## 1.0 INTRODUCTION

Spent fuel storage capacities at some commercial light water reactors (LWRs) are inadequate to handle projected spent fuel discharges. This report presents estimates of potential near-term requirements for additional LWR spent fuel storage capacity, based on information supplied by utilities operating commercial nuclear power plants. These estimates provide information needed for planning the Department of Energy's (DOE) activities to be carried out under the DOE's Commercial Spent Fuel Management (CSFM) Program, in conjunction with the requirements of the Nuclear Waste Policy Act of 1982. This report is the latest in a series published by the DOE on LWR spent fuel storage requirements. Previous reports in this series are DOE/RL-84-1<sup>(1)</sup>, DOE/RL-83-1<sup>(2)</sup>, DOE/RL-82-1<sup>(3)</sup>, DOE/SR-0007<sup>(4)</sup>, DOE/NE-0002<sup>(5)</sup>, and DOE/ET-0075<sup>(6)</sup>.

The estimates in this report cover the period from the present through the year 2000. Although the DOE objective is to begin accepting spent fuel for final disposal in 1998, types of fuel and the receipt rates to be shipped are not yet known.<sup>(7)</sup> Hence, this report makes no assumption regarding such fuel shipments. The report also assesses the possible impacts of increased fuel exposure and spent fuel transhipment on the requirements for additional storage capacity.

## 2.0 SUMMARY

This section describes the cases analyzed in the current study and summarizes the resulting estimates of requirements for additional storage capacity for spent nuclear fuel from commercial LWRs in the United States. A comparison of these results with those of previous studies in this series is also included.

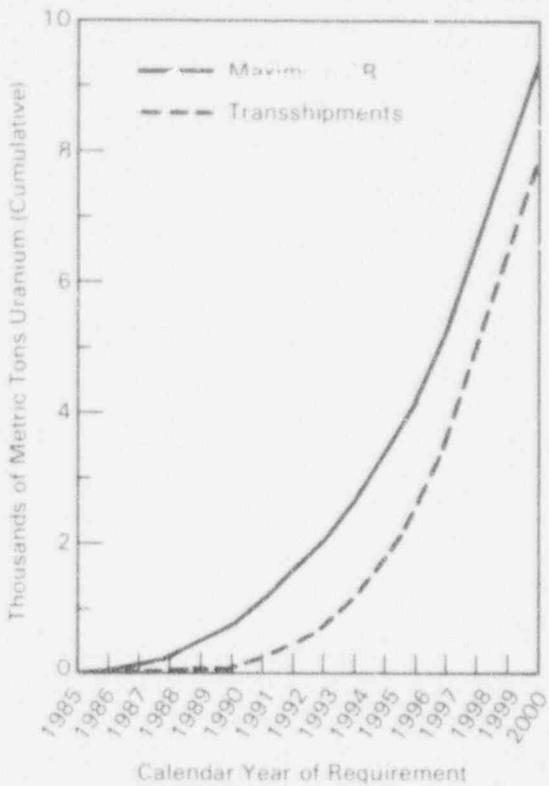

### 2.1 RESULTS

Estimates of potential near-term requirements for additional spent fuel storage capacity are based on information supplied by the nuclear utilities to the Energy Information Administration (EIA) as of the end of calendar year 1984. Two reference cases were used to develop the estimates. These cases are based on the maximum at-reactor (AR) storage capacities of the individual reactor pools, as determined by the utilities. Both cases include allowances for maintaining full core discharge capability, also referred to as full core reserve (FCR), for each separate reactor. A single FCR is assumed to be maintained for all units at multiple reactor stations employing either a single common spent fuel storage pool, or separate pools with interconnections allowing spent fuel transfer between them. These reference cases directly correspond to cases analyzed in the previous study in this series<sup>(1)</sup>.

The only difference between the two reference cases is in the consideration of transshipment to other reactor sites. The first reference case assumes that transshipments occur only as currently planned by the utilities. The second reference case includes the additional assumption that there are no constraints on transshipments of spent fuel among reactors of like type (i.e., among boiling water reactors [BWRs] or among pressurized water reactors [PWRs]) within a given utility system. This allows unused spent fuel storage capacity at one reactor to offset needs for additional capacity at another reactor in the same utility system, thus delaying the utility's need for additional storage capacity. Such transshipments are included in the spent fuel management plans of several utilities. The two reference cases therefore define a range of potential storage requirements.

A summary of the additional spent fuel storage requirements in the U.S. between 1985 and 2000 is shown in Figure 2.1. The figure is based on the detailed projections of spent fuel storage requirements presented in the Appendix. As shown in the figure, the "maximum AR capacity" case results in the largest requirements for additional storage, with a projected storage shortfall of 9332 Metric Tons Uranium (MTU) (34029 assemblies) in 2000. For the "maximum AR capacity with transshipment" case, intra-utility transshipments are projected to reduce these requirements, to 7919 MTU (29701 assemblies) in 2000.

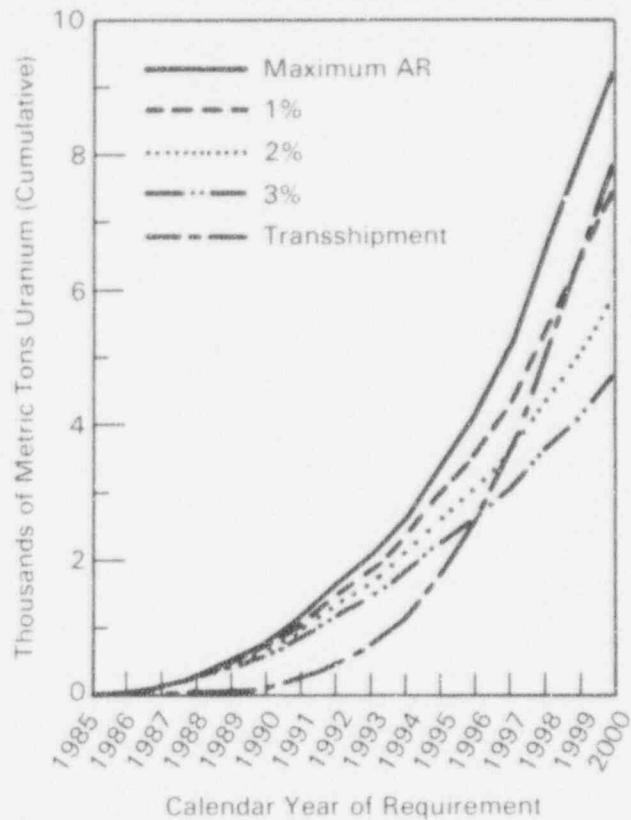

A variation on the reference case is also examined. This variation is based on the potential reduction of future discharges resulting from improved fuel utilization obtained by increasing the goal exposure of the fuel in the reactor core. This increase in fuel utilization would result in a net decrease

**FIGURE 2.1.** Additional Spent Fuel Storage Requirements  
(December 31, 1984, data)

in the overall rate of spent fuel discharges, and thus delay the utilities' needs for additional storage capacity. A simple model was used to estimate the potential impacts of increased fuel utilization. Goal exposures for future operating cycles (starting in 1985) were assumed to increase by a fixed percentage each year at each reactor (up to a maximum limit for each reactor type), resulting in net decreases in spent fuel discharges and, consequently, net decreases in additional storage requirements. Calculations were performed for three possible exposure-increase percentages and compared with the reference case without transshipment. While individual reactors are likely to exhibit unique exposure-increase patterns, the application of a fixed percentage to all reactors provides an adequate model for the purposes of projecting aggregate total discharges.

The net impact of extended fuel exposure on the requirements for additional storage, based on the model used in this analysis, is shown in Figure 2.2. The result is a significant reduction of storage requirements, to 7492 MTU (27275 assemblies) by 2000 for a 1.0% exposure increase per year, compared with the maximum AR case in 2000. Similarly, 2% and 3% per year increases in exposure results in reductions to 5885 MTU (21294 assemblies) or 4742 MTU (17176 assemblies), respectively by 2000. The 2% to 3% per year rate

**FIGURE 2.2.** Additional Spent Fuel Storage Requirements: Extended Fuel Exposure (December 31, 1984, data)

of increase in exposure is consistent with projections in the latest Fuel Performance Annual Report<sup>(8)</sup>, and historical exposure increases from 1978 through 1984.

## 2.2 COMPARISON WITH PREVIOUS RESULTS

The projections of additional spent fuel storage requirements in this report are lower than those reported in last year's report. For the maximum AR capacity case, the current projections of additional cumulative storage requirements are about 9332 metric tons of fuel in 2000, as compared with 11419 metric tons previously projected for the same year (although the previous report only presented projections through 1993). Several factors contributed to this decrease in projected additional storage requirements as estimated by the utilities. Prominent among these are:

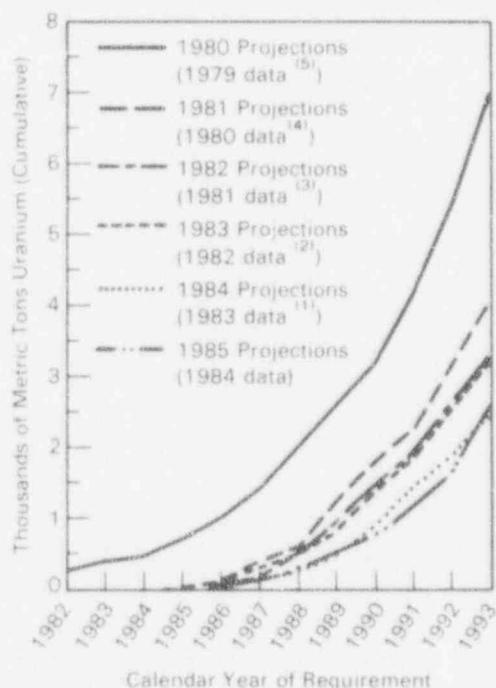

- Increased utilization of fuel cycles with longer periods between discharges, and of innovative cycles involving reuse of previously discharged fuel assemblies, and

- Increased estimates of maximum storage capacity in some reactor pools, caused in part by continued utility use of reracking to increase pool storage capacities.

During 1984 several utilities re-evaluated the maximum capacities of the storage pools at their plants, which in some cases increased the projected maximum capacity, and in others decreased it. The changes at some plants were relatively large, and the net capacity change over all plants was an increase of 4714 assemblies.

The first plant to require additional storage is projected to be Millstone-2 in 1985. In 1986, Surry-1&2 are projected to require additional storage, while in 1987 four additional plants are projected to have storage needs: Palisades, St. Lucie-1, Millstone-1, and Peachbottom-2.

Spent fuel for which storage capability may not be available is projected to accumulate at the rate of 1445 MTU/year in 2000, and to increase at a rate of over 2000 MTU/year by 2003 (not taking into account the quantities accepted by the U.S. government for final disposal beginning in 1998). Figure 2.3 shows

- (1) From DOE/RL-84-1 (DOE 1984).
- (2) From DOE/RL-83-1 (DOE 1983).
- (3) From DOE/RL-82-1 (DOE 1982).
- (4) From DOE/SR-0007 (DOE 1981).
- (5) From DOE/NE-0002 (DOE 1980).

FIGURE 2.3. Comparisons of Annual Projections of Additional Spent Fuel Storage Requirements

a comparison of the projected storage needs from this and previous reports in the series. Although there is a continued decline in near-term requirements, it is evident that there are still significant projected requirements for additional storage capacity over the next decade.

## 3.0 DISCUSSION

### 3.1 METHOD OF CALCULATION

The calculations required for this report were performed in a similar manner to those in the previous report<sup>(1)</sup>. Calculational procedures were modified only as needed to correspond to the different data collection method. In the previous reports in this series, the data was supplied by the utilities on a voluntary basis. The data for this report was collected by EIA under a mandatory data collection instrument, the RW-859 Spent Fuel Data survey form, which included requests for data in addition to those required for this report.

The data presented here are based on historical records of spent fuel discharges, inventories, and shipments as of the end of December, 1984. The data also include the utilities' estimates as of December, 1984, of plans for future nuclear plant operations and spent fuel discharges. These data provide the bases for the estimates of additional spent fuel storage requirements presented in this report.

### 3.2 FACTORS AFFECTING STORAGE REQUIREMENTS

The projections of future requirements for additional spent fuel storage capacity can be affected by many factors associated with nuclear power plant operation. The primary factors are discussed below.

#### Increased At-Reactor Storage Capacity

Spent fuel storage capacities supplied by the utilities were used to develop the projections of additional storage capacity requirements presented in this report. The "maximum AR capacities" used in the analyses included allowances only for technologies currently licensed by the Nuclear Regulatory Commission (NRC) (i.e., reracking). Several demonstration programs are in progress relating to currently unlicensed technologies. Only the fuel presently scheduled to be utilized in these demonstration programs was included in calculating storage capacity adjustments. Follow-on programs are mentioned in Section 3.5 of this report.

Several utilities are investigating the possibility of increasing their existing pool storage capacity by using rod consolidation. This technique, when licensed, could increase the maximum pool storage capacity at some plants by a factor of 1.5 to 2 above that attainable using currently licensed methods. However, the applicability of this dense-storage technology at any given reactor may be limited because of possible structural and seismic constraints.

Similarly, a number of utilities have expressed interest in supplementing pool storage of fuel with onsite dry storage in large-capacity metal casks or concrete silos. Use of such dry storage technologies could significantly decrease the requirements for additional spent fuel storage capacity and is likely to be a major factor in meeting the additional storage requirements.

indicated through 2000. However, like rod consolidation, dry storage technologies are still being developed and are not yet licensed by the NRC; therefore, except for the active DOE cooperative demonstration programs, they were not considered in projecting the available storage capacity used to derive the projected additional storage requirements.

#### Reactor Fuel Cycles

Utilities normally project reactor operating cycles for several years into the future. These projections, which form the bases for the projected patterns of spent fuel discharges used in this report, are usually based on a defined reactor operating "norm." Future circumstances resulting in changes from this norm may affect both the timing and the quantities of fuel discharges.

In addition, many utilities are moving toward increased utilization of the fuel, either by adopting modified fuel cycles involving longer periods between discharges resulting in increased fuel exposure, or by re-inserting previously discharged fuel to "balance out" new fuel loads.<sup>(8)</sup> The net result of this increased fuel utilization is a reduction in the amount of spent fuel discharged.

#### Offsite Transshipments

Some utilities plan to ship fuel between reactor pools at different sites; this transshipment may be undertaken to delay the need for additional storage within a utility system. In some instances, transshipments have been barred by state laws or local ordinances. Court challenges to these legal impediments are underway, but the results are not yet final. Transshipment also requires NRC licensing, a process which can take considerable time. Thus, there is uncertainty regarding the wide-spread use of transshipments, although they are currently being used in some cases to provide temporary relief from storage problems. Analyses of the possible impacts of transshipment on the requirements for additional spent fuel storage are included in this report.

Some of the utilities may be planning on either shipping fuel to an off-site storage facility or receiving fuel from an offsite storage facility. These plans are not made public until after the shipments have been completed because of safeguards considerations; specifically, the quantities and dates of shipments are withheld. These shipments will affect inventories at several currently operating reactors. Shipments are planned from West Valley to several utilities to remove the remaining fuel from the West Valley basin. In this report it is assumed that the following shipments will be made from West Valley: 81 assemblies to Ginna during 1985, 224 assemblies to Oyster Creek during 1985, and 125 assemblies to the Idaho National Engineering Laboratory (INEL) during 1985 (this shipment consists of 85 Big Rock Point and 40 Ginna assemblies). Also, a total of 1058 assemblies are planned to be shipped from Monticello to the GE Fuel Storage Facility at Morris, Illinois between 1984 and 1989 (with 72 shipped during 1984). As part of the DOE cooperative demonstration program 117 assemblies are planned to be shipped from Surry 1&2 to INEL between 1985 and 1987.

### Onsite Transfers

The transfer of spent fuel between two unconnected pools at a single site, referred to as onsite transfer, is practiced at some installations, and allows for more efficient use of available space in the near term. Although this delays the need for additional storage, it does not significantly change the long-term storage requirements.

### Reactor Operating Dates

Projections of spent fuel discharges are affected by changes in the scheduled startup dates of reactors. Significant delays in the startup dates of many reactors continue to occur. However, these changes have little impact on the near-term requirements for additional storage. This is because the storage pools at these reactors are planned to have sufficient capacity for discharges for a minimum of ten years of operation. Near-term storage requirements are thus only affected in cases where the utility had planned to use the storage capacity at new plants to receive transshipments from currently operating plants.

### 3.3 CONDITIONS ASSUMED FOR THE CASES ANALYZED

A number of general conditions were assumed for all of the cases analyzed in this report, and specific assumptions were made for the analysis of each of the individual cases. The conditions and assumptions used are described in this section.

#### General

The following conditions and assumptions were applied to all of the cases of projected additional storage requirements analyzed in this study:

1. Reactor operating cycles, discharge rates, startup dates, operating lifetimes, and pool capacities were assumed to be as specified by the utilities as of the end of calendar year 1984.
2. FCR is assumed to be maintained for each reactor. A single FCR is assumed to be maintained for all units at multiple-unit reactor stations employing either a single common spent fuel storage pool, or separate pools with interconnections allowing spent fuel transfer between them. Multiple units on a single site with individual, unconnected pools are assumed to maintain FCR for each unit (except for Southern California Edison, which intends to maintain only a single FCR at the three San Onofre units). Reactors that need to ship fuel to maintain FCR, but have a capacity increase scheduled within two years following loss of FCR, are assumed to operate without FCR until that capacity increase takes place.

3. All licensable actions to increase storage capacity at reactor sites are assumed to be taken. Thus, if a utility indicates that the maximum pool capacity is larger than that currently licensed, the larger pool capacity is used in this report.
4. Due to missing, inconsistent, or incomplete data on some of the utility survey forms submitted to EIA, certain data have been assumed for these analyses. These data were either derived from data supplied elsewhere on the survey or from the data supplied previously under the voluntary data collection used in previous reports.

#### Maximum AR Capacity Case (Reference Case 1)

The maximum AR capacity case was developed to correspond with conditions that either currently exist or are judged likely to occur. In addition to the common assumptions listed above, the following assumptions were made for the maximum AR capacity case:

1. Utilities will increase their spent fuel storage pool capacities to the maximum extent possible using currently licensed technology (i.e., reracking). The maximum storage capacities shown may not be the actual maximum pool capacity. Many utilities (especially those with very near-term additional storage requirements) are conducting careful studies of expanding the storage capability of their pools. These studies are expected to result in capacity increases beyond those listed in this report as maximum pool capacities for some reactor sites.
2. Offsite transshipment of spent fuel will not take place except in those cases currently licensed by the NRC. Onsite transfers will occur as planned; additional onsite transfers will occur, if necessary, at reactor sites where such transfers have taken place in the past.

#### Maximum Capacity with Intra-Utility Transshipment Case (Reference Case 2)

This case retains the same assumptions as the maximum AR capacity case, with the exception that transshipment of spent fuel within a utility system is assumed. Reactors requiring additional storage are assumed to ship fuel to any reactor of the same type (PWR to PWR or BWR to BWR) operated by the same utility system as needed to meet storage requirements.

#### Maximum Capacity with Increased Fuel Exposure Case

The increased fuel exposure case was analyzed to evaluate the effects of utilities gradually increasing the discharge exposure of the fuel. Four scenarios were used to bracket the possible effects. The "no-action" scenario, in which fuel exposures remain as projected by utilities, is identical to the maximum AR capacity case. The remaining scenarios assumed a constant yearly increase in discharged fuel exposure resulting in a corresponding decrease in fuel discharged (thus maintaining the reactor energy generation constant at the

level indicated by the utilities). Increases of 1.0% per year, 2.0% per year and 3.0% per year were assumed. The maximum average discharge exposure was assumed to be 45,000 mega-watt days (thermal) per metric ton initial heavy metal (MWD/MTIHM) for PWR reactors and 38,000 MWD/MTIHM for BWR reactors.<sup>(9)</sup> Although a few lead reactor fuel assemblies have been discharged with exposures in excess of these values, they appear to be reasonable maximum values for use on an industry wide basis.

### 3.4 ADDITIONAL SPENT FUEL STORAGE REQUIREMENTS

The projected cumulative storage requirements through the year 1998 were shown in Figure 2.1. Numerical, year-by-year projections of requirements are given in Tables 3.1a through 3.1e. Detailed data on plant characteristics and on present and potential storage capacities at each reactor are given in the Appendix (Table A.1). Tables A.2 and A.3 list, on a plant-by-plant basis, inventories of spent fuel in the storage pools and future spent fuel discharges planned by the utilities. Projections are given both as annual and cumulative discharges. Projected shipments either into or out of pools are not shown in these tables; only reactor discharge additions are included. Thus, shipments from West Valley to reactor sites or between reactors are not indicated, although these are included in calculating the additional storage requirements. Tables A.4 and A.5 show, again on a plant-by-plant basis, annual and cumulative additional storage requirements through the year 2000, for the maximum AR capacity case (Reference Case 1), while Tables A.6 and A.7 show the maximum capacity with intra-utility transshipment case (Reference Case 2). When more than one reactor shares a pool, the sharing reactors are listed with a single entry.

The maximum AR capacity case (Reference Case 1) is considered to be the maximum projection of future spent fuel storage requirements, while the alternative case projections represent approximate limits to the potential range of requirements under the assumptions noted. The reracking of reactor storage pools to increase storage capacity is becoming an increasingly common practice. It seems reasonable that most, if not all, utilities will adopt this relatively cost-effective means of increasing storage capacity when possible. On the other hand, while intra-utility, offsite transshipments of fuels to other reactor pools have been used by some utilities to alleviate severe spent fuel storage problems, it does not appear that this will become general practice. Even these optimistic scenarios result in significant additional storage requirements that will need to be met if orderly plant operation is to continue.

Figure 3.1 and Table 3.2 compare the utility total spent fuel discharge projections presented in Table A.3 with projections of spent fuel discharges calculated by EIA as DOE's official source of energy projections.<sup>(10)</sup> The projected discharges for all EIA cases are lower than those derived from utility data. EIA assumes average plant capacity factors derived from historical data, and also assumes delays of reactor startup dates depending upon known utility financial problems and other institutional considerations. The utility projections represent desired operating schedules. Unscheduled or

NOTE: The Annual and Cumulative values in Tables 3.1a-e may not total because of rounding error.

**FIGURE 3.1.** Projected Cumulative Spent Fuel Discharges--Comparison of DOE/EIA Scenarios and Utility Projections

extended outages are not usually part of a utility's planning. If the EIA projections, which are lower than the utility projections, prove to be accurate, the additional spent fuel storage requirements will be lower than estimated in this report. However, the maximum AR capacity case (based on utility projections) should be used as an upper limit for planning purposes. Reductions in additional storage requirements based upon utility data modified to approximately EIA total discharges for 1983 year-end-data are given in a report by Heeb, et al.<sup>(11)</sup>

### 3.5 UTILITY ACTIONS/COMPARISON WITH PREVIOUS RESULTS

Changes affecting spent fuel pool storage capacities and discharge rates continue to be reported by the utilities. These include changes of pool capacity, dates for reactor refueling, number of assemblies to be discharged at each refueling, number of assemblies to be re-inserted into the core, and plant startup dates. At the end of December, 1984, two plants (shown in Table 3.3) did not have FCR. Pool capacity changes from those in the previous report are shown in Table 3.4.

TABLE 3.2. Projected Cumulative Spent Fuel Discharges--Comparison of DOE/EIA Scenarios and Utility Projections

Year	Utility Projections	Cumulative Spent Fuel Discharge (MTIHM)			
		EIA Middle Case	EIA No New Orders Case	EIA Middle Case No Increased Burnup	EIA No New Orders Case No Increased Burnup

2000	50,441	41,658	39,861	46,118	44,345

Several plants were cancelled or indefinitely postponed during 1984. These plants include: Carroll County-1&2, Marble Hill-1&2, Midland-2, Seabrook-2, WNP-1, and Zimmer-1.

Plants with near-term additional storage requirements are identified in Tables A.4 through A.7 for Reference Cases 1 and 2. Plants with near-term changes in the dates of first requirements from those reported last year (i.e., through 1993) are listed below; those plants for which the projected dates have not changed are not included unless additional information regarding planned operation is available.

TABLE 3.3. Reactors Without FCR as of December 31, 1984

Reactor	Change to Restore FCR
Humboldt Bay	Core unloaded into pool-reactor will not restart
San Onofre-1	Shipments planned to San Onofre-2 and -3

Changes in Plants Projected to Lose FCR in 1986

Surry-1 and -2: Virginia Power Company. Surry-1 and Surry-2 share a common pool. Last year loss of FCR was projected to occur in 1987 due to a discharge from Unit 1. Virginia Power now has a cooperative agreement with the DOE that will involve the use of dry storage casks. There are two parts to the program: transfer of at least 117 assemblies to DOE for research and development (R&D) at INEL. The second part is onsite storage in casks, which will require an NRC license and thus is not considered in this report, since it does not involve a currently licensed technology. Only the shipment of 117 assemblies from the pool during calendar years 1985, 1986, and 1987 were considered in the analysis. Last year's report assumed 144 assemblies would be involved in the program.

Changes in Plants Projected to Lose FCR in 1987

Peach Bottom-2: Philadelphia Electric Company. Revised projected discharge quantities and dates have moved the additional requirements for Peach Bottom-2 from 1990 to 1987. In addition the inventory and maximum pool capacity have changed, resulting in the earlier loss of FCR.

#### Changes in Plants Projected to Lose FCR in 1988

Oconee-1 and -2: Duke Power Company. In the previous report, the loss of FCR for Oconee-1 was 1991 while for Oconee-2 it was 1990. The sharing of pool space for the Oconee and McGuire reactors has changed since last year. Oconee-1 and -2 have an earlier loss of FCR in 1988, while Oconee-3 has a later FCR loss in 1990.

#### Changes in Plants Projected to Lose FCR in 1989

Brunswick-2: Carolina Power and Light Company. Changes in projected discharge quantities move loss of FCR from 1990 to 1989.

La Salle Cty-1 and -2: Commonwealth Edison Company. The additional storage requirements for these reactors have moved from 1990 to 1989 due to revisions in the projected discharge dates and the number of assemblies to be discharged from unit 2.

Peach Bottom-3: Philadelphia Electric Company. The maximum pool capacity was reduced by 208 assemblies which is approximately one year's spent fuel discharge. This moves FCR loss to 1989 from 1990 in last year's report.

#### Changes in Plants Projected to Lose FCR in 1990

Robinson-2: Carolina Power and Light Co. Robinson-2's loss of FCR has not changed from last year. CP&L has a cooperative agreement with the DOE which involves dry, on-site storage in a concrete horizontal silo. This analysis assumes that 21 assemblies will be stored in this silo during 1986.

Oconee-3: Duke Power Company. Revised fuel sharing plans within the Duke Power system has moved the projected loss of FCR from 1987 to 1990. See Oconee-1 and -2.

Prairie Island-1 and -2: Northern States Power Co. Revised projected discharge quantities and dates have moved the need for additional storage from 1989 to 1990.

#### Changes in Plants Projected to Lose FCR in 1991

Calvert Cliffs-1 and -2: Baltimore Gas and Electric Company. An increased 1984 discharge for unit 2 has moved the loss of FCR from 1992 to 1991.

La Crosse: Dairyland Power Cooperative. Reduced discharges during 1984 have moved loss of FCR from 1990 to 1991.

#### Changes in Plants Projected to Lose FCR in 1992

Brunswick-1: Carolina Power and Light Co. Changes in fuel pool sharing within the Brunswick site have moved FCR loss from 1991 to 1992.

#### Changes in Plants Projected to Lose FCR in 1993

Fort Calhoun: Omaha Public Power District. Larger spent fuel discharges are being projected which will move FCR loss up to 1993.

Indian Point-3: Power Authority of the State of New York. Revised projected discharge dates will move the loss of FCR from 1994 to 1993.

#### Plants with Storage Needs Moving Beyond 1993

Oyster Creek: Jersey Central Power and Light Company. Projected discharges are smaller than reported previously, which results in FCR loss moving from 1992 to 1994.

Turkey Point-3 and -4: Florida Power and Light Company. A large increase in spent fuel storage capacity moves the loss of FCR from 1986 to 2001.

Monticello: Northern States Power Company. A significant planned fuel shipment program from Monticello to the GE Morris Facility will move the need for additional storage requirements from 1990 to 2002.

Ginna: Rochester Gas and Electric. A large increase in spent fuel storage capacity moves the loss of FCR from 1990 to 2002.

Arkansas Nuclear One-1: Arkansas Power and Light Company and Sequoyah-1 and 2: Tennessee Valley Authority. Changes in projected discharge dates and quantities move the loss of FCR from 1993 to 1995 for these reactors.

#### 3.6 RECONCILIATION OF SPENT FUEL INVENTORIES

Not all of the fuel discharged from operating nuclear power plants in the past is currently in the storage basins of those plants. Some fuel is now stored at offsite storage basins in Morris, Illinois, and West Valley, New York. In recent years, however, portions of the fuel originally shipped to these basins have been returned to the originating utility. As currently planned, all fuel in the West Valley basin is to be removed. DOE will take possession of 26 metric tons of the West Valley spent fuel for R&D purposes. Some fuel was reprocessed to recover contained uranium and plutonium during the operation of the West Valley fuel reprocessing plant, and some was utilized in R&D programs at government laboratories or in the commercial nuclear industry. Additional previously discharged fuel is currently re-inserted into either the original or into a different reactor core. Table 3.5 indicates the

TABLE 3.5. Spent Fuel Inventory Reconciliation (as of December 31, 1984)

Status of Fuel	Number of Assemblies			MTIHM		
	BWR	PWR	Total	BWR	PWR	Total
In Storage at Reactor Sites	24272	15616	39888	4412.2	6609.2	11021.4
