THE	CASE STUDY FOR THE LOSS OF RER COOLING EVENT AT DIABLO CANYON	NUMBER:	LO-LP-60990-02-0
PROGRAM:	LICENSED OPERATOR	REVISION:	2
AUTHOR:	L. FITZWATER	DATE:	1/26/89
APPROVED:	Tout Brown	DATE: 3	12/89
		and the second	more any for the transmission of the set

- I. LESSON FORMAT
  - A. Lecture with Visual Aids
- II. MATERIALS

1.8

- A. Overhead Projector
- B. Student Handout
- C. Dry Erase Board and Markers

### III. EVALUATION

- A. Written or oral exam in conjunction with other lesson plans
- IV. REMARKS
  - A. This LP satisfies the requirements of the commitments listed on the Reference Page of this LP.

THSTRUCTOR GUIDELINES: U

# I. PURPOSE STATEMENT:

This case study is designed to provide understanding of the events leading up to, during, and the corrective actions associated with the loss of RhR cooling at Diablo Canyon. Included in the case study are the actions taken at Plant Vogtle to reduce the possibility of a similar event occurring.

## II. LIST OF OBJECTIVES:

- Describe briefly the initial conditions for operating with the RCS at mid-loop.
- List the instrumentation used to monitor RCS level when operating at mid-loop.
- List the instrumentation used to monitor RCS temperature when operating at mid-loop.
- Discuss the events that led to the loss of RHK cooling at Diablo Canyon.
- 5. Describe the actions that the operators took to mitigete the loss of RHR cooling.
- Describe the possible consequences that could result from a loss of RHR cooling.
- Describe actions taken to reduce the probability of a similar event from occurring at Plant Vogtle.

III. DETAIL	ED EVENT DESCRIPTION	and the second
A. In	tial Conditions	
1	Mode 5	
2.	The containment building equipment hatch was removed	
3.	The personnel airlock was open	
4.	Containment purge was in progress	
5.	Removal of steam generator manways was in progress	
÷.	Local leak rate testing of containment penetrations was in progress	
7,	The RHR pump 2-1 was operating through both RHR heat exchangers, both trains were cross connected	
ε.	The RCS was drained down to the mid-loop level	
9.	RV level was being monitored by:	
	a. A tygon cube mancester inside containment	
	b. 2 electrical systems (a wide and narrow range)	
	c. Normal RVLIS was out of service	
10,	The RV was vented to the pressurizer	
11.	The SI pueps circuit breakers were racked out	
12.	RV level maintained by:	
	u. Sending excess mater to the RWST	
	b. Makeup from the RWSY	
. EVENT IN	ITIATION	
A. A pl leak	ant engineer opened a value to perfore a local rate test, creating a leak from the RCS	
B. Loss	of RHR cooling	
	RHR pump began cavitating	

#### LESSON OUTLINE: 111.

NOTES 2. Operator shutdown the running pump Operator started and then shutdown the 3. standby pump a. It also cavitated RHR cooling capability lost 4. a. No method of monitoring incore temperatures b. Validity of the temporary RV level indication suspected 1) Operator dispatched to check local RV tygon tube indication 5. Operator attempted to verify RCS integrity Operators attempted to stop leak 6. 7. NOLIE declared Leak stopped after approximately 1.5 hours by C. engineer 1. Operators refilled the system from the RWST via a RHR pump . FUNDAMENTAL CAUSES (ND DISCUSSION TOPICS A. RV level indication system problems. Improperly seated valve Β. Operator awareness of evolutions in prograss С. D. Containment integrity problems Mid-loop coerstion E. F. Instrumentation 6. Communicacions H. Event Classification POST-EVENT TECHNICAL AND ADMINISTRATIVE INVESTIGATIVE VI. ACTIONS TAKEN AT PLANT VOGTLE Several procedure-related deficiencies were A. identified and corrected

- B. Hardware Changes
- VII. PROBLEM UPDATES
  - A. GL-88.014 Loue of Decay Heat Removal
    - Significant new information has been generated since the Diablo Canyon event, April 10, 1987
      - Several previously unrecognized phenomena need to be addressed.
        - Some of these realistically can cause core uncovery or complete core voiding in less than half an hour (previously believed that 4 hours would be required).
        - 2) New phenomena not previously understood
          - a) Pressurization
            - Caused by steam formation in unvented reactor vessel
            - (2) Inappropriate use of BG nozzle das can lead to core voiding within 15-20 minutes following loss of RHR
            - (3) Cold leg opening can allow water to be ejected from vessel following loss of RMR until sufficient water is lost that steam is relieved by clearing the crossover pipes
              - (4) Pressure difference within RCS may prevent water from reaching the RV
              - (5) Rapid RCS pressurization may prevent gravity feed from tanks anticipated to be available
              - (6) Rapid pressurization may cause instruments to selfunction or provide eisleading indications

8

III. LESSON OUTL	INE a	NOTES
	(7) Rapid pressurization may cause the RCS to respond in ununticipated ways	i an a she ta an
	(3) Small RCS openings (vents and drains) may lead to instrument mulfunctions or unanticipated RCS responses	
	(7) Large RCS pressure boundary openings (SG manway RCP seals, pressurizer manways) may lead to instrument malfunction or unanticipated RCS responses	
	(10) S6 secondary side inventory and opening may influence RCS behavior	
b)	Vortexing	
	<ol> <li>Small amount of air into RHR pump suction may lead to subtle changes that occur over a time of minutes to an hour or more</li> </ol>	
	(2) Large amounts of air may cause immediate loss of RHR	
	(3) Vortexing may occur at levels higher than anticipated	
	(4) Vortexing may not be reflected by pump current and flow rate instruments until it is sufficiently severe to cause a loss of RHR	
	(5) Vortexing may cause RCS level indication errors	
c)	86 tube draining	
	<ol> <li>Draining SG U-tube im frequently done by draining the RCS to point where vortexing could occur</li> </ol>	
d)	RCS level differences

Β.	SOER	88.003	
	1.	This document addresses the following specific training concerns associated with this problem	
		a. Response to discrepancies in or loss of indicated level	
		b. Methods to determine decay heatup rates	
		c. Indications of pump cavitation and actions needed to restore core cooling flow	
		d. Response to a loss-of-core conling flow with no indication of core coolant temperature	
	2.	Review this SDER with the class	
		a. A detailed study of the SOER and associated concerns is covered in LO-LP-12101 and associated handouts and instructional units
