Reviewer is Independent.

## Remarks:

## Non-Proprietary

Note: This document is a non-proprietary version of BWNT 51-1229187-00. The location of deleted proprietary information is indicated by brackets, and the reason for the deletion is indicated within the brackets by a code letter from the following table:

- d. The information consists of test data or other similar data concerning a process, method or component, the application of which results in a competitive advantage to BWNT.
- e. The information reveals special aspects of a process, method, component or the like, the exclusive use of which results in a competitive advantage to BWNT.

A report has been written documenting the root cause evaluation of the McGuire Unit 1 tube/sleeve leak which occurred in August, 1993. This report also discusses the consequences of a sleeved tube failure. The report "Evaluation of BWNT's Kinetic Sleeving Process" (BWNT Doc. #51-1228682-00, Proprietary-1 or #51-1128707-01, Non-Proprietary) has been used as the basis for an evaluation of the McGuire Unit 1 and 2 sleeves currently in service.

A total of 1,488 kinetic sleeves (859 Unit 1, 625 Unit 2) have been installed in the McGuire units. During previous outages and the outages associated with the tube/sleeve failure a total of 233 sleeved tubes were removed from service. The tubes removed from service during the recent outages were selected due to their position in the tube bundle (un-restrained tubes), the tube yield strength over 64 ksi, or exhibiting a predicted tube life less than 8.3 Effective Full Power Years (EFPY).

This results in a total of 1251 sleeved tubes currently in service. Tables 1 and 2 provide a full listing of the sleeved tubes with current and projected sleeve life for their respective re-fueling dates. The prediction of tube life based on tube material properties (yield strength and % Carbon) are also shown. The details of the algorithm that was used to determine the predicted tube life can be found in the evaluation report. No tube life prediction is provided for tube locations which do not have known material properties.

Based on the predicted tube life algorithm, and using a safety factor of [d] as recommended by the evaluation report, all sleeved tubes currently in service will maintain a margin of predicted life at the end of the current fuel cycle.

A projection of the sleeve life to the end of the next fuel cycle (ending in 1995) concludes that no additional sleeves will require plugging during the 1994 refueling outages to maintain a safety factor of [d] on predicted life.

Since McGuire Unit 1 is scheduled for steam generator replacement during the 1995 outage, no additional sleeve life projections are provided past this date. For McGuire Unit 2, projections for sleeve life are provided up to the steam generator replacement outage in 1997. Sleeved tubes with projected life less than the predicted tube life at the end of the fuel cycle with a safety factor of [d] are designated to be plugged. This indicates that a total of 34 sleeves would be plugged during the 3/96 outage.

Please note that all outage dates are projections and were confirmed with input from the "Duke Power 6 Year Overview Outage Schedule" revised on 7/21/93.

BWNT is currently planning additional testing (both X-Ray Diffraction and Corrosion) to evaluate kinetic sleeves installed in high yield strength tube material. These tests are being made to gain additional confidence in the algorithm for sleeve life projection. The safety factors applied to the projected tube/sleeve life will be re-evaluated once these test results are available.
