AVAILABILITY NOTICE

Availability of Reference Materials Cited in NRC Publications

Most documents cited in NRC publications will be available from one of the following sources:

1. The NRC Public Document Room, 2120 L Street, NW, Lower Level, Washington, DC 20555
2. The Superintendent of Documents, U.S. Government Printing Office, P.O. Box 37082, Washington, DC 20013-7082
3. The National Technical Information Service, Springfield, VA 22161

Although the listing that follows represents the majority of documents cited in NRC publications, it is not intended to be exhaustive.

Referenced documents available for inspection and copying for a fee from the NRC Public Document Room include NRC correspondence and internal NRC memoranda; NRC bulletins, circulars, information notices, inspection and investigation notices; licensee event reports; vendor reports and correspondence; Commission papers; and applicant and licensee documents and correspondence.

The following documents in the NUREG series are available for purchase from the GPO Sales Program: formal NRC staff and contractor reports, NRC-sponsored conference proceedings, international agreement reports, grant publications, and NRC booklets and brochures. Also available are regulatory guides, NRC regulations in the *Code of Federal Regulations*, and *Nuclear Regulatory Commission Issuances*.

Documents available from the National Technical Information Service include NUREG-series reports and technical reports prepared by other Federal agencies and reports prepared by the Atomic Energy Commission, forerunner agency to the Nuclear Regulatory Commission.

Documents available from public and special technical libraries include all open literature items, such as books, journal articles, and transactions. *Federal Register* notices, Federal and State legislation, and congressional reports can usually be obtained from these libraries.

Documents such as theses, dissertations, foreign reports and translations, and non-NRC conference proceedings are available for purchase from the organization sponsoring the publication cited.

Single copies of NRC draft reports are available free, to the extent of supply, upon written request to the Office of Administration, Distribution and Mail Services Section, U.S. Nuclear Regulatory Commission, Washington, DC 20555.

Copies of industry codes and standards used in a substantive manner in the NRC regulatory process are maintained at the NRC Library, 7920 Norfolk Avenue, Bethesda, Maryland, for use by the public. Codes and standards are usually copyrighted and may be purchased from the originating organization or, if they are American National Standards, from the American National Standards Institute, 1430 Broadway, New York, NY 10018.

ABSTRACT

Population radiation dose commitments have been estimated from reported radionuclide releases from commercial power reactors operating during 1988. Fifty-year dose commitments for a one-year exposure from both liquid and atmospheric releases were calculated for four population groups (infant, child, teen-ager and adult) residing between 2 and 80 km from each of 71 reactor sites. This report tabulates the results of these calculations, showing the dose commitments for both water and airborne pathways for each age group and organ. Also included for each of the sites is a histogram showing the fraction of the total population within 2 to 80 km around each site receiving various average dose commitments from the airborne pathways.

The total collective dose commitments (from both liquid and airborne pathways) for each site ranged from a high of 16 person-rem to a low of 0.0011 person-rem for the sites with plants operating throughout the year with an arithmetic mean of 1.1 person-rem. The total population dose for all sites was estimated at 75 person-rem for the 150 million people considered at risk.

The site average individual dose commitment from all pathways ranged from a low of 3×10^{-7} mrem to a high of 0.02 mrem. No attempt was made in this study to determine the maximum dose commitment received by any one individual from the radionuclides released at any of the sites. However, licensee calculation of doses to the maximally exposed individual at some sites indicated values of up to approximately 100 times average individual doses (on the order of a few millirem per year).

ACKNOWLEDGMENTS

The author greatly appreciates the development of the population distributions around each site from census data by Donald P. Cleary of the U.S. Nuclear Regulatory Commission. The author also gratefully acknowledges the contributions and suggestions by Richard A. Hartfield, Thomas H. Essig, Charles A. Willis, and Kazimieras Campe, also of the U.S. Nuclear Regulatory Commission.

INTRODUCTION

All commercial nuclear power reactors release small amounts of radioactive materials to the environment during normal operation. Because of these releases, concern was expressed about the magnitude of the collective dose received by the general population residing around these nuclear power plants. In response to this concern, the Pacific Northwest Laboratory (PNL)^(a) contracted with the Nuclear Regulatory Commission (NRC) to undertake a series of studies to estimate radiation dose commitments produced by radionuclide releases from commercial light-water power reactors starting in 1975 (see previous reports in this series, p. ii). This document is a continuation of these studies and considers the doses from releases during 1988. In this study, as in those previous, we estimated the collective (population) dose commitment^(b) from both the liquid and gaseous releases to four age groups making up the population residing in the region of the site: infant (0 to 1 yr), child (1 to 11 yr), teen-ager (11 to 17 yr), and adult (17 yr and older).

The particular organs of reference in this study are listed in Table 1. The major pathways by which radionuclides travel from the reactor to the individual receptors are shown in Table 2. Other possible liquid pathways such as direct exposure from waterborne activities (swimming, boating, shoreline recreation) and internal exposure through ingestion of food produced using contaminated irrigation water were not included; we have found from past experience that the doses from these pathways are generally much smaller than the doses from the pathways considered in this study.

TABLE 1. Organs Considered in This Study

<u>Organs Affected by Airborne Releases</u>	<u>Organs Affected by Waterborne Releases</u>
Total body	Total body
Thyroid	Thyroid
Bone	Bone
GI tract	GI tract
Liver	Liver
Lung	

(a) Operated by Battelle Memorial Institute for the Department of Energy.

(b) As used in this report, dose commitment describes the total-body or specified organ dose equivalent in rem (1 rem = 0.01 sievert) received over 50 years from intake during the year in which radioactive materials were released into the environment from the power plants.

TABLE 2. Pathways Considered in This Study

Pathways for Airborne Releases	Pathways for Waterborne Releases
Air submersion	Ingestion of drinking water
Ground irradiation	Ingestion of fish and
Inhalation	invertebrates
Ingestion of food crops and animal products	

The "source terms" used to estimate dose commitments produced from each site were the annual measured releases of radioactive materials as reported to the NRC by the plant operators and subsequently published in an NRC public document (Tichler, et al. 1991). Doses from carbon-14 generally are not included, because carbon-14 releases from most plants are not measured or reported.

The regional population for which we estimated dose commitments included those persons estimated to be living in a region between 2 and 80 km around the reactor sites during 1988. Population distributions were supplied by the NRC's Office of Nuclear Reactor Regulation. Atmospheric transport factors (annual average dilution and annual average deposition) were calculated for the region around each site using appropriate meteorological data supplied by the NRC or the utility. To calculate the doses, we used models approved by the NRC. We incorporated these models into two computer programs to expedite the dose calculations involved for each site.

Site-specific parameters other than releases, meteorology, and population were obtained from environmental statements [both final (FES) and draft (DES)] for the various reactors when available (see Table 3). Such parameter values include the total population drinking contaminated water, river flow, dilution flow from the reactors (for sites not on rivers), fish and invertebrate harvest for the region, and dilution factors for drinking water and aquatic foods. In those cases in which site-specific data are not readily available and the particular pathway is not expected to result in a large dose, conservative assumptions have been used to estimate doses. The use of more realistic data should result in lower dose estimates in most cases.

The reactors included in this study, their type, licensed thermal power rating and net electrical output for 1988 are listed in Table 4. Populations at risk and the dose commitments derived in the study are also shown in this table.

(a) 1 TW-Hr = 3.6E18 joules.

(b) Does not have charcoal delay beds in the gaseous effluent line from air ejector.

(c) Does not include doses from nuclides not in reported release, such as carbon-14.

Site-Dependent Parameters

In the Site Summaries section, the location (including latitude and longitude) for each reactor site and the estimated 1988 population within 2 to 80 km around each site is given. In addition, the locations of major metropolitan centers within 80 km are listed along with their 1988 extrapolated populations. The populations of the Standard Metropolitan Statistical Areas (SMSA) are given where applicable. Next, the site-specific data pertinent to the airborne pathways are specified. The average production rates of vegetable crops and animal products are given for the area within an 80-km radius based upon the statewide average. This production has been reduced for sites on lakes and seacoasts to account for the presence of the body of water. An animal grazing factor is estimated for each site location. This factor accounts for the fraction of the year during which grazing animals such as milk cows and beef cattle graze on fresh pasture in the region around the site. After average production rates are given, the period of record and the percent data recovery of the meteorological data used in calculating diffusion factors are indicated.

Various site-dependent factors associated with the waterborne pathways are presented next. For lake and ocean sites, we used the average dilution of plant effluents for the year 1988 specified by Tichler, et al. (1991). For river sites, the average annual river flow is tabulated. This flow was used in place of a dilution flow from the plant to account for dilutions of liquid releases at the locations of probable intake of drinking water and aquatic food catch. Any exceptions to this scheme have been footnoted. Next is shown the estimated 1988 population utilizing drinking water drawn from supplies containing diluted effluents from the site. These are shown with an estimated dilution factor where applicable. Fish and invertebrate catch data taken from the respective plant environmental statement, when available (see Table 3), are listed next, along with estimated dilution factors for the lake and ocean sites. When site-specific fish and invertebrate catch data were not available, the generic consumption rates were used for the particular site. Sites on salt water were assumed to contribute no dose from drinking water. Any invertebrate catch from fresh water was not considered.

RESULTS

This report consists of a summary of values used for site-specific parameters at each site, as explained above, and the results of population dose commitment calculations. The population dose commitments are presented in two tables facing the page summarizing site-specific parameters for that site. These tables include both waterborne and airborne pathway dose commitments for the several organs of reference for each age group investigated. They also include the dose to the whole population, which includes all age groups. The airborne population dose commitments for each of 160 segments^(a) partitioning the region around the site were divided by the population residing within that segment to derive an average individual dose for that segment. These doses are summarized as a histogram showing percent of the population receiving a given dose level for each site. The fractional population dose from the waterborne pathway was not determined in this manner, because the NRC does not at present take into account the location of individuals exposed via this pathway, except those exposed through ingestion of drinking water.

Population dose commitments estimated for both the waterborne pathways and airborne pathways varied widely over the sites studied. The total dose commitments (from both pathways) varied from a high of 16 to a low of 0.0011 person-rem for plants in operation during the whole year. The arithmetic mean for the total dose from liquid pathways (0.92 person-rem) and airborne pathways (0.14 person-rem) was 1.1 person-rem (see Table 4).

As in past years, most of the plants accounted for less than a person-rem to their surrounding population from plant releases of radio-nuclides into liquid effluent streams. Only two sites had waterborne releases that resulted in population doses exceeding 10 person-rem. The sites were McGuire with 16 person-rem and Summer with 13. These waterborne doses were due almost totally to tritium via the drinking water pathway in the case of McGuire and cesium from fish consumption in the case of Summer.

The doses from radionuclide releases from plant vents and/or stacks into the atmosphere also accounted for less than a person-rem for most sites. Only one site had airborne releases resulting in 1 or more person-rem. The site was Oyster Creek with 2 person-rem. This airborne dose was the result of krypton-88 and Xenon-135.

The total population dose commitments from all sites for 1988 were estimated to be 65 person-rem via waterborne pathways and 10 person-rem via airborne pathways for a total of 75 person-rem (see Table 4).

(a) See Appendix for definition of segments.

Figure 1 is a histogram for all sites taken together. We can see from this plot that about 97% of the total population at risk from airborne releases (140 million) would each receive a dose commitment of less than 3×10^{-4} mrem. We can see further that about 9% receive a dose which is less than 1×10^{-6} mrem. However, no attempt was made in this study to estimate the maximum dose commitment received by any one individual from the radionuclides released at any of the sites. However, licensee calculation of doses to the maximally exposed individual at some sites indicated values of up to approximately 100 times average individual doses (on the order of a few millirem per year).

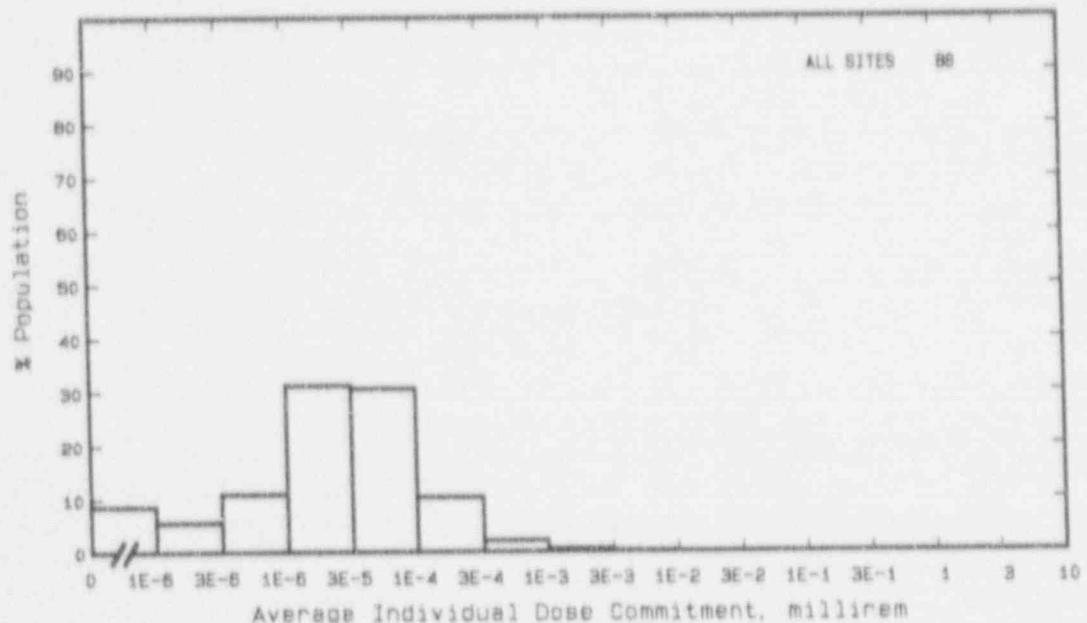

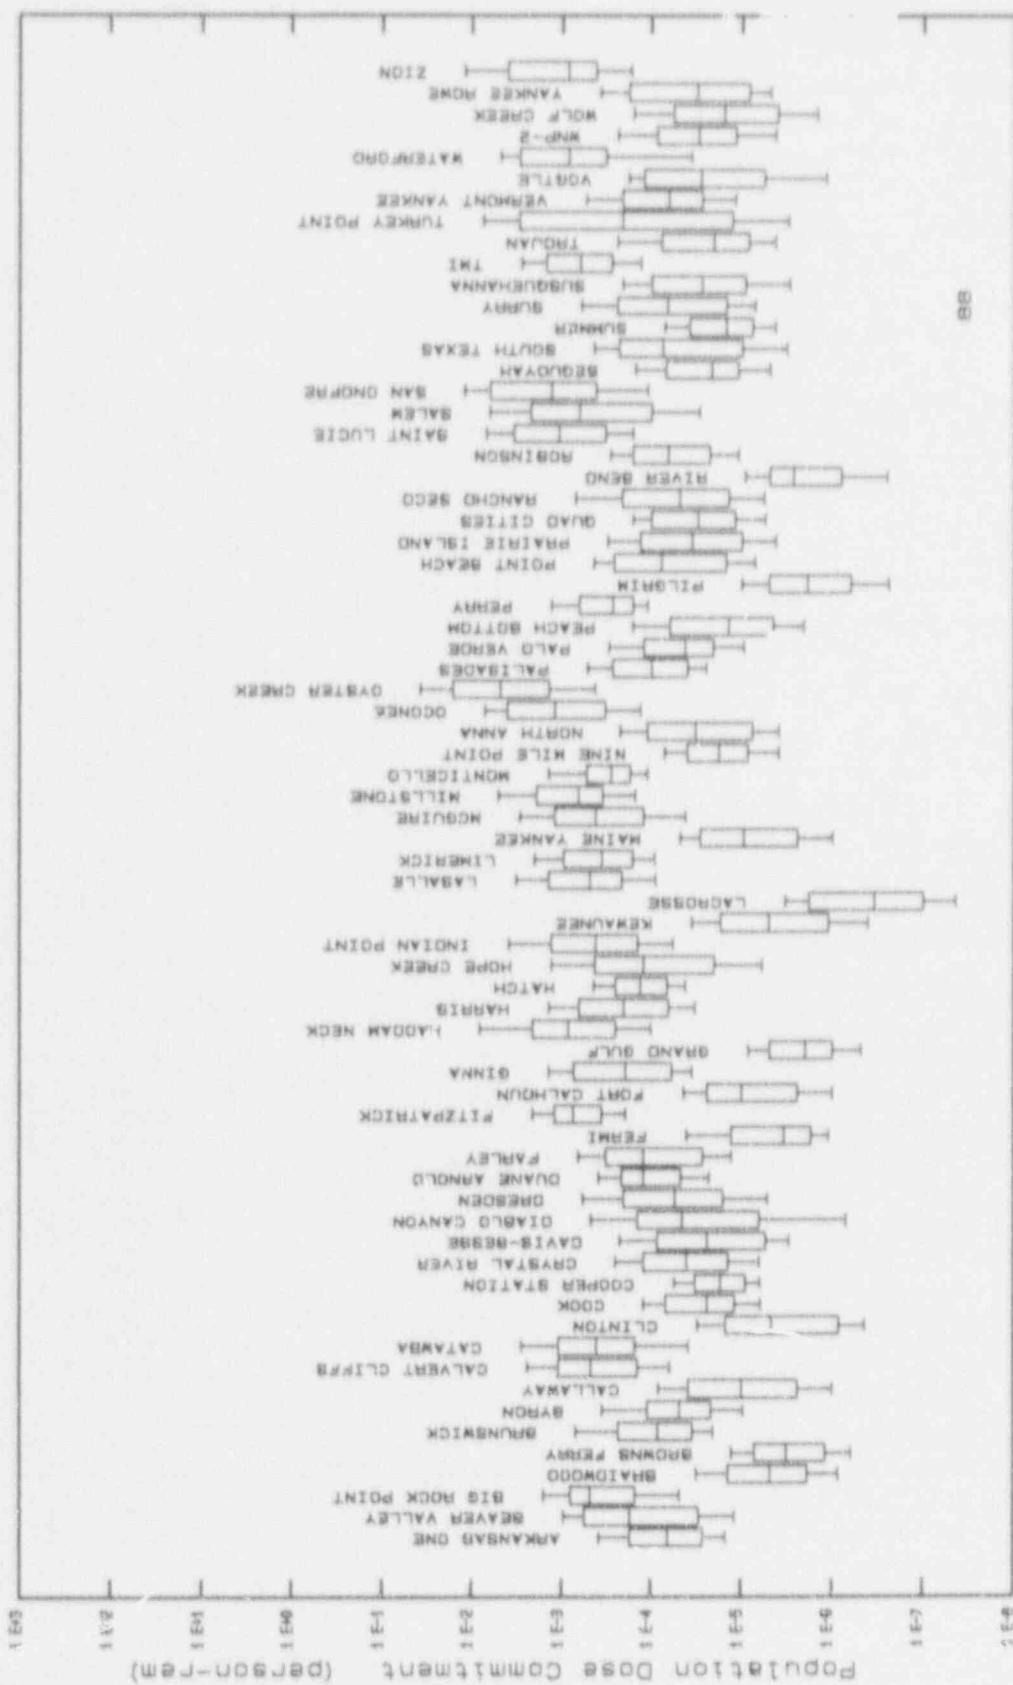

FIGURE 1. Fraction of Total Population Receiving Various Average Individual Total-Body Dose Commitments for All Sites

Figure 2 shows graphically by "Box-and-Whisker Plots" the wide range of the airborne population dose commitments for the reactor sites. The median, upper and lower quartiles and upper and lower octiles for the distribution of doses calculated for each of 160 segments are indicated for each site. The upper and lower octiles are shown as the horizontal bars on the "whiskers;" the upper and lower quartiles are indicated as the top and bottom of the "box." The median is indicated as the horizontal line inside the box. No airborne releases were reported for the Shoreham site for 1988; therefore, none are plotted.

FIGURE 2. Airborne population dose commitments for the Reactor Sites, 1988

We should point out here, however, that the doses estimated in this study are extremely low compared to an average annual background dose of approximately 100 mrem (neglecting radon daughters). We have compared dose commitments calculated in this study with annual background. However, this comparison is not quite exact, since these dose commitments are those total-body doses received from the year's effluent release over 50 years of a person's lifetime. However, most of the dose commitment calculated here is delivered in the first year, so the comparison is reasonably valid.

For comparison purposes, the doses in the site summary tables are given to two significant figures; however, the data and models used to calculate the doses limit their accuracy to at most one significant figure.

SITE COMPARISONS

Table 5 shows the dose commitments for the past 14 years along with the energy produced in that year. The last column shows the cost/benefit for commercial nuclear power as a ratio of population dose to generated power. Except for 1979 (the year of the TMI-2 accident) this ratio has been tending downward even though the population around many of the sites has been rising.

TABLE 5. Comparison of Annual Population Dose Commitments and Energy Output for the Past 14 Years

Year	Dose Commitments			Energy Output (TW-hr)	Cost/Benefit (person-rem TW-hr)
	Liquid	Air	Total (Person-rem)		
1975	76	1300	1300	170	7.6
1976	82	390	470	180	2.5
1977	160	540	700	250	2.8
1978	110	530	640	270	2.3
1979	220	1600	1800	250	7.2
1980	120	57	180	250	0.73
1981	87	63	150	280	0.54
1982	50	87	140	270	0.51
1983	95	76	170	280	0.60
1984	160	120	280	320	0.87
1985	91	110	200	370	0.54
1986	71	44	110	410	0.27
1987	56	22	78	450	0.17
1988	65	10	75	510	0.15

The reactor sites are compared in Table 6 as to the total population dose over the years of this study, 1975-1988. The sites were placed within six groupings by person-rem depending on resulting population dose summed over each of the years through 1988:

- I Greater than 100
- II 31 - 100
- III 11 - 30
- IV 3.1 - 10
- V 1 - 3
- VI Less than 1

Table 6 shows the sites within the groups along with the reactor manufacturer, year of commercial operation commencement, and the indicated population doses in person-rem. The manufacturer codes are as follows:

AC	Allis Chalmers
B	Babcox and Wilcox
CE	Combustion Engineering
GE	General Electric
W	Westinghouse

Table 7 shows the average population dose in person-rem for the last three years. The sites are listed in order of average dose with the high doses toward the top. Breaks in the table are indicated every half order of magnitude: 0.03, .01 .03, etc.

Table 8 shows the present contributions of all radionuclides contributing over 3% to the population dose from 1988 effluents. The contributors are shown for each site for both liquid (L) and air (A) pathways. Note that only a few nuclides of those reported by the sites (Tichler, et al. 1991) usually contribute to the dose.

APPENDIX

MODELS AND GENERIC PARAMETERS

The calculational models used were primarily those given in the Nuclear Regulatory Commission's Regulatory Guide 1.109, Rev. 1 (NRC 1977). Computer programs were written to use these models to generate population dose commitments for four age groups. The percentages of the population comprising the four age groups were 1.44%, infant; 16.0%, child; 11.7%, teenager; and 70.9%, adult (Population Estimates and Projections 1975). Where possible, the site-dependent parameters were taken from the environmental statements issued for each reactor (see Table 3). The generic parameters used for this study such as consumption rates, occupancy factors and holdup times are given in Tables A-1 and A-2 below. It should be noted that generic consumption rates for aquatic foods and inhalation rates are taken from Regulatory Guide 1.109 (NRC 1977). Bioaccumulation factors and terrestrial food transfer factors were taken from Regulatory Guide 1.109 (NRC 1977). Dose commitment factors for the four age groups were taken from Hedges and Soldat (1977).

TABLE A-1. Generic Consumption Rates and Occupancy Factors Used for the Study of Average Members of the Population^(a)

Pathway	Infant	Child	Teen-ager	Adult
Fruits, vegetables and grain (kg/yr)	0	200	240	190
Milk (L/yr)	170	170	200	110
Meat and poultry (kg/yr)	0	37	59	95
Fish (kg/yr) ^(b)	0	2.2	5.2	6.9
Invertebrates (kg/yr)	0	0.33	0.75	1.0
Drinking water (L/yr)	170 ^(c)	260	260	370
Inhalation (m ³ /yr)	1400 ^(d)	3700	8000	8000
Air submersion and ground irradiation occupancy factor	0.5	0.5	0.5	0.5

(a) Regulatory Guide 1.109 (NRC 1977).

(b) Both fresh and salt water.

(c) Assumed to be equal to milk consumption.

(d) Same as for maximum individual.

TABLE A-2. Holdup Times Between Harvest and Consumption of Foods^(a)

Food	<u>Holdup Time (days)</u>
Fruits, grains and vegetables	14
Milk ^(b)	4
Meat ^(b)	20
Aquatic foods (fish and invertebrates)	7
Drinking Water	1

(a) Regulatory Guide 1.109 (NRC 1977)

(b) Value given is time after milking or slaughter. For the portion of the time animals were fed stored feed, an additional 90 days was added to the holdup time

SOURCE TERMS

The doses were estimated using the measured releases as reported by the site operators for 1988 (Tichler, et al. 1991).^(a) These releases include all radionuclides specified by the NRC to be measured and reported by the operators of all commercial nuclear power plants. Radionuclides given as a combination of parent-daughter isotopes such as Y/Sr-90, Zr/Nb-95, Ba/La-140, I/Xe-133 and Pr/Ce-144 were divided evenly between the parent and daughter.

The radionuclides used in this study, along with their decay constants, are given in Table A-3. Note that the "+D" after some of the nuclides indicates that the decay energy of the daughter is included with the parent. Thus, whenever a parent nuclide release is specified, the result of the dose calculation is as though an additional equilibrium amount of the daughter nuclide is specified. The daughter nuclide itself is included separately if it can be released independently of the parent and/or if it has a relatively long half-life.

METEOROLOGY

When more than one set of meteorological (joint frequency) data was available for a site, the one which appeared to be the most reliable was used to generate atmospheric transport factors. Factors were calculated for 16 compass points and for ten radii from 2 to 80 km (see Table A-4) using the NRC computer program XQQDOQ (Sagendorf and Goll 1977).

(a) Very shortlived isotopes such as Kr-90, 91, 93, 94, Xe-139, 140, 141, 143 and Rb-88M; those not likely to be produced; and those that were daughters whose decay energies were accounted for in the dose factor for the parent were not included in the dose.

9 - 14	11.5
14 - 20	17
20 - 30	25
30 - 40	35
40 - 60	50
60 - 80	70

The X0QDOQ program generates four sets of atmospheric transport factors:

- average annual atmospheric dilution factors, which are not corrected for cloud depletion or radioactive decay
- dilution factors that are only corrected for decay assuming a 2.26-day half-life
- dilution factors that are corrected for depletion and for decay assuming an 8-day half-life
- relative deposition per unit area.

These factors were used to estimate the dose from airborne releases using methods similar to the NRC GASPAR program (Eckerman et al. 1980). The transport factors used this year were the same as those used for the previous estimates. The assumptions used in the calculation of these transport factors were as follows:

- 50-m source height with no correction for plume rise or building wake effects
- semi-infinite cloud model with sector-average, Gaussian plume dispersion
- no correction for terrain height variation.

Since information about height and locations at each site for the releases given in Tichler, et al. (1991) was unavailable, a single generic height of 50 m was used at each site for the release point. Because the heights and locations of releases are uncertain, estimates of dose to persons

living within 2 km of the site could be in serious error; only persons living between 2 to 80 km from the site were included in the dose estimates.

POPULATION

The population distribution within 2 to 80 km around each site was determined from information supplied by the NRC from an updated reduction of 1980 census data (Sinisgalli 1982). Also the NRC supplied updated estimates of the number of people residing in major metropolitan centers within the 80-km region around each site (Brauner 1982) and D. P. Cleary.^(a) Population variations between 1980 and 1986 (population factors) were derived from census data (U. S. Bureau of the Census 1988).

FOOD PRODUCTION VERSUS FOOD CONSUMPTION

The total food production for the region within 80 km around each site was the product of the NRC state-wide productivity figure for each state and a site productivity factor. At some sites this total production may be more or less than total consumption; i.e., population times average individual consumption (see Table A-1 for generic consumption rates). When production was more than consumption for a site, it was assumed that all persons in the 2-to-80-km region ate contaminated food; when production was less than consumption, it was assumed that dilution would occur because uncontaminated food would be shipped into the area from outside. Thus, the calculated doses for a particular food type were reduced in proportion to the ratio of production divided by consumption (production/consumption less than 1).

The dose to persons outside the 80-km limit from food shipped out of the region, in the case of production being greater than consumption, is not included in this report because we are concerned only with the dose within the 80-km radius. These production/consumption factors are given for reference as footnotes to the tables showing airborne dose commitment in the Site Summaries section.

DRINKING WATER

The population between 2 and 80 km distance from each plant site exposed to drinking water contaminated with released radionuclides was generally obtained from the environmental statement (ES) for the plant. For all sites located on salt water, it was assumed that no dose was received from drinking water. The generic consumption rates used for drinking water are given in Table A-1.

(a) Letter from D. P. Cleary, U.S. Nuclear Regulatory Commission, to D. A. Baker, Pacific Northwest Laboratory, June 1987.

The radionuclide concentration in the drinking water consumed by a population downstream from a site was usually estimated assuming 100% mixing of the plant effluent with the river. For lakes, an overall dilution factor was estimated from dilution factors given in the ES for each population center along the shore (within 80 km) that consumes the contaminated lake water. These individual factors were weighted by population and averaged to obtain an effective dilution factor for the total population exposed to contaminated drinking water.

AQUATIC FOOD

Wherever possible, the fish-catch data from the plant ES were used to estimate aquatic food consumption rates for the population living within the region. When these data were not found in the ES or were considered unrealistic, the generic values of Table A-1 were used.

The average radionuclide concentration of the waters in which this food was harvested was estimated assuming an additional dilution over the effluent flow from the reactor. For rivers, it was assumed that the fish were caught in waters in which the plant effluent was completely diluted. For lakes, an additional factor as given in the ES was used; when none was given in the ES, a generic value of 0.01 was used. For ocean and bay sites, generic values of 0.001 and 0.002 were used for fish and invertebrates, respectively, if the ES yielded no values for these parameters. Invertebrates were not assumed to be caught in sufficient quantity at freshwater sites (river and lake) to affect the population dose and therefore were not included in the dose calculation. Any exceptions to these general guidelines are explained in the footnotes to the individual site summaries.

10. SUPPLEMENTARY NOTES

11. ABSTRACT (200 words or less)

Population radiation dose commitments have been estimated from reported radionuclide releases from commercial power reactors operating during 1988. Fifty-year dose commitments from a one-year exposure were calculated from both liquid and atmospheric releases for four population groups (infant, child, teenager and adult) residing between 2 and 80 km from each of 71 sites. This report tabulates the results of these calculations, showing the dose commitments for both liquid and airborne pathways for each age group and organ. Also included for each of the sites is a histogram showing the fraction of the total population within 2 to 80 km around each site receiving various average dose commitments from the airborne pathways.

The total dose commitments (from both liquid and airborne pathways) for each site ranged from a high of 16 person-rem to a low of 0.001 person-rem for the sites with plants operating throughout the year with an arithmetic mean of 1.1 person-rem. The total population dose for all sites was estimated at 75 person-rem for the 150 million people considered at risk.
