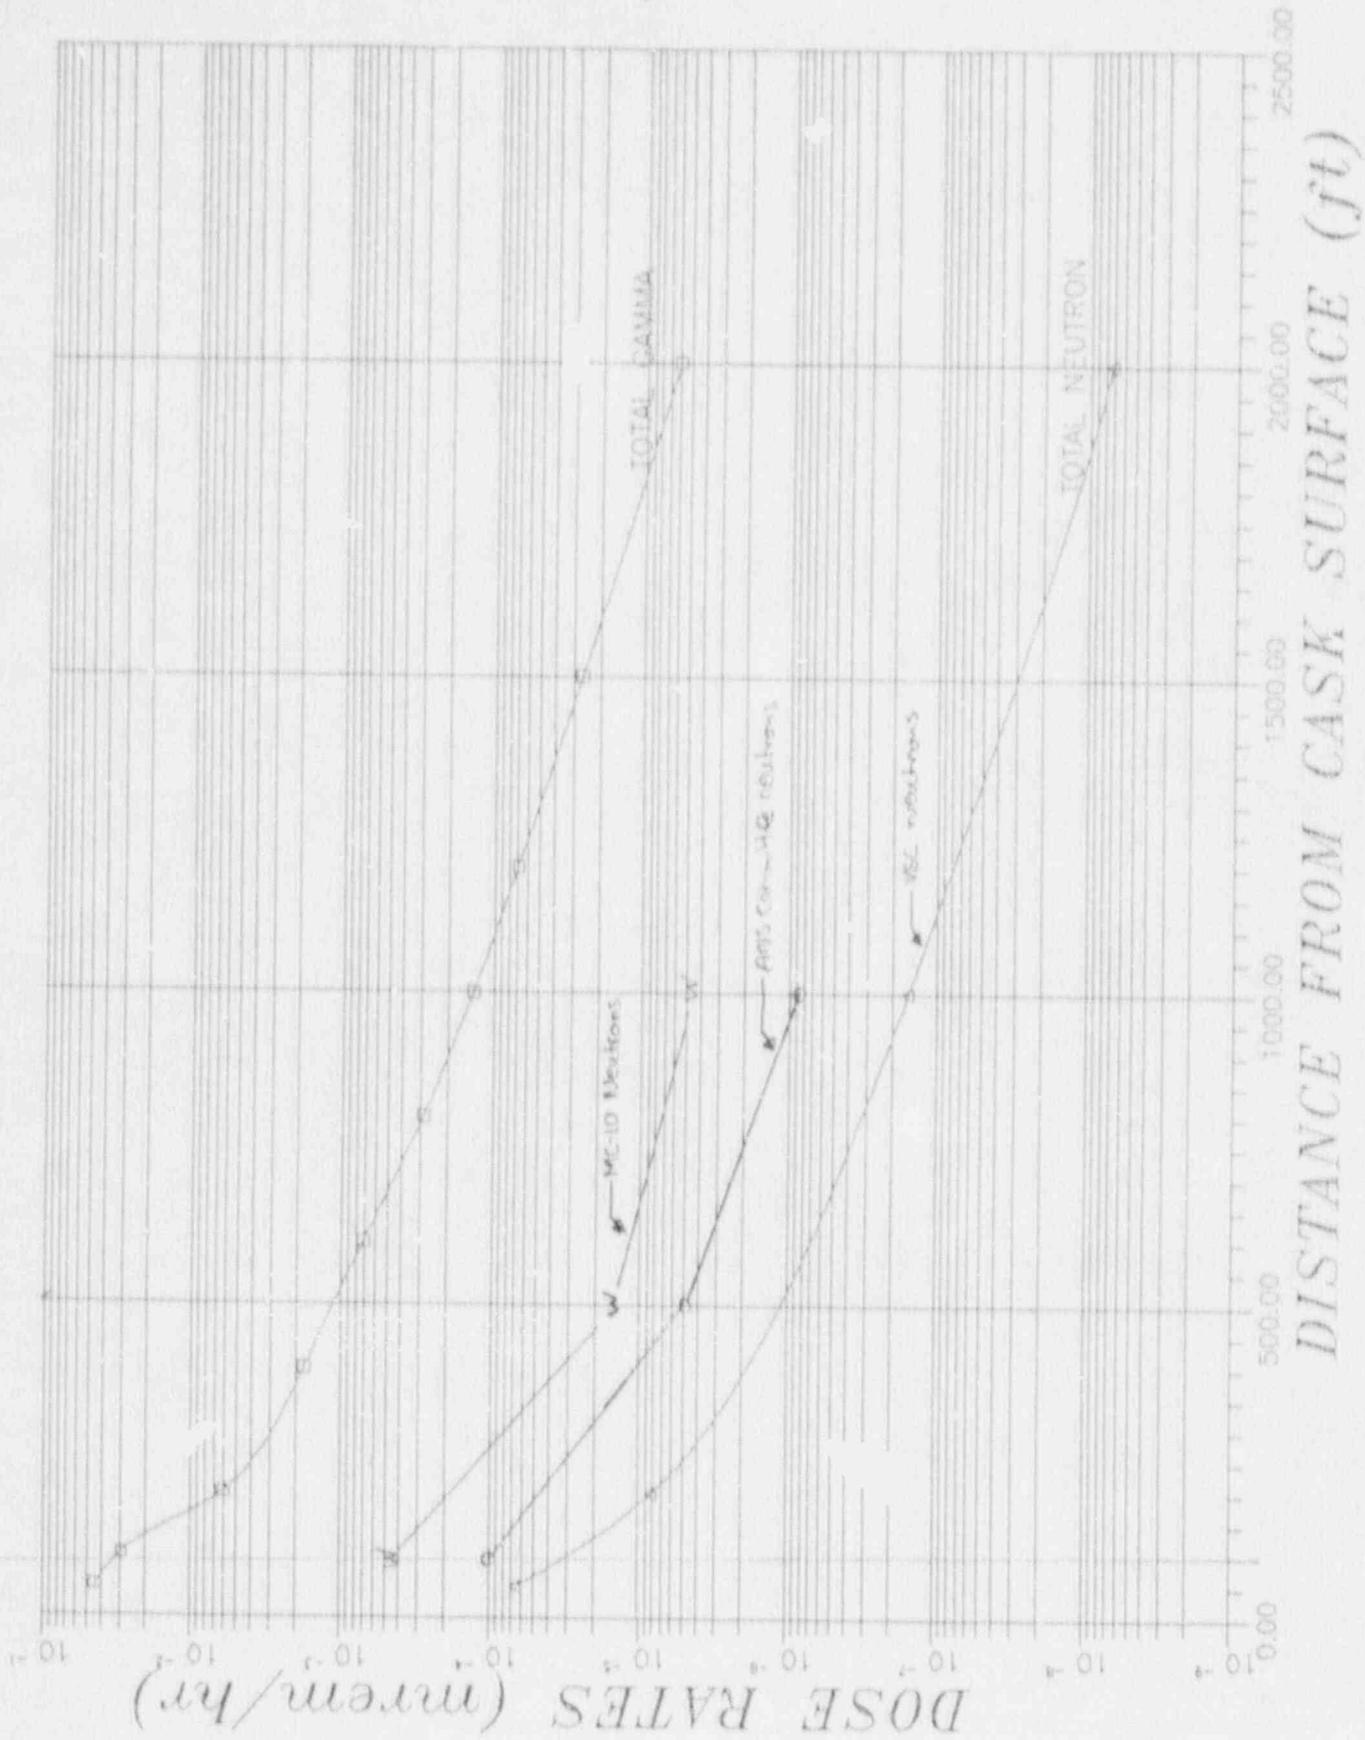

As a summary, Figure 1 shows a comparison between PSN's calculation, the ANS committee calculation and another dry storage technology topical (MC-10). The table above provides a comparison of the surface dose rates. The curves shown in Figure 1 are corrected by the product of surface dose rate times the area to account for source differences. While the VSC doses are lower than the other calculations they are within one order of magnitude variation from the results found by the ANS committee.

Furthermore, there are two very specific reasons why the VSC doses would be lower.

For the MC-10 metal cask:

- (1) The concrete VSC will have a much softer neutron leakage spectrum than the metal MC-10 cask. This could easily cause variations in skyshine of an order of magnitude or more.
- (2) Most all the VSC neutrons go through the top not the side. Thus, they are directed at 90° to the detector. This also can cause an order of magnitude or more difference.

FIGURE 1
 COMPARISON OF NEUTRON DOSES
 FROM AHS CORNITE, MC-10 and USC

For the ANS committee calculation:

- (1) Same as (2) above. Specifically, the ANS cask had a side dose of 10 mrem/hr. Two orders of magnitude higher than the VSC.

Of the above reasons why the VSC doses are lower than the doses from other cask, #2 is the most convincing. Our data shows decreases by two to three orders of magnitude if the source is directed at right angles to the detector. Metal cask, NUHOMs and the ANS Committee Cask all have substantial side sources.

Also, in regard to the question of the gamma dose rate: Figure 2 is presented to show that our calculation compares excellently with other calculations.

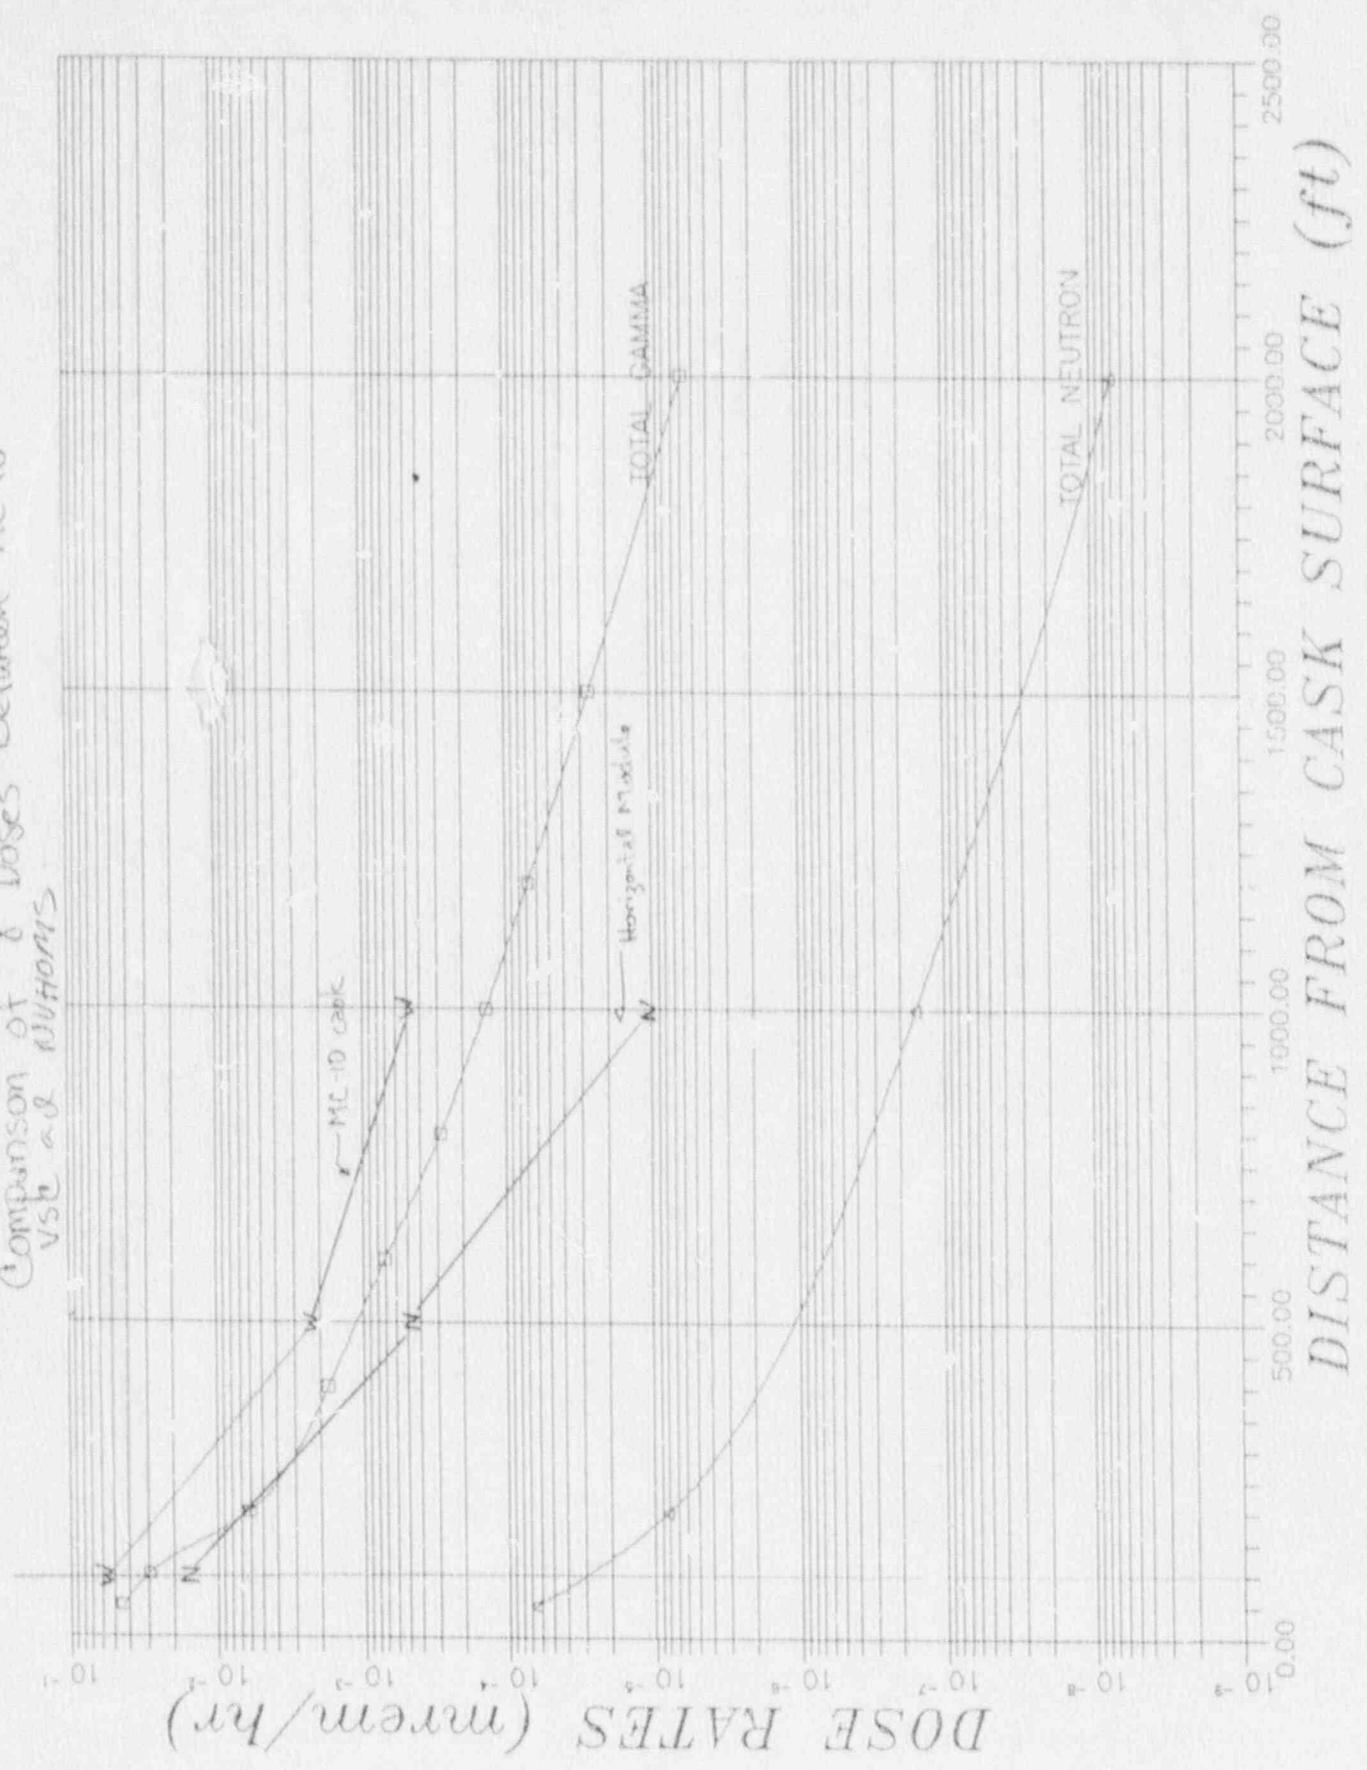

Sources were similar for all casks as shown below.

SURFACE DOSES (mrem/hr)

	Horizontal Module	MC-10	VSC	GNSI
Side (front)	10	43	11	24
Top (roof)	14	11	19.5	36

In closing, we have validated our SKYSHINE analysis against other calculations for both neutron and gamma radiation as evidenced by the enclosed graphs. As our surface doses are lower than other, already licensed casks, we believe this to be sufficient.

Figure 2
Comparison of γ Doses Between MC-10
vs. a. & NUHOMIS

III. DRAWINGS

Comment 1

The drawing has already been changed to correspond with Figure 3.4-1.

Comment 2

The note will be added to the referenced drawing.
