I.

INTRODUCTION

During January 1990, while TMI-1 was shut down for Refueling Outage 8R, GPUN performed Eddy Current (ECT) examinations of the tubing in the Once Through Steam Generators (OTSGs). The examinations were required by Technical Specification 4.19 (Reference 1), and GPUN engineering requirements.

Following the completion of the scheduled examinations on February 1, 1990 and the return to power on March 4, 1990, the unit was removed from service on March 6, 1990 due to a tube leak in OTSG A. During this unscheduled shutdown (designated BU1) additional examinations of the tubing in OTSG A were performed.

During Outage 8R, a total of 2210 tubes in OTSG A and 992 tubes in OTSG B were examined. Based on these examinations, five tubes in OTSG A and three tubes in OTSG B were removed from service by plugging.

During the Outage BU1 examinations, a total of 419 tubes were examined in OTSG A. This includes 417 lane/lane wedge tubes and two tubes which were examined as suspected leakers. Following the completion of these examinations, two tubes were removed from service by plugging. No examinations were performed in OTSG B during this outage.

This report was prepared to satisfy the reporting requirements of Technical Specification 4.19.5.b (Reference 1). The data was extracted from GPUN TDR 1026 (Reference 15).

II.

METHODS

EDDY CURRENT AQUISITION SYSTEM

The ECT examinations were performed using the same basic techniques which were used during the 1f 1-7R examinations. These techniques were initially qualified for use at TMI in 1982 (References 2 & 3) and have been refined and upgraded during subsequent outages. For 1990-8R and 8U1, the only significant change was the use of the .510" diameter bobbin probe for screening indications for further evaluation using the .540" diameter bobbin probe. This change was made to reduce the incidence of "stuck" probes, which, in the past has accounted for significant radiation exposure to personnel. The basis for using the .510" is documented in Reference 11.

For Outage 8R, the data aquisition system included the Zetec Miz 18 Digital Eddy Current System and the B&W "ROGER" in-head manipulator. In Outage 8U1, the data aquisition system (Miz 18) was used in conjunction with a Zetec SM3-10 in-head fixture.

While the use of different in-head fixtures requires a different configuration for data aquisition, the recorded eddy current data is unchanged.

PROBES

The 8R and 8U1 ECT examinations were performed using Zetec probes. The probe types and uses included:

Bobbin Coil - Two sizes of bobbin coil probes were used. The .540" diameter (A-540-LC/NF/M/HF) probe was used to examine all tubes with previously identified indications. This includes tubes in the ISI, S/N and 8x1ACC data sets. (See Section III for data set descriptions). The .540" probe was also used to confirm indications recorded as 20% through wall or greater by the .510" bobbin coil probe.

The .510" diameter bobbin coil probes (A-510-LC/NF/M/HF and A-520-M/TBS/HF) were used to examine tubes with no previous indications. Data sets examined with the .510" probe include the 3%-TS, 6%-TS and lane/wedge tubes.

All three of the above bobbin coil probes have the same electrical characteristics. The A-540-LC/NF/M/HF and A-510-LC/NF/M/HF probes are identical except for the probe diameters. The A-520-M/TBS/HF probe uses the same coils as the LC probes but has a stainless steel nose and tail piece in place of Delrin plastic. The center section, which houses the ECT coils, is Delrin plastic on all three probes; therefore, the eddy current characteristics are not affected by the body change. The metal body probe was used in an attempt to increase probe life thereby reducing personnel exposure and improving data consistency. No major improvement was noted and the LC type probes were used for most of the examinations.

8x1-ABS - The Zetec 8x1 Absolute probe was used to examine the lane and lane/wedge tubes from the 14th T.S.P. to the kinetic expansion zone in the upper tubesheet. This probe was also used to confirm indications screened by the bobbin coil probes. The specific probe used was the Zetec BC-5240-555-A0187.

MRPC - The Zetec Motorized Rotating Pancake Probes (MRPC) were used to examine specific areas of tubing screened by the bobbin or 8x1-ABS probes. The MRPC probe used for the tubing examinations was a Zetec Model B-510-MRPC/PH with a .125" diameter coil.

TECHNIQUES

The following is a summary of the examination methods used. The detailed procedures are contained in TMI-1 Surveillance Procedure 1300-4B (Reference 4).

- Dual Examination Method, for the un-expanded portion of tube
- Bobbin Coil Absolute Method, for the detection of wear
- Motorized Rotating Pancake Probe, (MRPC) for the characterization of select indications

Dual Examination Method: The portion of tubing between the roll expansion in the lower tubesheet and the kinetic expansion in the upper tubesheet is examined using the Dual Examination Method which GPUN developed and qualified in 1982 (Reference 2). This technique consists of examining the tubes using the bobbin coil (.540" or .510" diameter) to screen indications for further evaluations. Tubes with indications requiring further analysis are then examined using the 8x1 absolute technique to determine if the indications are relevant and to determine the circumferential extent. For confirmed indications, the characterization and disposition of the tubes are based on the following:

- | | |
|------------------------|---|
| Percent Through Wall | - Based on phase analysis of the bobbin coil probe.
If the tube is to remain in service, the percent through wall is based on the .540" probe results. |
| Circumferential Extent | - Based on number of 8x1 coils. |
| Signal Voltage | - Based on Bobbin Coil. |
| Axial Location | - Based on Bobbin Coil. |

Wear Examinations: The examination for the detection of gradual, outer diameter tube wear is performed during the Bobbin Coil examinations. This is done by operating one channel of the multi-frequency ECT instrument in the 200 KHz absolute mode. The use of the absolute mode permits detection of gradual changes in the tube wall which cannot be detected during a differential examination. Indications which appear only in the absolute channel are therefore screened as possible wear. The suspect area is then examined using the 8x1 absolute probe to provide additional data.

Motorized Rotating Pancake Probe (MRPC): In addition to the dual examination method, the MRPC probe was used to examine tubes with questionable indications. This probe provides a three dimensional (C-Scan) display of the examination area and provides a detailed insitu characterization of defects.

EXAMINATION EXTENT

The Bobbin Coil probe is used to examine the un-expanded length of the tube from the lower roll transition in the lower tubesheet to the kinetic expansion transition in the upper tubesheet. Although Technical Specification 4.19 requires the examination of only the portion of tubing between the secondary faces of the upper and lower tubesheets, all of the inspected tubes were examined over the entire un-expanded length.

RECORDING OF INDICATIONS

When analyzing the eddy current data, various indications are recorded by the data analyst. These indications fall into two basic groups, indications which require additional evaluations and indications which do not require additional evaluations. A complete list of all abbreviations and definitions used to classify indications is included as Appendix I.

Indications Which Require Additional Evaluations: Indications which are recorded as 40% T.W. or greater, ADR, DTS or DSS are all re-examined using the 8x1 Absolute Probe to determine if they are relevant indications and must be dispositioned. Indications of 20-39% T.W. or S/N are considered relevant indications and are monitored during future examinations but do not require additional evaluations using the 8x1 Absolute probe. (See Appendix I).

Indications Which Do Not Require Additional Evaluations: Indications such as IDC, DNT, DNG and PVN are recorded for information only and do not require a follow-up 8x1 Absolute examination. (See Appendix I).

Indication Locations: The locations of the ECT indications are recorded to identify their "elevation" or "axial location" in the OTSGs. For free span indications the locations are recorded in inches above "+" the tubesheet surfaces or tube support plate center. For indications located within or adjacent to the tube support plates, the indications are recorded as "+" or "--" from the center of the T.S.P. The relative locations of the tubesheets and tube support plates (T.S.P.) are shown in Figure II-1.

DATA ANALYSIS PROCESS

The data analysis process is based on the recommendations of the EPRI, PWR Steam Generator Inspection Guidelines. (Reference 7). The process included the use of written interpretation guidelines, which are filed with the examination data; site specific training and testing; and independent two party analysis of the data.

The data analysis process was performed by personnel qualified and certified to at least Level IIA, in accordance with the ECT contractor's approved programs. As a supplement to this qualification, site specific indoctrination and training was attended by all data analyst personnel. The program included both classroom lectures and hands on practice using eddy current data and experience from both TMI and another BWX designed plant. The training covered generic OTSG degradation mechanisms and examination methods and also specifically addressed both the Bobbin Coil and 8x1 Absolute methods which are used at TMI.

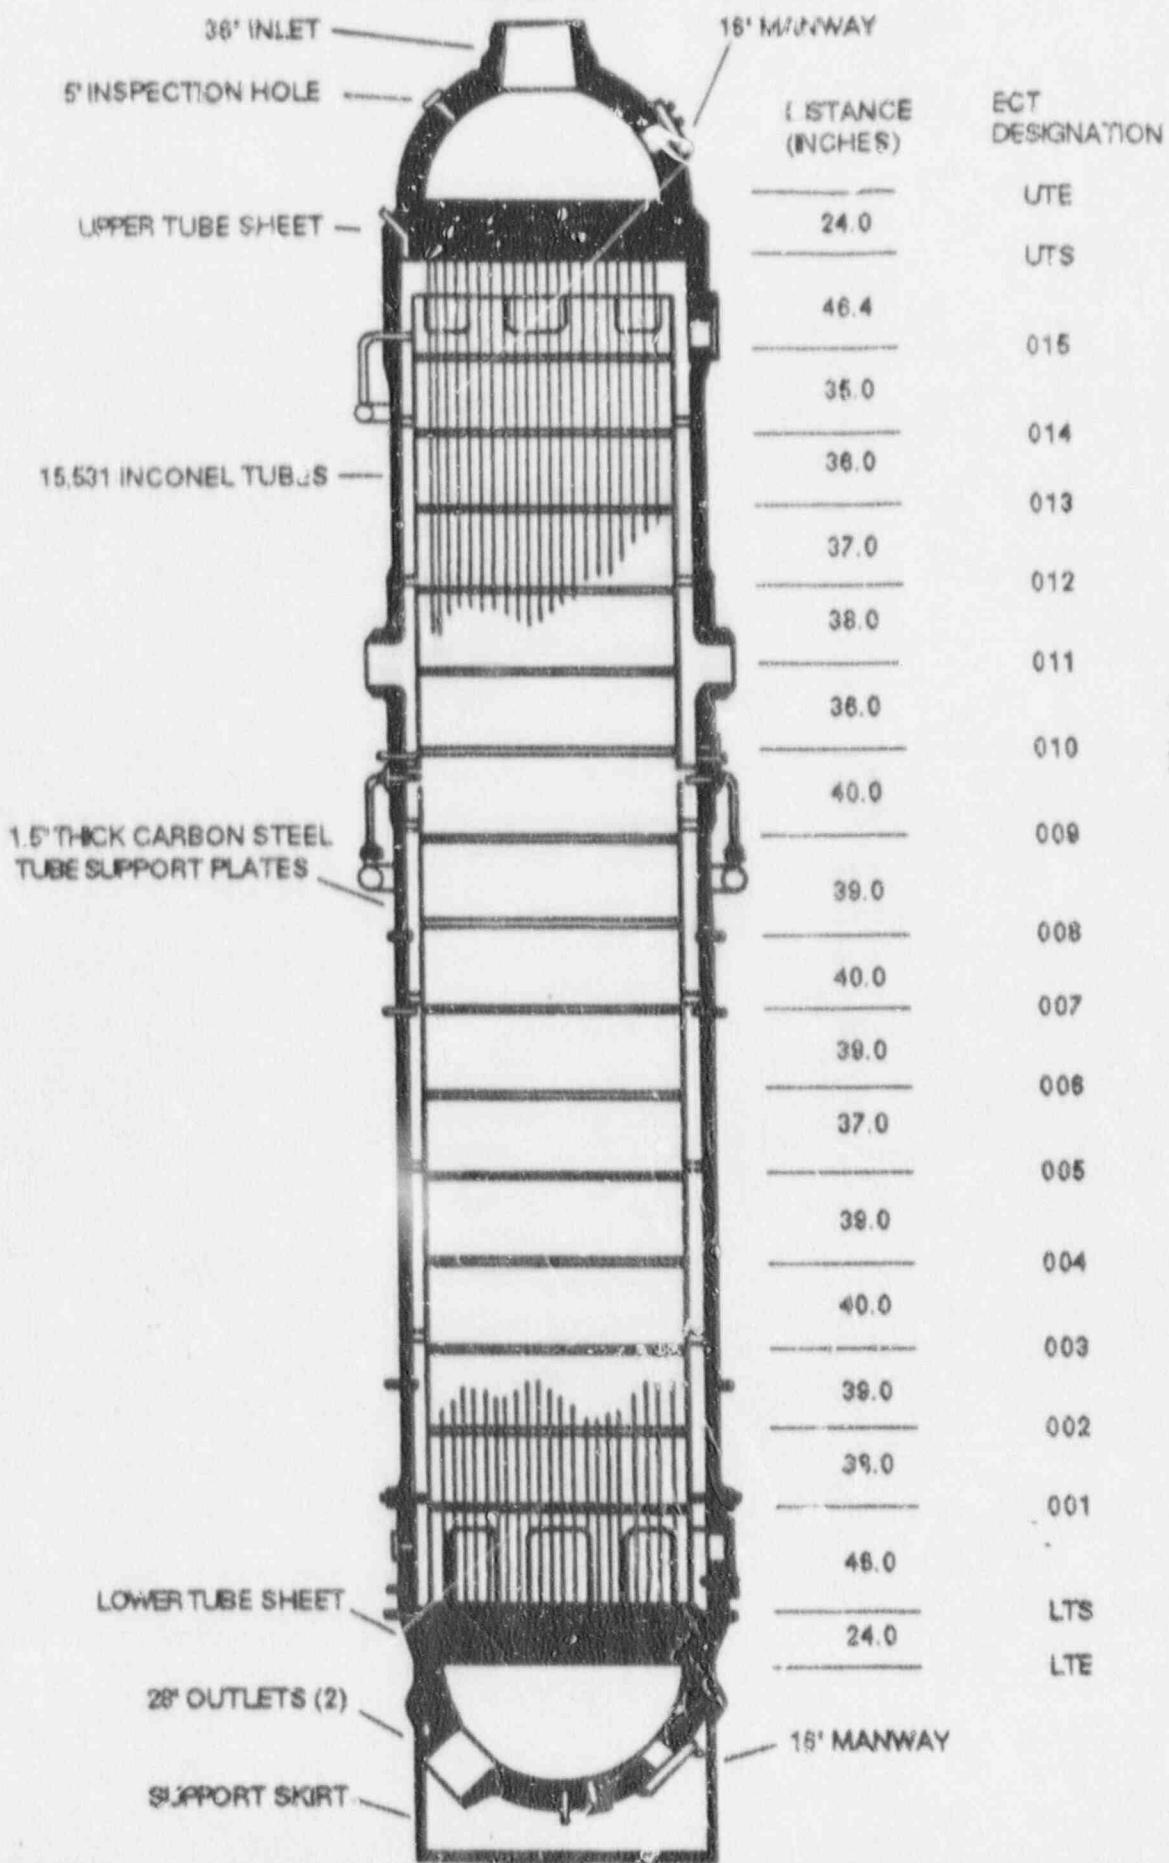

The total indoctrination process encompassed approximately 16 hours and was conducted by the designated lead analyst. At the completion of the indoctrination, each data analyst was required to pass a performance demonstration for each method to be analyzed. Appendix VI is an outline of the program.

Data Analysis Sequence

The data analysis process was performed in accordance with the same guidelines used for the data analyst indoctrination and training. The data analysis process was performed in three (3) parts with at least two (2) separate data analysts evaluating 100% of the Bobbin Coil and 8x1-ABS data for each tube. The data analysis process included:

1. Primary Analysis: The primary analysis included a 100% evaluation of the ECT data and the recording of all attributes identified in Appendix I. This analysis included recording the phase angle, percent through wall, voltage, circumferential extent and location of the indications.
2. Secondary Analysis: The secondary analysis also included a 100% review of the ECT data for the attributes identified in Appendix I. This analysis, performed as a blind review, was performed in the same manner as the primary analysis.
3. Official Results: To complete the analysis process, the results of both the primary and secondary analyses are reviewed by the designated lead analyst. This review combines the primary and secondary analyst's results and also resolves any discrepancies.

The data analysis of the MRPC data is considered a specialized examination and the process varies from the production analysis process. The evaluation of the data from the MRPC examinations of the tubing was done either by a Level IIA or Level III data analyst. No additional reviews were required for these evaluations because of the focused area under evaluation.

TMI - 1 OTSG
LONGITUDINAL SECTION

III.

OUTAGE 8R EXAMINATION CATEGORIES AND RESULTS

The locations of the tubes examined during Outage 8R are shown on Figures III-1 and III-2. The examinations were performed in two major groups, based on the examination requirement.

- A. Examinations Required by Technical Specification 4.19
- B. GPUN Elective Examinations

These groups are further divided into specific categories of tubes. This section defines the examination scope, purpose and examination results by category. When classifying the tubes by examination category, some tubes may satisfy the criteria for more than one category. In those cases, the tube is placed into the first category which applies following the sequence of this report. The sequence accounts for variations in tube counts as shown in categories such as B-2 and B-4, where some of the tubes were previously included as Category A-1 tubes.

A. EXAMINATIONS REQUIRED BY TECHNICAL SPECIFICATION 4.19

A-1 PREVIOUSLY DEGRADED TUBES

Data Sets: ISI
Probe: .540" - Bobbin
Extent: Full Length

SCOPE

In OTSG 'A', 262 tubes were examined.

In OTSG 'B', 26 tubes were examined.

REASON FOR EXAMINATION

The examination of the "Degraded" tubes serves a dual purpose. First, new examination results are compared to the results of previous examinations to determine if there is evidence of an active degradation mechanism occurring in the OTSGs. Second, the examination provides assurance that no tubes with indications exceeding the plugging criteria remain in service.

INCLUDED TUBES

The "Degraded Tube" population was selected to meet the requirements of Tech. Spec. 4.19.2.a.1. This population consists of all inservice tubes which had confirmed indications of 20% through wall or greater identified during any previous examinations.

RESULTS

The results of the 8R examinations of the "Degraded" tubes were consistent with previous examination results. The majority of the previously identified indications showed no evidence of change from previous examinations. In three cases however, the reported % through wall values exceeded the established plugging criteria and the tubes were removed from service.

OTSG A

Three (3) tubes (A-3-25, A-4-28, A-104-121) had indications of >40% through wall in the freespan portion of the tube and were removed from service by plugging. The indications in these tubes were all 1-coil in circumferential extent.

OTSG B

No indications >40% through wall were recorded.

TRENDING OF I.D. INDICATIONS

To monitor for evidence of continuing degradation of identified indications, the 1990-8R examination results were compared to the 1988-7R. The indications included in this comparison were previously recorded indications with through wall values of 16% or greater in both 1990-8R and 1988-7R. The breakdown of the indications is shown in Table 1 and Appendix II.

In "A" OTSG, 167 indications met the above criteria. The mean change in the indications was 0.0% of wall thickness between 7R and 8R (standard deviation 7.5% of wall). The amplitude of these indications showed a mean change of -0.26 volts (standard deviation 0.36 volts).

In "B" OTSG, 29 indications met the criteria. The average change in the indications was +2.3% of wall thickness between 7R and 8R (standard deviation 5.76% of wall). The amplitude of these indications showed a mean change of -0.17 volts (standard deviation 0.19 volts).

When combined, the average change per indication for both OTSGs was +0.2% of wall (standard deviation 7.43% of wall). The mean amplitude change was -0.25 volts (standard deviation 0.35 volts).

To determine the significance of these changes, the data was compared to similar evaluations performed during previous examinations. Based on this comparison (see Table 2) in which the mean change has been both positive and negative, the identified changes are considered to be within the qualified repeatability of the ECT process, and do not indicate a trend of ongoing degradation. This variability is discussed in Reference 3.

TABLE 1
 COMPARISON OF INDICATIONS IN DEGRADED TUBES

	NUMBER OF TUBES				
	OTSG A	OTSG B	TOTAL		
Degraded Tube Population	262	26	288		
Included in Comparison *	167	22	189		
Excluded from Comparison **	95	4	99		

* Comparison includes only indications >16% T.W. in 7R and 8R.

** Excluded indications are primarily threshold level indications which were below the recording threshold or recorded as S/N indications in either 7R or 8R.

OTSG	Number Indica-tions	No. Inds % T.W.	No. Inds % T.W.	No. Inds % T.W.	Mean Change % T.W.	Std Deviation % T.W.
		Increased 7R-8R	Decreased 7R-8R	Unchanged 7R-8R	7R-8R	7R-8R
A	262	99	101	62	0.0	7.55
B	29	15	7	7	+2.3	5.76
Both A&B	291	114	108	69	+0.2	7.43

OTSG	Number Indica-tion	No. Inds Volts	No. Inds Volts	No. Inds. Volts	Mean Change Volts	Std Deviation Volts
		Increased 7R-8R	Decreased 7R-8R	Unchanged 7R-8R	7R-8R	7R-8R
A	262	29	231	2	-0.26	0.36
B	29	3	26	0	-0.17	0.19
Both A&B	291	32	257	2	-0.25	0.35

TABLE 2

COMPARISON OF STATISTICAL EVALUATION TO PREVIOUS EVALUATIONS

Period	Number Indica- tions	Mean % T.W.	STD Deviation % T.W.	Mean Volts	STD Deviation Volts
1984/1986-5M	152	-2.6	6.1	-0.2	0.3
1986-5M/1986-6R	118	+1.1	6.6	0.0	0.2
1986-6R/1988-7R	119	+2.6	5.5	+0.2	0.3
1988-7R/1990-8R	291	+0.2	7.43	-0.25	0.35

1986-5M data extracted from GPUN TDR 781, Revision 1 (Reference 8).

1986-6R data extracted from GPUN TDR 839, Revision 0 (Reference 9).

1988-7R data extracted from GPUN TDR 935, Revision 0 (Reference 10).

NOTE: For outages 1984 through 1988-7R, all indications were examined with both the 8x1-ABS and .540" bobbin coil probes and only indications >20% T.W. and confirmed by both probes were included. For 1990-8R, all indications >16% T.W. were included, which accounts for the increased number of indications.

A-2 TECH. SPEC. RANDOM SAMPLES

Data Sets: 3%-TS, 6%-TS
Probe: .510" Bobbin
Extent: Full Length

SCOPE

In OTSG "A", 1406 tubes were examined.
In OTSG "B", 468 tubes were examined.

REASON FOR EXAMINATION

The tubes in this sample have no history of degradation below the kinetic expansion. They are examined to monitor the overall condition of the steam generator tubing.

INCLUDED TUBES

The initial sample included at least 3% of all the tubes in each OTSG. As required by T.S. 4.19.2.a.2, at least 50% of the tubes were located in the outer periphery of the OTSG which is an area where experience has indicated potential problems. (The outer periphery is defined as the tubes located outside the radius of the outer support rods). The remainder of the tubes were selected to provide a representative sample of the tube bundle. The samples were selected to include tubes which have not been examined since the 1984 examinations.

As a result of examinations of the "Degraded Tubes", an additional sample of 6% was examined in OTSG A. The tubes for this sample were also biased towards the periphery of the OTSG, since the tubes which forced the expanded sample were in this area.

RESULTS

OTSG A

In OTSG A, the examination of the 3%-TS sample did not reveal any indications of 20% T.W. or greater. The examination of the "Degraded Tubes" did however, require the examination of an additional 6%-TS sample. No indications of 20% T.W. or greater were identified in this sample. The examinations (3%-TS and 6%-TS) did result in two tubes (A-17-62 and A-150-24) being screened for distorted support plate signals, which were then determined to be non-relevant based on the 8x1-ABS probe. In addition, one tube (A-59-72) had a low amplitude (S/N) indication recorded and will be monitored during the next examination.

OTSG B

In the OTSG B, the examination of the 3% sample resulted in six tubes being screened for indications exceeding 20% through wall. Of these six indications, five were between 20 and 40% through wall and one tube had a 63% through wall indication. The five tubes with indications 20-40% T.W. were re-examined using the .540" diameter probe to confirm the percent through wall depths. These tubes (B-26-13, B-50-39, B-73-78, B-82-14 and B-103-33) will be monitored as degraded tubes during the next examination. The tube with the 63% through wall indication (B-123-1) was removed from service by plugging. This indication was located at 6.4" above the secondary face of the upper tubesheet. The indication was re-evaluated using the .540" probe and assigned a value of 60% through wall from the inside surface. The 8x1-ABS probe was used to confirm the circumferential extent as 2-coils.

A review of the last examination of this tube (1984) showed the indication had been present but was not screened during the analysis process. A review of the signals amplitude and phase angle showed the indication had not changed. Based on the indications location and the review of the 1984 data, it was determined no scope expansion was required (Reference 12).

B. GPUN ELECTIVE EXAMINATIONS

B-1 TUBES WITH INDICATIONS NOT CONFIRMED BY 8x1
ABSOLUTE EXAM IN PREVIOUS EXAMINATIONS

Data Set: 8x1ACC
Probe: .540" Bobbin
Extent: Full Length

SCOPE

In OTSG "A", 29 tubes were examined.
In OTSG "B", 14 tubes were examined.

REASON FOR EXAMINATION

These tubes were examined to continue monitoring the status of the previously recorded indications.

INCLUDED TUBES

All in-service tubes with indications recorded as 20% through wall or greater but not confirmed by 8x1-ABS during Outages 86-5M, 86-6R or 88-7R were included in this category. This population represents threshold level indications which are below the threshold of detection for the 8x1-ABS probe. These may be relevant indications which are not detectable due to their geometry or may be non-relevant indications caused by something other than material degradation. Since 1986, this population of tubes had ranged in size from:

	OTSG "A"	OTSG "B"	TOTAL
1986-5M	228	50	278
1986-6R	18	7	25
1988-7R	33	13	46
1990-8R	29	14	43

This change in the population is a result of indications being re-categorized as the examination and analysis techniques are refined. When indications are re-categorized, the tubes may be placed in another data set such as "Degraded Tubes", removed from service by plugging or returned to the general tube population.

RESULTS

OTSG A

In OTSG A, the indications in 15 of the 29 tubes were recorded as 20%-40% through wall and will be monitored as degraded (ISI) tubes during the next examination. In the remaining tubes, four tubes had small amplitude indications less than 1.0 volts and will be monitored as S/N tubes during the next outage. In nine tubes, no recordable indications were identified and the tubes will be returned to the general sample. In one tube, the previously identified indication was recorded as >40% T.W. but not confirmed by 8x1 and the tube will remain in this same category during the next examination.

OTSG B

In OTSG B, three of the 14 tubes had indications of 20-40% T.W. and will be monitored as degraded (ISI) tubes during the next examination. Three tubes had small amplitude indications less than 1.0 volts and will be monitored as S/N tubes during the next examination. The remaining eight tubes had no recordable indications and will be returned to the general sample for the next examination.

B-2 LANE/WEDGE TUBES

Data Set: LANWEG
Probe: .510" Bobbin, 8x1-ABS
Extent: .510" Bobbin - Full Length
8x1-ABS - 14th T.S.P. to UTS

SCOPE

In OTSG "A", 403 Bobbin coil examinations, 419 8x1-ABS examinations.
In OTSG "B", 416 Bobbin coil examinations, 418 8x1-ABS examinations.

REASON FOR EXAMINATION

OTSGs have typically experienced degradation in the lane/wedge tubes. In consideration of the possibility of accelerated degradation in this area, GPUN elected to examine all of the lane/wedge tubes in accordance with paragraph 4.19.2.a.4.(1) of the Tech. Spec. (Reference 1).

INCLUDED TUBES

This examination included all in-service tubes in the Lane and Wedge area. This includes the tubes in the three rows on each side of the open inspection lane (Rows 73, 74, 75, 77, 78, 79) from tube 1 to the center of the OTSG, which are the lane tubes. The wedge tubes are the tubes included in the wedge formed by drawing a line from Row 66 Tube 1 to Row 75 Tube 15 and from Row 86 Tube 1 to Row 77 Tube 15.

RESULTS

OTSG A

In OTSG A, two tubes (A-73-44, A-78-19) had indications >40% through wall and were removed from service by plugging. The indication in A-73-44 was located at the 4th T.S.P. and was evaluated as 52% T.W. from the O.D. surface. The indication in A-78-19 was located at the entrance to the upper tube sheet. This indication could not be sized using the bobbin coil technique; however, based on the MRPC and 8x1-ABS probes, it was considered to be 40% T.W. or greater originating on the O.D. surface.

In addition, four tubes had distorted tubesheet or tube support plate indications. Two tubes (A-73-52, A-74-1) had distorted tubesheet indications on the 8x1-ABS examinations. These areas were examined using the MRPC probe and the indications were determined to be non-relevant. Two tubes (A-77-37, A-79-49) had distorted tube support plate indications (7th T.S.P. and 8th T.S.P., respectively) using the bobbin coil probe. These indications were confirmed as non-relevant using the 8x1-ABS probe.

One other tube (A-79-47) had small amplitude (S/N) indication in the upper tubesheet. This indication was recorded and the tube will be monitored during the next examination.

OTSG B

In OTSG B, one tube (B-77-12) had an indication at the secondary face of the upper tubesheet. This indication was distorted and could not be sized using the bobbin coil probe. Based on the MRPC and 8x1-ABS probes, the indication was determined to be >40% through wall from the O.D. and 1-coil in circumferential extent and the tube was removed from service by plugging.

Indications of 20-40% through wall were recorded in two tubes (B-73-45, B-74-56) and these tubes will be monitored as degraded tubes during the next examination. Two other tubes (B-67-1, B-78-56) had small amplitude (S/N) indications recorded. These indications were recorded and the tubes will be monitored during the next examination.

B-3 TUBES WITH S/N INDICATIONS

Data Set: S/N, S/N-7R
Probe: .540" Bobbin
Extent: Full Length

SCOPE

In OTSG "A", 60 tubes were examined.
In OTSG "B", 18 tubes were examined.

REASON FOR EXAMINATION

These tubes were examined to verify the minor nature of the indications.

INCLUDED TUBES

During previous OTSG examinations, poor signal to noise ratio (S/N) indications of less than 1.0 volt have been detected and recorded using the bobbin coil probe. The through wall depth of these indications cannot be quantified due to the poor (less than 3:1) signal to noise ratio; however, the 8x1-ABS technique has been used to verify the small circumferential extent. Based on the results of these examinations the indications have always been 2 coils or less in circumferential extent and the tubes have remained in service to be monitored as "S/Ns".

S/N indications recorded since 1986-5M which had phase angles of 6° to 110° by .540-HGSD and were confirmed by 8x1-ABS were examined during this outage. In addition, all S/Ns which met this phase angle criteria in 1988-7R were included whether or not they were confirmed by 8x1-ABS.

RESULTS

OTSG A

The indications in 22 of the 60 tubes continued to be below the threshold for evaluating percent through wall. In 11 of the tubes (A-7-4, A-24-19, A-25-2, A-26-96, A-31-24, A-50-2, A-75-26, A-95-127, A-100-90, A-144-2, A-149-30), the indications were of an acceptable level for evaluation and were determined to be 20-39% through wall. These tubes will be considered degraded tubes during the next examination. In 27 tubes, the indications were outside the recording range and the tubes will be returned to the general samples.

OTSG B

The indications in eight of the 18 tubes continued to be below the threshold for evaluation. Four tubes (B-8-44, B-42-74, B-79-47, B-131-27) had indications evaluated as 20-39% through wall and will be examined as degraded tubes during the next outage. In six tubes, the indications were outside the recording range and the tubes will be returned to the general samples.

B-4 MECHANICAL CLEANING BASELINE

Data Set: WSC
Probe: .540" Bobbin
Extent: Full Length

SCOPE

In OTSG "A", 47 tubes were examined.
In OTSG "B", 50 tubes were examined.

REASON FOR EXAMINATION

During Outage 7R, GPUN performed mechanical cleaning (Water Slap Cleaning) to remove deposits from the secondary side of the OTSGs. Since this cleaning process involves pulsing nitrogen into the secondary side of the OTSG and displacing large volumes of water, a pre-cleaning and post-cleaning baseline was desired in areas where the tubes were exposed to the highest stress during the cleaning process.

INCLUDED TUBES

The tubes selected for examination were located near the nitrogen injection nozzle locations. As stated in Reference 5, the tubes exposed to the most adverse loadings are located 18 tubes from the centerline of the nozzle and three tubes in from the periphery. The tubes were therefore selected from this envelope in front of four of the eight nozzles in each OTSG.

RESULTS

OTSG A

No evidence of damage from the mechanical cleaning process was observed in these tubes. Three tubes (A-3-14, A-4-30, A-95-1) did have small amplitude (S/N) inner diameter indications identified and the tubes will be examined as S/Ns during the next outage. In addition, one tube (A-63-128) had an indication in the absolute channel of the bobbin probe, however, the indication was determined to be non-relevant, based on the 8x1-ABS examination.

OTSG B

No evidence of damage from the mechanical cleaning process was noted in these tubes. One tube (B-113-114) did have a distorted support plate signal which was determined to be non-relevant based on the 8x1-ABS probe. In addition, one tube (B-114-4) had a small amplitude (S/N) inner diameter indication and will be examined as a S/N next examination.

B-5 EXTRA

Data Set: Extra
Probe: .510" Bobbin
Extent: Full Length

SCOPE

OTSG "A", 3 tubes were examined.

REASON FOR EXAMINATION

During the course of the examinations, Eddy Current data was acquired on tubes not identified on the ECT data sheets. The tubes were examined as a result of the typographical or interpretive errors on the part of the data acquisition personnel. Once the ECT data is recorded, it is evaluated and the tubes dispositioned accordingly.

INCLUDED TUBES

These tubes are randomly located.

RESULTS

No indications were identified in these tubes.

C. DISCUSSION OF RESULTS

Characterization Of Indications

The indications reported during 1990-8R were characterized by location, percent through wall, amplitude, and circumferential extent. (See Figures III-5 through III-8). This characterization showed that the majority of indications are inner diameter initiated and are located towards the top of the OTSGs. In OTSG "A", the indication rates are higher towards the outer periphery while the distribution is more uniform across OTSG "B". This is the same distribution of indications as identified during the previous examinations.

The amplitudes (voltage) of the 1990-8R indications were typically small, <2.0 volts. The characterization by percent through wall shows most of the indications are partial through wall with 98% of the indications recorded as <50% through wall. These are both consistent with previous examination results.

The circumferential extent of the 1990-8R indications was 1 coil for all indications except two 2-coil indications. This is consistent with the previous examination results.

Review of Previous Data

The ECT examination process included a review of previous examination data. This review was performed to better characterize and understand apparent changes in the ECT results from previous outages. This review and comparison included all tubes which were plugged during Outage 8R.

Based on the results of this review, the tubes can be categorized in the following groups.

1. Tubes with indications >40% through wall in 8R which exhibited >10% change from 7R-8R.

This category includes three tubes, all in OTSG A (A-3-25, A-4-28, A-104-121). These tubes had previously recorded indications of less than 40% through wall and the tubes were examined to monitor the indications. The indications in these tubes now exceed the 40% through wall plugging limit and the changes in the indications since the last examination are >10% through wall. A comparison of the signal amplitude shows in each case the amplitude (voltage) of the indications has decreased since the last examination. This would indicate the changes may be attributed to the repeatability of the ECT process and do not positively indicate there is an active mechanism.

2. Tubes with indications >40% through wall which exhibited less than 10% change from the last examination.

This group includes two tubes in OTSG B. (B-123-1, B-138-52). Both of these tubes had indications >40% through wall recorded during 1990 8R and the tubes were removed from service. The indication in B-123-1 was located in the upper tubesheet just below the kinetic expansion transition. A review of the 1984 data for this tube revealed the indication had been present but not detected during the examination. A review of the signal's phase angle and amplitude indicated it had not changed from 1984 to 1990-8R.

In tube B-138-52, a previously screened but not confirmed indication was confirmed by the 8x1-ABS probe at the 6th T.S.P. Based on the .540" bobbin probe examination, this indication had not changed from 1988-7R to 1990-8R.

3. Tubes with indications >40% T.W. which were previously distorted or undetectable.

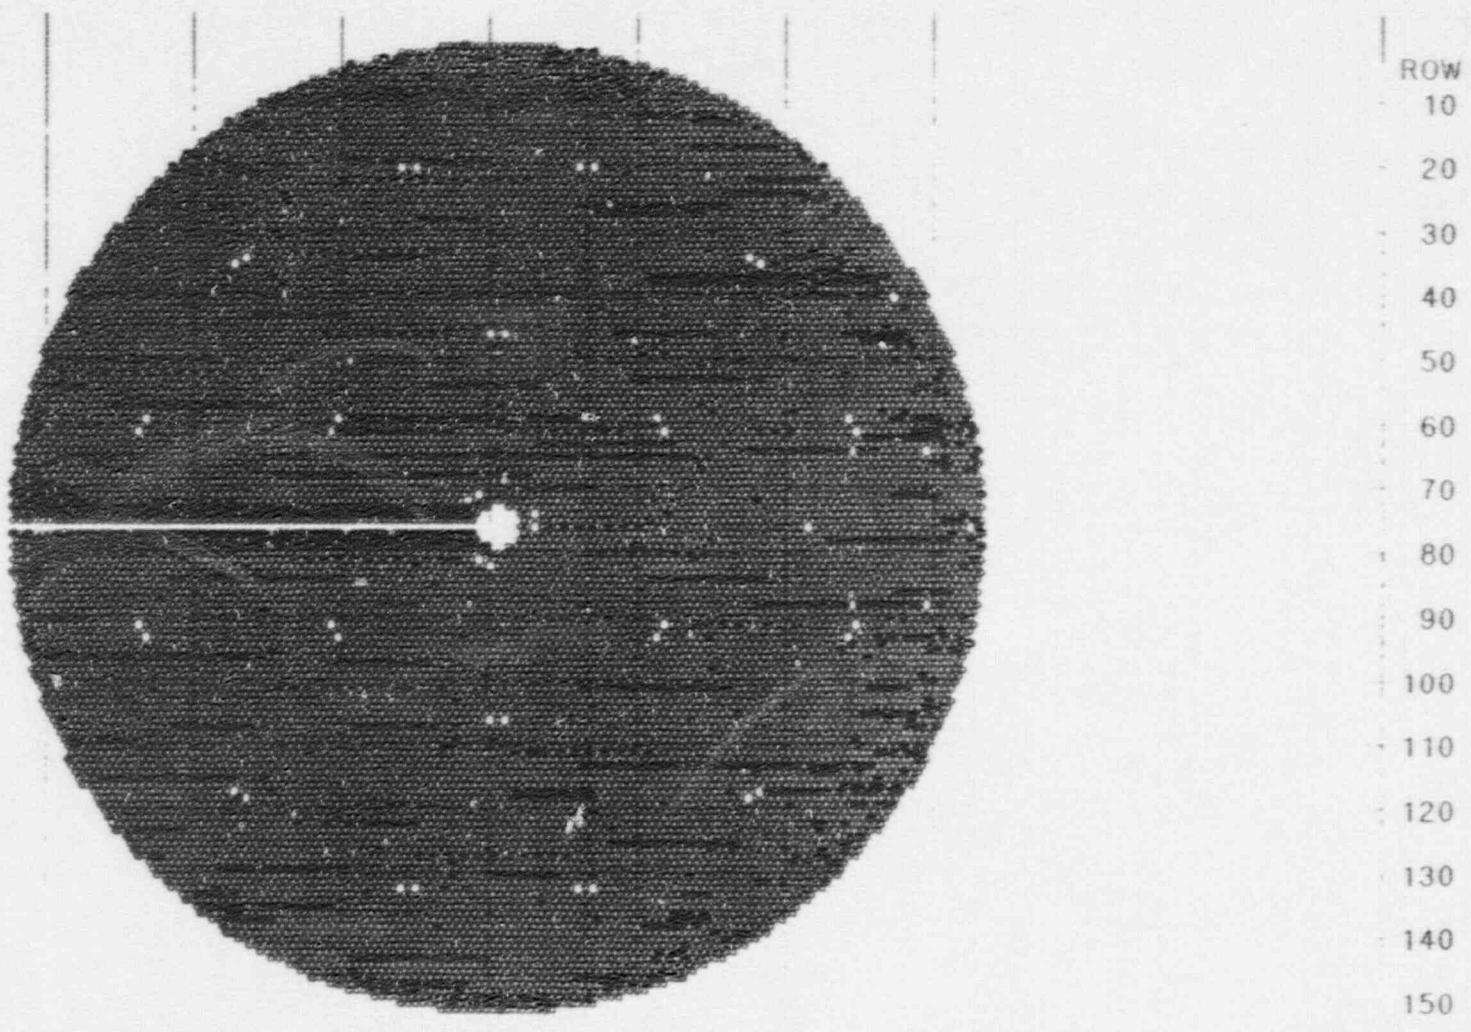

This category includes two tubes (A-73-44, A-78-19) in OTSG-A and one tube (B-77-12) in OTSG-B.

Two tubes were removed from service, one in each OTSG because of indications at the entrance to the upper tubesheet. In OTSG A, tube A-78-19 had a 2-coil indication detected during the 8x1-ABS examination of the lane area. In OTSG B, tube 77-12 had a distorted tubesheet indication (DTS) recorded during the .510" bobbin coil examination.

Both of these tubes were then examined using the MRPC probe, which showed the indications to be rounded, outer diameter initiated and located immediately above the entrance to the upper tubesheet. Based on a comparison of the size and shape of the indication with the flat bottom holes in the ASME calibration standard, the indications were determined to be >40% T.W. and the tubes were removed from service.

The remaining tube, A-73-44, had a previously recorded distortion at the 4th T.S.P. which was determined to be a relevant indication during Outage 1990-8R. This tube was also removed from service.

IV. OUTAGE 8U1 EXAMINATION CATEGORIES AND RESULTS

The locations of the tubes examined during Outage 8U1 are shown in Figure IV -1. The tubes were categorized in two groups based on the examination purpose.

- A. Tubes suspected as leakers
- B. Lane/lane wedge tubes

The results of these examination are summarized below.

A. TUBES SUSPECTED AS LEAKERS

Data Set: Suspect
Probe: .540" Bobbin
8x1-ABS
Extent: Various

SCOPE

In OTSG "A", three tubes were examined.

REASON FOR EXAMINATION

Following the plant shutdown, a bubble test was performed to determine the source of primary to secondary leakage.

During the test, tube A-77-1 (lane wedge tube) was identified as an obvious leaker and tubes A-48-64 and A-85-92 (interior tubes) were identified as suspected leakers. The tubes were then examined to locate any possible defects.

EXTENT

Tube A-77-1 was an obvious leaker and had temporary plugs installed in each end during the bubble and subsequent drip tests. This stopper limited subsequent examinations to the upper portion of the tube. The .540" bobbin examination was performed from the 9th tube support plate to the upper tube end while the 8x1-ABS examination was performed from the 14th tube support plate through the tube end. These extents were acceptable to permit dispositioning the tube in accordance with the approved repair criteria.

Tubes A-48-64 and A-85-92 were examined from the 10th tube support plate to the tube end using the 8x1-ABS probe and over their entire length using the .540" bobbin.

RESULTS

Tube A-77-1, which was the obvious leaker, was identified as having a large amplitude 100% through wall defect at the entrance to the upper tubesheet. Based on the 8x1-ABS, the indication was determined to be 8-coils in circumferential extent indicating it was nearly 360°. This circumferential extent was also confirmed by the MRPC probe and visual examination.

Tubes A-48-64 and A-85-92 had no detectable indications using either probe. Post repair bubble testing also confirmed this result.

B. LANE/LANE WEDGE TUBES

Data Set: Lane, Lane-1
Probe: 8x1-ABS
Extent: 14th T.S.P.

SCOPE

In OTSG "A", 417 tubes were examined.

REASON FOR EXAMINATIONS

As noted in Section III, OTSGs have typically experienced higher degradation rates in the upper portions of the lane and lane wedge tubes. This was further evidenced by the fact that tube A-77-1, a lane wedge tube, had failed at the secondary face of the upper tubesheet. This failure mode, type and location were typical of failures observed in other OTSGs.

INCLUDED TUBES

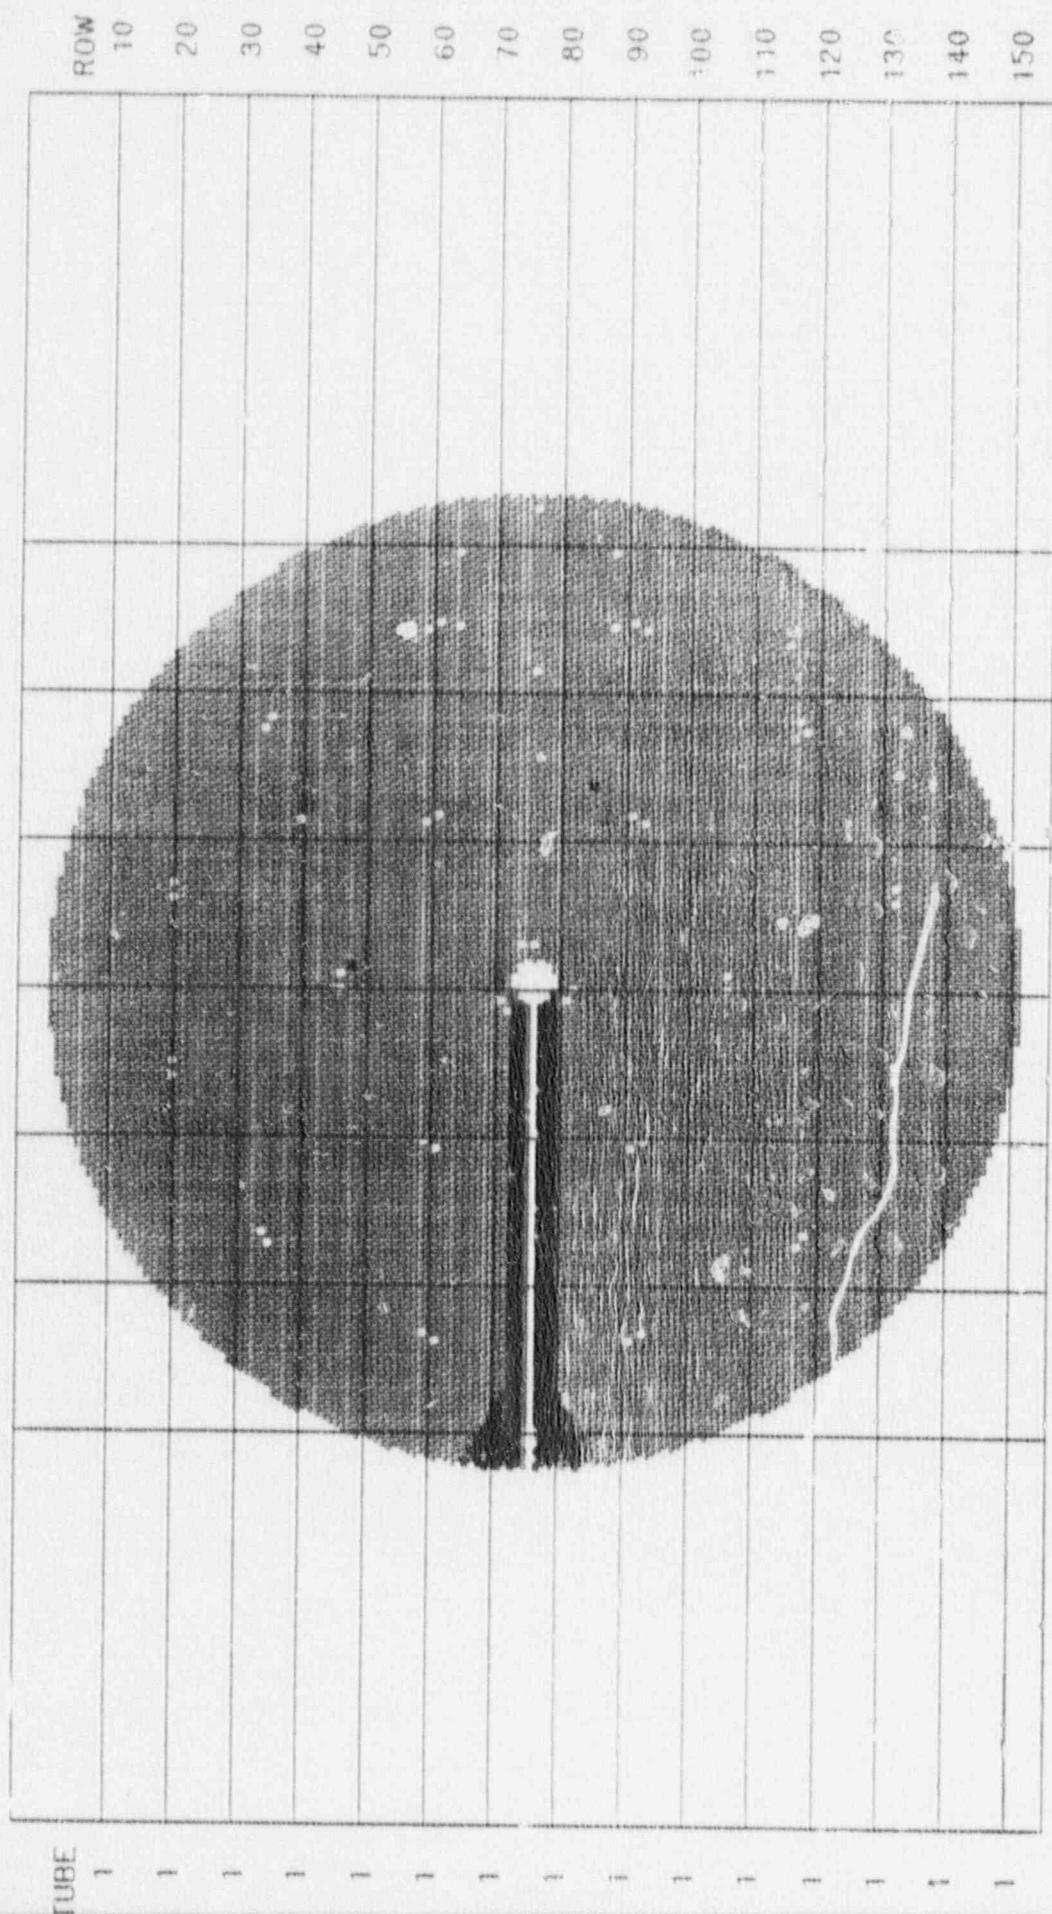

This examination included all inservice tubes in the previously defined lane and wedge regions. This includes the tubes in the three rows on each side of the open inspection lane (Rows 73, 74, 75, 77, 78, 79) from tube 1 to the center of the OTSG, which are the lane tubes. The wedge includes all tubes inside the area formed by drawing a line from Row 66 Tube 1 to Row 75 Tube 15 and from Row 86 Tube 1 to Row 77 Tube 15.

RESULTS

Based on the 8x1-ABS examination of these tubes, four tubes were identified as having suspect indications. These tubes A-73-37, A-74-1, A-75-62 and A-78-28 were examined using the MRPC probe. Based on the combined results of the 8x1-ABS and MRPC, tube A-78-28 was removed from service as a precautionary measure. This tube had an indication considered to be >40% through wall, however, no depth could be assigned.

C. DISCUSSIONS OF RESULTS

Based on the characterisation of the defect in tube A-77-1 and the results of the ECT examinations, GPUN determined the occurrence of the tube leak was most probably the result of high cycle fatigue. Failures of this type have previously been identified at other B&W plants and typically occur over a short period of time prohibiting the detection and preventive plugging of suspected defects. The scope of the examinations was therefore not expanded beyond the initial scope. This evaluation and disposition is documented in References 13 and 14.

ACRYL TEST Tubes

V.

CONCLUSIONS

Based on the results of the 1990, Outage 8R and 8U1, ECT examinations and data evaluations, GPUN was able to reach the following conclusions:

1. The examinations of the previously "Downgraded Tubes" do not indicate a trend of ongoing degradation.
2. The examination results of the Czech. Spec. random samples did not reveal a trend of new or continuing damage mechanisms. The majority of the indications identified during this examination were determined to have been present during previous inspections.
3. The GPUN Elective Examinations confirmed the minor nature of indications in this category. The few indications which exceeded the 40% through wall plugging limit indicate GPUN should continue to monitor indications of this type.
4. The results from the 8U1 examinations indicate the tube leak was an isolated occurrence, the result of high cycle fatigue, similar to failures which have been identified at other B&W plants.

EXPLANATION OF DDA-4 ANALYSIS CODES

Absolute Drift (ADR) - Normally refers to drift in the crevice of non-expanded tube sheets. Can also be used for tube to tube wear in free standing section of tubing. Possible indicator of Inner Granular Attack (IGA). Recorded in low frequency absolute.

Bad Data (BDA) - Self explanatory.

Dent (DNT) - Tube I.D. smaller than nominal I.D., occurring at support plate intersections or top of tube sheets. Recorded in differential mix.

Ding (DNG) - Similar to dent but in free-standing part of tube. Either caused in manufacturing or by mechanical cause. Recorded in prime frequency.

Dent With Possible Indication (DNI) - Possible discontinuity indication associated with dent but is not measurable. Recorded from differential mix.

Distorted Roll Transition (DRT) - Self explanatory.

Distorted Roll Transition With Possible Indication (DRI) - A distorted roll transition that has sufficient distortion that a discontinuity may be creating the distortion.

Distorted Support Signal (DSS) - An indication at the intersection of a support plate which may be indicative of a possible discontinuity. The signal may be distorted by deposit, dents, or saturated drilled hole supports.

Distorted Tube Sheet (DTS) - An indication at the intersection of the upper or lower secondary tube sheets which may be indicative of a possible discontinuity. The signal may be distorted by deposits, dents, or saturated tube sheet signals.

Expansion Transition Location (ETL) - Used to record the location of the kenetic expansion.

Fixture (FIX) - Used when tubes cannot be examined because the fixture foot is obstructing tube or the fixture will not reach a particular tube.

ID Chatter (IDC) - Caused by manufacturing process (pilgering). Characterized by long areas of horizontal motion. Recorded in prime frequency.

Incomplete Test (INC) - Tube not run to the extent required or complete tube not recorded.

Indication Not Found (INF) - Indication that has been previously reported but is not found on current examination.

Indication Not Reportable (INR) - Indication that has been previously reported but does not meet current reporting criteria.

No Detectable Discontinuity (NDD) - Entry not required if DBASE system used.

Obstructed (OBS) - Tube that is obstructed by foreign material, i.e., dirt, chunk of metal, broken off probe head, etc.

Permeability Variation (PVN) - Self explanatory. Recorded in prime frequency free-standing tube, measured in differential mix at support plate intersections.

Plugged (PLG) - Permanent mechanical plug, not to be confused with obstruction.

Sludge (SLG) - Accumulation of ferromagnetic material on top of tube sheets or support plates. Recorded in lowest absolute frequency as per specific plant requirements.

Signal To Noise Ratio (S/N) - Small amplitude indications (less than 1 volt with 540 HGSD, less than 1/2 volt normal gain) that do not have a minimum of a 3 to 1 signal to noise ratio.

Template Obstruction (TMO) - Self explanatory.

Tube No Test (TNT) - Self explanatory.

Tube Number Check (TNC) - Used when the tube identity is in doubt.

Tube Restricted (TRS) - Caused by tube itself, i.e. bent tube lip, large dents or dings.

Undefined Signal (UDS) - A signal that is re-examined with the 8x1 technique to determine if the signal is relevant.
