Beaver Valley Power Station, Unit No. 2 Docket No. 50-412, License No. NPF-73 LER 92-004-00

United States Nuclear Regulatory Commission Document Control Desk Washington, DC 20555

Centlemen:

In accordance with Appendix A, Beaver Valley Technical Specifications, the following Licensee Event Report is submitted:

LER 92-004-00, 10 CFR 50.73.a.2.v.D, "Diesel Generator Sequencing Relays Found Inoperable During Functional Testing".

Very truly yours,

T. P. Noonan General Manager Nuclear Operations

When these relays Were installed during the last refueling outage, the relays' installation was modified to constantly energize the clock circuits in an effort to enhance the relays' time response (See figure 2). This was done by removing the "jumper" between terminals 1 and 15 and rewiring terminal 15 directly to a voltage However, source. this configuration resulted in the clock circuit being constantly energized at 112 VDC, which is not consistent with the cests used to qualify the relays.

#### Corrective Actions

The failed relays were replaced. The relay installations were returned to the original design (figure 1) so that the clock circuit and the power supply would energize simultaneously (which is consistent with the relay qualification test). Subsequent testing by plant relay perconnel verified proper relay operations, including time response.

## Previously Similar Events

Review of station records showed no previous similar events.

### Reportability

This event is being reported in accordance with 10 CFR 50.73.a.2.v.D, as an event or condition that alone could have prevented the fulfillment of the safety function of structures or systems that are needed to mitigate the consequences of an accident.

# Safety Implications

Sequencer design provides operational redundancy so that the failed relays would only have delayed the start of the quench spray and auxiliary feedwater pumps by 45 seconds during the initial sequencer operation. The failed relays would not have prevented manual operation of ary of the affected components. An engineering evaluation is being performed to determine the safety implications of this event. A supplemental report will be issued detailing the results of this evaluation.

# Description of Event

AC FORM 366A

On 3/30/92, during a refueling outage, relay personnel were performing a periodic surveillance test on the #1 emergency diesel generator sequencing relays. During this test, three relays were found to be inoperable: relay 162-EGSAAX1, relay 762-EGSAA and relay 862-EGSAA. Relay 162-EGSAAX1 provides a two second window of opportunity for the motor driven auxiliary feedwater pump (FWE-P23A) and the quence spray pump (QSS-P21A) to start if required between 15 and 17 seconds after the diesel generator has reached its rated speed and voltage. Relays 762-EGSAA and 862-EGSAA reset and reinitiate the sequencer operation if a safety injection or Hi-Hi containment pressure occur before the sequencer has finished timing out (60 seconds after diesel start). Later testing found two of the three similar relays on the other train were also inoperable.

#### Cause of Event

The relay failures were due to improper design application. These relays were installed via a design change during the last refueling outage. They were designed for 24 VDC applications, but were installed in a configuration that caused the relay clock circuits to be constantly energized with 112 volts. The excessive constant voltage on the clock circuits caused high heac loads that resulted in relay failures. The relays are a sealed case configuration and the only means of heat dissipation is through radiative heat transfer. This design compounded the higher heat loads in the "as installed" configuration.

The relays have two separate internal circuits, a clock circuit and a power supply circuit. Both circuits are designed for 24 VDC operation. h ever, Beaver Valley's diesel generator sequencer operates on 124 VDC. For sequencer applications at this voltage, the manufacturer states a 650 Ohm series resistor can be installed to drop the voltage applied to the relay to 24 VDC. (See figure 1 for typical normal installation.)
