VOGTLE ELECTRIC GENERATING PLANT
UNITS 1 & 2
CONFIRMATORY LABORATORY TESTING PROGRAM
FOR CATEGORY 1 BACKFILL

1.0 INTRODUCTION

At the request of the Nuclear Regulatory Commission (NRC), a laboratory testing program of Category 1 backfill was developed by Bechtel and Southern Company Services (SCS). The purpose of the testing program was to verify the typical maximum dry densities which have been determined throughout the backfilling process by Georgia Power Company (GPC), and used to determine the degree of compaction achieved in the field. This was determined by having both Georgia Power Company and an independent laboratory perform maximum dry density tests (ASTM 1557) on split samples. Additional testing was to be performed by the independent laboratory. Law Engineering Testing Company (LETCO) was selected by the NRC to implement the confirmatory laboratory testing program.

A total of 12 samples of representative Category 1 backfill material were tested by LETCO and GPC. Data developed by LETCO and GPC are attached to this report as Appendices 1 and 2 respectively. A discussion of the data generated by the two laboratories follows.

2.0 SAMPLING

Sampling of the backfill material was done by GPC. Seven of the twelve samples were obtained directly from borrow sources; the other five were obtained in a manner that was consistent with the normal handling of the fill in the field. Each sample weighed approximately 100 lbs and was obtained in the following manner.

First a large bulk sample of approximately 400 lbs was obtained from the borrow source or the fill. Each large bulk sample obtained from the borrow source was thoroughly mixed and then subdivided into 4 - 100 lb test samples. Large bulk samples obtained from the fill were not mixed prior to splitting them. Of the 4 - 100 lb test samples, one was shipped to LETCO and the other three were retained by GPC. Of the retained samples, one was used for testing by GPC and the others were stored for record purposes. Prior to shipping, testing and storing samples, testing in accordance with ASTM D1140 was performed by GPC on material obtained from each 100 lb sample. The purpose of the ASTM D 1140 testing was to determine percent passing the US No. 200 sieve size and thus help GPC establish whether the samples selected for testing met the criteria for soil types defined in the testing program. The above procedure of obtaining and selecting samples was followed for all twelve test samples. The testing program developed by Bechtel and SCS called for selection of 6 samples with fines of less than 5 percent and 4 samples each with fines ranging from 5 to 9 percent and 9 to 12 percent respectively. However because of sampling difficulties encountered in the field, only two samples in the 5 to 9 percent range of fines could be obtained. This was due to the unavailability of this range of materials in the borrow sources. Therefore a total of 12 samples were tested instead of 14 as originally planned.

3.0 LABORATORY TESTING

Both LETCO and GPC's field soils laboratory performed the modified Procter (ASTM D 1557) and sieve analysis (ASTM D 422) tests on the twelve soil samples. LETCO also performed the soil tests listed below as required by the testing program. These tests were not performed by GPC as their field laboratory was not equipped to perform them.

<u>No.</u>	<u>Type of Test</u>	<u>Test Standard</u>
1	Hydrometer Analysis	ASTM D 422
2	Relative Density of Cohesionless Soils	ASTM D 4253-83 & D 4254-83 (New Standards issued in 1983)
3	Permeability of Soils	US Army Corps. of Engineers, EM-1110-2-1906 Appendix VII
4	Liquid Limit of Soils	ASTM D 423
5.	Plastic Limit of Soils	ASTM D 424

Description of testing procedures used is given in LETCO's report (Appendix 1)

4.0 EVALUATION

4.1 Maximum Dry Density

Maximum dry densities obtained by LETCO and GPC from the modified Procter test (ASTM D 1557) are summarized in Table 1. The data in Table 1 show that for material with less than 5 percent fines, LETCO's maximum dry densities ranged from 103.3 to 108.2 pcf and GPC's ranged from 101.9 to 104.7 pcf. LETCO's maximum dry densities are higher than those obtained by GPC and the difference ranges from 0.8 to 3.5 pcf with an average of 2.0 pcf. When expressed as a percentage of the mean of the maximum dry densities for each sample obtained from the two laboratories, the differences range from 0.8 to 3.3 percent. This is less than the maximum limit of 4 percent specified for multilaboratory precision in Table 3 of the ASTM D 1557 test standard. Therefore the test results of both laboratories are considered to be in agreement.

A similar trend is apparent for material ranging in fines from 5 to 12 percent. For this type of material, LETCO's maximum dry density ranged from 107.8 to 115.3 pcf and GPC's ranged from 106.8 to 114.2 pcf. LETCO's dry densities exceed those obtained by GPC. The difference in dry density ranges from 1.0 to 3.2 pcf with an average value of 1.7 pcf. When expressed as a percentage of mean value, the differences range from 0.9 to 2.9 percent which is less than the maximum limit of 4.0 percent for multilaboratory precision. Again, the test results of both laboratories are considered to be in agreement.

A comparison of the maximum dry densities obtained by ASTM D 1557 with those obtained by ASTM D 4253-83 is presented in Table 2. These data show that for material with less than 5 percent fines, the ASTM D 4253 dry method generally yields higher maximum dry densities than the ASTM D 4253-83 wet method and the ASTM D 1557 test. The ASTM D 4253-83 dry method values exceed GPC's ASTM D 1557 values by 2.4 to 4.3 pcf. While the ASTM D 4253-83 dry method maximum densities are consistently higher than those yielded by ASTM D 1557, the ASTM D 4253-83 wet method shows no such trend. However for material with fines ranging from 5 to 12 percent, ASTM D 1557 yielded higher maximum dry densities than the ASTM D4253-83 wet and dry methods.

The data shown in Tables 1 and 2 indicate the following:

1. As expected, maximum dry density increases with increasing percent passing the No. 200 sieve size. This trend is evident in the data generated by both laboratories.
2. Maximum dry densities obtained by LETCO using the ASTM D 1557 test exceed those obtained by GPC by an average of approximately 2.0 pcf. One possible cause for this difference may be the fact that GPC employs an automatic rammer as compared to a manually operated rammer used by LETCO. However the differences for all samples tested are well within the 4 percent maximum precision limit specified in the ASTM D 1557 test standard. The higher LETCO densities when applied to the compaction test records would not significantly reduce the percent compaction reported by GPC. Therefore the conclusion that the fill meets the specification based on the compaction records remains unchanged.
3. For material with fines ranging from 5 to 12 percent, the ASTM D 1557 test standard currently used by GPC yields densities higher than the relative density test. For materials with less than 5% fines the ASTM D 4253-83 (dry method) yields higher maximum dry densities than the D 1557 test. However the differences in maximum unit weights between the two types of tests are less than an average of about 4 pcf and the fill would meet the specified compaction if the higher maximum unit weight were used.

4.2 Moisture Content

Review of the Optimum Moisture Content (OMC) data shown in Table 1 indicates the following:

1. For material with fines ranging from 5 to 12 percent the agreement between the LETCO and GPC optimum values is within the precision limits of ASTM D 1557, with the exception of samples S-7 and S-10. In the case of sample S-10, the compaction curves prepared by the two laboratories are very similar and very flat. GPC has selected the moisture content at the maximum measured density for their optimum moisture content, which is reasonable. However, since three of the GPC points, covering a range of moisture contents from 10.4 to 16.6 percent, have dry densities of 106.8, 106.6 and 106.6 pcf, it can be concluded that density is not very sensitive to moisture changes for this sample. The optimum probably lies

somewhere in the range of 10.4 to 16.6 percent. The LETCO value of 14.7 percent is within that range. Similarly for Sample S-7, GPC has reported dry densities of 108.4 and 108.6 pcf at moisture contents of 12.1 and 13.8 percent respectively. The optimum value appears to range from 12.1 to 13.8 percent with the LETCO value of 11.3 percent being closer to the GPC lower bound value.

2. For material with less than 5 percent fines the differences between the LETCO and GPC optimum moisture contents exceed the precision limits of ASTM D 1557. The reasons for these differences are not apparent from the test data.
3. Using the LETCO data, the following table was prepared to show moisture contents over which the required 97 percent relative compaction can be achieved.

Sample No.	γ_D at 97% $\times \gamma_D$ max	Moisture Range at 97% γ_D max	OMC
	(PCF)	(percent)	(percent)
S-1	102.3	8-21*	15.5
S-2	100.2	6-22*	16.7
S-3	101.1	5-22*	19.3
S-4	105	10-21	18.1
S-5	102.6	13-22	18.5
S-6	103.8	10-19	16.0
S-7	107.2	6-20*	11.3
S-9	107.0	6-20*	14.8
S-10	104.6	6-19*	14.7
S-11	111.8	4-16.5*	13.2
S-12	109.9	3-16.5*	11.2

* Curve extrapolated

4.3 Permeability

Permeability tests were performed on two backfill samples; one with approximately 5.9 percent fines and the other with 11 percent fines. No permeability tests were performed on material with less than 5 percent fines. The data show that for material with 5.9 percent fines the coefficient of permeability ranged from approximately 2.0×10^{-3} in/sec to 6.0×10^{-3} cm/sec. For material with 11 percent fines, the permeability ranged from approximately 4.0×10^{-4} cm/sec to 4.0×10^{-3} cm/sec. A review of the data indicates the following:

1. The coefficient of permeability of both samples tested increases with decrease in the degree of compaction.
2. The coefficient of permeability decreases with increase in the fines content of the backfill material.
3. Based on criteria developed by Terzaghi and Peck (Reference 1), material with 5.9 percent fines may be classified as possessing medium permeability. Material with 11.0 percent fines may be classified as possessing medium to low permeability depending on the degree to which the material is compacted.
4. Materials with 5 to 12 percent fines when compacted to the specification requirements (97 percent or higher relative compaction) have medium to low permeability.

5.0 SUMMARY OF CONCLUSIONS

1. Based on the laboratory test data developed by LETCO and GPC it is concluded that differences in the maximum dry density values between the two laboratories are well within the precision limits set in the ASTM D 1557 test standard. Data from both laboratories show that for material types tested, the maximum dry density from ASTM D 1557 ranges from 101.9 to 115.3 pcf. These values of maximum dry density from laboratory tests are typical for these materials and are consistent with results previously obtained from laboratory tests performed by GPC and other laboratories. Maximum dry density values obtained by LETCO are slightly higher than those obtained by GPC but not enough to influence the degree of compaction reported by GPC. The laboratory test data support the conclusion that Category 1 backfill at Plant Vogtle has been compacted to the high degree of compaction committed to by GPC in the PSAR. For materials with fines ranging from 5 to 12 percent, the ASTM D 4253-83 method of test yields maximum densities that are lower than those obtained from ASTM D 1557. For materials with less than 5 percent fines the ASTM D 4253-83 (dry method) yielded higher maximum dry densities than the ASTM D 1557 test. However the differences in maximum unit weights between GPC's ASTM D 1557 and LETCO's ASTM D 4253-83 tests average 3.2 pcf for material with less than 5% fines. These differences are not considered significant in view of the fact that the field records indicate the compaction achieved by GPC to be well over the specified compaction criteria for materials within this range.

2. The compaction curves presented by LETCO show that for material types tested the required 97 percent relative compaction can be achieved over a wide range of moisture contents. This range is much wider than the limiting range of the construction specifications.
3. Permeability tests show that backfill material with 5 to 12 percent fines when compacted to 97 percent relative compaction will have medium to low permeability.

Attention: Mr. J. A. Bailey

Subject: Report of Confirmatory Laboratory Testing Program
For Category I Backfill
Vogtle Electrical Generating Plant
LETCo Job Number 7429

Gentlemen:

Law Engineering has completed the requested confirmatory laboratory testing of backfill materials, except for permeability testing. The results of the tests are presented in this report.

Twelve bags of soil were received from Plant Vogtle on June 15 and June 19, 1984. Initially testing of fourteen samples was planned. Due to sampling difficulties in the field, samples initially numbered 8 and 14 were not delivered to us.

In the laboratory the following tests were performed:

- ASTM D 422-63 Particle Size Analysis of Soil
- ASTM D 1557-78 Moisture Density Relations of Soils and Soil Aggregate Mixtures using 10 lb. Rammer and 18 inch Drop (Method A).
- ASTM D 2049-69 Relative Density of Cohesionless Soil.
- ASTM D 4253-83 Maximum Index Density of Soils using a Vibratory Table (Appendix non-mandatory information included).
- ASTM D 4254-83 Minimum Index Density of Soils and Calculation of Relative Density.
- ASTM D 423-66 Liquid Limit of Soil.
- ASTM D 424-59 Plastic Limit and Plasticity Index of Soils.

Tests are presently underway to evaluate the permeability of two samples, Number 10 and 11. The results of the permeability testing will be reported to you as soon as it is completed.

Grain Size Tests

The grain size distribution of the twelve samples received was determined by procedures outlined in ASTM D 422-63. Six of the samples had less than 5% passing the No. 200 sieve, two of the samples had between 5 and 9% passing the No. 200 sieve and four of the samples had greater than 9% but less than 12% passing the No. 200 sieve. The particle size distribution for materials coarser than the No. 200 sieve was determined by passing the materials over a set of nested sieves. The particle size distribution for materials finer than the No. 200 sieve was determined by Hydrometer analysis for the three samples initially thought to be in the range of 9 to 12% passing the No. 200 sieve. One sample, Number 10, contained 10% passing the No. 200 sieve, so was outside its planned range of 5% to 9% passing the No. 200 sieve.

During the relative density testing, three grain size tests were performed on samples to determine if grain size changes (degradation) occurred due to performing several relative density tests on the same sample. This grain size testing indicated that the gradation of the soil did not change appreciably during the relative density testing.

The results of the grain size testing is shown on the individual grain size sheets and on the tabulated laboratory test results in the Appendix.

Modified Proctor Compaction Tests

Twelve modified proctor compaction tests were performed to evaluate the moisture density relations of the soils. During testing the soils typically "bled" water from the compaction mold. To evaluate this condition moisture content tests were performed on the soil samples both before and after compaction in the compaction mold. The loss of water from the compaction mold during compaction was measured to vary from approximately one half percent to approximately four percent for tests performed wet of optimum moisture content.

The results of the modified Proctor compaction testing are shown on the individual modified Proctor compaction test sheets and on the Table of Laboratory Test Results in the Appendix.

Relative Density Testing

Relative density testing was initiated using procedures outlined in ASTM D 2049-69. At the request of Mr. Joe Kane of the Nuclear Regulatory Commission, with approval from Mr. Walter Ferris of Bechtel Incorporated, who visited our laboratory to observe the testing from June 27, 1984 through June 29, 1984, the relative density program was modified. Three soil samples were selected from each of the grain size ranges, less than 5% passing the No. 200 sieve, 5% to 9% passing the No. 200 sieve, and 9% to 12% passing the No. 200 sieve to evaluate the optimum amplitude of vibration. Utilizing procedures outlined in ASTM D 4253-83, the

maximum density was determined by the dry method at selected points over a range of amplitudes of vibration. For each grain size range, the amplitude of vibrations which produced the highest maximum density was determined. This optimum amplitude of vibration (3600 cycles per second frequency) was then used within each grain size range for determining maximum density by both the wet and dry methods.

The minimum density of each sample was determined by procedures outlined in ASTM D 4254-83.

The results of the maximum and minimum density testing are shown on the attached relative density test sheets and on the plots of maximum density versus amplitude of vibration in the Appendix.

Plasticity Index

Plasticity index testing was performed on the three soil samples initially expected to fall within the range of 9% to 12% passing the No. 200 sieve by procedures outlined in ASTM D 423-66 and D-424-59. The testing indicated that each of the three samples was non-liquid, non-plastic.

Discussion

We understand that the results of the modified proctor compaction tests performed in our laboratory will be compared with like tests performed at Plant Vogtle. We point out the precision of this test as shown on Table 3 of ASTM D-1557 allows an acceptable range of two results from different laboratory to be 4% of the mean value. The multilaboratory standard deviation of maximum density by the ASTM D 1557-82 method is shown as ± 1.66 .

For samples in the 0 - 5% and 5% - 9% passing the #200 sieve grain size range, the relative density test indicated maximum densities ranging from approximately one pound per cubic foot less to approximately three and one half pounds per cubic foot greater than the modified Proctor maximum density. For soils in the 9% to 12% passing the No. 200 sieve grain size range, maximum density determined by the relative density method ranged from approximately three to eight pounds per cubic foot less than the modified Proctor maximum density.

Thank you for the opportunity of working with you on this project. If you have any questions concerning this project or if we can be of additional assistance to you, please contact us.

Very truly yours,

LAW ENGINEERING TESTING COMPANY

Attention: Mr. J. A. Bailey

Subject: Confirmatory Laboratory Testing Program
For Category I Backfill Permeability Testing
Vogtle Electrical Generating Plant
LETCo Job Number 7429

Gentlemen:

This report presents the results of the permeability tests which were performed on two (2) backfill materials for Plant Vogtle Project of Georgia Power Company.

I. INTRODUCTION:

Sample No. 10 and No. 11 were selected representing different grain size ranges, (5% to 9% passing the No. 200 sieve and 9% to 12% passing the No. 200 sieve respectively), to evaluate the coefficient of permeability by falling head method. Sample No. 10 had 5.9% passing the No. 200 sieve and sample No. 11 contained 11.0% passing the No. 200 sieve.

II. PROCEDURE:

A Modified Proctor Compaction Test (ASTM D1557-78, Method A) was performed on each sample to evaluate the maximum dry density of the soils, and permeability specimens then were compacted at approximately 100, 97, 94, and 91 percent of the modified proctor density. The samples were compacted in six layers using a moist tamping method utilizing a small height controlled tamper.

The permeability tests were performed in general accordance with the procedure described in Appendix VII of the Laboratory Testing Manual (EM 1110-2-1906, Permeability Tests with Back Pressure) published by the U.S. Army Corps of Engineers. The permeability tests with back pressure were performed in a pressure chamber (Triaxial Cell), and

by increasing the chamber pressure and back pressure at the same time, the saturation processes were completed. A pressure transducer was used to measure the "B" value, with the values ranging from 0.90 to 1.00. Utilizing a 2 KSF confining pressure, the sample then was consolidated until primary consolidation was completed. The coefficient of permeability by falling head method was calculated directly from computations using data obtained from a series of readings for each sample. At the end of each test, the sample was removed from the pressure chamber and the wet weight was obtained in order to calculate the unit weight and moisture content. Based on the final data, the actual density of each specimen was computed.

The results of moisture content, unit weights, void ratio, and permeability tests are shown on the tabulated laboratory test sheets which are attached to this report.

III. DISCUSSION:

Results of the permeability tests show that for sample No. 10 with 5.9% passing the No. 200 sieve, the coefficient of permeability ranges from approximately 2.0×10^{-3} cm/sec. to 6.0×10^{-3} cm/sec. For sample No. 11 with 11.0% passing the No. 200 sieve, the coefficient of permeability ranged from approximately 4.0×10^{-4} cm/sec. to 4.0×10^{-3} cm/sec.

If you have any questions concerning this report or if we can be of additional assistance to you, please contact us.

Very truly yours,

LAW ENGINEERING TESTING COMPANY

Dear Mr. Bailey:

Attached are the results of the on site soil testing carried out as required in references 1, 2, and 3. Also, attached is a summary sheet which shows the grain size and Modified Proctor results for each sample taken.

If you have any questions, please contact Winston Davis at extension 422 on site.
