Dear Joe:

A copy of the January monthly report for our program on "Environmentally Assisted Cracking in LWR Systems" is enclosed. If you have any questions regarding this report, please contact either myself or any of the Principal Investigators.

Sincerely yours,

ILL

Subtask A: Leak Detection and NDE (D. S. Kupperman)

Work on modifying the acoustic leak detection facility is continuing. The frame to support the new pipe section (containing four laboratory grown cracks) has been installed. The cracks are now being welded into the new pipe section. The second field IGSCC does not show much leakage under low applied stresses (<2000 psi). Additional tests will be carried out at higher stress levels.

Two waveguide systems for field installation are being tested. Modifications are being made to provide the most effective waveguide system. One system is a "quick connect" type which uses spring loading to press the rounded waveguide tip to the pipe surface. The waveguide is attached to a plate which is strapped on the outside of the reflective insulation. In the other system the waveguide tip passes through the insulation and is screwed into a plate strapped on the pipe outer surface.

Six cracks in two 6-in. pipe sections recovered from an operating BWR have been located by dye penetrant techniques. The samples have been sectioned and decontaminated to a level that allows work to be carried out in a conventional laboratory environment. The cracks found are skewed (2), longitudinal (2), and circumferential (2).

A welded cast stainless steel pipe (28-in. O.D.) has been received from PNL. We have demonstrated, in a blind test, that longitudinal velocity of sound measurements can be used to differentiate between isotropic and anisotropic (long columnar grains) microstructures. In this case normal incidence longitudinal waves at 1 MHz were employed. Results were confirmed by PNL.

Subtask B: Analysis of Sensitization (J. Y. Park)

EPR values are being measured on Types 304 and 316 NG SS specimens which were heat treated at 500-750°C for 10-130 min in order to determine seeding treatments for LTS studies. The seeding treatment at 700°C for 10 min produces too much scatter (because the thermal mass of the sepcimens significantly affects the thermal history) or too large EPR values (>2 C/cm^2) as reported previously. An increase in EPR value was observed for a Type 304 SS (Heat No. 30956) specimen with a 500°C/24 h treatment after a seeding treatment at 650°C/10 min in the mill-annealed condition, while EPR value did not increase for a specimen with a prior solution heat treatment (1050°C/0.5 h) before the seeding treatment. This is in agreement with the general observation that low temperature sensitization kinetics are faster in the millannealed condition than those in the solution-annealed condition.

Studies on the effect of DOS on IGSCC susceptibility are continuing. IGSCC propagation rate measurements have been performed for LTS-treated Type 304 SS (Heat No. 10285) ITCT specimen in water with 8 ppm oxygen at 289°C and 8.3 MPa. The specimen was furnace sensitized at 700°C/10 min followed by an additional 500°C/24 h heat treatment. The EPR value of a companion coupon was 4 C/cm². Crack propagation rates under a variety of loading conditions were reported previously. During the present reporting period, tests have been carried out at R = 0.7, $f = 2 \times 10^{-3}$ Hz and $K_{max} = 30$ MPa·m^{1/2}. Preliminary analysis shows a propagation rate of 4×10^{-10} m/s. The construction of two additional CERT facilities was completed. Calibration of extension rate as a function of motor speed was carried out. The extension rates in the gage section of CERT specimens varied linearly with respect to motor speeds and were relatively independent of load in the range of steady load beyond yield. In addition to the simple tension CERT tests, cyclic tests can be run

under load control. The specimens are electrically isolated from the rest of the system to permit better control of electrochemical experiments and use of the electric potential drop technique for crack length determination. Fabrication of 4-in. diameter Type 304 SS (Heat No. 53319) pipe weldments with the remedy treatments (IHSI, HSW, LPHSW and CRC) was completed. Specimens were out from the weldment for LTS studies. ASTM A262-A tests are being performed in the as-welded condition before low temperature aging.

Subtask C: Crack Growth Rate Studies (J. Y. Park and W. J. Shack)

Crack growth rate tests have been continued for a Type 304 SS (Heat No. 10285 EPR = 15 C/cm²) ITCT specimen in water with 8 ppm oxygen at 289°C and 8.3 MPa (1200 psi). Growth rates at maximum stress intensities (K_{max}) ranging from 30 to 34 MPa·m^{1/2}, load ratios (R) of 0.5, 0.94, and 1, and frequencies (f) of 0, 2 x 10⁻³, and 1 x 10⁻¹ Hz have been reported previously. The cyclic loading tests have been performed using sawtooth waveforms with a loading-to-unloading time ratio of 99. The current series of tests will establish (at a fixed K) the effect of R ratio and frequency on the growth rate, and whether these effects can be understood in terms of the crack tip strain rate. During the present reporting period, the tests have been carried out at $K_{max} = 28-29$ MPa·m^{1/2}, R = 0.6 and f = 2 x 10⁻³ Hz. The crack has propagated 0.7 mm during a 341-h period at an average rate of 5.6 x 10⁻¹⁰ m/s. The tests are being performed at R = 0.7 and f = 2 x 10⁻³ Hz. Crack propagation rate measurements for Type 304 SS (Heat No. 10285) to date are summarized in Table 1.

The investigation of the electric potential drop method for crack length measurement has been continued. A.C. potential drop measurements have been made for a growing crack in a Type 304 SS 1TCT specimen under a fatigue load in air at room temperature. A sensitivity of 1.2 volts/amp/in was obtained at

crack lengths (a/w) between 0.25 and 0.32. Temperature dependence was less than 2.6 x 10^{-3} in/°C and long-term stability better than 1 x 10^{-3} in/day was observed. The calibration is now being extended to a wider range of crack lengths.

Subtask D: Non-environmental Corrective Actions (P. S. Maiya and W. J. Shack)

CERT experiments on Type 3'6 NG (Heat No. P91576) in chloride-containing water environments (8 ppm 0_2) have established that the material becomes susceptible to TGSCC at a strain rate of 2 x 10^{-6} s⁻¹ and 289°C after heat treatments at 650°C/2 h or 700°C/4 h. Whether the prior furnace heat treatment of the specimens is essential for the occurrence of TGSCC (in a manner similar to that observed for IGSCC in conventional Types 304 and 316 SS) remains to be established. TGSCC adversely affects CERT properties such as failure time and reduction in area just like IGSCC. The dependence of the TGSCC crack growth rates on strain rate in this environment is similar to that for IGSCC growth, and the results to date can be described by a power law i.e. $\dot{a} = 1.17 \times 10^{-7}$ ($\dot{\epsilon}$)^{0.29} m/s. A comparison of the transgranular crack growth rates (in 316 NG) with intergranular crack growth rates (observed in sensitized Type 316 SS) in this environment showed clearly that the transgranular crack growth rate is approximately 1/10th of the intergranular crack growth rate over the range of strain rates used (2 x 10^{-6} to 1 x 10^{-7} s⁻¹). These experiments are being continued to investigate whether SCC susceptibility can occur under impurity environments which are consistent with the operating limits in BWRs as specified in Regulatory Guide 1.56 (e.g., 0.2 ppm $0_2 + 0.2$ ppm C1⁻).

Subtask E: Evaluation of Environmental Corrective Actions (W. E. Ruther,

W. K. Soppet, and T. F. Kassner)

The crack growth experiment on Type 304 stainless steel CT specimens (Heat No. 30956) in high-purity water with 8 ppm oxygen (289°C) continues. During January the test was conducted at a K_{max} of 48 MPa·m^{1/2}, R = 0.95, and a frequency of 8 x 10⁻³ Hz. The crack in the more heavily sensitized specimen (EPR = 20 C/cm²) grew at a linear rate of 15 mm/y over an 800-h period. No crack growth occurred in the EPR = 2 C/cm² and EPR = 0 specimens during this period. K_{max} has been increased to 60 MPa·m^{1/2} for the specimen sensitized to an EPR value of 20 C/cm².

The second crack growth experiment with the same heat of Type 304 SS in water containing 0.1 ppm $SO_4^=$ (as H_2SO_4) and 0.2 ppm oxygen (289°C) also continues. The loading conditions are $K_{max} = 28$ MPa·m^{1/2}, R = 0.95 and f = 8×10^{-2} Hz. Even with fatigue precracks, no crack growth has occurred in 625 h. Measurements of the oxygen levels in the outflow of the autoclave indicate that because of oxygen scavenging the actual oxygen levels are less than 0.2 ppm. The gas mixture used to aerate the water is being altered to correct this.

Results from CERT experiments performed in January are given in Table II. These tests provide additional information on the effect of dissolved oxygen, hydrogen, and sulfate impurities on the SCC susceptibility of sensitized Type 304 SS. In the A-series of experiments, we are evaluating the relative effect of pH and sulfate concentration (at a dissolved oxygen concentration of 0.2 ppm) on the SCC behavior of this heat of material.

The performance of a 1.85-liter refreshed titanium autoclave system for high-temperature pH and corrosion-potential measurements in simulated BWRquality water has been evaluated at 285°C and 8.3 MPa pressure. The titanium

system has several advantages relative to a stainless steel autoclave that was being used for these experiments (viz., better control of the dissolved oxygen concentration, less interference from corrosion-product species, and more rapid replacement of the solution due to a smaller volume in the autoclave).

The problem of emf drift in the 0.1 M KC1/Ag/AgC1 external reference electrodes, which are being used to monitor the corrosion and redox potentials, has been identified. The seal produced by the thin-wall heatshrinkable teflon (TFE) tubing, between the porous zirconia frit and the electrolyte compartment of the reference electrode, degrades during thermal and pressure cycling in the high-temperature (~289°C) environment. The seal has been modified to minimize dilution of the electrolyte by slow transport through the high-temperature region of the electrode. This will allow more reliable potential measurements during long term tests.

Subtask F: Mechanistic Studies (F. A. Nichols and T. F. Kassner)

The topical report entitled "Mechanistic Aspects of Stress-Corrosion Cracking of Type 304 Stainless Steel in LWR Systems" has been reviewed and revised and is currently being processed for release.

The apparatus for the Mode I versus Mode III SCC experiments has operated satisfactorily in an autoclave at 289°C and 8.3 MPa pressure. Specimens for the initial series of experiments in simulated BWR-quality water have been heat treated.

	Review models for vario volved in SCC of austen steels in aqueous envir a topical report Assemble small refreshe for calibration of refe trodes, electrochemical passive film breakdown in simulated crack-tip Mode I/Mode III crack-g	itic and ferritic onments and prepare d autoclave systems rence and pH elec- measurements of on stainless steels solutions, and																	
	Evaluate the performanc Ag/AgCl reference and O electrodes for use in e measurements	Zr02-Cu/Cu20 pH												V					
	Construct loading syste and Mode III loading te Type 304 SS in simulate at high temperature to mechanism of crack grow	sts on sensitized d BWR-quality water identify the																	
	Determine experimental models of crevice chemi and correlate crack tip chemistry at high tempe	stry of Type 304 SS with bulk solution																	
	Conduct critical experim microprocesses involved and propagation of stre- in other structural mate reactor environments	in the initiation ss-corrosion cracks																	
	Develop predictive mode tion and growth in reac different environmental	tor materials under						-										-
