

U.S. NUCLEAR REGULATORY COMMISSION
STANDARD REVIEW PLAN
OFFICE OF NUCLEAR REACTOR REGULATION

SECTION 2.4.3

PROBABLE MAXIMUM FLOOD (PMF) ON STREAMS AND RIVERS

REVIEW RESPONSIBILITIES

Primary - Site Analysis Branch (SAB)

Secondary - None

I. AREAS OF REVIEW

In this section of the safety analysis report (SAR) the hydrometeorological design basis is developed to determine the extent of any flood protection required for safety-related plant systems, as discussed in Regulatory Guide 1.59. The areas of review include the precipitation potential, precipitation losses, the runoff response characteristics of the watershed, the accumulation of flood runoff through river channels and reservoirs, the estimate of the discharge rate trace (hydrograph) of the probable maximum flood (PMF) at the plant site, the determination of PMF water level conditions at the site, and the evaluation of coincident wind-generated wave conditions that could occur with the PMF. Included is a review of the details of design bases for site drainage (which is summarized in SAR Section 2.4.2) and a review of the probable maximum precipitation (PMP) potential and resulting runoff for site drainage and drainage areas adjacent to the plant site, and including the roofs of safety-related structures. The analyses involve modeling of physical rainfall and runoff processes to estimate the upper level of possible flood conditions adjacent to and onsite.

Regulatory Guide 1.59 describes two positions with respect to flood protection. While both require an estimate of the PMF in determining the controlling design basis conditions, Position 2 limits the applicability of the design bases to specific equipment and facilities. If Position 2 is applicable, the review will be limited to the equipment and facilities identified in the guide.

II. ACCEPTANCE CRITERIA

The probable maximum flood as defined in Regulatory Guide 1.59 has been adopted as one of the conditions to be evaluated in establishing the applicable stream and river flooding design basis referred to in General Design Criterion 2, Appendix A, 10 CFR Part 50. The criteria for accepting the applicant's PMF-related design bases depend on the relative significance of the flood. PMF estimates are required for all adjacent streams or rivers

USNRC STANDARD REVIEW PLAN

Standard review plans are prepared for the guidance of the Office of Nuclear Reactor Regulation staff responsible for the review of applications to construct and operate nuclear power plants. These documents are made available to the public as part of the Commission's policy to inform the nuclear industry and the general public of regulatory procedures and policies. Standard review plans are not substitutes for regulatory guides or the Commission's regulations and compliance with them is not required. The standard review plan sections are keyed to Revision 2 of the Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants. Not all sections of the Standard Format have a corresponding review plan.

Published standard review plans will be revised periodically, as appropriate, to accommodate comments and to reflect new information and experience.

Comments and suggestions for improvement will be considered and should be sent to the U.S. Nuclear Regulatory Commission, Office of Nuclear Reactor Regulation, Washington, D.C. 20555.

and site drainage (including the roofs of safety-related structures). One of three conditions may exist at the site under review, as follows:

1. The elevation attained by the PMF (with coincident wind waves) establishes a required protection level.
2. The elevation attained by the PMF (with coincident wind waves) is not controlling; the design basis flood protection level is established by another flood phenomena (e.g., the probable maximum hurricane).
3. The site is "dry", that is, the site is well above the elevation attained by a PMF (with coincident wind waves).

When condition 1 is applicable the staff will estimate the flood level as described below. The estimate may be made independently from basic data, by detailed review and checking of the applicant's analyses, or by comparison with estimates made by others which have been reviewed in detail. Acceptance is based on agreement of the staff and applicant estimates of static flood level to within about 2 feet or higher and of coincident wave action to within about 1 foot or higher.

When conditions 2 or 3 apply, the staff analyses may be less rigorous, as described below. For condition 2, acceptance is based on the protection level estimated for another flood-producing phenomenon exceeding the staff estimate of PMF water levels. For condition 3, the site grade must be well above the staff estimate of PMF water levels. The evaluation of the adequacy of the margin (difference in flood and site elevations) is generally a matter of engineering judgement. The judgement is based on the confidence in the flood level estimate and the degree of conservatism in each parameter used in the estimate.

III. REVIEW PROCEDURES

The review procedure is outlined in Figures 2.4.3-1 and -2, attached to this plan. In addition, Appendix A to Regulatory Guide 1.59, "Design Basis Floods for Nuclear Power Plants," is a codification of techniques used by the staff during the review and verification of PMF estimates. The evaluation of flooding potential is, for review purposes, separated into two parts; PMF on adjacent streams and local PMF. The review procedure for the former is indicated on Figure 2.4.3-1. The review procedure for evaluating a local PMF is indicated on Figure 2.4.3-2. (The procedure for evaluating the adequacy of site drainage facilities based on a local PMF is outlined in Standard Review Plan 2.4.2.) PMF estimates approved by the Chief of Engineers, Corps of Engineers, and contained in published or unpublished reports of that agency, or generalized estimates may be used in lieu of staff-developed estimates. In the absence of such estimates, the staff will use both large and small basin PMP estimates by the National Oceanic and Atmospheric Administration (NOAA) and published techniques of the World Meteorological Organization in conjunction with Corps of Engineers' runoff, impoundment, and river routing models to estimate PMF discharge and water level at the site. These methods are used for conditions 1 and 2, described in the acceptance criteria. When detailed independent estimates are necessary (see acceptance criteria), the applicant will be requested to provide any necessary basic data. Wind-generated wave action

will be independently estimated using Corps of Engineers criteria. Where sufficient water depth is available, the significant wave height and runup are used for structural design purposes, and the maximum (one percent) wave height and runup are used for flood level estimates. Where depth limits wave height, the breaking wave height and runup is used for both purposes.

When an applicant has chosen to demonstrate a "dry" site (i.e., condition 3, one not subject to stream flooding by virtue of local topographic considerations), the following procedures apply:

1. Use Corps of Engineers PMF estimates for other sites in the region to develop "regional drainage area vs. PMF discharge (cubic feet per second/square mile)" data, for extrapolation to the site.
2. Envelope the above data points to obtain an estimate of the PMF applicable to the site.
3. Increase the estimate based on a judgement as to the applicability of the basic estimates. An increase in the range of 10 to 50 percent is generally appropriate.
4. Estimate the flood level at the site using slope-area techniques or water surface profile computations, if warranted by relative elevation differences between the site and adjacent stream.
5. Estimate wind (40 mph over land) wave runup based on breaking, or maximum (one percent) wave.
6. Compare resultant water level with proposed plant grade and lowest safety-related facility that can be affected.

Consultants may be employed in an advisory role in developing independent staff flood effect estimates, depending on the complexity of the analysis required and available staff manpower. The consultants may be from the Hydrometeorological Branch of the U. S. Weather Service, the Corps of Engineers Coastal Engineering Research Center, or private contractors.

The above items of review are performed only when applicable to the site or site region. Some items of review may be done on a generic basis.

IV. EVALUATION FINDINGS

For construction permit (CP) reviews the findings consist of a statement describing the applicant and staff estimates of the peak PMF runoff rate and water level (including allowance for coincident wind-generated wave activity) at the site. If the estimates are similar, staff concurrence will be stated. If the staff predicts substantially more severe flood conditions which may adversely affect the proposed plant, and the applicant has been unable to support his estimates, a statement requiring use of the staff bases will be made. If the flood conditions do not constitute a design basis, the statement will so indicate.

For operating license (OL) reviews which have received detailed PMF reviews during the CP review, the CP conclusions will be referenced. If no CP PMF review was undertaken (of the scope indicated), this fact will be indicated in the OL findings. Any flood potential not identified during the CP review will be noted.

If Regulatory Guide 1.59, Position 2, is elected by the applicant, a statement describing lesser design bases will be included in the findings with a staff conclusion of adequacy.

A sample statement for a CP review follows:

"The Probable Maximum Flood (PMF) resulting from the Probable Maximum Precipitation (PMP) on the ABC River drainage basin yielded an estimated maximum stillwater level at the intake structure on the D & E Canal of about 5.0 feet MSL.

"The PMF resulting from a local PMP storm on the drainage basins for the small streams near the site yielded an estimated maximum stillwater level of about 60 feet MSL, which is about 20 feet below plant grade.

"The local PMF resulting from the estimated local PMP was found not to cause flooding of safety-related facilities, since the site drainage system will be capable of functioning adequately during such a storm. Catch basins will be provided as part of the storm drainage system and will be located throughout the plant site to drain local areas. The plant yard will be graded with gentle slopes away from high points at the plant buildings, and storm water will drain away from the buildings into the local streams at lower elevations."

V. REFERENCES

In addition to the following specific references, Design Memoranda, Civil Works Investigations and research and development reports of the Corps of Engineers and reports of other federal and state agencies relevant to flood estimates at a specific site will be used on an "as available" basis.
